**2:15PM F50.00014 Spin diffusion in ultracold spin-orbit coupled <sup>40</sup>K gas**, T. YU, M. W. WU, Univ of Sci & Tech of China — We investigate the steady-state spin diffusion for ultracold spin-orbit coupled <sup>40</sup>K gas by the kinetic spin Bloch equation approach. It is found that the behaviors of the steady-state spin diffusion are determined by three characteristic lengths in the system: the mean free path, the Zeeman oscillation length and the spin-orbit coupling oscillation length. It is further revealed that by tuning the scattering strength, the system can be divided into *five* regimes, in which the behaviors of the spacial evolution of the steady-state spin polarization shows different dependencies on the scattering strength, Zeeman field and spin-orbit coupling strength. These rich behaviors of the spin diffusions in different regimes are hard to be understood in the framework of the simple drift-diffusion model or the direct inhomogeneous broadening picture in the literature. However, almost all these rich behaviors can be well understood by means of our *modified* drift-diffusion model and/or *modified* inhomogeneous broadening picture. Specifically, several anomalous features of the spin diffusion are revealed, which are in contrast to those obtained from *both* the simple drift-diffusion model and the direct inhomogeneous broadening picture.

**2:27PM F50.00015 Prediction of the expansion velocity of ultracold 1D quantum gases for integrable models**, ZHONGTAO MEI, University of Cincinnati, LEV VIDMAR, FABIAN HEIDRICH-MEISNER, Ludwig-Maximilians-Universitaet Muenchen, CARLOS BOLECH, University of Cincinnati — In the theory of Bethe-ansatz integrable quantum systems, rapidities play an important role as they are used to specify many-body states. The physical interpretation of rapidities going back to Sutherland is that they are the asymptotic momenta after letting a quantum gas expand into a larger volume rendering it dilute and noninteracting. We exploit this picture to calculate the expansion velocity of a one-dimensional Fermi-Hubbard model by using the distribution of rapidities defined by the initial state [1]. Our results are consistent with the ones from time-dependent density-matrix renormalization. We show in addition that an approximate Bethe-ansatz solution works well also for the Bose-Hubbard model. Our results are of interests for future sudden-expansion experiments with ultracold quantum gases. [1] Z. Mei et al., arXiv:1509.00828

## Tuesday, March 15, 2016 11:15AM - 2:15PM –

Session F51 FIAP: 2DEG and Quantum Hall Effect Hilton Baltimore Holiday Ballroom 2 - Mansour Shayegan, Princeton University

**11:15AM F51.00001 Reorientation of quantum Hall stripes within a partially filled Landau level**, Q. SHI, M.A. ZUDOV, University of Minnesota, J.D. WATSON, G.C. GARDNER, M.J. MANFRA, Purdue University — We investigate the effect of the filling factor on transport anisotropies, known as stripes, in high Landau levels of a two-dimensional electron gas. We find that at certain in-plane magnetic fields, the stripes orientation is sensitive to the filling factor within a given Landau level. This sensitivity gives rise to the emergence of stripes away from half-filling while orthogonally-oriented, native stripes reside at half-filling. We attribute this switching of the anisotropy axes within a single Landau level to a strong dependence of the native symmetry breaking potential on the filling factor.

### 11:27AM F51.00002 Magnetic Response Functions in Landau Levels , YANG GAO, QIAN NIU, UT Austin —

We propose a new quantization scheme which generates Landau levels consistent with the zero-field magnetic response functions from the semiclassical theory. It reproduces the Onsager's rule in the leading order, and re-formulates corrections to the Berry phase and magnetic moment effect in terms of one single magnetic response: the zero-field magnetization. It can yield higher order corrections by including successively magnetic susceptibility and higher order magnetic response functions. In application, it can be easily applied to obtain Landau levels in lattice models. Moreover, it provides an experimental method of measuring different magnetic response functions directly from the measurement of Landau level fan diagram or Hofstadter spectrum.

### 11:39AM F51.00003 Hall Potential Distribution in Anti-Hall bar Geometry<sup>1</sup> , VINICIO TARQUINI,

TALBOT KNIGHTON, ZHE WU, JIAN HUANG, Wayne State University, LOREN PFEIFFER, KEN WEST, Princeton — A high quality system has been fabricated in an Anti-Hall bar geometry, by opening a  $1.4 \times 2.0$  mm rectangular window using wet etching in the middle of a  $2.4 \times 3.0$  mm two-dimensional high-mobility ( $\mu = 2.6 \times 10^6$  cm<sup>2</sup>/(V·s)) hole system confined in a 20 nm wide (100) GaAs quantum well. Topologically this system is equivalent to a normal Hall bar even though there is an extra set of edges in the center. This configuration allows us to probe the Hall potential distribution in relation to the formation of edge channels. The Quantum Hall measurements at 30 mK show a standard behavior of the outer edges. At each Hall plateau the inner edge becomes an equipotential and the Hall voltage between the inner and outer edges exhibits a drastic asymmetry for the upper and lower arms of the sample. At various integer fillings, depending on the chirality, the voltage drop across one of the arms measures 0 while the drop across the other one is equal to the Hall voltage. This behavior will be explained in terms of the dynamical process of forming the edge channels which also will account for the more irregular behavior of the Hall potential in more disordered systems.

<sup>1</sup>NSF DMR-1410302

### 11:51AM F51.00004 Finite-wavevector Electromagnetic Response in Quantum Hall Systems: Lattice Corrections and Signatures of Hall Viscosity , FENNER HARPER, THOMAS JACKSON, RAHUL ROY, Univ of

California - Los Angeles — It has recently been shown that the electromagnetic response of a quantum Hall fluid at finite wavevector includes a dependence on the Hall viscosity, raising the possibility of measuring this quantity in an experiment. We present a new, quantum mechanical derivation of this relationship and extend the result to include lattice corrections, which may be significant in a real sample. We find that these corrections have a universal structure whose form depends only on the symmetries of the underlying lattice, and provide numerical estimates for cases of experimental interest. Finally, we consider the Hall viscosity of lattice models more generally and discuss our results in this broader context.

### 12:03PM F51.00005 Insulating States in the Integer Quantum Hall Regime<sup>1</sup> , TALBOT KNIGHTON,

Wayne State University, ALESSANDRO SERAFIN, National High Magnetic Field Laboratory, ZHE WU, VINICIO TARQUINI, Wayne State University, J. F. XIA, NEIL SULLIVAN, National High Magnetic Field Laboratory, LOREN PFEIFFER, KEN WEST, Princeton University, JIAN HUANG, Wayne State University — Quantum Hall measurements are performed at temperatures 20-300 mK in high quality *p*-type GaAs quantum well systems having mobility  $\mu = 4 \times 10^6$  cm<sup>2</sup>/V·s for density  $5 \times 10^{10}$  cm<sup>-2</sup>. We report a series of insulating phases appearing at or near integer filling factors  $\nu \geq 1$ . The DC resistance demonstrates a maximum of 25M $\Omega$ , much larger than the quantum resistance  $h/e^2$ , with threshold transport behavior at low currents around 10 pA at low temperatures. The threshold diminishes upon heating up to 200 mK, consistent with a finite temperature melting of bubble phases or Wigner crystal. Additionally, these peaks have a complex electrical impedance for AC signals, with large phase shifts down to 1Hz. In this regime, the ac impedance of the two chiral edges show distinct correlated characteristics.

<sup>1</sup>NSF DMR-1410302

### 12:15PM F51.00006 Geometry of Landau Level without Galilean or Rotational Symmetry<sup>1</sup> ,

YU SHEN, F. D. M. HALDANE, Department of Physics, Princeton University, Princeton NJ 08544-0708 — The integer quantum Hall effect is usually modeled using Galilean-invariant or rotationally-invariant Landau levels. However, these are not generic symmetries of electrons moving in a crystalline background. We explicitly break both symmetries by considering an inversion-symmetric Hamiltonian with quartic terms. We carry out exact diagonalization numerically with a truncated Hilbert space, and define an emergent metric  $g_{ab}^n$  for each Landau level as the expectation value of a bilinear form in momentum. With an appropriate choice of the guiding center coherent state, the Landau level wavefunctions are holomorphic functions of  $z^*$  times a Gaussian (this is distinct from a well-known property of rotationally-invariant lowest-Landau-level wavefunctions). We show that the zeroes of the wavefunction define a "topological spin  $s_n$ ", with its original definition as an "intrinsic angular momentum" no longer valid without rotational symmetry. This is now related to the number of zeroes  $n$  encircled by the classical orbit by  $s_n = n + \frac{1}{2}$ . Finally we introduce a mass tensor  $m_{ab}^n$  for each Landau level using a Lagrangian formalism. We conclude that topological and geometric information can be extracted without resort to Galilean or Rotational symmetries.

### 12:27PM F51.00007 Quantum Hall states in strained InAs heterostructures<sup>1</sup> , JESSE KANTER,

FRANCESCA ARESE LUCINI, ALEXANDRA DUBOY, The Graduate Center, City College, City University of New York, T.D. MISHIMA, M.B. SANTOS, University of Oklahoma, JAVAD SHABANI, The Graduate Center, City College, City University of New York — In a recent development it was realized that non-Abelian quasiparticles, parafermion zero-modes emerge at an interface between a superconductor and two dimensional electron system (2DES) in the quantum Hall regime. [1]. Unlike widely used GaAs systems, surface level pinning in InAs could allow for fabrication of transparent contacts to superconductors. However, no fractional quantum Hall state has been observed in InAs quantum wells so far. Whether this is due to the type of disorder present in the quantum well is not clear. In this work, we study the transport and dingle mobility of 2DEs confined to strained InAs quantum wells as a function of electron density and spacer thickness to the surface. We compare our results to early observation of fractional quantum Hall states in GaAs. [1] R. S. K. Mong, et al. Phys. Rev. X 4, 011036 (2014)

### 12:39PM F51.00008 Universal response of quantum hall states to lattice curvature , RUDRO BISWAS,

Department of Physics, Purdue University, DAM SON, Kadanoff Center for Theoretical Physics, University of Chicago — In this talk I shall present general results for the response of quantum Hall states to points of singular real-space curvature. The salient results are that (i) points of singular curvature bind an excess fractional charge and (ii) bound states appear in the inter-Landau level energy gap whose energies are universal functions of bulk parameters and the curvature. Time permitting, I will comment on the implications of these results.

**12:51PM F51.00009 Microwave Spectroscopic Observation of Multiple Phase Transitions of Bilayer Electron Solids in a Wide Quantum Well**, LLOYD ENGEL, ANTHONY HATKE, National High Magnetic Field Laboratory, YANG LIU, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Princeton University — For a single-layer two dimensional electron system, the fractional quantum Hall effect (FQHE) series terminates to form an insulating phase (IP) for Landau filling factor  $\nu < 1/5$ . In a wide quantum well the charge distribution can separate into two layers as density increases resulting in a modification of the IP onset to  $\nu < 1/2$  [1]. The IP is understood as an electron solid pinned by residual disorder. The solid exhibits a microwave pinning mode resonance, which is due to pieces of the solid oscillating within the disorder potential. We have previously observed that the microwave pinning mode spectra reveal phase transitions between different types of solid within the terminating IP [2]. In this talk we extend our studies of microwave spectroscopic measurements of a wide quantum well by investigating these phase transitions in the presence of an in-plane magnetic field. Applying an in-plane field forces the system to be more bilayer-like and for small tilt angles we find that the transitions move to higher  $\nu$ . However, at sufficiently high angles the resonance onset extends above  $\nu = 1/2$  and the  $\nu$  of the transitions saturate. [1] Manoharan et al., Phys. Rev. Lett. 77, 1813 (1996). [2] A. T. Hatke et al., Nature Commun. 6, 7071 (2015).

**1:03PM F51.00010 Dicke Model for Quantum Hall Systems**, YUSUKE HAMA, RIKEN, MOHAMMAD FAUZI, Tohoku University, KAE NEMOTO, National Institute of Informatics, YOSHIRO HIRAYAMA, Tohoku University, ZYUN EZAWA, RIKEN — Quantum Hall (QH) systems comprise of many-body electron spins and nuclear spins. They are weakly coupled with nuclear spins through the hyperfine interaction so that electron spin dynamics is scarcely affected by the nuclear spins. The dynamics of the QH systems, however, may drastically change when the nuclear spins interact with low energy collective excitation modes of the electron spins. In connection with this, the nuclear spin relaxation measurement have revealed novel behaviors in the canted antiferromagnetic phase in the total filling factor two bilayer QH systems [1,2]. Here, we theoretically study the interaction between the nuclear spins and the linear dispersing Nambu-Goldstone mode mediated by the hyperfine interaction. We show that such interaction is effectively represented by the Dicke model, and predict that collective spin phenomena realized in quantum optical systems are also observed in the QH systems [3]. References: [1] N. Kumada et al., Science 313, 329 (2006). [2] M. H. Fauzi et al., Phys. Rev. B 90, 235308 (2014). [3] Y. Hama et al., arXiv:1510.04792v1.

**1:15PM F51.00011 Large-filling-factor giant Shubnikov-de Haas oscillations in the ultrahigh-mobility two-dimensional GaAs/AlGaAs electron system**, ZHUO WANG, RAMESH.G. MANI, GEORGIA STATE UNIVERSITY, WERNER WEGSCHEIDER, ETH Zurich — The observation of microwave-induced zero-resistance states (ZRS) produced new interest in transport studies of very high filling factors in the high mobility GaAs/AlGaAs 2D electron system. In particular, there has been interest in the study of the overlap of such ZRS with high filling factor quantum Hall effect.[1] Ref. 1 reported different phase relations between oscillatory resistances at high filling factors. In an effort to clarify the observations, we examine the influence of a dc current bias on the lineshape of oscillatory resistances in the ultrahigh-mobility two-dimensional GaAs/AlGaAs electron system. With increasing dc current bias, a change is also observed in the characteristic lineshape of the SdH oscillations. To quantify the change, we carry out lineshape fits of the oscillatory resistance obtained at different dc bias. In this talk, we will summarize the results of the study. [1] R. G. Mani, W. B. Johnson, V. Umansky, V. Narayanamurti, and K. Ploog, Phys. Rev. B 79, 205320 (2009).

**1:27PM F51.00012 Landau-level mixing, floating-up extended states, and scaling behavior in a GaAs-based two-dimensional electron system containing self-assembled InAs dots<sup>1</sup>**, CHI-TE LIANG, CHIEH-WEN LIU, CHIEH-I LIU, Graduate Institute of Applied Physics, National Taiwan University, Taipei, Taiwan 106, R.O.C., GIL-HO KIM, Sungkyunkwan University, Korea, C. F. HUANG, 2nd Patent Division, Intellectual Property Office, Ministry of Economic Affairs, Taipei, Taiwan 106, R.O.C., DA-REN HANG, Department of Materials and Optoelectronic Science, National Sun Yat-sen University, Kaohsiung, Taiwan 804, R.O.C., D. A. RITCHIE, Cavendish Laboratory, University of Cambridge, United Kingdom — Temperature-driven flow lines corresponding to Landau level filling factor  $\nu = 2 \sim 4$  were studied in the  $\sigma_{xx} - \sigma_{xy}$  plane in a GaAs-based two-dimensional electron system with self-assembled InAs dots. In the insulator-quantum Hall (I-QH) transition resulting from the floating-up extended states, the flow diagram showed the validity of the scaling and we observed the expected semicircle. On the other hand, the curve  $\sigma_{xx}(\sigma_{xy})$  in the low-field insulator demonstrated the existence of Landau-level mixing. By decreasing the effective disorder, we found that such flow lines can leave the I-QH regime and follow the scaling for the plateau transition between  $\nu = 4$  and 2. The semicircle in the observed I-QH transition, in fact, originated from the distortion on the plateau-transition curve due to Landau-level mixing. Our study showed the importance of the level-mixing effects to the scaling and semicircle law as the extended states float up.

<sup>1</sup>We thank the MOST, Taiwan (grant number: MOST 104-2622-8-002 -003) for financial support.

**1:39PM F51.00013 Probing the excited subband dispersion of holes confined to GaAs wide quantum wells<sup>1</sup>**, INSUN JO, YANG LIU, H. DENG, M. SHAYEGAN, L. N. PFEIFFER, K. W. WEST, K. W. BALDWIN, Dept. of Electrical Engineering, Princeton University, Princeton, NJ08544, USA, R. WINKLER, Dept. of Physics, Northern Illinois University, DeKalb, IL 60115, USA — Owing to the strong spin-orbit coupling and their large effective mass, the two-dimensional (2D) holes in modulation-doped GaAs quantum wells provide a fertile test bed to study the rich physics of low-dimensional systems. In a wide quantum well, even at moderate 2D densities, the holes start to occupy the excited subband, a subband whose dispersion is very unusual and has a non-monotonic dependence on the wave vector. Here, we study a 2D hole system confined to a 40-nm-thick (001) GaAs quantum well and demonstrate that, via the application of both front and back gates, the density can be tuned in a wide range, between  $\sim 1$  and  $2 \times 10^{11} \text{ cm}^{-2}$ . Using Fourier analysis of the low-field Shubnikov-de Haas oscillations, we investigate the population of holes and the spin-orbit interaction induced spin-splitting in different subbands. We discuss the results in light of self-consistent quantum calculations of magneto-oscillations.

**1:51PM F51.00014 Formation of a helical channel in a 2D system in a quantum Hall regime<sup>1</sup>**, ALEKSANDR KAZAKOV, Purdue University, V. KOLKOVSKY, Z. ADAMUS, G. KARCEWSKI, T. WOJTOWICZ, Institute of Physics, Polish Academy of Sciences, LEONID ROKHINSON, Purdue University — A two-dimensional system with reconfigurable network of one-dimensional p-wave superconducting channels is a perfect platform to perform braiding of non-Abelian excitations. Such channels can be realized in CdTe:Mn quantum wells in a quantum Hall effect regime, where counterpropagating edge states with opposite spin polarization can be formed by electrostatic gating. These edges form helical channels similar to the edges of 2D topological insulators and, coupled to a superconductor, should support non-Abelian excitations. While long channels are localized at low temperatures, we found that resistance in short ( $\sim 6 \mu\text{m}$ ) helical channels remains finite at low temperatures. Transport data and resistance scaling with channel length will be presented.

**2:03PM F51.00015 Enhanced thermopower of gate-induced ZnO two-dimensional electron gas<sup>1</sup>**, SUNAO SHIMIZU, RIKEN CEMS, MOHAMMAD S. BAHRAMY, RIKEN CEMS, University of Tokyo, TAKAHIKO IIZUKA, University of Tokyo, SHIMPEI ONO, RIKEN CEMS, CRIEPI, KAZUMOTO MIWA, CRIEPI, YOSHINORI TOKURA, YOSHIHIRO IWASA, RIKEN CEMS, University of Tokyo — Control of dimensionality has proven to be an effective way to manipulate the electronic properties of materials, thereby enabling exotic quantum phenomena, such as superconductivity<sup>2</sup>, quantum Hall effects, and valleytronic effects<sup>3</sup>. Another example is thermoelectricity, which has been proposed to be favorably controllable by reducing the dimensionality<sup>4</sup>. We report the thermopower in a gate-induced two-dimensional electron gas (2DEG) formed at the surface of ZnO. Combining electric double layer transistor experiments and realistic tight-binding calculations, it is shown that, for a wide range of carrier densities, the 2DEG channel comprises a single subband, and its effective thickness can be reduced to several nanometers at sufficiently high gate biases. We demonstrate that the thermopower of the 2DEG region is significantly higher than that of bulk ZnO. Our approach opens up a novel route to exploit the peculiar behavior of 2DEG electronic states and realize thermoelectric devices with advanced functionalities.

## Tuesday, March 15, 2016 11:15AM - 1:51PM – Session F52 GERA FIAP: Physics of Batteries II Hilton Baltimore Holiday Ballroom 3 -

**11:15AM F52.00001 First principles studies of structure stability and lithium intercalation of ZnCo2O4**, YANNING ZHANG, Chengdu Green Energy and Green Manufacturing Technology RD Center, WEIWEI LIU, Beijing Computational Science Research Center, BEIJING COMPUTATIONAL SCIENCE RESEARCH CENTER TEAM — Among the metal oxides, which are the most widely investigated alternative anodes for use in lithium ion batteries (LIBs), binary and ternary transition metal oxides have received special attention due to their high capacity values. ZnCo2O4 is a promising candidate as anode for LIB, and one can expect a total capacity corresponding to 7.0 - 8.33 mol of recyclable Li per mole of ZnCo2O4. Here we studied the structural stability, electronic properties, lithium intercalation and diffusion barrier of ZnCo2O4 through density functional calculations. The calculated structural and energetic parameters are comparable with experiments. Our theoretical studies provide insights in understanding the mechanism of lithium ion displacement reactions in this ternary metal oxide.

**11:27AM F52.00002 First-principles investigations of ionic conduction in Li and Na borohydrides**, JOEL VARLEY, TAE-WOOK HEO, KEITH RAY, STANIMIR BONEV, BRANDON WOOD, Lawrence Livermore Natl Lab — Recent experimental studies have identified a family of alkali borohydride materials that exhibit superionic transition temperatures approaching room temperature and ionic conductivities exceeding 0.1 S/cm<sup>-1</sup>, making them highly promising solid electrolytes for next-generation batteries. Despite the rapid advances in improving the superionic conductivity in these materials, an understanding of the exact mechanisms driving the transport remains unknown. Here we use *ab initio* molecular dynamics calculations to address this issue by characterizing the diffusivity of the Li and Na species in a representative set of closoborane ionic conductors. We investigate both the Na and Li-containing borohydrides with icosahedral (B<sub>12</sub>H<sub>12</sub>) and double-capped square antiprism (B<sub>10</sub>H<sub>10</sub>) anion species and discuss the trends in ionic conductivity as a function of stoichiometry and the incorporation of various dopants. Our results support the borohydrides as a subset of a larger family of very promising solid electrolytes and identify strategies to improving the conductivity in these materials. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

**11:39AM F52.00003 Defect Physics and Ionic conduction in Solid Electrolyte Interphase for Lithium Ion Batteries<sup>1</sup>**, JIE PAN, YANG-TSE CHENG, University of Kentucky, YUE QI, Michigan State University — The ionic conduction through the solid electrolyte interphase (SEI) is important to the rate capability of the battery. The origin of ionic conduction in the SEI is defect formation and transport. In this study, we developed a theoretical method based on density functional theory to calculate the ionic conductivity in LiF, an important SEI component, in contact with electrode materials. Seventeen native defects with their relevant charge states were investigated to determine the dominant defects on various electrodes. The contacted electrode serves as a Li reservoir with adjustable Li chemical potential ( $\mu_{Li}$ ) for defect formation. The formation energy and diffusion barrier of defects were mapped to ionic conductivity by the Nernst-Einstein relationship. The main defect is Schottky pair in the intrinsic region and Li ion vacancy in the p-type region. The ionic conductivity is calculated to be approximately 10<sup>-31</sup> S/cm when LiF is in contact with an anode but it can increase to 10<sup>-12</sup> S/cm on a cathode. Comparing with other SEI components, the ionic conductivity is very low in LiF if it is coated on an anode surface. However, due to the low concentration of electronic carriers, LiF can act as a good passivation layer on the electrode and prevent further electrolyte decomposition.

<sup>1</sup>This work is supported by Department of Energy and National Science Foundation.

**11:51AM F52.00004 First Principles Study of Electrochemical and Chemical Stability of the Solid Electrolyte-Electrode Interfaces in All-Solid-State Li-Ion Batteries<sup>1</sup>**, YIZHOU ZHU, XINGFENG HE, YIFEI MO, Department of Materials Science and Engineering, Univ of Maryland-College Park — All-solid-state Li-ion battery is a promising next-generation energy-storage technology. Using novel ceramic solid electrolyte materials, all-solid-state battery has advantages of intrinsic safety and high energy density compared to current Li-ion batteries based on organic liquid electrolyte. However, the power density achieved in all-solid-state battery is still unsatisfactory. The high interfacial resistance at electrode-electrolyte interface is one of the major limiting factors. Here we demonstrated a computational approach based on first principles calculation to systematically investigate the chemical and electrochemical stability of solid electrolyte materials, and provide insightful understanding of the degradation and passivation mechanisms at the interface. Our calculation revealed that the intrinsic stability of solid electrolyte materials and solid electrolyte-electrode interfaces is limited and the formation of interphase layers are thermodynamically favorable. Our study demonstrated a computational scheme to evaluate the electrochemical and chemical stability of the solid interfaces. Our newly gained understanding provided principles for developing solid electrolyte materials with enhanced stability and for engineering interfaces in all-solid-state Li-ion batteries.

**12:03PM F52.00005 Using Defects in Materials to Store Energy: a Theoretical Study**, I-TE LU, MARCO BERNARDI, Department of Applied Physics and Materials Science, California Institute of Technology — We study the energy stored by defects in materials using density functional theory (DFT) calculations. Leveraging experimental data to estimate the energy density of defects, expressed as the defect formation energy per unit volume (units of MJ/L) or weight (units of MJ/kg), we identify candidates for high energy density storage, including tungsten, diamond, graphite, silicon, and graphene. DFT calculations are applied to these materials to study the formation energy of vacancies, interstitials, and Frenkel pairs. Our results indicate that the energy density stored by defects in these materials, with experimentally accessible non-equilibrium defect concentrations, can be higher than that of common energy storage technologies such as lithium batteries and supercapacitors. We discuss storage of solar energy and electrical energy (through ion bombardment) using defects.

**12:15PM F52.00006 Strain-induced tuning of surface energy, electron conductivity, and reduction drive in spinel  $\text{LiMn}_2\text{O}_4$  cathodes<sup>1</sup>**, IVAN SCIVETT, GILBERTO TEOBALDI, University of Liverpool —  $\text{LiMn}_2\text{O}_4$  (LMO) implementation in rechargeable Li-ion batteries (LIBs) for stationary storage is hampered by the limited lifetime of the material and its interfaces, starting from the Solid Electrolyte Interphase [1,2]. Recent experiments [2] and Density Functional Theory (DFT) simulations [3] indicate that the formation and effectiveness of the SEI on LMO are related to the surface orientation and reduction drive. In this context, we analyse the role of geometrical strain for the relative energy, magnetic ordering and the reduction drive of several LMO surfaces. DFT simulations reveal LMO surfaces to be markedly sensitive to geometrical strain. Strain lower than 10% can induce insulator-metal and ferromagnetic-antiferromagnetic transitions, alter the relative energy of LMO surfaces, and induce changes as large as 1.0 eV in the surface chemical potential, thence reduction drive. Prompted by advances in the synthesis of metal-oxide core-shell nanostructures [4], use of strained LMO coating as SEI-formation agent is put forward towards engineering of longer lived SEI on LMO substrates.

**12:27PM F52.00007 Atomic dynamics in  $\text{PrBaCo}_2\text{O}_6$** , ELVIS SHOKO, UDO SCHWINGENSCHLOGL, King Abdullah University of Science and Technology, Thuwal, 23955-6900 — We have used a combination of lattice dynamics and *ab initio* molecular dynamics (MD) to study atomic dynamics in  $\text{PrBaCo}_2\text{O}_6$ , a prototype material for a large class of layered compounds of both fundamental and technological interest. With the layered structure as the framework for understanding the dynamics, our analysis reveals clear signatures of this structural motif in the overall atomic dynamics, especially for O atoms. In particular, we find that O atom dynamics in the PrO layer is predominantly in-plane (*ab*-plane) in contrast to the predominantly out-of-plane dynamics in the  $\text{CoO}_2$  layer. This finding suggests that the oxide ionic conductivity is dominated by the O atoms in the PrO layer. Additionally, we find sharp low-energy modes below 20 meV for both Ba and Pr atoms, reminiscent of rattler modes known for reducing thermal conductivity in cage compounds.

**12:39PM F52.00008  $\text{MnO}_2$  Encapsulated Electrospun  $\text{TiO}_2$  Nanofibers: A Strategic Approach towards the Development of Aqueous Electrolyte Based Asymmetric Supercapacitors**, MUHAMED SHAREEF, Kansas State University, MILAN PALEI, TIRUPATTUR NATARAJAN SRINIVASAN, Indian Institute of Technology Madras, GURPREET SINGH, Kansas State University — An aqueous electrolyte based asymmetric supercapacitor was designed from  $\text{MnO}_2$  coated  $\text{TiO}_2$  nanofibers which were prepared by electrospinning and post hydrothermal process. The core shell fiber architecture exhibit highest specific capacitance of 868 F/g in aqueous  $\text{Na}_2\text{SO}_4$  electrolyte as compared to the similar structures. The Asymmetric supercapacitor (ASC) fabricated based on these core shell fibers demonstrates large voltage window of 2.6 V which is one of the widest voltage window among aqueous electrolyte based asymmetric supercapacitors. In addition, the ASC delivers large specific capacitance and energy density as revealed by the electrochemical studies. The thin  $\text{MnO}_2$  shell, of thickness 6 nm, contributes to the extraordinary electrochemical performance for charge storage by redox reaction and intercalation mechanisms, while the anatase phase  $\text{TiO}_2$  core provides an easy pathway for electronic transport with additional electrochemical stability over thousands of charge discharge cycles.

**12:51PM F52.00009 Helically coiled carbon nanotube forests for use as electrodes in supercapacitors**, ANTHONY CHILDRESS, KEVIN FERRI, RAMAKRISHNA PODILA, APPARAO RAO, Clemson Univ — Supercapacitors are a class of devices which combine the high energy density of batteries with the power delivery of capacitors, and have benefitted greatly from the incorporation of carbon nanomaterials. In an effort to improve the specific capacitance of these devices, we have produced binder-free electrodes composed of helically coiled carbon nanotube forests grown on stainless steel current collectors with a performance superior to traditional carbon nanomaterials. By virtue of their helicity, the coiled nanotubes provide a greater surface area for energy storage than their straight counterparts, thus improving the specific capacitance. Furthermore, we used an Ar plasma treatment to increase the electronic density of states, and thereby the quantum capacitance, through the introduction of defects.

**1:03PM F52.00010 High-Energy-Density Cost-Effective Graphene Supercapacitors**, VLADIMIR SAMUILOV, YING YING MU, NADER HEDAYAT, Department of Materials Science and Engineering, SUNYSB, VYACHESLAV SOLOVYOV, Graphene ESD, SENSOR CAT AT STONY BROOK TEAM — We introduce a cost-effective graphene platelet composite material as a replacement of an expensive reduced graphene oxide for electrodes in high energy density supercapacitors. We have tested a low size supercapacitor prototypes with the graphene platelets electrodes and newly developed polymer-gel  $\text{Li}^+$  ion electrolyte. We discuss the ways how to increase the capacitance and the energy densities of the supercapacitor significantly. A working prototype for testing the concept of the high voltage supercapacitor has been developed as well. The first test done up to 10 V showed excellent performance of the multi-cell multi-layer high voltage test assembly.

**1:15PM F52.00011 Dipolar self-consistent field theory for ionic liquids between charged plates: Effects of dielectric contrast between cation and anion under external electrostatic fields<sup>1</sup>**, ISSEI NAKAMURA, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We develop a new dipolar self-consistent field theory (DSCFT) for both incompressible and compressible ionic liquids under external electrostatic fields. Our theory accounts for the difference between the dipole moments and the molecular volumes of the cation and anion, and the double layer caused by the strong association of the ions with the electrodes. To date, few theoretical studies have considered the dielectric contrast between the cation and anion. Thus, our study focuses on the effect of the dielectric inhomogeneity on the ion distribution and the capacitance. Our theory shows that the capacitance changes with the applied voltage in agreement with experimental observations. Importantly, the dielectric contrast and the difference in molecular volumes between the cation and anion have equal effects on the magnitude of the capacitance. We also consider compressible ionic liquids by developing a hybrid of DSCFT combined with Monte Carlo simulations. We then demonstrate that the hard-core nature of the ions causes oscillations in the density profile and dielectric value near the charged plates. Accordingly, the dielectric constants derived from the classical theories of Onsager and Kirkwood are shown to be gross approximations of the true situation in nanochannels.

## 1:27PM F52.00012 Theoretical Investigation of oxides for batteries and fuel cell applications

PANCHAPAKESAN GANESH, ANDREW A. LUBIMTSEV, JANAKIRAMAN BALACHANDRAN, Center for Nanophase Materials Sciences, ORNL — I will present theoretical studies of Li-ion and proton-conducting oxides using a combination of theory and computations that involve Density Functional Theory based atomistic modeling, cluster-expansion based studies, global optimization, high-throughput computations and machine learning based investigation of ionic transport in oxide materials. In Li-ion intercalated oxides, we explain the experimentally observed (Nature Materials 12, 518522 (2013)) 'intercalation pseudocapacitance' phenomenon, and explain why  $Nb_2O_5$  is special to show this behavior when Li-ions are intercalated (J. Mater. Chem. A, 2013, 1, 14951-14956), but not when Na-ions are used. In addition, we explore Li-ion intercalation theoretically in  $VO_2(B)$  phase, which is somewhat structurally similar to  $Nb_2O_5$  and predict an interesting role of site-trapping on the voltage and capacity of the material, validated by ongoing experiments. Computations of proton conducting oxides explain why Y-doped  $BaZrO_3$ , one of the fastest proton conducting oxide, shows a decrease in conductivity above 20% Y-doping. Further, using high throughput computations and machine learning tools we discover general principles to improve proton conductivity. Acknowledgements: LDRD at ORNL and CNMS at ORNL

## 1:39PM F52.00013 Atomic-Scale Mechanisms for Electrolyte Decomposition in Li-ion Battery Cathodes<sup>1</sup>

MALLORY FUHST, University of Michigan Department of Applied Physics, DONALD SIEGEL, University of Michigan Department of Mechanical Engineering — Li-ion batteries using high energy density  $LiCoO_2$  (LCO) intercalation cathodes are known to generate gaseous species inside the cell, which can lead to venting flammable solvent vapor. It has been hypothesized that reactions at the cathode/electrolyte interface catalyze the production of these gaseous species. To elucidate the underlying reaction mechanism, first principles calculations were used to model interactions between LCO surfaces and Ethylene Carbonate (EC), a commonly used solvent in Li-ion batteries. A Metropolis Monte Carlo algorithm was used to identify likely low energy adsorption configurations for EC on the (10-14) surface of LCO. Several of these geometries were further analyzed with DFT. The thermodynamics and kinetics of EC decomposition were evaluated for plausible reaction pathways and associated various solvent decomposition mechanisms, such as hydrogen abstraction. Preliminary results indicate that hydrogen abstraction may lead to the spontaneous decomposition of EC into CO and other adsorbed species at the surface.

## 11:15AM F53.00001 Earle K. Plyler Prize for Molecular Spectroscopy & Dynamics: Photochemistry of Phenol: A Full-Dimensional Semiclassical Simulation<sup>1</sup>

DONALD TRUHLAR, University of Minnesota, Minneapolis, MN — This lecture will present a simulation of the photodissociation of phenol that is made possible by combining four methods in a complementary way: (1) the fourfold way for generating diabatic electronic states, based on diabatic molecular orbitals and configurational uniformity; (2) anchor points reactive potentials for fitting the 33-dimensional diabatic potentials; (3) coherent switches with decay of mixing for multistate dynamics governed by coupled potential energy surfaces, including density matrix coherence and decoherence; (4) army ants tunneling, including electronically nonadiabatic tunneling. By combining all these methods, one can thoroughly sample an ensemble of trajectories with potential energy surfaces and couplings that include multireference dynamic electron correlation. By including army ants tunneling, the trajectory simulation of phenol photodissociation dynamics based on accurate full-dimensional anchor-points reactive potential surfaces and state couplings successfully reproduces the experimentally observed bimodal total kinetic energy release spectra. Analysis of the trajectories uncovers an unexpected dissociation pathway. The new method for including tunneling in full-dimensional molecular dynamics simulations is general, and it can also be used for electronically adiabatic processes.

## 11:51AM F53.00002 Jankunas Doctoral Dissertation Award: Attosecond science with recolliding electrons

PETER KRAUS, University of California, Berkeley — Measuring the motion of valenceshell electrons in molecules is one of the main research thrusts in modern ultrafast science. The process of highharmonic generation (HHG), the conversion of many infrared photons into one XUV photon, relies on the laserdriven ionization, acceleration and precisely timed recombination in a strong laser field. The frequencies emitted upon recollision can be uniquely mapped to a transit time of the electron in the continuum thus providing attosecond temporal and Angstrom spatial resolution encoded in the HHG spectrum. In this talk we present experiments that utilize these capacities of HHG for following a coherent valenceshell electron current in nitric oxide on the femtosecond time scale in a classical pumpprobe experiment. Furthermore, we use the intrinsic time resolution of the HHG process to measure attosecond timescale electron dynamics: The motion of an electron hole across a molecular chain after ionization in spatially oriented iodoacetylene molecules.

## 12:27PM F53.00003 Multi-Configuration Pair-Density Functional Theory

LAURA GAGLIARDI, Department of Chemistry, University of Minnesota — We have recently developed a new theoretical framework, called Multiconfiguration Pair-Density Functional Theory (MC-PDFT), [1] which combines multiconfigurational wave functions with a generalization of density functional theory (DFT). In this talk I will describe the basic principles of the theory and I present our latest results with MC-PDFT on spectroscopy, [2] charge-transfer systems [3] and molecules containing transition metals [4].

**1:03PM F53.00004 MN15-L and MN-15: New Kohn-Sham Density Functionals with Board Accuracy for Main-Group and Transition Metal Chemistry and Noncovalent Interactions<sup>1</sup>**, HAOYU YU, Department of Chemistry, University of Minnesota, XIAO HE, East China Normal University, DONALD G. TRUHLAR, University of Minnesota, DONALD G. TRUHLAR TEAM — The accuracy of Kohn-Sham density functional theory depends on the exchange-correlation functional. Local functionals depending on only the density ( $\rho$ ), density gradient (grad), and possibly kinetic energy density ( $\tau$ ) have been popular because of their low cost and simplicity, but the most successful functionals for chemistry have involved nonlocal Hartree-Fock exchange (hybrid functionals). We have designed a new meta gradient approximation called MN15-L and a new hybrid meta gradient approximation called MN15 and tested them systematically for 17 absolute atomic energies, 51 noncovalent interaction energies, 56 data on transition metal atoms and molecules, and for 298 other atomic and molecular energetic data, including main-group and transition metal bond energies, ionization potentials, proton affinities, reaction barrier heights, hydrocarbon thermochemistry, excitation energies, and isomerization energies. When compared with 84 previous density MN15 and MN15-L give respectively the smallest and second smallest mean unsigned errors (MUEs, in kcal/mol) on all 422 data with errors for the 4 subsets above being: MN15: 6, 0.26, 4.4, 1.6; MN15-L: 7, 0.45, 4.3, 2.0. Third best: M06: 4, 0.35, 7.7, 2.2. Best previous local functional: M06-L: 7, 0.42, 6.0, 3.5. Other popular functionals: B3LYP: 18, 0.82, 8.2, 4.3; HSE06: 33, 0.58, 8.8, 3.6; TPSS: 18, 0.89, 7.25, 5.0; PBE, 47, 0.88, 9.1, 6.0. MN15-L also performs well for solid-state cohesive energies.

**1:15PM F53.00005 Density functionals from deep learning**, JEFFREY MCMAHON, Department of Physics and Astronomy, Washington State University — Density-functional theory is a formally exact description of a many-body quantum system in terms of its density; in practice, however, approximations to the universal density functional (DF) are necessary. Machine learning has recently been proposed as a novel approach to discover such a DF (or components of it)<sup>1</sup>. Conventional machine learning algorithms, however, are limited in their ability to process data in their raw form, leading to invariance and/or sensitivity issues. In this presentation, an alternative approach based on deep learning will be demonstrated<sup>2</sup>. Deep learning allows computational models that are capable of discovering intricate structure in large and/or high-dimensional data sets with multiple levels of abstraction, and do not suffer from the aforementioned issues. Results from the application of this approach to the prediction of the kinetic-energy DF of noninteracting electrons will be presented. Using theoretical results from computer science, a connection between the underlying model and the theorems of Hohenberg and Kohn will also be suggested.

**1:27PM F53.00006 Enhancing Linear-Scaling DFT for Extended Systems via a QM/QM Fragment Approach**, LAURA RATCLIFF, Argonne National Laboratory, LUIGI GENOVESE, CEA Grenoble, STEPHAN MOHR, Barcelona Supercomputing Center, THIERRY DEUTSCH, CEA Grenoble — We recently introduced a minimal basis approach to the wavelet-based BigDFT code, wherein a minimal set of localized support functions are expressed in an underlying wavelet basis and optimized to reflect their chemical environment. This not only forms the basis of an accurate linear-scaling DFT approach, allowing systems of 10,000 atoms or more to be treated with modest computational resources, but also facilitates the straightforward definition of a fragment approach. Such an approach can reduce the computational cost by an order of magnitude while also offering additional flexibility. We have previously demonstrated the suitability of a molecular fragment approach for the treatment of environmental effects within the context of constrained DFT and have now also expanded the method to include the treatment of extended, periodic systems. In this talk we will describe the extended fragment approach and present examples of its application to large defect systems, as well as offering a perspective on future directions for the treatment of very large systems, such as an embedded approach.

**1:39PM F53.00007 Complex wet-environments in electronic-structure calculations<sup>1</sup>**, GIUSEPPE FISICARO, University of Basel, LUIGI GENOVESE, Laboratoire de simulation atomistique (L-Sim), SP2M, INAC, CEA-UJF, OLIVIERO ANDREUSSI, Institute of Computational Science, Università della Svizzera Italiana & THEOS-MARVEL École Polytechnique Fédérale de Lausanne, NICOLA MARZARI, THEOS-MARVEL École Polytechnique Fédérale de Lausanne, STEFAN GOEDECKER, University of Basel — The computational study of chemical reactions in complex, wet environments is critical for applications in many fields. It is often essential to study chemical reactions in the presence of an applied electrochemical potentials, including complex electrostatic screening coming from the solvent. In the present work we present a solver to handle both the Generalized Poisson and the Poisson-Boltzmann equation. A preconditioned conjugate gradient (PCG) method has been implemented for the Generalized Poisson and the linear regime of the Poisson-Boltzmann, allowing to solve iteratively the minimization problem with some ten iterations. On the other hand, a self-consistent procedure enables us to solve the Poisson-Boltzmann problem. The algorithms take advantage of a preconditioning procedure based on the BigDFT Poisson solver for the standard Poisson equation. They exhibit very high accuracy and parallel efficiency, and allow different boundary conditions, including surfaces. The solver has been integrated into the BigDFT and Quantum-ESPRESSO electronic-structure packages and it will be released as an independent program, suitable for integration in other codes. We present test calculations for large proteins to demonstrate efficiency and performances.

**1:51PM F53.00008 Investigating the Self-assembled Structure of Polycyclic Aromatic Hydrocarbons Using Two Dimensional Infrared Spectroscopy**, JENEE D. CYRAN, Max Planck Institute of Polymer Research, AMBER T. KRUMMEL, Colorado State University — Self-assembly mechanisms are required for many biological and material processes, such as chlorophyll in photosynthesis, the tobacco mosaic virus and in the formation of molecular crystals. The self-assembly process can be favorable in the case of formation of nanoparticles for electronic devices. However, self-assembly processes, such as asphaltene nanoaggregation, can be unwarranted. Studying the structure of self-assembled supramolecules is important to understand how to mimic or inhibit the formation of the nanoaggregates. In this research, we studied the monomer and self-assembled structure of two polycyclic aromatic hydrocarbons (PAHs), lumogen orange and violanthrone-79, using two-dimensional infrared spectroscopy (2D IR). The carbonyl stretching and the ring breathing vibrational modes were used as vibrational probes. For violanthrone-79, a local mode basis and an electrostatic coupling model were applied to three nanoaggregate structures; parallel, antiparallel, and 28 degrees rotation. The experimental and simulated 2D IR spectra are best represented by majority of the antiparallel configuration with some angular distribution. For lumogen orange, vibrational cross peaks appear as the concentration is increased from a monomer to a nanoaggregate. The 2D IR cross peaks indicate vibrational coupling, which relates directly to the nanoaggregate structure. Comparison between the self-assembled structure of lumogen orange and violanthrone-79 can determine the role of side chains in the nanoaggregate structure.

**2:03PM F53.00009 Reversible electro-strain coupling in K-doped BaTiO<sub>3</sub><sup>1</sup>**, SHI LIU, Geophysical Laboratory, Carnegie Institution of Washington, RONALD E. COHEN, Geophysical Laboratory, Carnegie Institution of Washington and Department für Geo- und Umweltwissenschaften, Ludwig-Maximilians-Universität — Ferroelectric materials that possess a spontaneous polarization have a wide range of applications. Coupled with a non-180° polarization switching, the strain of a ferroelectric crystal will change, due to the exchange of nonequal crystallographic axes. The field-induced large electro-strain coupling accompanied by non-180° domain switching, however, is usually an one-time effect, because the system lacks the driving force to recover to its original state, thus limiting its usefulness. It is suggested that defect dipoles introduced by dopant-vacancy pairs could serve as the driving force for reversible domain switching. However, there is still a lack of first-principles-supported microscopic understanding of the role of defect dipoles in reversible domain switching. In this work, we explore the intrinsic effects of K-dopants and oxygen vacancy on the 90° polarization switching in the prototypical ferroelectric BaTiO<sub>3</sub> with density functional theory. The interplay between polar defect dipole, vacancy concentration and electromechanical properties is investigated. We find that defect dipoles could drive the system back to its original state spontaneously after the electric field is turned off.

**Session F54 GERA: Materials for Sustainable Development** Hilton Inner Harbor Holiday Ballroom 5 - Talat Rahman, University of Central Florida

**11:15AM F54.00001 Materials for sustainable development**, MARTY GREEN, NIST —

**11:51AM F54.00002 Teaching Sustainability in Materials Science and Engineering (and Beyond).**, R. LESAR, Department of Materials Science and Engineering, Iowa State University — Since 2008 we have been teaching various aspects of sustainability to undergraduate students at Iowa State University. In our first courses we introduced the ideas of sustainability in the context of global development. These courses were taught mostly to engineering students and took primarily a technical view of sustainability, both in the class room and on the ground in Africa. Since 2010, however, our focus has been on a course that presents a very broad view of sustainability to a highly diverse set of students from all parts of the University. This course presents interesting challenges owing to the breadth of the material and the rather large range of technical knowledge and skills (especially in mathematics) of the students. Our goals are to guide the students to a better understanding of the challenges of sustainability given the many constraints. Since there is a clear need for broadly creating a more informed view of sustainability, this course is the focus of today's talk. In it we will present our basic objectives for the course and our approach to covering the broad and disparate range of material. Having taught the course six (and a fraction) times, we will also comment on what we feel works well and what is still evolving.

In collaboration with K.M. Bryden, Department of Mechanical Engineering, Iowa State University and A.Hallam, Department of Economics, Iowa State University

**12:27PM F54.00003 Room temperature Creep and Elastic Anisotropy of LaCoO<sub>3</sub> based perovskites**, NINA ORLOVSKAYA, University of Central Florida — LaCoO<sub>3</sub> is the parent compound of the La<sub>1-x</sub>Ca<sub>x</sub>CoO<sub>3-δ</sub> system that is a mixed electronic and oxide-ion conductor of technical interest for oxygen separation membranes, the cathode of solid oxide fuel cells, oxygen sensors, and catalysis. Its high-temperature properties, such as electronic-ionic conductivity, electrochemical performance, and catalytic activity, have been studied to a great extent, while the mechanical behavior of the lanthanum cobaltites is still not completely understood. LaCoO<sub>3</sub>-based ceramics do not demonstrate elastic deformation during loading, but rather exhibit ferroelastic behavior with non-linearity and hysteresis, which provides time, temperature and loading rate dependent deformation. The goal of this research was to investigate room temperature creep at different stresses in polycrystalline ferroelastic LaCoO<sub>3</sub> based perovskites under compression. The attempt was made to identify the most important parameters which affect creep strain over different time periods. New phenomenological approach of ferroelastic creep was developed to describe mechanical behavior of cobaltites. Simple analytical expression was obtained to estimate equilibrium strain at given stress. Driving force of ferroelastic switching was defined for loading and unloading and the expression was proposed that allowed calculations of characteristic time for domain switching from driving force. The anisotropy of elastic behavior of the cobaltites was also studied.

**1:03PM F54.00004 Sustainable materials for catalysis**, JUDITH YANG, University of Pittsburgh —

**1:39PM F54.00005 The Next Fifty Years: Electricity, Storage and Sustainability**, ELIZABETH A. KOCS, University of Illinois at Chicago — Energy since the industrial revolution has been marked by historic transitions in sources, carriers and impacts, with each transition requiring a fifty-year time scale. Sustainability and clean energy, emergent themes with origins in the 1970s, are receiving increasing attention as climate change becomes more urgent. Transportation and the electricity grid, which account for nearly two thirds of carbon emissions, are ready for transitions to cleaner and more sustainable operation driven by electricity storage. The development of the lithium-ion battery and prospects for next generation beyond lithium-ion technology with the potential to electrify transportation and accelerate the deployment of renewable wind and solar will be discussed. The energy storage frontier: lithium ion batteries and beyond, George Crabtree, Elizabeth Kocs, Lynn Trahey, MRS Bulletin 40, 1067 (2015) Energy, society and science: the next fifty years, George Crabtree, Elizabeth Kocs, Thomas Alaan, Futures 58, 53 (2014)

## **Tuesday, March 15, 2016 11:15AM - 2:15PM –**

**Session F55 DBIO GSOFT: Brain Morphology and Mechanics: From Cortex Folding to Neuronal Growth to Compression Stiffening** Hilton Baltimore Holiday Ballroom 6 - Jennifer Schwartz, Syracuse University

**11:15AM F55.00001 How does the cortex get its folds? The role of tension-based morphogenesis**, DAVID VAN ESSEN, Washington University in St Louis — The cerebral cortex is a sheet-like structure that is convoluted to varying degrees in different species and, for human cortex, shows remarkable variability across individuals – even in identical twins. This talk will discuss key biological events and physical forces involved in how the cortex gets its folds. The early stages of cortical morphogenesis are established by exquisitely regulated patterns of cellular proliferation and migration that place the right numbers of cells in an appropriate starting configuration. A major focus will be on the proposed role of mechanical tension in the next stages of morphogenesis. Does tension along apical dendrites of cortical pyramidal cells help make the cortex a sheet? Does tension along long-distance axons cause the cortex to fold? These are attractive but controversial ideas. I will suggest ways in which physicists can contribute critical models and analyses that may help distinguish the relative contributions of several mechanisms (differential proliferation, buckling of the cortical sheet, and tension-based cortical folding). Physicists can also help in evaluating the degree to which cortical circuits reflect principles of compact wiring and the putative role of tension-based morphogenesis in wiring length minimization.

**11:51AM F55.00002 Gyrfication from constrained cortical expansion** , TUOMAS TALLINEN, University of Jyväskylä — The convolutions of the human brain are a symbol of its functional complexity. But how does the outer surface of the brain, the layered cortex of neuronal gray matter get its folds? In this talk, we ask to which extent folding of the brain can be explained as a purely mechanical consequence of unpatterned growth of the cortical layer relative to the sublayers. Modeling the growing brain as a soft layered solid leads to elastic instabilities and the formation of cusped sulci and smooth gyri consistent with observations across species in both normal and pathological situations. Furthermore, we apply initial geometries obtained from fetal brain MRI to address the question of how the brain geometry and folding patterns may be coupled via mechanics.

**12:27PM F55.00003 Elastic instabilities in a layered cerebral cortex: A revised axonal tension model for cortex folding**<sup>1</sup> , J. M. SCHWARZ, Department of Physics, Syracuse University — Despite decades of research, there is still no consensus regarding the mechanism(s) driving cerebral cortex folding. Two different mechanisms—axonal tension based on efficient wiring of the neurons and differential growth-induced buckling—are the prevailing hypotheses, though quantitative comparison with data raises issues with both of them. I will present a model for the elasticity of the cerebral cortex as a layered material with bending energy along the layers and elastic energy between them. The cortex is also subjected to axons pulling from the underlying white matter. Above a critical threshold force, a 'flat' cortex configuration becomes unstable and periodic undulations emerge, i.e. a buckling instability occurs, to presumably initiate folds in the cortex. This model builds on the original axonal tension model for cortex folding based on the efficient wiring of neurons but with no buckling mechanism and allows one to understand why small mice brains exhibit no folds, while larger human brains do. Finally, an estimate of the bending rigidity constant for the cortex can be made based on the critical wavelength to quantitatively test this revised axonal tensional model.

<sup>1</sup>This work was done in collaboration with Oksana Manyuhina and David Mayett.

**1:03PM F55.00004 Effects of surface asymmetry on neuronal growth**<sup>1</sup> , CRISTIAN STALL, Tufts University, Physics and Astronomy — Understanding the brain is of tremendous fundamental importance, but it is immensely challenging because of the complexity of both its architecture and function. A growing body of evidence shows that physical stimuli (stiffness of the growth substrate, gradients of various molecular species, geometry of the surrounding environment, traction forces etc.) play a key role in the wiring up of the nervous system. I will present a systematic experimental and theoretical investigation of neuronal growth on substrates with asymmetric geometries and textures. The experimental results show unidirectional axonal growth on these substrates. We demonstrate that the unidirectional bias is imparted by the surface ratchet geometry and quantify the geometrical guidance cues that control neuronal growth. Our results provide new insight into the role played by physical cues in neuronal growth, and could lead to new methods for stimulating neuronal regeneration and the engineering of artificial neuronal tissue.

<sup>1</sup>We acknowledge support from NSF through CBET 1067093

**1:39PM F55.00005 COMPRESSION STIFFENING OF BRAIN AND ITS EFFECT ON MECHANONSENSING BY GLIOMA CELLS** , KATARZYNA POGODA, Institute of Nuclear Physics, Polish Academy of Sciences — The stiffness of tissues, often characterized by their time-dependent elastic properties, is tightly controlled under normal condition and central nervous system tissue is among the softest tissues. Changes in tissue and organ stiffness occur in some physiological conditions and are frequently symptoms of diseases such as fibrosis, cardiovascular disease and many forms of cancer. Primary cells isolated from various tissues often respond to changes in the mechanical properties of their substrates, and the range of stiffness over which these responses occur appear to be limited to the tissue elastic modulus from which they are derived. Our goal was to test the hypotheses that the stiffness of tumors derived from CNS tissue differs from that of normal brain, and that transformed cells derived from such tumors exhibit mechanical responses that differ from those of normal glial cells. Unlike breast and some other cancers where the stroma and the tumor itself is substantially stiffer than the surrounding normal tissue, our data suggest that gliomas can arise without a gross change in the macroscopic tissue stiffness when measured at low strains without compression. However, both normal brain and glioma samples stiffen with compression, but not in elongation and increased shear strains. On the other hand, different classes of immortalized cells derived from human glioblastoma show substantially different responses to the stiffness of substrates *in vitro* when grown on soft polyacrylamide and hyaluronic acid gels. This outcome supports the hypothesis that compression stiffening, which might occur with increased vascularization and interstitial pressure gradients that are characteristic of tumors, effectively stiffens the environment of glioma cells, and that *in situ*, the elastic resistance these cells sense might be sufficient to trigger the same responses that are activated *in vitro* by increased substrate stiffness.

**G1.00002 Simple thermal treatment for the size control of pore arrays in a polystyrene colloidal crystal films**<sup>1</sup> , RYAN M. JAMIOLKOWSKI<sup>2</sup>, Pennsylvania Muscle Institute, University of Pennsylvania, Philadelphia, PA, USA, SHANE A. FIORENZA<sup>3</sup>, Department of Physics, West Chester University of Pennsylvania, West Chester, PA, USA, KEVIN CHEN, ALYSSA M. TATE, Pennsylvania Muscle Institute, University of Pennsylvania, Philadelphia, PA, USA, SHAWN H. PFEIL, Department of Physics, West Chester University of Pennsylvania, West Chester, PA, USA, YALE E. GOLDMAN, Pennsylvania Muscle Institute, University of Pennsylvania, Philadelphia, PA, USA — Nanosphere Lithography (NSL) offers an attractive route to fabricating periodic structures with nanoscale features, without e-beam or deep UV lithography. In particular, it is uniquely suited to the low cost fabrication of large repeated arrays pores or pillars created by taking advantage of the interstitial spaces in close-packed monolayers of nano to micro-scale beads. However pore size, shape, and spacing cannot be controlled independently. We present both a robust method for producing large, approximately 1 cm<sup>2</sup>, hexagonally close packed monolayer films of 1 micron diameter polystyrene beads on glass substrates, and thermal treatment of these films near the glass temperature, T<sub>g</sub>, of polystyrene to modify the pore size. This builds on earlier work showing that pore size can be modified for colloidal crystals formed at a liquid gas interface [2]. These processes promise a simple, reproducible, and low cost route to periodic pore arrays for nano-phonic applications such as zero mode waveguides (ZMWs)

**G1.00003 Synthesis of Novel Birnessite Type  $\text{MnO}_2$  Nanochains by Electrospinning and their Application as Supercapacitor Electrodes**, MUHAMED SHAREEF, Kansas State University, MILAN PALEI, SAMERENDER HANU-MANTHA RAO, TIRUPATTUR NATARAJAN, Indian Institute of Technology Madras, GURPREET SINGH, Kansas State University — A first time method for the synthesis of continuous nanochains by employing electrospinning and post processes are reported with theoretic support. High aspect ratio electrospun PAN nanofibers were stabilized in air at a specific heating rate followed by functionalization in aqueous  $\text{KMnO}_4$  solution. The composite membrane was calcined in air in order to remove polymer skeleton along with reduction of  $\text{KMnO}_4$  into  $\text{MnO}_2$ . The highly crystalline and phase pure birnessite type  $\text{MnO}_2$  nanochains were characterized by different microscopic and spectroscopic techniques. Electrochemical studies of these nanochains were carried out using three electrode and two electrode set up with 0.5 M  $\text{Na}_2\text{SO}_4$  aqueous electrolyte. A possible mechanism for the formation of nanochains was also explained

**G1.00004 Spin torque resonant vortex core expulsion for an efficient radio-frequency detection scheme**, V. CROS, A.S. JENKINS, R. LEBRUN, P. BORTOLOTTI, E. GRIMALDI, Unit Mixte de Physique CNRS/Thales, Univ. Paris-Sud, Univ. Paris-Saclay, S. TSUNEGI, H. KUBOTA, K. YAKUSHIJI, A. FUKUSHIMA, S. YUASA, Spintronic Research Center, AIST — It has been proposed by Tulapurkar et al.[1ref] that a high frequency detector based on the so called spin-diode effect in spin transfer oscillators could eventually replace conventional Schottky diodes, due to their nanoscale size, frequency tunability, and large output sensitivity. Although a promising candidate for ICT applications, the output voltage generated from this effect is consistently low. Here we present a scheme for a new type of spintronics-based high frequency detector based on the expulsion of the vortex core of a magnetic tunnel junction. The resonant expulsion of the core leads to a large and sharp change in resistance associated with the difference in magnetoresistance between the vortex ground state and the final C-state, which is predominantly in either the parallel or anti-parallel direction relative to the polariser layer [2]. Interestingly, this reversible effect is independent of the incoming rf current amplitude, offering a compelling perspective for a fast real-time rf threshold detector. REF : EU FP7 grant (MOSAIC No. ICT-FP7-317950 is acknowledged. [1] Tulapurkar et al. Nature 438, 339, [2] A.S. Jenkins et al., Nat. Nanotech (2015)

**G1.00005 Physics Incubator at Kansas State University**, BRET FLANDERS, AMITABHA CHAKRABARTI, Kansas State University — Funded by a major private endowment, the physics department at Kansas State University has recently started a physics incubator program that provides support to research projects with a high probability of commercial application. Some examples of these projects will be discussed in this talk. In a parallel effort, undergraduate physics majors and graduate students are being encouraged to work with our business school to earn an Entrepreneurship minor and a certification in Entrepreneurship. We will discuss how these efforts are promoting a “culture change” in the department. We will also discuss the advantages and the difficulties in running such a program in a Midwest college town.

**G1.00006 Radiation Pattern and Scattering Properties of Optical Antennas<sup>1</sup>**, ZEYAN XU, University of Texas at Dallas, KEVIN MESSER, ELI YABLONOVITCH, University of California, Berkeley — When light emitting devices (e.g. LEDs) are coupled with optical antennas of the same resonance frequency, their spontaneous emission rate can be enhanced drastically. The ultimate goal is to have the rate of spontaneous emission faster than the stimulated emission so that the LEDs would be as fast as lasers and enable us to achieve energy efficient interconnects for on-chip communication. In this project, we built multiple optical setups to experimentally measure the far field radiation pattern, light scattering properties and photoluminescence of a series of optical antennas. We also used Lumerical FDTD software to theoretically simulate the structure and found out that the simulated results agree with experimental values. As the longitudinal length increased, the spectrum shifted towards higher wavelengths on the spectrum. Also, by studying the radiation patterns of the optical antennas, we are able to understand their strengths as a function of direction, and how the geometrical shape contribute to the shape of radiation patterns. Understanding the radiation pattern and the scattering spectrum of optical antennas will enable us to design devices with specific requirements on radiational directions and resonance frequencies for optical antennas.

**G1.00007 Visible WGM emissions from rare earth ion doped ZnO microspheres**, FABITHA K, Research scholar, M S RAMACHANDRA RAO, Professor — ZnO is known to be an ideal candidate for short wavelength range opto-electronic device applications due to its wide and direct bandgap (3.37 eV) and high excitonic binding energy (60 meV). Apart from the UV emission at ~380 nm (free exciton emission) ZnO also possesses a broad emission band centered at ~530 nm which is expected to be originated from the oxygen vacancy (Vo) defects. In rare earth (RE) ion doped ZnO, emissions originate from the 4f levels of RE ions will be obtained in addition to the characteristic emissions of ZnO. Small micro/nanostructures made of ZnO with high crystalline quality show unique characteristics in light emission, especially in lasing applications. A micro/ nanostructured ZnO crystal generally has a wurtzite structure with a natural hexagonal cross section, which serves as a WGM lasing micro cavity owing to its high reflective index (~2). However, there exists a potential optical loss at corners of hexagons; therefore, an isotropic structure like spheres may be a better candidate to achieve efficient light confinement. In our work, highly smooth micro spheres with different diameters were grown. Raman spectroscopy measurements confirm the hexagonal wurtzite structure of ZnO, SEM and AFM studies shows the smooth surfaced spheres. WGM lasing characteristics of ZnO spheres have been investigated using optical pumping with 488 nm laser in a micro-PL system. Details of the results will be presented.

**G1.00008 Title: Development of Single photon Quantum Optical Experiments using Type-I and Type-II Spontaneous Parametric Down Conversion**, ANDREW LAUGHARN, SEYFOLLAH MALEKI, Union College — We constructed a quantum optical apparatus to control and detect single photons. We generated these photons via Type-I and Type-II spontaneous parametric down conversion by pumping a GaN laser (405nm) incident on a BBO crystal. We detected the two down converted photons (810nm), denoted signal and idler, in coincidence so as to measure and control single photons. We implemented a coincidence counting unite onto an Altera DE2 board and used LabView for data acquisition. We used these photon pairs to demonstrate quantum entanglement and indistinguishability using multiple optical experiments.

**G1.00009 High speed Infrared imaging method for observation of the fast varying temperature phenomena**, REZA MOGHADAM, KAMBIZ ALAVI, University of Texas at Arlington Department of Electrical Engineering, BAOHONG YUAN, University of Texas at Arlington Department of Biomedical Engineering — With new improvements in high-end commercial R&D camera technologies many challenges have been overcome for exploring the high-speed IR camera imaging. The core benefits of this technology is the ability to capture fast varying phenomena without image blur, acquire enough data to properly characterize dynamic energy, and increase the dynamic range without compromising the number of frames per second. This study presents a noninvasive method for determining the intensity field of a High Intensity Focused Ultrasound Device (HIFU) beam using Infrared imaging. High speed Infrared camera was placed above the tissue-mimicking material that was heated by HIFU with no other sensors present in the HIFU axial beam. A MATLAB simulation code used to perform a finite-element solution to the pressure wave propagation and heat equations within the phantom and temperature rise to the phantom was computed. Three different power levels of HIFU transducers were tested and the predicted temperature increase values were within about 25% of IR measurements. The fundamental theory and methods developed in this research can be used to detect fast varying temperature phenomena in combination with the infrared filters.

**G1.00010 Room temperature lasing in GeSn alloys: A path to CMOS-compatible infrared lasers**, ZAIRUI LI, YUN ZHAO, Electro-Optics Program, University of Dayton, Dayton, OH, JAMES GALLAGHER, JOS MENNDEZ, Department of Physics, Arizona State University, Tempe, AZ, JOHN KOUVETAKIS, Department of Chemistry and Biochemistry, Arizona State University, Tempe, AZ, IMAD AGHA, JAY MATHEWS, Electro-Optics Program, University of Dayton, Dayton, OH and Department of Physics, University of Dayton, Dayton, OH — *h —abstract—* The semiconductor industry has been pushing silicon photonics development for many years, resulting in the realization of many CMOS-compatible optoelectronic devices. However, one challenge that has not been overcome is the development of Si-based lasers. Recently, GeSn alloys grown on Si have shown much promise in the field of infrared optoelectronics. These alloy films are compatible with CMOS processing, have band gaps in the infrared, and the band structure of GeSn can be tuned via Sn concentration to induce direct band gap emission. In this work, we report on room temperature lasing in optically-pumped waveguides fabricated from GeSn films grown epitaxially on Si(100) substrates. The waveguides were defined using standard UV photolithography and dry-etched in a Cl plasma. The end facets were mirror polished, and Al was deposited on one facet to enhance cavity quality. The waveguides were optically-pumped using a 976nm wavelength solid-state laser, and the corresponding emission was measured. The dependence of the emission power on the pump power shows a clear transition between spontaneous and stimulated emission, thereby demonstrating room temperature lasing.

**G1.00011 Field-induced activation of metal oxide semiconductor for low temperature flexible transparent electronic device applications**, PUSHPA RAJ PUDASAINI, JOO HYON NOH, ANTHONY WONG, AMADA HAGLUND, The University of Tennessee, THOMAS ZAC WARD, Materials Science and Technology Division, ORBL, Oak Ridge, TN 37831, USA, DAVID MANDRUS<sup>1</sup>, PHILIP RACK<sup>2</sup>, The University of Tennessee — Amorphous metal-oxide semiconductors have been extensively studied as an active channel material in thin film transistors due to their high carrier mobility, and excellent large-area uniformity. Here, we report the athermal activation of amorphous indium gallium zinc oxide semiconductor channels by an electric field-induced oxygen migration via gating through an ionic liquid. Using field-induced activation, a transparent flexible thin film transistor is demonstrated on a polyamide substrate with transistor characteristics having a current ON-OFF ratio exceeding 10<sup>8</sup>, and saturation field effect mobility of 8.32 cm<sup>2</sup>/(V.s) without a post-deposition thermal treatment. This study demonstrates the potential of field-induced activation as an athermal alternative to traditional post-deposition thermal annealing for metal oxide electronic devices suitable for transparent and flexible polymer substrates.

**G1.00012 Dependence of superconducting properties of NbN thin films on sputtering parameters**,<sup>1</sup> TRUPTI KHAIRE, FAUSTIN CARTER, JUNJIA DING, CHRYSTIAN POSADA, AMY BENDER, GENSHENG WANG, VOLODYMYR YEFREMENKO, JOHN PEARSON, Argonne National Laboratory, STEVE PADIN, University of Chicago, CLARENCE CHANG, AXEL HOFFMANN, VALENTYN NOVOSAD, Argonne National Laboratory, SPT3G COLLABORATION — Recently, there has been growing interest in utilizing NbN, TiN, NbTiN thin films in superconducting device applications (e.g. detectors for CMB, mm and sub-mm astronomy). In this work, we have fabricated NbN superconducting thin films by DC reactive magnetron sputtering of Nb in the presence of argon and nitrogen gases. We found that the critical temperature of NbN films is sensitive to various deposition parameters like nitrogen flow rate, target voltage, base pressure, RF substrate bias, and the substrate temperature. By studying each of these factors we have been able to create highly reproducible NbN thin films. We obtained a T<sub>c</sub> of 15.25±0.25 K for 300 nm thick NbN film grown on silicon substrate at modest temperature of 250 °C in the presence of RF substrate bias. We are also investigating the microwave properties of these NbN films at temperatures well below 50 mK by fabricating quarter wavelength CPW resonators out of NbN and characterizing their frequency shifts and quality factors as functions of temperature and power. In this work we present the results of these analyses.

**G1.00013 Nano crystalline palladium disposable electrode development for electrochemical spectroscopy application**<sup>1</sup>, WEI CHEN, Natl Chiao Tung Univ, CHIEN-HAO SU, Cheeshin Technology Co., PENG-JEN CHEN, Natl Chiao Tung Univ, KUO-CHEN HSU, Cheeshin Technology Co., CHIA-CHING CHANG, Natl Chiao Tung Univ, CHEESHIN TECHNOLOGY CO. COLLABORATION — Electrochemical spectroscopy is a highly sensitive and selective detection method to revealing the intermolecular interaction. Gold electrode provides excellent charge transfer property and has been widely used in electrochemical analysis. However, gold electrode is expensive. Moreover, it is time consuming and complicated to regenerate a reaction active gold electrode. Therefore, a ready-to-use electrode is highly desired for electrochemical analysis. In this study, we have developed a novel nano-crystalline palladium (Pd) film electrode which is deposited on flexible polyethylene terephthalate (PET) by sputtering. This Pd electrode is as good as well prepared gold electrode both in cyclic voltammetry (CV) and electric impedance spectroscopy (EIS) due to its highly dispersive {1 1 1} facets-exposed nanocrystalline Pd on high quality. By using this ready-to-use Pd film electrode, the interactions between DNA and drugs can be detected at sub-nanogram level.

**G1.00014 Nanopore gating with an anchored polymer in a switching electrolyte bias**<sup>1</sup>, CRAIG WELLS, INING JOU, DMITRIY MELNIKOV, MARIA GRACHEVA, Clarkson Univ — We theoretically study the interaction between a tethered, negatively charged polymer chain of varying lengths and a solid state membrane with a nanopore when subject to a time-dependent applied electrolyte bias. Brownian dynamics is used to describe the movement of a biomolecule interacting with a membrane immersed in an electrolyte solution. With the help of an applied electrolyte bias, we can control polymer's equilibrium position, extending it inside the pore for a sufficiently positive bias. We find that the amount of time a polymer takes to enter and extend inside a nanopore in a positive bias increases nearly linearly with the chain length, corresponding to an electrically driven process. The time it takes for the chain to exit the pore, however, increases nearly quadratically with chain length, corresponding to a diffusion process. Understanding the dynamical behavior of the tethered polymer chain will facilitate further advances in this area of nanotechnology.

**G1.00015 Nanoindentation of Chitosan Doped with Silver Nanoparticles**, MATTHEW PALUMBO, ALEM TEKLU, NARAYANAN KUTHIRUMMAL, Coll of Charleston, NICOLE LEVI-POLYACHENKO, Wake Forest, DEPARTMENT OF PHYSICS AND ASTRONOMY, COLLEGE OF CHARLESTON COLLABORATION, DEPARTMENT OF PLASTIC AND RECONSTRUCTIVE SURGERY, WAKE FOREST UNIVERSITY HEALTH SCIENCES COLLABORATION — Imaging and spectroscopic analysis via nanoindentation was performed with the Nanosurf EasyScan2 AFM on the pure and silver doped chitosan samples allowing for a more localized determination of their stiffness, hardness, and reduced Young's modulus. The pure chitosan sample was tested to have a stiffness of 0.367 N/m, a hardness of 1.12 GPa, and a reduced Young's modulus of 30.5 MPa. The film with 5mg Ag nanoparticle per gram of chitosan was tested on the boundaries between the chitosan and Ag nanoparticles to show an increase in stiffness of about 4.6% at 0.384 N/m, an increase in hardness of about 5.4% at 1.18 GPa, and an increase in the reduced Young's modulus of about 5.0% at 3.2 MPa in comparison to the pure chitosan sample. On the other hand, upon increasing the doping to 10mg Ag nanoparticle per gram of chitosan showed a decrease in stiffness of about 6.3% at 0.344 N/m, a decrease in hardness of about 27.0% at 0.820 GPa, and a decrease in the reduced Young's modulus of about 6.0% at 28.7 MPa in comparison to the pure chitosan sample. Obviously, films doped with 5mg Ag nanoparticle per gram of chitosan provided the composites with improved mechanical strength compared to chitosan alone.

**G1.00016 Thin film metallic sensors in an alternating magnetic field for magnetic nanoparticle hyperthermia cancer therapy**, Z. A. HUSSEIN, Z. BOEKELHEIDE, Lafayette College — In magnetic nanoparticle hyperthermia in an alternating magnetic field for cancer therapy, it is important to monitor the temperature in situ. This can be done optically or electrically, but electronic measurements can be problematic because conducting parts heat up in a changing magnetic field. Microfabricated thin film sensors may be advantageous because eddy current heating is a function of size, and are promising for further miniaturization of sensors and fabrication of arrays of sensors. Thin films could also be used for in situ magnetic field sensors or for strain sensors. For a proof of concept, we fabricated a metallic thin film resistive thermometer by photolithographically patterning a 500Å Au/100Å Cr thin film on a glass substrate. Measurements were taken in a solenoidal coil supplying 0.04 T (rms) at 235 kHz with the sensor parallel and perpendicular to the magnetic field. In the parallel orientation, the resistive thermometer mirrored the background heating from the coil, while in the perpendicular orientation self-heating was observed due to eddy current heating of the conducting elements by Faradays law. This suggests that metallic thin film sensors can be used in an alternating magnetic field, parallel to the field, with no significant self-heating.

**G1.00017 Effect of pore's geometry on the electroosmotic flow and nanoparticle dynamics in the nanopore**<sup>1</sup>, ZACHERY HULINGS, DMITRIY MELNIKOV, MARIA GRACHEVA, Clarkson University — We theoretically study how the electroosmotic fluid velocity in a charged cylindrical nanopore in a solid state membranes depends on the pore's geometry, electrolyte concentration, and applied electrolyte bias. We find that in long pores, the fluid velocity follows the classical von Smoluchowski result for an infinite pore with a maximum along the pore axis. However, when the pore's length is comparable to its diameter, the velocity profile develops a local minimum along the pore axis with a maximum value near the membrane walls. The minimum becomes more pronounced when the electrolyte concentration and/or applied bias become larger. We attribute this effect to the inhomogeneous electric field distribution in the nanopore with the field along the axis of the pore being smaller than along the pore's walls due to the effects of access resistance on each side of the channel. We also investigate repercussions of such a velocity profile on the transport of a nanoparticle through the nanopore.

**G1.00018 Thermocouples in an alternating magnetic field (AMF) for studying magnetic nanoparticle hyperthermia**, S. HARTZELL, Z. BOEKELHEIDE, Lafayette College — Magnetic nanoparticle hyperthermia, a method of cancer therapy, is currently a subject of active research. A critical parameter during therapy or laboratory research is the temperature of the system (tissue or nanoparticle suspension). Thermocouples are affordable and ubiquitous temperature sensors which could be used in this capacity; however, their metallic nature results in self-heating due to eddy currents when placed in an AMF. This presentation will quantitatively discuss calculations and measurements of the self-heating of three common types of thermocouples. Type T, K, and E thermocouples of both thin (40 gauge) and thick (20 gauge) wires were tested in a range of applied magnetic field magnitudes (235 kHz, 0-0.4 T rms). Among the thermocouples, all three types demonstrated large self-heating in 20 gauge wires. For the 40 gauge wires, type K showed large self-heating, while type T showed small but significant self-heating and type E showed no significant self-heating in comparison to the background. Our results indicate that thin type E thermocouples can be accurately used as temperature sensors in an AMF environment similar to the one used here, and type T thermocouples may be appropriate under conditions with lower magnetic field strength or frequency.

**G1.00020 Quantum Generation Dynamics of Coherent Phonon in Semiconductors: Transient and Nonlinear Fano Resonance**, YOHEI WATANABE, Grad. School of PAS. Univ. Tsukuba, KEN-ICHI HINO, MUNEAKI HASE, NOBUYA MAESHIMA, Div. of PAS. Univ. Tsukuba — The coherent phonon (CP) generation is one of the representative phenomena induced by ultrashort pulsed laser. In particular, in the initial stage of the CP generation in lightly *n*-doped Si, the vestige of Fano resonance (FR) manifested in a flash was observed in time-resolved spectroscopy experiments, in which it was speculated that this phenomenon results from the birth of transient polaronic quasiparticles composed of electrons and phonons strongly interacting each other [1]. This study is aimed at constructing a fully-quantum-mechanical model for the CP generation and tracking the origin of the transient FR. We calculate two physical quantities in both of polar and non-polar semiconductors such as GaAs and undoped Si. One is a retarded longitudinal susceptibility which allows one to calculate a transient induced photoemission spectrum. The other is the Fourier-transform of LO-phonon displacement into frequency domain. We have succeeded in showing that the transient FR is exclusively caused in Si in harmony with the experiments, though, not observed in GaAs [2]. [1] M. Hase, M. Kitajima, A. M. Constantinescu and H. Petek, Nature 426, 51 (2003). [2] Y. Watanabe, K. Hino, M. Hase and N. Maeshima, Phys. Rev. B (submitted), arXiv:1510.00263.

**G1.00021 Transition Metal and Vacancy Defect Complexes in Phosphorene**, MUKUL KABIR, ROHIT BABAR, Department of Physics, Indian Institute of Science Education and Research, Pune 411008, India — Inducing magnetic moment in otherwise nonmagnetic two-dimensional semiconducting materials is the first step to design spintronic material. Here, we study the adsorption of transition-metals on pristine and defected phosphorene, within density functional theory. We predict that increased transition-metal diffusivity on the pristine phosphorene would hinder controlled magnetism. In contrast, point-defects anchor the transition-metal to reduce metal diffusivity. The di-vacancy complex is more important in this context due to their increased thermodynamic stability over the mono-vacancy. For most cases, the defect-transition metal complexes retain the intrinsic semiconducting properties, and induce a local moment. We provide a simple microscopic model which describe the local moment of these transition metal and defect complexes.

## G1.00022 Magnetotransport in Pulsed Laser Deposited Manganese Doped Lead Sulfide Films

, GAURAB RIMAL, KESHAB SARKOTA, Department of Physics & Astronomy, University of Wyoming, ARTUR MAKSYMOW, LEONARD SPINU, Advanced Materials Research Institute, University of New Orleans, WENYONG WANG, JINKE TANG, Department of Physics & Astronomy, University of Wyoming — Diluted magnetic semiconductors (DMS) have been proposed as promising candidates for spintronic applications. Most research in this field has been confined to III-V and II-VI semiconductor system. There are reports on IV-VI semiconductors, however reports on lead sulfide (PbS) based DMS is limited. We study the transport, magnetic and structural properties of manganese doped lead sulfide (Mn:PbS) films produced by pulsed laser deposition (PLD). The films are found to show hopping transport at low temperature. Low temperature magnetoresistance (MR) studies show that the sign of MR can be changed by application of gate voltage. The magnetic properties of the films were also studied which showed ferromagnetic behavior at room temperature.

## G1.00023 Towards thermally induced spin accumulation in Fe/GaAs structures<sup>1</sup>, THOMAS WAGNER,

Department of Materials Science and Metallurgy, University of Cambridge, Cambridge, UK, KAMIL OLEJNIK, Institute of Physics ASCR, Praha, Czech Republic, JAMES HAIGH, Hitachi Cambridge Laboratory, Cambridge, UK, ANDREW IRVINE, Cavendish Laboratory, University of Cambridge, Cambridge, UK, SYLVAIN MARTIN, Hitachi Cambridge Laboratory, Cambridge, UK, RICHARD CAMPION, School of Physics and Astronomy, University of Nottingham, Nottingham, UK, JOERG WUNDERLICH, Hitachi Cambridge Laboratory, Cambridge, UK — We study non-local spin valves of semiconductor-ferromagnetic metal hybrid systems [1]. The epitaxially grown samples consist of a low doped GaAs transport channel with ultrathin Fe top contacts. Magnetic fields applied along the easy and hard axis show spin-valve and Hanle-type curves, respectively. The latter can be used to determine the spin-dephasing time in our samples [2]. We further investigate the potential of non-local spin valves for electrical detection of thermally induced spin accumulation in semiconductors. Thermal spin injection is driven by temperature gradients across interfaces between ferromagnetic and non-magnetic materials [3]. Common ways to establish the required temperature gradients are Joule heating and absorption of focused laser light. We present finite-element simulations of the temperature profile expected in our microdevices. This is of interest in the emerging field of spin caloritronics.

## G1.00024 Spin-orbit coupling in InSb semiconductor nanowires: physical limits for majorana states<sup>1</sup>, GUILHERME SIPAHI, TIAGO DE CAMPOS, Universidade de So Paulo, SUNY at Buffalo, PAULO E. FARIA JUNIOR, Universidade de So Paulo,

Universitt Regensburg, MARTIN GMITRA, Universitt Regensburg, IGOR ZUTIC, SUNY at Buffalo, JAROSLAV FABIAN, Universitt Regensburg — The search for Majorana fermions is a hot subject nowadays [1]. One of the possibilities for their realization is the use of semiconductor nanowires and p-type superconductors coupled together. Following this path, the first step is the determination of realistic band structures of these wires including spin-orbit effects. To consider the spin-orbit effects, its common to use models that take into account only the first conduction band. Although these reduced models have been successfully used to determine some physical properties, a more realistic description of the spin-orbit coupling between the bands is required to further investigate possible ways to realize the Majorana fermions. In this study we use a state of the art 14 band k.p formalism together with the envelope function approach [2] to determine the band structure of InAs semiconductor nanowires and analyze how the quantum confinement change the coupling between the bands. As a result we have extracted the effective masses and the spin-orbit splitting for a large range of nanowire radial sizes and for several conduction bands that can be used in effective models. [1] J. Alicea, Rep. Prog. Phys. 75, 076501 (2012). [2] P. E. Faria Junior and G. M. Sipahi, J. Appl. Phys. 10, 10, 103716 (2012).

## G1.00025 Effect of magnetic polaron for acceptor bound exciton in CdTe:Dy crystals, PETRO BUKIVSKIY, YURIY GNATENKO, ANATOLII BUKIVSKII, Institute of Physics of National Academy of Sciences of Ukraine, ROMAN GAMERNYK, Lviv

National University — We investigated low temperature ( $T = 4.2$  K) photoluminescence (PL) spectra and temperature dependence ( $T = 1.8 - 40$  K) of excitonic PL for CdTe doped by dysprosium. Dysprosium concentration was  $10^{20} \text{ cm}^{-3}$ . We detected the effect of magnetic polaron for acceptor bound excitons. Theoretical analysis of temperature dependency of emission energy of these excitons was performed. The calculations based on Spalek-Deitl-Kossut theory gave us an opportunity to estimate the magnetic polaron energy  $\varepsilon_p$  and its temperature dependence  $\varepsilon_p(T)$  in  $T = 1.8$  to  $40$  K temperature range. In addition, we calculated the temperature dependence of contributions of mean exchange field and thermodynamic fluctuations of magnetization to the spin splitting value  $\Delta$ . Also, we calculated the temperature dependence of probability distribution function  $P(\Delta, T)$  of the spin splitting value for acceptor bound excitons. It was found that calculated total contributions of mean exchange field and thermodynamic fluctuations of magnetization to spin splitting value is in good agreement with experimental data.

## G1.00026 Hematite nanoribbons based on (110) and (104) surfaces and their unusual character<sup>1</sup>

, PRABATH WANAGURU, JIAO AN, QIMING ZHANG, The University of Texas at Arlington — Atomically thin hematite nanoribbons based on (110) and (104) surfaces are studied systematically by first-principles methods. Calculations have performed using the GGA+U approach and structures were fully relaxed to identify the geometric, electronic and magnetic properties. The studied hematite nanoribbons are formed by cutting the atomically-thin hematite nanosheets along their [100] and [010] directions. The (110) surface based nanoribbons show definite tunable semiconducting character while one type of the (104) based nanoribbons display surface modifications or bending nature indicating pseudo-Jahn-Teller effect. The remaining type of (104) based nanoribbons show built-in oxygen vacancy on one edge despite preserving the stoichiometry and introduces the half-metallicity into the nanoribbons at larger widths. We will present the optimized structures, their electronic properties and energetics in detail.

<sup>1</sup>This research is supported by NSF SusChEM Program (Award DMR-1306291).

## G1.00027 Optimized Energy Transfer from Electron-hole pairs to Eu ions in GaN, RUOQIAO

WEI, NATALIE HERNANDEZ, Lehigh University, BRANDON MITCHELL, University of Mount Union, YASUFUMI FUJIWARA, Osaka University, VOLKMAR DIEROLF, Lehigh University — Europium doped Gallium Nitride (GaN:Eu) has demonstrated potential for the red-emitting active layer in nitride-based light emitting diodes. Under above band gap excitation, the red emission was shown to increase due to the optimization of crystal growth conditions. This suggests that excitation efficiency had been improved, which would imply that the energy transfer from electron-hole pairs to Eu ions occurred on a faster time-scale. To test this assumption, we performed time-resolved spectroscopy measurements, under ps-scale time resolution, on samples with a variety of co-dopants and growth conditions. Results show that the energy is transferred on a time scale faster than ns and the excitation efficiency is influenced by the various growth parameters and co-dopants.

**G1.00028 Free-carrier absorption from shallow donors in transparent conducting oxides<sup>1</sup>**, ANDREW SHAPIRO, PHILIP WEISER, MICHAEL STAVOLA, Lehigh University — An experimental study of the free-carrier absorption in a few transparent conducting oxides (TCO's) has been performed to compare the strength of the absorption in different hosts and its dependence on wavelength and temperature. The goal of our work is to make the IR absorption arising from free carriers a quantitative tool for characterizing the conductivity of doped TCO's.

<sup>1</sup>Supported by NSF Grant DMR 1160756

**G1.00029 Structural and electronic properties of amorphous ternary and quaternary oxide semiconductors<sup>1</sup>**, K. NOCONA SANDERS, RABI KHANAL, JULIA E. MEDVEDEVA, Missouri University of Science and Technology — Amorphous structures of several multi-cation wide-bandgap oxides (In-Ga-Zn-O, In-Sc-O, In-Y-O, and In-La-O) were obtained via first-principles molecular dynamics liquid-quench approach using different cooling rates and different oxygen and metal compositions. A detailed comparison of the structural properties, namely, the distribution of metal-oxygen (M-O) and metal-metal (M-M) distances, bond angles, and coordination, allows us to determine how the MO polyhedra network is affected by the crystalline-to-amorphous transition. Furthermore, the role of oxygen non-stoichiometry in defect formation is investigated. Specifically, local structural defects associated with severe distortions in the metal-oxygen polyhedra, such as under-coordinated metal and oxygen atoms, or M-M bonds, appear in the electronic band structure of amorphous oxides. Both carrier-generating defects and carrier trapping/scattering defects are identified. The results help determine the optimal composition and preparation conditions (i.e., oxygen partial pressure, deposition temperature) in order to achieve the desired properties of the technologically-appealing amorphous oxide semiconductors.

**G1.00030 Anomalous Magneto-Optical Behavior of Rare Earth Doped Gallium Nitride<sup>1</sup>**, ANDREW HELBERS, Department of Physics, Lehigh University, BRANDON MITCHELL, Department of Physics and Astronomy, University of Mt. Union, NATHANIEL WOODWARD, U.S. Army Research Laboratory, VOLKMAR DIEROLF, Department of Physics, Lehigh University — We have observed unusual magneto-optical properties in rare earth doped gallium nitride. Specifically, the reversal of a magnetic field applied parallel to the c-axis produces unexpected, marked differences in luminescence spectra in several of our samples. Notably, relative emission strengths of Zeeman-split lines from the rare earth ions appear to change when the field is reversed. These effects were not observed in rare earth doped lithium niobate and lithium tantalate, which are also hexagonal and polar. Measurements for erbium doped gallium nitride suggest that these asymmetries seem to be linked to the degree of ferromagnetism of the samples. Results are presented showing these differences. The symmetry of the observed effects requires a perturbation of the RE states with a screw like symmetry. We explore whether this may be accomplished by defects such as threading dislocations.

<sup>1</sup>The work related to ferroelectric materials was supported by NSF grant (DMR-1008075).

**G1.00031 Optical and Electrical Studies of Gamma-Irradiated AlGaIn/GaN High Electron Mobility Transistors**, ANUPAMA YADAV, ELENA FLITSIYAN, LEONID CHERNYAK, Department of Physics, University of Central Florida, Orlando, USA, SHIHYUN AHN, FAN REN, Department of Chemical Engineering, University of Florida, Gainesville, USA, STEPHEN PEARTON, Department of Materials Science and Engineering, University of Florida, Gainesville, USA, IGOR LUBOMIRSKY, SERGEY KHODOROV, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel — The impact of <sup>60</sup>Co gamma-irradiation on n-channel AlGaIn/GaN High Electron Mobility Transistors (HEMTs) was studied by means of temperature dependent Cathodoluminescence (CL) and Electron Beam Induced Current (EBIC) technique. Increase in diffusion length after low dose of gamma-irradiation ( $\leq 200$  Gy) is consistent with the decrease in the CL intensity. The observed effect is explained via the mechanism involving trapping of Compton electrons on irradiation induced nitrogen vacancies. For high dose ( $>200$  Gy), diffusion length was observed to decrease which is presumably associated with the mobility degradation. It is shown that calculated activation from the EBIC and CL measurements follows exactly the same trend, which implies that same underlying phenomenon is responsible for observed findings. In addition, DC current-voltage measurements were conducted on the devices in order to relate the material's fundamental properties to the device performance.

**G1.00032 Computational modelling of the Li effects on the electronic structure of porous silicon<sup>1</sup>**, MARÍA LUCERO GOMEZ-HERRERA, Facultad de Ingeniería Universidad Autónoma de Querétaro C. P. 76000, México Querétaro, ÁLVARO MIRANDA DURÁN, ALEJANDRO TREJO BAÑOS, MIGUEL CRUZ IRISSON, Instituto Politécnico Nacional, ESIME Culhuacán, Av. Santa Ana 1000 C, P. 04918 México D. F. — This work analyses the effects of Li impurities on the electronic structure of pSi by means of the density functional theory with the generalized gradient approximation and the supercell scheme. The porous structures were modeled by removing atoms in the [001] direction of an otherwise perfect Si crystal. All surface dangling bonds were saturated with H atoms. To model the Li impurities some H atoms are replaced with Li atoms at the surface. Results show additional bands around the Fermi level with the insertion of a single Li atom on the pore surface, which suggests a trap-like state of localized charge. With increasing concentration of surface Li the band gap gradually decreases approaching to a metallic behavior. This results could be important to the application of pSi in Li-ion batteries

**G1.00033 Tuning the electronic band-gap of fluorinated 3C-silicon carbide nanowires<sup>1</sup>**, ÁLVARO MIRANDA DURÁN, ALEJANDRO TREJO BAÑOS, ESIME-Culhuacán, Instituto Politécnico Nacional, Av. Santa Ana 1000, 04430 México D.F., México, LUIS ANTONIO PÉREZ, Instituto de Física, Universidad Nacional Autónoma de México, Apartado Postal 20-364, 01000 México D.F., México, MIGUEL CRUZ IRISSON, ESIME-Culhuacán, Instituto Politécnico Nacional, Av. Santa Ana 1000, 04430 México D.F., México — The possibility of control and modulation of the electronic properties of silicon carbide nanowires (SiCNWs) by varying the wire diameter is well known. SiCNWs are particularly interesting and technologically important, due to its electrical and mechanical properties, allowing the development of materials with specific electronic features for the design of stable and robust electronic devices. Tuning the band gap by chemical surface passivation constitutes a way for the modification of the electronic band gap of these nanowires. We present, the structural and electronic properties of fluorinated SiCNWs, grown along the [111] crystallographic direction, which are investigated by first principles. We consider nanowires with six diameters, varying from 0.35 nm to 2.13 nm, and eight random covering schemes including fully hydrogen- and fluorine terminated ones. Gibbs free energy of formation and electronic properties were calculated for the different surface functionalization schemes and diameters considered. The results indicate that the stability and band gap of SiCNWs can be tuned by surface passivation with fluorine atoms

**G1.00034 Excitonic photoluminescence lifetimes in PbI<sub>2</sub> nanoclusters for PbCdI<sub>2</sub> semiconductor materials**, ANATOLII BUKIVSKII, YURIY GNATENKO, YURI PIRYATINSKI, Institute of Physics of National Academy of Sciences of Ukraine, BEES TEAM — We investigated excitonic photoluminescence (PL) spectra and kinetics of PL decays for various wavelengths for Pb<sub>1-x</sub>Cd<sub>x</sub>I<sub>2</sub> solid solutions (X = 0.2, X = 0.3, X = 0.4, X = 0.5, X = 0.7). Earlier we had shown that by approximation of the experimental data with stretched exponential function and applying the inverse Laplace transformation to this function we can estimate the average time constant  $\langle\tau\rangle$  of the PL decay. Now, instead of measuring single kinetics for several wavelengths, we performed Time Resolved Emission Scanning continuously for all of the self-trapped excitons emission ranges. We developed analytical software that enables us to calculate both the average time constant  $\langle\tau\rangle$  of the decay and average lifetime  $\tau$  of the emission process. This software also enables us to calculate distribution of rate constants  $H(k)$  for each concentration for each wavelength. By using the demo version of Edinburgh Instruments FAST software, we also calculated continuous distribution of time constants of PL kinetics in Pb<sub>1-x</sub>Cd<sub>x</sub>I<sub>2</sub> solid solutions. These distributions show the presence of three different components of the PL signal, which are time-separated. These results strongly correlate with obtained spectral data.

**G1.00035 Evidence of iridescence in TiO<sub>2</sub> nanostructures. A probably photonic effect**, RAFAEL REY-GONZALEZ<sup>1</sup>, HEIDY P. QUIROZ<sup>2</sup>, CLAUDIA BARRERA-PATIO<sup>3</sup>, ANDERSON DUSSAN<sup>4</sup>, Universidad Nacional de Colombia, GRUPO DE OPTICA E INFORMACION CUANTICA COLLABORATION, GRUPO DE MATERIALES NANOESTRUCTURADOS Y SUS APLICACIONES COLLABORATION — In this work, we present a study of optical properties of titanium dioxide nanotubes (TiO<sub>2</sub>). Nanotubes were obtained by electrochemical anodization method, using ethylene glycol solutions containing different amounts of water and fluoride. A complex structure is observed between nanotubes and Ti foils on surface when nanotubes are released from the sheet. These forms can be associated with replicas or marks in surface of the Ti foil. The optical response of replicas is studied by Uv-Vis spectrophotometry using white light and varying the angle of the incident light. Absorbance measurements reveal that these replicas exhibit a shift towards lower values of lambda when the angle of the incident light increases of 20° to 60°. These changes may be associated with iridescent effects in this material. The concavity of the replicas in association with air could be generating photonic-like effects. Using a 2D model of replicas - air system, the photonic band structures are found through a plane wave approach. Correlations between photonic properties and iridescent effects are explored.

**G1.00038 Simple Screened Hydrogen Model of Excitons in Two-Dimensional Materials**, THOMAS OLSEN, SIMONE LATINI, FILIP RASMUSSEN, KRISTIAN THYGESEN, Tech Univ of Denmark — We present a generalized hydrogen model for the binding energies ( $E_B$ ) of excitons in two-dimensional (2D) materials that sheds light on the fundamental differences between excitons in two and three dimensions. In contrast to the well-known hydrogen model of three-dimensional (3D) excitons, the description of 2D excitons is complicated by the fact that the screening cannot be assumed to be local. We show that one can consistently define an effective 2D dielectric constant by averaging the screening over the extend of the exciton. For an ideal 2D semiconductor this leads to a simple expression for  $E_B$  that only depends on the excitonic mass and the 2D polarizability  $\alpha$ . The model is shown to produce accurate results for 51 transition metal dichalcogenides. Remarkably, over a wide range of polarizabilities the expression becomes independent of the mass and we obtain  $E_B^{2D} \approx 3/(4\pi\alpha)$ , which explains the recently observed linear scaling of exciton binding energies with band gap. It is also shown that the model accurately reproduces the non-hydrogenic Rydberg series in WS<sub>2</sub> and can account for screening from the environment.

**G1.00039 Measurement of Exciton Binding Energy of Monolayer WS<sub>2</sub>**<sup>1</sup>, XI CHEN<sup>2</sup>, BAIREN ZHU, XIAODONG CUI, The University of Hong Kong — Excitonic effects are prominent in monolayer crystal of transition metal dichalcogenides (TMDCs) because of spatial confinement and reduced Coulomb screening. Here we use linear differential transmission spectroscopy and two-photon photoluminescence excitation spectroscopy (TP-PLE) to measure the exciton binding energy of monolayer WS<sub>2</sub>. Peaks for excitonic absorptions of the direct gap located at K valley of the Brillouin zone and transitions from multiple points near  $\Gamma$  point of the Brillouin zone, as well as trion side band are shown in the linear absorption spectra of WS<sub>2</sub>. But there is no gap between distinct excitons and the continuum of the interband transitions. Strong electron-phonon scattering, overlap of excitons around  $\Gamma$  point and the transfer of the oscillator strength from interband continuum to exciton states make it difficult to resolve the electronic interband transition edge even down to 10K. The gap between excited states of the band-edge exciton and the single-particle band is probed by TP-PLE measurements. And the energy difference between 1s exciton and the single-particle gap gives the exciton binding energy of monolayer WS<sub>2</sub> to be about 0.71eV.

**G1.00042 Metal to insulator quantum-phase** RHODES, ZHENGUANG LU, DMITRY SMIRNOV, EFSTRATIOS MANOUSAKIS, FL-32310, USA, AMBER MCCREARY, SIMIN FENG, MAURICO TERRONE, MADAN DUBEY, U.S. Army Research Laboratory, Adelphi, MD 20783, USA, TERRONES, Dept. of Physics, RPI, NY 12180, USA — ReS<sub>2</sub> a layer-independent material for optoelectronic applications. Here, we present an overall evaluation of transport properties. ReS<sub>2</sub> behaves as an *n*-type semiconductor with an intrinsic carrier mobility surpassing 1000 cm<sup>2</sup>/Vs. Semiconducting behavior is observed at low electron densities *n*, but at high values of *n* the material exhibits a metallic *T*<sup>2</sup>-dependence. The electric-field induced metallic state observed in MoS<sub>2</sub> is reproduced in ReS<sub>2</sub> through a scaling analysis of the conductivity as a function of *T* and *n*, we find that the transition is driven by electronic correlations.

**G1.00043 Finite two-dimensional electron gas in a patterned semiconductor system<sup>1</sup>**, ORION CIFTJA, VICTORIA LIVINGSTON, ELSA THOMAS, SETH SAGANTI, Prairie View AM University — On various occasions, fabrication of a two-dimensional semiconductor quantum dot leads to a small system of electrons confined in a domain that is not circular and may have a pronounced square (or rectangular) shape. In this work we consider a square-shaped semiconductor quantum dot configuration and treat the system of electrons as a finite two-dimensional electron gas. Within this framework, we adopt a Hartree-Fock approach and study the properties of a small two-dimensional system of electrons confined in a finite square region. We calculate the energy for various finite systems of fully spin-polarized (spinless) electrons interacting with a Coulomb potential. The results give a fairly accurate picture of how the energy of the finite system evolves towards the bulk value as the size of the system increases. The calculations for a square domain are challenging since expressions depend in each component of particle's position and not the radial distance from the center of the square-shaped semiconductor quantum dot. Therefore, we also consider a possible circularly symmetric approximation to the problem. We assess the quality of this approximation and discuss instances where its use is not only desirable, but also accurate.

**G1.00044 Strain Engineered Direct-indirect Band Gap Transition and its Mechanism in 2D Phosphorene.**, XIHONG PENG, QUN WEI, ANDREW COPPLE, Arizona State University — Phosphorene, a two-dimensional puckered honeycomb structure of black phosphorus, showed promising properties for applications in nano-electronics. In this work, we report strain effect on the electronic band structure of phosphorene, using first principles density-functional theory (DFT) including standard DFT and hybrid functional methods. It was found that phosphorene can withstand a tensile strain up to 30%. The band gap of phosphorene experiences a direct-indirect-direct transition when axial strain is applied. The origin of the gap transition was revealed and a general mechanism was developed to explain energy shifts with strain according to the bond nature of near-band-edge electronic orbitals. Effective masses of carriers in the armchair direction are an order of magnitude smaller than that of the zigzag axis indicating the armchair direction is favored for carrier transport. Ref: X.-H. Peng, Qun Wei, A. Copple, Phys. Rev. B 90, 085402 (2014).

**G1.00045 STM study on the structures of SnSe surfaces<sup>1</sup>**, TAE HOON KIM, SANG-UI KIM, TRINH THI LY, ANH TUAN DUONG, SUNGLAE CHO, Department of Physics, EHSRC, and BRL, Univ of Ulsan, S. H. RHIM, Department of Physics and EHSRC, Univ of Ulsan, JUNGDAE KIM, Department of Physics, EHSRC, and BRL, Univ of Ulsan — SnSe is a 2 dimensional layered material, and each layer is coupled by van der Waals forces allowing very easy cleaving though the layer surfaces. SnSe has been studied for various potential applications because of its high stability and elemental abundance in earth. Recently, it was also reported that bulk SnSe has an excellent thermoelectric property of  $ZT=2.6$  at 923 K along the b axis (Zhao et al, Nature 508 373 (2014)). The surface of a single crystal SnSe was studied via a home-built low temperature scanning tunneling microscopy (STM). Clear atomic images of SnSe surfaces were observed at the filled and empty state measurements, and detail atomic structures were analyzed by comparing with DFT simulations. We found that the atomic image of SnSe surfaces measured by STM is not trivial to understand. Only Sn atoms were visible on STM topographic images for the both of filled and empty state probing.

**G1.00046 STM study on the surface defects of SnSe induced by thermal annealing<sup>1</sup>**, TRINH THI LY, SANG-UI KIM, TAE HOON KIM, ANH TUAN DUONG, SUNGLAE CHO, Department of Physics, EHSRC, and BRL, Univ of Ulsan, S. H. RHIM, Department of Physics and EHSRC, Univ of Ulsan, JUNGDAE KIM, Department of Physics, EHSRC, and BRL, Univ of Ulsan — SnSe is a IV - VI semiconductor with 0.86 eV gap, and a single crystal SnSe usually exhibits a p-type characteristic. SnSe is one of 2D layered materials, and it has attracted researchers' attentions due to excellent physical properties for future applications. In particular, exceptionally high ZT value ( $ZT = \sim 2.6$  at 923 K) was reported for SnSe single crystal (Zhao et al, Nature 508 373 (2014)). Even though many researches on SnSe have proposed the possibilities of various applications so far, surprisingly little information is available regarding the microscopic structure of SnSe surfaces. We conducted a systematic study on the surface defect of SnSe induced by thermal annealing via a home-built low temperature scanning tunneling microscopy (STM). Various defects were characterized by STM/STS, and we found that Sn vacancy is a dominating intrinsic defect. The size of vacancy was changed after annealing process in UHV at different temperatures.

<sup>1</sup>This work was supported by the National Research Foundation of Korea(NRF) [Nos. NRF-2013R1A1A1A1008724, NRF-2009-0093818, and NRF-2014R1A4A1071686]

**G1.00047 Polarization-dependent photocurrents in polar stacks of van der Waals solids<sup>1</sup>**, SONGCI LI, Univ of Washington, YULI LYANDA-GELLER, Purdue University, ANTON ANDREEV, Univ of Washington — Monolayers of semiconducting van der Waals solids, such as transition metal dichalcogenides (TMDs), acquire significant electric polarization normal to the layers when placed on a substrate or in a heterogeneous stack. This causes linear coupling of electrons to electric fields normal to the layers. Irradiation at oblique incidence at frequencies above the gap causes interband transitions due to coupling to both normal and in-plane ac electric fields. The interference between the two processes leads to sizable in-plane photocurrents and valley currents. The direction and magnitude of currents is controlled by light polarization and is determined by its helical or nonhelical components. The helicity-dependent ballistic current arises due to asymmetric photo generation. The non-helical current has a ballistic contribution (dominant in sufficiently clean samples) caused by asymmetric scattering of photoexcited carriers, and a side-jump contribution. Magneto-induced photocurrent is due to the Lorentz force or due to intrinsic magnetic moment related to Berry curvature.

<sup>1</sup>This work was supported by the U. S. Department of Energy Office of Science, Basic Energy Sciences under awards number DE-SC0010544 (YLG) and DE-FG02-07ER46452 (S. L. and A. A.)

**G1.00048 Anisotropic diffusion of oxygen on a few layers of black phosphorous.**, HECTOR NOE FERNANDEZ-ESCAMILLA, VCTOR HUGO GONZALEZ-CHVEZ, UNIVERSIDAD AUTNOMA DE NUEVO LEN, EDUARDO MARTNEZ-GUERRA, ANDRS GARAY-TAPIA, Centro de Investigacin en Materiales Avanzados, EDGAR MARTNEZ-GUERRA, UNIVERSIDAD AUTNOMA DE NUEVO LEN — Recently, phosphorene has also been scored well as a functional material for two-dimensional electronic and optoelectronic devices. That is, because in contrast to graphene, black phosphorous has an inherent, direct and appreciable band gap that can be modulated with the numbers of layers. However, the presence of exposed lone pairs at the surface makes phosphorous very reactive to air and humidity and consequently, degradation of its properties. No such fundamental explanation have been made, thus corresponding first principle predictions to evaluate diffusion of O over and along a mono- and a few layers are indispensable. Energy barriers and the mechanisms of oxygen diffusion on mono- and a few layer of black phosphorous were calculated using the NEB(Nudge Elastic band) method as implemented in Quantum Espresso. The electronic states are expanded in plane waves with kinetic-energy cutoffs of 25 and 200 Ry for the wave function and charge density, respectively. Also, as the H<sub>2</sub>O and O<sub>2</sub> are polar molecules, spin-polarized calculations have been carried out. We evaluated the diffusion barriers for O<sub>2</sub> and H<sub>2</sub>O on phosphorene along zigzag, armchair and intermediated directions. Our calculations show that diffusion of O is preferred on zigzag directions and dissociation of O<sub>2</sub> is favored as a result of energy gains of about 2 eV. Also, apparently diffusion pathways are blocked along layers.

**G1.00049 Effect of the electric field on buckled and puckered arsenene.** , VICTOR HUGO CHAVEZ, HECTOR NOE FERNANDEZ-ESCAMILLA, EDGAR MARTNEZ-GUERRA, UNIVERSIDAD AUTONOMA DE NUEVO LEON — With the emergence of new 2D materials, more recently phosphorene, arsenene appears as a new candidate to be explored for electronic devices. We have studied the stability of arsenene pristine and the effect of a transversal electric field on its electronic properties. The calculations were performed using the SIESTA code, with the GGA exchange-correlation functional in the PBE form. We have used numerical atomic orbitals as the basis set for the valence wavefunctions employing a double  $\zeta$ -polarized basis. We use the Perdew-Becke pseudopotential for an As atom that includes the scalar-relativistic effect and Troullier-Martins parametrization. We adopt the Monkhorst-Pack scheme for k-point sampling of Brillouin zone integrations with 25 25 1 and 25 25 1 for the buckled/planar and puckered systems, respectively. We found that buckled and puckered arsenenes are stable and posses indirect gap. The effect of the electric field on the electronic structure of the buckled arsenene is the modulation of indirect to direct gap, while in puckered arsenene the gap linearly decreases as electric field is increased. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 43830-F.

**G1.00052 A theoretical study on the thermal oxidation of silicon carbide: Chemical species at the SiO<sub>2</sub>/SiC interface**<sup>1</sup> , NOBUO TAJIMA, The University of Tokyo, TOMOAKI KANEKO, JUN NARA, TAKAHIRO YAMASAKI, TATSUO SCHIMIZU, National Institute for Materials Science, KOICHI KATO, The University of Tokyo, TAKAHISA OHNO, National Institute for Materials Science — Silicon carbide (SiC) is potentially a suitable candidate of the channel materials of power devices since it has wide bandgap, high electron mobility, and thermal conductivity. Furthermore, it is favorable for device fabrication as it can be thermally oxidized to create insulating silicon oxide (SiO<sub>2</sub>) layer. However, the SiC devices of current technology do not show acceptable performance because of a defective nature of the created SiO<sub>2</sub>/SiC stacking structure, which causes problems such as channel mobility degradation, threshold voltage increase, and leakage current. The origins of the defective nature are not understood so far, though it is presumed that they are rather concentrated at the interface. In the present study, we have performed first principles calculations to know the chemical species possibly produced at the oxide interface of thermally oxidized SiC. The First principles simulation code PHASE/0 (<http://www.ciss.iis.u-tokyo.ac.jp/riss/english/project/device/>) was used in the theoretical calculations.

<sup>1</sup> A portion of this research was supported by the grant from MEXTs project and carried out in partnership with the University of Tokyo

**G1.00053 Preparation and study of Titanium Nitride films by reactive sputtering and an investigation of target poisoning during the process.**<sup>1</sup> , TAREQUE AZIZ, ABDUL RUMAIZ, Brookhaven Natl Lab — Titanium Nitride (TiN<sub>x</sub>) thin films were prepared by reactive dc sputtering in presence of Ar-N<sub>2</sub> plasma. The thin films were grown on Quartz and pure Si surfaces. The Ar-N<sub>2</sub> content ratio was gradually varied while the substrate and the Titanium target were kept at room temperature. Structural properties, optical and electrical properties of the thin films were studied by using X-ray Photoelectron Spectroscopy (XPS) and XRD and 4 probe resistivity measurement. Target poisoning of the Ti target was also studied by varying reactive gas concentration and measuring the target current. A study of target current vs growth rate of the films was performed to investigate the onset of "poison" mode. Although there was an insignificant drop in plasma current, we noticed a drop in the deposition rate. This result was tested against Monte Carlo simulations using SRIM simulations. Effects of annealing on the crystallinity and the sheet resistance will also be discussed.

**G1.00054 Optimization of metamorphic buffers for molecular epitaxial growth of high quality AlInSb/InSb quantum structures** , YINQIU SHI, WIN, Department of Physics and Astronomy, DENISE GOSSELINK, WIN, Department of Electrical and Computer Engineering, KAVEH GHARAVI, IQC, Department of Physics and Astronomy, JONATHAN BAUGH, IQC, Department of Chemistry, ZBIGNIEW WASILEWSKI, WIN, Department of Electrical and Computer Engineering, University of Waterloo, Canada — Strong spin-orbit interaction in InSb quantum wells and wires makes them attractive candidates for the realization of Majorana bound states. Molecular beam epitaxy (MBE) is the best tool to obtain these structures but lack of suitable substrates demands development of low dislocation density, smooth metamorphic buffer layers, lattice matched to the InAlSb/InSb material system. Here we present a comparative study of MBE growth of such buffers on GaAs substrates oriented in [001] crystallographic direction and [001] offcut 2° towards [100]. 1 $\mu$ m-thick AlSb nucleation buffers were grown on both substrates with optimized growth conditions. The high density of surface terraces on the offcut substrates effectively suppressed the formation of undesirable hillocks, typical of growth on [100] substrates. Further lattice constant grading and dislocation filtering was achieved through repetitions of Al<sub>0.24</sub>In<sub>0.76</sub>Sb interlayers in the Al<sub>0.12</sub>In<sub>0.88</sub>Sb matrix. Surface morphology evolved quite differently through these stages of metamorphic buffer preparation on both types of substrates, resulting in up to 50nm-high hillocks for the on-orientation substrates and hillock-free morphology for 2° off substrates. Mechanism of hillock suppression is discussed.

**G1.00055 Epitaxial aluminum on hybridized InAs/GaSb quantum wells** , BING-BING TONG, TING-XIN LI, XIAO-YANG MU, CHI ZHANG, RUI-RUI DU, Peking University — Hybridized InAs/GaSb quantum wells (QW) are approved the existence of helical edge channels. According to the theoretical prediction, the combination with superconductor will lead to superconducting topological phase and realization of Majorana bound state (MBS). Besides, InAs/GaSb material shows a low Schottky barrier to superconductor, and high quality of superconductor-topological insulator interface will result in hard induced gap. In recent report [1], under low temperature of substrate, there is a good lattice match between InAs nanowire and Al in the same direction. In our lab, we perform aluminum epitaxy on the in-situ cleaved InAs/GaSb QW with similar methods in our ultra-high vacuum STM system. After metal epitaxy, the Al layer can be selectively etched for fabricating the superconductor-topological insulator junction devices. [1] P. Krogstrup, N. L. B. Ziino, W. Chang, S. M. Albrecht, M. H. Madsen, E. Johnson, J. Nygård, C. M. Marcus, T. S. Jespersen, Nature Materials 14, 400 (2015).

**G1.00056 Synthesis and Analysis of MnTiO<sub>3</sub> Thin Films on ITO Coated Glass Substrates**<sup>1</sup> , EMERICK MARTIN, MEHMET-ALPER SAHINER, Seton Hall Univ — Perovskites like Manganese Titanium Oxide have interesting chemical properties that may be advantageous to the development of p-n junction photovoltaic cells. Due to the limited understanding behind the compound, it is essential to know the characteristics of it when it is deposited in thin film form. The cells were created using pulsed laser deposition method for two separate mediums (first layers after ITO). ZnO was deposited onto ITO glass for the first sample. For the second sample, a layer of pure Molybdenum was deposited onto the ITO glass. The MnTiO<sub>3</sub> was then deposited onto both samples. There was a target thickness of 1000 Angstroms, but ellipsometry shows that, for the Mo based sample, that film thickness was around 1500 Angstroms. There were inconclusive results for the ZnO based sample. The concentration of active carriers was measured using a Hall Effect apparatus for the Mo based sample. The XRD analyses were used to confirm the perovskite structure of the films. Measurements for photoelectric conversion efficiency were taken using a Keithley 2602 SourceMeter indicated low values for efficiency. The structural information that is correlated with the low electrical performance of this sample will be discussed.

<sup>1</sup> SHU-NJSGC Summer 2015 Fellowship

**G1.00057 The Study of the Thermoelectric Properties of Phase Change Materials<sup>1</sup>** , MING YIN, MOHAMMED ABDI, ZIBUSISU NOIMANDE, GODWIN MBAMALU, Benedict College, DHEYAA ALAMEERI, TIMIR DATTA, University of South Carolina — We study thermoelectric property that is electrical phenomena occurring in conjunction with the flow of heat of phase-change materials (PCM) in particular GeSbTe (GST225). From given sets of material parameters, COMSOL Multiphysics heat-transfer module is used to compute maps of temperature and voltage distribution in the PCM samples. These results are used to design an apparatus including the variable temperature sample holder set up. An Arbitrary/ Function generator and a circuit setup is also designed to control the alternation of heaters embedded on the sample holder in order to ensure sequential back and forward flow of heat current from both sides of the sample. Accurate values of potential differences and temperature distribution profiles are obtained in order to compute the Seebeck coefficient of the sample. The results of elemental analysis and imaging studies such as XRD, UV-VIS, EDEX and SEM of the sample are obtained. Factors affecting the thermoelectric properties of phase change memory are also discussed.

**G1.00058 Electron Density and Capacitance at the interface of Au-ZnO Based Schottky Diode** , CHIN-SHENG WU, Yuan Ze university, Taiwan — ZnO with wide direct band gap (3.37 eV) is a well-known and an interesting compound semiconducting material, which have been used for the fabrication of optical, electrical, and piezoelectric devices such as light emitting diodes, solar cells. Schottky diodes are associated with quicker switching and lower turn on voltages compared to p-n junction diodes. J-V characteristics exhibit nonlinear rectifying behavior with threshold voltage of 2.1 V. The barrier heights were found to be 0.61 eV. The measured capacitance for the Schottky junction depends on the reverse bias potential and frequency. At the lower frequencies the capacitance has the higher values due to the trapping occurred at the interface through the surface roughness and lattice mismatch. We perform model potential calculation with quantum well around the interface. Model potentials allow some degree of freedom in the design of the emitted wavelength through adjustment of the energy levels. We apply the various well width  $w$  and barrier height  $V$  in order to match the device information made by Willander. Solving the Schrödinger equation with exchange- correlation energy and effective mass of electrons will produce values of the energy levels and states. The variational barrier heights result in the change of the electron density This accounts for the excessive capacitance at the interface of Schottky diode.

**G1.00059 Electronic structure and magnetism in partially gated graphene nano-ribbons** , RITA MAJI, JOYDEEP BHATTACHARJEE, NATIONAL INSTITUTE OF SCIENCE EDUCATION AND RESEARCH, BHUBANESWAR, ODISHA, INDIA — Properties of 3-coordinated carbon networks evolve upon physical or chemical functionalization depending on the resultant modification to  $\pi$ -conjugation and its interplay with the anti-ferromagnetic (AFM) correlation between unpaired  $2p_z$  electrons at nearest neighbor (nn) sites. Although the former generally dominates the latter in determining the ground state, we propose it to be possible to enhance and modify nn magnetic correlations by inducing non-uniform density of electrons through application of bias partially within a periodic unit. Using tight-binding based mean-field Hubbard model and the DFT based first principles calculations, we show in ZGNRs as well as AGNRs, a systematic emergence of nn ferromagnetic (FM) correlation and spin-separation within and in the vicinity of positively biased region in a unit-cell, as an intermediate phase, as the ground state evolves from AFM to non-magnetic as a function of bias voltage. The associated evolution of the degenerate band-structure from direct to indirect is also punctuated by lifting of degeneracy coinciding exactly with the appearance of nn FM correlation and accommodating energy windows for half-metallic transport. In ZGNR such localization driven nn FM correlation leads to non-trivial edge magnetism and band-structure.

**G1.00060 Effective multiband Hamiltonian for InAs in wurtzite phase<sup>1</sup>** , PAULO E. FARIA JUNIOR, TIAGO CAMPOS, CARLOS M. O. BASTOS, GUILHERME M. SIPAHI, University of Sao Paulo, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg — Recent advances in nanostructure growth techniques allowed the synthesis of new III-V compounds with wurtzite crystal structure[1]. Although ab initio band structures for these new wurtzite materials can be found in the literature[2], we still lack multiband models and parameter sets that can be simply used to investigate, for instance, quantum confinement effects. In this study, we calculated the ab initio band structure of bulk InAs wurtzite and developed a multiband k.p Hamiltonian to describe the energy bands around the energy gap. In order to correctly describe the spin splitting effects we included the k-dependent spin-orbit term, often neglected in literature. We showed that our model is very robust to describe the important features of the band structure and also the spin splittings with great agreement to the ab initio values. [1] P. Caroff et al., Nat. Nanotechnol. 4, 50 (2009). [2] A. De and C. E. Pryor, PRB 81, 155210 (2010).

<sup>1</sup>CNPq (149904/2013-4 and 88887.110814/2015-00), CAPES PVE (88881.068174/2014-01), DFG SFB 689 and FAPESP (2012/05618-0)

**G1.00061 Magneto-Electronic Energy Spectra of Monolayer Tinene** , S. C. CHEN, Center for Micro/Nano Science and Technology, National Cheng Kung University, F. L. SHYU, Department of Physics, Chinese Military Academy, J. Y. WU, Department of Physics, National Cheng Kung University, C. W. CHIU, Department of Physics National Kaohsiung Normal University, C.H. LEE, Institute of Applied Physics, National Chengchi University, M. F. LIN, Department of Physics, National Cheng Kung University — The novel magnetic quantization in monolayer tinene, being closely related to the  $sp^3$  bondings, spin-orbital coupling and magnetic field, is investigated by the generalized tight-binding model. The feature-rich two groups of low-lying LLs, which are, respectively, dominated by the  $2p_z$  orbitals and  $(2p_x, 2p_y)$  orbitals, are revealed near the Fermi level simultaneously. They are very different in the spatial distributions, state degeneracy, spin configurations and  $B_z$ -dependence. The  $B_z$ -dependent energy spectra might be approximated by the simple relationships. The splittings of LLs in the second groups are due the effects of magnetic fields. The unique magnetic-electronic properties in tinene are absent in graphene, silicene and germanene. The predicted magneto-electronic energy spectra could be directly verified by the STS measurements.

**G1.00062 Ab-Initio Computations of Electronic and Related Properties of cubic Lithium Selenide ( $Li_2Se$ )** , ABDOULAYE GOITA, Department of Electrical Engineering, Southern University and AM College, Baton Rouge, LA 70813, USA, IFEANYI H. NWIGBOJI, Department of Computational Science, University of Texas at El Paso, El-Paso, TX 79968 USA, YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813, USA — We present theoretical predictions, from ab-initio, self-consistent calculations, of electronic and related properties of cubic lithium selenide ( $Li_2Se$ ). We employed a local density approximation (LDA) potential and the linear combination of atomic orbitals (LCAO). We performed the computations following the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). Our results include electronic energies, total and partial densities of states, effective masses, and the bulk modulus. The theoretical equilibrium lattice constant is 5.882 Å. We found cubic  $Li_2Se$  to have a direct band gap of 4.363 eV (prediction), at  $\Gamma$ . This gap is 4.065 eV for a room temperature lattice constant of 6.017 Å. The calculated bulk modulus is 31.377 GPa. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASIGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0002630), LaSPACE, and LONI-SUBR.

**G1.00063 Ab-initio Density Functional Theory (DFT) Studies of Electronic, Transport, and Bulk Properties of Sodium Oxide ( $\text{Na}_2\text{O}$ ).** , DANIEL POLIN, Department of Physics New York University, New York, NY 10003, USA, JOSHUA ZIEGLER, Department of Physics Case Western Reserve University, Cleveland, OH 44106, USA., YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics Southern University and AM College, Baton Rouge, LA 70813, USA — We present the findings of *ab-initio* calculations of electronic, transport, and structural properties of cubic sodium oxide ( $\text{Na}_2\text{O}$ ). These results were obtained using density functional theory (DFT), specifically a local density approximation (LDA) potential, and the linear combination of Gaussian orbitals (LCGO). Our implementation of LCGO followed the Bagayoko, Zhao, and Williams method as enhanced by the work of Ekuma and Franklin (BZW-EF). We describe the electronic band structure of  $\text{Na}_2\text{O}$  with a direct band gap of 2.22 eV. Our results include predicted values for the electronic band structure and associated energy eigenvalues, the total and partial density of states (DOS and pDOS), the equilibrium lattice constant of  $\text{Na}_2\text{O}$ , and the bulk modulus. We have also calculated the electron and holes effective masses in the  $\Gamma$  to L,  $\Gamma$  to X, and  $\Gamma$  to K directions. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0002630), LaSPACE, and LONI-SUBR.

**G1.00064 Auger recombination in InGaN/GaN** , CHI-CHAN HUANG, WEN-CHING CHAO, WEI-SHENG CHEN, ANTARYAMI MOHANTA, DER-JUN JANG, Department of Physics, National Sun Yat-sen University — The radiative and nonradiative recombination of In-GaN/GaN samples were studied by time-resolved photoluminescence apparatus and time-integrated photoluminescence by photoexcitation with laser pulses of temporal resolution of 100 ps and energies of 3.0 and 4.5 eV. We found that the Shockley-Read-Hall and Auger coefficients derived from the analysis of TRPL using the rate equation of carrier concentration were much larger than those derived from the time-integrated PL photoexcited with various numbers of carrier concentration. We will discuss the discrepancy.

**G1.00065 Effect of GaAs spacer layer thickness on optical properties of multi-stacked InAs/GaAs quantum dots** , CHIA-HSIANG WANG, ANTARYAMI MOHANTA, DER-JUN JANG, FU-YU WANG, Department of Physics, National Sun Yat-sen University, J. S. WANG, Department of Physics, Chung Yuan Christian University — Effect of GaAs spacer layer thickness ( $d_{\text{GaAs}}$ ) on multi-stacked InAs/GaAs quantum dots are investigated by photoluminescence (PL) and excitation wavelength ( $\lambda_{\text{exc}}$ ) dependent pump-probe reflection spectroscopy. Dominance of light hole transition in the PL spectra is observed at smaller  $d_{\text{GaAs}}$  (<15 nm). Double maxima  $(\Delta R/R)_1$  and  $(\Delta R/R)_2$  appear in the differential reflection spectra (DRS) at intermediate  $\lambda_{\text{exc}}$  beyond which positive to negative reversal of the DRS is observed due to dominating effect of inter band absorption in InAs wetting layer. The  $\lambda_{\text{exc}}$  at which double maxima occur, and the positive to negative reversal starts is found to be dependent on  $d_{\text{GaAs}}$ .

**G1.00066 Observation of weak carrier localization in green emitting InGaN/GaN multi-quantum well structure** , WEN-CHING CHAO, ANTARYAMI MOHANTA, TSU-CHIANG YEN, WEI-SHENG CHEN, DER-JUN JANG, Department of Physics, National Sun Yat-sen University — Green emitting InGaN/GaN multi-quantum well samples were investigated using photoluminescence (PL) and time-resolved photoluminescence (TRPL) spectroscopy. Weak carrier localization with characteristic energy of ~12 meV due to an inhomogeneous distribution of In in the InGaN quantum well (QW) layer is observed. The temperature dependence of the PL peak energy exhibits S-shape phenomenon and is comparatively discussed within the framework of the Varshni's empirical formula. The full width at half maximum (FWHM) of the PL emission band shows an increasing-decreasing-increasing behavior with increasing temperature arising from the localized states caused by potential fluctuations. The radiative life time,  $\tau_r$ , extracted from the TRPL profile shows  $\sim T^{3/2}$  dependence on temperature above 200 K, which confirms the absence of the effect of carrier localization at room temperature.

**G1.00067 The carrier recombination in  $\text{ZnO}/\text{Al}_2\text{O}_3$  superlattice** , KO MAI, WEI-SHENG CHEN, TSU-CHIANG YEN, DER-JUN JANG, YUNG-SUNG CHEN, Department of Physics, National Sun Yat-sen University — The optical properties of  $\text{ZnO}/\text{Al}_2\text{O}_3$  superlattice are studied by a time-correlated single-photon counting apparatus with temporal resolution of 150 ps using laser pulses of energy 4.5 eV from a Ti:sapphire laser. Photoluminescence emission around 550 nm is clear evident for photoexcitation with energies of 3.0 and 4.5 eV. The differences of the widths of the PL spectrum and lifetimes of carrier recombination are compared for both photoexcitation and are explained by the spatial overlap of the carriers inside the superlattices.

**G1.00068 Quantum Interference, Geometric-phase Effects, and Semiclassical Transport in Quantum Hall Systems at Low Magnetic Fields** , CHUN-FENG HUANG, 2nd Patent Division, Intellectual Property Office, Ministry of Economic Affairs, Taipei, Taiwan 106, R.O.C., I.-H. TSAI, Department of Mathematics, National Taiwan University, Taipei, Taiwan, R. O. C. — It is well-established how the quantum interference induces strong localization leading to quantum Hall effect at high enough magnetic fields. Decreasing the magnetic fields, however, the localization strength can be reduced and the semiclassical magneto-oscillations following Shubnikov-de Haas formula appear in most quantum Hall systems. To understand the transport properties as the localization strength becomes weak, our team has investigated the magneto-resistance in some quantum Hall systems at low magnetic fields. Under the semiclassical transport, the crossing points in Hall plateaus showed Landau-band quantization and microwave-induced heating demonstrated the band-edge equivalence important to Landau-level addition transformation [1-2]. We note that such equivalence is consistent with the edge universality based on the random matrices of Wigner type, and the Landau-band quantization can be explained by considering geometric phase effects. From our study, some quantum Hall features can survive as the semiclassical transport reveals the insufficient localization. [1] Solid State Commun. 141, 17 (2007). [2] Solid State Commun. 156, 45 (2013).

**G1.00069 Stability of composite fermion states in Chern insulators<sup>1</sup>** , PAWEŁ POTASZ, BLAZEJ JAWOROWSKI, wroclaw university of technology — We analyze an existence of composite fermion (CF) states in fractional Chern insulators (FCI) using exact diagonalization. The consider Chern insulator models for spinless fermions exhibit a signature of CF states at 2/5 and 3/7 filling factors. Evidences of fractional quantum Hall type phases for a region in a parameter space with larger energy gap are shown by looking at momenta of the n-fold degenerate ground state, spectral flow, quasihole excitation spectrum, and entanglement spectra. We analyze stability of phases as a function of model parameters showing strong correlation with flatness of Berry curvature.

**G1.00070 Multi-state magnetoresistance in ferromagnet/organic-ferromagnet/ferromagnet junctions.**<sup>1</sup>, GUICHAO HU, Shandong Normal University, SHIJIE XIE, Shandong University — Organic ferromagnets (OFs) are fascinating in the field of organic spintronics, since they combine both the ferromagnetic and organic properties. The utilization of OFs in the design of organic spintronic is promising to generate some novel effects [1-4]. Here, we designed an organic spin valve by sandwiching the OF between two ferromagnets. By calculating the spin-dependent transport property, we found that the current through the device strongly depends on the alignment of the magnetization orientation of the electrodes and the OF. The spin-related electron tunneling between the ferromagnetic electrodes suffers a further spin selection from the spin-polarized states of the central OF. This work indicates a realization of four-state magnetoresistance based on OFs, which may be manipulated by a magnetic field to control the magnetization orientations of the ferromagnets and the OF. **G1.00071 Theoretical study on electronic structure of bathocuproine: Renormalization of the band gap in the crystalline state and the large exciton binding energy**<sup>1</sup>, SUSUMU YANAGISAWA, Department of Physics and Earth Sciences, Univ. of the Ryukyus, SHIN-NO-SUKE HATADA, YOSHITADA MORIKAWA, Department of Precision Science and Technology, Osaka Univ. — Bathocuproine (BCP) is a promising organic material of a hole blocking layer in organic light-emitting diodes or an electron buffer layer in organic photovoltaic cells. The nature of the unoccupied electronic states is a key characteristic of the material, which play vital roles in the electron transport. To elucidate the electronic properties of the molecular or crystalline BCP, we use the GW approximation for calculation of the fundamental gap, and the long-range corrected density functional theory for the molecular optical absorption. It is found that the band gap of the BCP single crystal is 4.39 eV, and it is in agreement with the recent low-energy inverse photoemission spectroscopy measurement. The polarization energy is estimated to be larger than 1 eV, demonstrating the large polarization effects induced by the electronic clouds surrounding the injected charge. The theoretical optical absorption energy is 3.68 eV, and the exciton binding energy is estimated to be 0.71 eV, implying the large binding in the electron-hole pair distributed around the small part of the molecular region.

**G1.00072 Magneto-conductance of hybrid quantum ring**, NAMMEE KIM, HEESANG KIM, DAE-HAN PARK, Soongsil University — Magneto-conductance behaviors of hybrid magnetic-electric quantum rings are studied. The hybrid magnetic-electric quantum rings are formed by spatially in-homogeneous distributions of magnetic fields and the additional antidot electrostatic potential. Electrons are both magnetically and electrostatically confined to the plane. Electronic structures of hybrid magnetic-electric quantum rings and two terminal conductance taking into account the resonant backscattering via the magnetic edge channels are shown including comparison with the case of a conventional electric quantum ring with uniform external magnetic field.

**G1.00073 Local current-voltage characteristic of thin film ferroelectric SrTiO<sub>3</sub>**, ANDREW JOHNSON, Hope College, RYAN COTTIER, NIKOLETA THEODOROPOLU, Texas State University, JOSHUA VEAZEY, Grand Valley State University — Certain thin-film ferroelectric oxide-semiconductor heterostructures allow for reversible, local changes in conductivity, with potential applications including non-volatile memory devices. Force microscopy techniques were used to investigate the impact of the ferroelectric polarization state on local conductive properties of ferroelectric SrTiO<sub>3</sub> (STO) thin films deposited by molecular beam epitaxy onto both p- and n-type Si(001) substrates. Under certain conditions, local current voltage (I-V) curves exhibited pronounced hysteresis under forward bias. These characteristics are not, however, well-correlated with the polarization state of the ferroelectric STO. Alternative explanations for the current hysteresis are presented. This work was generously supported by the Hope College Department of Physics Frissel Research Fund, and the National Science Foundation under NSF-MRI Grant No. CHE-1126462. Support by the NSF-Career grant, DMR-1255629 is gratefully acknowledged. Portions of this work were conducted in the CMP group facilities at Michigan State University; we would like to gratefully acknowledge R. Loloee and the MSU physics department for their support.

**G1.00074 Resonant Transmission through Serially Connected Hexagonal Nanorings with Magnetic Flux Effects**<sup>1</sup>, ERIC HEDIN, YONG JOE, Ball State University — Nanostructures composed of six quantum dots (QDs) connected in a ring are linked together in a linear chain with each ring separated by a coupling segment from adjoining rings. A tight-binding model is used to obtain the electron transmission through an arbitrary number of rings in series as a function of energy, external magnetic field, coupling parameters, and QD site energy values. Modifications of the transmission band structure as a function of external field, due to the Aharonov-Bohm and Zeeman effects, demonstrate control over the conductance properties of the linear chain of nano-rings. Resonant transmission effects (with electron energy equal to the QD site energy values) show a complex dependence upon an interplay of magnetic flux, inter-ring coupling, and the strength of the coupling between the ring system and the external leads. For specific values of lead and ring couplings, nearly full transmission (ballistic transport) is seen to occur across a broad energy range, independent of the number of rings in series.

**G1.00075 Achieving Thermodynamic Limit of Subthreshold Slope in Nanoscale Schottky Barrier MOSFET with Pillar Structure Inserted**<sup>1</sup>, JUNG-YONG LEE, SUNGCHUL JUNG, KIBOG PARK, Ulsan Natl Inst of Sci & Tech — As the device size decreases continuously by scaling in the current Si CMOS technology, subthreshold slope which is related to device operation and leakage current becomes more and more important. Especially, the drain induced barrier lowering (DIBL) modulation for improving subthreshold slope in metal/oxide/metal field effect transistor (MOSFET) is difficult to achieve. We propose a new device structure, edge-over Schottky Barrier MOSFET (EO-SB-MOSFET), which shows low DIBL and subthreshold slope approaching the thermodynamic limit of 60 mV/DEC at room temperature. EO-SB-MOSFET has a pillar structure which elongates the transistor channel by forming it over the edge of pillar. Hence, EO-SB-MOSFET has a much longer channel compared with planar MOSFET in the same pitch. We performed 2-dimensional TCAD modeling on an EO-SB-MOSFET with channel lateral size of 6.5 nm and pillar height of 36 nm. The TCAD modeling predicts DIBL of ~5 mV/V, subthreshold slope of ~61.3 mV/DEC, and off-state current of ~0.1 nA/μm at drain bias 0.5 V. It is also noticed that the subthreshold slope gets further close to the thermodynamic limit as the pillar height increases.

## **G1.00076 Study of quantum transport in a magnetic wire<sup>1</sup> , SANKALPA GHOSH<sup>2</sup>, PUJA MONDOL, ANKIP KUMAR,**

Physics Department, Indian Institute of Technology, Delhi, ALAIN NOGARET<sup>3</sup>, Department of Physics, University of Bath, Bath BA2 7AY, UK, HARVEY BEERE, DAVID RITCHIE, Cavendish Laboratory, University of Cambridge, CB3 0HE, UK — Spatially varying magnetic fields lead to some very interesting physics for two dimensional electron gas. In this work we present some recent results based on the experimental observation of edge states confined by magnetic potentials and their dependence on the strength of the magnetic field strength as well as electrostatic gate voltage. By numerically integrating Schrödinger Equation we explain the behavior of such magneto-electric edge states in such two dimensional electron gas.

**G1.00078 Flexo-Electro-Optical Properties of Fullerene-C(Buckyballs) Suspended in 4'-Pentyl-4-Biphenyl (5CB)** , JONATHAN FOUST, ANGELO VISCO, RIZWAN MAHMOOD, Slippery Rock Univ — We have investigated electro optical properties of a widely studied liquid crystal (5CB) when fullerene C-60 (buckyballs) is suspended in various concentrations as a function of temperature. Under a polarizing microscope, we have observed disclination (defect) points at the sites of buckyballs suggesting a strong interaction between the two components. The data indicate a shift in the transition temperature and sudden decrease in dielectric anisotropy ( $\Delta\epsilon$ ) at some critical concentration (~0.15 wt. %) of fullerene. A sudden increase was also observed upon increasing the concentration of buckyballs that remains constant within the experimental uncertainty. **Keywords:** buckyballs, fullerene, liquid crystal, dielectric anisotropy **Acknowledgements:** RM acknowledges the financial support of the Grant Office, Slippery Rock University.

## **G1.00079 ABSTRACT WITHDRAWN —**

**G1.00080 Electrical response of monolayer MoS<sub>2</sub> to vapors of aliphatic alcohols<sup>1</sup>** , PABLO SEPULVEDA, IDALIA RAMOS, University of Puerto Rico-Humacao, CARL NAYLOR, A.T. CHARLIE JOHNSON, University of Pennsylvania, NICHOLAS PINTO, University of Puerto Rico-Humacao — Monolayer MoS<sub>2</sub> crystals were used to sense vapors of Methanol, Ethanol and 1-Propanol. Due to the large surface area, these sensors are expected to show rapid response and recovery times. The current through the sensor was monitored as a function of time with a constant applied voltage. This current decreased in the presence of the sensing gas and recovered upon its removal. Our results show that the response time gets longer as the size of the alcohol increases, but the recovery time stays approximately the same (~20s) regardless of the size of the alcohol. The sensitivity was also seen to decrease as the size of the alcohol increased. These observations could be associated with the slower diffusion of the larger alcohol molecules into the MoS<sub>2</sub> crystal. The sensors are also fairly robust since the same sensor was used in all of the measurements after annealing in air at 70C for 10 minutes. Additional sensing measurements as a function of gas concentration will also be presented.

**G1.00081 Schottky diode based on WS<sub>2</sub> crossed with PEDOT/PSSA<sup>1</sup>** , DELIRIS ORTIZ, NICHOLAS PINTO, University of Puerto Rico - Humacao, CARL NAYLOR, A.T. CHARLIE JOHNSON, University of Pennsylvania — An easy technique to fabricate a Schottky diode with WS<sub>2</sub> and PEDOT-PSSA under ambient conditions is presented. WS<sub>2</sub> is an air stable transition metal dichalcogenide semiconductor. When connected as a field effect transistor, WS<sub>2</sub> exhibited n-type behavior with a charge mobility of ~7cm<sup>2</sup>/V-s on SiO<sub>2</sub>. PEDOT/PSSA is a conducting polymer that can be electro-spun to form fibers with a conductivity of ~1 S/cm. In this work we fabricated a Schottky diode by crossing a CVD grown monolayer WS<sub>2</sub> crystal with a single electro-spun PEDOT/PSSA fiber. The resulting diode characteristics were analyzed assuming the standard thermionic emission model of a Schottky junction. Analysis of the results includes the ideality parameter of 4.75, diode rectification ratio ~10, and a turn on voltage of 1.4V. Efforts to investigate if these parameters are tunable with a back gate will also be presented.

<sup>1</sup>This work was supported by NSF-DMR-1523463 and NSF DMR RUI-1360772. ATJ acknowledges support from EFRI 2DARE EFMA-1542879.

**G1.00082 Opto-electronic Properties of Monolayer-Protected Clusters of Au functionalized with a New Fluorescent Ligand** , THOMAS KOUNTZ, Towson University, VIRAJ THANTHIRIGE, Western Michigan University, KEITH REBER, MARY SAJINI DEVADAS, Towson University — Metal nanoclusters are the focus of intense study due to their interesting optical, electronic, and catalytic properties; specifically gold clusters. The applications of gold monolayer-protected clusters (MPCs) are being researched by a series of optical spectroscopic and voltammetric analyses to determine core size, atom-level composition, charge states, and optical/electrical properties. Understanding these fundamental properties is critical for both expansion of applications and creation of new MPCs. The purpose of this study is to expand the applications of gold MPCs, with the attachment of a new coumarin surface ligand - synthesized specifically for this experiment. Our focus in this research is on quantum clusters - specifically Au<sub>25</sub>(C<sub>6</sub>S)<sub>18</sub>. This MPC is researched particularly because of its inherent stability being a magic number cluster. It is created by means of a modified Brust-Schiffrin method. The applications that are influenced include but are not limited to: catalytic activity, solar energy conversion, size-tunable fluorescence, sensors, and optical electronics.

**G1.00083 Crystallization Trends of PEO-b-PCL with Solvent and Temperature Effects** , KRISTI ALLEN, ALLISON CARANDANG, RYAN VAN HORN, Allegheny College — There is a great deal of interest in being able to selectively modify properties of certain polymers. This increases the amount of control that can be exercised over end products in terms of the hydrophobicity or hydrophilicity, transparency, and brittleness and is highly valued in the biomedical industry. In this case, the crystallization trends of the diblock co-polymer poly(ethylene-oxide)-b-poly( $\epsilon$ -caprolactone) (PEO-b-PCL) were observed with the manipulation of solvent and drying temperatures in a variety of samples. The solvents utilized included tetrahydrofuran, chloroform, and toluene. The crystallized samples were scanned via infrared spectroscopy. Results showed highest amounts of PEO crystallization compared to PCL crystallization in toluene while the lowest values were seen in samples in tetrahydrofuran. The chloroform samples fell in the middle. Moderate differences were observed in different molecular weight samples.

**G1.00084 Collective dynamics of non-transitively coupled active oscillators** , ARGHYADIP MUKHERJEE, Indian Institute of Science, PAWAN NANDAKISHORE, SHASHI THUTUPALLI, National Center for Biological Sciences-TIFR, NCBS THEORY TEAM — Non-transitive relations between coupled nonequilibrium units are a central feature of many natural and engineered systems ranging from interacting organismal populations to cells in a tissue. As a generalised abstraction for such interactions, we consider a system comprised of units whose internal degrees of freedom are intertwined to their orientation. Specifically, the individual elements are amplitude-phase oscillators with an orientation which can interact with the oscillation phase. An emergent mean field couples their dynamics causing the mesoscopic orientational order of the oscillators to affect their phase dynamics and vice versa. Here, we report on theoretical and experimental results on the emergent dynamics in a system built from mechanical oscillators. We show that the phase space consists of a rich variety of behaviors ranging from orientationally ordered synchronized states, traveling waves and even states with partial ordering. We briefly discuss the biological context for our abstract physical models.

**G1.00085 Silicon Photomultipliers Characterization** , CHRISTOPHER BOWSER, MARIAN TZOLOV, Lock Haven Univ, NICK BARBI, PulseTor LLC — Low noise and high sensitivity photon detectors such as the Photomultiplier Tube (PMT) are very common instruments used in research and many other applications. The PMTs have drawbacks such as durability, size, and sensitivity to magnetic field which make them unsuitable for some tasks. Silicon Photomultipliers (SiPMs) are compact, solid state detectors with gain close to that of a PMT, which are a promising replacement of a PMT. We have studied two types of SiPMs designed for optimum response in the visible and near-UV spectral range. We have verified the basic electrical parameters of the devices using current-voltage characteristics and impedance spectroscopy in dark. The spectral response was measured in DC mode, which is very simple to realize and still delivers very good sensitivity. We have established the linearity of the photoresponse and the limits at high intensity illumination. The pairing of the SiPMs with several common scintillators was studied with the goal of optimum performance of the SiPM/scintillator pair.

**G1.00086 Fabrication of a three dimensional particle focusing microfluidic device using a 3D printer, PDMS, and glass**<sup>1</sup> , ROBYN COLLETTE, DANIEL ROSEN, KATHRYN SHIRK, Shippensburg University of Pennsylvania — Microfluidic devices have high importance in fields such as bioanalysis because they can manipulate volumes of fluid in the range of microliters to picoliters. Small samples can be quickly and easily tested using complex microfluidic devices. Typically, these devices are created through lithography techniques, which can be costly and time consuming. It has been shown that inexpensive microfluidic devices can be produced quickly using a 3D printer and PDMS. However, a size limitation prohibits the fabrication of precisely controlled microchannels. By using shrinking materials in combination with 3D printing of flow-focusing geometries, this limitation can be overcome. This research seeks to employ these techniques to quickly fabricate an inexpensive, working device with three dimensional particle focusing capabilities. By modifying the channel geometry, colloidal particles in a solution will be focused into a single beam when passed through this device. The ability to focus particles is necessary for a variety of biological applications which requires precise detection and characterization of particles in a sample.

<sup>1</sup>We would like to thank the Shippensburg University Undergraduate Research Grant Program for their generous funding.

**G1.00087 Statistical Modeling of Robotic Random Walks on Different Terrain** , AUSTIN NAYLOR, LAURA KINNAMAN<sup>1</sup>, Morningside College — Issues of public safety, especially with crowd dynamics and pedestrian movement, have been modeled by physicists using methods from statistical mechanics over the last few years. Complex decision making of humans moving on different terrains can be modeled using random walks (RW) and correlated random walks (CRW). The effect of different terrains, such as a constant increasing slope, on RW and CRW was explored. LEGO robots were programmed to make RW and CRW with uniform step sizes. Level ground tests demonstrated that the robots had the expected step size distribution and correlation angles (for CRW). The mean square displacement was calculated for each RW and CRW on different terrains and matched expected trends. The step size distribution was determined to change based on the terrain; theoretical predictions for the step size distribution were made for various simple terrains.

<sup>1</sup>It's Dr. Laura Kinnaman, not sure where to put the Prefix.

**G1.00088 Novel Fabrication of Carbon Spheres Decorated with Nickel Nanoparticles for Supercapacitors**<sup>1</sup> , CESAR NIEVES, Univ of Puerto Rico - Humacao, JOSHUA ROBLES, University of South Florida, NICHOLAS PINTO, IDALIA RAMOS, Univ of Puerto Rico - Humacao, PENN-UPR PARTNERSHIP FOR RESEARCH AND EDUCATION IN MATERIALS COLLABORATION — Carbon spheres (CS) were synthesized by hydrothermal method using a 0.8M aqueous sucrose solution as the carbon source. The starting solution was heated in a stainless steel autoclave at 200°C for 4h to produce carbon spheres with regular shapes having diameters in the range of 1-20 $\mu$ m. Ni-nanoparticles were deposited on the CS surfaces by an electro-less deposition technique. Our work is the first attempt to decorate CS with nickel nanoparticles using this method. The obtained Ni-CS was studied using Scanning Electron Microscopy (SEM), Energy Dispersive Spectroscopy (EDS) and Ultra-Violet/Visible Spectroscopy (UV-Vis). CS decorated with Nickel nanoparticles increase their capacity to conduct a current making them useful in catalysts and in supercapacitors. Conductivity measurements on these Ni decorated CS and their use in supercapacitors will be presented.

<sup>1</sup>This work was supported by NSF under grant NSF-DMR-1523463 (PENN-UPR PREM).

**G1.00089 Utilizing Diffuse Reflection to Increase the Efficiency of Luminescent Solar Concentrators**<sup>1</sup> , SETH BOWSER, SETH WEIBLE, JOEL SOLOMON, JONATHAN SCHRECENGOST, BRUCE WITTMERSHAUS, School of Science, Pennsylvania State University: Erie, The Behrend College — A luminescent solar concentrator (LSC) consists of a high index solid plate containing a fluorescent material that converts sunlight into fluorescence. Utilizing total internal reflection, the LSC collects and concentrates the fluorescence at the plates edges where it is converted into electricity via photovoltaic solar cells. The lower production costs of LSCs make them an attractive alternative to photovoltaic solar cells. To optimize an LSCs efficiency, a white diffusive surface (background) is positioned behind it. The background allows sunlight transmitted in the first pass to be reflected back through the LSC providing a second chance for absorption. Our research examines how the LSCs performance is affected by changing the distance between the white background and the LSC. An automated linear motion apparatus was engineered to precisely measure this distance and the LSCs electrical current, simultaneously. LSC plates, with and without the presence of fluorescent material and in an isolated environment, showed a maximum current at a distance greater than zero. Further experimentation has proved that the optimal distance results from the backgrounds optical properties and how the reflected light enters the LSC.

**G1.00090 Improving the Stability of Fluorescent Silver Nanoclusters<sup>1</sup>**, NICHOLAS SWANSON, DANIELLE STANKO, IAN CAMPBELL, BRUCE WITTMERSHAUS, School of Science, Pennsylvania State University: Erie, The Behrend College — The quantum mechanical nature of noble metal nanoparticles results in them having optical properties much different from the bulk metal. Silver nanoclusters (AgNC), groups of 4 to 20 atoms, are characterized by strong optical transitions in the visible part of the spectrum giving them an appearance like fluorescent organic dyes. These nanoclusters can also have fluorescence quantum yields over 90%. Following the analysis of published results of DNA templated nanoclusters, we created a procedure for synthesizing AgNC. The AgNC have a high fluorescence quantum yield but degrade with a lifetime of only a few days when in solution at room temperature. Our goal in this study was to increase the stability of the AgNC towards improving their value as a fluorescent material in various applications, such as luminescent solar concentrators. To increase their stability, we've chosen to modify our procedure by removing oxygen from the solution after the sample has reacted. Oxygen removal caused a significant increase in the stability of the clusters over a given period of time.

**G1.00091 Equivalence Principle tests as probes of Modified Newtonian Dynamics**, ALEX POYNEER, JONAS PEREIRA, THOMAS KRAUSE, JAMES OVERDUIN, Towson University — Modified Newtonian dynamics (MOND) has been proposed as a way to reconcile gravitational theory and observational cosmology without the need for large amounts of unseen dark matter. Instead, a change is postulated to the Newtonian limit of standard theory in the regime of very small accelerations. We consider whether it might be possible to constrain this idea using proposed space tests of the Equivalence Principle (EP). Such tests could be sensitive to accelerations as small as  $10^{-18}$  g over 20 orbits.

**G1.00092 Concentration Dependence of Gold Nanoparticles for Fluorescence Enhancement<sup>1</sup>**, JOEL SOLOMON, BRUCE WITTMERSHAUS, School of Science, Pennsylvania State University: Erie, The Behrend College — Noble metal nanoparticles possess a unique property known as surface plasmon resonance in which the conduction electrons oscillate due to incoming light, dramatically increasing their absorption and scattering of light. The oscillating electrons create a varying electric field that can affect nearby molecules. The fluorescence and photostability of fluorophores can be enhanced significantly when they are near plasmonic nanoparticles. This effect is called metal enhanced fluorescence (MEF). MEF from two fluorescence organic dyes, Lucifer Yellow CH and Riboflavin, was measured with different concentrations of 50-nm colloidal gold nanoparticles (Au-NP). The concentration range of Au-NP was varied from 2.5 to 250 pM. To maximize the interaction, the dyes were chosen so their emission spectra had considerable overlap with the absorption spectra of the Au-NP, which is common in MEF studies. If the dye molecules are too close to the surface of Au-NP, fluorescence quenching can occur instead of MEF. To try to observe this difference, silica-coated Au-NP were compared to citrate-based Au-NP; however, fluorescence quenching was observed with both Au-NP.

**G1.00093 Local density of states measurements via STM and TS on clean fresh cleaved HOPG and Gold thin films on HOPG under ambient conditions.<sup>1</sup>**, CASEY MOREAN, ROMAN MARIJCZUK, INDRAJITH SENEVIRATHNE, Lock Haven University — Highly Oriented Pyrolytic Graphite (HOPG) has many applications in physics and engineering thus understanding affiliated physical and chemical phenomena is important. This also makes HOPG an important and interesting system to study. This is an investigation of surfaces of HOPG and Au thin films (ranging about 20nm) via Scanning Tunneling Microscopy (STM) and Tunneling Spectroscopy (TS) with a Pt-Ir tip equipped Nanosurf Naio STM. In this investigation, clean fresh cleaved HOPG substrates were used. Surfaces of HOPG and Au sputter deposited at different film thicknesses were imaged via constant current mode to assess the surface consistency and roughness. Consistent atomic resolution images were obtained. The systems were then investigated via TS by applied tip voltage (V) vs. tunneling current (I) curves. These spectroscopic data were then used to assess the local density of states (LDOS) and the surface variation of LDOS. The discussion will attempt to assess the surface electronic environment of these systems in relation to the Au deposition and variation of Au thicknesses on HOPG. Since measurements were carried out in ambient conditions this adds to the complexity which will also be discussed.

<sup>1</sup>Lock Haven University Nanotechnology Program

**G1.00094 Gravity Wave Disturbances in the F-Region Ionosphere Above Large Earthquakes**, MARGIE BRUFF, North Carolina School of Science and Mathematics — The direction of propagation, duration and wavelength of gravity waves in the ionosphere above large earthquakes were studied using data from the Super Dual Auroral Radar Network. Ground scatter data were plotted versus range and time to identify gravity waves as alternating focused and de-focused regions of radar power in wave-like patterns. The wave patterns before and after earthquakes were analyzed to determine the directions of propagation and wavelengths. Conditions were considered 48 hours before and after each identified disturbances to exclude waves from geomagnetic activity. Gravity waves were found travelling away from the epicenter before all six earthquakes for which data were available and after four of the six earthquakes. Gravity waves travelled in at least two directions away from the epicenter in all cases, and even stronger patterns were found for two earthquakes. Waves appeared, on average, 4 days before, persisting 2-3 hours, and 1-2 days after earthquakes, persisting 4-6 hours. Most wavelengths were between 200-300 km. We show a possible correlation between magnitude and depth of earthquakes and gravity wave patterns, but study of more earthquakes is required. This study provides a better understanding of the causes of ionospheric gravity wave disturbances and has potential applications for predicting earthquakes.

**G1.00095 Work function measurements via STM and TS on clean fresh cleaved HOPG and Gold thin films on HOPG under ambient conditions.<sup>1</sup>**, ROMAN MARIJCZUK, CASEY MOREAN, INDRAJITH SENEVIRATHNE, Department of Geology & Physics Lock Haven University — Stability and homogeneity of HOPG has enabled it to be used as a platform for various applications in understanding many physical and chemical phenomena. Novel emergence of graphene as a derivative of graphite also makes HOPG an interesting system to study. This is an ambient investigation of HOPG and Au thin films (ranging about 20nm) surfaces via Scanning Tunneling Microscopy (STM) and Tunneling Spectroscopy (TS) with a Pt-Ir tip equipped Nanosurf Naio STM. In this investigation, clean fresh cleaved HOPG substrates were used. Surfaces of HOPG and Au sputter deposited at different film thicknesses were imaged via constant current mode to assess the surface consistency and roughness. Consistent atomic resolution images were obtained. The same systems were then investigated via TS by tunneling current (I) vs. height (z) curves. These spectroscopic data were then used to assess the localized work function measurements and surface variation of the work function. The discussion will attempt to assess the surface electronic environment of these systems in relation to the Au deposition and variation of Au thickness on HOPG. Ambient measurements will inherently complicate these measurements and the complexities will also be discussed.

<sup>1</sup>Lock Haven University Nanotechnology Program

**G1.00096 Basic atmospheric measurements via Arduino Uno microcontroller with commercially available sensors towards simple real-time weather forecasting for increased classroom engagement**<sup>1</sup>, RYAN ECKEL, MEGHAN TANNER, INDRAJITH SENEVIRATHNE, Lock Haven University Department of Geology and Physics — Makers, engineers and the applied physics community have adapted Arduino microcontrollers due to their versatility, robustness and cost effectiveness. Arduino microcontroller environment coupled with commercially available sensors have been used to systematically measure, record and analyze temperature, humidity and barometric pressure for building a simplified weather station for subsequent educational purposes. This data will become available in classroom settings for real-time analysis towards simple weather forecasting. Setup was assembled via breadboard, wire and simple soldering with an Arduino Uno ATmega328P microcontroller connected to a PC. The microcontroller was programmed with Arduino Software while the bootloader was used to upload the code. Commercial DHT22 humidity and temperature sensor, and BMP180 barometric pressure sensor were used to obtain relative humidity, temperature and the barometric pressure. A weather resistant enclosure protected the system while stable real-time data measurements were obtained, and uploaded onto the PC. The data was used to predict atmospheric conditions and lifting condensation level (LCL). Discussion will focus on capabilities and limitations of these systems and corresponding teaching aspects.

<sup>1</sup>Lock Haven University Nanotechnology Program

**G1.00097 Enhanced low current, voltage, and power dissipation measurements via Arduino Uno microcontroller with modified commercially available sensors.**<sup>1</sup>, MEGHAN TANNER, RYAN ECKEL, INDRAJITH SENEVIRATHNE, Lock Haven University Department of Geology & Physics — The versatility, simplicity, and robustness of Arduino microcontroller architecture have won a huge following with increasingly serious engineering and physical science applications. Arduino microcontroller environment coupled with commercially available sensors have been used to systematically measure, record, and analyze low currents, low voltages and corresponding dissipated power for assessing secondary physical properties in a diverse array of engineering systems. Setup was assembled via breadboard, wire, and simple soldering with an Arduino Uno with ATmega328P microcontroller connected to a PC. The microcontroller was programmed with Arduino Software while the bootloader was used to upload the code. Commercial Hall effect current sensor modules ACS712 and INA169 current shunt monitor was used to measure corresponding low to ultra-low currents and voltages. Stable measurement data was obtained via sensors and compared with corresponding oscilloscope measurements to assess reliability and uncertainty. Sensor breakout boards were modified to enhance the sensitivity of the measurements and to expand the applicability. Discussion of these measurements will focus on capabilities, capacities and limitations of the systems with examples of possible applications.

<sup>1</sup>Lock Haven Nanotechnology Program

**G1.00098 Photocurrent of Photovoltaic Cells**, SETH PEELER, MAX MCINTYRE, RAQUEL COSSEL, CHRIS BOWSER, MARIAN TZOLOV, Lock Haven University of PA — Photovoltaic cells can be used to harness clean, renewable energy from light. Examined in this project were photovoltaic cells based on a bulk heterojunction between PCPDTBT and PCBM sandwiched between an ITO anode and an Al cathode. Current-voltage characteristics and impedance spectra for multiple photovoltaic devices were taken under varying DC electrical bias and different level of illumination. This data was interpreted in terms of an equivalent circuit with linear elements, e.g. capacitance, series resistance, and parallel resistance. A physical interpretation of each circuit element will be presented. The spectral response of the devices was characterized by optical transmission and photocurrent spectroscopy using a spectrometer in the spectral range from 300 to 900 nm. The DC measurements confirmed that the devices are electrically rectifying. The AC measurements allowed modeling of the devices as a dielectric between two electrodes with injection current passing through it. The characteristic peaks for both PCPDTBT and PCBM are clearly visible in both the photocurrent and transmission data. The good correlation between the photocurrent and transmission data indicates photocurrent generation due to absorption in both materials constituting the heterojunction.

**G1.00099 Characterization of the Pseudocapacitive Nature of Surface Bound Prussian Blue Analogues**<sup>1</sup>, DANIEL CLARK, JENNIFER HAMPTON, Hope College — With the increased use of intermittent renewable energy sources, more efficient methods of energy storage must be explored. Electrochemical capacitors provide a larger volumetric charge density than physical capacitors while maintaining fast charge and discharge rates. Prussian Blue analogues (nickel and cobalt hexacyanoferrate) are ideal pseudocapacitors for frequent charge and discharge cycles since the crystalline structure does not physically change during switching, causing less stress on the film. This project examines the charge transfer and diffusion coefficients for nickel and nickel-cobalt thin films modified with potassium hexacyanoferrate. The films were examined using a scanning electron microscope, an atomic force microscope and an electrochemical workstation to determine their composition, topography and pseudocapacitive nature. Preliminary data suggest that nickel-cobalt films have a larger quantity of charge and have a lower diffusion coefficient per charge than nickel films.

<sup>1</sup>This work is supported by the Hope College Nyenhuis Faculty Development Fund, the Hope College Department of Physics Guess Research Fund, and the National Science Foundation under Grants RUI-DMR-1104725, MRI-CHE-0959282, and MRI-CHE-1126462.

**G1.00100 Dealloying NiCo and NiCoCu Alloy Thin Films Using Linear Sweep Voltammetry**<sup>1</sup>, BENJAMIN PEECHER, JENNIFER HAMPTON, Hope College — When electrodeposited into thin films, metals have well-known electrochemical potentials at which they will be removed from the film. These potential differences can be utilized to re-oxidize only certain metals in an alloy, altering the films structure and composition. Here we discuss NiCo and NiCoCu thin films response to linear sweep voltammetry (LSV) as a means of electrochemical dealloying. For each of four different metal ratios, films were dealloyed to various potentials in order to gain insight into the evolution of the film over the course of the LSV. Capacitance, topography, and composition were examined for each sample before and after linear sweep voltammetry was performed. For NiCo films with high percentages of Ni, dealloying resulted in almost no change in composition, but did result in an increased capacitance, with greater increases occurring at higher LSV potentials. Dealloying also resulted in the appearance of large (100–1000 nm) pores on the surface of the film. For NiCoCu films with high percentages of Ni, Cu was almost completely removed from the film at LSV potentials greater than 500 mV. The LSV first removed larger copper-rich dendrites from the films surface before creating numerous nano-pores, resulting in a net increase in area.

<sup>1</sup>This work is supported by an award to Hope College from the HHMI Undergraduate Science Education Program, the Hope College Department of Physics Frissel Research Fund, and the National Science Foundation under Grants RUI-DMR-1104725 and MRI-CHE-0959282.

**G1.00101 Effects of Stress on Corrosion in a Molten Salt Environment**, SAMUEL GIRDZIS, DENNIS MANOS, WILLIAM COOKE, The College of William and Mary — Molten salt is often used as a heat transfer and energy storage fluid in concentrating solar power plants. Despite its suitable thermal properties, molten salt can present challenges in terms of corrosion. Previous studies have focused extensively on mass loss due to molten salt-induced corrosion. In contrast, we have investigated how corrosion begins and how it changes the surface of stainless steel. Samples of alloys including 304 and 316 stainless steel were exposed to the industry-standard NaNO<sub>3</sub>-KNO<sub>3</sub> (60%-40% by weight) mixture at temperatures over 500°C and then analyzed using Hinox, SEM, and TOF-SIMS. We compare the corrosion at grain boundaries to that within single grain surfaces, showing the effect of the increased internal stresses and the weakened passivation layer. Also, we have examined the enhanced corrosion of samples under mechanical stress, simulating the effects of thermal stresses in a power plant.

**G1.00102 Exact and Approximate Solutions for a Class of Cooperative Stochastic Models<sup>1</sup>**, REBECCA MELKERSON, GILLENHAAL BECK, ESTEVAN HALL-MEJIA, SABIN NSHIMYUMUKIZA, Washington and Lee University, CARLOS DA FONSECA, Kuwait University, DAN MAZILU, IRINA MAZILU, Washington and Lee University — We present a class of cooperative sequential adsorption models with evaporation defined on general lattice structures. Using matrix algebra theory to solve the associated master equations, we find the time-dependent probability distributions. We discuss these models in the context of ionic self-assembly of silica nanoparticles in order to also find the time-dependent surface coverage. To test the limits of the matrix theory, we add the possibilities for evaporation either once the surface is fully covered or at intermediate steps. We justify our mathematical models by comparing the results to customized experiments and computer simulations.

<sup>1</sup>Washington and Lee University Summer Research Scholars

**G1.00103 Potential Mapping of an Indium-Tin-Oxide Glass Box in a GEC Reference Cell<sup>1</sup>**, REBECCA KAPLAN, Towson Univ, JORGE CARMONA-REYES, TRUELL HYDE, LORIN MATTHEWS, Baylor University, CASPER PROGRAM TEAM — The use of indium-tin-oxide (ITO) coated boxes, as well as boxes coated with other substances, placed on or floating above the lower electrode in studies using Gaseous Electronics Conference Radio Frequency Reference Cells have increased in interest, as have the use of plain glass boxes. This increase in interest is due to the greater ability to control the confinement forces and in effect create dust chain structures which aid in studies within other areas of physics such as; entropy, kinetic dust temperature, plasma balls and coulomb explosions. Further analysis of the data obtained using these boxes shows what appear to be at least two different regions of confinement inside the boxes as well as some unexpected phenomena related to anomalous values and behavior of the electric field. These areas affect the dust to dust and dust to plasma interactions independently in the separate regions and are therefore of great interest. In this study electric potential and electric field maps created in MatLab with data obtained using two probes mounted on CASPER's S-100 nano-manipulator will be presented, connecting the information obtained from these maps to the behavior of the dust observed for different experimental conditions.

<sup>1</sup>All of this has been made possible by the opportunity and funding from the CASPER program and the National Science Foundation grant number PHY-1262031.

**G1.00104 Deducing Shape of Anisotropic Particles in Solution from Light Scattering: Spindles and Nanorods.**, ILONA TSUPER, DANIEL TERRANO, KIRIL A. STRELETZKY, Cleveland State University, OLGA V. DEMENT'EVA, SERGEY A. SEMYONOV, VICTOR M. RUDOY, Frumkin Institute of Physical Chemistry and Electrochemistry, Moscow, Russia — Depolarized Dynamic Light Scattering (DDLS) enables to measure rotational and translational diffusion of nanoparticles suspended in solution. The particle size, shape, diffusion, and interactions can then be inferred from the DDLS data using various models of diffusion. Incorporating the technique of DDLS to analyze the dimensions of easily imaged elongated particles, such as Iron (III) oxyhydroxide (FeOOH) Spindles and gold Nanorods, allows testing of the models for rotational and translational diffusion of elongated particles in solution. This, in turn, can help to better interpret DDLS data on hard-to-image anisotropic wet systems such as micelles, microgels, and protein complexes. This study focused on FeOOH Spindles and gold nanorod particles. The light scattering results on FeOOH analyzed using the basic model of non-interacting prolate ellipsoids yielded dimensions within 17% of the SEM measured dimensions. The dimensions of gold nanorod obtained from the straight cylinder model of DDLS data provided results within 25% of the sizes that were obtained from TEM. The nanorod DDLS data was also analyzed by a spherocylinder model.

**G1.00105 Developing Affordable Wet-Sample Electron Microscopy Integrated with a Temperature Controlled Sample Holder.**, DANIEL TERRANO, PETRU S. FODOR, KIRIL A. STRELETZKY, Cleveland State University — Scanning electron microscopy (SEM) is widely used to analyze the size, shape and composition of material systems. However, using this tool for analyzing systems such as particles suspended in solution, requires drastic sample alterations, such as precipitation and fixation. Besides altering their environment, this exposes the particles to the harsh conditions within an electron microscope, such as high vacuum and electron beam exposure. To this end, the first goal of this study was to develop methodologies for imaging wet samples using electron microscopy. This is realized by creating a sandwich structure containing the solution of interest between a partially electron transparent window and a silicon substrate. The ability of the developed imaging cells to provide good imaging conditions is demonstrated with a variety of samples including polystyrene spheres, polymeric microgels and spindle shaped nanoparticles. As some of the systems investigated are temperature sensitive, the second goal of the project was to develop a temperature controlled stage that can be integrated with the SEM. In the future this heating stage will be used alongside the wet samples to image microgels above and below their critical solution temperature.

**G1.00106 Deposition of Highly Luminescent Zinc Tungstate Thin Films on Various Substrates**, RASHAD FARRAKHAN, Lock Haven University — Zinc tungstate films have promising applications in small form factor backscatter electron detectors. We are developing a multistep technology for synthesis of these films. Zinc and tungsten were co-sputtered onto substrates through the process of magnetron sputtering. The metallic films were oxidized in a vacuum sealed tube furnace in controlled flow of argon and oxygen at 800 C. The chemical composition of the film was characterized by Energy-Dispersive X-Ray Spectroscopy (EDS). The structure of the film was investigated by Raman Spectroscopy. The photoluminescence quantum efficiency of the films was found to be 60%. Process parameters for obtaining the desired 1-1 ratio of zinc to tungsten in the film is explored through varying factors such as: the composition of the target used in the sputtering, the power and or voltage used in the sputtering process. Our experiments show that zinc tungstate thin films can be deposited on various substrates with good adhesion and mechanical integrity, and still be efficient light emitters.

**G1.00107 ABSTRACT WITHDRAWN —**

**G1.00108 Synthesis of Polymeric Microgels and their Characterization with Light Scattering.**, CHRISTIAN GUNDER, KIRIL A. STRELETZKY, KRISTA FREEMAN, JANNA MINO, Cleveland State University — Polymeric microgels were synthesized in by chemically crosslinking hydroxypropylcellulose (HPC) chains in aqueous solutions of sodium hydroxide at temperatures above the low critical solution temperature (LCST) of HPC. In order to create a narrower size distribution of HPC microgels, surfactant was added. It was found that the LCST of the solution moved from 40C up to 80C with an increase in surfactant concentration from 0 to 12 g/l. Formed microgels were characterized by dynamic light scattering (DLS). Microgel solutions synthesized resulted in reasonably monodispersed nanoparticles with Rh of 90-150 nm below the transition, and Rh of 50-90 nm above the transition. The effect of synthesis temperature and crosslinker concentration on microgel size, polydispersity, and swelling ratio were also studied.

**G1.00109 Monte Carlo and Exact Diagonalization of Copper (II) Trimer Spin Frustrated Systems<sup>1</sup>**, HAILEY X. EGIDO-BETANCOURT, LEONARD W. TER HAAR, CHRISTOPHER N. VARNEY, University of West Florida — We discuss the use and importance of trimer-based systems because of the spin frustration that may arise within extended lattices comprised of trimers. The possible intra- and inter-trimer exchange pathways they possess due to interconnections are evaluated using density functional theory (DFT) to identify the optimal structures that may be used in designing extended lattices. As example, trinuclear Cu<sub>3</sub><sup>2+</sup> cores with each pair of copper atoms bridged by carboxylate ligands have three-fold symmetry. As trimers these structures have the potential to be modeled as a frustrated quantum spin-1/2 system. To analyze the magnetic ground state and topological properties, we utilize exact diagonalization on small clusters and compare with Monte Carlo simulations for a range of system sizes.

**G1.00110 Tensile Strain Effects on the Magneto-transport in Calcium Manganese Oxide Thin Films: Comparison with its Hole-doped Counterpart**<sup>1</sup>, BRIDGET LAWSON, SAMUEL NEUBAUER, ADEEL CHAUDHRY, CACIE HART, NATALIE FERRONE, DAVID HOUSTON, GRACE YONG, RAJESWARI KOLAGANI, Towson University — Magnetoresistance properties of the epitaxial thin films of doped rare earth manganites are known to be influenced by the effect of bi-axial strain induced by lattice mismatch with the substrate. In hole-doped manganites, the effect of both compressive and tensile strain is qualitatively consistent with the expected changes in unit cell symmetry from cubic to tetragonal, leading to Jahn-Teller strain fields that affect the energy levels of Mn<sup>3+</sup> energy levels. Recent work in our laboratory on CaMnO<sub>3</sub> thin films has pointed out that tetragonal distortions introduced by tensile lattice mismatch strain may also have the effect of modulating the oxygen content of the films in agreement with theoretical models that propose such coupling between strain and oxygen content. Our research focuses on comparing the magneto-transport properties of hole-doped manganite LaCaMnO<sub>3</sub> thin films with that of its electron doped counter parts, in an effort to delineate the effects of oxygen stoichiometry changes on magneto-transport from the effects of Jahn-Teller type strain.

**G1.00111 Heat of Combustion of Dried and Undried Coffee**<sup>1</sup>, MATHEW GISO, SAMUEL AMANUEL, Dept. of Phys. & Astro., Union College — Globally, over two billion cups of coffee are consumed per day. During roasting, 15-20% of the weight of the coffee beans is lost. We studied the gasses released during the roasting process using an IR spectrometer and identified the evaporation profile of water as a function of temperature. The heat of combustion (H<sup>o</sup>c) of the beans was also determined using an Isoperibol Oxygen-Bomb calorimeter and the H<sup>o</sup>c of dry beans were determined to be 21.24 0.13 MJ/kg while the H<sup>o</sup>c of the wet beans were determined to be 19.56 0.12 MJ/kg. This study can potentially lead to developing more economical and environmentally friendly techniques of roasting coffee beans.

<sup>1</sup>This work was partially supported by NSF-DMR: 1229142.

**G1.00112 Visualizing Sound: Demonstrations to Teach Acoustic Concepts**, VALERIE RENNOLL, American University — Interference, a phenomenon in which two sound waves superpose to form a resultant wave of greater or lower amplitude, is a key concept when learning about the physics of sound waves. Typical interference demonstrations involve students listening for changes in sound level as they move throughout a room. Here, new tools are developed to teach this concept that provide a visual component, allowing individuals to see changes in sound level on a light display. This is accomplished using a microcontroller that analyzes sound levels collected by a microphone and displays the sound level in real-time on an LED strip. The light display is placed on a sliding rail between two speakers to show the interference occurring between two sound waves. When a long-exposure photograph is taken of the light display being slid from one end of the rail to the other, a wave of the interference pattern can be captured. By providing a visual component, these tools will help students and the general public to better understand interference, a key concept in acoustics.

**G1.00113 Effect of Uniaxial Strain on Band Structure of Multi-layer WS<sub>2</sub>**<sup>\*1</sup>, CONRAD TROHA<sup>2</sup>, DUY LE, TALAT RAHMAN, Univ of Central Florida — The ability to tailor band structure of a multi-layer transition metal dichalcogenide is of interest because it opens up utilizations of the material for various applications. Strain is considered a robust way to alter the electronic structure of a material. We performed calculations, using density functional theory, of band structure of multi-layer WS<sub>2</sub> under the effects of uniaxial strain. We show that the position of the bottom of conduction band (BCB) at  $\Sigma$  moves to higher, and at K to lower, energy levels under the effects of uniaxial tensile strain, making multi-layer WS<sub>2</sub> closer to a direct band gap material. Our results suggest that uniaxial tensile strain can be used to alter band structure of multi-layer WS<sub>2</sub> to achieve higher yield photo luminescence.

**G1.00114 Complexity and Fly Swarms**, GRANT CATES, JOELLE MURRAY, Linfield College — Complexity is the study of phenomena that emerge from a collection of interacting objects and arises in many systems throughout physics, biology, finance, economics and more. Certain kinds of complex systems can be described by self-organized criticality (SOC). An SOC system is one that is internally driven towards some critical state. Recent experimental work suggests scaling behavior of fly swarms—one of the hallmarks of an SOC system. Our goal is to look for SOC behavior in computational models of fly swarms.

**G1.00115 Gas separation by adsorption in carbon nanohorns.**<sup>1</sup>, ANTON NEKHAI<sup>2</sup>, Rensselaer Polytechnic Institute, SILVINA GATICA, Howard University — Gas separation by adsorption can be accomplished by three basic physical mechanisms: equilibria, kinetics, and steric effects. Equilibrium mechanisms rely on the strength of attraction between gas molecules and their substrate. For example, CO<sub>2</sub> possesses the strongest, attractive interactions with its substrate. As a result, the equilibrium mechanism presents the most plausible strategy to separate carbon dioxide from mixtures. The specification of a sound adsorbent is the key for separation by adsorption. In this paper we investigate carbon nanohorns for selectivity of carbon dioxide over methane. Carbon Nanohorns resemble short, wide, highly defected single-wall nanotubes that end in conical tips ("horns"). In contrast to regular nanotubes that assemble into parallel bundles, nanohorns form spherical aggregates with the nanohorns arranged along radial directions. Using the simulation technique Grand Canonical Monte Carlo (GCMC) we obtained the adsorption isotherms of CH<sub>4</sub> and CO<sub>2</sub> in a 2D array of carbon nanohorns. We estimated the selectivity based on the IAST approximation. We also study the adsorption of argon and neon and compare with experimental results.

**G1.00116 Doped Lanthanum Hafnates as Scintillating Materials for High-Energy Photon Detection**<sup>1</sup>, KAREEM WAHID, MADHAB POKHREL, YUANBING MAO, University of Texas Rio Grande Valley — Recent years have seen the emergence of nanocrystalline complex oxide scintillators for use in X-ray and gamma-ray detection. In this study, we investigate the structural and optical properties of La<sub>2</sub>Hf<sub>2</sub>O<sub>7</sub> nanoparticles doped with varying levels of Eu<sup>3+</sup> or Ce<sup>3+</sup> by use of X-ray diffraction, Raman spectroscopy, scanning electron microscopy, transmission electron microscopy, and optical photoluminescence. In addition, scintillation response under X-ray and gamma-ray exposure is reported.

<sup>1</sup>The authors thank the support from the Defense Threat Reduction Agency (DTRA) of the U.S. Department of Defense (Award HDTRA1-10-1-0114).

**G1.00117 ABSTRACT WITHDRAWN —**

**G1.00118 Controlled, Pulsed Frequency Chirped Laser Light at Large Detuning**, TRACY PALTOO, TANNER GROGAN, BRIAN KAUFMAN, MATTHEW WRIGHT, Adelphi Univ — We have developed a technique to create pulsed, frequency chirped laser light (1 GHz in 5 ns) at large detuning ( $>7$  GHz). Laser light is passed through an electro-optical phase modulator, where the light is modulated with a 7 GHz carrier signal whose frequency is modulated on the nanosecond time scale. The modulated light is passed into a diode laser which becomes injection locked. The injection-locked laser system amplifies and filters the laser light to create a single frequency chirped laser pulse whose detuning is some multiple of the carrier frequency. We have developed the ability to pulse the laser on timescales less than 3 ns and create an arbitrary frequency chirp shape.

**G1.00119 Whispering Gallery Modes Used to Determine the Changing Size of Levitated Aerosol Droplets in a Fluctuating Optical Trap**, ANGELA LUDVIGSEN, LOWELL MCCANN, University of Wisconsin - River Falls — A laser can be used as an optical trap to catch and hold small, transparent objects. Observations of optically trapped aqueous aerosol droplets have demonstrated that the droplet moves between two or more stable positions dependent upon the power of the trapping laser. It is hypothesized that this movement coincides with a resonance between the trapping light and the droplet's surface, called a Whispering Gallery Mode. When this resonance occurs, forces acting on the droplet cause it to move. To investigate this behavior, Raman scattered light from the droplet as well as the droplet's position are measured. The Raman spectrum exhibits a series of peaks resulting from the droplet's spherical shape, referred to as Cavity Enhanced Raman Spectroscopy. The location and spacing of these peaks are known to be related to the diameter and the optical properties of the droplet. From this spectrum, the magnitude of the electric and magnetic fields of the scattered light are calculated. This allows for a precise measurement of the droplet's radius at the moment that the droplet moves between stable positions. After determining the droplet's radius from the spectrum, the effect of varying the intensity of the trapping laser beam on the droplet radius can be investigated.

**G1.00120 Apparatus for the Measurement of Thermoelectric Power<sup>1</sup>**, SHOJI HISHIDA, PEI-CHUN HO, Physics/CSU-Fresno — The Seebeck Effect refers to the electric potential that is established in a material under an imposed temperature gradient. This effect provides a useful tool for characterizing the thermal and electric transport behavior of materials. A measurement probe is under development in order to measure the Seebeck Coefficient (Thermoelectric Power) of a sample over the temperature range from 10 - 300 K in a cryocooler system. The sample is mounted between two platforms: one that is thermally connected with the measurement probe and another that is thermally isolated, referred to as the cold and hot platforms respectively. A  $2k\Omega$  resistance heater on the hot platform is used to establish a temperature gradient across the sample and between the two platforms. A Cernox resistance thermometer measures the temperature of the cold platform, and a Type T differential thermocouple, composed of copper-constantan-copper wires, is used to measure the temperature difference. The probe will be calibrated using the known thermopowers of Nickel, Platinum, and Chromel samples. The performance results of this design will be presented.

<sup>1</sup>Research at CSU-Fresno is supported by NSF DMR-1506677. Shoji Hishida is also supported by the Undergraduate Research Grant at CSU Fresno

**G1.00121 Two Undergraduate Projects for Data Acquisition and Control**, KELLY HIERSCHE, TARA PENA, TANNER GROGAN, MATTHEW WRIGHT, Adelphi Univ — We are designing two separate instruments for use in our undergraduate laboratory. In the first project, a Raspberry Pi is used to simultaneously monitor a large number of current and voltage readings and store them in a database. In our second project, we are constructing our own microcontrollers to work as a general-purpose interface based off work carried out in Review of Scientific Instruments **84**, 103101 (2013). It was designed for low cost and simple construction, making it ideal for undergraduate level work. This circuit has room for two interchangeable daughter boards, giving it the capability to work as a general lab interface, lock-in detector, or waveform generator.

**G1.00122 Anion Photoelectron Spectroscopy of the Homogenous 2-Hydroxypyridine Dimer Electron Induced Proton Transfer System<sup>1</sup>**, ALEXANDRA VLK, SARAH STOKES, Towson University, YI WANG, ZACHARY HICKS, XINXING ZHANG, NICOLAS BLANDO, Johns Hopkins University, ANDREW FROCK, Baltimore Polytechnic Institute, SARA MARQUEZ, KIT BOWEN<sup>2</sup>, Johns Hopkins University, BOWEN LAB JHU TEAM — Anion photoelectron spectroscopic (PES) and density functional theory (DFT) studies on the dimer anion of (2-hydroxypyridine)<sub>2</sub><sup>-</sup> are reported. The experimentally measured vertical detachment energy (VDE) of 1.21eV compares well with the theoretically predicted values. The 2-hydroxypyridine anionic dimer system was investigated because of its resemblance to the nitrogenous heterocyclic pyrimidine nucleobases. Experimental and theoretical results show electron induced proton transfer (EIPT) in both the lactim and lactam homogeneous dimers. Upon electron attachment, the anion can serve as the intermediate between the two neutral dimers. A possible double proton transfer process can occur from the neutral (2-hydroxypyridine)<sub>2</sub> to (2-pyridone)<sub>2</sub> through the dimer anion. This potentially suggests an electron catalyzed double proton transfer mechanism of tautomerization.

**G1.00123 Charge Transport and Structural Dynamics in Phosphonium-based Ionic Liquids**, ZACHARIAH VICARS, TYLER COSBY, Univ of Tennessee, Knoxville, YANGYANG WANG, Oak Ridge National Laboratory, KATSUHIKO TSUNASHIMA, Wakayama College, JOSHUA SANGORO, Univ of Tennessee, Knoxville — A series of phosphonium-based ionic liquids are investigated by broadband dielectric spectroscopy, rheology, and differential scanning calorimetry. Varying the molecular structure of the anion leads to significant changes in charge transport and structural dynamics. The results are discussed within the framework and current understanding of anion/cation interactions in determining physicochemical properties of ionic liquids.

**G1.00124 Protein Folding and Self-Organized Criticality**, ARUN BAJRACHARYA, JOELLE MURRAY, Linfield College — Proteins are known to fold into tertiary structures that determine their functionality in living organisms. However, the complex dynamics of protein folding and the way they consistently fold into the same structures is not fully understood. Self-organized criticality (SOC) has provided a framework for understanding complex systems in various systems (earthquakes, forest fires, financial markets, and epidemics) through scale invariance and the associated power law behavior. In this research, we use a simple hydrophobic-polar lattice-bound computational model to investigate self-organized criticality as a possible mechanism for generating complexity in protein folding.

**G1.00125 Construction of a Laser Induced Breakdown Spectroscopy Setup<sup>1</sup>**, JOSEPH MAYS, ANDRIA PALMER, JAMES AMOS, TOM DYNKA, LAZLO UJJ, University of West Florida — Laser Induced Breakdown Spectroscopy (LIBS) is a practical spectroscopy to determine the chemical and atomic composition of materials. The third harmonic output of a Nd:YAG Q-switched laser generating 5ns pulses with 10Hz repetition rate was used to ablate the sample and create a micro-plasma. The emission of the radiating plasma was focused into an optical fiber with 0.22 numerical aperture. The spectra was measured with an Ocean Optics micro spectrometer. A synchronized shutter was used to select single laser pulses. In order to reach the breakdown threshold of the sample using the available energy of the laser pulses ( $<5$  mJ) a beam expander and a parabolic mirror was used for tight focusing. The optical and technical details including the characterization of the system will be presented. LIBS spectra taken from a variety of metal and organic samples show appropriate selectivity for quantitative and qualitative analysis for materials.

**G1.00126 Assessing the Effectiveness of Gravitational Wave Outreach Video Games in High School Students**, JONATHAN WHEELER, Andrews University — Students and faculty at the Gravitational Wave Group in Birmingham, UK developed a remake of the classic 1972 game of Pong. Black Hole Pong was developed to be used in events such as science fairs as a way to engage children and pique interest in black holes. I present the results of a study which assesses the utility of Black Hole Pong and its successors in raising awareness of gravitational wave research, and in fostering conceptual understanding of astrophysics and gravity. Of particular interest in this study is potential use in high school science classrooms during astrophysics units.

**G1.00127 All-Optical Quasi-Phase Matching of Frequency Doubling Using Counterpropagating Light**<sup>1</sup>, RICHARD CAMUCCIO, RACHEL MYER, ALLISON PENFIELD, ETIENNE GAGNON, AMY LYTLE, Franklin & Marshall College — Nonlinear optical frequency conversion is a useful method for creating coherent light sources with unique capabilities. The main challenge for conversion efficiency of processes like frequency doubling is the chromatic dispersion of the nonlinear medium. Successful techniques for correcting the phase mismatch between the different frequencies are often limited by the type of nonlinear medium that may be used. An all-optical method of quasi-phase matching using counterpropagating light has recently been demonstrated for high-order harmonic generation, an extreme nonlinear process. Sequences of counterpropagating pulses are used to interfere with the harmonic generation process periodically, correcting the phase mismatch and boosting efficiency. We report progress on an experimental investigation of the effect of counterpropagating light on the more commonly used low-order nonlinear optical processes. We present data showing the effects of a single counterpropagating pulse on the efficiency of frequency doubling of a Ti:sapphire ultrafast laser oscillator in beta-Barium Borate.

**G1.00128 Phenomenological Modeling for Langmuir Monolayers**<sup>1</sup>, DIMITRI BAPTISTE, DAVID KELLY, TWYMMUN SAFFORD, CHANDRA PRAYAGA, CHRISTOPHER N. VARNEY, AARON WADE, University of West Florida — Experimentally, Langmuir monolayers have applications in molecular optical, electronic, and sensor devices. Traditionally, Langmuir monolayers are described by a rigid rod model where the rods interact via a Leonard-Jones potential. Here, we propose effective phenomenological models and utilize Monte Carlo simulations to analyze the phase behavior and compare with experimental isotherms.

**G1.00129 The effect of drainage channels on the hydrodynamic drag of non-colloidal spheres down an inclined plane.**<sup>1</sup>, BRIAN RYU, CHARLES DHONG, JOELLE FRECHETTE, Johns Hopkins University — While it is well known that surface asperities and roughness alter the hydrodynamic drag of a non-colloidal sphere down an inclined plane, less is known about how the hydrodynamic drag is modified if the asperities and roughness are connected through a network of drainage channels, which allows the movement of fluid between asperities. We investigate the rotational and translation motion of spheres on several pairs of surfaces that have the same porosity and asperity size, but one surface has interconnected drainage channels whereas the other does not. These can have direct relevance to lubricated surfaces such as ball bearings in industrial settings, or biological relevance of leucocyte movement across rough surfaces.

**G1.00130 Magnetic and Magnetocaloric Properties in Non-Stoichiometric Gallium Deficient  $\text{Ni}_2\text{MnGa}_{1-x}$  Heusler Alloys**, ALEXANDER MADDEN, MOLLIE CORRIGAN, LINDA BARTON, Rochester Institute of Technology — Magnetic data show that off-stoichiometric gallium deficient Heusler alloys of the form  $\text{Ni}_2\text{MnGa}_{1-x}$  have structural martensite transition temperatures that increase strongly with  $x$ , while their ferromagnetic Curie temperatures remain nearly unchanged. The martensite transition approaches room temperature for  $x = 0.13$ . Samples were prepared by rf induction heating. The influence of quenching and post annealing on magnetic properties, as well as structural grain sizes and magnetic domain structure, were investigated. Since the first order structural phase transition can be adjusted to any convenient temperature, these materials offer intriguing possibilities as magnetic refrigerants. Magnetocaloric properties were investigated by direct measurement of  $\Delta T$  with the application of field  $\Delta H$ .

**G1.00131 First-principles study of low-frequency phonon modes in heterostructures of transition metal dichalcogenides**<sup>1</sup>, NATHAN PRINS, DANNA DORATOTAJ, JIA-AN YAN, Towson University — Transition metal dichalcogenides (TMDs) are layered compounds with weak interlayer interactions and have attracted tremendous attention because of their remarkable electronic, optical and transport properties. Heterostructures made of TMDs offer an additional degree of freedom to tune their electronic properties. In this work, we present a first-principles study of the low-frequency modes in  $\text{WS}_2/\text{MoS}_2$  and  $\text{WSe}_2/\text{MoSe}_2$  heterostructures for various stacking geometry and stacking sequence. Our calculations show that the low-frequency layer shearing modes and layer breathing modes provide a useful way to characterize the stacking geometry of these heterostructures. Finally, the simulated Raman spectra for these heterostructures are discussed.

**G1.00132 ABSTRACT WITHDRAWN —**

**G1.00133 Understanding Binding Peptide Design Using a Synthesis of Residue Physicality and Energetic Frustration**, LENAYA FLOWERS, Department of Physics, University of Houston, SWARNENDU TRIPATHI, MARGARET CHEUNG, Department of Physics, University of Houston and Center for Theoretical Biological Physics, Rice University — The ubiquitous nature of Calmodulin (CaM) allows it to bind to numerous peptides, thus altering the function of a protein complex. Variations in CaMs function are a product of the numerous binding targets (BT) and their significant biological pathways. Given that CaM is a well-studied protein, we have found that certain amino acids in CaMs sequence play an important role in the event of protein binding. 36 CaM binding targets were analyzed to find sequential, physical commonalities. Using the *Frustrometer* (frustrometer.tk), we obtained z-scores (a numerical value for level of frustration) for each amino acids in a given binding target sequence. From those results, we were able to identify which residues show a highly favorable energetic change after binding and those that do not. We have found charged residues show the most prominent change when bound to CaM, these amino acids may provide a critical role in the overall design and function of a CaM-BT complex.

**G1.00134 Weyl semimetal state in TaP: experimental discovery<sup>1</sup>** , PAVEL SHIBAYEV, SU-YANG XU, ILYA BELOPOLSKI, DANIEL S. SANCHEZ, Princeton University, SHUANG JIA, Peking University, HSIN LIN, National University of Singapore, M. ZAHID HASAN, Princeton University, HASAN RESEARCH GROUP TEAM<sup>2</sup> — Despite their extreme rareness in nature, Weyl semimetals provide the first realization of Weyl fermions. After families of tantalum-based (TaAs, TaP) and niobium-based (NbAs, NbP) compounds were recently predicted as Weyl semimetal candidates, our group experimentally realized the Weyl semimetal state in TaP. Angle-resolved photoemission spectroscopy (ARPES) was used to probe the surface features of TaP. Weyl fermion cones and nodes were directly observed in the bulk, and Fermi arcs were observed on the surface. The surface states were found to possess a rich structure, containing topological Fermi arcs and topologically trivial closed contours in the neighborhood of Weyl points. This finding opens up possibilities to study the relationship between trivial and topological surface states on the surface of a Weyl semimetal. By determining the number of chiral edge modes on a closed path enclosing the Weyl node, bulk-boundary correspondence was demonstrated, leading to the establishment of a topologically nontrivial nature of the Weyl semimetal state in TaP.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.

<sup>2</sup>Research group led by Professor M. Zahid Hasan (Princeton University)

**G1.00135 The effects of impurities and incidence angle on the secondary electron emission of Ni(110)<sup>1</sup>** , HADAR LAZAR, University of Chicago, MARLENE PATINO, University of California, Los Angeles, YEVGENY RAITSES, Princeton Plasma Physics Laboratory, BRUCE KOEL, Department of Chemical and Biological Engineering, Princeton University, CHARLES GENTILE, ELIOT FEIBUSH, Princeton Plasma Physics Laboratory — The investigation of secondary electron emission (SEE) of conducting materials used for magnetic fusion devices and plasma thrusters is important for determining device lifetime and performance. Methods to quantify the secondary electron emission from conducting materials and to characterize the effects that impurities and incidence angles have on secondary electron emission were developed using 4-grid low energy electron diffraction (LEED) optics. The total secondary electron yield from a Ni(110) surface was continuously measured from the sample current as surface contamination increased from reactions with background gases in the ultrahigh vacuum chamber. Auger electron spectroscopy (AES) and temperature programmed desorption (TPD) were used to examine the composition and impurity levels on the Ni(110) surface. The total secondary electron yield was also measured at different incidence angles.

<sup>1</sup>Thank you to the Princeton Plasma Physics Laboratory (PPPL) and the Department of Energy (DOE) for the opportunity to work on this project through the Science Undergraduate Laboratory Internships (SULI).

**G1.00136 Frequency and voltage dependence of series resistance in a solar cell** , ALEXANDER OGLE, THADDEUS COX, JENNIFER HEATH, Linfield College — While admittance measurements of solar cells are typically conducted in reverse or at zero bias, and analyzed using the depletion approximation, the operating point of the solar cell is in forward bias, and the series resistance is often estimated using IV curves with a high forward current. In this mode, the device is no longer in the depletion regime, and the large number of injected minority carriers alter the transport properties significantly. In our Cu(In,Ga)Se<sub>2</sub> devices, we measure negative values of capacitance at high forward bias, which may be linked to injected minority carriers and carrier transport limitations, although our calculations of capacitance may also be influenced by series resistance. In this study, we compare ac and dc measurements of voltage dependent series resistance to try to better understand the negative capacitance signal.

**G1.00137 Improving Qubit Quality Factors Through Exotic Materials** , VICTORIA NORMAN, University of Chicago — In the time since the first qubits were successfully fabricated, the coherence times of superconducting Josephson junction qubits have improved by several orders of magnitude. Yet as the quantum information and computation field moves forward, these coherence times still need further improvement. We are now finding that in some superconducting systems, non-thermal equilibrium quasiparticles are becoming the limiting factor in qubit lifetimes. For SIS superconducting qubits, the T<sub>1</sub> and T<sub>2</sub><sup>\*</sup> values may be improved by the use of materials with higher superconducting band gap, E<sub>G</sub>, for which low values may allow for quasiparticles to break up Cooper pairs more easily, leading to a shorter lifetime. At this time, Al-Al<sub>2</sub>O<sub>3</sub>-Al transmons are very well characterized and understood and will therefore serve as an appropriate baseline with which to compare the more exotic junction materials. Using tantalum and niobium, which have E<sub>G</sub> values of 3 times and 10 times that of aluminum respectively, we expect the T<sub>1</sub> and T<sub>2</sub><sup>\*</sup> values to increase significantly for the Al-Al<sub>2</sub>O<sub>3</sub>-Nb, Al-Al<sub>2</sub>O<sub>3</sub>-Ta, and Ta-Ta<sub>2</sub>O<sub>5</sub>-Nb qubits.

**G1.00138 Development of a cost effective microscope heater stage<sup>1</sup>** , JOSHUA DUGRE, CHANDRA PRAYAGA, AARON WADE, University of West Florida — Utilizing 3D printing technology, a heater stage has been developed and implemented for microscopic systems. Due to the flexibility of 3D printing, the heater stage can be easily modified to fit any sample size with only slight modifications to the heating element being required. The sample in contact with the heating element can also easily be secured in a thermal insulator, such as aluminum foil. The thermal gradient of the heater stage has been recorded to be less than 1°C and has been compared to more expensive designs, and the cost effectiveness of the system has been determined. The system has been tested with a sample of the liquid crystal 8CB in order to determine the exact temperatures of the phase transitions of the crystal to verify that the system is applicable to a wide range of experimental physics.

<sup>1</sup>UWF Quality Enhancement Plan Award

**G1.00139 Van der Waal Interactions in Ultrafine Nanocellulose Aerogels<sup>1</sup>** , BYRON FRITCH, DEREK BRADLEY, TIM KIDD, University of Northern Iowa — Nanocellulose aerogels have shown an ability to be used in many different applications ranging from oil sponges to conductive materials to possibly a low calorie food substitute. Not much is known about the structural and physical property changes that occur when the composition of the aerogel changes. We studied what properties change when the aerogel amounts change, as well as how sticky the aerogels are and how strong they are. The higher concentrations appeared to have more plate-like structures while the lower concentrations had a more fibrous material. These fibers in the low concentrations had a smaller diameter than a human hair. Only the low concentration aerogels were able to stick to a glass surface in the adhesion test, but were able to support a mass much larger than their own. These low concentrations also would stick to your finger when lightly touched. Preliminary tests show that a concentration that is not too low, but not too high, is best for tensile strength. All concentrations were able to hold many times their own mass. Cellulose should be studied more because it is a renewable material and is easily accessed. Nanocellulose is also not environmentally dangerous allowing it to be used in applications involving humans and the environment like noted above.

**G1.00140 ABSTRACT WITHDRAWN —**

**G1.00141 Study of Langmuir and Langmuir-Blodgett Thin films<sup>1</sup>** , ROSS GOODWIN, CHANDRA PRAYAGA, AARON WADE, University of West Florida — Arachidic Acid, Cholesterol, and Stearic Acid thin films were created and studied utilizing the Langmuir method in order to obtain a single molecule or monomolecular layer out of a desired substance at an air-water interface. The phase transitions are observed by measuring the surface pressure vs. area isotherms. Langmuir-Blodgett (LB) films were created on a prepared substrate. The LB film structures were then studied using X-ray Diffraction, and Raman Spectroscopy.

<sup>1</sup>UWF Office of Undergraduate Research Project Award, UWF ITEP-Technology Fee Project Award, UWF Quality Enhancement Plan Award

**G1.00142 Spatially varying geometric phase in classically entangled vector beams of light<sup>1</sup>** , ANDREW KING-SMITH, CODY LEARY, The College of Wooster — We present theoretical results describing a spatially varying geometric (Pancharatnam) phase present in vector modes of light, in which the polarization and transverse spatial mode degrees of freedom exhibit classical entanglement. We propose an experimental setup capable of characterizing this effect, in which a vector mode propagates through a Mach-Zehnder interferometer with a birefringent phase retarder present in one arm. Since the polarization state of a classically entangled light beam exhibits spatial variation across the transverse mode profile, the phase retarder gives rise to a spatially varying geometric phase in the beam propagating through it. When recombined with the reference beam from the other interferometer arm, the presence of the geometric phase is exhibited in the resulting interference pattern.

<sup>1</sup>We acknowledge funding from the Research Corporation for Science Advancement by means of a Cottrell College Science Award.

**G1.00143 Deterministic and Stochastic Modeling of an Artificial Bistable Switch in E. coli** , DANIEL FINKELSTEIN, East Chapel Hill High School and Duke University, NICOLAS BUCHLER, SARGIS KARAPETYAN, Duke University — Networks of mutually interacting genes are common in natural regulatory networks. To better understand these interactions, scientists have recently been constructing artificial genetic networks. Much of the effort is focused on creating genetic oscillators and bistable switches. In this project, we analyzed the possibility to create a bistable switch in E. coli. In this realization of the switch, the Repressor (basic leucine zipper CEBP/alpha) represses the transcription of the Inhibitor (artificial dominant negative 3HF). The Inhibitor, in turn, sequesters the Repressor by binding to it. Using deterministic modeling we identified a range of parameters suitable for bistability. We then analyzed the resulting solutions with the full model taking the reaction rates corresponding to E. coli and the including stochastic nature of gene expression. We have shown that the bistability is not destroyed by stochastic fluctuations if several copies of genes are present. Specifically, taking a realistic number of plasmids (10) we show that the number of proteins in the systems undergoes sizable fluctuations; however, the two states with low and high concentrations of inhibitor stay distinct in the relevant range of parameters.

**G1.00144 Alpha Background Rejection in Bolometer Detectors** , NICHOLAS DEPORZIO, Northeastern Univ, CUORE COLLABORATION — This study presents the modification of bolometer detectors used in particle searches to veto or otherwise reject alpha radiation background and the statistical advantages of doing so. Several techniques are presented in detail – plastic film scintillator vetoes, metallic film ionization vetoes, and Cherenkov radiation vetoes. Plastic scintillator films are cooled to bolometer temperatures and bombarded with 1.4MeV to 6.0MeV alpha particles representative of documented detector background. Quantum dot based liquid scintillator is similarly bombarded to produce a background induced scintillation light. Photomultipliers detect this scintillation light and produce a veto signal. Layered metallic films of a primary metal, dielectric, and secondary metal, such as gold-polyethylene-gold films, are cooled to milli-kelvin temperatures and biased to produce a current signal veto when incident 1.4MeV to 6.0MeV alpha particles ionize conduction paths through the film. Calibration of veto signal to background energy is presented. These findings are extrapolated to quantify the statistical impact of such modifications to bolometer searches. Effects of these techniques on experiment duration and signal-background ratio are discussed.

**G1.00145 Green Chemistry Techniques for Gold Nanoparticles Synthesis** , SARAH A. CANNAVINO, CHRISTY A. KING, DAVON W. FERRARA, Belmont University — Gold nanoparticles (AuNPs) are often utilized in many technological and research applications ranging from the detection of tumors, molecular and biological sensors, and as nanoantennas to probe physical processes. As these applications move from the research laboratory to industrial settings, there is a need to develop efficient and sustainable synthesis techniques. Recent research has shown that several food products and beverages containing polyphenols, a common antioxidant, can be used as reducing agents in the synthesis of AuNPs in solution. In this study, we explore a variety of products to determine which allow for the most reproducible solution of nanoparticles based on the size and shapes of particles present. We analyzed the AuNPs solutions using extinction spectroscopy and atomic force microscopy. We also develop a laboratory activity to introduce introductory chemistry and physics students to AuNP synthesis techniques and analysis.

**G1.00146 Solvent vapor induced morphology variation in thin films of PS-b-PLA copolymers** , LAUREN FOOTE, MAXIMILIAN HERES, THOMAS KINSEY, JOSHUA SANGORO, Univ of Tennessee, Knoxville — Molecular dynamics in thin films of PS-b-PLA copolymers annealed by solvent vapor annealing is investigated using broadband dielectric spectroscopy, atomic force microscopy and ellipsometry. Impact of morphology changes on molecular dynamics are analyzed. The results of this study are discussed within the framework of current understanding of morphology control of copolymer thin films.

**G1.00147 Optical Properties of Silver Nanoparticulate Glasses** , RACHEL N. EVANS, SARAH A. CANNAVINO, CHRISTY A. KING, JOSEPH A. LAMARTINA, ROBERT H. MAGRUDER, DAVON W. FERRARA, Belmont University — The ion exchange method of embedding metal nanoparticles (NPs) into float glass is an often used technique of fabricating colored glasses and graded-index waveguides. The depth and size of NP formation in the glass depends on the concentration and temperature of metal ions in the molten bath. In this study we explore the dichroic properties of silver metal ion exchange restricted to only one side of a glass microscope slide using reflection and transmission spectroscopy and its dependence on temperature, concentration of silver ions, and length of time in the molten bath.

**G1.00148 Simulation of Thin Film Equations on an Eye-Shaped Domain with Moving Boundary<sup>1</sup>** , JOSEPH BROSCHE, TOBIN DRISCOLL, RICHARD BRAUN, University of Delaware — During a normal eye blink, the upper lid moves, and during the upstroke the lid paints a thin tear film over the exposed corneal and conjunctival surfaces. This thin tear film may be modeled by a nonlinear fourth-order PDE derived from lubrication theory. A major stumbling block in the numerical simulation of this model is to include both the geometry of the eye and the movement of the eyelid. Using a pair of orthogonal and conformal maps, we transform a computational box into a rough representation of a human eye where we proceed to simulate the thin tear film equations. Although we give up some realism, we gain spectrally accurate numerical methods on the computational box. We have applied this method to the heat equation on the blinking domain with both Dirichlet and no-flux boundary conditions, in each case demonstrating at least 10 digits of accuracy. We are able to perform these simulations very quickly (generally in under a minute) using a desktop version of MATLAB.

### **G1.00149 Constructing Dual Beam Optical Tweezers for Undergraduate Biophysics Research**

, BRIAN DAUDELIN, DEVON WEST-COATES, JON DEL'ETOILE, ERIC GROTZKE, THAYAPARAN PARAMANATHAN, Bridgewater State University, MA — Optical tweezing, or trapping, is a modern physics technique which allows us to use the radiation pressure from laser beams to trap micron sized particles. Optical tweezers are commonly used in graduate level biophysics research but seldom used at the undergraduate level. Our goal is to construct a dual beam optical tweezers for future undergraduate biophysical research. Dual beam optical tweezers use two counter propagating laser beams to provide a stronger trap. In this study we discuss how the assembly of the dual beam optical tweezers is done through three main phases. The first phase was to construct a custom compressed air system to isolate the optical table from the vibrations from its surroundings so that we can measure pico-newton scale forces that are observed in biological systems. In addition, the biomaterial flow system was designed with a flow cell to trap biomolecules by combining several undergraduate semester projects. During the second phase we set up the optics to image and display the inside of the flow cell. Currently we are in the process of aligning the laser to create an effective trap and developing the software to control the data collection. This optical tweezers set up will enable us to study potential cancer drug interactions with DNA at the single molecule level and will be a powerful tool in promoting interdisciplinary research at the undergraduate level.

### **G1.00150 Landau Damping in a Mixture of Bose and Fermi Superfluids**

, HUITAO SHEN, WEI ZHENG, Tsinghua Univ — We study Landau damping in Bose-Fermi superfluid mixture at finite temperature. We find that at low temperature, the Landau damping rate will be exponentially suppressed at both the BCS side and the BEC side of Fermi superfluid. The momentum dependence of the damping rate is obtained, and it is quite different from the BCS side to the BEC side. The relation between our result and the collective mode experiment in recently realized Bose-Fermi superfluid mixture is also discussed.

### **G1.00151 PHYSICS EDUCATION —**

### **G1.00152 The Physics of Quidditch Summer Camp: An Interdisciplinary Approach**

, DONNA HAMMER, TIM UHER, University of Maryland — The University of Maryland Physics Department has developed an innovative summer camp program that takes an interdisciplinary approach to engaging and teaching physics. The Physics of Quidditch Camp uniquely sits at the intersection of physics, sports, and literature, utilizing the real-life sport of quidditch adapted from the Harry Potter novels to stimulate critical thinking about real laws of physics and leaps of imagination, while actively engaging students in learning the sport and discussing the literature. Throughout the camp, middle school participants become immersed in fun physics experiments and exciting physical activities, which aim to build and enhance skills in problem-solving, analytical thinking, and teamwork. This camp has pioneered new ways of teaching physics to pre-college students, successfully engaged middle school students in learning physics, and grown a large demand for such activities.

### **G1.00153 Peer Grading in Astronomy Massive Open Online Course<sup>1</sup>**

, MARTIN FORMANEK, MATTHEW WENGER, CHRISTOPHER IMPEY, SANLYN BUXNER, University of Arizona — In this work we thoroughly investigate the peer grading process as it happened in the University of Arizona session based MOOC Astronomy: Exploring Time and Space offered during Spring 2015 through Coursera. Overall, 25400 learners from over 100 countries registered for this course. Of those, 14900 accessed at least one part of the course and 1332 users engaged in the peer grading. First of all we provide description of the peer graded assignments and we identify trends in behavior of people who participated in these exercises. E.g. time they spent on grading, number of assignments graded and patterns arising from comparing all three assignments. Furthermore, for the second assignment, we graded random sample of 300 essays by a group of trained undergraduate students and a group consisting of one of the course instructors together with graduate TAs and we compared results with grades from the peer grading. Specifically we look on Intraclass Correlation Coefficients for all three groups of graders to determine reliability of each group and correlations between final grades. Finally we assess factors influencing reliability of the peer graders participating in the MOOC based on the difference from our grades.

### **G1.00154 Roadrunner physics: using cartoons to challenge student preconceptions**

, RACHAEL HUXFORD, MATHEW RIDGE, JAMES OVERDUIN, JIM SELWAY, Towson University — The cartoon universe is governed by laws that differ radically from those in the real world, but also mirror some of our preconceptions of how the world "should" work. We all know that Wile E. Coyote will never be able to catch the Roadrunner with a fan attached to a sailboard, or an outboard motor submerged in a pail of water—but *why*, exactly? Can we attach some numbers to this knowledge? We have designed some classroom demonstrations accompanied by personal-response-type questions that use classic cartoon clips to challenge student thinking in introductory courses, prompting them to rediscover the truths of physics for themselves. We extend this idea to intermediate-level modern physics, showing that some phenomena in the cartoon universe can be reconciled with standard physics if the values of fundamental constants such as  $c$ ,  $G$  and  $h$  differ radically from those in the real world. Such an approach can both heighten student interest and deepen understanding in various physics topics.

### **G1.00155 The Hunt for Red October II: a demonstration for introductory electromagnetism**

, DANIEL ZILE, THOMAS SEBASTIAN, VIKTOR POLYAK, Towson University, ANJALEE RUTAH, Bryn Mawr School, JAMES OVERDUIN, Towson University — We have designed, constructed and tested a small-scale version of the silent submarine depicted in the 1990 Sean Connery thriller *The Hunt for Red October*. This vessel contains no moving parts. It uses onboard batteries and magnets to propel seawater salt ions out of the back of the boat, producing an equal and opposite forward thrust on the submarine thanks to Newton's third law. Such a craft could be very hard to detect by conventional means. Our objectives were to create a striking teaching demonstration for introductory electromagnetism courses and to determine why (to our knowledge) no navy has yet exploited such a seemingly revolutionary propulsion system for purposes of national defense. As teaching demonstrations, our prototypes are very successful at capturing student interest and convincing them of the reality and practical importance of electromagnetic fields. We have also identified a number of factors that may help to explain why a scaled-up model might not quite function as depicted in the film. We discuss several promising avenues for future student research.

### **G1.00156 Enhancing Student Success in Biology, Chemistry, and Physics by Transforming the Faculty Culture<sup>1</sup>**

, HOWARD JACKSON, LEIGH SMITH, KATHLEEN KOENIG, JILL BEYETTE, BRIAN KINKLE, ANNE VONDERHEIDE, University of Cincinnati — We present preliminary results of an effort to enhance undergraduate student success in the STEM disciplines. We explore a multistep approach that reflects recent literature and report initial results by each of the Departments of Biology, Chemistry, and Physics of implementing several change strategies. The central elements of our approach involve identified departmental Teaching and Learning Liaisons, a unique faculty development component by our teaching center, a vertical integration of leadership across department heads, the Dean, and the Provost, and the explicit acknowledgement that change happens locally. Teaching and Learning lunches across the departments have attracted an attendance of ~65% of the faculty. The use of Learning Assistants in classrooms has also increased sharply. Modest changes in the student success rates have been observed. These efforts and others at the decanal and provostal levels promise changes in student success.

**G1.00157 Students' Attitudes and Enrollment Trends in Physics and Engineering** , DELPHINE BANJONG, University of North Dakota — Science, Technology, Engineering, and Mathematics (STEM) fields are critical for meeting ever-increasing demands in the U.S. for STEM and related skills, and for ensuring the global competitiveness of the United States in technological advancement and scientific innovation. Nonetheless, few U.S. students consider a STEM degree after high school and fewer STEM students end up graduating with a STEM degree. In 2012, the United States ranked 35<sup>th</sup> in math and 27<sup>th</sup> in science out of 64 participating countries in the Program for International Student Assessment (PISA), sponsored by the Organization for Economic Cooperation and Development (OECD). Considering the significant role physics and engineering play in technological advancement, this work investigates the attitudes of students and recent enrollment trends in these important subject areas.

## **G1.00158 OUTREACH AND ENGAGING THE PUBLIC —**

**G1.00159 The World's Biggest Movie Theater: Promoting the Stars** , ARTHUR PALLONE, JACQUE DAY-PALLONE, Norwich University — A great celestial story is only as effective as the teller of the tale. With passion and knowledge at the helm, we must search for ways to pass on that enthusiasm to others while conveying sound science. At the core, our common link is an age-old awe of the sky. From the scientist to the elementary school student, we ask remarkably similar questions. What's out there? When will some object slam into the Earth? Are we alone? In our view as advocates for astronomy at the community level, the public will emerge to discover answers to their questions, if given the forum. It's our responsibility as astronomy advocates to help one another provide those forums. While some regions, perhaps through a school or by a turn of good fortune, offer public observatories with sophisticated telescopes, we also know that an observing event can take place in an open field or a parking lot, and be fully palpable as seen through a pair of binoculars, or by the naked eye. Based on our experience, we present an integrated approach—one that borrows elements from education, entertainment, advertising, and public relations—to help choose an event, hook and keep the public's attention while making them want more, and provide some tips for increasing media presence.

## **G1.00160 INTERNATIONAL ISSUES —**

**G1.00161 The African Synchrotron Light Source (AfLS)** , SEKAZI MTINGWA, Retired, AHMADOU WAGUE, Universite Cheikh Anta Diop, SIMON CONNELL, University of Johannesburg, SA, BRIAN MASARA, South African Institute of Physics (Zimbabwean), TSHEPO NTSOANE, Neasa, SA, LAWRENCE NORRIS, NSBP, USA, HERMAN WINICK, SLAC National Accelerator Laboratory, KENNETH EVANS-LUTTERODT, Brookhaven National Laboratory, TABBETHA DOBBINS, Rowan University, USA, TAREK HUSSEIN, Cairo University, Egypt, FEENE MARESHA, Ethiopian Academy of Sciences, Ethiopia, KRYSTLE MCLAUGHLIN, Lehigh University, PHILIP OLADIJO, Int. U. of Sci. & Tech. Botswana (Nigeria), ESNA DU PLESSIS, SASOL, SA, ROMAIN MURENZI, Executive Director of TWAS, Rwanda, KENNEDY REED, LLNL, USA, FRANCESCO SELTE, ESRF, Europe, SVERKER WERIN, MAX IV, Sweden, JONATHAN DORFAN, OIST, JAPAN, MOHAMMAD YOUSEF, Cairo University, Egypt — Africa is the only habitable continent without a synchrotron light source. An interim Steering Committee held a major conference on November 16-20, 2015 at the European Synchrotron Radiation Facility (ESRF) in Grenoble, France to bring together African scientists, policy makers, and stakeholders to discuss the possibility of a synchrotron light source in Africa. The use of light sources as a premier tool for research was highlighted for a broad range of disciplines. A Roadmap towards a synchrotron in Africa was discussed. Firm outcomes of the Conference were a set of Resolutions and a Roadmap document, with the election of a Steering Committee. ([www.africanlightsource.org](http://www.africanlightsource.org)).

## **G1.00162 HISTORY OF PHYSICS —**

**G1.00163 The Discovery of Electrography.** , LARISSA SAMUILOVA, Department of Mathematics, SUNYSuffolk, VLADIMIR SAMUILOV, Department of Materials Science and Engineering, SUNYSB — Prof. Jakob Narkiewicz-Jodko (1947–1905) major discoveries are: Electrography – the method of the visualization of corona discharge (corona discharge photography) from the bodies due to the application of high strength and high frequency electric fields [1-4], and the first observation of the propagation of the electromagnetic waves for information transfer over the distances [5,6]. They were made in his laboratory, located at his manor home Nadniemen in Eastern Europe. We describe these experiments and equipment used in the Lab for these discoveries. We also introduce a mathematical algorithm for the analysis of the electrography images. [1] Decrespe M. ## **G1.00164 SUPERLATTICES, NANOSTRUCTURES, AND OTHER ARTIFICIALLY STRUCTURED MATERIALS —**

**G1.00165 Thermite Reaction to Produce Artificial Reefs** , ALEXANDRO TREVINO, KAREN MARTIROSYAN, RICHARD KLINE, University of Texas, Rio Grand Valley — The degradation of coral reefs is an ecological issue that has prompted new collaboration by different scientific communities that would assist in the regeneration of the reefs. Unfortunately, these processes can be inefficient and extremely expensive prompting a new scientific approach by using solid-state combustion synthesis to regenerate the reefs. In this report we aimed to consolidate a multi-composite material to produce artificial reefs by initiating thermite reaction based on aluminum and polytetrafluoroethylene (PTFE) with natural reefs. By Thermodynamic analysis and experimentation it was established that a range between .03-.07 number of moles of PTFE was sufficient to reach an adiabatic temperature of over 1900 K, a sustained reaction and a physically stable product was achieved. Reefs are primarily composed of carbonates but their exact chemical composition can vary. X-ray diffraction analysis was used to determine the chemical composition of the reef and revealed presence of oxides, carbonates, silicates. The dominant chemical compounds that were identified are, SiO<sub>2</sub> -17%, MgSiO<sub>3</sub>-14.5%, CaCO<sub>3</sub>- 11.4%, Ca(Si<sub>3</sub>O<sub>4</sub>). Using our thermite reaction we aimed to achieve optimal physical, chemical, and biological properties and maintain cost efficiency of the multi-composite material.

**G1.00166 Synthesis and Characterization of ZnS:Eu<sup>3+</sup> - CMC nanophosphors emitting white light over broad excitation range** , DILIP DE, Covenantuniversity, Ota, Ogun State, Nigeria, IKORYA AHMEN, Department of Physics, University of Agriculture, Makurdi, Benue State, Nigeria, VIENA BRUNO, Laboratoire de Chimie de la Matiere Condensee de Paris — In this paper we report for the first time the synthesis and characterization of nanophosphors of ZnS:Eu<sup>3+</sup> - embedded in sodium carboxymethyl cellulose matrix (CMC) that emits high quality white light over broad range of excitation. The nano-phosphors of cubic (zinc blende) structure were synthesized using precipitation technique with doping concentrations of Eu<sup>3+</sup> ions 1 mol% and 5 mol%. The crystal sizes were 2.56 nm and 2.91 nm respectively. Annealing at 300 °C in a sulfur-rich atmosphere altered the crystal size to 4.35 nm and 3.65 nm respectively and the band gap from 4.2 eV to 3.76 eV and 3.81 eV respectively. The as-synthesized samples gave pure orange-red emission when excited at wavelengths of 394 nm and 465 nm. After thermal annealing of the samples, a broad emission band in the blue-green region assigned to defect related states emerged or were enhanced. Also enhanced were the emission lines of Eu<sup>3+</sup> ions in the orange-red region. A combination of these two transitions gave white light of different shades (recorded on the CIE 1931 chromaticity diagram) from cool white through Day-light to warm white light, depending on Eu<sup>3+</sup> concentration and the excitation wavelengths (UV-330 to blue 465 nm), thus showing great potential applications of these nano-phosphors.

**G1.00167 Thermally Engineered Blue Photoluminescence of Porous Anodic Alumina Membranes for Promising Optical Biosensors** , SANG DON BU, SAM YEON CHO, Chonbuk National University, YONG CHAN CHOI, Chonbuk National University, Daegu Gyeongbuk Institute of Science & Technology, JIN WOO KIM, JIN KYU HAN, JIN HO KWAK, SUN A YANG, Chonbuk National University — Optical biosensors based on porous anodic alumina membranes (PAAMs) have shown to be an effective device because of their unique optical properties and biocompatibility. Among various optical properties, photoluminescence (PL) emission derived from PAAMs is one of the most suitable characteristics. However, the origin of PL from PAA is unclear and still in doubt. Therefore, it is essential for further potential practical applications to understand the origin of PL and PL variations. Here, we investigate the effects of post-annealing temperatures on the blue PL of amorphous PAAMs fabricated in oxalic acid. We find that the blue PL emission is strongly dependent on the thermal properties. A strong blue PL at a peak of ~460 nm is observed from the initial PAAM (not annealed PAAM) and this PL band can be divided into two Gaussian components at 458 ± 4 nm (P1 band) and 517 ± 7 nm (P2 band). As the temperature increases to 600 °C, the intensities of two PL bands gradually increase. During temperature increases from 600 to 700 °C, the P2 band increases but the P1 band decreases. The analyses of electron paramagnetic resonance, Fourier transform infrared spectroscopy, and ultraviolet-visible absorption spectroscopy show that the P1 and P2 bands originate from the unstable carboxylates and the stable carboxylates, respectively.

**G1.00168 Imaging TiO<sub>2</sub> nanoparticles on GaN nanowires with electrostatic force microscopy<sup>1</sup>** , TING XIE, ECE, University of Maryland, College Park, BAOMEI WEN, N5 sensors, Inc, GUANNAN LIU, ECE, University of Maryland, College Park, SHIQI GUO, ECE, The George Washington University, ABHISHEK MOTAYED, N5 sensors, Inc, THOMAS MURPHY, IREAP, University of Maryland, College Park, R.D. GOMEZ, ECE, University of Maryland, College Park — Gallium nitride (GaN) nanowires that are functionalized with metal-oxides nanoparticles have been explored extensively for gas sensing applications in the past few years. These sensors have several advantages over conventional schemes, including miniature size, low-power consumption and fast response and recovery times. The morphology of the oxide functionalization layer is critical to achieve faster response and recovery times, with the optimal size distribution of nanoparticles being in the range of 10 to 30 nm. However, it is challenging to characterize these nanoparticles on GaN nanowires using common techniques such as scanning electron microscopy, transmission electron microscopy, and x-ray diffraction. Here, we demonstrate electrostatic force microscopy in combination with atomic force microscopy as a non-destructive technique for morphological characterization of the dispersed TiO<sub>2</sub> nanoparticles on GaN nanowires. We also discuss the applicability of this method to other material systems with a proposed tip-surface capacitor model.

<sup>1</sup>This project was sponsored through N5 Sensors and the Maryland Industrial Partnerships (MIPS, 5418).

**G1.00169 Management of the von Roos operator.<sup>1</sup>** , MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comision Nacional del Agua, LAMBERTO CASTRO-ARCE, Departamento de Fisica, Matematicas e Ingenieria, Unidad Regional Sur, Universidad de Sonora, CARLOS FIGUEROA-NAVARRO, Departamento de Ingenieria Industrial, Unidad Regional Centro, Universidad de Sonora, JULIO CAMPOS-GARCIA, Departamento de Ciencias de la Salud, Unidad Cajeme, Universidad de Sonora — When an electron is inside a semiconductor medium its effective mass rises from the shielding of the crystalline structure. When we have a semiconductor with a constant concentration the effective mass has a fixed value, and in this case, it can be easy to solve the Schrodinger equation of the particle, but if the concentration varies spatially, the effective mass will no longer constant and the solution can be difficult to find. The general form of the kinetic energy operator for a particle with variable mass is proposed for von Roos, this operator is characterized by some parameters whose values are subjected to a restriction. From a numerical solution of the Schrodinger equation we analyze the energies of an electron with position-dependent effective mass working with some values of the parameter of the von Roos operator.

<sup>1</sup>We acknowledge the support of SNI CONACYT

**G1.00170 Oscillation modes and transmission into a Fibonacci slab.<sup>1</sup>** , LAMBERTO CASTRO-ARCE, Departamento de Fisica, Matematicas e Ingenieria, Unidad Regional Sur, Universidad de Sonora, MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comisin Nacional del Agua, JULIO CAMPOS-GARCIA, Departamento de Ciencias de la Salud, Unidad Cajeme, Universidad de Sonora, CARLOS FIGUEROA-NAVARRO, Departamento de Ingenieria Industrial, Unidad Regional Centro, Universidad de Sonora, LEONARDO ISASI-SIQUEIROS, Departamento de Fisica, Matematicas e Ingenieria, Unidad Regional Sur, Universidad de Sonora, BETSABE MANZANARES-MARTINEZ, Departamento de Fisica, Unidad Regional Centro, Universidad de Sonora — In our contribution we developed a study on the behavior of the transmission modes and a Pt / Zn slab of a Fibonacci array of longitudinal and transverse acoustic waves. We have worked with arrangements from n = 1 to 10 and has managed to find the energy bands and transmission, filling factor 0.4 observing the appearance of Pseudo-Gaps in the evolution of the study when the arrangement Fibonacci increases.

<sup>1</sup>We acknowledge the support of SNI CONACYT

**G1.00171 Shedding Light on the Formation of Gold Nanorods<sup>1</sup>** , ORLANDO LOPEZ, Brookhaven National Laboratory, DAMIEN HUDRY, Brown University, DMYTRO NYKYRANCHUK, Brookhaven National Laboratory — A significant interest in the study and synthesis of one-dimensional materials such as nanorods or nanowires is sparked by their potential application in electronics, photonics and biodetection. However, the synthesis of these low dimensional materials is not always reliable due to kinetic effects in symmetry breaking and high sensitivity to impurities. In this work we discuss the synthesis of gold nanorods and new ways to achieve symmetry breaking during the growth from seed solution, hence maximizing the yield of nanorods. We discuss the mechanism involved in symmetry breaking and general strategies to improve the nanorod morphology and synthetic yield. This work can serve as a starting point to design reproducible synthetic strategies for preparing high quality gold nanorods.

<sup>1</sup>This project was supported by the U.S. Department of Energy, Office of Science, under the Science Undergraduate Laboratory Internships Program and used resources of the C.F.N., which is a U.S. DOE Facility, at B.N.L., Contract No. DE-SC0012704

**G1.00172 Exciton Emission from Bare and Alq<sub>3</sub>/Gold Coated GaN Nanorods**, FATEMESADAT MOHAMMADI, University of Cincinnati, GERD KUHNERT, DETLEF HOMMEL, University of Bremen, Germany, HEIDRUN SCHMITZER, Xavier University, Cincinnati, HANS-PETER WAGNER, University of Cincinnati — We study the excitonic and impurity related emission in bare and aluminum quinoline (Alq<sub>3</sub>)/gold coated wurtzite GaN nanorods by temperature-dependent time-integrated (TI) and time-resolved (TR) photoluminescence (PL). The GaN nanorods were grown by molecular beam epitaxy. Alq<sub>3</sub> as well as Alq<sub>3</sub>/gold covered nanorods were synthesized by organic molecular beam deposition. In the near-band edge region a donor-bound-exciton (D<sup>0</sup>X) emission is observed at 3.473 eV. Another emission band at 3.275 eV reveals LO-phonon replica and is attributed to a donor-acceptor-pair (DAP) luminescence. TR PL traces at 20 K show a nearly biexponential decay for the D<sup>0</sup>X with lifetimes of approximately 180 and 800 ps for both bare and Alq<sub>3</sub> coated nanorods. In GaN nanorods which were coated with an Alq<sub>3</sub> film and subsequently with a 10 nm thick gold layer we observe a PL quenching of D<sup>0</sup>X and DAP band and the lifetimes of the D<sup>0</sup>X transition shorten. The quenching behaviour is partially attributed to the energy-transfer from free excitons and donor-bound-excitons to plasmon oscillations in the gold layer.

**G1.00173 Role of polymers and surfactants in synthesis of high quantum yield upconverting nanoparticles.**, KEVIN NEWCOMBE, BRIAN YUST, Univ of Texas Rio Grande Valley — Rare earth doped fluoride nanoparticles with a size of about 25 nm have been synthesized by either solvothermal or microwave assisted techniques. The role of differing biocompatible polymeric compounds to act as nucleation agents and surfactants, including polyethylene glycol, polyvinylpyrrolidone, and polyethylene oxide, in the final size, crystallinity, and optical properties is investigated in depth. These upconverting nanoparticles which can be excited in the near-infrared (NIR) are ideal for biomedical applications because of the low absorption of these excitation wavelengths by soft tissues in the body. Their fluorescence can be used for NIR imaging as well as non-invasive activation of drugs conjugated to the surface for cancer therapy. After optimizing the synthesis parameters, wide angle x-ray diffraction, FTIR, Raman, and Vis-NIR spectroscopy are used to characterize the samples. By varying the polymer added to the precursor solution, we can elucidate the primary mechanisms of interaction during the synthesis process and optimize for the best possible optical properties. Finally, the dependence of the fluorescence intensity on the biocompatible polymer type and concentration will also be investigated.

**G1.00174 Diagnostics of defects in AlGaIn/GaN high electron mobility transistor (HEMT) epi-layers via spectroscopic photo current-voltage (IV) measurements with variable-wavelength ultraviolet (UV) and visible light excitation.**, MIN P. KHANAL, BURCU OZDEN, VAHID MIRKHANI, KOSALA YAPABANDARA, MUHAMMAD SHEHZAD SULTAN, MINSEO PARK<sup>1</sup>, Dept. of Physics, Auburn University, LI SHEN, Dept. of Electrical and Computer Engineering, Auburn University — The reliability and performance of the nitride high electron mobility transistors (HEMTs) have been plagued by deleterious phenomena such as current collapse which is believed to be produced by electrically-active deep-level defects (or traps) that reside at the surface/interfaces and in the bulk of the AlGaIn/GaN HEMT layers. Therefore, identification of their physical/spectral locations and understanding the nature of defects is very important to improve the reliability of AlGaIn/GaN HEMTs. In this work, deep-level defects and traps located in the AlGaIn/GaN HEMT epi-layers were investigated by using spectroscopic photo IV measurements. An array of Schottky contacts was constructed on the HEMT layer produced by metal-organic chemical vapor deposition (MOCVD). The photo IV measurement was performed by collecting the photo current generated by the variable-wavelength UV/visible light illumination. It was successfully demonstrated that this technique can provide the information on the distribution of electrically-active defects along the in-depth direction and across the HEMT wafers. Therefore, it can be concluded that the spectroscopic measurements can be useful to assess the uniformity of defect distribution both along the in-depth direction and across the AlGaIn/GaN wafers.

<sup>1</sup>Corresponding author.

**G1.00175 Multifrequency scanning probe microscopy study of nanodiamond agglomerates<sup>1</sup>**, VASUDEVA ARAVIND, STEPHEN LIPPOLD, Clarion University, QIAN LI, EVGHENY STRELCOV, BARIS OKATAN, Oak Ridge National Laboratory, BENJAMIN LEGUM, Clarion University, SERGEI KALININ, Oak Ridge National Laboratory, CLARION UNIVERSITY TEAM, OAK RIDGE NATIONAL LABORATORY TEAM — Due to their rich surface chemistry and excellent mechanical properties and non-toxic nature, nanodiamond particles have found applications such as biomedicine, tribology and lubrication, targeted drug delivery systems, tissue scaffolds and surgical implants. Although single nanodiamond particles have diameters about 4-5nm, they tend to form agglomerates. While these agglomerates can be useful for some purposes, many applications of nanodiamonds require single particle, disaggregated nanodiamonds. This work is oriented towards studying forces and interactions that contribute to agglomeration in nanodiamonds. In this work, using multifrequency scanning probe microscopy techniques, we show that agglomerate sizes can vary between 50-100nm in raw nanodiamonds. Extremities of particles and Interfaces between agglomerates show dissipative forces with scanning probe microscope tip, indicating agglomerates could act as points of increased adhesion, thus reducing lubricating efficiency when nanodiamonds are used as lubricant additives.

**G1.00176 Comparison of photoluminescence properties of HSA-protected and BSA-protected Au<sub>25</sub> nanoclusters**, MASATO TSUKAMOTO, HIDEYA KAWASAKI, TADASHI SAITOH, MITSURU INADA, Kansai Univ., KANSAI UNIV. COLLABORATION, KANSAI UNIV. COLLABORATION — Gold nanoclusters (NCs) have attracted great interest for a wide range of applications. In particular, red light-emitting Au<sub>25</sub> NCs have been prepared with various biological ligands. It has been shown that Au<sub>25</sub> NCs have Au<sub>13</sub>-core/6Au<sub>2</sub>(SR)<sub>3</sub>-semiring structure. The red luminescence thought to be originated from both core (670 nm) and semiring (625 nm). It is important to reveal a structure of Au<sub>25</sub> NCs to facilitate the progress of applications. However, the precise structure of Au<sub>25</sub> NCs has not been clarified. There is a possibility of obtaining structural information about Au<sub>25</sub> NCs to compare optical properties of the NCs that protected by slightly different molecules. Bovine and human serum albumin (BSA, HSA) are suitable one for this purpose. It has been suggested that rich tyrosine and cysteine residues in these molecules are important to produce the thiolate-protected Au NCs. If Au<sub>25</sub> NCs have core/shell structure, only the luminescence of the semiring will be affected by the difference of the albumin molecules. We carefully compared PL characteristics of BSA- and HSA- protected Au<sub>25</sub> NCs. As a result, there was no difference in the PL at 670 nm (core), while differences were observed in the PL at 625 nm (semiring). The results support that Au<sub>25</sub> NCs have core/semiring structure.

**G1.00177 Simulations of terahertz pulse emission from thin-film semiconductor structures**, ANDREY SEMICHAEVSKY, Lincoln University (PA) — The photo-Dember effect is the formation of transient electric dipoles due to the interaction of semiconductors with ultrashort optical pulses. Typically the optically-induced dipole moments vary on the ns- or ps- scales, leading to the emission of electromagnetic pulses with terahertz (THz) bandwidths. One of the applications of the photo-Dember effect is a photoconductive dipole antenna (PDA). This work presents a computational model of a PDA based on Maxwell's equations coupled to the Boltzmann transport equation. The latter is solved semiclassically for the doped GaAs using a continuum approach. The emphasis is on the accurate prediction of the emitted THz pulse shape and bandwidth, particularly when materials are doped with a rare-earth metal such as erbium or terbium that serve as carrier recombination centers. Field-dependent carrier mobility is determined from particle-based simulations. Some of the previous experimental results [1] are used as a basis for comparison with our model. [1] J. O'Hara, J.M.O. Zide, A.C. Gossard, A.J Taylor, R.D. Averitt, "Enhanced Terahertz Detection via ErAs:GaAs nanoisland superlattices", Applied Physics, 88, 251119, 2006.

**G1.00178 Nonlocal spin-confinement of electrons in graphene with proximity exchange interaction**, YEE SIN ANG, SHI-JUN LIANG, KELVIN J. A. OOI, Singapore University of Technology and Design, CHAO ZHANG, University of Wollongong, ZHONGSHUI MA, Peking University, LAY KEE ANG, Singapore University of Technology and Design — In graphene-magnetic-insulator hybrid structure such as graphene-Europium-oxide (EuO-G), proximity induced exchange interaction opens up a spin-dependent bandgap and spin splitting in the Dirac band. We study the bound state formation in a hetero-interface composed of EuO-G. We theoretically predict a remarkable nonlocal spin-confinement effect in EuO-G and show that spin-polarized quasi-1D electron interface state can be generated in a magnetic-field-free channel. Quasiparticle transport mediated by the interface state can be efficiently controlled by the channel width and electrostatic gating. Our results suggest a pathway to further reduce the dimensionality of graphene quasiparticles from 2D to 1D, thus offering an exciting graphene-based platform for the search of exotic 1D physics and spintronic applications.

**G1.00179 The electronic and transport properties of monolayer transition metal dichalcogenides: a complex band structure analysis<sup>1</sup>**, DOMINIK SZCZESNIAK, Qatar Energy and Environment Research Institute, Hamad bin Khalifa University, Qatar Foundation — Recently, monolayer transition metal dichalcogenides have attracted much attention due to their potential use in both nano- and opto-electronics. In such applications, the electronic and transport properties of group-VIB transition metal dichalcogenides ( $MX_2$ , where  $M=Mo, W$ ;  $X=S, Se, Te$ ) are particularly important. Herein, new insight into these properties is presented by studying the complex band structures (CBS's) of  $MX_2$  monolayers while accounting for spin-orbit coupling effects. By using the symmetry-based tight-binding model a nonlinear generalized eigenvalue problem for CBS's is obtained. An efficient method for solving such class of problems is presented and gives a complete set of physically relevant solutions. Next, these solutions are characterized and classified into propagating and evanescent states, where the latter states present not only monotonic but also oscillatory decay character. It is observed that some of the oscillatory evanescent states create characteristic complex loops at the direct band gaps, which describe the tunneling currents in the  $MX_2$  materials. The importance of CBS's and tunneling currents is demonstrated by the analysis of the quantum transport across  $MX_2$  monolayers within phase field matching theory.

<sup>1</sup>Present work has been prepared within the Qatar Energy and Environment Research Institute (QEERI) grand challenge ATHLOC project (project no. QEERI- GC-3008).

**G1.00180 Shot noise in quantum dots in presence of Fano and Dicke effects in Kondo regime<sup>1</sup>**, PEDRO ORELLANA, NATALIA CORTES, Universidad Tecnica Federico Santa Maria, VICTOR APEL, Universidad Catolica del Norte — The quantum dots allow studying systematically quantum-interference effects as Fano and Dicke effects due to the possibility of continuous tuning the relevant parameters governing the properties of these resonances, in equilibrium and nonequilibrium regimes. The condition for the Fano resonance is the existence of two scattering channels: a discrete level and a broad continuum band. On the other hand, the electronic version of the Dicke effect is analogous to the Dicke effect in optics, which takes place in the spontaneous emission of two closely-lying atoms radiating a photon into the same environment. In quantum dots this effect is due to quantum interference in the passage of an electron through two closely lying resonant states of the quantum dots coupled to common leads. In this work, we present a systematic investigation of the influence of the Dicke effect on shot-noise and Fano factor in a cross-shaped quantum dot array. The relevant quantities are obtained by the non-equilibrium Greens function technique. Our results show that at zero temperature, the electrical current, shot-noise and Fano factor exhibit characteristics of the Dicke effect.

**G1.00181 Self assembly and optical properties of CdSe nanoplatelet superlattice**, YUNAN GAO, WILLIAM TISDALE, MIT, TISDALE LAB MIT TEAM — Colloidal CdSe nanoplatelets (NPs) are 1-D confined materials with atomic uniform thickness, and only have homogeneous broadening in energy level distributions and very narrow emission spectrum. Additionally, NPs have a giant oscillator strength that leads to a faster emission rate compared to quantum dots and rods. Due to these properties, NPs have shown promising potential applications in light-emitting diodes, colloidal lasers, and harvesting multiple exciton generation in photovoltaic cells. Self-assembly of superlattice has been studied broadly for many nano-particles, but not yet for CdSe NPs. We will show for the first time a selective control of CdSe NP superlattice self-assembly, i.e., self-assembled into columnar or lamellar superlattice. Moreover, we will present that the assembly morphology of superlattice has direct effects on their optical properties, like polarization, absorption efficiency and emission rate, etc., and also on their Forster energy transfer properties. The self-assembly is based on liquid interfacial self-assembly and transfer technique. The structure and properties of the superlattice are characterized by transmission electron microscopy, and time-, polarization- and space-resolved photo-luminescent micro-spectroscopy.

**G1.00182 Novel Application of Cluster Analysis to Transport Data in Single Molecule Break Junctions**, BEN WU<sup>1</sup>, JEFFREY IVIE<sup>2</sup>, TYLER JOHNSON<sup>3</sup>, ROLAND HIMMELHUBER<sup>4</sup>, OLIVER MONTI<sup>5</sup>, Univ of Arizona — Single molecule based devices represent the ultimate limit in device design, but uncovering the major factors that determine energy level alignment in single molecule junctions and their effect on the charge transport properties of single molecules is still a major challenge. Analysis of break junction data using a novel density based hierarchical clustering algorithm reveals the deep structure of the highly stochastic data that will help hypothesis-driven elucidation of some of the key parameters for quantum transport. The strength of this approach is its scale-invariance and the identification of nested structure that may be overlooked by standard data analysis techniques. The statistical relevance of identified clusters can be gauged using a density based validation index.

**G1.00183 The effect of oxidation on charge carrier motion in PbS quantum dot thin films studied with Kelvin Probe Microscopy<sup>1</sup>**, LAN PHUONG NGUYEN HOANG, PHEONA WILLIAMS, JASON MOSCATELLO, KATHERINE E. AIDALA, Mt Holyoke Coll, AIDALA GROUP TEAM — We developed a technique that uses scanning probe microscopy (SPM) to study the real-time injection and extraction of charge carriers in thin film devices. We investigate the effects of oxidation on thin films of Lead Sulfide (PbS) quantum dots with tetrabutyl-ammonium-iodide (TBAI) ligands in an inverted field effect transistor geometry with gold electrodes. By positioning the SPM tip at an individual location and using Kelvin Probe Force Microscopy (KPFM) to measure the potential over time, we can record how the charge carriers respond to changing the backgate voltage with grounded source and drain electrodes. We see relatively fast screening for negative backgate voltages because holes are quickly injected into the PbS film. The screening is slower for positive gate voltages, because some of these holes are trapped and therefore less mobile. We probe these trapped holes by applying different gate voltages and recording the change in potential at the surface. There are mixed reports about the effect of air exposure on thin films of PbS quantum dots, with initial exposure appearing to be beneficial to device characteristics. We study the change in current, mobility, and charge injection and extraction as measured by KPFM over hours and days of exposure to air.

**G1.00184 Electron Transport through Polyene Junctions in between Carbon Nanotubes: an Ab Initio Realization<sup>1</sup>**, YIING-REI CHEN, KAI-YU CHEN, Department of Physics, National Taiwan Normal University, KUN-PENG DOU, JUNG-SHEN TAI, Research Center for Applied Sciences, Academia Sinica, HSIN-HAN LEE, Department of Physics, National Taiwan Normal University, CHAO-CHENG KAUN, Research Center for Applied Sciences, Academia Sinica — With both *ab initio* and tight-binding model calculations, we study a system of polyene bridged armchair carbon nanotube electrodes, considering one-polyene and two-polyene cases, to address aspects of quantum transport through junctions with multiple conjugated molecules. The *ab initio* results of the two-polyene cases not only show the interference effect in transmission, but also the sensitive dependence of such effect on the combination of relative contact sites, which agrees nicely with the tight-binding model. Moreover, we show that the discrepancy mainly brought by *ab initio* relaxation provides an insight into the influence upon transmission spectra, from the junction's geometry, bonding and effective potential.

**G1.00185 Band alignment study on Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface with the presence of point defect<sup>1</sup>**, JIANQIU HUANG<sup>2</sup>, ERIC TEA<sup>3</sup>, CELINE HIN<sup>4</sup>, Virginia Tech — Metal-Oxide interface has a wide use in electronic devices. Currently, technological development is aiming on the shrinkage of electronic devices' size. Based on the knowledge of electron tunneling effect, the reduction of dielectric thickness would cause an exponential increase on electron tunneling probability which contributes to current leakage. It might cause dielectric breakdown, which could make a severe and irreversible damage to the devices. Therefore, the main purpose of this study is to explore the possible factors that can lead to dielectric breakdown at metal-oxide interface. Density functional theory *ab initio* calculation has been applied to study the Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface. Results on oxygen (di)vacancies at the interface will be presented and compared with the defect free model. The band alignment has been constructed to describe the variation of potential barrier height due to defect at interface. Results show the oxygen (di)vacancies at interface might trap electron and reduce potential barrier height. Moreover, the potential barrier height has a significant dependence on defects charge states.

**G1.00186 Band alignment study on Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface with the presence of H atom impurity and external electric field<sup>1</sup>**, JIANQIU HUANG<sup>2</sup>, ERIC TEA<sup>3</sup>, CELINE HIN<sup>4</sup>, Virginia Tech — Metal-Oxide interface has a wide use in electronic devices. Currently, technological development is aiming on the shrinkage of electronic devices' size. Based on the knowledge of electron tunneling effect, the reduction of dielectric thickness would cause an exponential increase on electron tunneling probability, which contributes to current leakage. It might cause dielectric breakdown, which could make a severe and irreversible damage to the devices. Therefore, the main purpose of this study is to explore the possible factors that could lead to dielectric breakdown at metal-oxide interface. Density functional theory *ab initio* calculation has been applied to study the Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface. Previous study revealed the facts that oxygen (di)vacancies at interface might trap electron and vary potential barrier height. In this study, we introduced the H atom impurity at interface, and applied external electric field to the system. Charge density differences have been calculated to observe the charge alternation at the interface when impurity and external electric field existed. Band alignment revealed the potential barrier height variation due to the impurity and external electric field, which provided us how barrier height would respond to these two types of defects.

**G1.00187 Single crystal complex oxide on flexible substrate.**, SAIDUR BAKAUL, CLAUDY SERRAO, OUKJAE LEE, SAYEEF SALAHUDDIN, University of California Berkeley — Flexible ferroelectrics are needed for various applications such as biocompatible energy harvesting and flexible memory. In this sector, most of the current research is focused on organic piezoelectric materials which have advantage of flexibility but suffers severely from poor energy conversion and generation efficiency. On the contrary, owing to very high electromechanical coupling factor (representing energy conversion efficiency) complex oxides are the best choices as energy harvesting and transduction elements, especially for transforming mechanical energies into electronic energy. Still their usage in energy harvesting is very limited mainly due to the stringent growth conditions of single crystals, high temperature needed for crystallization and lack of flexibility and stretchability. We have shown that single crystal Pb<sub>0.8</sub>Zr<sub>0.2</sub>TiO<sub>3</sub> can be epitaxially transferred on flexible plastic substrate. The transferred PZT shows 70 uC/cm<sup>2</sup> remnant polarization and dielectric constant over 100 even when it is bent. These results suggest the possibility of single crystal complex oxide devices on flexible platform.

**G1.00188 Charge reorganization in LaMnO<sub>3</sub>/LaNiO<sub>3</sub> superlattice interfaces**, FEDERICO IORI, ALEXANDRE GLOTER, Universite' Paris Sud - CNRS, UNRAVEL PROJECT TEAM, STEM GROUP TEAM — Functional properties of oxide heterostructure can recently be controlled and tuned through the electronic and structural mismatch at the interface. Artificial superlattices thin film can thus present complex magnetic structure at the interface different from their corresponding bulk building blocks. In this scenario when an antiferromagnetic bulk LMO and the paramagnetic bulk LNO are combined in thin film superlattices, LaMnO<sub>3</sub>/LaNiO<sub>3</sub>, strong exchange bias, new metal-insulator transition or antiferromagnetic order at the interface appear. In this work we study by *ab initio* Density Functional Theory how the induced magnetic moments in LNO films in LMO/LMO (111)-oriented can lead to charge transfer and reorganization at the interface among the Ni and Mn metal ions for different periodicities of the superlattices (3/3, 5/5, 7/7) and how it is possible to control them through atomic intermixing at the interface.

**G1.00189 Engineering SrTiO<sub>3</sub>/LaAlO<sub>3</sub> heterostructures thickness through a metallic capping layer electrodes**, FEDERICO IORI<sup>1</sup>, Universite Paris Sud - CNRS — The possibility to achieve conducting and superconducting properties at the interface between two bulk insulator oxides as SrTiO<sub>3</sub> (STO) and LaAlO<sub>3</sub> (LAO) in 2004 [1] has wide opened the route toward the discovery and control of broad functional emerging properties in different oxides heterostructures. Nonetheless the STO/LAO system still present not clarified questions concerning the possibility to control the presence of the 2DEG at the interface. In this work we present our theoretical results supported by experimental measurements concerning the possibility to tune the critical thickness of the LAO topmost layer through the deposition of a metallic capping layer at the surface. Our *ab initio* Density Functional Theory calculations show how different metallic contact can lead to a reduction of the LAO critical thickness of 4 u.c. still preserving the 2D electronic gas at the interface. **G1.00190 Growth and Study of Cuprate Thin Film Heterostructures Combining  $\text{La}_2\text{CuO}_{4+\delta}$  and  $\text{LaCuO}_{3-\delta}$** , RODRIGO MARMOL, FRANKLIN BURQUEST, NICHOLAS COX, BRITTANY NELSON-CHEESEMAN, University of St Thomas — Cuprate materials have shown promise as fuel cell cathode materials. Both the layered perovskite,  $\text{La}_2\text{CuO}_{4+\delta}$ , and its 3D perovskite counterpart,  $\text{LaCuO}_{3-\delta}$ , demonstrate the simultaneous electronic and ionic conduction necessary for fuel cell cathode materials. The layered perovskite allows for oxygen interstitial diffusion through the material. Meanwhile, the 3D perovskite readily creates oxygen vacancies, allowing for oxygen vacancy diffusion through the material. In this work, we investigate thin film heterostructures created from these two disparate materials to understand how the local oxygen diffusion phenomena affect the local structure and electrical transport of cuprates. The growth of these heterostructures is possible through the atomic monolayer control of Molecular Beam Epitaxy with in-situ monitoring via Reflective High Energy Electron Diffraction. The superlattice structure is characterized by x-ray reflectivity, and the crystal structure of the disparate phases is characterized by x-ray diffraction. A custom electrical transport system is used to characterize the electrical transport of the films. We compare these heterostructures with the single-phase films of  $\text{La}_2\text{CuO}_{4+\delta}$  and  $\text{LaCuO}_{3-\delta}$  in order to understand how this heterostructuring may modify the structure and electrical properties.

**G1.00191 Thermoelectric Properties of Barium Plumbate Doped by Alkaline Earth Oxides**, ANDREZA EUFRASIO, RUDRA BHATTA, IAN PEGG, BIPRODAS DUTTA, Vitreous State Laboratory. The Catholic University of America — Ceramic oxides are now being considered as a new class of thermoelectric materials because of their high stability at elevated temperatures. Such materials are especially suitable for use as prospective thermoelectric power generators because high temperatures are encountered in such operations. The present investigation uses barium plumbate ( $\text{BaPbO}_3$ ) as the starting material, the thermoelectric properties of which have been altered by judicious cation substitutions.  $\text{BaPbO}_3$  is known to exhibit metallic properties which may turn semiconducting as a result of compositional changes without precipitating a separate phase and/or altering the basic perovskite crystal structure. Perovskite structures are noted for their large interstitial spaces which can accommodate a large variety of “impurity” ions. As  $\text{BaPbO}_3$  has high electrical conductivity,  $\sigma = 2.43 \times 10^5 \Omega^{-1} \text{m}^{-1}$  at room temperature, its thermopower,  $S$ , is relatively low,  $23 \mu\text{V/K}$ , as expected. With a thermal conductivity,  $k$ , of  $4.83 \text{Wm}^{-1} \text{K}^{-1}$ , the figure of merit ( $ZT = S^2 \sigma T k^{-1}$ ) of  $\text{BaPbO}_3$  is only 0.01 at  $T = 300\text{K}$ . The objective of this investigation is to study the variation of thermoelectric properties of  $\text{BaPbO}_3$  as Ba and Pb ions are systematically substituted by alkaline earth ions.

**G1.00192 The way to enhance thermoelectric properties of  $\text{Bi}_2\text{O}_2\text{Q}$  (Q=S and Se) system by introducing chalcogen mixture net.**<sup>1</sup>, CHANGHOON LEE, JISOOK HONG, Pohang University of Science and Technology, WANG RO LEE, Chonbuk National University, DAE YEON KIM, 4Agency for Defense Development (ADD), JI HOON SHIM, Pohang University of Science and Technology — First principles density functional theory calculations were carried out for the series of bilayered semiconducting  $\text{Bi}_2\text{O}_2\text{Q}$  (Q=S, Se) and hypothetically constructed  $\text{Bi}_2\text{O}_2\text{S}_{0.5}\text{Se}_{0.5}$  compounds in which chalcogen square net of pure  $\text{Bi}_2\text{O}_2\text{Q}$  compound is replaced with having stripe type structure of chalcogen mixture net to explore their electronic structures, the change in their electronic structures under the chalcogen mixing, and the possibility for improving in their thermoelectric properties. By introducing chalcogen mixture net in pure  $\text{Bi}_2\text{O}_2\text{Q}$ , the band gap should be adjusted, and the indirect band gap in pure  $\text{Bi}_2\text{O}_2\text{Q}$  compound is changed to direct band gap. According to the analysis of calculated thermoelectric properties of  $\text{Bi}_2\text{O}_2\text{Q}$  and  $\text{Bi}_2\text{O}_2\text{S}_{0.5}\text{Se}_{0.5}$  compounds, thermoelectric properties are strongly enhanced in  $\text{Bi}_2\text{O}_2\text{S}_{0.5}\text{Se}_{0.5}$  compound. It seems to be due to the fact that the electrical conductivity is strongly enhanced by the decrease of dimensionality of its electronic structure and the broadening of sharpness of density of states near the Fermi level. Therefore, we believe that band modulation by introducing chalcogen mixture net in its pure compound  $\text{Bi}_2\text{O}_2\text{Q}$  compound gives a help to improve their thermoelectric properties.

**G1.00193 Tunneling of Heat: Potential-Barrier Analysis.**, DAVID SAROKA, KAMIL WALCZAK, Pace University — We examine quantum processes of heat (energy) transfer as carried by electrons tunneling via potential barriers of different shapes. As a starting point, we use analytical expressions for transmission functions related to rectangular and triangular potential barriers as well as point-like defects connecting two heat reservoirs (thermal baths). To calculate thermal conductance, we use Landauer formula for heat flux in its linear Taylor expansion with respect to temperature difference. Our results are discussed with respect to temperature, resonant states, specific parameters characterizing potential barrier (its height and width), and the effective mass of heat carriers. To get time-dependent heat fluxes reflected from and scattered on potential barriers, we use Gaussian-type wave-packet approach to tunneling of heat carried by electrons. Time-domain formulation of the scattering problem is performed by using the quantum mechanical concept of Gaussian wave packets.

**G1.00194 Inelastic Heat Transfer in Molecular Quantum Dots**, JOANNA DYRKACZ, KAMIL WALCZAK, Pace Univ — We examine electronic heat conduction via molecular complexes in the presence of local electron-phonon coupling effects. In off-resonance transport regime, even weak electron-phonon interactions lead to phonon-mediated changes of transport characteristics. In the nearly resonance conditions, the strong electron-phonon coupling reduces the height of the main conductance peak, generating additional satellites (phonon sidebands) in transport characteristics and shifting molecular energy spectrum via reorganization (polaron) energy. In the past, it was shown that inclusion of electron-phonon coupling effects into computational scheme reduces discrepancy between theoretical results and experimental data. The aim of this project is to study electron-phonon coupling effects on electronic heat transfer at molecular level. For that purpose, we use non-perturbative computational scheme based on inelastic version of Landauer formula, where the Green's functions technique combined with polaron transformation was used to calculate multi-channel transmission probability function, while accessibility of individual conduction channels is governed by Boltzmann statistics. Our analysis is based on the hypothesis that the dynamics created by electron-phonon interaction onto the molecular quantum dot asymmetrically connected to two thermal reservoirs will lead to thermal rectification effect. Our results will be discussed in a few aspects: electron-phonon coupling strength, phonon dispersion relationship, and heat fluxes generated by temperature difference as well as bias voltage.

**G1.00195 Electronic band gaps and transport properties in periodically alternating mono- and bi-layer graphene superlattices**, XIONG FAN, WENJUN HUANG, TIANXING MA, Beijing Normal University, LI-GANG WANG, Zhejiang University, HAI-QING LIN, Beijing Computational Science Research Center — We investigated electronic band structure and transport properties of periodically alternating mono- and bi-layer graphene superlattices (MBLG SLs). In such MBLG SLs, there exists the zero-averaged wave vector (zero- $\bar{k}$ ) gap, which is insensitive to the lattice constant, and this zero- $\bar{k}$  gap can be controlled via changing both the ratio of potentials' widths and the interlayer coupling coefficient of bilayer graphene. It is also found that there exist the extra Dirac points and their conditions are analytically presented. Lastly, it shows that the electronic transport properties and the energy gap ( $E_g$ ) of the first two bands in MBLG SLs are tunable by the interlayer coupling and the widths' ratio of the periodic mono- and bi-layer graphene.

**G1.00196 Exact solutions for 1D lattice models with topological complicated configuration<sup>1</sup>**, LEI FANG, DAVID SCHMELTZER, The City College of The City University of New York — In this work a transfer matrix method is developed to study 1D lattice models within the tight binding framework. Employing this method we show, from simple to difficult, the solutions of a semi-infinite wire, a finite open wire, a single closed ring and two coupled rings. We start by studying local properties of solutions in a homogeneous region. It is found that a calculation of the exponential of the transfer matrix is necessary for us to obtain the general form of wave functions in the entire homogenous region. Then by matching wave functions at boundaries or connecting junctions we can get equations that determine the spectrum. In this way we have solved the problem of two coupled rings (a topologically complicated configuration) and it is shown there can exist bound state in this system.

<sup>1</sup>This work was supported in part by the U.S. DOE Office of Basic Energy Sciences (Program Code: E304).

**G1.00197 Identifying radiation induced point defect in SiC nanowires: computational modeling.**, MING UU, University of Louisville — SiC nanowires (NWs) are expected to possess higher radiation tolerance compared to their crystalline counterpart due to their efficiency in eliminating point defects generated by the radiations. In this study, we will develop a computational modeling scheme to identify the radiation induced point defects in SiC NWs. A preliminary study on the hexagonal 2H-SiC NWs has demonstrated that the point defects on the surface of the SiC NWs only create local distortions and will not cause the destruction of the entire structure of the SiC NWs. It is also found that the local strain created by the antisite, the C-vacancy, and the Si-interstitial defects induces a few impurity states inside the energy gap, while defects such as the Si-vacancy and C-interstitial defects tend to produce a small tail at the top of the valence band. These observations suggest that the electronic properties of the SiC NWs will not be affected to any great extent by these types of point defects on the surface of the SiC NWs, and therefore the SiC NWs are expected to be tolerant or resistant responding to these types of radiation effect.

**G1.00198 Magnetotransport experiments in two-dimensional electron gases exposed to electromagnetic hybrid superlattices**, JAKOB SCHLUCK, STEFAN FASBENDER, STEPHAN WISSENBERG, THOMAS HEINZEL, Heinrich-Heine University Dusseldorf, KLAUS PIERZ, HANS-WERNER SCHUMACHER, PTB Braunschweig, DIMITRIS KAZAZIS, ULF GENNSER, CNRS-LPN Marcoussis — Hybrid lateral superlattices composed of a square array of antidots and a periodic one-dimensional magnetic modulation are prepared in Ga[Al]As heterostructures. The two-dimensional electron gases exposed to these superlattices are characterized by magnetotransport experiments in various magnetic field configurations. Commensurability resonances as a function of a parallel external magnetic field are observed even in the absence of closed orbits, and interpreted with the help of numerical simulations based on the semiclassical Kubo model. [1] In additional homogeneous perpendicular magnetic fields, quantum effects emerge, which can be attributed to the formation of closed quantized orbits.  
[1] J. Schluck et al., Phys. Rev. B 91, 195303 (2015)

**G1.00199 Electric field dependent Electoreflectance of GaAs/AlGaAs multiple quantum well Bragg structure at second quantum state**, MIM NAKARMI, Department of Physics, Brooklyn College and the Graduate Center of the CUNY, Brooklyn, NY 11210, USA, NARESH SHAKYA, Department of Applied Physics, NYU Tandon School of Engineering, Brooklyn, NY 11201, USA, VLADIMIR CHALDYSHEV, Ioffe Institute, 26 Polytekhnikeskaya, St. Petersburg 194021, Russia — Electoreflectance Spectroscopy was employed to study the effect of electric field on the excitonic transitions in a GaAs/AlGaAs multiple quantum well (MQW) Bragg structure. The sample used in this experiment consists of 60 periods of quantum well structures with GaAs well layer (~13 nm) and AlGaAs barrier layer (~94 nm), grown by molecular beam epitaxy on a semi-insulating GaAs substrate. The sample structure was designed to coincide the Bragg resonance peak with the  $x(e2-hh2)$  exciton transitions. We observed a significant enhancement of excitonic feature around the  $x(e2-hh2)$  exciton transition due to the double resonance along with the sharp features of  $x(e1-hh1)$  and  $x(e1-lh1)$  ground state exciton transitions by tuning the angle of incidence of the light. We will present the results on electric field dependent electoreflectance measurements of this structure and discuss the effect of electric field on the first and second energy states.

**G1.00200 "Flash" synthesis of "giant" Mn-doped CdS/ZnSe/ZnS nanocrystals with ZnSe layer as hole quantum-well**, RUILIN XU, JIAYU ZHANG, Advanced Photonics Center, Southeast University, Nanjing — Usually, exciton-Mn energy transfer in Mn-doped CdS/ZnS nanocrystals (NCs) can readily outcompete the exciton trapping by an order of magnitude. However, with the accumulation of non-radiative defects in the giant shell during the rapid growth of the thick shell (up to ~20 monolayers in no more than 10 minutes), the photoluminescence (PL) quantum yield of this kind of giant NCs is significantly reduced by the accumulation of non-radiative defects during the rapid growth of thick shell. That is because the exciton-Mn energy transfer in Mn-doped CdS/ZnS NCs is significantly inhibited by the hole trapping as the major competing process, resulting from the insufficient hole-confinement in CdS/ZnS NCs. Accordingly flash synthesis of giant Mn-doped CdS/ZnSe/ZnS NCs with ZnSe layer as hole quantum-well is developed to suppress the inhibition. Meanwhile  $Mn^{2+}$  PL peak changes profoundly from ~620 nm to ~540 nm after addition of ZnSe layer. Studies are under the way to explore the relevant mechanisms.

**G1.00201 Electron spin decoherence in silicon carbide nuclear spin bath**, LI-PING YANG, Beijing CSRC — In this paper, we study the electron spin decoherence of single defects in silicon carbide (SiC) nuclear spin bath. We find that, although the natural abundance of  $^{29}Si$  (4.7%) counter-intuitive result, is the suppression of heteronuclear-spin flip-flop process in finite magnetic field. Our results show that electron spin of defect centers in SiC are excellent candidates for solid state spin qubit in quantum information processing.

**G1.00202 Current conserving theory at the operator level**, JIANGTAO YUAN, YIN WANG, JIAN WANG, The university of Hongkong — The basic assumption of quantum transport in mesoscopic systems is that the total charge inside the scattering region is zero. This means that the potential deep inside reservoirs is effectively screened and therefore the electric field at interface of scattering region is zero. Thus the current conservation condition can be satisfied automatically which is an important condition in mesoscopic transport. So far the current conserving theory is well developed by considering the displacement current which is due to Coulomb interaction if we just focus on the average current. However, the frequency dependent shot noise does not satisfy the conservation condition since we do not consider the current conservation at the operator level. In this work, we formulate a generalized current conserving theory at the operator level using non-equilibrium Green's function theory which could be applied to both average current and frequency dependent shot noise. A displacement operator is derived for the first time so that the frequency dependent correlation of displacement currents could be investigated. Moreover, the equilibrium shot noise is investigated and a generalized fluctuation-dissipation relationship is presented.

**G1.00203 Photonic Surface-Bulk Waves in 1D All-Dielectric Metamaterials**, ANNE DELUA, DAVID KEENE, MAXIM DURACH, Georgia Southern University — It has been previously reported that it is impossible to satisfy the strong condition for the propagation of Dyakonov Surface Waves in 1D all-dielectric metamaterials. The strong condition requires that both evanescent and ordinary waves decay into the metamaterial. We show that the weak condition, when only ordinary waves decay, can be satisfied in 1D all-dielectric metamaterials, which gives rise to a new class of photonic resonances that combine evanescent extraordinary and non-evanescent ordinary waves in one excitation. By combining thin layers of such metamaterials with different dielectric and metal substrates one can excite resonances that are a hybrid between Fabry-Perot modes in the metamaterial layer and surface waves on the boundaries of this layer.

**G1.00204 Scattering on hyperbolic microspheres: From photonic nanojets to Poisson-Arago bright spots**, REED HODGES, CLEON DEAN, MAXIM DURACH, Georgia Southern University — We investigate optical properties of metal-dielectric metamaterial microspheres composed of subwavelength spherical shells of two different materials alternating in an onion-layer fashion. Recently such metamaterial spheres were considered as cavities and their whispering gallery modes were investigated. We focus on the scattering of external radiation by the meta-microspheres in this work. We show that different scenarios are produced by altering the metal fraction in the spheres: as the microsphere transitions from all-dielectric to hyperbolic to all-metal, the photonic nanojets transform into Poisson-Arago bright spots. A new phenomenon also emerges as the percentage of metal in the microsphere increases. “Hot spots” of optical fields intensity appear at the center of the sphere. Their intensity is much higher than that of the incident plane wave.

**G1.00205 Image magnification in transformation optics devices based on tapered waveguides**<sup>1</sup>, WILLIAM ZIMMERMAN, CHRISTOPHER JENSEN, VERA SMOLYANINOVA, Towson Univ, IGOR SMOLYANINOV, University of Maryland — Recent progress in metamaterial and transformation optics (TO) research gave rise to such fascinating devices as perfect lenses, invisibility cloaks, and numerous other unusual electromagnetic devices. However, the metamaterials have problems with low-loss broadband performance and complexity of fabrication, especially in the visible frequency range. Our TO devices allow us to circumvent these difficulties by using lithographically defined metal/dielectric waveguides to emulate metamaterial properties [1]. Adiabatic variations of the waveguide shape enable control of the effective refractive index experienced by light propagating inside the waveguide. The achieved image magnification is consistent with numerical simulations. We have studied wavelength and polarization dependent performance of the waveguides. Our experimental designs appear to be broadband, which has been verified in the 480-633 nm range. These novel optical devices considerably extend our ability to control light on sub-micrometer scales. [1]. V.N. Smolyaninova, et al., Phys. Rev. B 87, 075406 (2013)

**G1.00206 OPTICAL SPECTRA OF A MULTILAYER STACK COMPOSED OF HIGH-TEMPERATURE SUPERCONDUCTOR AND DIELECTRIC**, SILVIA CORTES-LOPEZ, FELIPE PEREZ-RODRIGUEZ, Benemerita Universidad Autonoma de Puebla — Layered high-temperature superconductors behave as negative-refractive-index hyperbolic metamaterials, having effective permittivity components, parallel and perpendicular to the superconducting planes, with different infrared Josephson plasma frequencies [1]. Here, we theoretically study the reflectivity and transmissivity of a multilayer stack with alternating high-temperature superconductor and dielectric slabs. For TM electromagnetic waves, it was found that both reflectivity and transmissivity exhibit narrow photonic pass bands corresponding to two types of Fabry-Perot resonances, one occurring in the superconductor, whereas the other in the dielectric slab. For a stack of N unit cells, in each narrow photonic pass band there are N-1 transmissivity peaks, associated to the quantization of the Bloch phase within the stack. In contrast, when both types of Fabry-Perot resonances are close to each other, the infrared pass bands become wide and the N-1 strong peaks in the optical spectra are clearly-separated. In addition, new resonances are observed at the top and the bottom of the pass bands, and a photonic band just below the lower Josephson plasma frequency appears. A.L. Rakhmanov, et al, Phys. Rev. B 81, 075101 (2010).

**G1.00207 Microwave propagation in chiral metamaterials**, AIDA PRYBYLSKI, Norfolk State Univ, LUIS YON, Granby High School, Norfolk, VA, NATALIA NOGINOVA, Norfolk State Univ — Chiral hyperbolic metamaterials are predicted to show interesting properties associated with possible topological photonic states in these materials, which present new opportunities for light control and manipulation. As prototypes, we consider two metal-dielectric systems designed for microwave range: a twisted wires array, where chirality is associated with shape of metal inclusions, and a rotated layer system, with parallel wires in each layer, and direction of the wires orientation rotated from layer to layer. Systems with different content of metal and layer-to-layer distance were fabricated and studied in the free space propagation experiment. The results were discussed in terms of effective media consideration.

**G1.00208 Temperature-dependent thermal transport in holey silicon nanostructures investigated by impulsive stimulated thermal scattering**, RYAN DUNCAN, ALEJANDRO VEGA-FLICK, ALEXEI MAZNEV, Department of Chemistry, Massachusetts Institute of Technology, ZHENGMAO LU, LINGPING ZENG, JIAWEI ZHOU, JEAN-PHILIPPE PERAUD, EVELYN WANG, GANG CHEN, Department of Mechanical Engineering, Massachusetts Institute of Technology, KEITH NELSON, Department of Chemistry, Massachusetts Institute of Technology — Nanostructuring of semiconductor materials provides a promising means for the decoupling of their electronic and thermal conductivities, making such systems of great interest to the fields of thermoelectrics and microelectronics. Prior investigations indicated that Brillouin zone-folding and phononic band-gap formation may play a role in the diminished thermal conductivity observed in such structures, although it is unclear to what degree such effects manifest themselves over different temperature ranges. We investigate thermal transport properties as a function of temperature for a series of nanoporous silicon membranes using impulsive stimulated thermal scattering (ISTS)—a non-contact optical technique for measuring in-plane thermal transport. Measurements were carried out at temperatures ranging from 350 to 84 K on samples with pore diameters of 130 nm and pitch sizes ranging from 150 to 500 nm. Monte Carlo simulations for phonon transport were performed for comparison to experimental observations. We will discuss the experimental and computational results, and attempt to determine whether the experimental data are consistent with the diffuse boundary scattering model in which phononic crystal effects are absent.

**G1.00209 Counterintuitive behavior of simulated network’s conductance analogous to the Braess paradox**<sup>1</sup>, SÉBASTIEN TOUSSAINT, IMCN/NAPS, Université catholique de Louvain, Belgium, DEMETRIO LOGOTETA, MARCO PALA, IMEP-LAHC, Université Grenoble Alpes, France, VINCENT BAYOT, BENOIT HACKENS, IMCN/NAPS, Université catholique de Louvain, Belgium — Suppressing a channel from a two-terminal mesoscopic network defined in a two-dimensional electron system (2DES) can paradoxically increase its conductance. This counterintuitive behavior analogous to the Braess paradox is evidenced in [1] by simulating the networks conductance (G) when progressively depleting one of its channels with a biased local probe. By means of 3D self-consistent Poisson-Schrödinger simulations based on the NEGF formalism we investigate the occurrence circumstances of this transport anomaly under the influence of a scanning tip. By simulating the current density and local density of states within the network in the coherent and ballistic transport regime, we can follow the modification of the electron flow when the anomaly occurs. This allows to get insights about the role of a simulated disordered potential within the 2DES and permit to evaluate the tip influence on the 2DES potential landscape. Interference phenomena between different network paths can be modified by simulating G under a magnetic field orthogonal to the 2DES. Different geometries and network congestion are also discussed. [1] M. G. Pala et al., Phys. Rev. Lett. 108, 076802 (2012).

**G1.00210 SURFACES, INTERFACES AND THIN FILMS —**

**G1.00211 Evolution of the Adsorption Phases on (111) Terraces With Their Width<sup>1</sup>**, ALAIN PHARES, Villanova University, DAVID GRUMBINE, St. Vincent College — We study the evolution of the crystallization patterns, or phases, of monomer adsorption on (111) terraces, with the number  $M$  of atomic sites in the width of the terrace up to and including  $M = 8$ . Pairwise adsorbate-adsorbate first, second and third neighbor interactions, whether attractive or repulsive, are taken into account.

<sup>1</sup>This work is supported in part by the National Institute for Computational Sciences under grant number TG-CHE050014N.

**G1.00212 Studies of Surface morphology and Atomic Force Microscope-induced Surface Modifications in Calcium Manganese Oxide (CaMnO) Thin Films<sup>1</sup>**, ANTHONY JOHNSON, CACIE HART, ADEEL CHAUDHRY, BRIDGET LAWSON, NATALIE FERRONE, SAMUEL NEUBAUER, DAVID HOUSTON, RAJESWARI KOLAGANI, DAVID SCHAEFER, Towson University — CaMnO is a material of interest for applications as a catalyst for renewable energy applications. Our recent work on epitaxial thin films of this material has shown that films with a tensile lattice mismatch strain exhibit structural and electrical properties that indicate oxygen deficiency. We are studying the influence of strain and oxygen stoichiometry variations on surface morphology as revealed by atomic force microscopy. Our previous work in epitaxial thin films of the hole doped manganite nanoscale has demonstrated surface modifications induced by a voltage-biased AFM tip. Such surface modifications have been shown to be associated with changes in cation and oxygen stoichiometry. We will report results of similar studies on strained CaMnO thin films; relevant for understanding the surface mobility of oxygen vacancies.

<sup>1</sup>We acknowledge support from the Towson Office of University Undergraduate Research, Fisher Endowment Grant and Undergraduate Research Grant from the Fisher College of Science and Mathematics, and Seed Funding grant from the School of Emerging technologies

**G1.00213 Glow-Discharge Production of Oxygen from the Martian Atmosphere**, CALEB HUGHES, RONALD OUTLAW, None — One of the most crucial aspects of any mission to Mars is a continual supply of oxygen for astronaut respiration on site. The most popular approach to this problem favors in-situ oxygen production on Mars, utilizing the  $\text{CO}_2$  Martian atmosphere. However, this requires a large energy budget. NASA's current plans for Mars include sending a system called MOXIE, which produces oxygen through solid oxide electrolysis at high temperatures. An alternative approach utilizes the 6 Torr Martian atmosphere to provide a continual source of oxygen by breaking down the molecule into CO and O using a glow-discharge. After dissociation, a thin film Ag membrane uniquely permeates the atomic oxygen which then recombines to  $\text{O}_2$  on the downstream side, where it is subsequently stored. By taking advantage of recent advances in thin film technology to reduce the thickness of the film to many orders of magnitude less than used in the initial study, a corresponding increase in  $\text{O}_2$  flux can be realized. The Ag thin film requires the support of a porous ceramic substructure. With this system, it is shown that this method produces a viable energy efficient alternative to MOXIE.

**G1.00214 Electronic Phase Exhibits Attraction Between Like Net Charges**, THOMAS MANZ, New Mexico State Univ — A new electronic phase transition was observed in thin plastic films metallized with gold, optionally with an additional layer of aluminum metallization. This phase transition occurred only when the dielectric layers of two metallized films faced each other. When charged to high voltage magnitudes and then grounded, an electronic phase transition occurred during the discharge step that led to a strong attraction between the paired metallized films, even though the films carried like net charges. The resulting electronic phase (and its attractive force) persisted for several days with no apparent decay at ambient temperatures (c. 25 C). After rotating the films along an axis not parallel to the films, the magnetic field due to rotational motion of the charge carriers relative to the thin films persisted for seconds before dissipation. This demonstrates free current lifetimes lasting seconds. Computations and experiments were performed that show the underlying mechanism for the attraction of like net charges is scattering of electromagnetic waves by an electric field cusp at the charged interfaces. Scattering theory calculations reveal this scattering should be most prevalent in the infrared and microwave regions. This has potential applications for shielding electronic circuits from electromagnetic noise at these wavelengths.

**G1.00215 Resistivity Effects of Cation Ordering in Highly-Doped  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  Epitaxial Thin Films**, FRANKLIN BURQUEST, School of Engineering, University of St. Thomas, St. Paul, MN 55105, RODRIGO MARMOL, University of Saint Thomas, NICHOLAS COX, BRITTANY NELSON-CHEESEMAN, School of Engineering, University of St. Thomas, St. Paul, MN 55105 — Highly-doped  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  (LSCO) films ( $0.5 \leq x \leq 1.0$ ) are promising for many applications due to their electronic, ionic, and phonon transport. In this study, we investigate the effect of "electrostatic strain" on the electrical transport of LSCO thin films with large doping ( $x=0.5, 0.75, \text{ and } 1.0$ ). This "electrostatic strain" is applied by ordering differently charged A-site cations ( $\text{La}^{3+}$  vs.  $\text{Sr}^{2+}$ ) into charged A-O layers within the crystal structure. This causes internal polar electrostatic forces, which have been shown to cause stretching of the apical oxygen bond in analogous epitaxial nickelate films. Thin film samples are grown concurrently to minimize extraneous effects on film structure and properties. Atomic force microscopy and x-ray reflectivity demonstrate that the films are single crystalline, epitaxial, and smooth. X-ray diffraction is used to measure the c-axis of the films as a function of doping and dopant cation ordering. Electrical transport data of the ordered samples is compared with transport data of conventional disordered cation samples. Preliminary data indicates significant differences in resistivity at both 300K and 10K between the cation-ordered and cation-disordered samples. This work indicates that dopant cation ordering within the layered cuprates could significantly modify the conduction mechanisms at play in these materials.

**G1.00216 Effects of Cd Interlayer on CdS/CdTe Thin Film Photovoltaics**, DAVID RIVELLA, LUIS CERQUEIRA, M. ALPER SAHINER, Seton Hall University — CdS/CdTe thin films are well known for their photovoltaic effects. However, it is also known that there are various factors that limit the output of the photovoltaic cells. In these particular thin films, a limiting factor is the interaction of CdS and the CdTe layers. By adding a Cd layer between CdS and CdTe, a buffer zone was created. Therefore, the interaction between the aforementioned layers was changed. In this study, the buffer zone was added to the photovoltaic cells, while the ratio of Cd to Te in the CdTe layer was varied, in order to observe the effects of the buffer in regards to the diffusion of Te in traditional CdTe/CdS photovoltaics. The samples were created on ITO coated glass using pulsed laser deposition. This created uniform samples with an approximate thickness of 0.75 microns. In order to test the effect of the Cd buffer layer, the CdTe layers were deposited with varying ratios of Cd to Te. XRD analysis confirmed that the deposited Cd and Te formed crystalline CdTe. The active carrier concentrations were then determined using Hall Effect measurements. The photovoltaic properties were measured using Keithley source meter set-up. The effect of structural modifications on the active carrier concentrations and photovoltaic properties will be discussed.

**G1.00217 Exploration of Al-Doped ZnO in Photovoltaic Thin Films**, CHRISTOPHER CICCARIANO, M. ALPER SAHINER, Seton Hall University — The electrical properties of Al doped ZnO-based thin films represent a potential advancement in the push for increasing solar cell efficiency. Doping with Aluminum will theoretically decrease resistivity of the film and therefore achieve this potential as a viable option in the P-N junction phase of photovoltaic cells. The n-type semi-conductive characteristics of the ZnO layer will theoretically be optimized with the addition of Aluminum carriers. In this study, Aluminum doping concentrations ranging from 1-3% by mass were produced, analyzed, and compared. Films were developed onto ITO coated glass using the Pulsed Laser Deposition technique. Target thickness was 250 nm and ellipsometry measurements showed uniformity and accuracy in this regard. Active dopant concentrations were determined using Hall Effect measurements. Efficiency measurements showed possible applications of this doped compound, with upwards of 7% efficiency measured, using a Keithley 2602 SourceMeter set-up. XRD scans showed highly crystalline structures, with effective Al intertwining of the hexagonal wurtzite ZnO molecular structure. This alone indicates a promising future of collaboration between these two materials.

**G1.00218 Electrical Properties Analysis of Copper doped CdTe/CdS Deposited Thin Films on ITO Coated Glass Substrates**, DARREN LESINSKI, JAMES FLAHERTY, M. ALPER SAHINER, Seton Hall University — CdTe proves to be a viable source for renewable energy in the form of photovoltaic conversion. While CdTe/CdS naturally provide interesting results adding dopants to the cell can yield higher conversion efficiencies. Copper, famous for its electrical properties, can be used as a dopant in the CdTe layer. In conjunction with its dopant characteristics Copper also improves cell performance by acting as a low resistant and high current back contact. All thin films were synthesized using pulsed laser deposition onto ITO coated glass substrates. The CdS layer across all cells has an approximate thickness of 1500 Angstroms. The following CdTe layer has an approximate thickness of 5500 Angstroms. This created the base cell that was then doped. Cu, typically deposited using sublimation or vapor deposition, was done by PLD as well. Two of the three base cells were treated with Cu using the same deposition parameters. The third cell also received a CdCl treatment on top of the Cu layer to understand the effect when the oxygen layer is deferred. Ellipsometer measurements were used to confirm layer thickness. XRD analysis was used to confirm the presence of Cu and the crystal structure of the thin films. A Hall Effect Measurement system was used to measure active charge carrier concentration introduced by dopant. Also, a Keithley sourcemeter was utilized to determine photovoltaic properties. Notable results discussed will be the effects of Copper dopant on the electrical properties of CdS/CdTe based solar cells.

**G1.00219 Synthesis and Characterization of Varying Concentrations of Ag-doped ZnO Thin Films**, JUSTIN HACHLICA, PATRICK WADIE-IBRAHIM, M. ALPER SAHINER, Seton Hall Univ — Silver doped ZnO is a promising compound for photovoltaic solar cell use. Doping this compound with varying amounts of silver will theoretically make this type of thin film more efficient by reducing the overall resistance and increasing the voltage and current output. The extent of this promise is being tested experimentally, by analysis of both the electrical and the surface roughness properties of the cells. Ag-doped Zinc Oxide is deposited by method of Pulsed Laser Deposition (PLD) onto Indium Tin Oxide (ITO) coated Glass. Annealing effects were also observed by varying the temperature at which the annealing occurred after synthesis of the sample. Thickness is confirmed by use of Ellipsometry. X-Ray Diffraction (XRD) measurements confirmed a ZnO crystal structure on the thin films. The active dopant carrier concentrations were determined using a Hall Effect Measuring System. Finally, the photovoltaic properties of the film are recorded by using a Keithley Source Meter. The structural characterization and electrical results of the effect of Ag doping on ZnO will then be discussed.

**G1.00220 Tetrahedral cluster and pseudo molecule: New approaches to Calculate Absolute Surface Energy of Zinc Blende (111)/(-1-1-1) Surface<sup>1</sup>**, YIOU ZHANG, JINGZHAO ZHANG, KINFAT TSE, LUN WONG, CHUNGKAI CHAN, BEI DENG, JUNYI ZHU, Chinese Univ of Hong Kong — Determining accurate absolute surface energies for polar surfaces of semiconductors has been a great challenge in decades. Here, we propose pseudo-hydrogen passivation to calculate them, using density functional theory approaches. By calculating the energy contribution from pseudo-hydrogen using either a pseudo molecule method or a tetrahedral cluster method, we obtained (111)/(-1-1-1) surfaces energies of Si, GaP, GaAs, and ZnS with high self-consistency. Our findings may greatly enhance the basic understandings of different surfaces and lead to novel strategies in the crystal growth.

<sup>1</sup>We would like to thank Su-huai Wei for helpful discussions. Computing resources were provided by the High Performance Cluster Computing Centre, Hong Kong Baptist University. This work was supported by the start-up funding and direct grant with the Project

**G1.00221 Surface studies of gallium nitride quantum dots grown using droplet epitaxy on bulk, native substrates**, CHRISTINA JONES, SUNYEOL JEON, RACHEL GOLDMAN, Univ of Michigan - Ann Arbor, YIZHAK YACOBY, Hebrew University, ROY CLARKE, Univ of Michigan - Ann Arbor — Gallium nitride (GaN) and its applications in light-emitting diodes play an integral part in efficient, solid-state lighting, as evidenced by its recognition in the 2014 Nobel prize in physics. In order to push this technology towards higher efficiency and reliability and lower cost, we must understand device growth on bulk GaN substrates, which have lower defect densities and strain than template GaN substrates grown on sapphire. In this work, we present our findings on the surface properties of GaN quantum dots (QDs) grown on commercial bulk GaN. QDs are grown using the droplet epitaxy method and analyzed using a surface X-ray diffraction technique called Coherent Bragg Rod Analysis (COBRA), which uses phase retrieval to reconstruct atomic positions near the substrate surface. While several QD growth conditions in our study produce dense QDs, COBRA reveals that only low nitridation temperatures result in GaN QDs that are coherent with the bulk GaN substrate. Results are supported with atomic force microscopy and high-resolution transmission electron microscopy.

**G1.00222 Noncontact Atomic Force Microscopy Study of Surface Structural Transitions and Charge Distribution Modulations on SrTiO<sub>3</sub>(100)**, OMUR DAGDEVIREN, GEORG SIMON, KE ZOU, CHARLES AHN, FRED WALKER, ERIC ALTMAN, UDO SCHWARZ, Yale University — The surface structures of SrTiO<sub>3</sub>(100) single crystals were examined as a function of annealing time and temperature in either oxygen or ultra-high vacuum (UHV) using noncontact atomic force microscopy (NC-AFM), Auger electron spectroscopy (AES), and low-energy electron diffraction (LEED). Samples were subsequently analyzed for the effect the modulation of their charge distribution had on their surface potential. It was found that the evolution of the surface roughness, termination, and reconstruction depends crucially on the preparation scheme. For example, transitions from (1x1) termination to an intermediate c(4x2) reconstruction to ultimately a (sqrt(13) x sqrt(13))-R33.7 surface were observed for annealing in oxygen. In UHV, the inverse transition occurred and was accompanied by an increase in surface Sr while the surface oxygen content decreased. Complementary NC-AFM measurements showed a non-monotonic trend for surface roughness with annealing temperature, which is explained by electrostatic modulations of the surface potential caused by increasing oxygen depletion. This is further corroborated by experiments in which the apparent roughness tracked in NC-AFM could be correlated with changes in the surface charge distribution.

**G1.00223 Diffusion of Copper through Ti overlayer<sup>1</sup>**, BRITT LONG, A. MENCHACA, A. R. CHOURASIA, Texas AM University-Commerce — The Cu/Ti interface has been characterized by x-ray photoelectron spectroscopy and resistivity measurements. Thin films of titanium were deposited on copper substrates by e-beam method. The thickness of the Ti film was kept at 50 Å. The interface was annealed at temperatures of 100, 200, 300 and 400C. The Ti 2p and Cu 2p regions were analyzed by XPS. The diffusivity of copper through titanium has been investigated. The resistivity measurements were done by the four probe method. The correlation between the resistivity and the surface composition has been evaluated.

<sup>1</sup>Work supported by Organized Research, TAMU-Commerce

**G1.00224 Fabrication and structural characterization of highly ordered titania nanotube arrays**, HONGTAO SHI, Department of Physics and Astronomy, Sonoma State University, Rohnert Park, CA 94928, ROSITA ORDONEZ, Department of Physics and Astronomy, Sonoma State University — Titanium (Ti) dioxide nanotubes have drawn much attention in the past decade due to the fact that titania is an extremely versatile material with a variety of technological applications. Anodizing Ti in different electrolytes has proved to be quite successful so far in creating the nanotubes, however, their degree of order is still not nearly as good as nanoporous anodic alumina. In this work, we first deposit a thin layer of aluminum (Al) onto electropolished Ti substrates, using thermal evaporation. Such an Al layer is then anodized in 0.3 M oxalic acid, forming an ordered nanoporous alumina mask on top of Ti. Afterwards, the anodization of Ti is accomplished at 20 V in solutions containing 1 M NaH<sub>2</sub>PO<sub>4</sub> and 0.5% HF or H<sub>2</sub>SO<sub>4</sub>, which results in the creation of ordered titania nanotube arrays. The inner pore diameter of the nanotubes can be tuned from ~50 nm to ~75 nm, depending on the anodization voltage applied to Al or Ti. X-ray diffractometry shows the as-grown titania nanotubes are amorphous. Samples annealed at different temperatures in ambient atmosphere will be also reported.

**G1.00225 High-Performance Simulations of the Diffusion Characteristics of a Pentacene Derivative on Gold Surfaces**, RYAN MILLER, AMANDA LARSON, KARSTEN POHL, Univ of New Hampshire — Pentacene serves as a backbone for several molecules that provide attractive qualities for organic photovoltaic devices. One of these pentacene derivatives is 5,6,7-trithiapentacene-13-one (TTPO), which is unique in that it achieves its lowest energy configuration on Au(1 1 1) surfaces with the thiol group angled down towards the surface, allowing many molecules to pack closely together and form molecular nanowires. However, TTPO diffuses on flat surfaces, making it difficult for the self-assembly process to be initiated. With the help of the low-energy sites in surface defects and Au(7 8 8) step edges, TTPO molecules can be anchored in place on surfaces, allowing for chain formation to begin. By using high-performance Density Functional Theory based molecular dynamics calculations, the molecules can be shown to stay localized to these bonding sites and serve as a basis for chain formation. In addition, by simulating various temperatures with a Nose-Hoover thermostat, we can analyze how temperature affects anchoring ability and diffusion properties.

**G1.00226 Resistance of superhydrophobic and oleophobic surfaces to varied temperature applications on 316L SS**, HAMZA SHAMS, DHA Suffa University (DSU), Pakistan, KANZA BASIT, SAJID SALEEM, National University of Sciences and Technology (NUST), Pakistan, BILAL A. SIDDIQUI, DHA Suffa University (DSU), Pakistan — 316L SS also called Marine Stainless Steel is an important material for structural and marine applications. When superhydrophobic and oleophobic coatings are applied on 316L SS it shows significant resistance to wear and corrosion. This paper aims to validate the coatings manufacturer's information on optimal temperature range and test the viability of coating against multiple oil based cleaning agents. 316L SS was coated with multiple superhydrophobic and oleophobic coatings and observed under SEM for validity of adhesion and thickness and then scanned under FFM to validate the tribological information. The samples were then dipped into multiple cleaning agents maintained at the range of operating temperatures specified by the manufacturer. Coating was observed for deterioration over a fixed time intervals through SEM and FFM. A comparison was drawn to validate the most critical cleaning agent and the most critical temperature at which the coating fails to leave the base substrate exposed to the environment.

**G1.00227 XPS and AFM Investigation of Ti-CuO Interface**, DARIUS DURANT, RITESH BHAKTA, A. R. CHOURASIA, Texas AM University-Commerce — The techniques of x-ray photoelectron spectroscopy and atomic force microscopy have been employed to study the Ti/CuO interface. Thin films of titanium were deposited on CuO at room temperature by e-beam method. The thickness of the titanium film was varied between 3 Å and 10 Å. The titanium 2p, oxygen 1s and copper 2p regions were investigated by XPS. The spectral data show the reduction of CuO to elemental copper. Titanium is observed to get oxidized to TiO<sub>2</sub>. The thickness of TiO<sub>2</sub> depended upon the initial thickness of the titanium overlayer. The reaction is observed to continue until the titanium overlayer is 7 Å thick. Beyond this thickness unreacted titanium is observed. The AFM study shows nonuniformity of the TiO<sub>2</sub> film on copper. The study provides a means of preparing TiO<sub>2</sub> of nano-dimensions.

**G1.00228 Neutron scattering study of the freezing of water near a cupric oxide surface<sup>1</sup>**, J. TORRES, Z. N. BUCK, F. Z. ZHANG, T. CHEN, R. A. WINHOLTZ, H. KAISER, H. B. MA, H. TAUB, U. Mo., M. TYAGI, NIST — Oscillating heat pipes (OHP) offer promising two-phase heat transfer for a variety of applications, including cooling of electronic devices.<sup>2</sup> Recently, it has been shown that a hydrophilic CuO coating on either the evaporator or condenser sections of a flat-plate OHP can significantly enhance its thermal performance.<sup>3</sup> This finding has motivated us to assess the strength of the CuO/H<sub>2</sub>O interaction by investigating the freezing behavior of H<sub>2</sub>O in proximity to a CuO surface. Using the High-Flux Backscattering Spectrometer at NIST, we have measured the intensity of neutrons scattered elastically from a well-hydrated sample of CuO-coated Cu foils that mimic the oxide surfaces in a flat-plate OHP. We observe abrupt freezing of bulk-like H<sub>2</sub>O above the CuO surface at 270 K followed by continuous freezing of the interfacial H<sub>2</sub>O down to 265 K. This freezing behavior is qualitatively similar to that found for water near a zwitterionic single-supported bilayer lipid membrane.<sup>3</sup> Further studies are planned to compare the diffusion coefficients of the interfacial water for the coated and uncoated OHPs.<sup>2</sup> F. Z. Zhang *et al.*, submitted to J. Heat Transfer. <sup>3</sup>M. Bai *et al.*, Europhys. Lett. **98**, 48006 (2012); Miskowiec *et al.*, Europhys. Lett. **107**, 28008 (2014).

**G1.00229 The effect of ultraviolet irradiation on data retention characteristics of resistive random access memory.**, KENTARO KINOSHITA, KOUHEI KIMURA, KOUTOKU OHMI, SATORU KISHIDA, Tottori University — It is getting more and more serious to generate soft-errors by cosmic radiation, with increasing the density of memory devices. Therefore, the irradiation resistance of resistance random access memory (ReRAM) to cosmic radiation has to be elucidated for practical use. In this paper, we investigated the data retention characteristics against ultraviolet irradiation to ReRAM with Pt/NiO/ITO structure. Soft-errors were confirmed to be caused by ultraviolet irradiation in both low and high resistance states. The analysis of irradiation frequency dependence of data retention characteristics suggested that electronic excitation by the irradiation caused the errors. Based on a statistically estimated soft-error rate, the errors were suggested to be caused by aggregation and dispersion of oxygen vacancies due to the generation of electron-hole pairs and valence change by the ultraviolet irradiation.

**G1.00230 Effects of Post-Deposition Annealing on the Properties of Calcium Manganese Oxide Thin Films<sup>1</sup>**, NATALIE FERRONE, ADEEL CHAUDHRY, CACIE HART, BRIDGET LAWSON, DAVID HOUSTON, SAMUEL NEUBAUER, ANTHONY JOHNSON, DAVID SCHAEFER, RAJESWARI KOLAGANI, Towson University — We will present our results on the effects of post-deposition annealing on the structural and electrical properties of CaMnO<sub>3-d</sub> thin films grown by Pulsed Laser deposition. The thin films are epitaxially grown on (100) LaAlO<sub>3</sub> which has larger in-plane lattice parameters than that of bulk CaMnO<sub>3</sub>, which leads to bi-axial tensile strain in the thin films. Results from our laboratory show that bi-axial tensile strain leads to low resistivity in thinner films, the resistivity increasing with increasing thickness. These results are suggestive of a coupling between strain and oxygen stoichiometry in the thin films. We have investigated the effects of post-deposition annealing in various gas ambients towards the goal of understanding the effects of relaxation and oxygen stoichiometric changes. We will present a comparison of the structural and electrical properties of as-grown and post-annealed films over a range of thicknesses.

## G1.00231 ATOMIC, MOLECULAR AND OPTICAL (AMO) PHYSICS —

**G1.00232 Second quantization of propagation of light through Rb vapor**, ZHIHAO XIAO, ROBERT LANNING, Department of Physics & Astronomy, Louisiana State University, MI ZHANG, IRINA NOVIKOVA, EUGENIY MIKHAILOV, Department of Physics, College of William & Mary, JONATHAN DOWLING, Department of Physics & Astronomy, Louisiana State University — We model the propagation of squeezed light, in Laguerre-Gaussian spatial modes, through a non-linear medium such as Rb vapor. We examine the changes in both quantum state and spatial modes. We simulate the injection into a Rb vapor cell a linearly polarized laser beam to create squeezed vacuum state of light linearly polarized in the perpendicular direction. We fully quantize the optical field's propagation which is originally based on semi-classical calculation. The Rb atomic structure is simplified to a three-level system. We reveal the mechanism that how squeezed state of light is generated in this process and compare the theory with our experiment. We further investigate the impact on squeezing due to the change of parameters and produce schemes which improve the squeezing in the desired spatial modes.

**G1.00233 Modelling Spatial Modes of Squeezed Vacuum**, R. NICHOLAS LANNING, ZHIHAO XIAO, Louisiana State University, MI ZHANG, IRINA NOVIKOVA, EUGENIY E. MIKHAILOV, College of William and Mary, JONATHAN P. DOWLING, Louisiana State University — We develop a fully quantum model to describe the spatial mode properties of squeezed light generated as a strong laser beam propagates through a Rb vapor cell. Our results show that a Gaussian pump beam can generate a collection of higher order Laguerre-Gaussian squeezed vacuum modes, each carrying a particular squeeze parameter and squeeze angle. We show that a proper sorting of modes could lead to improved noise suppression and thus make this method of squeezed light generation very useful for precision metrology.

**G1.00234 Ground state configurations in two-mode quantum Rabi models<sup>1</sup>**, SUREN CHILINGARYAN, B. M. RODRÍGUEZ-LARA, Instituto Nacional de Astrofísica, Óptica y Electrónica — We study two models describing a single two-level system coupled to two boson field modes in either a parallel or orthogonal configuration. Both models may be feasible for experimental realization through Raman adiabatic driving in cavity QED. We study their ground state configurations; that is, we find the quantum precursors of the corresponding semi-classical phase transitions. We found that the ground state configurations of both models present the same critical coupling as the quantum Rabi model. Around this critical coupling, the ground state goes from the so-called normal configuration with no excitation, the qubit in the ground state and the fields in the quantum vacuum state, to a ground state with excitations, the qubit in a superposition of ground and excited state, while the fields are not in the vacuum anymore, for the first model. The second model shows a more complex ground state configuration landscape where we find the normal configuration mentioned above, two single-mode configurations, where just one of the fields and the qubit are excited, and a dual-mode configuration, where both fields and the qubit are excited.

**G1.00235 Quantum Phase Slip Localization on the Percolation Cluster Backbone<sup>1</sup>**, NOAH BRAY-ALI, Joint Quantum Institute, University of Maryland, College Park and National Institute of Standards and Technology, Gaithersburg, MD 20899 — Quantum phase slips proliferate at the superfluid-to-Mott insulator transition of interacting lattice bosons with commensurate filling in one dimension. The backbone of the incipient infinite cluster at percolation threshold is topologically one-dimensional but localizes quantum phase slips. We calculate the quantum depletion of the condensate fraction on the percolation cluster for weak interactions. Finally we estimate the critical interaction strength where quantum phase slips delocalize using a strong-disorder renormalization group approach applied to the percolation backbone.

**G1.00236 Quantum-coherence driven self-organized criticality and non-equilibrium light localization.**, PANKAJ JHA, KOSMAS TSAKMAKIDIS, YUAN WANG, XIANG ZHANG, Univ of California - Berkeley — In its 28 years since its introduction in 1987, self-organized criticality (SOC) has had a major impact across a broad range of seemingly dissimilar fields of science. However, until now, it has primarily been applied to classical systems, and it remains a fundamental open question whether the theory also finds a place in complex systems driven by quantum coherence (QC). Here, on the basis of a many-body quantum-field theory and corroborating Maxwell-Bloch-Langevin computations, we report on the first example of fractal SOC driven, in the nano-world, by quantum coherence. We show that a quantum-coherently controlled active nano-plasmonic heterostructure allows, in the regime where the light speed is very close to zero, for the phase-synchronization in space of a continuous ensemble of nano-optical oscillators, giving rise to a fundamentally new kind of non-equilibrium light localization. We observe all hallmarks of SOC in this quantum many-body photonic nano-system of interacting heavy bosons, and we identify two critical points, one signifying the onset of spontaneous spatial self-organization, followed in time by another one that signifies the onset of activity. Our analysis reveals a quantum-coherence driven self-organized double-critical property in photonics and a new type of robust light localization, far out of thermodynamic and optical equilibria, with a broad range of potential applications in nano-optics and condensed-matter photonics.

**G1.00237 Anomalous diffusion of light in complex media**, ROXANA REZVANI NARAGHI, CREOL and Department of Physics, University of Central Florida, MARIELENA BURDGE, ARISTIDE DOGARIU, CREOL, University of Central Florida — Light propagation in random materials is often modeled by a diffusion approximation to the radiation transfer equation. This approach inherently ignores interference effects and describes only the energy propagation. When the interaction is strong, however, the scattering events become correlated and wave interferences can cause the diffusion to be slow down. One result of this process is the appearance of localized modes, whereby the energy inside the material is confined to small spatial regions due to constructive interferences. This anomalous, sub-diffusive character of energy propagation could be justified within the scaling theory of localization where the optical diffusion coefficient is size dependent. Moreover, when the concentration of scatterers increases, the near-field interactions between scatterers placed in close proximity of each lead to a new transport regime. In these conditions, the energy spread is not only diffusive but it also evolves through evanescent coupling between individual scatterers. Based on measurements of photon path-length distributions, we report the observation of such distinct regimes of energy transport.

**G1.00238 Topological photonics: an observation of Landau levels for optical photons<sup>1</sup>**, NATHAN SCHINE, ALBERT RYOU, ARIEL SOMMER, JONATHAN SIMON, Univ of Chicago — We present the first experimental realization of a bulk magnetic field for optical photons. By using a non-planar ring resonator, we induce an image rotation on each round trip through the resonator. This results in a Coriolis/Lorentz force and a centrifugal anticonfining force, the latter of which is cancelled by mirror curvature. Using a digital micromirror device to control both amplitude and phase, we inject arbitrary optical modes into our resonator. Spatial- and energy- resolved spectroscopy tracks photonic eigenstates as residual trapping is reduced, and we observe photonic Landau levels as the eigenstates become degenerate. We show that there is a conical geometry of the resulting manifold for photon dynamics and present a measurement of the local density of states that is consistent with Landau levels on a cone. While our work already demonstrates an integer quantum Hall material composed of photons, we have ensured compatibility with strong photon-photon interactions, which will allow quantum optical studies of entanglement and correlation in manybody systems including fractional quantum Hall fluids.

**G1.00239 Topological  $Z_2$  Gapless Photonic Crystals**, BIYE XIE, ZIDAN WANG, The University of Hong Kong — Topological properties of electronic materials with gapless band structure such as Topological Semimetals (TSMs) and Topological Metals (TMs) have drew lots of attention to both theoretical and experimental physicists recently. Although theoretical prediction of TSMs and TMs have been done well, experimental study of them is quite difficult to perform due to the fact that it is very difficult to control and design certain electronic materials. However, since the topological properties stem from the geometric feature, we can study them in Photonic Crystals (PhCs) which are much easy to be controlled and designed. Here we study 2-dimension PhCs consisting of gyrotropic materials with hexagonal structure. In the Brillouin corner, the dispersion relation has gapless points which are similar to Dirac Cones in electronic materials. We firstly derive the effective Hamiltonian of this system and show that if certain perturbation is added to this effective Hamiltonian, this system belongs to All class according to Altland and Zirbauer topological classification and is described by a  $Z_2$  topological charge. Finally we also propose a way to detect this  $Z_2$  topological charge using momentum space Aharonov-Bohm interferometer which is firstly proposed by L.Duca and T.Li, etc.

**G1.00240 Real-time emission spectrum from a hybrid atom-optomechanical cavity**, IMRAN MIRZA, Department of Physics, University of Michigan, Ann Arbor, USA — Hybrid quantum systems are promising candidates for opening new avenues for quantum technologies [G. Kurizki et. al, PNAS, 112 (13), 3866-3873 (2015)]. Hybrid atom-optomechanical (HAOM) systems set an intriguing example in this context. From the perspective of practical utilizations of these HAOM systems in future quantum devices, it is crucial to fully understand the excitation dynamics as well as the spectral features of these systems. In this poster, I'll present my calculations of single-photon time-dependent (TD) spectrum emitted by such a HAOM system in a strong atom-cavity as well as strong cavity-mechanics (strong-strong) coupling regime ["Real-time emission spectrum from a hybrid atom-optomechanical cavity", Imran M. Mirza, J. Opt. Soc. Am. B, 32 (8), 1604-1614 (2015)]. In order to make the system more realistic the effects of dissipation through the mechanical oscillator, optical cavity and spontaneous emission from the two-level emitter are also incorporated. The TD spectrum reveals some novel features that are not possible to observe otherwise. For instance, time order in which different side bands appears which explains different photon-phonon interactions responsible for the production of distinct spectral resonances. .

**G1.00241 Cooling a nanomechanical resonator using spin-dependent transport and noise interference in Andreev reflections**, PASCAL STADLER, WOLFGANG BELZIG, GIANLUCA RASTELLI, University of Constance — Nanoelectromechanical systems promise to manipulate mechanical motion in the quantum regime using electron transport. For such a goal, a necessary condition is the ability of cooling the resonator into or near to its quantum ground state. A still open challenge in this field is the achievement of active cooling using purely electron transport in, for instance, suspended carbon nanotube quantum dots. We consider the quantum transport in a carbon nanotube quantum dot suspended between two electric nanocontacts. Due to the interaction between electrons and flexural mechanical modes, the electron transport results in inelastic vibration-assisted tunneling processes. These give rise to a mechanical damping and to a steady nonequilibrium phonon occupation of the resonator. We discuss these effects for two different coherent transport regimes: (i) spin-polarized current between two ferromagnets [1,2] and (ii) subgap Andreev current between a superconductor and normal metal [3].

**G1.00242 Transient Loschmidt Echo and Orthogonality Catastrophe in highly excited Quantum Ising Spin Chains**, MARCO SCHIRO, Institut de Physique Theorique, Universite Paris Saclay, CNRS, CEA, CARLA LUPO, Politecnico di Torino, Corso Duca degli Abruzzi, 24, 10129 Torino Italy and Universite Paris Sud Paris XI, 15 Rue Georges Clemenceau, 91400 Orsay — We study the response to sudden local perturbations of highly excited Quantum Ising Spin Chains. The key quantity encoding this response is the overlap between time-dependent wave functions, which we write as a transient Loschmidt echo. We compute the Echo perturbatively in the case of a weak local quench and study its asymptotics at long times, which contains crucial information about the structure of the highly excited non-equilibrium environment induced by the quench. Our results reveal that the Echo decays exponentially, rather than power law as in the low-energy Orthogonality Catastrophe, a further example of quench-induced decoherence. The emerging decoherence scale is set by the strenght of the local potential and the bulk excitation energy. In addition, the transient evolution features aging behavior at the Ising quantum critical point.

**G1.00243 Minimally entangled typical thermal states versus matrix product purifications for the simulation of equilibrium states and time evolution**, MORITZ BINDER, THOMAS BARTHEL, Duke Univ — We compare matrix product purifications and minimally entangled typical thermal states (METTS) for the simulation of equilibrium states and finite-temperature response functions of strongly correlated quantum many-body systems. For METTS, we highlight the interplay of statistical and DMRG truncation errors, discuss the use of self-averaging effects, and describe schemes for the computation of response functions. We assess the computation costs and accuracies of the two methods for critical and gapped spin chains and the Bose-Hubbard model. For the same computation cost, purifications yield more accurate results than METTS except for temperatures well below the systems energy gap. (Phys. Rev. B 92, 125119 (2015))

**G1.00244 Investigation of the coupling of the momentum distribution of a BEC with its collective of modes<sup>1</sup>**, EMANUEL HENN, PEDRO TAVARES, AMILSON FRITSCH, FRANKLIN VIVANCO, GUSTAVO TELLES, VANDERLEI BAGNATO, Physics Institute of São Carlos - University of São Paulo — In our group we have a strong research line on quantum turbulence and the general investigation of Bose-Einstein condensates (BEC) subjected to oscillatory excitations. Inside this research line we investigate first the behavior of the normal modes of the BEC under this excitation and observe a non-linear behavior in the amplitude of the quadrupolar mode. Also, inside this same procedure of investigation we study the momentum distribution of a BEC to understand if it is possible to extract Kolmogorov like excitation spectra which would point to a turbulent state of matter. The condensate is perturbed, and we let it evolve in-trap after which we perform standard time-of-flight absorption imaging. The momentum distribution is extracted and analyzed as a function of the in-trap free evolution time for a 2D projected cloud. We show that the momentum distribution has its features varying periodically with the same frequency as the quadrupolar mode displayed by the atomic gas hinting at a strong coupling of both. The main consequence of that one cannot be assertive about the quantitative features of the extract spectrum of momentum and we can only rely on its qualitative features.

**G1.00245 One-dimensional Bose-Einstein condensation of photons in a microtube**, ALEX KRUCHKOV, École Polytechnique Fédérale de Lausanne (EPFL) — This study introduces a quasiequilibrium one-dimensional Bose-Einstein condensation of photons trapped in a microscopical waveguide. Light modes with a cut-off frequency ("photon's mass") interact through different processes of absorption, re-emission, and scattering on molecules of dye. In this work I consider conditions for the one-dimensional condensation of light and the role of photon-photon interactions in the system. The computational technique in use is the Matsubara's Green's functions formalism modified for the quasiequilibrium system under study.

**G1.00246 Spontaneous Exciton Condensate in Transition Metal Dichalcogenides electron-hole bilayer System<sup>1</sup>**, BISHWAJIT DEBNATH, YAFIS BARLAS, DARSHANA WICKRAMARATNE, MAHESH NEUPANE, ROGER LAKE, University of California Riverside — Spontaneous Bose-Einstein Exciton condensation (BEC) in spatially separated graphene layers has received intense theoretical and experimental attention, due to its promise for low-dissipation electronic devices. We have investigated BN-separated monolayers of transition metal dichalcogenides (TMDs) to explore the possibility of achieving exciton superfluidity in this class of 2D materials. The top and bottom monolayers can consist of either same TMD (homo-bilayer) or a combination of different TMDs (hetero-bilayer). The particle density in each monolayer is tuned by independent gate biasing. In TMDs, the almost equivalent particle-hole symmetry is an assisting factor towards achieving condensation. The calculated exciton binding energies are found to be as large as 50 – 250 meV, which is a result of the large effective masses in the TMDs. For BN thicknesses of around 3nm, the interaction strength is large and no longer in the weak coupling regime. Therefore, to calculate the excitonic gap, we use a modified Eliashberg formalism in which the phonon-mediated interaction is replaced with the inter-layer screened coulomb interaction between TMD bilayers.

**G1.00247 Josephson Effect in Trapped Spin-orbit Coupled Bose-Einstein Condensation**, WAI HO TANG, The Univ of Hong Kong — Spin-orbit coupling (SOC) has given rise to many novel states of matter including topological insulators and superconductors. Recent experimental realization of SOC in neutral cold atom systems have opened a new avenue to study its effects in Bose-Einstein condensate. In this study, we discuss the Josephson-like mode in the spin-orbit coupled condensate, and study its decoherence due to thermal effect. We discuss experimental implications of our results.

**G1.00248 Entanglement like properties in Spin-Orbit Coupled Ultra Cold Atom and violation of Bell like Inequality**, SANKALPA GHOSH, RAHUL KUMAR, Physics Department, Indian Institute of Technology, Delhi, India — We show that the general quantum state of synthetically spin-orbit coupled ultra cold bosonic atom whose condensate was experimentally created recently (Y. J. Lin *et al.*, Nature, **471**, 83, (2011)), shows entanglement between motional degrees of freedom (momentum) and internal degrees of freedom (hyperfine spin). We demonstrate the violation of Bell-like inequality (CHSH) for such states that provides a unique opportunity to verify fundamental principle like quantum non-contextuality for commuting observables which are not spatially separated. We analyze in detail the Rabi oscillation executed by such atom-laser system and how that influences quantities like entanglement entropy, violation of Bell like Inequality etc. We also discuss the implication of our result in testing the quantum non-contextuality and Bell's Inequality violation by macroscopic quantum object like Bose-Einstein Condensate of ultra cold atoms.

**G1.00249 Measurement of optical nonlinearity of highly dispersive medium using optical heterodyne detection technique**, ARUP BHOWMICK, Senior Research Fellow, ASHOK MOHAPATRA, Reader-F — We discuss the optical heterodyne detection technique to study the absorption and dispersion of a probe beam propagating through a medium with a narrow resonance. The technique has been demonstrated for Rydberg Electro-magnetically induced transparency (EIT) in rubidium thermal vapor and the optical non-linearity of a probe beam with variable intensity is studied. A quantitative comparison of the experimental result with a suitable theoretical model is presented. The limitations and the working regime of the technique are discussed.

**G1.00250 Pair condensation of a spin-imbalanced two-dimensional Fermi gas**, DEBAYAN MITRA, PETER BROWN, STANIMIR KONDOV, PETER SCHAUSS, WASEEM BAKR, Princeton University — Strongly interacting Fermi gases of ultracold atoms are a clean and tunable platform for exploring high critical temperature superfluidity. This is particularly interesting because the physics of these gases has a close connection to superconductivity in strongly correlated materials. Early experiments in 3D gases have shed light on the crossover from BCS superfluidity to Bose-Einstein condensation of molecules and on the fate of superfluidity in spin-imbalanced gases. Here we study a strongly-interacting spin-imbalanced Fermi gas in two dimensions, where the low dimensionality enhances correlations and phase fluctuations in the gas. We observe pair condensation in the imbalanced gas and map out the temperature-polarization phase diagram for a range of interactions strengths. At low temperatures, we observe phase separation between the superfluid and the normal gas over a wide range of imbalance. The measurement of the phase diagram of strongly interacting fermions in two dimensions opens the door for a detailed investigation of exotic phases enhanced in two dimensions and in optical lattices like the elusive FFLO phase.

**G1.00251 Supersolidity in the one-dimensional Bose-Hubbard Model**, B. TANATAR, B. HETENYI, BILKENT UNIVERSITY — We show how a variational Monte Carlo method can be constructed based on the Baeriswyl wavefunction to calculate the ground-state properties of one-dimensional Bose-Hubbard model. The phase diagram obtained is in excellent agreement with previous quantum Monte Carlo results. We also investigate the sensitivity of the system to a boundary twist, and find that it is sizeable even for integer fillings. To understand the nature of the phase we use a single-particle and a many-particle localization quantity and find that at integer fillings the system exhibits many-particle localization, at the same time, single particles as a result of bosonic exchange, can delocalize over the entire lattice. Away from integer fillings, where the system is known to be superfluid, delocalization is found at both the single-particle and many-particle level. We interpret these results as a signature of supersolidity in the Bose-Hubbard model at integer filling.

**G1.00252 A spinor boson AB chain**, GREIS JULIETH CRUZ REYES, Universidad Santo Tomas, ROBERTO FRANCO, JERESON SILVA VALENCIA, Universidad Nacional de Colombia, UNIVERSIDAD SANTO TOMAS COLLABORATION, UNIVERSIDAD NACIONAL DE COLOMBIA COLLABORATION — Recent research is focused on superlattices arising from optical lattices, which allow a tunable environment. Experimentally bosons present transitions from superfluid to Mott insulator by changing the energy offset in the unit cell [Nat. Commun. 5:5735 (2014)]. Many studies displayed that ground state of spinless boson systems on superlattices present superfluid, Mott insulator and an additional CDW phase created by the energy shift between the sites into the unit cell [Phys. Rev. A 83, 053621 (2011)]. The first confinement methods were magnetic traps, which freezes the spin; with optical lattices the grade of freedom of spin plays an important role. We consider bosons with spin  $S=1$  on a superlattice made by two sites with energy offset per unit cell (AB chain). The Hamiltonian that describes the system is the Bose-Hubbard model with the superlattice potential (W) and the exchange interaction (V) parameters. This model supports CDW, Mott insulator and superfluid phases. For W near to U, with  $V=0$ , Mott phase disappears, but for V increasing, a new CDW appears due to the spin interaction, while the half-integer CDW decrease. These results are widely different from spinless boson, where the CDW phases are stables.

**G1.00253 Bose-Hubbard Model on Penrose Tiling Lattice**, JOHNSON CHAN, The Univ of Hong Kong, DIMITRIOS GALANAKIS, None — The standard Bose-Hubbard model has provided a paradigmatic example to explore the quantum phases in a strongly interacting boson system. However, studies so far have considered lattice models with the conventional lattice symmetry (square, triangular, honeycomb etc. in two dimensions), and very few studies in the case of a quasi-crystal. Experimentally, quasi-crystal optical lattices have been realized in the experiments and this provides a very timely opportunity to investigate the possible quantum states of a Bose-Hubbard model in a quasi-crystal. In our work, we performed the first Quantum Monte Carlo of Bose-Hubbard model on a Penrose tiling lattice at finite temperature. We compute the phase diagram and investigate the behavior of phase transitions by looking at several observables, including momentum distribution, distribution of condensate fraction and density distributions. Our work can be checked in future experiments.

**G1.00254 Photoelectric devices with quantum coherence**, SU SHANHE, Beijing CSRC — A photoelectric device consisting of a three-level system contacted with two fermionic baths and a photon bath is built. Making the Born-Markov approximation, the equation of motion for the density operator in a Lindblad-like form is derived. We obtain the coherence and the efficiency of the system under the steady-state condition. Results show that quantum coherence can enhance the photoelectric conversion efficiency. The efficiency at maximum power can be larger than the CA efficiency bound with the existence of coherence.

**G1.00255 Spectral singularity in composite systems and simulation of laser resonant chamber**<sup>1</sup>, XIZHENG ZHANG, Beijing CSRC — A non-Hermitian system with spectral singularity (SS) exhibits fascinating phenomena which never appear in a Hermitian system. We investigate the existence of SS for a composite system which is consisted of two separated scattering centers A and B embedded in a one-dimensional free space, one of which is non-Hermitian at last. We show that the composite system has a SS at  $k_c$  if the reflection amplitudes  $r^A(k_c)$  and  $r^B(k_c)$  of two scattering centers satisfy the condition  $r_R^A(k_c) r_L^B(k_c) e^{i2k_c(x_B - x_A)} = 1$ , based on the theorem proposed by Ali (PRL 102, 220402 (2009)). Multi-scattering-centers generalization of the theorem is also obtained. As an application, we construct a simple system to simulate the resonant chamber for generating laser light.

<sup>1</sup>Spectral singularity in composite systems and simulation of laser resonant chamber

**G1.00256 Dark state in a nonlinear optomechanical system with quadratic coupling<sup>1</sup>**, YUE-XIN HUANG, XIANG-FA ZHOU, GUANG-CAN GUO, YONG-SHENG ZHANG, Univ of Sci & Tech of China — We consider a hybrid system consisting of a cavity optomechanical device with nonlinear quadratic radiation pressure coupled to an atomic ensemble. By considering the collective excitation, we show that this system supports nontrivial, nonlinear dark states. The coupling strength can be tuned via the lasers that ensure the population transfer adiabatically between the mechanical modes and the collective atomic excitations in a controlled way. In addition, we show how to detect the dark-state resonance by calculating the single-photon spectrum of the output fields and the transmission of the probe beam based on two-phonon optomechanically induced transparency. Possible application and extension of the dark states are also discussed.

**G1.00257 Bose gas with generalized dispersion relation plus an energy gap<sup>1</sup>**, M. A. SOLIS, Instituto de Fisica, UNAM, J. G. MARTINEZ, J. GARCIA, Facultad de Ciencias, UNAM — We report the critical temperature, the condensed fraction, the internal energy and the specific heat for a  $d$ -dimensional Bose gas with a generalized dispersion relation plus an energy gap, i.e.,  $\varepsilon = \varepsilon_0$  for  $k = 0$  and  $\varepsilon = \varepsilon_0 + \Delta + c_s k^s$ , for  $k > 0$ , where  $\hbar k$  is the particle momentum,  $\varepsilon_0$  the lowest particle energy,  $c_s$  a constant with dimension of energy multiplied by a length to the power  $s > 0$ . When  $\Delta > 0$ , a Bose-Einstein critical temperature  $T_c \neq 0$  exists for any  $d/s \geq 0$  at which the internal energy shows a peak and the specific heat shows a jump. The critical temperature and the specific heat jump increase as functions of the gap but they decrease as functions of  $d/s$ . Thermodynamic properties are  $\varepsilon_0$  independent since this is just a reference energy. For  $\Delta = 0$  we recover the results reported in Ref. [1].

**G1.00258 Derivation and Inter-relationship of Planck time, the Hubble constant, and Cosmic Microwave Background Radiation from the Neutron and the Quantum Properties of Hydrogen**, D. W. CHAKERES, Department of Radiology, The Ohio State University, Columbus, OH, 43210, R. VENTO, Retired, S. S. MOSES, J. B. SAUZA, V. M. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA, 94508 — Planck time,  $t_P$ , is presently the only fundamental constant that unites the physical domains of  $c$ ,  $\hbar$ , and  $G$ , and is therefore a globally defined normalized time constant. This study shows a method to derive  $t_P$ ,  $H_0$ ,  $G$ , and the Cosmic Microwave Background Radiation (CMBR) peak spectral radiance from the frequency equivalents of the neutron and the quantum properties of hydrogen such as Rydberg's constant, Bohr radius, electron mass and electron charge. All of the derivations are within the experimental ranges, including errors. Moreover, these results exceed what is experimentally possible because the natural unit data are of high precision. The constants are evaluated within a combined classic integer and harmonic fraction, power law relationship. The logarithmic base of the annihilation frequency of the neutron, approximately  $2.27 \cdot 10^{23}$  Hz, scales the independent axis to an integer and partial harmonic fraction system. The dependent axis is scaled by the properties of hydrogen. On the line that defines Planck time squared,  $t_P^2$ , there exist unique points directly related to  $H_0$ , and the CMBR. Therefore these three fundamental cosmic constants are mathematically and conceptually closely inter-related, and each derivable from the others.

**G1.00259 Strong Field QED Simulation of Laser-Plasma Interaction Using BUMBLEBEE.**, XIAOLIN JIN, YUNXIAN TIAN, TAO HUANG, WENLONG CHEN, BIN LI, University of Electronic Science and Technology of China — Next generation laser intensity could reach  $10^{24}$  W/cm<sup>2</sup>, making strong field quantum electrodynamics (QED) effects in laser-plasma interaction a promising research field. The model of photon and pair production in strong field QED is implemented into our 1D3V particle-in-cell (PIC) code BUMBLEBEE with Monte Carlo (MC) algorithm. We apply the kirk and bell model to simulate the photon and pair production, where photon is produced through bremsstrahlung process and the pair is produced through the Bethe-Heitler process. There are two stages in the QED pair production process. Firstly, the intense laser interacts with a relativistic electron or positron to produce the photon. Secondly, the photon interacts with the same laser field to produce the  $e^+e^-$  pair. The QED process is coupled to laser-plasma interaction processes before pushing the particles at each step. Using this code, the evolutions of the particles in ultrahigh intensity laser ( $\sim 10^{23}$ W/cm<sup>2</sup>) interaction with aluminum foil target are observed. Four different initial plasma profiles are considered in the simulations.

**G1.00260 A Control Based System of Mechanical Loss Measurement for High Quality Factor Oscillators**, LOUIS LOUIS GITELMAN, American University, NICOLAS SMITH, California Institute of Technology, ISAAC JAFAR, Columbia University, GREGORY HARRY, JONATHAN NEWPORT, American University, MATT ABERNATHY, California Institute of Technology, LIGO COLLABORATION — In this poster we will present the control system being developed to measure the quality factor of optics used in the Advanced LIGO gravitational wave detectors to predict thermal noise levels. It works by locking the phase between the optic's exciter and normal mode to  $\pi/2$  and locking the optics's amplitude allowing one to equate the energy output of the exciter to the mechanical loss of the optic. To do this the amplitude of the normal mode is detected using a birefringence meter and lockin amplifier, which is then fed back to an electrostatic exciter to control the mode's amplitude and phase with a PID controller written on a python script. The poster will discuss the components and assembly of this system and the theoretical control structure behind it. It will also discuss the speed, accuracy and general feasibility of this method of quality factor measurement relative to other methods, and steps to improve and develop this method of quality factor measurement and the possible applications for LIGO and in general.

**G1.00261 ABSTRACT WITHDRAWN** —

**G1.00262 Abnormal Dispersion of Optical Modes in a non-Hermitian system: Feasibility and Applications**, JING CHEN, RUIPENG GUO, LITING WU, School of Physics, Nankai University, Tianjin 300071, China — We analyze the dispersions of optical eigen-modes in a non-Hermitian system. We show that abnormal dispersion of optical modes can be realized by using the concept of optical parity-time symmetry. Physical significance of these effects is discussed. The feasibility in realizing these abnormal dispersions in passive systems and the connection with damped polaritons in various photonic and phononic systems are discussed. This investigation can find many attractive applications in manipulating the dynamic of coupled optical waves, if the parasite tradeoff of loss effect can be relieved by proper gain effects.

**G1.00263 Optical tweezers theory near a flat surface: a perturbative method<sup>1</sup>**, HENRIK FLYVBJERG, RAFAEL S. DUTRA, Department of Micro- and Nanotechnology, Technical University of Denmark, PAOLO A. MAIA NETO, H. MOYSES NUSSENZVEIG, Institute of Physics, Universidade Federal do Rio de Janeiro — We propose a perturbative calculation of the optical force exercised by a focused laser beam on a microsphere of arbitrary radius that is localized near a flat glass surface in a standard optical tweezers setup. Starting from the Mie-Debye representation for the electric field of a Gaussian laser beam, focused by an objective of high numerical aperture, we derive a recursive series that represents the multiple reflections that describe the reverberation of laser light between the microsphere and the glass slide. We present numerical results for the axial component of the optical force and the axial trap stiffness. Numerical results for a configuration typical in biological applications a microsphere of 0.5  $\mu$ m radius at a distance around 0.25  $\mu$ m from the surface show a 37% [1] Viana N B, Rocha M S, Mesquita O N, et al. (2007) Towards absolute calibration of optical tweezers. Phys Rev E 75:021914-114. [2] Dutra R S, Viana N B, Maia Neto P A, et al. (2014) Absolute calibration of forces in optical tweezers. Phys Rev A 90:013825-113.

**G1.00264 Hard X-ray Pump, X-ray Probe Spectroscopy of Single Crystals.<sup>1</sup>**, AARON LOETHER, MATT DECAMP, Univ of Delaware, DONALD WALKO, Argonne National Lab — Recent advancements in intense x-ray pulses have made it possible to perform hard x-ray pump probe spectroscopy. Inspired by optical pump probe, we've built a retroreflector for use with synchrotron based x-rays, using Germanium crystals at Bragg condition in place of mirrors, to control relative timing of x-ray pulses and perform time resolved measurements. Testing of multiple versions of the retroreflector was done both experimentally and via simulation; the comparison allows us to show efficiencies achievable theoretically and realistically. A proof of concept time resolved diffraction experiment on a Germanium 111 crystal was performed utilizing high intensity broadband x-ray pulses and the resulting heating and propagated strains were measured by low intensity monochromatic x-ray pulses.

**G1.00265 Observations of the high vibrational levels of the  $B''B^1\Sigma_u^+$  state of  $H_2$** , ROBERT EKEY, University of Mount Union, ALEXANDER CHARTRAND, Bryn Mawr College, WENQI DUAN, University of Iowa, ELIZABETH MCCORMACK, Bryn Mawr College — Double-resonance laser spectroscopy via the  $EF^1\Sigma_g^+, v' = 6, J' = 0 - 2$  state was used to probe the high vibrational levels of the  $B''B^1\Sigma_u^+$  state of molecular hydrogen. Resonantly-enhanced multiphoton ionization spectra were recorded by detecting ion production as a function of energy using a time of flight mass spectrometer. New measurements of energies for the  $v = 51 - 66$  levels for the  $B''B^1\Sigma_u^+$  state are reported, which, taken with previous results, span the  $v = 46 - 69$  vibrational levels. Results for energy levels are compared to theoretical calculations [L. Wolniewicz, T. Orlikowski, and G. Staszewska, J. Mol. Spec. 238, 118 (2006)]. The average difference between the 84 measured energies and calculated energies is  $-3.8 \text{ cm}^{-1}$  with a standard deviation of  $5.3 \text{ cm}^{-1}$ . This level of agreement showcases the success of the theoretical calculations in accounting for the strong rovibronic mixing of the  $^1\Sigma_u^+$  and  $^1\Pi_u^+$  states.

**G1.00267 QUANTUM INFORMATION, CONCEPTS AND COMPUTATION —**

**G1.00268 Geometric Decompositions of Bell Polytopes with Practical Applications**, PETER BIERHORST, National Institute of Standard and Technology, Boulder, CO — In the well-studied (2,2,2) Bell experiment consisting of two parties, two measurement settings per party, and two possible outcomes per setting, it is known that if the experiment obeys no-signaling constraints, then the set of admissible experimental probability distributions is fully characterized as the convex hull of 24 distributions: 8 Popescu-Rohrlich (PR) boxes and 16 local deterministic distributions. Here, we refine this result to show that in the (2,2,2) case, any nonlocal nonsignaling distribution can always be uniquely expressed as a convex combination of exactly one PR box and (up to) eight local deterministic distributions. In this representation each PR box will always occur only with a fixed set of eight local deterministic distributions with which it is affiliated. This decomposition has multiple applications: we demonstrate an analytical proof that the minimum detection efficiency for which nonlocality can be observed is  $2/3$  even for theories constrained only by the no-signaling principle, and we develop new algorithms that speed the calculation of important statistical functions of Bell test data. Finally, we enumerate the vertices of the no-signaling polytope for the (2, n, 2) "chained Bell" scenario and find that similar decomposition results are possible in this general case. Here, our results allow us to prove the optimality of a bound, derived in (Barrett et al., PRL, 2006) on the proportion of local theories in a local/nonlocal mixture that can be inferred from the experimental violation of a chained Bell inequality.

**G1.00269 Implementing entangling gates via quantum walks through branching graphs.**, DMITRY SOLENOV, THOMAS CAVIN, Department of Physics, Saint Louis University, St. Louis, MO 63103 — Efficient quantum gates are essential to quantum computing. It was found recently that quantum walks can enhance performance of quantum gates. We investigate how the propagation of a complicated, branching system can be solved analytically by first mapping it to linear chain. We found that certain types of systems, including systems of  $n$  qubits, can be algorithmically mapped to a system of disjoint linear chains. In particular, we found a solution for the 3 qubit system that performs either a trivial return walk or a return walk with a phase of  $\pi$  introduced.

**G1.00270 Error Threshold for the 4.6.12 Topological Color Code**, COLIN TROUT, Georgia Inst of Tech, SHOTA NAGAYAMA COLLABORATION<sup>1</sup> — Topological color codes are interesting candidates for fault-tolerant quantum computation. Relative to surface codes, color codes have a larger set of transversal gates, which reduces the resources required for state distillation to achieve universal quantum computation. Here we study a family of color codes defined by the 4.6.12 semi-regular lattice. We adapt a minimum weight perfect matching decoder to report an error threshold for the 4.6.12 topological color code under the circuit-based error model.

**G1.00277 The Quantum-Classical Boundary for Optical Interferometric Measurements** , PATRICK M. BIRCHALL, JONATHAN C. F. MATTHEWS, HUGO CABLE, Centre for Quantum Photonics, University of Bristol — We study the fundamental precision limits for measurements of optical phase when loss of probe light dominates the decoherence, and a limited number of photons are passed through the sample. It has long-been argued that non-classical states can be used to achieve an important advantage in precision in measurements of this sort, where it is not possible to use high-power laser light. As well as being of fundamental interest for understanding the ultimate physical limits for precision measurement, there are practical applications to measurements of delicate or photosensitive samples. Here we compare optimal measurement strategies using classical and non-classical probe states, where the number of passes through the unknown phase can be freely controlled. We find that the increase in precision that can be achieved using non-classical techniques is in fact small. Our results narrow the potential applications of measurements using non-classical states to cases where there is greater quantum advantage due to practical constraints on the measurements involved.

**G1.00279 Experimental realization of optimal control with robustness to coupling errors** , FEIHAO ZHANG, GUILU LONG, Tsinghua Univ — Optimal control theory is applied in quantum information processing for its ability to find objective evolution in complex quantum system. The negative factors, like the coupling to the environment, will impede the ideal evolution and increase their effect over time. In this work, we introduce a new method for finding objective propagator with robustness to coupling errors. The bath disturbance is analyzed by the time scale decomposition of spin dynamics. And the optimization is based on a gradient algorithm. We will give the experimental comparison between this robust optimal control method and the original one in spin system. Results show the advantage of this method in a noisy environment.

**G1.00280 Nonlinear Effects in Coupled Microtoroidal Optical Microcavities** , XIAOFEI LIU, GUI LU LONG, Tsinghua Univ, QUANTUM INFORMATION GROUP IN DEPARTMENT OF PHYSICS, THU TEAM — Nonlinear effect plays an important role in modern physics. Thanks to the great improvement of the fabrication technology, the quality factor of microcavities can reach more than 100 million. This gives rise to many amazing phenomena. Recently, a new kind of nonlinear effect, optomechanics, which involves the interaction between the photon and phonon, has made important progress both in experiment and theory. Here, we will study the nonlinear effect in coupled microcavities, and three-way electromagnetic induced transparency and so on.

**G1.00281 First-principles hyperfine tensors for electrons and holes in silicon and GaAs** , PERICLES PHILIPPOPOULOS, McGill University, STEFANO CHESI, Beijing Computational Science Research Center, WILLIAM COISH, McGill University — Knowing (and controlling) hyperfine interactions in silicon and III-V semiconductor nanostructures is important for quantum information processing with electron and nuclear spin states. We have performed density-functional theory (DFT) calculations that fully account for spin structure of the Bloch states (in contrast with approaches that rely on the density alone). Using this method, we confirm the known value for the contact hyperfine coupling in the conduction band of silicon, but find a significant deviation in the value for the conduction band of GaAs relative to the accepted value, estimated in ref. [1]. Moreover, this method can be used to calculate the full hyperfine tensor for the valence band, where spin-orbit effects may be strong, precluding methods that determine hyperfine couplings from the density alone. This general method can be applied to a broad class of materials with strong combined spin-orbit and hyperfine interactions. [1] D. Paget, G. Lampel, B. Sapoval, and V. I. Safarov Phys. Rev. B 15, 5780 (1977)

**G1.00282 Hyperfine interaction mediated electric-dipole spin resonance: The role of the frequency modulation<sup>1</sup>** , RUI LI, Beijing Computational Science Research Center — The electron spin in semiconductor quantum dot can be coherently controlled by an external electric field, an effect called electric-dipole spin resonance (EDSR). There are several mechanisms underlie the EDSR, among which there is a hyperfine mechanism, where the spin-electric coupling is mediated by the electron-nucleus hyperfine interaction. Here, we investigate the influence of the frequency modulation (FM) to the driving electric field on the spin-flip efficiency. Our results reveal that FM plays an important role in the hyperfine mechanism. Without FM, the electric field almost cannot flip the electron spin, the spin-flip probability is only about 20%. While under the FM, the spin-flip probability can be improved approximately to 70%. Especially, we find there is a lower bound on the modulation amplitude, which is related to the width of the hyperfine field fluctuation of the nuclear spins.

**G1.00283 Entangled Terahertz photon pair emitting diode with a HgTe quantum dot** , LI-KUN SHI, Beijing CSRC, KAI CHANG, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, P. R. China, CHANG-PU SUN, Beijing Computational Science Research Center, Beijing 100094, China — We propose an experimentally feasible scheme for generating entangled terahertz photons in topological insulator quantum dots (TIQDs). We demonstrate theoretically that in TIQDs with disorders and irregular shapes: 1) the fine structure splitting, which is the obstacle to produce entangled photons in conventional semiconductor quantum dots, is inherently absent for one-dimensional massless excitons due to the time-reversal symmetry; 2) the selection rules obey winding number conservation instead of the conventional angular momentum conservation between edge states with a linear dispersion. With these two advantages, the entanglement of the emitted photons during the cascade in our scheme is robust against unavoidable disorders and morphology fluctuations of the TIQD.

**G1.00284 Measure of the Quantum Speedup in Closed and Open systems<sup>1</sup>** , ZHEN-YU XU, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China — We construct a general measure for detecting the quantum speedup in both closed and open systems. This speed measure is based on the changing rate of the position of quantum states on a manifold with appropriate monotone Riemannian metrics. Any increase in speed is a clear signature of real dynamical speedup. To clarify the mechanisms of quantum speedup, we first introduce the concept of longitudinal and transverse types of speedup, and then apply the proposed measure to several typical closed and open quantum systems, illustrating that entanglement and the memory effect of the environment together can become resources for longitudinally or transversely accelerating dynamical evolution under certain conditions. Remarkably, a direct measurement of such speedup is feasible without the need for a tomographic reconstruction of the density matrix, which greatly enhances the feasibility of practical experimental tests.

**G1.00285 Has Macroscopic Superposition in Superconducting Qubits Really Been Demonstrated?** , ALAN M. KADIN, Princeton Junction, NJ, STEVEN B. KAPLAN, Estes Park, CO — Quantum computing depends on many qubits coupled via quantum entanglement, where each qubit must be a simultaneous superposition of two quantum states of different energies, rather than one state or the other as in classical bits. It is widely believed that observations of energy quantization and Rabi oscillations in macroscopic superconducting circuits prove that these are proper qubits with quantum superposition. But is this really the only interpretation? We propose a novel paradigm for macroscopic quantum systems, in which energies are quantized (with photon-mediated transitions), but the quantized states are realistic objects without superposition. For example, a circuit could make a transition from one quantized value of flux to another, but would never have both at the same time. We further suggest a superconducting circuit that can put this proposal to a test [1]. Without quantum superposition, most of the potential benefit of quantum computing would be lost. [1] A.M. Kadin and S.B. Kaplan (2014), "Superconducting Quantum Computing Without Entanglement?", <http://arxiv.org/abs/1408.5410>.

**G1.00286 A local realistic model of quantum information systems explaining the four Bell states** , JEFFREY BOYD, Retired — Can quantum computers and other information systems (like cryptography) be explained by local realism? The overwhelming consensus is NO. Thirty years of Bell test experiments proved Einstein, Podolsky and Rosen (EPR) wrong. Unknown to most physicists a new form of local realism has arisen, drastically different than EPR. The Theory of Elementary Waves (TEW) proposes that two entangled particles are both following the same elementary bi-ray. The same Bell test experiments that invalidate EPR, validate TEW. What is an elementary bi-ray? In TEW waves and particles usually travel in opposite directions. In entanglement experiments the picture is more complex. A bi-ray consists of two coaxial elementary rays, moving in opposite directions. Such bi-rays can explain all four Bell states on the basis of this peculiar form of local realism. Bell theory would classify TEW as nonlocal, even though it is local and realistic. The word nonlocal needs to be discarded, since elementary bi-ray is a more accurate and fertile descriptor of the same phenomena. TEW explains entanglement swapping heralding entanglement between distant spinning electrons in NV cavities, or trapped ions. The question is: So what? Would anything in quantum information science change if TEW were true? We think not.

**G1.00287 Quantum Dualism: Hypermind?** , R. JONES, Emporia State University — Today the consensus view is that thought and mind is a combination of processes like memory, generalization, comparison, deduction, organization, analogy, etc. performed by classical computational machinery. (R. Jones, Trans. Kansas Acad. Sci., vol. 109, 3/4, 2006) But I believe quantum mechanics is a more plausible dualist theory of reality. (R. Jones, Bull. Am. Phys. Soc., vol. 5, 2011) In a quantum computer the processing (thinking) takes place either in computers in Everett's many worlds or else in the many dimensional Hilbert space. (Depending upon your interpretation of QM.) If our brains were quantum computers then there might be a world of mind which is distinct from the physical world that our bodies occupy. (4 space) This is much like the spirit-body dualism of Descartes and others. My own view is that thought and mind are classical phenomena (see [www.robert-w-jones.com](http://www.robert-w-jones.com), philosopher, theory of thought and mind) but it would be interesting to run an artificial intelligence like my A.S.A. H. on a quantum computer. Might this produce, for the first time, a hypermind in its own universe?

**G1.00288  $P \neq NP$  Millenium-Problem(MP) TRIVIAL Physics Proof Via NATURAL TRUMPS Artificial-"Intelligence" Via: Euclid Geometry, Plato Forms, Aristotle Square-of-Opposition, Menger Dimension-Theory Connections!!! **G1.00289 A Practical Experiment to Obtain Either Which-Way or Interference Photon Distributions at a Distance Using Delayed Choice and Without Correlating Measurement Results on Entangled Photons** , DOUGLAS SNYDER, None — For a pair of entangled signal-idler photons, one may "lose" the idler photon (that provides which-way information to the entangled signal photon) in many other photons with similar characteristics to the idler photon before the signal photon is detected, thereby losing the which-way information supplied to the signal photon and eliminating the entanglement. The experiment allows for a delayed choice on the idler photons (whether or not to lose the idler photon before the signal photon is detected) to determine the distribution of distant signal photons (either overall which-way or overall interference) without making correlations between signal and idler photon detections. When the idler photon is lost, it is lost in an optical microcavity filled with photons in the same mode as the idler photon. The experiment could provide the basis for a useful quantum communications device. It might be possible to use a micropost coated with a material such as Vantablack in place of the optical microcavity.

**G1.00290 Quantum Entanglement in a two-atom two photon system** , SAMINA MASOOD, University of Houston Clear Lake — We study the quantum entanglement in a two atom and two photon system and show that the quantum entanglement can be used in quantum computation to develop more efficient systems.

**G1.00291 Quantum Knowledge Diagrams-2, Principles and Application** , DOUGLAS SNYDER, None — The principles behind quantum knowledge can be extracted from the specific empirical implementations so that pictorial elements can be developed representing fundamental concepts of quantum knowledge. With these elements, one can represent quantum knowledge principles underlying specific empirical implementations more simply and in a way that allows for a more direct comparison of quantum knowledge principles underlying various specific empirical implementations. These representations are quantum knowledge diagrams. Basic diagram elements include: 1) a which-way process; 2) a non-which-way process (showing interference); 3) availability of the which-way or non which-way information to the environment, generally through detection, or lack of such availability; 4) particles; 5) entanglement, or lack thereof, of 2 or more particles; 6) delayed choice. Quantum knowledge principles underlying specific empirical implementations are developed and diagrammed.

**G1.00292 MATTER AT EXTREME CONDITIONS** —

**G1.00293 New impact sensitivity test of liquid explosives.** <sup>1</sup>, ANDREI TIUTIAEV, Samara state technical university, VALERI TREBUNSKIY, Retired — The sensitivity of liquid explosive in the presence of gas bubbles increases many times as compared with the liquid without gas bubbles. Local hot spot in this case formed as a result of compression and heating of the gas inside the bubbles. If we consider that in the liquid as a result of convection, wave motion, shock, etc. gas bubbles are easily generated, the need to develop a method for determining sensitivity of liquid explosives to impact and a detailed study of the ignition explosives with bubbles is obvious. On a mathematical model of a single steam bubbles in the fluid theoretically considered the process of initiating explosive liquid systems to impact. For the experimental investigation, the well-known K-44 -II with the metal cap were used. Instead of the metal cap in the standard method in this paper there was polyurethane foam cylindrical container with LHE, which is easily deforms by impact. A large number of tests with different liquid explosives were made. It was found that the test LHE to impact with polyurethane foam to a large extent reflect the real mechanical sensitivity due to the small loss of impact energy on the deformation of the metal cap, as well as the best differentiation LHE sensitivity due to the higher resolution method.

<sup>1</sup>Results obtained in the samara state technical university

**G1.00294 Ultrafast laser diagnostics for understanding hot spot initiation in energetic materials**, IAN KOHL, DARCIE FARROW, SEAN KEARNEY, ROBERT KNEPPER, JEFFREY KAY, Sandia Natl Labs — Ultrafast laser diagnostics have opened new pathways for investigation of shock physics and initiation of energetic materials. Recent work (Bolme LANL/Armstrong LLNL) has demonstrated that short laser pulses can be utilized for direct laser drive and coupled with imaging, spectroscopic, and interferometric tools for studies of dynamic shock loading on picosecond time scales. At Sandia, we are developing diagnostic platforms which extend this earlier work by combining Ultrafast Shock Interferometry (USI) (Armstrong LLNL) and femtosecond transient absorption spectroscopy for tabletop measurement of Hugoniot/Equation-of-state data and characterization of shock structure in heterogeneous materials with micron spatial resolution while probing shock-induced changes in the electronic structure, which have been proposed to drive rapid chemical changes behind the shock front. We will describe the details of our measurement systems, as well as recent progress toward new laser-diagnostic data on inert/explosive thin-film samples.

**G1.00295 High Pressure Structures and Equations of State of HIO<sub>3</sub> and HI<sub>3</sub>O<sub>8</sub>**<sup>1</sup>, JOSEPH ZAUG, ELISSAIO STAVROU, Lawrence Livermore National Laboratory, BRIAN LITTLE, Air Force Research Laboratory - RWM, SORIN BASTEA, JONATHAN CROWHURST, Lawrence Livermore National Laboratory — Knowledge of high-pressure thermodynamic properties of iodine containing oxides and acids is important toward improving the accuracy of semi-empirical predictions of extreme condition explosive and combustive chemistry of iodine containing formulations. Here we report on the synthesis of explosive chemical products HIO<sub>3</sub> and HI<sub>3</sub>O<sub>8</sub> and on the structures and isotropic equations of state up to 35 and 45 GPa respectively. EOS model parameters are provided including parametrized exponential-6 interatomic potential values used to conduct thermochemical calculations of iodine containing reactants.

<sup>1</sup>This work was performed under the auspices of the U.S. Department of Energy jointly by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

**G1.00296 Anomalous bond length behavior and a new solid phase of bromine under pressure**, MIN WU, Zhejiang University of Technology, JOHN TSE, YUANMING PAN, University of Saskatchewan — The behavior of diatomic molecular solids under pressure have attracted great interests and been extensively studied. Under ambient pressure, the structure of bromine is known to be a molecular phase (phase I). With increasing pressure, it transforms into an incommensurate phase (phase V) before eventually to a monoatomic phase (phase II). However, between phases I and V, the interatomic distance was found to first increase with pressure and then decrease abruptly. This anomalous bond length behavior is accompanied by the splitting of the Raman bands. These phenomena have not been resolved. Here we suggest a new solid phase that explains the Raman spectra. Furthermore, the anomalous bond length behavior is found to be the result of subtle second neighbor intermolecular interactions and is an intrinsic property of bromine in molecular phases.

**G1.00297 Propagation of light in a Dense Medium.**, SAMINA MASOOD, University of Houston Clear Lake, IRAM SALEEM, University of Houston — Propagation of light is studied in a very dense system. Renormalization scheme of QED is used to understand the propagation of light in a hot and dense medium. We consider a medium of a very large chemical potential with relatively small temperature. The generalized results of vacuum polarization of photon in a hot and dense medium is used to study the behavior of light in such a system. Our hypothetical system corresponds to a heat bath of electrons at an equilibrium temperature and the density of electrons is larger as compared to the temperature of the medium. Such type of systems have previously been identified as classical systems because the chemical potential is large enough to dominate temperature.

**G1.00298 High Pressure synchrotron XRD and Raman studies of Ho<sub>0.5</sub>Y<sub>1.5</sub>Ti<sub>2</sub>O<sub>7</sub>.**<sup>1</sup>, MELANIE WHITE, RAVHI KUMAR, JASON BAKER, BRIAN LIGHT, Univ of Nevada - Las Vegas — Pyrochlore oxides are of interest for their spin-frustrated systems and their proposed use in high-level nuclear waste management. We sought to examine the structural stability of these materials under extreme conditions in order to help determine their viability for applications. A compression and decompression study of Ho<sub>0.5</sub>Y<sub>1.5</sub>Ti<sub>2</sub>O<sub>7</sub> was done in approximately 5 GPa intervals to above 55 GPa with both synchrotron powder x-ray diffraction at the Argonne National Laboratory Advanced Photon Source, and Raman spectroscopy at the University of Nevada - Las Vegas High Pressure Science and Engineering Center (HiPSEC). In both studies, pressurization of sample was achieved using a symmetric-style diamond anvil cell (DAC). The results are compared with the high pressure behavior of other rare earth titanates. A reversible phase transition is observed between 45 and 49 GPa in both studies. The x-ray diffraction patterns are analyzed in order to identify the crystal structure of the new phase. Vibrational modes are assigned to the Raman spectra and tracked as a function of pressure. Our poster will discuss the results in detail.

**G1.00299 PHYSICS OF CLIMATE —**

**G1.00300 A new model of the electron temperature in the topside ionosphere** , ZAHRA PANAH ESTARKHI<sup>1</sup>, ALI BAKHSHAYESHI<sup>2</sup>, Islamic Azad University of Mashhad — hra Panahi Estarkhi, Ali Bakhshayeshi *Young Researchers and Elite club, Mashhad Branch, Islamic Azad University, Mashhad, Iran Department of physics, Mashhad Branch, Islamic Azad University, Mashhad, Iran* -abstract- By using empirical models of electron density in the ionosphere, height equations as a function of electron density from  $\alpha$ -Chapman, Epstein and exponential functions have been achieved. Plotting the achieved height equations, the one derived from Epstein function has been known as the best fit for height. Locating height derived from Epstein function in an empirical function for electron temperature, a new empirical model for electron temperature as a function of electron density has been achieved and applied to obtain directly the electron temperature for every electron density in the topside ionosphere. Latitudinal and seasonal variations for Te have been plotted in the heights above hmF2 to 1000km to compare the new Te model with the previous empirical model and the measured data from the ISIS database. The results are compared and the possible reasons for difference and similarities are also discussed.

**G1.00301 Algorithms for ice halo detection in all-sky images**<sup>1</sup> , MICHELLE KING, MORTON GREENSLIT, SYLKE BOYD, University of Minnesota - Morris — The effect of cirrus clouds on the radiation budget of the atmosphere depends not only on optical depth and frequency of occurrence, but also on the composition of the clouds. Ice halo phenomena signal the presence of hexagonal crystal habits. Long-term observations on frequency, duration, and type of halo appearances can give ground-based insight into the behavior of cirrus composition. We are capturing images of the entire sky at 30 second intervals using an all-sky camera. We have created a program that analyzes these images for the presence of halos. The algorithm removes the lens distortion, excludes low-level clouds from further analysis, measures the radial RGB color channel intensity, and uses this radial intensity to assess for ice halo presence. We will present our algorithms for image analysis, including removing the lens distortion and low-level clouds, as well as the algorithm to assign a halo probability. We will also present our observation results for the year 2015.

**G1.00302 Construction of a low-cost LIDAR for cirrus cloud observations**<sup>1</sup> , BRITTNEY FERRIAN, KEVIN J BOYD, SYLKE BOYD, University of Minnesota - Morris — Our physical understanding of the Earth's climate is critically linked to our quantitative understanding of cloud coverage and behavior. In particular, cirrus clouds are pivotal players in the radiation balance of the Earth. We have taken a route to capture the characteristics of cirrus clouds using an all-sky camera, and analyzing halo phenomena. That gives us a 2d distribution of the cloud. Neither altitude nor optical thickness can be determined from photographs alone. We are interested in combining altitude and thickness information with the brightness information gathered in images. That requires that the Lidar measures are taken at the time at which a halo photograph is taken. A simple LIDAR instrument with cheap and readily available components is being constructed for this purpose. We will present the layout of the instrument design, challenges in construction and weather-proofing and preliminary measurement results.

**G1.00303 Measurement of Water Vapor in the Lower Troposphere Using LIDAR** , FRANCIS MENSAH<sup>1</sup>, Virginia Union University, Richmond, VA, PETER INSTIFUL<sup>2</sup>, Prairie View A & M University, Houston, TX, ARTHUR THORPE<sup>3</sup>, Howard University — Water vapor is an important atmospheric variable which plays a key role in air quality, global warming, and climate change. It is known as a highly variable atmospheric constituent. Moreover, water vapor remains one of the most poorly characterized meteorological parameters. For example, water vapor measurements have proven to be difficult below 500 m in the lower troposphere. The overlap which exists between the incident laser beam and the receiver FOV is a factor affecting the lidar observation in the near field range. Because of its particular importance in tropospheric processes and the extraordinary ability of Raman Lidar through the SOLEX system to sense accurately its high temporal and spatial structure in the atmosphere, we present here some particular details about the use of Raman Lidar SOLEX system to measure water vapor at lower atmosphere at several fixed ranges. A comparison is made between data obtained from the laser system and the ones obtained from calibrated temperature and relative humidity's sensors at the same location.

**G1.00304 Effect of Seasonal Variation of Anomalous Condition on Radio Propagation in Nigeria** , ISRAEL EMMANUEL, BABATUNDE ADEYEMI, EMMANUEL OGOLO, ADEKUNLE ADEDIJI, Federal University of Technology Akure Nigeria — Daily variation of effective earth radius factor and seasonal variation of refractivity gradients from surface to around 1000 m above ground level in the tropospheric layer are presented based on observation from the meteorological data obtain from ECMWF database. Thirty four years (1979 -2014) of data from surface and profile of Era Interim of the temperature and relative humidity are used to determine the surface anomalous propagation over some selected location I Nigeria. Estimation of anomalous propagation are observed for onset and peak of rainy and dry seasons. The occurrence of anomalous strongly depends on the local time and synoptic weather conditions which have an appreciable on the refractivity vertical profile, especially the seasonal north – south movement of inter tropical Convergence Zone (ITCD) which provide wet and dry seasonal variations of anomalous were also determined. Spatial distribution of refractivity gradient for both wet and dry seasons are also obtained. The highest occurrence of duct were noticed in the night and morning (00:00 UTC and 06:00UTC) across the country though it was low in the northern part of the country, while low or no occurrence of duct were observed in the afternoon and evening (12:00 UTC and 18:00 UTC). Also percentage occurrence of duct were also high and low during the wet and dry seasons respectively.

### **G1.00306 Charge Content In Nanometer Rings from Atomic Force Microscope (AFM) Traces<sup>1</sup>**

, F. ZYPMAN, Yeshiva University, S. EPPPELL, Case Western Reserve University, M. FEINSTEIN, Y. FRIED, D. LAZAREV, C. METZGER, Yeshiva University — The last few years have seen a growing interest in identifying charge content in small structures such as graphene ribbons and aromatic borings. More generally it is believed that charge content in proteins holds the key to the ultimate understanding of biological self-assembly. Here we describe a model system, a charged ring inside liquid probed by an AFM tip, and show how the charge content and the relative size of the ring with respect to the tip affect the measured force. More importantly, we explain how to measure the charge from the AFM experimental data [1]. The process involves the modeling of the dynamics of the tip-cantilever sensor under the influence of the charged sample, but also of ambient hydrodynamic forces, electrostatic interactions that appear due to charge induction in the tip and electrolytic screening. Of particular relevance is the possibility of our approach to treat analytically the size of ions. This is relevant when the tip-sample distance becomes sub-nanometric, and the more common description via Poisson-Boltzmann equation breaks down. [1] Mehlman and F.R. Zypman, Scanning Probe Microscope Force Reconstruction Algorithm via Time-Domain Analysis of Cantilever Bending Motion, J. Adv. Microsc. Res. 9, 268-274 (2014).

### **G1.00307 Analyzing qPlus sensor assemblies for optimized simultaneous scanning tunneling and non-contact atomic force microscopy operation using finite element method**

, OMUR DAGDEVIREN, UDO SCHWARZ, Yale University — Scanning tunneling microscopy (STM) and non-contact atomic force microscopy (NC-AFM) are powerful methods that can not only visualize a surface's atomic structure, but also probe its electronic and chemical properties with picoampere, piconewton, and picometer resolution. Quartz tuning forks in qPlus configuration that have a metallic probe tip attached to the end of the free prong have gained considerable popularity in recent years for simultaneous high-resolution STM/NC-AFM experiments. Due to the small size of the tuning forks and the complexity of the sensor architecture, it is, however, not intuitive to judge how variations in the execution of the individual assembly steps affect the completed sensor's performance. In this presentation, we analyze the influence of each assembly step on the sensor's final performance using finite element method. The results show that when the tunneling current is collected using a separate wire, the exact realization of this wire connection has major effect on the sensor's performance. In addition, we show how other design choices such as the exact amount of epoxy used at key interfaces affects parameters such as spring constant,  $Q$ -factor, and resonance frequency.

### **G1.00308 Angle-Resolved Light-Matter Interaction in Anisotropic Layered Black Phosphorus**

, SHENGXI HUANG, XI LING, MIT, EDDWI HASDEO, Tohoku University, LIANGBO LIANG, RPI, ORNL, WILLIAM PARKIN, UPenn, YUKI TATSUMI, AHMAD NUGRAHA, Tohoku University, ALEXANDER PURETZKY, ORNL, PAUL DAS, UPenn, BOBBY SUMPTER, DAVID GEOHEGAN, ORNL, JING KONG, MIT, RIICHIRO SAITO, Tohoku University, MARIJA DRNDIC, UPenn, VINCENT MEUNIER, RPI, MILDRED DRESSELHAUS, MIT — Orthorhombic black phosphorus (BP) and other layered materials, such as gallium telluride and tin selenide, stand out among two-dimensional (2D) materials owing to their anisotropic in-plane structure. This anisotropy adds a new dimension to the properties of 2D materials and stimulates the development of angle-resolved photonics and electronics. However, understanding the effect of anisotropy has remained unsatisfactory to-date, as shown by a number of inconsistencies in the recent literature. We use angle-resolved absorption and Raman spectroscopies to investigate the role of anisotropy on the electron-photon and electron-phonon interactions in BP. We highlight, both experimentally and theoretically, a non-trivial dependence between anisotropies and flake thickness, photon and phonon energies. We show that the anisotropic optical absorption is a reliable and simple way to identify the crystalline orientation of BP, which cannot be determined from Raman spectroscopy without the explicit consideration of excitation wavelength and flake thickness.

### **G1.00309 Open-Source Programming for Automated Generation of Graphene Raman Spectral Maps<sup>1</sup>**

, P. VENDOLA, M. BLADES, W. PIERRE, S. JEDLICKA, S.V. ROTKIN, Lehigh University — Raman microscopy is a useful tool for studying the structural characteristics of graphene deposited onto substrates. However, extracting useful information from the Raman spectra requires data processing and 2D map generation. An existing home-built confocal Raman microscope was optimized for graphene samples and programmed to automatically generate Raman spectral maps across a specified area. In particular, an open source data collection scheme was generated to allow the efficient collection and analysis of the Raman spectral data for future use.

<sup>1</sup>NSF ECCS-1509786

### **G1.00310 Effects of magnetic field and pressure in magnetoelastic stress reconfigurable thin film resonators for magnetic field sensing**

, PETER FINKEL, MARGO STARUCH, Naval Research Laboratory — The magnetic response of microdevices is significantly enhanced at structural resonance allowing for improved sensitivity and signal-to-noise ratio. The magnetic field resolution of these devices can be further improved when operating in vacuum due to an increase in mechanical quality factor. In this work, free-standing CoFe thin film doubly clamped stress reconfigurable resonators were investigated as a function of magnetic field and pressure. A large uniaxial anisotropy resulting from residual uniaxial tensile stress was revealed from magnetic hysteresis loops with the easy magnetization axis aligned along the length of the beams. The quality factor of the driven resonator beams under vacuum is increased by 30 times which is expected to lead to improved signal to noise ratio, combined with a predicted reduction in the intrinsic magnetic noise by a factor of 6 potentially reaching as low as  $\sim 25$  pT/ $\sqrt{\text{Hz}}$  at 1 Torr. Stress reconfigurable sensors operating under vacuum could thus further improve the limit of detection and advance development of magnetic field sensing technology.

### **G1.00311 Fabrication and performance analysis of a simple, cost-effective copper oxide / zinc oxide semiconductors composite for gas sensing**

, RAFAEL VELAZQUEZ, MANUEL RIVERA, ERIC LI, PETER FENG, University of Puerto Rico — We report on our studies of composite zinc oxide semiconductor (COS) nanoparticles as sensing materials for the development of high-performance gas sensors. The average diameter of the nanoparticles is 40 nm. The basic electrical properties of sensing materials have been measured. The morphologic surface and crystalline structures of COS are characterized by using scanning electron microscopy (SEM) and Raman scattering spectroscopy, respectively. By using synthesized COS of CuO-ZnO materials, prototypic highly sensitive gas sensors have been designed, fabricated and tested. Important stability and repeatability features have been obtained. The sensitivities of the COS based sensors to methane and hydrogen gases as a function of time and the gas concentrations have been determined. Various sensing parameters including the sensitivity, response time, recovery time, and thermal effect on the gas sensor performance have also been investigated in order to reveal the sensing ability. Analyses of experimental data indicate that the obtained response and recovery are almost 10 times faster than conventional sensors constructed solely from one material.

**G1.00312 Microfabrication of Arrays of Superconducting Transition Edge Sensors for CMB Measurements**, CHRYSTIAN POSADA, JUNJIA DING, AMY BENDER, TRUPTI KHAIRE, Argonne National Laboratory, SERGI LENDINEZ, Universitat de Barcelona, SAMUEL CIOCYS, University of California, Berkeley, GENSHENG WANG, VOLODYMYR YEFREMENKO, Argonne National Laboratory, STEVE PADIN, JOHN CARLSTROM, University of Chicago, CLARENCE CHANG, VALENTINE NOVOSAD, Argonne National Laboratory, SPT3G COLLABORATION<sup>1</sup> — The cosmic microwave background (CMB) provides a unique window for exploring fundamental physics. Increasing the sensitivity of CMB experiments requires fabricating focal planes with orders of magnitude more detectors than current instruments. This work presents the procedures used at Argonne National Laboratory for the fabrication of large arrays of dual-polarized multichroic detectors for CMB measurements. The detectors are composed of a broad-band sinuous antenna coupled to a Nb microstrip transmission line. In-line filters define the spectral response, allowing for individual measurement of three band-passes (95 GHz, 150GHz and 220 GHz). A Ti /Au termination resistor is used to couple the mm-wave signal to Ti/Au transition edge sensor (TES) bolometers. There are six bolometers per pixel, for a total of 16,140 detectors in the CMB receiver being fabricated. The monolithic microfabrication of the detector arrays will be presented and discussed in detail.

<sup>1</sup>The SPT3G collaboration is developing the third-generation camera for CMB measurements with the South Pole Telescope. Additional information can be found in the following link: <https://pole.uchicago.edu/spt/>

**G1.00313 Measurement of the low energy spectral contribution in coincidence with valence band (VB) energy levels of Ag(100) using VB-VB coincidence spectroscopy**<sup>1</sup>, R.W. GLADEN, P.V. JOGLEKAR, Z.H. LIM, K. SHASTRY, Univ of Texas, Arlington, S.L. HULBERT, Brookhaven National Laboratory, A.H. WEISS, Univ of Texas at Arlington — A set of coincidence measurements were obtained for the study and measurement of the electron contribution arising from the inter-valence band (VB) transitions along with the inelastically scattered VB electron contribution. These Auger-unrelated contributions arise in the Auger spectrum (Ag 4p VVV) obtained using Auger Photoelectron Coincidence Spectroscopy (APECS). The measured Auger-unrelated contribution can be eliminated from Auger spectrum to obtain the spectrum related to Auger. In our VB-VB coincidence measurement, a photon beam of energy 180eV was used to probe the Ag(100) sample. The coincidence spectrum was obtained using two Cylindrical Mirror Analyzers (CMA's). The scan CMA measured the low energy electron contribution in the energy range 0-70eV in coincidence with VB electrons measured by the fixed CMA. In this talk, we present the data obtained for VB-VB coincidence at the valence band energy of 171eV along with the coincidence measurements in the energy range of 4p core and valence band.

**G1.00314 Simulation-based Extraction of Key Material Parameters from Atomic Force Microscopy**<sup>1</sup>, HUSEEN ALSAFI, GRAY PENNINGTON, Towson Univ — Models for the atomic force microscopy (AFM) tip and sample interaction contain numerous material parameters that are often poorly known. This is especially true when dealing with novel material systems or when imaging samples that are exposed to complicated interactions with the local environment. In this work we use Monte Carlo methods to extract sample material parameters from the experimental AFM analysis of a test sample. The parameterized theoretical model that we use is based on the Virtual Environment for Dynamic AFM (VEDA) [1]. The extracted material parameters are then compared with the accepted values for our test sample. Using this procedure, we suggest a method that can be used to successfully determine unknown material properties in novel and complicated material systems.

<sup>1</sup>We acknowledge Fisher Endowment Grant support from the Jess and Mildred Fisher College of Science and Mathematics, Towson University.

**G1.00315 Modeling of the energy resolution of a 1 meter and a 3 meter time of flight positron annihilation induced Auger electron spectrometers.**<sup>1</sup>, A FAIRCHILD, V CHIRAYATH, R GLADEN, A MCDONALD, Z LIM, M CHRYSLER, A KOYMEN, A WEISS, Univ of Texas, Arlington — Simion 8.1® simulations were used to determine the energy resolution of a 1 meter long Time of Flight Positron annihilation induced Auger Electron Spectrometer (TOF-PAES). The spectrometer consists of: 1. a magnetic gradient section used to parallelize the electrons leaving the sample along the beam axis, 2. an electric field free time of flight tube and 3. a detection section with a set of ExB plates that deflect electrons exiting the TOF tube into a Micro-Channel Plate (MCP). Simulations of the time of flight distribution of electrons emitted according to a known secondary electron emission distribution, for various sample biases, were compared to experimental energy calibration peaks and found to be in excellent agreement. The TOF spectra at the highest sample bias was used to determine the timing resolution function describing the timing spread due to the electronics. Simulations were then performed to calculate the energy resolution at various electron energies in order to deconvolute the combined influence of the magnetic field parallelizer, the timing resolution, and the voltage gradient at the ExB plates. The energy resolution of the 1m TOF-PAES was compared to a newly constructed 3 meter long system. The results were used to optimize the geometry and the potentials of the ExB plates for obtaining the best energy resolution.

<sup>1</sup>This work was supported by NSF grant NSF grant No. DMR 1508719 and DMR 1338130

**G1.00316 Spectra of electrons emitted as a result of the sticking and annihilation of low energy positrons to the surfaces of graphene and highly oriented pyrolytic graphite (HOPG)**<sup>1</sup>, M CHRYSLER, V CHIRAYATH, A MCDONALD, Z LIM, K SHASTRY, R GLADEN, A FAIRCHILD, A KOYMEN, A WEISS, University of Texas at Arlington — Positron annihilation induced Auger electron spectroscopy (PAES) was used to study the positron induced low energy electron spectra from HOPG and a sample composed of 6-8 layers of graphene grown on polycrystalline copper. A low energy (~2eV) beam of positrons was used to implant positrons into a surface localized state on the graphene and HOPG samples. Measurements of the energy spectra of the positron induced electrons obtained using a TOF spectrometer indicate the presence of an annihilation induced KLL C Auger peak (at ~263 eV) along with a narrow low energy secondary peak due to an Auger mediated positron sticking (AMPS) process. A broad spectral feature was also observed below ~15 eV which we believe may be due to a VVV C Auger transition not previously observed. The energy dependence of the integrated intensity of the AMPS peak was measured for a series of incident positron kinetic energies ranging from ~1.5 eV up to 11 eV from which the binding energy of the surface localized positron state on graphene and HOPG was estimated. The implication of our results regarding the applicability of AMPS and PAES to the study of graphene surfaces and interfaces will be discussed.

<sup>1</sup>This work was supported by NSF grant No. DMR 1508719 and DMR 1338130

**G1.00317 Scanning SQUID microscopy in a cryogen-free refrigerator**, BRIAN T. SCHAEFER, DAVID LOW, LASSP/Department of Physics, Cornell University, Ithaca, New York, USA, GUENEVERE E. D. K. PRAWIROATMODJO, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark, J. KEVIN NANGOI, JIHOON KIM, KATJA C. NOWACK, LASSP/Department of Physics, Cornell University, Ithaca, New York, USA — With helium prices rising and supply becoming increasingly uncertain, it has become attractive to use dry cryostats with cryocoolers rather than liquid helium to reach low temperatures. However, a cryocooler introduces vibrations at the sample stage, making scanning probe experiments more challenging. Here, we report our progress on a superconducting quantum interference device (SQUID) microscope implemented for the first time in a compact, cryogen-free 5 K system. Our microscope is designed to reach submicron spatial resolution and a flux sensitivity of approximately  $1 \mu\Phi_0/\sqrt{\text{Hz}}$ , where  $\Phi_0$  is the magnetic flux quantum. To enable height feedback while approaching and scanning samples, we mount the SQUID on a quartz tuning fork. Our system promises to meet the capabilities of similar systems implemented in helium cryostats.

**G1.00318 Refocusing and high field generation of terahertz radiation in two-color laser filamentation**<sup>1</sup>, YUNGGUN YOO, DONGHOON KUK, KI-YONG KIM, Univ of Maryland-College Park — We have demonstrated strong terahertz (THz) field generation by using femtosecond two-color laser mixing in air. In this experiment, we have tested THz energy scaling and refocusing by varying the lens focal length from 200 mm to 1 m. We find that the output THz energy greatly enhances with increasing focal length (or plasma filament length), which is consistent with previous reports. In addition, contrary to our previous concern that long filamentation may yield more THz energy but unfavorably increase the focused spot size, both short and long filamentation provide small spot sizes (35–50 microns in FWHM). This implies that the peak field 8 MV/cm, previously achieved with a 200 mm focal length, can be greatly enhanced with long filamentation and tight refocusing. In addition, for real-time THz beam profiling, an uncooled microbolometer camera is used with lock-in detection, providing enhanced signal-to-noise ratios at a broad range of THz (1–40 THz) frequencies.

<sup>1</sup>Work supported by DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award No. 014216-001

**G1.00319 Generation of scalable terahertz radiation from cylindrically focused laser pulses in air**<sup>1</sup>, DONGHOON KUK, YUNGGUN YOO, ERIC ROSENTHAL, NIHAL JHAJJ, HOWARD MILCHBERG, KI-YONG KIM, Univ of Maryland-College Park — We have demonstrated scalable terahertz (THz) generation via cylindrical focusing of two-color laser pulses in air. In this experiment, we have used a terawatt (TW) laser system which can deliver >50 mJ, 800 nm, 50 fs pulses at a 10 Hz repetition rate. A 800 nm pulse passing through a nonlinear crystal (BBO) generates its second harmonic pulse (400 nm). Both pulses pass through a cylindrical lens and are focused together to generate a 2-dimensional plasma sheet in air. This yields two diverging THz lobes, characterized by an uncooled microbolometer. This observed radiation angle and pattern is explained by the optical-Cherenkov radiation theory. The diverging THz radiation is re-focused to yield strong THz field strengths (>20 MV/cm) at the focus. At laser energy of 40 mJ, cylindrical focusing provides THz energy of >30 microjoules, far exceeding the output produced by spherical focusing. This shows that cylindrical focusing can effectively minimize ionization-induced defocusing, previously observed in spherical focusing, and can allow scalable THz generation with relatively high laser energies (>20 mJ).

<sup>1</sup>Work supported by DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award No. 014216-001

**G1.00320 Interaction of high density, thin, gas jets with ultrashort laser pulses at 1 kHz repetition rates**<sup>1</sup>, YAN TAY, DONGHOON KUK, HOWARD MILCHBERG, KI-YONG KIM, Univ of Maryland-College Park — We have investigated the interaction of thin (50–150 microns), high-density ( $10^{19}$ – $10^{21}$  cm<sup>-3</sup>) gas jets with 30 fs, >5 mJ, 800 nm laser pulses at a 1 kHz repetition rate. Capillary tubes with various diameters (50–500 microns) are used to produce dense gas jets in continuous flow at high backing pressure (~1000 psi) and cryogenic temperature (130 K). The gas/plasma density profiles are characterized by optical interferometry, and Rayleigh/Mie scattering is measured to characterize coexisting atomic clusters. Our result shows a peak plasma density of  $10^{21}$  cm<sup>-3</sup> near the nozzle orifice, approaching the critical plasma density at 800 nm laser wavelength. This high density plasma efficiently produces X-rays and terahertz radiation, as well as energetic electrons and ions at high-repetition-rates (kHz), without generating unwanted debris as in solid targets.

**G1.00321 Ultrasmall Angle X-ray Scattering (USAXS) and Wide Angle X-ray Scattering (WAXS) Studies on the Complex Metal Hydride NaAlH<sub>4</sub>**, TABBETHA DOBBINS, CHRISTOPHER BENNETT<sup>1</sup>, JAMES TORRES, Rowan University, Dept. of Physics & Astronomy, JAN ILAVSKY, Argonne National Laboratory, Advanced Photon Source — This research seeks to understand the role of ScCl<sub>3</sub>, ZrCl<sub>4</sub>, and VCl<sub>3</sub> catalysts in NaAlH<sub>4</sub>. We have examined these hydrides at multiple length scales using an X-ray scattering instrument which is capable of measuring scattering wave vector, Q, of 0.0001 Å<sup>-1</sup> to 6.0 Å<sup>-1</sup>. The ultrasmall angle X-ray scattering (USAXS) instrument sector 9ID-D of the Advanced Photon Source (APS) simultaneously collects using USAXS, SAXS, and WAXS detectors. Studies were performed during in-situ heating up to 170°C (just below the H desorption temperature for uncatalyzed NaAlH<sub>4</sub>). Results showed that NaAlH<sub>4</sub> has a surface fractal (highly porous) morphology. Isothermal studies performed at 30°C, 65°C, 100°C, 135°C, and 170°C reveals changes at low Q (Q~0.001 Å<sup>-1</sup> to 0.01 Å<sup>-1</sup>) associated with highly interconnected intraparticle porosity which is suitably described by a power-law slope for a Gaussian polymer chain structure of p~2. At high scattering wave vector, Q~0.03 Å<sup>-1</sup>, the presence of a pore population which obeys Porod scattering and appears to have a size at 21 nm is present. These fine pores increase in their population density as temperature is elevated. The WAXS data reveals thermal expansion to occur, but no solid state phase transformation to the product phase.

**G1.00322 Adaptive measurement of spin decoherence time  $T_2$** , YIHAO ZHANG, WEN YANG, Beijing Computational Science Research Center — Spin decoherence time  $T_2$  is an important parameter in quantum mechanics. In order to estimate it accurately and efficiently, we propose a scheme for spin decoherence time  $T_2$  estimation of a single spin using adaptive measurement. While the ordinary scheme of measuring  $T_2$  yield an estimate precision scales with mean-square error  $\sim 1/\sqrt{N}$  (N is the number of measurements). We present some simulated measurement which shows that the adaptive scheme, that is, the time between measurements was depended on the prior measurement results, will give a better scaling than MSE.

**G1.00323 Single-shot ultrafast interferometric imaging**<sup>1</sup>, DAIWEI ZHU, DONGHOON KUK, KI-YONG KIM, Univ of Maryland-College Park — We have developed a new interferometric method capable of capturing 2-dimensional, time-varying phase and amplitude profiles in a single shot. Most single-shot interferometry provides one-dimensional spatial information as demonstrated in detecting laser-produced transients, phase transition, and plasma generation. By contrast, our new method can provide 2-dimensional spatial information at multiple time delays in a single shot. In this scheme, we analyze the limits of spatial and temporal resolution and have tested the working principle with a computer simulation. This new diagnostic holds a great potential in study ultrafast phenomena occurring on sub-picosecond time scales.

BASAK, Department of Physics, University of Rajshahi, Rajshahi-6205, Bangladesh — The differential, integrated elastic, total and momentum transfer cross sections with Sherman functions for the elastic scattering of electrons and positrons by cadmium atom have been calculated. These calculations are done within the framework of complex electron/positron-atom optical potential and relativistic Dirac partial wave analysis at energies 6.4 to 1000 eV for both electrons and positrons impact. Our results are compared with available experimental and other theoretical cross section values. Details of our findings will be presented at the conference. \*) BCSaha is thankful to NNSA for partial support.

**G1.00325 Low energy  $C^{6+} + H_2$  scattering: Molecular Close-Coupling Treatment\*)** \pard\pard<sup>1</sup> , BIDHAN SAHA, Department of Physics, Florida AM University, Tallahassee, FL-32307. — h —abstract—\pard Collisions of multiply charged ions with molecules are very common in astrophysical plasmas[1]. The ion-molecule calculations are rather more complicated than their atomic counter part. For multi charged ions in X-ray ionized astronomical environments the charge exchange provides a recombination mechanism. To understand this detailed information on the collision cross sections is essential. In highly charged ion-molecule problem the Coulomb term plays an important role; using a pseudo-diatomic technique the colliding system can be approximated by a model potential for the ionic core of  $H_2$  with encouraging results [2-5]. Freezing the target,  $H_2$  can easily be treated as an atom with appropriate ionization potential (Ip). Our results show good agreement with available experimental findings.\pard[1] B. C. ## G1.00326 GENERAL PHYSICS —

**G1.00327 Absolute Summ** , ALFRED PHILLIPS JR., Source Institute — Summ means the entirety of the multiverse. It seems clear, from the inflation theories of A. Guth and others, that the creation of many universes is plausible. We argue that Absolute cosmological ideas, not unlike those of I. Newton, may be consistent with dynamic multiverse creations. As suggested in W. Heisenberg's uncertainty principle, and with the Anthropic Principle defended by S. Hawking, et al, human consciousness, buttressed by findings of neuroscience, may have to be considered in our models. Predictability, as A. Einstein realized with Invariants and General Relativity, may be required for new ideas to be part of physics. We present here a two postulate model geared to an Absolute Summ. The seedbed of this work is part of Akhnaton's philosophy (see S. Freud, Moses and Monotheism). Most important, however, is that the structure of human consciousness, manifest in Kenya's Rift Valley 200,000 years ago as Homo sapiens, who were the culmination of the six million year co-creation process of Hominins and Nature in Africa, allows us to do the physics that we do. .

**G1.00328 Analysis about the force of electrons revolve around the nucleus** , HAN YONGQUAN, 15611860790 — 1, Let's compare the difference of two algorithms: the electrostatic force between protons and electrons,  $F_1 = ke^2 / r^2$ ,  $r$  is the radius of the electron around the nucleus movement – within  $10^{-10}$  meters; Electronic movement speed is close to the light- about  $10^7$  meters per second, the size of the centripetal force  $F_2 = v^2 m / r$ .  $F_1$  should be approximately equal to  $F_2$ , calculate the ratio of  $F_1$  and  $F_2$ ,  $F_2 / F_1 = (v^2 m / r) (ke^2 / r^2) / = (10^7 * 10^7 * 0.91 * 10^{-30} / r) / (9 * 10^9 * 1.6 * 10^{-19} * 1.6 * 10^{-19} / r^2) = 4 \times 10^3$ . The calculation shows that not only the electrostatic force and other force. 2, The radius of the electron orbiting around the nucleus named  $r$ ,  $F = Ke^2 / r^2 = 9 \times 10^9 \times 1.6 \times 10^{-19} / r^2 = v^2 m / r$ ,  $r = 2.5 \times 10^{-14}$  meters, namely that the radius of hydrogen atom is about  $2.5 \times 10^{-14}$  meters, that is different with the observed result ( $10^{-10}$  meters). Electrons revolve around the nucleus may faster than  $10^7$  m/s, can almost reach  $10^8$  meters per second, if the electronic moves by  $10^8$  meters per second, hydrogen atom radius is approximately  $2.5 \times 10^{-16}$  meters, has converged in the interior of the nucleus, it is not possible. Use density to instead of electricity, can solve this problem. Author: hanyongquan TEL: 15611860790

**G1.00329 Nuclear Structure of the Noble Gas** , NAKYEONG SEONG, life and light institute — Modern physics usually pictures the nuclear structure as about sphere and treats various detailed situation as perturbative, which may be obscured. In addition, the explanation why <sup>235</sup>U undergoes nuclear fission and <sup>238</sup>U does not is too difficult and unclear for the people to understand. However, in this paper, we introduce a new approach on the nuclear structure of the noble gas, which simultaneously can explain several phenomena that is obscurely elucidated by modern physics. We consider a 1:1 ratio between protons and neutrons and need the concept of the symmetry of the nuclear structure, because the electron's shell of the noble gas is fully occupied. From these, we can predict the number of neutrons of each noble gas exactly

**G1.00330 Negative Casimir entropies** , YANG LI, KIMBALL MILTON, Univ of Oklahoma — In the last decade, various results on the entropy related to the Casimir interactions between two bodies have been obtained and the striking feature that negative values of Casimir entropy frequently appear. The origin of this effect lies in many factors, such as the dissipation of the materials, the geometry of the configuration and so on. We recently investigated the entropies of one body systems. Although the self-free energy of one body systems are always divergent, the self-entropy could be finite in many cases. These phenomenon may throw more light on thermal dynamical behavior of quantum field systems.

## G1.00331 ABSTRACT WITHDRAWN —

**G1.00332 Number relativity** , PHILIP SHIN<sup>1</sup>, None — Number relativity 1. Every equation of the relativity is just the way to understand through to solve one question of the math problem. We just add the hypothesis into the number. 2. Sequence of number is the machine physics for software(computer) as the number order is program equation as calculator. 3. When zero is denominator, it is not existing as it is doing something by nothing. So nothing means time as we put zero denominator into time.

<sup>1</sup>My personal physics imagine.

**G1.00333 Kelvin Absolute Temperature Scale Identified as Length Scale and Related to de Broglie Thermal Wavelength.** , SIAVASH SOHRAB, Northwestern University — Thermodynamic equilibrium between matter and radiation leads to de Broglie wavelength  $\lambda_{d\beta} = h/m_{\beta}v_{r\beta}$  and frequency  $\nu_{d\beta} = k/m_{\beta}v_{r\beta}$  of matter waves and stochastic definitions of Planck  $h = h_k = m_k < \lambda_{rk} > c$  and Boltzmann  $k = k_k = m_k < \nu_{rk} > c$  constants,  $\lambda_{rk}\nu_{rk} = c$ , that respectively relate to spatial ( $\lambda$ ) and temporal ( $\nu$ ) aspects of vacuum fluctuations. Photon mass  $m_k = \sqrt{hk/c^3}$ ,  $amu = \sqrt{hkc} = 1/N^o$ , and universal gas constant  $R^o = N^o k = \sqrt{k/hc}$  result in internal  $U_k = Nh\nu_{rk} = Nm_k c^2 = 3Nm_k v_{mpk}^2 = 3NkT$  and potential  $pV = uN\hat{v}/3 = N\hat{u}/3 = NkT$  energy of photon gas in *Casimir vacuum* such that  $H = TS = 4NkT$ . Therefore, Kelvin absolute thermodynamic temperature scale [degree K] is identified as length scale [meter] and related to most probable wavelength and de Broglie thermal wavelength as  $T_{\beta} = \lambda_{mp\beta} = \lambda_{d\beta}/3$ . Parallel to Wien displacement law obtained from Planck distribution, the displacement law  $\lambda_w S T = c_2/\sqrt{3}$  is obtained from Maxwell–Boltzmann distribution of speed of “photon clusters”. The propagation speeds of sound waves in ideal gas versus light waves in photon gas are described in terms of  $v_{r\beta}$  in harmony with perceptions of Huygens. Newton formula for speed of long waves in canals  $\sqrt{p/\rho}$  is modified to  $\sqrt{gh} = \sqrt{\gamma p/\rho}$  in accordance with adiabatic theory of Laplace.

**G1.00334 Time Dilation And Changes Of Material Properties Of An Atom (Body) In Speed Of Near Light Speed Based On The ”Substantial Motion”;** Theory of Iranian Philosopher, Mulla Sadra , HASSAN GHOLIBEIGIAN<sup>1</sup>, No Company Provided, KAZEM GHOLIBEIGIAN<sup>2</sup>, None — Iranian Philosopher, Sadr-ol-Moteallehin (1571-1640) said in his famous book, Asfar: "the Universe moves in its entity... and time is its fourth dimension, and time is magnitude of the motion (momentum) of the matter in its entity". In other words, time for each atom is momentum of its involved fundamental particles, [APS March Meeting 2015, abstract V1.023]. When an atom (body) moves in speed of near light speed, speed of its involved fundamental particles become slow, and consequently the magnitude of its momentum (time) will decrease. On the other hands, when the spin and orbital angular momentum of an atom changed, it means that its properties, mass, strength of its electromagnetic field and its interaction with momentum changed. As a result, each atom (body) which moves in light speed, lower or faster than that, will get a new identity and vice versa. The special relativity can be the special form of this theory. In this way, black holes will be lighter than their involved masses at rest (a paradox with general relativity). Dark matter/energy may be created at first in B.B (Convection Bang) [AGU Fall Meeting 2015, abstract ID: 58425], in more than light speed, so, if we speed protons to more than light speed (in LHC), we may see dark mater/energy in new space-time.

**G1.00335 Exploring Baryons for Dark Matter** , SHANTILAL GORADIA, Retired — There is on-going research for the detection of WIMPs based on a speculative idea of supersymmetry, which attempts to unify the fundamental forces of nature, including gravity. The detection of WIMPs is expected to find a solution to the issue of dark matter. We continue to hold and support our view of the millennium that gravity is not a fundamental force of Nature. We are therefore exploring baryons as the particles to address the issue of dark matter. We poster present our analyses to support our proposal.

**G1.00338 Implications of the general constraints for single-qubit quantum process tomography<sup>1</sup>** , RAMESH BHANDARI, Laboratory for Physical Sciences, NICHOLAS PETERS, Oak Ridge National Laboratory — We revisit the general constraints of single qubit quantum process tomography and derive simplified forms in the Pauli basis. These forms give insight into the structure of the process matrix, which we examine in light of several examples. Specifically, we study some qubit leakage error models and show how different error models are manifest in the process matrix.

**G1.00339 Optical determination of MoSe<sub>2</sub> layer number**, XIAN ZHANG, JAMES HONE, Columbia University, COLUMBIA TEAM — We mechanically exfoliate mono- and few-layers of molybdenum diselenide. The exact number of layers is determined by atomic force microscopy, high-resolution Raman spectroscopy, and photoluminescence. We have quantitatively summarized the relation between Raman A<sub>1g</sub> mode positions and the layer numbers, from both 532nm wavelength and 633nm wavelength Raman lasers. The spectrum analysis is based on 1-4 layer MoSe<sub>2</sub> flakes. These observations provide useful information for the future opto-electronic devices based on these materials.

**G1.00340 Flexible low-power RF nanoelectronics in the GHz regime using CVD MoS<sub>2</sub>**, MARUTHI YOGESH, University of Texas at Austin — Two-dimensional (2D) materials have attracted substantial interest for flexible nanoelectronics due to the overall device mechanical flexibility and thickness scalability for high mechanical performance and low operating power. In this work, we demonstrate the first MoS<sub>2</sub> RF transistors on flexible substrates based on CVD-grown monolayers, featuring record GHz cutoff frequency (5.6 GHz) and saturation velocity (~1.8106 cm/s), which is significantly superior to contemporary organic and metal oxide thin-film transistors. Furthermore, multicycle three-point bending results demonstrated the electrical robustness of our flexible MoS<sub>2</sub> transistors after 10,000 cycles of mechanical bending. Additionally, basic RF communication circuit blocks such as amplifier, mixer and wireless AM receiver have been demonstrated. These collective results indicate that MoS<sub>2</sub> is an ideal advanced semiconducting material for low-power, RF devices for large-area flexible nanoelectronics and smart nanosystems owing to its unique combination of large bandgap, high saturation velocity and high mechanical strength.

**G1.00341 Experimental Greenberger-Horne-Zeilinger type six-photon quantum nonlocality**, CHAO ZHANG, YUN-FENG HUANG, ZHAO WANG, BI-HENG LIU, CHUAN-FENG LI, GUANG-CAN GUO, Univ of Sci & Tech of China, KEY LABORATORY OF QUANTUM INFORMATION TEAM — Quantum nonlocality gives us deeper insight into quantum physics. In addition, quantum nonlocality has been further recognized as an essential resource for device-independent quantum information processing in recent years. Most experiments of nonlocality are performed using a photonic system. However, until now, photonic experiments of nonlocality have involved at most four photons. Here, for the first time, we experimentally demonstrate the six-photon quantum nonlocality in an all-versus-nothing manner based on a high-fidelity (88.4%) six-photon Greenberger-Horne-Zeilinger (GHZ) state. Our experiment pushes multi-photon nonlocality studies forward to the six-photon region and might provide a larger photonic system for device-independent quantum information protocols.

**G1.00342 Theoretical studies of graphene nanoribbon quantum dot qubits<sup>1</sup>**, CHIH-CHIEH CHEN, Department of Physics, Zhejiang University, YIA-CHUNG CHANG, Research Center for Applied Sciences, Academic Sinica — Graphene nanoribbon quantum dot qubits have been proposed as promising candidates for quantum computing applications to overcome the spin-decoherence problems associated with typical semiconductor (e.g., GaAs) quantum dot qubits. We perform theoretical studies of the electronic structures of graphene nanoribbon quantum dots by solving the Dirac equation with appropriate boundary conditions. We then evaluate the exchange splitting based on an unrestricted Hartree-Fock method for the Dirac particles. The electronic wave function and long-range exchange coupling due to the Klein tunneling and the Coulomb interaction are calculated for various gate configurations. It is found that the exchange coupling between qubits can be significantly enhanced by the Klein tunneling effect. The implications of our results for practical qubit construction and operation are discussed.

<sup>1</sup>This work was supported in part by the Ministry of Science and Technology, Taiwan, under Contract No. MOST 104-2112-M-001-009-MY2.

**G1.00343 InAs Quantum Dots embedded in GaAs: Properties from Basic Electrical Measurements**, AZZOUZ SELLAI, Sultan Qaboos University, Physics Department, P.O. Box 36, ABDELMADJID MESLI, IM2NP, UMR 6242 CNRS, Aix-Marseille University, Av. Normandie-Niemen, 13397 Marseille Cedex 20 — C-V and I-V data from a GaAs Schottky diode in which InAs quantum dots (QDs) were embedded are analyzed. The capacitance due to QDs is fitted with an analytical equation that takes into account Gaussian broadening of sub-band levels and contribution of the wetting layer. The voltage range over which the excess capacitance extends is used to estimate the number of charges contained in the QDs. The energy levels of electrons, entirely confined in the QDs, are computed based on a model in which InAs dots are considered of conical shapes and where the effective mass is taken as both position- and energy-dependent. To reconcile the computed energy values with those from the C-V fits, one has to consider a confinement potential other than the potential due to the GaAs/InAs band discontinuity. I-V data could be analyzed using a model that combines field and thermionic emission processes with two distinct behaviors depending on the temperature and bias. Deviations occur at temperatures above 200 K and voltages above 0.4 V. In comparison with the structure with only the wetting layer, the structure with QDs exhibits an excess current in the low-bias forward regime, an indication of contributions from tunneling electrons.

**G1.00344 Effect of the In by Bi substitution in the Sm<sub>2</sub>InTaO<sub>7</sub> system for the photocatalytic splitting of water**, PABLO DE LA MORA, MELISSA MENDEZ GALVAN, Facultad de Ciencias, GUSTAVO TAVIZON, Facultad de Quimica, Universidad Nacional Autonoma de Mexico, JUAN RAMIREZ DE ARELLANO, Tecnologico de Monterrey, Campus Ciudad de Mexico — Tantalum oxide-based photocatalysts with octahedrally coordinated d<sup>10</sup> configuration, represent promising semiconductor systems to develop photocatalysts with visible-light response in the photochemical splitting of water. Several Indium oxide-based compounds have shown acceptable activity in water photolysis. Recently, the pyrochlore Sm<sub>2</sub>InTaO<sub>7</sub> (a 4f-d<sup>10</sup>-d<sup>0</sup> system) was reported as a visible-light photocatalyst for water splitting. In the present work, by solid state reaction, we have obtained and structurally characterized compounds of the Sm<sub>2</sub>In<sub>1-x</sub>Bi<sub>x</sub>TaO<sub>7</sub> system. In these systems we have found that the optical band gap value depends on the Bi content; this value is 2.7, 2.52 and 2.1eV for x=0, 0.15 and 0.30 respectively. The specific surface area values we have found are typical of solid state reaction products, 0.5-1.2 m<sup>2</sup>/g. To understand the effect of the In substitution by Bi, the compounds were studied with first principles calculations using the WIEN2k package and the gap was evaluated using the mBJ potential

**G1.00345 Motion of Ferrofluid Droplets Under Oscillating Magnetic Field<sup>1</sup>**, YU GU, HUIYANANGEL CHOW, KARL MORRIS, Saint Joseph's University — Ferrofluids are stable, colloidal suspensions of single-domain ferromagnetic particles of nanometer size. Because of their good sealing properties and ease of actuation, ferrofluids are ideal for applications in Lab-On-Chip, or micro-total analysis systems (μTAS). In particular, because of their changing viscosity and surface properties under magnetic fields, as well as previously reported nonlinear behavior in bulk volumes, understanding the periodic movement of ferrofluid droplets for applications in pumping, valving and switching is important. We characterize the movement of ferrofluid droplets with volumes from 80 nL to 200 nL under oscillating magnetic fields in the frequency range 1Hz to 100Hz. Oil-based ferrofluid droplets are placed in circular cross-sectional capillaries and motion is recorded using a high-speed camera, then distilled using computer-assisted image analysis. Kinematics variables such as the position and velocity of the droplets' centers of mass are observed. Nonlinear behaviors in droplet shape and travel distance per cycle of actuation are also presented.

**G1.00346 Electronic Transport and Spatial/Temporal Photocurrent in Monolayer Molybdenum Disulfide Grown by CVD.** , ZHENGFENG YANG, Univ of Illinois - Urbana, ROBERTO GRASSI, University of Minnesota, MARCUS FREITAG, IBM Thomas J. Watson Research Center, YI-HSIEN LEE, National Tsing Hua University, TONY LOW, University of Minnesota, WENJUAN ZHU, Univ of Illinois - Urbana — We systematically investigate the electronic transport in transistors/Hall-bar devices and spatial/temporal photocurrent in photodetectors based on monolayer MoS<sub>2</sub> grown by CVD. We found that the maximum photocurrent occurs when laser spot is close to the metal/MoS<sub>2</sub> contact and is tunable by the applied drain voltage, which can be explained by the modulation of the local electric field at the Schottky barrier, consistent with predictions from our quantum transport simulation. We observed that the maximum photocurrent at drain contact is much larger than the one at source contact, and the DC currents show rectifying behavior. These phenomena can be explained by the different Schottky barrier heights at the two contacts. By measuring Hall-bar device at various temperatures from 100K to 400K, the extracted barrier height at drain contact is about 50mV larger than the one at source contact, consistent with the photocurrent and DC current observations. Photocurrent was measured at various powers and a photoresponsivity of 3.07 mA/W was extracted at low powers. When the power increases above 20uW, the photocurrent starts to saturate. Temporal response of the photocurrent is also dependent on the laser power. These studies of photocurrents and electronic transport in CVD MoS<sub>2</sub> highlight the importance of the contacts in the electronic/optoelectronic devices and reveal the physical mechanism of the photocurrent/electronic transport in these devices.

**G1.00347 Modelling large-particle diffusion in porous media as anisotropic continuous-time random walk** , SHAHAR AMITAI, RAPHAEL BLUMENFELD, Imperial College London — We test the fidelity of modelling diffusion of finite-size particles in porous media by continuous-time random walk (CTRW), where the step-size and waiting-time distributions of the former,  $P_l$  and  $P_t$ , are used as input to the latter. As the particle size is increased, the diffusion undergoes a transition from normal to anomalous. We find that, based only on  $P_l$  and  $P_t$ , CTRW does not predict correctly this transition. We show that the discrepancy is due to the change in effective connectivity (topology) of the porous media with increasing particle size. We propose a method to capture this within the CTRW model by adding anisotropy. This adjustment yields good agreement with the simulated diffusion process, making it possible to use CTRW, with all its advantages, to model diffusion of any finite size particle in confined geometries.

**G1.00348 Deformation in Thin Glassy Polymer Films from Surface towards Interior** , MITHUN CHOWDHURY<sup>1</sup>, Princeton University, JOHANN P. DE SILVA, GRAHAM L.W. CROSS, Trinity College Dublin — Polymer thin glassy films occupy an important place in last two decades of condensed matter research, concerning its surprising surface mobility and spatially dependent structural relaxation. However, ranges of cleverly designed indirect measurements on confined polymer glassy films already probed its mechanical properties; it is still a challenging task to directly probe such small confined volume through conventional mechanical testing. We have designed confined layer compression testing with a precisely designed and aligned flat probe during nanoindentation, which was further accompanied with atomic force microscopy. Due to natural confinement from the surrounding material, we show that a state of 'uniaxial strain' is created beneath the probe under small axial strains. By this methodology we are able to directly probe uniaxial flows under both anelastic and plastic conditions while doing controlled creep studies at different positions in the film starting from surface towards interior. Depending on the extent of deformation, we found ranges of effects, such as densification, anelastic yield, and plastic yield. Enhanced creep rate upon deformation supports the idea of 'deformation induced mobility'.

<sup>1</sup>Work performed at Trinity College Dublin

**G1.00349 Many-Body Localization in Simulation of Fermionic Systems** , ADRIAN CHAPMAN, AKIMASA MIYAKE, Univ of New Mexico — In the widely-known setting of Anderson localization, noninteracting particles in a disordered potential remain confined to their initial positions, even in the infinite-time limit. Many-body localization (MBL) is the extension of this phenomenon to the regime in which the particles are weakly interacting. Recent results have demonstrated examples of many-body localized systems whose evolution may be approximately simulated classically as a result of this confinement to within a logarithmic light cone. Here we attempt to turn the question on its head and ask whether MBL could be used as a means of simulating quantum computations that na?vely appear difficult. We focus on one-dimensional fermionic systems, which admit techniques for classical simulation in the noninteracting case but are universal for quantum computation upon the introduction of interactions. I will describe some recent progress in this direction as well as discuss possible future endeavours.

**G1.00350 Graphene-hBN-Graphene Photodetector with Low Dark Current** , RUYUE ZHANG, School of Physics, Nankai University, ZHIBO LIU, Teda Applied Physics Institute, Nankai University — Graphene is a highly promising material for high speed, broadband, and high responsivity photo detection. However, the only 2.3% absorption of incident infrared-to-visible lights in graphene significantly limits their potential for applications. What is more, most of them are based on field effect transistor structures containing mechanically exfoliated graphene with high dark current, not suitable for practical large-scale device applications. We are aimed to study the photo response of pure monolayer graphene prepared by chemical vapor deposition and fabricate high efficient photodetectors by varying its structure. We performed the transfer of CVD-grown graphene by PMMA, studied the dark and photo I-V characteristics and the photosensitivity properties of pure monolayer graphene. A graphene-hBN-graphene structure of photodetector was designed, in which a boron nitride layer was sandwiched between two CVD graphene layers. Low dark current compared with the pure monolayer graphene photodetector was easily obtained for 532 nm incident lights due to the dielectric properties of boron nitride. And because of the low dark current, photocurrents can be easily distinguished from the background. High responsivity was obtained because incident light act on two layers of graphene simultaneously. The new structure graphene photodetector shows a great promise for a wide variety of application fields.

**G1.00351 Supporting Kibble-Zurek Mechanism in Quantum Ising Model through a Trapped Ion.** , CHANGKANG HU, JINMING CUI, YUNFENG HUANG, ZHAO WANG, DONGYANG CAO, JIAN WANG, WEIMIN LV, YONG LU, University of Science and Technology of China, LE LUO, Indiana University-Purdue University Indianapolis, ADOLFO CAMPO, University of Massachusetts Boston, YONGJIAN HAN, CHUANFENG LI, GUANGCAN GUO, University of Science and Technology of China — The Kibble-Zurek mechanism is the paradigm to account for the non adiabatic dynamics of a system across a phase transition. Its study in the quantum regime is hindered by the requisite of ground state cooling. We report the experimental quantum simulation of critical dynamics in the transverse-field Ising model by a set of Landau-Zener crossings in pseudo-momentum space, that can be probed with high accuracy using a single trapped ion. Our results support the Kibble-Zurek mechanism in the quantum regime and advance the quantum simulation of critical systems far-away from equilibrium.

**G1.00352 Extremely Large Magnetoresistance in Bi<sub>0.96</sub>Sb<sub>0.04</sub>** , SUDESH SUDESH, PAWAN KUMAR, SATYABRATA PATNAIK, School of Physical Sciences, Jawaharlal Nehru University, New Delhi-110067, India — Recent experimental evidence for Weyl fermions in topological semimetals has attracted considerable attention. These materials are three-dimensional analogue of graphene. The present work is motivated by the recent prediction of Weyl semi-metallic phase in Bi<sub>1-x</sub>Sb<sub>x</sub> alloys. In this paper we present the electronic transport properties studied under high applied magnetic fields in Bi<sub>0.96</sub>Sb<sub>0.04</sub> alloys. The sample exhibits extremely high magneto-resistance; MR(5 K, 8 T) = 9.810<sup>4</sup> %. This value is comparable to the MR observed in recently discovered other members of these emergent materials. Most importantly, this composition shows large MR at room temperature, MR (300 K, 8 T) = 435%, which is almost twice to that observed in Dirac semimetal Cd<sub>3</sub>As<sub>2</sub> (= 200 % at 14.5 T) and Weyl semimetal NbP (= 250% at 9 T). We also discuss single crystal growth techniques as well as Hall and Shubnikov de Haas (SdH) oscillation data. **References** [1] S. Singh et.al, *arxiv:1512.00863v2* (2015). [2] C. <sup>1</sup>We acknowledge the DIST-FIST supported low temperature-high magnetic field facility at JNU and AIRF, JNU for the access of experimental facilities to carry out this study. Sudesh and P. Kumar thank UGC, (Government of India) for financial support

**G1.00353 Observation of Superconductivity by Sr Intercalation in Topological Insulator Bi<sub>2</sub>Se<sub>3</sub>**, SHRUTI SHRUTI, VISHAL MAURYA, PRAKRITI NEHA, SUDESH SUDESH, SATYABRATA PATNAIK, Jawahar Lal Nehru University, New Delhi, India — Bi<sub>2</sub>Se<sub>3</sub> is a well-known 3D topological insulator. Here we show that Sr intercalation into the van der Waals gaps of Bi<sub>2</sub>Se<sub>3</sub> induces superconductivity with a maximum  $T_c$  of 2.9 K. The single crystals of Sr<sub>x</sub>Bi<sub>2</sub>Se<sub>3</sub> for  $x = 0$  to 0.2 were prepared by self-flux method. The optimally doped sample Sr<sub>0.1</sub>Bi<sub>2</sub>Se<sub>3</sub> shows a large superconducting shielding fraction of 93% with  $T_{c-onset}$  of 2.94 K. Using transport measurement, the anisotropy in Sr<sub>0.1</sub>Bi<sub>2</sub>Se<sub>3</sub> is found to be  $\Gamma = 1.5$  with an upper critical field  $H_{c2}(0)$  equal to 2.1 T for magnetic field applied along the  $ab$  plane of the sample. Along  $ab$  plane of the sample, the lower critical field  $H_{c1,ab}(0)$  is estimated to be 0.39 ± 0.02 mT. Hall and Seebeck measurements show electronic carrier concentration of  $n = 1.85 \times 10^{19} \text{ cm}^{-3}$  at 10 K. Such low carrier concentration indicates the possibility of unconventional pairing state.

**G1.00354 Effect of a vibrating side wall on convective heat transfer in an enclosure with varying bottom wall temperature distribution**, SAEID RAHEIMPOUR ANGENEH, MURAT K. AKTAS, TOBB ETU — This study mainly focuses on the thermal convection in a rectangular enclosure in the presence of streaming motion while temperature profile of bottom wall is sinusoidal. The effect of wall displacement amplitude and the bottom wall temperature profile on convective heat transfer in the enclosure are determined with the help of a parametric study. By vibrating side wall of the enclosure, oscillating flow is actuated. The top wall of the enclosure is kept at initial temperature and isothermal while the side walls are adiabatic. In order to predict the oscillatory and time averaged mean flow fields, fully compressible form of the Navier – Stokes equations are considered. Simulation of the convective transport in the enclosure is obtained by a control-volume method based, explicit computational scheme is used. The aim of this study is to provide interpretation of the flow and thermal transport physics. The influence of nonzero mean vibrational flow on the thermal convection from a surface with sinusoidal temperature distribution has never been investigated before. Conclusions may lead up to design of new heat removal applications.

**G1.00355 Maximum hydrogen production from genetically modified microalgae biomass<sup>1</sup>**, JOSE VARGAS, Florida State University, VANESSA KAVA, Universidade Federal do Paran, JUAN ORDONEZ, Florida State University — A transient mathematical model for managing microalgae derived H<sub>2</sub> production as a source of renewable energy is developed for a well stirred photobioreactor, PBR. The model allows for the determination of microalgae and H<sub>2</sub> mass fractions produced by the PBR in time. A Michaelis-Menten expression is proposed for modeling the rate of H<sub>2</sub> production, which introduces an expression to calculate the resulting effect on H<sub>2</sub> production rate after genetically modifying the microalgae. The indirect biophotolysis process was used. Therefore, an opportunity was found to optimize the aerobic to anaerobic stages time ratio of the cycle for maximum H<sub>2</sub> production rate, i.e., the process rhythm. A system thermodynamic optimization is conducted with the model equations to find accurately the optimal system operating rhythm for maximum H<sub>2</sub> production rate, and how wild and genetically modified species compare to each other. The maxima found are sharp, showing up to a ~60% variation in hydrogen production rate within 2 days around the optimal rhythm, which highlights the importance of system operation in such condition. Therefore, the model is expected to be useful for design, control and optimization of H<sub>2</sub> production.

**G1.00356 Upper and Lower Concurrence Bounds of Entanglement Swapping of Two Bell-Diagonal States**, BRIAN KIRBY, SIDDHARTHA SANTRA, VLADIMIR MALINOVSKY, MICHAEL BRODSKY, U.S. Army Research Laboratory — Entanglement swapping is one of the basic operations of a quantum network. While the swapping is easily understood for fully entangled states, it is less well understood for partially mixed states. A particularly important class of mixed states which we will consider are the Bell-diagonal states, comprising a mixture of the pure Bell states. Bell-diagonal states are versatile as they can range from completely mixed to completely pure and from zero to perfect entanglement. Also Bell-diagonal states have well defined entanglement measures, such as concurrence. Therefore, an understanding of entanglement swapping with Bell-diagonal states is essential to quantum information processing and the realization of quantum networks. Here we rigorously treat the result of swapping of two, generally different, partially mixed, Bell-diagonal states and present numerical bounds on the its concurrence. In addition, we give an analytical solution for the concurrence of the state resulting from the swapping of two identical rank-two Bell-diagonal states in terms of the concurrence of the input states. Our results provide a simple method for analyzing the performance of quantum networks which utilize entanglement swapping of Bell-diagonal states.

**G1.00357 Degradation mechanism of a low band gap polymer PTB7 by oxidation**, SOOHYUNG PARK, JUNKYEONG JEONG, Yonsei University, HYUNBOK LEE, Kangwon National University, YEONJIN YI, Yonsei University — Recently, the PCE of OPVs is at the 10% mark by using donor materials having a low band gap, such as poly(4,8-bis[(2-ethylhexyl)oxy]benzo[1,2-b:4,5-b']dithiophene-2,6-diyl-alt-3-fluoro-2-[(2-ethylhexyl)carbonyl]thieno[3,4-b]thiophene-4,6-diyl) (PTB7) and its analogues. In spite of the significant PCE improvement, the lifetime issue still remains open problem. To solve these technical limitations fundamentally, the degradation mechanism should be understood. It can be revealed by investigating the electronic structures of polymers with controlled exposure of oxygen, moisture and light. In this study, ultraviolet, X-ray and inverse photoelectron spectroscopy measurements were performed with step-by-step exposure of controlled oxygen, moisture and light to investigate the degradation mechanism of each polymer film. Theoretical calculations using density functional theory (DFT) were also performed to understand detailed degradation process. From the experimental results, we demonstrate that push-pull polymers are more sensitive to environmental conditions, compared with non-push-pull (conventional) polymers such as poly(3-hexylthiophene-2,5-diyl) (P3HT). In addition, we show high photo-oxidation of PTB7 is originated from the structural reason.

**G1.00358 Large and high-quality single-crystal growth of cuprate superconductor Bi-2223 using the traveling-solvent floating-zone (TSFZ) method<sup>1</sup>**, SHINTARO ADACHI, TOMOHIRO USUI, KENTA KOSUGI, NAE SASAKI, Hirosaki University, KENTARO SATO, MASAKI FUJITA, Tohoku University, KAZUYOSHI YAMADA, KEK, Japan, TAKENORI FUJII, University of Tokyo, TAKAO WATANABE, Hirosaki University — In high superconducting transition temperature (high- $T_c$ ) cuprates, it is empirically known that  $T_c$  increases on increasing the number of CuO<sub>2</sub> planes in a unit cell  $n$  from 1 to 3. Bi-family cuprates are ideal for investigating the microscopic mechanism involved. However, it is difficult to grow tri-layered Bi-2223, probably owing to its narrow crystallization field. Here, we report improved crystal growth of this compound using the TSFZ method under conditions slightly different from those in an earlier report [J. Cryst. Growth 223, 175 (2001)]. A Bi-rich feed-rod composition of Bi<sub>2.2</sub>Sr<sub>1.9</sub>Ca<sub>2</sub>Cu<sub>3</sub>O<sub>y</sub> and a slightly oxygen-reduced atmosphere (mixed gas flow of O<sub>2</sub> (10%) and Ar (90%)) were adopted for the crystal growth. In addition, to increase the supersaturation of the melts, we applied a large temperature gradient along the solid-liquid interface by shielding a high-angle light beam using Al foil around the quartz tube. In this way, we succeeded in preparing large ( $2 \times 2 \times 0.05 \text{ mm}^3$ ) and high-quality (almost 100% pure) Bi-2223 single crystals.

**G1.00359 Excitonic Lasing in Solution-Processed Subwavelength Nanosphere Assemblies.**<sup>1</sup>, KANNATASSEN APPAVOO, CFN, Brookhaven National Laboratory, XIAOZE LIU, VINOD MENON, Dept. of Physics, City College of New York, MATTHEW SFEIR, CFN, Brookhaven National Laboratory — Lasing in solution-processed nanomaterials has gained significant interest because of the potential for low-cost integrated photonic devices. Still, a key challenge is designing low-threshold lasing devices based on a comprehensive understanding of the system's spectral and temporal dynamics. Here we show low-threshold random lasing in sub-wavelength thin films of coupled, highly crystalline zinc oxide nanospheres, with an overall thickness on the order of  $\lambda/4$ . The cavity-free geometry consists of 35nm zinc oxide nanospheres that collectively localize the in-plane emissive light fields while minimizing scattering losses, resulting in excitonic lasing with fluence thresholds at least an order of magnitude lower than previous UV-blue random and quantum-dot lasers. Fluence-dependent effects, as quantified by sub-picosecond transient spectroscopy, highlight the role of phonon-mediated processes in excitonic lasing. Sub-picosecond evolution of distinct lasing modes, together with 3D electromagnetic simulations, indicate a random lasing process - in violation of the commonly cited criteria of strong scattering from individual nanostructures. These results show that coupled nanostructures with high crystallinity can function as building blocks for high-performance optoelectronics.

<sup>1</sup>Research is carried out at the Center for Functional Nanomaterials, Brookhaven National Laboratory, which is supported by the U.S.DOE (DE-AC02-98CH10886). This work is supported by the National Science Foundation through Grant No. DMR 1410249.

**G1.00360 Non-saturating magnetoresistance of  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  thin films in pulsed magnetic fields up to 60T.**<sup>1</sup>, WEI NIU, MING GAO, XUEFENG WANG, Nanjing University — The mixed-valence manganite  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  (LSMO) is an interesting material for spintronics due to its intrinsic magnetoresistance properties. In this work, high quality LSMO films with atomic terraces are epitaxially grown on  $\text{SrTiO}_3$  (100) substrates by laser molecular beam epitaxy. The magnetoresistance of LSMO thin films has been measured in pulsed magnetic fields up to 60T over a wide temperature range. Unsaturated magnetoresistances and resistance relaxation of LSMO thin films have been found at different temperatures. Unlike polycrystalline manganites, a linear increase with fields of the magnetoconductance at low temperature which is attributed to the spin-dependent tunneling via grain boundaries. However, the unsaturation magnetoresistances of our LSMO thin films at different temperature show two kinds of trends: quadratic at low temperature; quasi-linear at high temperature. We attribute the unsaturation behavior to the scattering of domain walls.

**G1.00361 Superconductive density-of-states (DOS) depletion effect manifested in interlayer magnetotransport of overdoped Bi-2212**<sup>1</sup>, TOMOHIRO USUI, SHINTARO ADACHI, YUKI TERAMOTO, Hirosaki Univ., ITSUHIRO KAKEYA, Kyoto Univ., AKIHIRO KONDO, KOICHI KINDO, ISSP, Univ. of Tokyo, SHOJIRO KIMURA, Tohoku Univ., TAKAO WATANABE, Hirosaki Univ. — To determine the mechanism of high superconducting transition temperature (high- $T_c$ ) superconductivity, we must understand the relationship between the pseudogap (PG) and superconductivity. For this purpose, we measure the out-of-plane resistivity  $\rho_c(T, H)$  of an overdoped  $\text{Bi}_{1.6}\text{Pb}_{0.4}\text{Sr}_2\text{CaCu}_{1.96}\text{Fe}_{0.04}\text{O}_{8+\delta}$  (Bi-2212) single crystal under pulsed magnetic fields up to 60 T. Above  $T_c$ , magnetoconductivity (MC) is due to two positive components: one component rapidly increases with increasing fields but saturates at higher fields, and the other component gradually increases as  $H^2$ . The former decreases with increasing temperature and vanishes around the onset temperature of superconductive fluctuation  $T_{scf}$ . Thus, it is attributed to the superconductive DOS depletion effect. The latter is present both below and above  $T_{scf}$ . Thus, it is attributed to the PG effect. Subsequent analysis below  $T_c$  shows that the peak structure for  $\rho_c(T, H)$  is primarily due to the superconductive DOS depletion effect. This result supports the scenario that the PG results in high- $T_c$  superconductivity.

**G1.00362 First-principles path-integral molecular dynamics study of diffusion process of hydrogen in face-centered cubic metals**, HAJIME KIMIZUKA, SHIGENOBU OGATA, Department of Mechanical Science and Bioengineering, Osaka University — We investigated the H diffusivity in face-centered cubic Pd and Al by performing path-integral molecular dynamics (PIMD) modeling in the framework of density functional theory (DFT); in our calculations, we took nuclear quantum effects into consideration. The DFT results showed that the H-migration barriers ( $E_m$ ) in Pd and Al exhibited similar values (approximately 0.16 eV), while the H atoms were stable at octahedral (O) sites for Pd and at tetrahedral (T) sites for Al. The PIMD-based free-energy profiles for H migration between the O-site and T-site were evaluated using the thermodynamic integration of the centroid forces at 150-600 K. We confirmed that the quantum effects significantly affected the  $E_m$  and the difference between the energies of the H atom at the O-site and the T-site ( $E_{O-T}$ ); The  $E_m$  and  $E_{O-T}$  values in Pd at 300 K *increased* by 32% and 98%, respectively, relative to the classical limit. On the other hand, the  $E_m$  and  $E_{T-O}$  (i.e.,  $-E_{O-T}$ ) values in Al at 300 K *decreased* by 3% and 41%, respectively. This suggested that the quantum nature of H nuclei was essential for understanding the H-diffusion kinetics in these metals even above ambient temperature.

**G1.00363 Nanoscale Properties and Stability Simulations of Alkali Activated Cement Phases from First Principle Calculations**, ONGUN OZCELIK, CLAIRE WHITE, Princeton University — Using first principle density functional calculations, we present the nanoscale properties of interactions, local bonds, charge distributions, mechanical properties and strength of alkali activated cement phases which are the most promising alternative to the ordinary Portland cement with a much lower cost to the environment. We present results on the stability and long term durability of various alkali activated cement structures, effects of external alkali agents on their properties and ways of utilizing them for further applications. We compare the calculated properties of alkali activated cement with those of ordinary Portland cement and contribute to the formation of long term durability data of these phases. Comparison with X-ray and neutron scattering experiment results are also provided via pair distribution functions extracted from simulation results.

**G1.00364 Investigation Into the Utilization of 3D Printing in Laser Cooling Experiments**, ERIC HAZLETT, Carleton College — With the advancement of 3D printing new opportunities are abound in many different fields, but with the balance between the precisions of atomic physics experiments and the material properties of current 3D printers the benefit of 3D printing technology needs to be investigated. We report on the progress of two investigations of 3D printing of benefit to atomic physics experiments: laser feedback module and the other being an optical chopper. The first investigation looks into creation of a 3D printed laser diode feedback module. This 3D printed module would allow for the quick realization of an external cavity diode laser that would have an adjustable cavity distance. We will report on the first tests of this system, by looking at Rb spectroscopy and mode-hop free tuning range as well as possibilities of using these lasers for MOT generation. We will also discuss our investigation into a 3D-printed optical chopper that utilizes an Arduino and a computer hard drive motor. By implementing an additional Arduino we create a low cost way to quickly measure laser beam waists

**G1.00365 Entanglement fidelity for elastic electron-electron scattering in a strongly coupled semiclassical plasmas under the influence of electric field**, BABATUNDE FALAYE, Ave Santa Barbara 145, Col Planetario Lindavista, Mexico D.F., C. P. 07730-CR -07051 — This study presents the effects of electric field, AB-flux field and uniform magnetic field directed along  $z$ -axis on electron-electron scattering encircled by a strongly coupled semiclassical plasmas. The all-inclusive effects result into a strongly repulsive system while the localizations of quantum levels change and the eigenvalues increase. We have employ perturbation formalism in our calculations. The condition  $|E_{nm}^{(0)}| \gg |E_{nm}^{(1)}| > |E_{nm}^{(2)}| > |E_{nm}^{(3)}| > \dots > |E_{nm}^{(n)}|$  holds. We find that, the combined effect of the fields is stronger than solitary effect and consequently, there is a substantial shift in the bound state energy of the system. We also find that to perpetuate a low-energy elastic electron-electron scattering in a strongly semiclassical plasmas, a strong electric field and a weak magnetic field are required where AB-flux field can be used as a regulator. The entanglement fidelity in the scattering process is also examined. We have used partial wave analysis to derive the entanglement fidelity. We find that for a low electric field intensity, the entanglement fidelity varies with projectile energy.

**G1.00366 “Multifractals in Transmission of Off-line & On-line E-Voting Systems”**<sup>1</sup>, WH- MAKSOED<sup>2</sup>, Prodi of Physics UI, Depok 16424- INDONESIA — An e-voting systems is a voting system in which the election data is recorded, stored & processed primarily as digital information. Those are 2 type of e-voting systems: off-line & on-line systems[Alaguvel & Gnanavel, 2013]. “Using transfer matrix method & multifractal theory, we studied the transmission properties of 1D generalized Fibonacci structures GF(m,n) in which m & n different intervals are integer according to a substitution rule[Yuannong Zhang, *et.al*:Multifractal properties of 1D quasi-period Photonic Crystal”. “Transmission spectra of 1D fractal multilayer structures are found to exhibit self-similar properties” says Zhukovsky & Lavrinenko in “Spectral self-similarity in fractal 1D photonic structures”, Photonics & Nanostructures, 2005 whereas Jacob Trevino, *et.al* studies ‘structural properties, photonic density of state & bandedge modes of Vogel spiral arrays of dielectric cylinders in air’.\_

**G1.00369 Probing voltage induced bond rupture in a molecular junction**<sup>1</sup>, HAIXING LI, Department of Applied Physics and Applied Mathematics, Columbia University, TIMOTHY SU, NATHANIEL KIM, Department of Chemistry, Columbia University, PIERRE DARANCET, Argonne National Laboratory Center for Nanoscale Materials, JAMES LEIGHTON, MICHAEL STEIGERWALD, COLIN NUCKOLLS, Department of Chemistry, Columbia University, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia University — We use scanning tunneling microscope break junction to study electric field breakdown at the single molecule level. We investigate breakdown phenomena in atomic chains composed of Si—Si, Si—O, Si—C, Ge—Ge and C—C bonds that are commonly found in the low- $\kappa$  dielectric material. We see different bond rupture behaviors in a range of molecular backbones, and use the results from a statistically large number of measurements to determine which bond breaks. We find that Si—Si and Ge—Ge bonds rupture above a 1V bias. We also find that the Si—C bond is more robust than Si—O or Si—Si bond at above 1V. Finally, we illustrate how an additional conductance pathway in parallel to the Si—Si bond changes bond rupture behavior under an electric field. We carry out ab initio calculations on these systems and demonstrate that the mechanism for bond rupture under electric field involves “heating” of the molecule through electron-vibrational mode coupling.

**G1.00370 On the magnetic structure and band gap of the double perovskite Ba<sub>2</sub>CuOsO<sub>6</sub>: Density functional analysis**<sup>1</sup>, CHANGHOON LEE, JISOOK HONG, JI HOON SHIM, Pohang University of Science and Technology, MYUNG-HWAN WHANGBO, North Carolina State University — The ordered double-perovskite Ba<sub>2</sub>CuOsO<sub>6</sub>, consisting of 3d and 5d transition-metal magnetic ions (Cu<sup>2+</sup> and Os<sup>6+</sup>, respectively), is a magnetic insulator. It obeys the Curie-Weiss law with  $\theta = -13.3$  K. We evaluated the spin exchange interactions of Ba<sub>2</sub>CuOsO<sub>6</sub> by performing energy-mapping analysis based on DFT+U calculations and determined the band gap of Ba<sub>2</sub>CuOsO<sub>6</sub> by DFT+U and DFT+U+SOC calculations. The antiferromagnetic ordering of Ba<sub>2</sub>CuOsO<sub>6</sub> is due largely to the spin exchange interactions between Cu<sup>2+</sup> ions, which are enhanced by the empty eg orbitals of the intervening Os<sup>6+</sup> ions. Both electron correlation and spin-orbit coupling are necessary to open a band gap for Ba<sub>2</sub>CuOsO<sub>6</sub>.

**G1.00371 Local nature of impurity induced spin-orbit torques** , SERGEY NIKOLAEV, SPINTEC, Grenoble, France, ALAN KALITSOV, MINT Center, University of Alabama, AL, USA, MAIRBEC CHSHIEV, SPINTEC, Grenoble, France, OLEG MRYASOV, MINT Center, University of Alabama, AL, USA — Spin-orbit torques are of a great interest due to their potential applications for spin electronics. Generally, it originates from strong spin orbit coupling of heavy 4d/5d elements and its mechanism is usually attributed either to the Spin Hall effect or Rashba spin-orbit coupling. We have developed a quantum-mechanical approach based on the non-equilibrium Green's function formalism and tight binding Hamiltonian model to study spin-orbit torques and extended our theory for the case of extrinsic spin-orbit coupling induced by impurities. For the sake of simplicity, we consider a magnetic material on a two dimensional lattice with a single non-magnetic impurity. However, our model can be easily extended for three dimensional layered heterostructures. Based on our calculations, we present the detailed analysis of the origin of local spin-orbit torques and persistent charge currents around the impurity, that give rise to spin-orbit torques even in equilibrium and explain the existence of anisotropy.

**G1.00372 An Experimental and Modeled Comparison of Diffraction in Imaging Systems** , SPENCER KETCHUM, WILBERT SLOWMAN, MEGAN PACIARONI, Fort Lewis College — The resolution limit of imaging systems is always ultimately limited by diffraction. However, diffraction is often neglected in the analysis and design of both front and back illumination imaging systems in favor of the simpler ray tracing model. In many systems, paraxial optics provides a reasonable model for the design of systems with high resolution. This is certainly true for the majority of front-illuminated imaging systems; however, in back illuminated (shadowgraphic) imaging systems resolution is very strongly affected by diffraction. In this paper, we present a detailed experimental comparison of imaging resolution differences between front and back illuminated imaging systems for non-scattering and scattering environments. Additionally, modeling results of both systems are compared with the experimental results and classical optical theory. Preliminary results and calculations show that physical optics creates a stronger effect on resolution in back illuminated systems in either scattering or non-scattering environments.

**G1.00373 Emergent Magnetism in Mesoporous Materials<sup>1</sup>** , SHER ALAM, CHEP, and Collaborative Research with KEK, Japan, AJAYAN VINU, University of Queensland — We discuss the emergence of magnetism in Mesoporous Materials. We have obtained experimental results showing a variety of magnetic behaviors arising, by using different types of mesoporous or nanoporous templates. Since the templates allow different magnetic properties to arise naturally we have dubbed this as dynamic templating method. Our procedure and realization incidentally demonstrates the idea of Nanoarchitectonics proposed by Aono, as a MANA concept. Which, simply means to allow different nano-blocks to interact to obtain a certain desired structure and properties.

<sup>1</sup>Emergent Magnetism in Mesoporous Materials

**G1.00375 Enhanced charge transport in highly conducting PEDOT-PSS films after acid treatment** , V. AKSHAYA SHIVA, RAVI BHATIA, REGHU MENON, Indian Inst of Science — The high electrical conductivity, good stability, high strength, flexibility and good transparency of poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) (PEDOT-PSS), make it useful for many applications including polymeric anodes for organic photovoltaics, light-emitting diodes, flexible electrodes, supercapacitors, electrochromic devices, field-effect transistors and antistatic-coatings. However, the electrical conductivity of PEDOT-PSS has to be increased significantly for replacement of indium tin oxide (ITO) as the transparent electrode in optoelectronic devices. The as prepared (pristine) PEDOT-PSS film prepared from the PEDOT-PSS aqueous solution usually has conductivity below  $1\text{Scm}^{-1}$ , remarkably lower than ITO. Significant conductivity enhancement has been observed on transparent and conductive PEDOT-PSS films after a treatment with inorganic acids. Our study investigates the charge transport in pristine and  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ,  $\text{HCl}$  treated PEDOT-PSS films. We have treated the films with various concentrations of acids to probe the effect of the acid treatment on the conduction mechanism. The study includes the measurement of dc and electric field dependent conductivity of films in the temperature range of 4.2K-300K. We have also performed magneto-resistance measurements in the range of 0-5T. An enhancement by a factor of  $\sim 10^3$  has been observed in the room temperature conductivity. The detailed magneto-transport studies explain the various mechanisms for the conductivity enhancement observed.

**G1.00376 Rouse–Bueche Theory and The Calculation of The Monomeric Friction Coefficient in a Filled System.** , LUCA MARTINETTI, CHRISTOPHER MACOSKO, FRANK BATES, Univ of Minnesota - Twin Cities — According to flexible chain theories of viscoelasticity, all relaxation and retardation times of a polymer melt (hence, any dynamic property such as the diffusion coefficient) depend on the monomeric friction coefficient,  $\zeta_0$ , i.e. the average drag force per monomer per unit velocity encountered by a Gaussian submolecule moving through its free-draining surroundings. Direct experimental access to  $\zeta_0$  relies on the availability of a suitable polymer dynamics model. Thus far, no method has been suggested that is applicable to filled systems, such as filled rubbers or microphase-segregated A–B–A thermoplastic elastomers at temperatures where one of the blocks is glassy. Building upon the procedure proposed by Ferry for entangled and unfilled polymer melts, the Rouse–Bueche theory is applied to an undiluted triblock copolymer to extract  $\zeta_0$  from the linear viscoelastic behavior in the rubber-glass transition region, and to estimate the size of Gaussian submolecules. At iso-free volume conditions, the so-obtained matrix monomeric friction factor is consistent with the corresponding value for the homopolymer melt. In addition, the characteristic Rouse dimensions are in good agreement with independent estimates based on the Kratky–Porod worm-like chain model. These results seem to validate the proposed approach for estimating  $\zeta_0$  in a filled system. Although preliminary tested on a thermoplastic elastomer of the A–B–A type, the method may be extended and applied to filled homopolymers as well.

**G1.00377 Collective organization in aerotactic motion** , MARCO G. MAZZA, Max Planck Institute for Dynamics and Self-Organization — Some bacteria exhibit interesting behavior in the presence of an oxygen concentration. They perform an aerotactic motion along the gradient until they reach their optimal oxygen concentration. But they often organize collectively by forming dense regions, called bands, that travel towards the oxygen source. We have developed a model of swimmers with stochastic interaction rules moving in proximity of an air bubble. We perform molecular dynamics simulations and also solve advection-diffusion equations that reproduce the aerotactic behavior of mono-flagellated, facultative anaerobic bacteria. If the oxygen concentration in the system sinks locally below a threshold value, the formation of a migrating aerotactic band toward the bubble can be observed.

**G1.00378 Estimating topological properties of weighted networks from limited information<sup>1</sup>**, ANDREA GABRIELLI, Istituto dei Sistemi Complessi (ISC) - Consiglio Nazionale delle Ricerche (CNR), GIULIO CIMINI, IMT - Institute of Advanced Studies (Lucca, Italy), DIEGO GARLASCHELLI, Lorentz Institute, Leiden University (NL), ANGELO SQUARTINI, IMT - Institute of Advanced Studies (Lucca, Italy) — A typical problem met when studying complex systems is the limited information available on their topology, which hinders our understanding of their structural and dynamical properties. A paramount example is provided by financial networks, whose data are privacy protected. Yet, the estimation of systemic risk strongly depends on the detailed structure of the interbank network. The resulting challenge is that of using aggregate information to statistically reconstruct a network and correctly predict its higher-order properties. Standard approaches either generate unrealistically dense networks, or fail to reproduce the observed topology by assigning homogeneous link weights. Here we develop a reconstruction method, based on statistical mechanics concepts, that exploits the empirical link density in a highly non-trivial way. Technically, our approach consists in the preliminary estimation of node degrees from empirical node strengths and link density, followed by a maximum-entropy inference based on a combination of empirical strengths and estimated degrees. Our method is successfully tested on the international trade network and the interbank money market, and represents a valuable tool for gaining insights on privacy-protected or partially accessible systems.

**2:30PM H1.00001 Chirality density wave of the "hidden order" phase in URu<sub>2</sub>Si<sub>2</sub><sup>1</sup>**, GIRSH BLUMBERG, Rutgers University — Many novel electronic ground states have been found to emerge from the hybridization between localized *d*- or *f*-electron states and conduction electron states in correlated electron materials. The heavy fermion compound URu<sub>2</sub>Si<sub>2</sub> exhibits the coexistence of two such ground states: so-called "hidden order" (HO) below T<sub>HO</sub> = 17.5 K and superconductivity below T<sub>c</sub> = 1.5 K. Despite 30 years of research the symmetry of the order parameter associated with HO phase below 17.5 K has remained ambiguous.

Here we report results of polarization resolved Raman spectroscopy study aimed to specify the symmetry of the low energy excitations above and below the HO transition. These excitations involve transitions between interacting heavy uranium *5f* orbitals, responsible for the broken symmetry in the HO phase. From the symmetry analysis of the collective mode, we determine that the HO parameter breaks local vertical and diagonal reflection symmetries at the uranium sites, resulting in crystal field states with distinct chiral properties, which order to a commensurate *chirality density wave* ground state [1]. We further explore the competition between the HO phase and large moment antiferromagnetic (LMAFM) phase [2], and the connection between the HO chirality density wave and the unconventional superconductivity which has recently been proposed to be of a chiral *d*-wave type [3].

**3:06PM H1.00002 Magneto-optical measurements as tests for time-reversal symmetry breaking in the hidden order and superconducting phases of URu<sub>2</sub>Si<sub>2</sub><sup>1</sup>**, AHARON KAPITULNIK<sup>2</sup>, Stanford University — It is now experimentally well established that the superconducting (SC) phase of URu<sub>2</sub>Si<sub>2</sub> with T<sub>c</sub> = 1.5 K emerges from the hidden order (HO) phase with T<sub>HO</sub> = 17.5 K. Thus, it is of great interest to discern the different symmetries of both phases. In particular, recent theoretical proposals for time-reversal symmetry breaking (TRSB) order parameters of either phases pose the question of whether the HO one drives the SC one, or TRSB appears in the SC phase independently. In this talk we report high resolution polar Kerr effect (PKE) measurements as a function of temperature for several high-quality single crystals of URu<sub>2</sub>Si<sub>2</sub>. We find an onset of PKE below the superconducting transition that is consistent with a TRS-breaking order parameter. This effect appears to be independent of an additional, possibly extrinsic, PKE generated in the hidden order phase, and contains structure below T<sub>c</sub> suggestive of additional physics within the superconducting state.

**3:42PM H1.00003 Colossal thermomagnetic response in chiral *d*-wave superconductor URu<sub>2</sub>Si<sub>2</sub><sup>1</sup>**, YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto, Japan — The heavy-fermion compound URu<sub>2</sub>Si<sub>2</sub> exhibits unconventional superconductivity at T<sub>c</sub> = 1.45 K deep inside the so-called hidden order phase. An intriguing aspect is that this system has been suggested to be a candidate of a chiral *d*-wave superconductor [1], and possible Weyl-type topological superconducting states have been discussed recently. Here we report on the observation of a highly unusual Nernst signal due to the superconducting fluctuations above T<sub>c</sub>. The Nernst coefficient is anomalously enhanced (by a factor of ~ 10<sup>6</sup>) as compared with the theoretically expected value of the Gaussian fluctuations. This colossal Nernst effect intimately reflects the highly unusual superconducting state of URu<sub>2</sub>Si<sub>2</sub>. The results invoke possible chiral or Berry-phase fluctuations associated with the broken time-reversal symmetry of the superconducting order parameter [2]. [1]Y. Kasahara et al. *Phys. Rev. Lett.* **99**, 116402 (2007). [2]T. Yamashita et al. *Nature Phys.* **11**, 17 (2015).

**4:18PM H1.00004 Evidence for preservation of crystallographic four-fold rotational symmetry in hidden order of  $\text{URu}_2\text{Si}_2$** <sup>1</sup>, HIROSHI AMITSUKA, Graduate School of Science, Hokkaido University — Recent experimental studies have suggested that the four-fold rotational symmetry around the tetragonal *c* axis is broken in the hidden-ordered state of  $\text{URu}_2\text{Si}_2$  below 17.5 K [1-5]. Those experimental findings give strong constraints on the theoretical arguments, and have provoked discussions on the electric/magnetic “nematic” ordering. However, the detected signals that suggest the broken symmetry are extremely weak in magnitude, and thus it is very important to test the reproducibility of the observations. Among the reported experiments, the orthorhombic distortion detected by X-ray diffraction is particularly important, because it may prove the broken rotational symmetry to be a thermodynamic phenomenon. We have performed synchrotron X-ray backscattering measurements of a high-quality single crystal with  $\text{RRR} > 350$  with the highest spatial resolution ever achieved. We will present the most reliable evidence for the preservation of crystallographic four-fold rotational symmetry in the hidden-order state. We will also present the tests for reproducibility of magnetic torque measurements, and discuss the intrinsic nature of  $\text{URu}_2\text{Si}_2$ . [1] R. Okazaki et al., Science 331, 439 (2011). **4:54PM H1.00005 The Optical Phase Diagram of  $\text{URu}_2\text{Si}_2$ : Effects of Anisotropy, Charge Coherence and Fermi Surface Gapping**, RICARDO LOBO, ESPCI PSL, CNRS, UPMC —  $\text{URu}_2\text{Si}_2$  is a heavy fermion with a Kondo temperature of 370 K. Hybridization between heavy *f* electrons with conduction electrons creates a crossover to a Kondo liquid state having coherent transport properties below 70 K. At 17.5 K, a second-order mean-field transition creates an electronically ordered state, which clear origin remains unknown. The formation of an unconventional superconducting phase below 1.5 K completes the thermal phase diagram. The charged nature of this phase diagram, makes it a fertile ground for optical investigations. Here I discuss the optical properties of the hidden order, the Kondo coherent and the Kondo phases. On the *ab*-plane, an incoherent conductor exists at room temperature. Upon crossing into the Kondo coherent state, a sharp Drude peak develops and narrows quickly upon further cooling. Along the *c*-axis the Drude peak is present at all temperatures and is mostly insensitive to the formation of the coherent Kondo state. When entering the hidden order phase, a 6.5 meV gap opens. It follows a mean-field temperature dependence in the *ab*-plane but remains constant along the *c*-axis where it fills-up rather than close. In parallel, phonons are very sensitive to the Kondo coherence and couple strongly to the electronic continuum. The optical properties of  $\text{URu}_2\text{Si}_2$  shows a strongly anisotropic behavior between the *ab*-plane and the *c*-axis.

**Session H2 DCMP DMP GMAG: Emergent Topological Phenomena in Pyrochlore Iridates II**  
 Ballroom II - Zhi-Xun Shen, Stanford Univ

**2:30PM H2.00001 Metal-insulator transitions of bulk and domain-wall states in pyrochlore iridates.**, KENTARO UEDA, RIKEN CEMS — A family of pyrochlore iridates  $R_2\text{Ir}_2\text{O}_7$  offers an ideal platform to explore intriguing phases such as topological Mott insulator and Weyl semimetal [1]. Here we report transport and spectroscopic studies on the metal-insulator transition (MIT) induced by the modulations of effective electron correlation and magnetic structures, which is finely tuned by external pressure, chemical substitutions ( $R = \text{Nd}_{1-x}\text{Pr}_x$  and  $\text{Sm}_y\text{Nd}_{1-y}$ ), and magnetic field. A reentrant insulator-metal-insulator transition is observed near the paramagnetic insulator-metal phase boundary reminiscent of a first-order Mott transition for  $R = \text{Sm}_y\text{Nd}_{1-y}$  compounds ( $y \sim 0.8$ ). The metallic states on the magnetic domain walls (DWs), which are observed for  $R = \text{Nd}$  in real space [2] as well as in transport properties [3], is simultaneously turned into the insulating one. These findings imply that the DW electronic state is intimately linked to the bulk states. For the mixed  $R = \text{Nd}_{1-x}\text{Pr}_x$  compounds, the divergent behavior of resistivity with antiferromagnetic order is significantly suppressed by applying a magnetic field along [001] direction [4]. It is attributed to the phase transition from the antiferromagnetic insulating state to the novel Weyl (semi-)metal state accompanied by the change of magnetic structure. The present study combined with experiment and theory suggests that there are abundant exotic phases with physical parameters such as electron correlation and Ir-5*d* magnetic order pattern. Work performed in collaboration with J. Fujioka, B.-J. Yang, C. Terakura, N. Nagaosa, Y. Tokura (University of Tokyo, RIKEN CEMS), J. Shiogai, A. Tsukazaki, S. Nakamura, S. Awaji (Tohoku University). <sup>1</sup>This work was supported by JSPS FIRST Program and Grant-in-Aid for Scientific Research (Grants No. 80609488 and No. 24224009). [1] W. Witczak-Krempa, G. **3:06PM H2.00002 Mobile metallic domain walls in an all-in-all-out magnetic insulator**<sup>1</sup>, ERIC YUE MA, Stanford Univ — Magnetic domain walls are boundaries between regions with different configurations of the same magnetic order. In a magnetic insulator where the magnetic order is tied to its bulk insulating property, it has been postulated that electrical properties are drastically different along the domain walls, where the order is inevitably disturbed. Here we report the discovery of highly conductive magnetic domain walls in a magnetic insulator  $\text{Nd}_2\text{Ir}_2\text{O}_7$ , which has an unusual all-in-all-out magnetic order, via transport and spatially resolved microwave impedance microscopy. The domain walls have a virtually temperature-independent sheet resistance (averaged over mesoscopic distances) of  $\sim 1$  kilohm per square, show smooth morphology with no preferred orientation, are free from pinning by disorders, and have strong thermal and magnetic field responses that agree with expectations for all-in-all-out magnetic order.

**3:42PM H2.00003 Topological Domain-Wall Metals in Pyrochlore Iridates**, YOUHEI YAMAJI, Quantum-Phase Electronics Center, The University of Tokyo — Emergent quantum phases [1-3] of pyrochlore iridium oxides  $R_2\text{Ir}_2\text{O}_7$  (*R*: rare-earth elements) have attracted a broad interest. Previous theoretical studies have predicted Weyl semimetals in non-collinear magnetic phases, called the all-in-all-out (AIAO) orders in  $\text{Y}_2\text{Ir}_2\text{O}_7$  [1]. The Weyl electrons are, however, easily annihilated in a pair [4]. Recently, we have predicted that magnetic domain walls in the AIAO phase of the pyrochlore iridium oxides host two-dimensional metallic states characterized by a zero-dimensional class A Chern number [5], even after the pair-annihilation of the Weyl electrons. By employing a symmetry adapted effective hamiltonian, we also predict a helical transport emerging from a spontaneous symmetry breaking at the magnetic domain wall as well as a subsequent metal-insulator transition [6]. **Session H3 DCMP GQI: Charge Noise Mitigation in Multiple Quantum Dot Qubits** Ballroom III - Thaddeus Ladd, Hrl Laboratories

**2:30PM H3.00001 Reduced sensitivity to charge noise in semiconductor spin qubits via symmetric operation**, MATTHEW REED, HRL Laboratories, LLC — Gated semiconductor quantum dots controlled with the exchange interaction are attractive candidates for quantum information processing because of their long coherence time and electrical controllability. Exchange is conventionally modulated by detuning the chemical potentials of neighboring dots over a fixed tunnel barrier, an approach whose precision is limited by charge noise. In this talk we demonstrate a "symmetric" mode of operation which substantially reduces the sensitivity of exchange operations to gate fluctuations. The method involves biasing a double-dot symmetrically between the charge-state anti-crossings, where the derivative of the exchange energy with respect to gate voltages is minimized. Exchange remains highly tunable by adjusting the tunnel coupling. We propose a metric, insensitivity, to quantify the techniques improvement and find that it increases by at least a factor of five between operating regimes. We also demonstrate a substantial increase in the number of Rabi fringes observed.

**3:06PM H3.00002 Symmetric operation and nuclear notch filtering in GaAs double quantum dots<sup>1</sup>**, FERDINAND KUEMMETH, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — Spin qubits based on few-electron semiconducting quantum dots are promising candidates for quantum computation, due to their potential for miniaturization, scalability and fault tolerance. In this talk I will present recent results on how to mitigate electrical and nuclear noise in GaAs singlet-triplet qubits.

The traditional way of implementing exchange rotations in singlet-triplet qubits involves detuning the qubit away from the symmetric (1,1) charge configuration, thereby temporarily hybridizing with the (0,2) charge state. Due to the large dipole coupling the resulting qubit oscillation suffers from detuning noise, motivating operation at sweet spots [1] or in the multi-electron regime [2]. Alternatively, exchange rotations can be implemented by symmetrically lowering the middle barrier. This method yields less relative exchange noise, significantly enhanced free induction decay times, and quality factors comparable to those reported in silicon quantum dot devices using similar techniques [3].

In order to decouple the singlet-triplet qubit from nuclear spin fluctuations, we investigate Carr-Purcell-Meiboom-Gill (CPMG) sequences in more detail. At high magnetic fields we find that qubit dephasing is limited by narrow-band high-frequency noise arising from Larmor precession of <sup>69</sup>Ga, <sup>71</sup>Ga, <sup>75</sup>As nuclear spins, similar to what has been observed at intermediate magnetic field [4]. By aligning the notches of the CPMG filter function with differences of the discrete nuclear Larmor frequencies we demonstrate a qubit coherence time of 0.87 ms, i.e. more than five orders of magnitude longer than the duration of a  $\pi$  exchange gate in the same device.

**3:42PM H3.00003 Optimizing fidelities of quantum dot hybrid qubits<sup>1</sup>**, SUSAN COPPERSMITH, University of Wisconsin-Madison — The quantum dot hybrid qubit, which can be viewed as a hybrid between a spin and charge qubit, has an attractive combination of speed and fabrication simplicity. The initial experiments implementing this qubit yielded process fidelities of  $\sim 88\%$  [1] and  $\sim 93\%$  [2] for pulsed-gating and ac-gating, respectively. We present experimental evidence that these fidelities were limited by charge noise, and we present theoretical and experimental evidence that the sensitivity of qubit operations to charge noise can be reduced substantially by appropriate adjustment of the tunnel couplings. Our work indicates that, with suitable optimization, this qubit can achieve gate fidelities of well over 99%. [1] D. Kim et al., *Nature* **511**, 70 (2014). [2] D. Kim, et al., *npj Quant. Inf.* **1**, 15004 (2015).

**4:18PM H3.00004 Double sweet-spot operation of the resonant exchange qubit in three-electron quantum dots<sup>1</sup>**, GUIDO BURKARD, University of Konstanz, Germany — The resonant exchange (RX) qubit is a promising variant of the exchange-only spin qubit in a triple quantum dot which responds to a narrow-band resonant frequency. But the advantage of a permanently applied exchange splitting for spin control generally entails an increased susceptibility to charge noise. We have investigated the influence of electrical charge noise on a resonant exchange (RX) qubit by taking into account uncorrelated noise in each quantum dot, giving rise to two independent noisy bias parameters  $\varepsilon$  and  $\Delta$  [1]. Calculating the energy splitting of the two qubit states as a function of these two bias detuning parameters, we have identified sweet spots, where the qubit is least susceptible to noise. Our investigation shows that the sweet spots exist within the low-bias regime, in which the bias detuning parameters have the same magnitude as the hopping parameters between the dots. By calculating and comparing the charge dephasing rates at the various operating points of the RX qubit, we identify a new favorable operating regime for the RX qubit in the case of weak noise, based on these double sweet spots. In contrast, spin noise can be mitigated using exchange-based dynamical decoupling sequences that have been optimized using two different strategies, Uhrig dynamical decoupling (UDD) and optimized filter function dynamical decoupling (OFDD) [2]. Finally, we give a brief outlook towards the possibility of long-distance coupling between resonant exchange qubits mediated by a microwave cavity [3].

**4:54PM H3.00005 Feedback-tuned, noise resilient gates for encoded spin qubits**, HENDRIK BLUHM, RWTH Aachen University — Spin 1/2 particles form native two level systems and thus lend themselves as a natural qubit implementation. However, encoding a single qubit in several spins entails benefits, such as reducing the resources necessary for qubit control and protection from certain decoherence channels. While several varieties of such encoded spin qubits have been implemented, accurate control remains challenging, and leakage out of the subspace of valid qubit states is a potential issue. Optimal performance typically requires large pulse amplitudes for fast control, which is prone to systematic errors and prohibits standard control approaches based on Rabi flopping. Furthermore, the exchange interaction typically used to electrically manipulate encoded spin qubits is inherently sensitive to charge noise. I will discuss all-electrical, high-fidelity single qubit operations for a spin qubit encoded in two electrons in a GaAs double quantum dot. Starting from a set of numerically optimized control pulses<sup>1</sup>, we employ an iterative tuning procedure based on measured error syndromes to remove systematic errors. Randomized benchmarking yields an average gate fidelity exceeding 98 % and a leakage rate into invalid states of 0.2 %. These gates exhibit a certain degree of resilience to both slow charge and nuclear spin fluctuations due to dynamical correction analogous to a spin echo. Furthermore, the numerical optimization minimizes the impact of fast charge noise. Both types of noise make relevant contributions to gate errors. The general approach is also adaptable to other qubit encodings and exchange based two-qubit gates<sup>2</sup>.

## Tuesday, March 15, 2016 2:30PM - 5:30PM –

Session H4 DPOLY: Dillon Medal Symposium Ballroom IV - Darrin Pochan, University of Delaware

**2:30PM H4.00001 John H. Dillon Medal: Tapered Block Copolymers: Tuning Self-Assembly and Properties by Manipulating Monomer Segment Distributions**, THOMAS EPPS, Univ of Delaware — The self-assembly of block copolymers (BCPs) presents unique opportunities to design materials with attractive chemical and mechanical properties based on the ability of BCPs to form periodic structures with nanoscale domain spacings. One area of recent progress in our group focuses on the behavior of tapered BCPs in which the segment distribution at the interface between blocks is synthetically varied to tune morphology, domain density profiles, thermal transitions as well as mechanical and transport properties. Two application targets for these materials are lithium-ion conducting membranes for batteries and nanostructured thin films for nanotemplates and barrier membranes. In the first target area, we found that the taper volume fraction and composition allow us to manipulate the self-assembly of salt-doped BCPs in a well-defined manner that permits optimization of morphology and ion-content. Additionally, we found that the tapered interfaces influence the glass-transition behavior of the ion-conducting block leading to significant changes in lithium-ion transport (ion conductivity). In the second target area, we found the taper content alters the rate of self-assembly as well as the rate of island/hole formation (and ultimate island/hole size) upon thermal annealing. Additionally, using reflectivity techniques, we probed the domain density profiles as a function of taper composition and linked these profiles to changes in domain spacing and glass transition temperature. Overall, these studies show the versatility of tapering to provide a unique handle for simultaneously optimizing multiple materials properties.

**3:06PM H4.00002 Dodecagonal Quasicrystal Phase in a Diblock Copolymer Melt<sup>1</sup>**, FRANK BATES, TIMOTHY GILLARD, University of Minnesota, SANGWOO LEE, RPI — Recent experiments with low molecular weight asymmetric poly(isoprene-*b*-lactide) (PI-PLA) diblock copolymers have established an equilibrium Frank-Kasper  $\sigma$ -phase at compositions between 18 and 22 percent by volume PLA, which transforms to a BCC phase followed by disordering with increasing temperature. This presentation will describe synchrotron small-angle x-ray scattering and dynamic mechanical spectroscopy experiments conducted following rapid temperature quenches from the disordered state to temperatures associated with the  $\sigma$ -phase. We document the development of a long-lived dodecagonal quasicrystalline (DQC) phase that transforms with time into the associated quasicrystal approximate  $\sigma$ -phase at a rate that is highly temperature dependent. Remarkably, the DQC does not form from either the  $\sigma$ -phase or BCC state. These finding will be discussed in the context of an apparent spontaneous structural transition that occurs when the disordered melt is supercooled below a threshold temperature coincident with the BCC to  $\sigma$ -phase order-order transition temperature.

**3:18PM H4.00003 A Cool Way to Form High-Conductivity Two-Dimensional Polymers Using Ice**, MOON JEONG PARK, Pohang University of Science and Technology — Ice surfaces are used as removable hard templates to form two-dimensional polyaniline (PANI) nanosheets. Distinctly high current flows of 5.5 mA at 1 V and a high electrical conductivity of 35 S/cm were obtained for the PANI nanosheets, which marked a significant improvement from the literature values on other PANIs reported over the past decades. These improved electrical properties of ice-templated PANI nanosheets were attributed to the long-range ordered edge-on p-stacking of the quinoid ring, ascribed to the ice surface-assisted vertical growth of PANI. The unprecedented advantages of the ice-templated PANI nanosheets are two-fold. First, the PANI nanosheet can be easily transferred onto various types of substrates via float off from the ice surfaces. Second, PANI can be patterned into any shape using predetermined masks, and this is expected to facilitate the eventual convenient and inexpensive application of conducting polymers in versatile electronic device forms.

**3:30PM H4.00004 Molecular transport into and out of ionic-liquid filled block copolymer vesicles in water** , TIMOTHY LODGE, LETITIA YAO, SOONYONG SO, University of Minnesota — We have developed a method to prepare stable, size-controlled block copolymer vesicles that contain ionic liquid in the interior, but that are dispersed in water. Such nanoemulsions are of interest as nanoreactors, because the mass transfer and cost limitations of ionic liquids are circumvented. However, a crucial question is whether target molecules (*e.g.*, reagents and products) can enter and leave the vesicles, respectively, on a useful time scale (*i.e.*, seconds or shorter). In this talk we will briefly describe methods to prepare such vesicles with narrow size distributions, using poly(styrene)-*block*-poly(ethylene oxide) and poly(butadiene)-*block*-poly(ethylene oxide) copolymers of various compositions. We will then present results of pulsed-field gradient NMR measurements of probe diffusion that yield independent measurements of the entry and escape rates for selected small molecules, as a function of membrane thickness and temperature.

**3:42PM H4.00005 Influencing the structure of block copolymer micelles with small molecule additives** , MEGAN ROBERTSON, AVANTIKA SINGH, TYLER COOKSEY, University of Houston, BRYCE KIDD, RACHELE PIEMONTE, Virginia Tech, SHU WANG, KIM MAI LE, University of Houston, LOUIS MADSEN, Virginia Tech — Amphiphilic block copolymer micelles in water are under broad exploration for drug delivery applications due to their high loading capacity and targeted drug delivery. We aim to understand the kinetic and thermodynamic processes that underlie the self-assembly of diblock copolymer micelle systems. The present work focuses on diblock copolymers containing poly(ethylene oxide) (a hydrophilic polymer) and polycaprolactone (a hydrophobic polymer), which spontaneously self-assemble into spherical micelles in water. Addition of a common good solvent (a co-solvent) for both of the constituting blocks, such as tetrahydrofuran (THF), reduces the interfacial tension at the core-corona interface. We are currently investigating the effect of this phenomenon on the micelle structural properties, using small-angle scattering and nuclear magnetic resonance. We have characterized the hydrodynamic radius, core radius, corona thickness, aggregation number, degree of swelling of the micelle core with the co-solvent, and unimer (free chain) concentration, as a function of the co-solvent concentration. Fundamental knowledge from these studies will inform design of drug delivery systems by allowing us to tailor micelle properties for optimal cargo loading.

**3:54PM H4.00006 Computationally Guided Design of Polymer Electrolytes for Battery Applications** , ZHEN-GANG WANG, MICHAEL WEBB, BRETT SAVOIE, THOMAS MILLER, California Institute of Technology — We develop an efficient computational framework for guiding the design of polymer electrolytes for Li battery applications. Short-times molecular dynamics (MD) simulations are employed to identify key structural and dynamic features in the solvation and motion of Li ions, such as the structure of the solvation shells, the spatial distribution of solvation sites, and the polymer segmental mobility. Comparative studies on six polyester-based polymers and polyethylene oxide (PEO) yield good agreement with experimental data on the ion conductivities, and reveal significant differences in the ion diffusion mechanism between PEO and the polyesters. The molecular insights from the MD simulations are used to build a chemically specific coarse-grained model in the spirit of the dynamic bond percolation model of Druger, Ratner and Nitzan. We apply this coarse-grained model to characterize Li ion diffusion in several existing and yet-to-be synthesized polyethers that differ by oxygen content and backbone stiffness. Good agreement is obtained between the predictions of the coarse-grained model and long-timescale atomistic MD simulations, thus providing validation of the model. Our study predicts higher Li ion diffusivity in poly(trimethylene oxide-*alt*-ethylene oxide) than in PEO. These results demonstrate the potential of this computational framework for rapid screening of new polymer electrolytes based on ion diffusivity.

**4:06PM H4.00007 Theory and Simulations of Tapered Diblock Polymers<sup>1</sup>** , LISA M. HALL, YOUNGMI SEO, JONATHAN R. BROWN, The Ohio State University — We study tapered block polymers, AB diblock polymers with a gradient region inserted between the pure A and B blocks such that composition smoothly transitions from A to B (or B to A in the case of inverse tapers). Phase diagrams were created using self consistent field theory (SCFT), and coarse-grained molecular dynamics (MD) simulations were used to study polymer conformations and diffusion, including diffusion of monomer-sized penetrants preferentially dissolved in one of the phases. As has been observed experimentally, we find that tapering makes the A and B blocks more miscible, decreasing domain spacing and shifting the order to disorder transition to lower temperatures. We predict a widening of the bicontinuous double gyroid region of the phase diagram for moderate length normal tapers versus diblocks, suggesting taper length can be used as a control parameter to obtain network phases even at high molecular weight, as may be desirable in transport applications. Additionally, in some inverse tapered systems, SCFT predicts phases not present in the standard AB diblock phase diagram, and MD simulations show how the chains fold back and forth across the interface. In these inverse tapered polymers, as segregation strength is increased, the competing effects of folding and stretching produces lamellae that have domain spacing nearly independent of temperature. We also find that diffusion of penetrants in normal tapers is significantly faster than that in inverse tapers, which is likely related to their unusual conformations.

<sup>1</sup>This material is based upon work supported by DOE Grant SC0014209.

**4:18PM H4.00008 High-Tg Polynorbornene-Based Block and Random Copolymers for Butanol Pervaporation Membranes** , RICHARD A. REGISTER, DONG-GYUN KIM, Princeton University, TAMAMI TAKIGAWA, TOMOMASA KASHINO, OLEKSANDR BURTOVYY, ANDREW BELL, Promerus LLC — Vinyl addition polymers of substituted norbornene (NB) monomers possess desirably high glass transition temperatures (T<sub>g</sub>); however, until very recently, the lack of an applicable living polymerization chemistry has precluded the synthesis of such polymers with controlled architecture, or copolymers with controlled sequence distribution. We have recently synthesized block and random copolymers of NB monomers bearing hydroxyhexafluoroisopropyl and n-butyl substituents (HFANB and BuNB) via living vinyl addition polymerization with Pd-based catalysts. Both series of polymers were cast into the selective skin layers of thin film composite (TFC) membranes, and these organophilic membranes investigated for the isolation of n-butanol from dilute aqueous solution (model fermentation broth) via pervaporation. The block copolymers show well-defined microphase-separated morphologies, both in bulk and as the selective skin layers on TFC membranes, while the random copolymers are homogeneous. Both block and random vinyl addition copolymers are effective as n-butanol pervaporation membranes, with the block copolymers showing a better flux-selectivity balance. While polyHFANB has much higher permeability and n-butanol selectivity than polyBuNB, incorporating BuNB units into the polymer (in either a block or random sequence) limits the swelling of the polyHFANB and thereby improves the n-butanol pervaporation selectivity.

**4:30PM H4.00009 Glassy Structural Trapping in Soft Multi-Face Colloids** , RODNEY PRIESTLEY, Princeton University — Nanoparticles with soft, heterogeneously patterned surfaces often exhibit unique, multi-functional behaviors in response to environmental stimuli. The soft, polymeric nature of the particle surface, moreover, allows for the tailoring of both surface architecture and chemical composition towards particular applications. We have recently demonstrated that Precipitation-Induced Self Assembly (PISA) can be used to form soft Janus colloids as well as multi-faceted colloids in a scalable approach in which many colloidal characteristics can be controlled independently. Here, we present evidence not only of kinetic trapping in the formation of rapidly precipitated, multi-surface polymer particles; but also delineate the role of polymer vitrification in the determination of multi-faceted particle structures.

**4:42PM H4.00010 Effect of Protein Supercharging on Interaction with Polyelectrolytes**, BRADLEY OLSEN, ALLIE OBERMEYER, CAROLYN MILLS, XUEHUI DONG, MIT — Complexation of proteins with polyelectrolytes can lead to a liquid-liquid phase separation to generate a viscous complex coacervate phase rich in protein and polyelectrolyte. However, many proteins do not readily coacervate at conditions near neutral pH and physiological ionic strength. Here, protein supercharging is used to systematically explore the effect of protein charge on the complex coacervation with polycations. Four model proteins were chemically modified to generate a panel of proteins with varying surface charge, with both the average charge and charge distribution quantified by mass spectrometry. Proteins phase separated with the qP4VP and qPDMAEMA polycations when the ratio of negatively charged residues to positively charged residues was greater than 1.1-1.2. Efficient partitioning of the protein into the coacervate phase required larger charge ratio (1.5-2.0). The model proteins were also encapsulated in complex coacervate core micelles. Dynamic light scattering was used to assess the formation of micelles with PEOGMA-*b*-qP4VP and revealed micellar hydrodynamic radii of approximately 25-30 nm. Small angle neutron scattering and transmission electron microscopy were used to confirm the formation of spherical micelles.

**4:54PM H4.00011 Self-assembly of Open-Shell-containing Block Polymer Thin Films**, BRYAN BOUDOURIS, LIZBETH ROSTRO, ADITYA BARADWAJ, JENNIFER LASTER, Purdue University — Radical polymers, where a stable open-shell group is present on each repeat unit of a non-conjugated macromolecular backbone, are emerging as promising materials in organic electronic and magnetic applications. As such, designing molecular motifs that allow for the self-assembly of these open-shell species into nanostructured domains could be beneficial in a host of next-generation flexible electronic applications. In addition, the relatively flexible nature of their macromolecular backbone and ability to conduct charge in the amorphous state offer distinct advantages regarding their self-assembly relative to block polymers based on conjugated semiconducting polymers. Here, we demonstrate the controlled synthesis and self-assembly of diblock copolymers containing radical polymer moieties. In fact, we show that A-B diblock copolymers, where the A moiety contains nitroxide radical functionalities and the B moiety is a closed-shell, low glass transition temperature polymer, self-assemble into ordered structures with domain spacing values that are consistent with common coil-coil diblock copolymers ( $d = 30$  nm). In this way, we present a means by which to readily generate electronically-active macromolecules that self-assemble into nanostructured thin films with controlled morphologies over long ranges.

**5:06PM H4.00012 Direct Immersion Annealing of Block Copolymer Thin Films**, ALAMGIR KARIM<sup>1</sup>, University of Akron — We demonstrate ordering of thin block copolymer (BCP) films via direct immersion annealing (DIA) at enhanced rate leading to stable morphologies. The BCP films are immersed in carefully selected mixtures of good and marginal solvents that can impart enhanced polymer mobility, while inhibiting film dissolution. DIA is compatible with roll-to-roll assembly manufacturing and has distinct advantages over conventional thermal annealing and batch processing solvent-vapor annealing methods. We identify three solvent composition-dependent BCP film ordering regimes in DIA for the weakly interacting polystyrene-poly(methyl methacrylate) (PS-PMMA) system: rapid short range order, optimal long-range order, and a film instability regime. Kinetic studies in the “optimal long-range order” processing regime as a function of temperature indicate a significant reduction of activation energy for BCP grain growth compared to oven annealing at conventional temperatures. An attractive feature of DIA is its robustness to ordering other BCP (e.g. PS-P2VP) and PS-PMMA systems exhibiting spherical, lamellar and cylindrical ordering. Inclusion of nanoparticles in these films at high concentrations and fast ordering kinetics study with neutron reflectivity and SANS will be discussed.

<sup>1</sup>This is (late) Contributed Talk Abstract for Dillon Medal Symposium at DPOLY - discussed with DPOLY Chair Dvora Perahia

**5:18PM H4.00013 Functional Thin Films from Aligned Block Copolymers and Blends**, BRYAN VOGT, ZHE QIANG, KEVIN CAVICCHI, Univ of Akron — Block copolymer (BCP) self-assembly provides a simple, cost effective route to fabricating nanoscale patterns. Here we describe how we can modulate the alignment/orientation of BCP films using a modified solvent vapor annealing (SVA) method where the BCP is covered with an elastomer during SVA and controlled deswelling of the elastomer macroscopically produces a shear force that aligns the BCP domains. By proper selection of the BCP or BCP + functional precursors, functional nanopatterns can be obtained. Thin films of cylindrical forming polystyrene-block-polydimethylsiloxane (PS-*b*-PDMS) are shear aligned. High temperature calcination converts the PDMS to silica and removes the PS to yield the silica nanolines. The spacing of these features is effectively halved by the use of bilayer films. Sequential shear-alignment of two distinct layers can generate arbitrary line based nanostructured features such as a rhombic array, but the size of the features is defined by the BCP. Oligomeric phenolic resin can effectively modulate the size and morphology of amphiphilic BCPs even at high loadings ( $\geq 70$  wt

**Session H5 GMAG DMP: Frustrated Magnetism: Spin Liquids in 2D** 301 - Arun Paramekanti, University of Toronto

**2:30PM H5.00001 Paired states of Chern-Simons fermions in quantum spin models**, ANDREW ALLOCCA, Univ of Maryland-College Park, TIGRAN SEDRAKYAN, Fine Theoretical Physics Institute, Univ of Minnesota and Physics Frontier Center, Joint Quantum Institute, Univ of Maryland, VICTOR GALITSKI, Univ of Maryland-College Park — We consider exotic states constructed from the two-dimensional quantum spin-1/2 XY model on the square and hexagonal lattices. By applying a Chern-Simons transformation we represent the quantum spin model as a system of spinless fermions interacting via attached fluxes. The interaction is then decoupled in the Cooper and excitonic channels giving possible unconventional states of Chern-Simons fermions. We examine the mean field properties of these states and their relations to the original spin model.

**2:42PM H5.00002 Symmetry fractionalization of visons in Z<sub>2</sub> spin liquids**, YANG QI, Perimeter Institute for Theoretical Physics, MENG CHENG, Station Q, Microsoft Research, CHEN FANG, Massachusetts Institute of Technology — In this work we study symmetry fractionalization of vison excitations in topological Z<sub>2</sub> spin liquids. We show that in the presence of the full SO(3) spin-rotational symmetry and if there is an odd number of spin- $\frac{1}{2}$  per unit cell, the symmetry fractionalization of visons is completely fixed. On the other hand, visons can have different classes of symmetry fractionalization if the spin-rotational symmetry is reduced. As a concrete example, we show that visons in the Balents-Fisher-Girvin Z<sub>2</sub> spin liquid have crystal symmetry fractionalization classes which are not allowed in SO(3) symmetric spin liquids, due to the reduced spin-rotational symmetry.

**2:54PM H5.00003 Haldane-Hubbard Mott Insulator: From Tetrahedral Spin Crystal to Chiral Spin Liquid**, CIARAN HICKEY, University of Toronto, LUKASZ CINICIO, Perimeter Institute for Theoretical Physics, ZLATKO PAPIC, University of Leeds, ARUN PARAMAKANTI, University of Toronto — Motivated by recent experimental realizations of artificial gauge fields in ultracold atoms, we study the honeycomb lattice Haldane-Hubbard Mott insulator of spin-1/2 fermions using exact diagonalization and density matrix renormalization group methods. We show that this model exhibits various chiral magnetic orders including a wide regime of triple-Q tetrahedral order. Incorporating third-neighbor hopping frustrates and ultimately melts this tetrahedral spin crystal. From analyzing low energy spectra, many-body Chern numbers, entanglement spectra, and modular matrices, we identify the molten state as a chiral spin liquid with gapped semion excitations.

**3:06PM H5.00004 Unification of bosonic and fermionic  $Z_2$  spin liquids on a rectangular lattice**, SHUBHAYU CHATTERJEE, JULIA STEINBERG, SUBIR SACHDEV, Harvard University — Recent theories [1] have postulated the presence of a fractionalized Fermi liquid ( $FL^*$ ) in the pseudogap metal phase of cuprates. The  $FL^*$  phase can be described as a spin liquid co-existing with fermionic charge carrying quasiparticles. Underdoped cuprates also show a variety of competing orders, including nematic order which reduce the  $C_4$  symmetry of the square lattice to  $C_2$ . Motivated by this, we classify mean-field bosonic spin liquids on a rectangular lattice using projective symmetry groups (PSG) [2], and find equivalent descriptions in terms of fermionic partons [3]. In particular, we find a fermionic spin liquid ansatz corresponding to a bosonic  $Z_2$  spin liquid with favorable mean field energy [4]. The fermionic ansatz might be useful to investigate the transition from a  $FL^*$  to a fermi liquid. [1]. Density-wave instabilities of fractionalized Fermi liquids: D. Chowdhury and S. **3:18PM H5.00005 Coupled wire construction of chiral spin liquids<sup>1</sup>**, RONNY THOMALE, Univ of Wuerzburg, TOBIAS MENG, TU Dresden, TITUS NEUPERT, PCTS, Princeton University, MARTIN GREITER, Univ of Wuerzburg — We develop a coupled wire construction of chiral spin liquids. The starting point are individual wires of electrons in the Mott regime that are subject to a Zeeman field and Rashba spin-orbit coupling. Suitable spin-flip couplings between the wires yield an Abelian chiral spin liquid state which supports spinon excitations above a bulk gap, and chiral edge states. The approach generalizes to non-Abelian chiral spin liquids at level k with parafermionic edge states.

**3:30PM H5.00006 Variational Monte Carlo study of chiral spin liquid in quantum antiferromagnet on the triangular lattice**, WENJUN HU, Rice University, SHOUSHU GONG, Florida State University, DONNA SHENG, California State University, Northridge, DONNA SHENG TEAM — We investigate the Heisenberg model with chiral coupling on the triangular lattice by using Gutzwiller projected fermionic states and the variational Monte Carlo technique. As the chiral coupling grows, a gapped spin liquid with non-trivial magnetic fluxes and nonzero chiral order is stabilized. Furthermore, we calculate the topological Chern number and the degeneracy of the ground state, both of which lead us to identify this flux state as the chiral spin liquid with  $C = 1/2$  fractionalized Chern number. Finally, we add spatial anisotropy in the model to study the effects for the chiral order.

**3:42PM H5.00007 Valence-bond-solid domain walls in a 2D quantum magnet<sup>1</sup>**, HUI SHAO, Beijing Computational Science Research Center, WENAN GUO, Beijing Normal University, ANDERS SANDVIK, Boston University — sing quantum Monte Carlo simulations, we study properties of domain walls in a square-lattice  $S=1/2$  Heisenberg model with additional interactions which can drive the system from an antiferromagnetic (AFM) ground state to a valence-bond solid (VBS). We study the finite-size scaling of the domain-wall energy at the putative "deconfined" critical AFM-VBS point, which gives access to the critical exponent governing the domain-wall width. This length-scale diverges faster than the correlation length and also is related to the scale of spinon deconfinement. Our results show additional evidence of deconfined quantum criticality and are compatible with critical exponents extracted from finite-size scaling of other quantities.

**3:54PM H5.00008 Field-induced magnetization jumps and quantum criticality in the 2D J-Q model<sup>1</sup>**, ADAM IAIZZI, ANDERS SANDVIK, Boston Univ — The J-Q model is a 'designer hamiltonian' formed by adding a four spin 'Q' term to the standard antiferromagnetic  $S = 1/2$  Heisenberg model. The Q term drives a quantum phase transition to a valence-bond solid (VBS) state: a non-magnetic state with a pattern of local singlets which breaks lattice symmetries. The elementary excitations of the VBS are triplons, i.e. gapped  $S=1$  quasiparticles. There is considerable interest in the quantum phase transition between the Néel and VBS states as an example of deconfined quantum criticality. Near the phase boundary, triplons deconfine into pairs of bosonic spin-1/2 excitations known as spinons. Using exact diagonalization and the stochastic series expansion quantum monte carlo method, we study the 2D J-Q model in the presence of an external magnetic field. We use the field to force a nonzero density of magnetic excitations at  $T=0$  and look for signatures of Bose-Einstein condensation of spinons. At higher magnetic fields, there is a jump in the induced magnetization caused by the onset of an effective attractive interaction between magnons on a ferromagnetic background. We characterize the first order quantum phase transition and determine the minimum value of the coupling ratio  $q \equiv Q/J$  required to produce this jump.

**4:06PM H5.00009 Chiral phase of a simple two-dimensional spin-1 quantum magnet<sup>1</sup>**, OLEG STARYKH, University of Utah, ZHENTAO WANG, Rice University, CRISTIAN D. BATISTA, T-Division and CNLS, Los Alamos National Laboratory — We investigate the evolution of the ground state of a simple spin-1 antiferromagnet with easy-axis single-ion anisotropy  $D(S^z)^2$ , with  $D < 0$ , on a two-dimensional triangular lattice. The ground state changes from a quantum paramagnet one, at sufficiently large  $|D|$ , to a magnetically ordered  $120^\circ$  one at small  $D \sim 0$ . Besides breaking the continuous  $U(1)$  symmetry of global spin rotations along the  $z$ -axis, this non-collinear ordering also breaks the discrete  $Z_2$  chiral symmetry, which raises the possibility of an intermediate chiral spin liquid state, spontaneously breaking spatial inversion and mirror symmetries. We show that this interesting novel state indeed appears as a result of the condensation of bound  $\langle S_n^+ S_m^- - S_n^- S_m^+ \rangle$  pairs. The resulting Ising-like nematic state supports a regular pattern of spin currents on the bonds of the triangular lattice. It represents quantum analogue of the classical chiral spin liquid proposed by Villain in 1977.

**4:18PM H5.00010 Critical scaling corrections in 2D dimerized antiferromagnets<sup>1</sup>**, NUSEN MA, Boston University, Sun Yat-sen University, HUI SHAO, Beijing Computational Science Center, Boston University, DAO-XIN YAO, Sun Yat-sen University, ANDERS SANDVIK, Boston University — 2D dimerized antiferromagnets can be driven through a quantum-critical point by tuning the ratio  $g = J_2/J_1$  between inter- and intra-dimer couplings. It has been shown [1] that the systems fall into two classes, depending on whether or not a certain bond-inversion symmetry is present in the dimer pattern. The two classes should have the same leading critical exponents but different exponents controlling the scaling corrections. We here investigate the scaling corrections using quantum Monte Carlo simulations for several different dimerization patterns. We will discuss systematic methods to extract the scaling corrections in the thermodynamic limit.

**4:30PM H5.00011 Novel spin liquid with a gapped Fermi surface in the kagome Kondo-lattice model**, GIA-WEI CHERN, University of Virginia, ZHENTAO WANG, Rice University, KIPTON BARROS, Los Alamos National Laboratory — Geometrical frustration in the Kagome lattice is well known as a source of many exotic phases. Here we study the under-screened Kondo-lattice model (KLM) on the kagome lattice at large electron-spin coupling, a regime in which perturbative approaches such as RKKY are invalid. We employ a recently developed linear-scaling, dynamical sampling method to study the KLM on large kagome lattices. At low temperatures, our simulations uncover an intriguing classical spin liquid phase with short-range correlations. Surprisingly, when  $T \rightarrow 0$  a wide gap in the electronic spectrum can appear at any filling fraction between 0.5 to 0.63. We characterize this new spin liquid and discuss the origin of spontaneous gap formation.

**4:42PM H5.00012 A tensor product state approach to spin-1/2 square J1-J2 antiferromagnetic Heisenberg model: evidence for deconfined quantum criticality**<sup>1</sup>, LING WANG, Beijing Computational Science Research Center, ZHENG-CHENG GU, Perimeter Institute, FRANK VERSTRAËTE, University of Vienna, XIANG-GANG WEN, Massachusetts Institute of Technology — We study this model using the cluster update algorithm for tensor product states (TPSs). We find that the ground state energies at finite sizes and in the thermodynamic limit are in good agreement with the exact diagonalization study. At the largest bond dimension available  $D = 9$  and through finite size scaling of the magnetization order near the transition point, we accurately determine the critical point  $J_2^{c1} = 0.53(1)J_1$  and the critical exponents  $\beta = 0.50(4)$ . In the intermediate region we find a paramagnetic ground state without any static valence bond solid (VBS) order, supported by an exponentially decaying spin-spin correlation while a power law decaying dimer-dimer correlation. By fitting a universal scaling function for the spin-spin correlation we find the critical exponents  $\nu = 0.68(3)$  and  $\eta_s = 0.34(6)$ , which is very close to the observed critical exponents for deconfined quantum critical point (DQCP) in other systems. Thus our numerical results strongly suggest a Landau forbidden phase transition from Neel order to VBS order at  $J_2^{c1} = 0.53(1)J_1$ .

**4:54PM H5.00013 Magnetic fluctuations and dynamics in the vicinity of quantum spin liquids: Cluster dynamical mean-field study of the Kitaev model**, JUNKI YOSHITAKE, Dept. of Appl. Phys., Univ. of Tokyo, JOJI NASU, Dept. of Phys., Tokyo Inst. Tech., YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — The quantum spin liquid, which does not show any long-range ordering down to the lowest temperature, has attracted broad interest as a new quantum state of matter. Since the ground state of the Kitaev model was shown to be a quantum spin liquid in two dimensions [1], there has been an explosion in both theoretical and experimental studies. Nevertheless, dynamical properties at finite temperatures remain a challenge, despite the relevance to analysis of recent experiments for Ir and Ru compounds. In this contribution, we address this problem by using the cluster dynamical mean-field approximation, which we newly develop on the basis of the Majorana fermion representation. Using the continuous-time quantum Monte Carlo method for the impurity solver, we calculate the magnetic susceptibility, dynamical spin structure factor, and relaxation time in the nuclear magnetic resonance. We find that these quantities show peculiar temperature dependences in the paramagnetic state when approaching the quantum spin liquid by decreasing temperature, which reflects the fractionalization of quantum spins. We will discuss the results while changing the anisotropy and sign (ferro/antiferro) of the exchange interactions, in comparison with experiments. [1] A. Kitaev, Ann. Phys. **321**, 2 (2006).

**5:06PM H5.00014 Protection against a spin gap in two-dimensional insulating antiferromagnets with a Chern-Simons term**, IMAM MAKHFUDZ, PIERRE PUJOL, LPT-IRSAMC and Univ. Paul Sabatier Toulouse France — We propose a mechanism for the protection against spin gapped states in doped antiferromagnets. It requires the presence of a Chern-Simons term that can be generated by a coupling between spin and an insulator. We first demonstrate that in the presence of this term the vortex loop excitations of the spin sector behave as anyons with fractional statistics. To generate such a term, the fermions should have a massive Dirac spectrum coupled to the emergent spin field of the spin sector. The Dirac spectrum can be realized by a planar spin configuration arising as the lowest-energy configuration of a square lattice antiferromagnet Hamiltonian involving a Dzyaloshinskii-Moriya interaction. The mass is provided by a combination of dimerization and staggered chemical potential. We finally show that for realistic parameters, anyonic vortex loop condensation will likely never occur and thus the spin gapped state is prevented. We also propose real magnetic materials for an experimental verification of our theory. Reference: Imam Makhfudz and Pierre Pujol, Phys. Rev. B **92**, 144507 (2015).

**5:18PM H5.00015 Interaction-driven fractional quantum Hall state of hard-core bosons on kagome lattice at one-third filling**<sup>1</sup>, D. N. SHENG, California State University, Northridge, S. S. GONG, National High Magnetic Field Lab, W. ZHU, California State University, Northridge — There has been a growing interest in realizing topologically nontrivial states of matter in band insulators, where a quantum Hall effect can appear as an intrinsic property of the band structure. While the on-going progress is under way with a number of directions, the possibility of realizing novel interaction-generated topological phases, without the requirement of a nontrivial invariant encoded in single-particle wavefunction or band structure, can significantly extend the class of topological materials and is thus of great importance. Here, we show an interaction-driven topological phase emerging in an extended Bose-Hubbard model on kagome lattice, where the non-interacting band structure is topological trivial with zero Berry curvature in the Brillouin zone. By means of an unbiased state-of-the-art density-matrix renormalization group technique, we identify that the groundstate in a broad parameter region is equivalent to a bosonic fractional quantum Hall Laughlin state, based on the characterization of universal properties including groundstate degeneracy, edge excitations and anyonic quasiparticle statistics. Our work paves a way of finding interaction induced topological phase at the phase boundary of conventionally ordered solid phases.

**2:30PM H6.00001 Electric-field-induced modification in Dzyaloshinskii-Moriya interaction of Co monolayer on Pt(111)**, KOHJI NAKAMURA, TORU AKIYAMA, TOMONORI ITO, Mie University, TERUO ONO, Kyoto University, MICHAEL WEINERT, University of Wisconsin - Milwaukee — Magnetism induced by an external electric field ( $E$ -field) has received much attention as a potential approach for controlling magnetism at the nano-scale with the promise of ultra-low energy power consumption. Here, the  $E$ -field-induced modification of the Dzyaloshinskii-Moriya interaction (DMI) for a prototypical transition-metal thin layer of a Co monolayer on Pt(111) is investigated by first-principles calculations by using the full-potential linearized augmented plane wave method that treats spin-spiral structures in an  $E$ -field. With inclusion of the spin-orbit coupling (SOC) by the second variational method for commensurate spin-spiral structures, the DMI constants were estimated from an asymmetric contribution in the total energy with respect to the spin-spiral wavevector. The results predicted that the DMI is modified by the  $E$ -field, but the change is found to be small compared to that in the exchange interaction (a symmetric contribution in the total energy) by a factor of ten.

**2:42PM H6.00002 Random Field effects in perpendicular-anisotropy multilayer films** , JIAN XU, University of Chicago, DANIEL SILEVITCH, THOMAS ROSENBAUM, California Institute of Technology — With the application of a magnetic field transverse to the magnetic easy axis, randomly-distributed 3D collections of dipole-coupled Ising spins form a realization of the Random-Field Ising Model. Tuning the strength of the site-specific random field, and hence the disorder, via the applied transverse field regulates the domain reversal energetics and hence the macroscopic hysteresis loop. We extend this approach to two dimensions, using sputtered Perpendicular Magnetic Anisotropy (PMA) Co/Pt multilayer thin films. We characterize the coercive fields and hysteresis loops at a series of temperatures and transverse fields.

**2:54PM H6.00003 Polarization dependent soft x-ray spectro-microscopy of local spin structures**<sup>1</sup> , MACCALLUM ROBERTSON, Center for X-Ray Optics, LBNL, CHRISTOPHER AGOSTINO , National Center for Electron Microscopy, LBNL, MI-YOUNG IM, Center for X-Ray Optics, LBNL, SERGIO MONTOYA , ERIC FULLERTON , Center for Magnetic Recording Research, UCSD, PETER FISCHER, Materials Sciences Division, LBNL — Quantitative information about element-specific contributions to local magnetic spin and orbital moments is readily available by XMCD spectroscopy and images of magnetic domain patterns with a few tens of nanometer spatial resolution. We show that the x-ray spectroscopic analysis of x-ray microscopy images provides quantitative information about local spin structures. We have investigated two prototypical multilayered PMA film systems prepared by sputtering, specifically (Co 0.3 nm/Pt 0.5 nm)<sub>x30</sub> and (Fe 0.7nm/Gd 0.4nm)<sub>x100</sub> systems. A spectroscopic sequence of full-field magnetic transmission soft x-ray microscopy (MTXM) images covering about 8mm field-of-views with a spatial resolution of about 20nm were recorded across the Co and Fe L edges, resp. To modulate the magnetic contrast, two sets of images were obtained with left and right circular polarization. Standard XMCD spectroscopy analysis procedures were applied to retrieve the local spectroscopic behavior. We observe a decrease of the L3/L2 ratio when approaching the domain walls, indicating a non-uniform spin configuration along the vertical profile of a domain, which we will discuss in view of both systems' magnetic anisotropies.

<sup>1</sup>U.S. DOE under Contract No. DE-AC02-05-CH11231

**3:06PM H6.00004 Nanoparticulate CoPt Thin Films**<sup>1</sup> , YASAMAN BAREKATAIN, GEORGE HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, MAGNETICS BLAB TEAM — Equiatomic FePt and CoPt alloys are very attractive for application in high density recording media because of the high magnetocrystalline anisotropy K of their **fct** (L1<sub>0</sub>) structure with values exceeding 2MJ/m<sup>3</sup>. The aim of this study is to fabricate a nanoparticulate CoPt film consisting of CoPt nanoparticles embedded in a matrix. To obtain this we have used co-sputtering of CoPt with different materials M= BN, C, Cu and SiO<sub>2</sub>. Our first experiments were done on CoPt films with thickness of 200 nm. The as-sputtered films had the **fcc** structure and a coercivity of 150 Oe. Annealing at 700 °C for 30 min led to an increase in coercivity to 4 kOe. Optimization studies are under way to find the optimum sputtering conditions to obtain a fully ordered tetragonal structure with the highest value of coercivity which can then be used in the nanoparticulate composites. **3:18PM H6.00005 Microscopic evidence of strain-mediated magnetoelectric coupling in Co/Pt multilayers/PMN-PT(011) heterostructures** , YING SUN, Tsinghua University, WENBO WANG, WEIDA WU, Rutgers University, XIAOLI ZHENG, JIANWANG CAI, Institute of Physics, Chinese Academy of Sciences, YONGGANG ZHAO, Tsinghua University, MING LIU, Xian Jiaotong University — A promising way to control magnetization(M) via an electric field(E-field) is using magnetoelectric(ME) effect in FM/FE heterostructures. We use magnetic(electric) force microscopy(M(e)FM) to study the strain-mediated E-field modulation of M in (Co/Pt)<sub>n</sub> with perpendicular magnetic anisotropy(PMA) or in-plane anisotropy on PMN-PT(011) substrates. MFM were performed on (Co/Pt)<sub>n</sub> with an DC E-field applied to PMN-PT. In MeFM, we superimpose an AC modulation on a DC one and utilize lock-in technique to detect weak ME effect. For (Co/Pt)<sub>n</sub> with PMA, MFM images show stripe domains with no obvious changes at varied DC E-fields. However, MeFM shows interesting structures and the image contrast reverses sign at opposite strain slopes of the PMN-PT substrate. For sample with in-plane anisotropy, both MFM and MeFM images show dipole-like domains. Interestingly, the MeFM image contrast reverses sign at opposite strain slopes of the substrate. The sign reversal of MeFM contrast indicates that features revealed by MeFM are intrinsic local ME effect. Our MeFM data are consistent with the ferromagnetic resonance results showing that strain-induced anisotropy change will cause part of M switching to the in-plane direction. Possible scenarios will be discussed.

**3:30PM H6.00006 Effect of perpendicular magnetic anisotropy and Dzyaloshinskii-Moriya interaction on the enhancement of domain wall creep velocity in Pt/Co thin films by piezoelectric strain**<sup>1</sup> , PHILIPPA M. SHEPLEY, GAVIN BURNELL, THOMAS A. MOORE, University of Leeds — We investigate piezoelectric strain control of domain wall creep motion in perpendicularly magnetized Pt/Co thin films. Domain wall (DW) motion has potential applications in data storage and spintronics, where the use of voltages rather than magnetic fields to control magnetization reversal could reduce power consumption. Materials with perpendicular magnetic anisotropy (PMA) are of particular interest due to their narrow domain walls and potential for efficient current-induced DW motion. Sputtered Ta/Pt/Co(t)/X films (t=0.78-1.0nm, X= Pt, Ir/Pt or Ir) on thin glass substrates were bonded to biaxial piezoelectric transducers, to which 150V was applied to produce a tensile out-of-plane strain of 9x10<sup>-4</sup>. This reduced the PMA by 10kJ/m<sup>3</sup> and increased the DW creep velocity by up to 90%. DW energy can be calculated from the PMA and the Dzyaloshinskii-Moriya interaction (DMI) field. DW creep measurements of DMI field found no change with strain. The change in DW velocity with strain is linear with the change in DW energy for Pt/Co DWs with a mixed Bloch-Neel structure. Pt/Co/Pt films with higher DW velocity changes were found to have purely Bloch DWs. We conclude that the velocity of Bloch DWs is more sensitive to strain-induced changes than that of Bloch-Neel DWs.

**3:42PM H6.00007 Thermal Stability of Magnetic States in Circular Thin-Film Nanomagnets with Large Perpendicular Magnetic Anisotropy<sup>1</sup>**, GABRIEL CHAVES-O'FLYNN, New York Univ NYU — The scaling of the energy barrier to magnetization reversal in thin-film nanomagnets with perpendicular magnetization as a function of their lateral size is of great interest and importance for high-density magnetic random access memory devices. Experimental studies of such elements show either a quadratic or linear dependence of the energy barrier<sup>2,3</sup> on element diameter. I will discuss a theoretical model we developed to determine the micromagnetic configurations that set the energy barrier for thermally activated reversal of a thin disk with perpendicular magnetic anisotropy as a function of disk diameter<sup>4</sup>. We find a critical length in the problem that is set by the exchange and effective perpendicular magnetic anisotropy energies, with the latter including the size dependence of the demagnetization energy. For diameters smaller than this critical length, the reversal occurs by nearly coherent magnetization rotation and the energy barrier scales with the square of the diameter normalized to the critical length (for fixed film thickness), while for larger diameters, the transition state has a domain wall, and the energy barrier depends linearly on the normalized diameter. Simple analytic expressions are derived for these two limiting cases and verified using full micromagnetic simulations with the string method. Further, the effect of an applied field is considered and shown to lead to a plateau in the energy barrier versus diameter dependence at large diameters. Based on these findings I discuss the prospects and material challenges in the scaling of magnetic memory devices based on thin films with strong perpendicular magnetic anisotropy.

**4:18PM H6.00008 Large electric-field control of perpendicular magnetic anisotropy in strained [Co/Ni] / PZT heterostructures**, DANIEL GOPMAN, CINDI DENNIS, P. J. CHEN, NIST - Natl Inst of Stds & Tech, YURY IUNIN, Institute of Solid State Physics, Russian Academy of Sciences, Chernogolovka, Moscow Region, Russia, ROBERT SHULL, NIST - Natl Inst of Stds & Tech — We present a piezoelectric/ferromagnetic heterostructure with PMA - a Co/Ni multilayer sputtered directly onto a Pb(Zr,Ti)O<sub>3</sub> (PZT) substrate. Chemical-mechanical polishing was used to reduce the roughness of PZT plates to below 2 nm *rms*, enabling optimal magnetoelectric coupling via the direct interface between PZT and sputtered Co/Ni films with large PMA ( $K_{\text{eff}} = (95 \pm 9 \text{ kJ/m}^3)$ ). We grew the following layer stack: Ta(3)/Pt(2)/[Co(0.15)/Ni(0.6)]<sub>x4</sub>/Co(0.15)/Pt(2)/Ta(3); numbers in parentheses indicate thicknesses in nm. Applied electric fields up to  $\pm 2 \text{ MV/m}$  to the PZT generated 0.05% in-plane compression in the Co/Ni multilayer, enabling a large electric-field reduction of the PMA ( $\Delta K_{\text{eff}} \geq 10^3 \text{ J/m}^3$ ) and of the coercive field (35%). Our results demonstrate that: (i) heterostructures combining PZT and [Co/Ni] exhibit larger PMA ( $K_{\text{eff}} \sim 10^5 \text{ J/m}^3$ ) than previous magnetoelectric heterostructures based on Co/Pt and CoFeB, enabling thermally stable hybrid magnetoelectric/spintronic devices only tens of nm in diameter and (ii) electric-field control of the PMA is promising for more energy efficient switching of spintronic devices.

**4:30PM H6.00009 Properties of easy-plane/ perpendicular magnetic anisotropy bilayers with varied interlayer exchange coupling<sup>1</sup>**, LORENZO FALLARINO<sup>2</sup>, VOLKER SLUKA, Department of Physics, New York University, New York, NY 10003, USA., BARTEK KARDASZ, MUSTAFA PINARBASI, Spin-Transfer Technologies Inc., Freemont, CA 94538, USA., ANDREW D. KENT, Department of Physics, New York University, New York, NY 10003, USA. — We explore the possibility of an easy-cone ground state in coupled easy plane/easy axis magnetic bilayers. The samples consist of a Co/Ni multilayer with perpendicular magnetic anisotropy and a CoFe layer with easy-plane anisotropy separated by a variable thickness Ru layer. Using ferromagnetic resonance spectroscopy, we characterize the magnetic behavior of the coupled thin films for different Ru thicknesses by determining the resonance fields for both the acoustic and optical FMR modes. In particular, we observe a gap in the resonance field opening up between the two modes in angular-dependent FMR, which is direct evidence for the presence of interlayer coupling. Quantitative comparisons with a theoretical model indicate that by varying the Ru thickness the coupling strength can be tuned continuously from ferromagnetic to the anti-ferromagnetic. These results are consistent with a canted magnetic ground state in zero field, a state of interest for applications in spin-torque devices, such as current tunable spin-torque oscillators.

**4:42PM H6.00010 Giant magnetic anisotropy of Co, Ru, and Os adatoms on MgO (001) surface.**, HONGBO WANG, XUEDONG OU, FENGREN FAN, ZHENGWEI LI, HUA WU, Fudan Univ — Large magnetic anisotropy energy (MAE) is desirable and critical for nanoscale magnetic devices. Here, using ligand-field level diagrams and density functional calculations, we well explain the very recent discovery [I. G. Rau *et al.*, Science **344**, 988 (2014)] that individual Co adatom on MgO (001) surface has a large MAE of more than 60 meV. More importantly, we predict that a giant MAE up to 110 meV could be realized for Ru adatoms on MgO (001), and even more for the Os adatoms (208 meV). This is a joint effect of the special ligand field, orbital multiplet, and significant spin-orbit interaction, in the intermediate-spin state of the Ru or Os adatoms on top of the surface oxygens. The giant MAE could provide a route to atomic scale memory.

**5:06PM H6.00012 Perpendicular Magnetic Anisotropy of Tb/Fe and Gd/Fe Multilayers Studied with Torque Magnetometer**, ATAUR CHOWDHURY, Physics Department, UAF — Perpendicular magnetic anisotropy (PMA) of multilayers critically depend on the magnetic and structural ordering of the interface. To study the effect of interface on PMA, Tb/Fe and Gd/Fe multilayers with varying Fe (0.8-9.0 nm) and Gd (0.5-2.8 nm) or Tb (0.3-6.3 nm) layer thicknesses were fabricated by planar magnetron sputtering. The magnetometer results of spin orientation clearly reveals that samples with Gd or Tb layer thickness of more than 1.2 nm display no PMA, regardless of the Fe layer thickness. Tb/Fe and Gd/Fe multilayers with thin (<1.2 nm) Tb or Gd layers display large PMA, but no PMA is observed when the Fe layer thickness is increased to 4.0 nm and higher. The bulk magnetization and anisotropy energy constant of the samples are found to increase with increasing Fe layer thickness. Torque measurement also reveals that there are two distinctly different axes of spin alignment at different energy. Tb/Fe and Gd/Fe multilayers with similar composition reveal similar magnetic and structural characteristics, and it may imply that single-ion-anisotropy of rare-earth element, which is quite large for Tb ions and very small for Gd ions, may not be the dominating cause of PMA in Tb/Fe and Gd/Fe multilayers. A detailed explanation of the results will be provided based on exchange interaction at the interface.

**5:18PM H6.00013 Stripe glasses in ferromagnetic thin films**, ALESSANDRO PRINCIPI, MIKHAIL KATSNELSON, Institute for Molecules and Materials, Radboud University — Domain walls in magnetic multilayered systems can exhibit a very complex and fascinating behavior. The magnetization of thin films of hard magnetic materials is in general perpendicular to the thin-film plane, but its direction changes periodically, forming an alternating spin-up and spin-down stripe pattern. The latter is stabilized by the competition between the ferromagnetic coupling and dipole-dipole interactions, and disappears when a moderate in-plane magnetic field is applied. It has been suggested that such a behavior may be understood in terms of a self-induced stripe glassiness. In this paper we show that such a scenario is compatible with the experimental findings. The strong out-of-plane magnetic anisotropy of the film is found to be beneficial for the formation of both the stripe-ordered and glassy phases. At zero magnetic field the system can form a glass only in a narrow interval of fairly large temperatures. An in-plane magnetic field, however, shifts the glass transition towards lower temperatures, therefore enabling it at or below room temperature. In good qualitative agreement with the experimental findings, we show that a moderate in-plane magnetic field of the order of 30 mT can lead to the formation of defects in the stripe pattern.

**2:30PM H7.00001 Anomalous organic magnetoresistance from competing carrier-spin-dependent interactions with localized electronic and nuclear spins**, MICHAEL E. FLATT, University of Iowa

— Transport of carriers through disordered electronic energy landscapes occurs via hopping or tunneling through various sites, and can enhance the effects of carrier spin dynamics on the transport. When incoherent hopping preserves the spin orientation of carriers, the magnetic-field-dependent correlations between pairs of spins influence the charge conductivity of the material. Examples of these phenomena have been identified in hopping transport in organic semiconductors and colloidal quantum dots, as well as tunneling through oxide barriers in complex oxide devices, among other materials. The resulting room-temperature magnetic field effects on the conductivity or electroluminescence require external fields of only a few millitesla. These magnetic field effects can be dramatically modified by changes in the local spin environment. Recent theoretical and experimental work has identified a regime for low-field magnetoresistance in organic semiconductors in which the spin-relaxing effects of localized nuclear spins and electronic spins interfere<sup>1</sup>. The regime is studied experimentally by the controlled addition of localized electronic spins, through the addition of a stable free radical (galvinoxyl) to a material (MEH-PPV) that exhibits substantial room-temperature magnetoresistance (initially suppressed by the doping, as the localized electronic spin mixes one of the two spins whose correlation controls the transport. At intermediate doping, when one spin is fully decohered but the other is not, there is a regime where the magnetoresistance is insensitive to the doping level. For much greater doping concentrations the magnetoresistance is fully suppressed as both spins that control the charge conductivity of the material are mixed. The behavior is described within a theoretical model describing the effect of carrier spin dynamics on the current. Generalizations to amorphous and other disordered crystalline semiconductors will also be described. This work was supported by DOE and an ARO MURI and was done in collaboration with N. J. Harmon, K. Sahin-Tiras, Y. Wang and M. Wohlgenannt.

**3:06PM H7.00002 Near-infrared induced charge dynamics of the nitrogen vacancy center in diamond**, DAVID A. HOPPER, RICHARD R. GROTE, ANNEMARIE L. EXARHOS, LEE C. BASSETT, University of Pennsylvania

— The nitrogen-vacancy (NV) center in diamond is a key functional element in emerging quantum technologies such as nodes in quantum information processing and nanoscale sensors for condensed matter physics and biology. Recent efforts to optimize the NV's functionality lead to the discovery of photoinduced charge-state switching between the negative (NV<sup>-</sup>) and neutral (NV<sup>0</sup>) states which holds great potential to enhance the fidelity of spin readout. While the charge state dynamics under visible illumination have been studied, the effect of infrared light remains unexplored. Here, we use a tunable, pulsed infrared source to illuminate NV centers under various spin and optical states. Precise time-domain control of visible, microwave, and infrared pulses together with single-shot charge readout allows for the direct probing of spin and charge dynamics induced by the infrared light. This new understanding is relevant for the development of advanced protocols to leverage the NV's complete spin, charge, and optical dynamics for quantum control and sensing applications.

**3:18PM H7.00003 Formation and Annealing Behaviors of Qubit Centers in 4H-SiC from First Principles**, MINGWEN ZHAO, Shandong University, XIAOPENG WANG, Tulane University, HONGXIA BU, Shandong University, HONGYU ZHANG, East China University of Science and Technology, XIUJIE HE, AIZHU WANG, Shandong University, MINGWEN ZHAO'S LAB IN SHANDONG UNIVERSITY

TEAM — Inspired by finding that the nitrogen-vacancy center in diamond is a qubit candidate, similar defects in silicon carbide have drawn considerable interest. However, the generation and annealing behaviors of these defects remain unclear. Using first-principles calculations, we describe the equilibrium concentrations and annealing mechanisms based on the diffusion of silicon vacancies. The formation energies and energy barriers along different migration paths, which are responsible for the formation rates, stability, and concentrations of these defects, are investigated. The effects on these processes of charge states, annealing temperature, and crystal orientation are also discussed. These theoretical results are expected to be useful in achieving controllable generation of these defects in experiments.

**3:30PM H7.00004 First principle investigation of isolated vacancy in (111) diamond surface<sup>1</sup>**, WENHAO HU, MICHAEL FLATTÉ, Department of Physics and Astronomy, University of Iowa

— As the simplest intrinsic defect, isolated vacancy has been studied intensively theoretically and experimentally in diamond's bulk phase. Nevertheless, its correspondence in surface phase still lacks people's attention. Nitrogen vacancy center has become the most ideal candidates for solid states computing due to its long coherence time at room temperature. Resembling NV center, the isolated vacancy on surface exhibits a similar ambient potential and the same 3-fold rotational symmetry due to the asymmetry of surface, which implies a similar character in them. In our work, the isolated vacancy in clean and hydrogen terminated (111) surface of diamond are investigated from first principle perspective. Full potential LAPW method implemented in WIEN2K is exploited under GGA approximation. To evaluate the surface effect, the defect depth from topmost layer to fifth subsurface are considered with different slab thickness. By checking the spin density distribution and electronic structure, the hydrogen vacancy in H-terminated surface exhibit a spin- $\frac{1}{2}$  center with a 0/-1 transition level located in the middle of band gap. The -1/-2 transition level of carbon vacancy in the subsurface approaches the 0/-1 transition level implying the potential stability of spin-1 center.

<sup>1</sup>The work was supported by an AFOSR MURI.

**3:42PM H7.00005 Coherence studies on silicon vacancies in SiC generated via proton irradiation**, PETER BRERETON, DON PUENT, US Naval Academy, EVAN GLASER, SAM CARTER, US Navy Research Laboratory

— Single spins in defects in wide bandgap semiconductors are the canonical platform for scalable quantum technologies in the solid state. The silicon vacancy (VSi) in silicon carbide has very recently been shown to exhibit similar spin coherence to the diamond nitrogen vacancy center but in a material that has a mature technological base for fabrication and is an order of magnitude cheaper. Additionally, SiC has several polytypes, allowing the engineering of the spin behavior of the silicon vacancy. In this work, we generate ensembles of VSi via proton irradiation of 4H-SiC. We then measure the spin lifetimes and coherence times of ensembles of defect spins via optically detected magnetic resonance and Hahn pulse techniques. We show that the spin coherence time is strongly dependent on distance from the proton damage layer, therefore setting important parameters for the fabrication of long-lifetime single defect devices.

**3:54PM H7.00006 Magnetoresistance Phenomena in a Variety of Amorphous Semiconductors and Insulators<sup>1</sup>**, MICHAEL MUTCH, DAVID WESTLEY, PATRICK LENAHAAN, Pennsylvania State University, SEMICONDUCTOR SPECTROSCOPY LAB AT PENN STATE UNIVERSITY TEAM — We report on near zero-field magnetoresistance (MR) phenomena in a variety of amorphous semiconductors and insulators. We utilize electrically detected magnetic resonance (EDMR) measurements at multiple fields and frequencies to complement MR measurements. EDMR, the electrically detected analog of electron paramagnetic resonance (EPR), provides both information about the chemical nature and energy levels of point defects involved. Semiconductors in this study include a-BC:H, a-C:H, diamond-like carbon (DLC), and a-Si:H. Insulators include a-SiN:H, a-SiOC:H, a-SiCN:H. In hydrogenated amorphous systems, near featureless EPR and EDMR spectra are often difficult to analyze. We utilize multiple field and frequency EDMR results including ultra-low field/frequency ( $\nu = 85$  MHz,  $B = 3$  mT) EDMR measurements to provide insight into defect chemistry in these systems. We have also made EDMR and MR conditions over a wide range of metal/semiconductor heterojunction and metal/insulator/semiconductor biasing conditions. By comparing variable bias measurements with band diagrams, we gain an elementary understanding of defect energy levels. We believe our results will be of significant importance for understanding defect mediated spin-dependent transport in these systems.

<sup>1</sup>The authors would like to thanks Dr. Sean King of Intel Corporation for the provision of samples.

**4:06PM H7.00007 Exploration of Defects in 4H-SiC MOSFETs via Spin Dependent Charge Pumping**, MARK ANDERS, PATRICK LENAHAAN, Pennsylvania State Univ, AIVARS LELIS, U.S. Army Research Laboratory — 4H-SiC MOSFETs have great promise for use in high temperature and high voltage applications. Unfortunately, defects at the SiC/SiO<sub>2</sub> interface reduce the performance of these devices. Previously, our group utilized electrically detected magnetic resonance (EDMR) detected via spin dependent recombination (SDR) to identify such SiC/SiO<sub>2</sub> interface defects utilizing the bipolar amplification (BAE) biasing scheme; we observed SiC silicon vacancies, E-prime centers, and hydrogen complexed E-prime centers. All of these defects must have levels around the middle of the SiC band gap because they are effective recombination centers. We expanded our studies to include EDMR detection via spin dependent charge pumping (SDCP) at low field, X band, and K band, allowing EDMR exploration of nearly the entire 4H-SiC band gap. Perhaps the most important finding of the (nearly) full band gap measurements is the absence of the carbon dangling bond spectrum in the SDCP. Additionally, in nMOSFETs, we observe an SDCP EDMR spectrum dominated by a silicon vacancy, whereas in pMOSFETs, we also observe a strong, nearly isotropic single line spectrum with  $g = 2.00244$  and  $2.00248$  when the c-axis is nearly parallel and perpendicular to the magnetic field, respectively. The results suggest that silicon vacancy centers dominate nMOSFET interfaces whereas additional defects clearly play important roles in pMOSFETs.

**4:18PM H7.00008 Double electron-electron resonance measurements of diamond to determine  $T_2$  dependence on concentration of paramagnetic impurities<sup>1</sup>**, VIKTOR STEPANOV, SUSUMU TAKAHASHI, University of Southern California — A nitrogen-vacancy (NV) center in diamond is a promising candidate for investigation of fundamental sciences and applications to a nanoscale magnetic field sensing device because of unique properties of a NV center in diamond including capability to detect optically detected magnetic resonance (ODMR) signals from a single NV and initialize its spin state. Fundamental studies and applications of NV centers rely on coherent control of the NV centers that is limited by decoherence time ( $T_2$ ) and, as often observed,  $T_2$  is limited by paramagnetic impurity contents in diamond crystals. In this work, we will investigate  $T_2$  dependence on concentration of nitrogen impurities in type-Ib and type-IIa diamond crystals. For precise determination of the nitrogen concentration, we employ a home-built high-frequency electron spin resonance spectrometer which enables broadband double electron-electron resonance spectroscopy with high spectral resolution. **4:30PM H7.00009 Electrical detection and imaging of individual phosphorus and silicon-dangling bonds states at the crystalline silicon to silicon dioxide interface**, KAPILDEB AMBAL, Univ of Utah, PHILIPP RAHE, University of Nottingham, ADAM PAYNE, Univ of Utah, JAMES SLINKMAN, RFSoI Technology Development, IBM Microelectronics, CLAYTON C WILLIAMS, CHRISTOPH BOEHME, Univ of Utah — Nuclear spins of phosphorus [P] donor atoms in crystalline silicon are promising qubit candidates, but utilizing these systems for scalable quantum devices will require the ability to probe individual donors on atomic length scales and address these systems by application of well-controlled electric fields<sup>1</sup>. In this talk we focus on identifying individual P donor and P<sub>b</sub> (dangling bond) states by measuring electric current through a crystalline silicon (100) - SiO<sub>2</sub> interface, observing charge flow through individual pairs of P donors and highly localized ( $\text{\AA}$ -range) silicon dangling bond states. The experiments were conducted with neutral P donor states using a low-temperature ( $T = 4.3\text{K}$ ) ultra-high vacuum scanning probe microscope with a quartz tuning fork sensor that allows simultaneous AFM and local current measurements in complete darkness. This so called conduction-atomic force microscopy experiment<sup>2</sup> yields images of the dangling bond states coupled to individual phosphorus donors. I-V responses on these isolated highly localized charge percolation paths further support the hypothesis that individual P-donor - P<sub>b</sub> states are being addressed, and that spin-states may be probed using spin-dependent charge-carrier recombination current between <sup>31</sup>P and the interface defects. [1] B. E. Kane, Nature **393**, 133 (1998); [2] S. Kremmer et al., Surf. Interface Anal. **33**, 168 (2002).

**4:42PM H7.00010 ESR Experiments on a Single Donor Electron in Isotopically Enriched Silicon<sup>1</sup>**, LISA TRACY, DWIGHT LUHMAN, STEPHEN CARR, JOHN BORCHARDT, NATHANIEL BISHOP, GREGORY TEN EYCK, TAMMY PLUYM, JOEL WENDT, WAYNE WITZEL, ROBIN BLUME-KOHOUT, ERIK NIELSEN, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Labs — In this talk we will discuss electron spin resonance experiments in single donor silicon qubit devices fabricated at Sandia National Labs. A self-aligned device structure consisting of a polysilicon gate SET located adjacent to the donor is used for donor electron spin readout. Using a cryogenic HEMT amplifier next to the silicon device, we demonstrate spin readout at 100 kHz bandwidth and Rabi oscillations with 0.96 visibility. Electron spin resonance measurements on these devices show a linewidth of 30 kHz and coherence times  $T_2^* = 10$  us and  $T_2 = 0.3$  ms. We also discuss estimates of the fidelity of our donor electron spin qubit measurements using gate set tomography. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

<sup>1</sup>ESR Experiments on a Single Donor Electron in Isotopically Enriched Silicon

**4:54PM H7.00011 Nanoscale thermal imaging using a scanning spin probe.** , ABDELGHANI LARAOUI, HALLEY AYCOCK-RIZZO, Department of Physics, CUNY-City College of New York, YANG GAO, ELISA RIEDO, CUNY-Advanced Research Science Center, Department of Physics, Georgia Institute of Technology, CARLOS MERILES, Department of Physics, CUNY-City College of New York — We use a 30-nm diamond-nanocrystal-hosted nitrogen-vacancy (NV) center attached to the apex of a silicon tip as a local temperature sensor. First, we apply an electrical current to heat up the tip to a predefined operating temperature and rely on the NV to monitor the small thermal changes the tip experiences as it is brought into contact with surfaces of varying thermal conductivity. With the aid of a combined AFM/confocal setup, we image engineered microstructures with nanoscale resolution, and attain excellent agreement between the thermal conductivity and topographic maps [1]. Given the small mass of the NV-hosting diamond nanoparticle, our technique shows a fast time response of order hundred microseconds, limited by the heat dissipation time of the tip. In a second approach, we heat nanostructured gold deposited on glass substrate by injecting a direct current. By monitoring the frequency shift of NV spin transitions upon scanning the AFM tip we reconstruct nanometer-resolved temperature maps. Our technique promises multiple applications ranging from the investigation of phonon dynamics in nanostructures to the characterization of heterogeneous phase transitions in various solid-state systems. [1] A. Laraoui, et al., Nat. Commun, in press.

**5:06PM H7.00012 Optimizing the Growth of (111) Diamond for Diamond Based Magnetometry<sup>1</sup>** , ERIC KAMP, PATRICK GODWIN, NITIN SAMARTH, Pennsylvania State University, DAVID SNYDER, Pennsylvania State University Applied Research Laboratory, CHARLES DE LAS CASAS, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago — Magnetometers based on nitrogen vacancy (NV) ensembles have recently achieved sub-picotesla sensitivities [Phys. Rev. X 5, 041001(2015)], putting the technique on par with SQUID and MFM magnetometry. Typically these sensors use (100) oriented diamond with NV centers forming along all four (111) crystal orientations. This allows for vector magnetometry, but is a hindrance to the absolute sensitivity. Diamond grown on (111) oriented substrates through microwave plasma enhanced chemical vapor deposition (MP-CVD) provides a promising route in this context since such films can exhibit preferential orientation greater than 99% [Appl. Phys. Lett. 104, 102407(2014)]. An important challenge though is to achieve sufficiently high NV center densities required for enhancing the sensitivity of an NV ensemble magnetometer. We report systematic studies of the MP-CVD growth and characterization of (111) oriented diamond, where we vary growth temperature, methane concentration, and nitrogen doping. For each film we study the Nitrogen to NV ratio, the  $NV^-$  to  $NV^0$  ratio, and alignment percentage to minimize sources of decoherence and ensure preferential alignment. From these measurements we determine the optimal growth parameters for high sensitivity, NV center ensemble scalar magnetometry.

**5:18PM H7.00013 First principles identification of divacancy configurations in 4H- and 6H-SiC** , ADAM GALI, Wigner Research Centre for Physics, Hungarian Academy of Sciences, VIKTOR IVÁDY, Linköping University, KRISZTIÁN SZÁSZ, Wigner Research Centre for Physics, Hungarian Academy of Sciences, IGOR. A. ABRIKOSOV, ERIK JANZÉN, Linköping University — Based on the combination of ab initio simulations and group theory considerations it was proposed earlier that the high spin divacancy defect in silicon carbide (SiC) with similar electronic structure as the NV center in diamond could be utilized as a solid state quantum bit [1]. Recent demonstrations have shown coherent manipulation of divacancy and related defect spins in 4H- [2], 6H- and 3C-SiC [3]. In hexagonal SiC polytypes, point defects can exist in numerous different configurations. Associating potentially interesting photoluminescence (PL) centers with their microscopic configurations is of great importance as quantum information applications often require single defect control. In our study, we carry out large-scale first principles calculation to identify the aforementioned divacancy related point defects. By resolving accuracy issues of ab initio supercell techniques, we were able to obtain convergent PL energies, zero-field-splitting, and hyperfine parameters. Our results confirm previous assignment of the divacancy related PL1-PL4 PL lines in 4H-SiC to their microscopic structure, provide the identification of QL1-QL6 PL lines in 6H-SiC, as well as propose defect configurations for the unknown PL5-PL6 centers in 4H-SiC that yields strong signal at room temperature. **2:30PM H8.00001 Universality of commensurate 4a-period charge density modulations throughout the cuprate pseudogap regime** , ANDREJ MESAROS, LASSP, Department of Physics, Cornell University, KAZUHIRO FUJITA, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, MOHAMMAD HAMIDIAN, Department of Physics, Harvard University, HIROSHI EISAKI, Institute of Advanced Industrial Science and Technology, Tsukuba, SHIN-ICHI UCHIDA, Department of Physics, University of Tokyo, J.C. DAVIS, MICHAEL J. LAWLER, EUN-AH KIM, LASSP, Department of Physics, Cornell University — Theories for the hole-doped Mott insulator, representing underdoped cuprates, are based upon the strong real space ( $r$ -space) interactions, and have long predicted a modulation of charge that is commensurate with the underlying lattice. Such a charge density modulation (CDM) state is unrelated to any momentum space ( $k$ -space) features such as the nesting of regions on a Fermi surface. Experimentally, with increasing hole density, the reported wavevector  $Q$  of the CDM diminishes continuously with increasing hole-density as if driven by  $k$ -space phenomena. Using a novel technique based upon phase-sensitive electronic structure visualization, we demonstrate that the cuprate CDM actually exhibits a commensurate 4a-period throughout the entire underdoped region of the  $Bi_2Sr_2CaCu_2O_8$  phase diagram. Our technique is designed for extracting  $Q$  from inhomogeneous, short-ranged CDM, as the ones observed in experiments. Thus, a strong-interaction  $r$ -space perspective appears to be relevant to achieving a predictive theory for the cuprate pseudogap regime.

**2:42PM H8.00002 Photoemission spectra of charge density wave states in cuprates** , WEI-LIN TU, Dept. of Physics, National Taiwan University, PENG-JEN CHEN, TING-KUO LEE, Institute of Physics, Academia Sinica — Angle-resolved photoemission spectroscopy (ARPES) experiments have reported many exotic properties of cuprates, such as Fermi arc at normal state, two gaps at superconducting state and particle-hole asymmetry at the antinodal direction[1]. On the other hand, a number of inhomogeneous states or so-called charge density waves (CDW) states have also been discovered in cuprates by many experimental groups. The relation between these CDW states and ARPES spectra is unclear. With the help of Gutzwiller projected mean-field theory[2], we can reproduce the quasiparticle spectra in momentum space. The spectra show strong correspondence to the experimental data with afore-mentioned exotic features in it. \pard1. I. Vishik et al, PNAS 109, 18332-18337(2012).. Wei-Lin Tu and Ting-Kuo Lee, arXiv: 1505.07728(2015).

**2:54PM H8.00003 Anisotropic Fermi surface reconstruction in the cuprate superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_y$** , NICOLAS DOIRON-LEYRAUD, OLIVIER CYR-CHOINIERE, SVEN BADOUX, BASTIEN MICHON, AREZOO AFSHAR, ALEXANDRE OUELLET, LOUIS TAILLEFER, University of Sherbrooke, RUIXING LIANG, DOUG BONN, WALTER HARDY, University of British Columbia — Recent X-ray scattering experiments on underdoped  $\text{YBa}_2\text{Cu}_3\text{O}_y$  have revealed a transition from two-dimensional short-range charge-density wave modulations to a state of three-dimensional long-range charge order as a function of magnetic field [1]. Transport experiments have shown that the Fermi surface reconstruction (FSR) occurs at that transition [2]. To examine the symmetry of this FSR we have measured the thermopower of high-quality single crystals of  $\text{YBa}_2\text{Cu}_3\text{O}_y$  with dopings  $p = 0.11$  and  $0.12$  as a function of magnetic field up to  $45$  T. At low temperatures we observe a clear anisotropy of the Seebeck coefficient between the  $a$  and  $b$  axes, strong evidence of a uniaxial stripe-like FSR. The onset of this  $a$ - $b$  anisotropy as a function of magnetic field and temperature correlates well with other transport, thermodynamic, and diffraction measurements, defining a high-magnetic field and low-temperature long-range quasi-1D charge-ordered state. [1] S. Gerber et al., Science aac6257 (2015). [2] G. Grissonanche et al., arXiv:1508.05486.

**3:06PM H8.00004 Correlation strength and  $T_c$ : quantum oscillations in  $\text{YBa}_2\text{Cu}_4\text{O}_8$  under hydrostatic pressure**, C. PUTZKE, L. MALONE, University of Bristol, S. BADOUX, B. VIGNOLLE, D. VIGNOLLES, W. TABIS, LNCMI-Toulouse, P. WALMSLEY, M. BIRD, N.E. HUSSEY, University of Bristol, C. PROUST, LNCMI-Toulouse, A. CARRINGTON, University of Bristol — The unusual normal state electronic structure of the cuprates is widely believed to be at the heart of understanding high-temperature superconductivity in these materials. Recent quantum oscillation measurements in  $\text{YBa}_2\text{Cu}_3\text{O}_{7-d}$  (Y123) have found a strong increase in the quasiparticle effective mass close to two separate critical points in the temperature-doping phase diagram [1]. Here we present a study of quantum oscillations in the double chain cuprate superconductor  $\text{YBa}_2\text{Cu}_4\text{O}_8$  (Y124). Instead of varying the doping by changing  $d$  (in Y123) we study the evolution of the quantum oscillations under hydrostatic pressure. Pressure increases  $T_c$  by around  $0.6\text{K/kbar}$ , primarily, it is thought, by increasing charge transfer between the chains and planes. Unlike in Y123, where the increase in  $T_c$  close to optimal doping is accompanied by a strong increase in quasiparticle mass, in Y124 we find that the mass decreases. Our results suggest that the mechanism that leads to the mass enhancement in the cuprates (most likely the emergence of a competing charge density wave instability) does not directly lead to an enhancement of the superconducting critical temperature. **3:18PM H8.00005 Spin-fermion model with overlapping hot spots and charge modulation in cuprates.**, PAVEL A. VOLKOV, Ruhr-Universitt Bochum, KONSTANTIN B. EFETOV, Ruhr-Universitt Bochum; National University of Science and Technology "MISIS", Moscow — We study particle-hole instabilities in the framework of the spin-fermion model. In contrast to previous studies, we assume that adjacent hot spots can overlap due to a shallow dispersion of the electron spectrum in the antinodal region and take the effects of a remnant Coulomb interaction into account. We demonstrate that at sufficiently small values  $|\varepsilon(\pi, 0) - E_F| < \Gamma$ , where  $\Gamma$  is a characteristic energy of the fermion-fermion interaction due to the paramagnons, the leading particle-hole instability is a d-form factor Fermi surface deformation rather than the charge modulation along the Brillouin zone diagonals. At lower temperatures, we find that the deformed Fermi surface is further unstable to formation of a d-form factor charge density wave (CDW) with a wave vector along one of the Brillouin zone axes. These findings can explain the robustness of this order in hole-doped cuprates. The approximations made are justified by a small parameter that allows one an Eliashberg-like treatment. Comparison with experiments suggests that in many cuprate compounds the prerequisites for the proposed scenario are indeed fulfilled and the results obtained may explain important features of the charge modulations observed recently.

**3:30PM H8.00006 X-ray diffraction study of charge density wave fluctuations in  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  under uniaxial pressure**, THOMAS CROFT, CHRISTOPHER LESTER, University of Bristol, ALESSANDRO BOMBARDI, BENJAMIN MOSER, Diamond Light Source, STEPHEN HAYDEN, University of Bristol — Charge density wave (CDW) order now appears to be a universal feature of the cuprate phase diagram.  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  (LSCO) is a canonical example with a simple crystal structure and  $T_{\text{CDW}} \sim 80$  K. In other 214-cuprates (LBCO, Eu/Nd-LSCO), the onset of CDW order is closely associated with a transition from a low-temperature orthorhombic (LTO) to a low-temperature tetragonal (LTT) phase. Despite lack of long range LTT order in LSCO, several experiments detect the presence of local LTT regions. These may arise from LTO domain boundaries that support the LTT structure and also serve as the origin of the CDW. Here we report X-ray diffraction measurements on LSCO ( $x = 0.13$ ) under applied uniaxial strain. The experiment utilized a piezo-based device allowing the sample to be detwinned *in-situ*. In the absence of applied strain, a transition to the LTO phase is observed at  $\sim 230$  K. LTT type peaks are also observed at this temperature and CDW order is seen to set in  $< 100$  K. On application of compressive strain, the amplitude and onset temperature of LTT and CDW phases are largely unaffected after removing domain boundaries suggesting these phases originate from a fluctuating state within the bulk and are not simply localized around boundary regions.

**3:42PM H8.00007 Seebeck coefficient of underdoped LSCO in high magnetic fields : Fermi-surface reconstruction by charge-density-wave order**, SVEN BADOUX, AREZOO AFSHAR, BASTIEN MICHON, ALEXANDRE OUELLET, SIMON FORTIER, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, DAVID LEBOEUF, LNCMI, Grenoble, France, THOMAS CROFT, STEPHEN HAYDEN, University of Bristol, Bristol, UK, HIDENORI TAKAGI, University of Tokyo, Tokyo, Japan, KAZUYOSHI YAMADA, Tohoku University, Sendai, Japan, DAVID GRAF, NHMFL, Tallahassee, USA — The Seebeck coefficient  $S$  of the hole-doped cuprate  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  (LSCO) was measured in magnetic fields large enough to suppress superconductivity, for a range of Sr concentrations  $x$  in the underdoped regime. For  $x = 0.12, 0.125$  and  $0.13$ ,  $S/T$  is seen to drop upon cooling and become negative at low temperature. The same behavior is observed in the Hall coefficient  $R_H(T)$ . In analogy with other hole-doped cuprates at similar hole concentrations [1-4], the sign change in  $S$  and  $R_H$  shows that the Fermi surface of LSCO undergoes a reconstruction caused by the onset of charge-density-wave modulations. Such modulations have indeed been detected in LSCO by X-ray diffraction in precisely the same doping range [5].

**3:54PM H8.00008 Doping dependence of the charge-density-wave order in  $\text{HgBa}_2\text{CuO}_{4+\delta}$** , BIQIONG YU, School of Physics and Astronomy, University of Minnesota — Following the original discovery of short-range charge-density-wave (CDW) order in the orthorhombic double-layer cuprate  $\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}$  (YBCO) below optimal doping, resonant X-ray scattering measurements have revealed that the simple tetragonal single-layer compound  $\text{HgBa}_2\text{CuO}_{4+\delta}$  (Hg1201;  $T_c = 71$  K) exhibits short-range CDW order as well [1]. Here we report on the doping dependence of the CDW order in Hg1201 and contrast our results with the extensive data available for YBCO [2]. Work done in collaboration with: W. Tabis, G. Yu, M.J. Veit, N. Barišić, M.K. Chan, C.J. Dorow, X. Zhao, M. Greven (University of Minnesota); M. Bluschke, E. Weschke (BESSY, Berlin); T. Kolodziej, I. Bialo, A. Kozłowski (AGH, Krakow); M. Hepting, H. **4:06PM H8.00009 Nematicity in Stripe Ordered Cuprates Probed via Resonant X-Ray Scattering**, CHRISTOPHER MCMAHON, ANDREW ACHKAR, University of Waterloo, MARTIN ZWIEBLER, Leibniz Institute for Solid State Materials Research IFW Dresden, FEIZHOU HE, RONNY SUTARTO, Canadian Light Source, ISIAH DJANTO, ZHIHAO HAO, MICHEL GINGRAS, University of Waterloo, MARKUS HUCKER, GENDA GU, Brookhaven National Laboratory, ALEXANDRE REVCOLEVSKI, Synthese, Propriétés et Modélisation des Matériaux (SP2M), HARRY ZHANG, None, YOUNG-JUNE KIM, University of Toronto, JOCHEN GECK, Leibniz Institute for Solid State Materials Research IFW Dresden, DAVID HAWTHORN, University of Waterloo — In underdoped cuprate superconductors, a rich competition occurs between superconductivity and charge density wave (CDW) order. Under debate, however, is whether rotational symmetry breaking (nematicity) also plays a central role - whether it occurs intrinsically and generically or merely as a consequence of other orders. Here we employ resonant x-ray scattering in stripeordered  $(\text{La,M})_2\text{CuO}_4$  to probe the relationship between electronic nematicity of the Cu  $3d$  orbitals, structure of the  $(\text{La,M})_2\text{O}_2$  layers and CDW order. We find distinct temperature dependencies of the structure of the  $(\text{La,M})_2\text{O}_2$  layers and the electronic nematicity of the  $\text{CuO}_2$  planes, with only the latter being enhanced by the onset of CDW order. These results suggest electronic nematicity is an order parameter that is distinct from a purely structural order parameter in underdoped cuprates.

**4:18PM H8.00010 Innovative uses of X-ray FEL and the pulsed magnets: High magnetic field X-ray scattering studies on quantum materials**, H. JANG, SLAC, H. NOJIRI, Tohoku Univ., S. GERBER, W.-S. LEE, D. ZHU, J.-S. LEE, C.-C. KAO, SLAC — X-ray scattering under high magnetic fields provides unique opportunities for solving many scientific puzzles in quantum materials, such as strongly correlated electron systems. Incorporating high magnetic field capability presents serious challenges at an x-ray facility, including the limitation on the maximum magnetic field even with a DC magnet (up to ~20 Tesla), expensive cost in development, radiation damage, and limited flexibility in the experimental configuration. These challenges are especially important when studying the symmetry broken state induced by the high magnetic field are necessary, for example, exploring intertwined orders between charge density wave (CDW) and high  $T_c$  superconductivity. Moreover, a gap in magnetic field strengths has led to many discrepancies and puzzling issues for understanding strongly correlated systems – is a CDW competing or more intimately intertwined with high-temperature superconductivity. To bridge this gap and resolve these experimental discrepancies, one needs an innovative experimental approach. Here, we will present a new approach to x-ray scattering under high magnetic field up to 28 Tesla by taking advantage of brilliant x-ray free electron laser (FEL). The FEL generates sufficiently high photon flux for single shot x-ray scattering experiment. In this talk, we will also present the first demonstration about the field induced CDW order in YBCO Ortho-VIII with 28 Tesla, which show the totally unexpected three-dimensional behavior.

**4:30PM H8.00011 Evidence for charge density wave order in the quasi-1D Superconductor  $\text{Ta}_4\text{Pd}_3\text{Te}_{16}$** , TONI HELM<sup>\*1</sup>, Lawrence Berkeley National Laboratory, University of California, Berkeley, CA, USA, ROBERT KEALHOFER, PHILIP J. W. MOLL\*, ZHENGLU LI, NICHOLAS P. BREZNAY, IAN HAYES, FELIX FLICKER, University of California, Berkeley, CA, USA, ROSS MACDONALD, LUIS BALICAS, National High Magnetic Field Laboratory, USA, STEVEN LUI, JAMES G. ANALYTIS, University of California, Berkeley, CA, USA — One dimensional metals are commonly susceptible to electronic instabilities such as density waves. Only recently the ternary Chalcogenide  $\text{Ta}_4\text{Pd}_3\text{Te}_{16}$  (TPT) was observed to superconduct below  $T_c = 4.6\text{ K}$  [1]. Band structure calculations predict a complex multiband Fermi surface in TPT, including strongly nested quasi 1D bands[2]. Despite this one-dimensional character, no evidence for a Peierls transition has been reported and its superconductivity below  $T_c$  was suggested to be unconventional. We investigate this puzzle by high-field quantum oscillation experiments and contrast them with first-principles band-structure calculations. Our quantum oscillation experiments in high magnetic fields confirmed the presence of 2D and 3D bands. Our magnetotransport measurements on microstructures fabricated by focused ion beam etching reveal an anomaly above  $T_c$ , suggesting the onset of charge density wave ordering. [1] W. H. Jiao et al. J. Am. Chem. Soc. 136, 1284 (2014) [2] D. Singh, PRB 90, 144501 (2014)

<sup>1\*</sup> Current address: Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany

**4:42PM H8.00012 Things that make  $\text{TiSe}_2$  superconducting**, IVO PLETIKOSIC, HUIXIA LUO, WEIWEI XIE, ELIZABETH SEIBEL, JASON KRIZAN, ROBERT CAVA, Princeton Univ, TONICA VALLA, Brookhaven National Laboratory — The unusual charge density wave phase in  $\text{TiSe}_2$  is accompanied by superconductivity when electron dopants like copper and palladium are intercalated between the layers of this transition-metal dichalcogenide. But when nominally one-electron donors like tantalum and niobium are brought in to replace titanium,  $\text{Ti}_{1-x}\text{Ta}_x\text{Se}_2$  is superconducting and  $\text{Ti}_{1-x}\text{Nb}_x\text{Se}_2$  not. We investigated by angle-resolved photoemission (ARPES) the origins of this behavior by comparing the electronic band structure of pristine  $\text{TiSe}_2$  and the two doped compounds. We question whether the effect can be attributed to the differences in electron doping only.

**4:54PM H8.00013 Resonance-state-induced superconductivity at high Indium contents in In-doped  $\text{SnTe}$** , NEEL HALDOLAARACHCHIGE, Saint Joseph's University, QUINN GOBSON, WEIWEI XIE, MORTEN NIELSEN, SATYA KUSHWAHA, ROBERT CAVA, Princeton University, CAVA'S GROUP TEAM — We report a reinvestigation of superconducting  $\text{Sn}_{1-x}\text{In}_x\text{Te}$  at both low and high In doping levels. Analysis of the superconductivity reveals a fundamental change as a function of  $x$ : the system evolves from a weakly coupled to a strongly coupled superconductor with increasing indium content. Hall Effect measurements further show that the carrier density does not vary linearly with Indium content; indeed at high Indium content, the samples are overall n-type, which is contrary to expectations of the standard picture of  $\text{In}^{1+}$  replacing  $\text{Sn}^{2+}$  in this material. Density functional theory calculations probing the electronic state of In in  $\text{SnTe}$  show that it does not act as a trivial hole dopant, but instead forms a distinct, partly filled In  $5s$  - Te  $5p$  hybridized state centered around  $E_F$ , very different from what is seen for other nominal hole dopants such as Na, Ag, and vacant Sn sites. We conclude that superconducting In-doped  $\text{SnTe}$  therefore cannot be considered as a simple hole doped semiconductor.

**5:06PM H8.00014 Fermiology of the low carrier density superconductor Tl-doped  $\text{PbTe}$ , and its non-superconducting analog, Na-doped  $\text{PbTe}$ .**, PAULA GIRALDO-GALLO, Stanford University and National High Magnetic Field Laboratory, PHILIP WALMSLEY, Stanford University, BORIS SANGIORGIO, MICHAEL FECHNER, ETH Zurich, LISA BUCHAUER, BENOIT FAUQUE, ESPCI, Paris, France, SCOTT RIGGS, National High Magnetic Field Laboratory, ROSS MCDONALD, Los Alamos National Laboratory, THEODORE GEBALLE, Stanford University, NICOLA SPALDIN, ETH Zurich, KAMRAN BEHNIA, ESPCI, Paris, France, IAN FISHER, Stanford University —  $\text{PbTe}$  is a narrow band gap semiconductor, which can be electron- or hole-doped, obtaining typical carrier densities of the order of  $1 \times 10^{20} \text{ cm}^{-3}$ . The only impurity known to produce superconductivity in this host material is Tl, resulting in a maximum critical temperature of 1.5K - an order of magnitude higher than the  $T_c$  observed in similar low carrier density semiconductors. In this work we performed a full Fermi surface characterization of  $\text{Pb}_{1-x}\text{Tl}_x\text{Te}$ , as well as its non-superconducting analog,  $\text{Pb}_{1-x}\text{Na}_x\text{Te}$ , via Shubnikov de Haas oscillations in magnetotransport, for magnetic fields up to 35T (DC). Our results show that beyond a critical impurity concentration close to the emergence of superconductivity, there are clear differences in the normal-state carriers. In non-superconducting  $\text{Pb}_{1-x}\text{Na}_x\text{Te}$ , all carriers reside at four ellipsoidal pockets of the Fermi surface, while in superconducting  $\text{Pb}_{1-x}\text{Tl}_x\text{Te}$ , there is an additional set of carriers, consistent with incoherent resonant impurity levels. The presence or absence of these states at or near the Fermi energy is intimately connected to the presence or absence of superconductivity in doped  $\text{PbTe}$ .

we would like to present back-to-back with the following contribution:

Paula Giraldo-Gallo et al., "Fermiology of the low carrier density superconductor Tl-doped  $\text{PbTe}$ , and its non-superconducting analog, Na-doped  $\text{PbTe}$ "

### 5:18PM H8.00015 First-principles Fermi surface of doped

Zurich, PAULA GIRALDO-GALLO, Stanford University, MICHAEL FECHNER, Materials Theory, ETH Zurich — PbTe is a narrow-gap semiconductor and one of the few materials where a superconducting state is observed. When doped with Tl atoms an unusual superconducting state is observed that persists to  $\sim 1.5$  K, the nature of the superconductivity is not well understood, with a charge Kondo effect suggested as the origin. We will discuss the electronic properties - in particular the Fermi surface - of doped PbTe using first-principles calculations. We compute de Haas-van Alphen frequencies and compare them to recent quantum-oscillations experiments. We confirm the usefulness of the rigid-band approximation for Na impurities. In contrast, we find for Tl impurities: a narrow "impurity band" (originating from hybridization between Tl  $s$  and Te  $p$  orbitals) and a charge disproportionation instability, such as a charge disproportionation, which is likely relevant for the superconductivity.

Thank you very much!

Session H11 DMP: Correlations and Superconductivity in Fe Chalcogenides | 307 - Amalia Coldea, Oxford University

### 2:30PM H11.00001 Systematic investigation of the electron Fermi surface dominated FeSe

based systems, DONGLAI FENG, Dept. of Physics, Fudan University — FeSe-based superconductors exhibit very rich phenomena. We systematically investigate the behavior of isovalent doping and electron carrier doping effects in a variety of FeSe-based superconductors with angle-resolved photoemission spectroscopy (ARPES). For the isovalent-doped  $A_x\text{Fe}_2(\text{Se}, \text{S/Te})_2$ , a continuous decreasing bandwidth is observed from the heavily S doped side to the highly Te doped side, while the system ground state evolves from a metal to a superconductor, and eventually to a correlation-driven insulator. On the other hand, when electron doping is introduced by surface K dosing on bulk FeSe or thick FeSe films, the system ground state evolves from a nematic metal to a superconductor, and then an insulator before it becomes a metal again. Correlation is found to increase with electron doping as well. These two intriguing phase diagrams of FeSe-based superconductors highlight the important role of correlations on the ground state, and provide a microscopic understanding of various FeSe-based superconductors, including the recently discovered  $(\text{Li,Fe})\text{OHFeSe}$ . Reference [1] X. H. Niu et al. Phys. Rev. B 92, 060504(R) (2015). [2] C. H. P. Wen et al. arXiv:1508.05848. [3] X. H. Niu et al. arXiv:1506.04018.

### 3:06PM H11.00002 Observation of two distinct $dxz/dyz$ band splittings in FeSe

, PENG ZHANG, TIAN QIAN, PIERRE RICHARD, Institute of Physics, CAS, XIAOPING WANG, Department of Physics, Tsinghua University, HU MIAO, BAIQING LV, BINBIN WU, Institute of Physics, CAS, THOMAS WOLF, CHRISTOPH MEINGAST, Institut für Festkörperphysik, Karlsruhe Institute of Technology, XIANXIN WU, Institute of Physics, CAS, ZIJIANG WANG, Department of Physics, Boston College, JIANGPING HU, HONG DING, Institute of Physics, CAS — We report the temperature evolution of the detailed electronic band structure in FeSe single crystals measured by angle-resolved photoemission spectroscopy (ARPES), including the degeneracy removal of the  $dxz$  and  $dyz$  orbitals at the  $\Gamma$  and M points, and the orbital-selective hybridization between the  $dxz$  and  $dyz$  orbitals. The temperature dependences of the splittings at the  $\Gamma$  and M points are different, indicating that they are controlled by different order parameters. The splitting at the M point is closely related to the structural transition and is attributed to orbital ordering defined on Fe-Fe bonds with a d-wave form in the reciprocal space that breaks the rotational symmetry. In contrast, the band splitting at the  $\Gamma$  points remains at temperature far above the structural transition. Although the origin of this latter splitting remains unclear, our experimental results exclude the previously proposed ferro-orbital ordering scenario.

### 3:18PM H11.00003 The effects of local correlations on the electronic structure of FeSe<sup>1</sup>

, MATTHEW WATSON, TIMUR KIM, Diamond Light Source, Harwell Campus, Didcot, OX11 0DE, AMIR HAGHIGHIRAD, AMALIA COLDEA, Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford OX1 3PU — FeSe is structurally the simplest of Fe-based superconductors, but its complex and unique properties pose important theoretical questions. One important aspect of the physics of FeSe is the understanding of the strength and effects of electronic correlations. In order to explore this, we have performed angle-resolved photo-emission spectroscopy (ARPES) measurements on high quality bulk single crystals of FeSe over a wide range of binding energies, in different scattering geometries and with varying incident photon energies, analysing the quasiparticle renormalisations, scattering rates and degree of coherence. We find that FeSe exhibits moderately strong, orbital-dependent correlation effects which are understood to arise primarily due to local electron-electron interactions on the Fe sites. We conclude that electronic correlations constitute a key ingredient in understanding the electronic structure of FeSe.

### 3:30PM H11.00004 Magnetic interactions in FeSe studied by first principle calculations<sup>1</sup>

, SHUAI WANG, FA WANG, Peking Univ — Based on first principle calculations we have investigated the evolution of magnetism in free-standing monolayer FeSe with respect to lattice constant and magnetism in bulk FeSe. The computational results show that the magnetic order in free-standing monolayer FeSe will change from anti-ferromagnetic pair-checkboard order to stripe collinear order along with enlarging lattice constant. The magnetic order in bulk FeSe will change from stripe collinear order to anti-ferromagnetic pair-checkboard order only if structure reconstruction is allowed. We use  $J_1$ - $J_2$ - $K_1$  model to fit the calculated total energies of different magnetic orders to study magnetic interaction strengths in FeSe. The fitting results of  $J_1$ - $J_2$ - $K_1$  indicate that magnetic interactions in FeSe are quite strong and highly frustrated, and increase slowly with enlarging lattice parameter.

**3:42PM H11.00005 Highly accurate calculation of the magnetic properties of FeSe and FeTe using first principles quantum Monte Carlo<sup>1</sup>**, BRIAN BUSEMEYER, University of Illinois at Urbana-Champaign, MARIO DAGRADA, SANDRO SORELLA, University Pierre et Marie Curie, MICHELE CASULA, SISSA, LUCAS K. WAGNER, University of Illinois at Urbana-Champaign — While the origin of superconductivity in the iron-based materials is still controversial, the proximity of the superconductivity to magnetic order is suggestive that magnetism may be important. We use first principles quantum Monte Carlo (QMC) techniques to obtain an accurate microscopic picture of the effects of magnetic configurations on the electronic structure of FeSe under pressure. The QMC calculations reproduce experimental values for bulk modulus, lattice constants, bandwidth, and lowest energy magnetic ordering. The relative energy of magnetic orderings is rather different from standard density functional theory calculations, which may warrant a reassessment of the role of magnetism in this material. We analyze the correlated wave functions to obtain a microscopic explanation for the spontaneous  $S_4$  symmetry-breaking in this material, and contrast these results with the non-superconducting case of FeTe.

**3:54PM H11.00006 Quadrupolar Spin Orders in FeSe**, ZHENTAO WANG, ANDRIY NEVIDOMSKYY, Department of Physics and Astronomy, Rice University — Motivated by the absence of long-range magnetic order and the strong spin fluctuations observed in the Fe-based superconductor FeSe, we study spin-1 model on a square lattice up to next-nearest neighbor Heisenberg and biquadratic spin exchanges. The zero-temperature variational phase diagram gives the conventional antiferromagnetic order and also more exotic quadrupolar spin phases. These quadrupolar phases do not host long-range magnetic order and preserve time-reversal symmetry, but break the spin  $SU(2)$  symmetry. In particular, we observe a robust ferroquadrupolar order (FQ) in immediate proximity to the columnar AFM phase. We envision that FeSe may be positioned within the FQ phase close to the phase boundary. Using the flavor-wave technique, we calculate the structure factor inside the FQ phase and find a Goldstone mode emerging from  $Q = (0, 0)$ , which however bears zero spectral weight at  $\omega = 0$  due to time reversal symmetry. At the same time, we observe strong spin fluctuations near  $(\pi, 0)/(0, \pi)$ , which agrees with the recent neutron scattering experiments. Further, we calculate the higher order interactions between the  $(\pi, 0)$  and  $(0, \pi)$  spin fluctuations inside the FQ phase, which may shed light on the  $C_4$  symmetry breaking in the nematic phase of FeSe.

**4:06PM H11.00007 Electronic correlations and topological Fermi surface transition in the iron-based chalcogenides**, S. SKORNYAKOV, Institute of Metal Physics, Yekaterinburg, Russia and Ural Federal Univ., Yekaterinburg, Russia, I. LEONOV, Theoretical Physics III, Center for Electronic Correlations and Magnetism, Univ. Augsburg, Germany, V.I. ANISIMOV, Institute of Metal Physics, Yekaterinburg, Russia and Ural Federal Univ., Yekaterinburg, Russia, D. VOLLHARDT, Theoretical Physics III, Center for Electronic Correlations and Magnetism, Univ. Augsburg, Germany — We present results of a theoretical investigation of the electronic structure and phase stability of paramagnetic FeSe obtained within a combination of *ab initio* methods for calculating band structure and dynamical mean-field theory. Our results reveal an entire reconstruction of the Fermi surface topology upon a moderate expansion of the lattice (Lifshitz transition), with a change of magnetic correlations from the in-plane magnetic wave vector  $(\pi, \pi)$  to  $(\pi, 0)$ . We attribute this behavior to a correlation-induced shift of the Van Hove singularity originating from the  $xy$  and  $xz/yz$  bands at the M-point across the Fermi level. Our results predict a structural transition of FeSe upon a ca. 10 % expansion of the lattice volume as well as a topological change of the Fermi surface of FeSe upon partial substitution Se by Te, which is accompanied with a sharp increase of the local moments. We expect that these changes are responsible for the experimentally observed increase of  $T_c$  in FeSe upon doping with Te. The microscopic origin for superconductivity in this system is then due to a Van Hove singularity close to the Fermi level. This identification may open a new route to increase  $T_c$  even further.

**4:18PM H11.00008 Effect of hydrostatic pressure on the structural and magnetic transitions in FeSe**, K. KOTHAPALLI\*, A. E. BÖHMER\*, W. T. JAYASEKARA\*, P. DAS\*, A. SAPKOTA\*, B. G. UELAND\*, V. TAUFOR\*, S. L. BUD'KO\*, P. C. CANFIELD\*, Y. XIAO<sup>+</sup>, A. I. GOLDMAN, A. KREYSSIG\*, \*Ames Laboratory, Dept. of Phys. and Astro., Iowa State University, IA, USA; <sup>+</sup>Argonne National Laboratory, Argonne, IL, USA — The phase diagram of FeSe is unique among all the iron-based superconductors. At ambient pressure, FeSe undergoes a tetragonal-to-orthorhombic structural phase transition at  $T_s = 90$  K, and becomes superconducting below  $T_c = 8$  K. Unlike other iron-based materials, it does not magnetically order down to the lowest measured temperature ( $T$ ). However, under the application of hydrostatic pressure ( $p$ ), a new magnetic phase is stabilized starting from  $\sim 1$  GPa. Higher pressure increases  $T_c$ , whose maximum onset reaches a surprising 37 K at  $\sim 7$  GPa. We investigate the  $p$ - $T$  phase diagram using high-quality vapor-grown single crystals, which shows features not seen previously in powder and mixed-phase samples. Specifically, using high-pressure low-temperature diffraction and synchrotron Mössbauer we elucidate the effect of pressure - evolution of orthorhombic distortion and emergence of magnetic ordering - in the vicinity of the crossover region of the structural, magnetic and superconducting transitions. Work at Ames Lab. was supported by the DOE, BES, Division of Materials Sciences & Engineering, under Contract No. DEAC02-07CH11358. This research used resources at Argonne National Lab.

**4:30PM H11.00009 Neutron Scattering Study of Low Energy Magnetic Excitation in superconducting Te-vapor annealed under-doped FeTeSe**, ZHIJUN XU, MING YI, UC Berkeley, GUANGYONG XU, J. A. SHNEELOCH, Brookhaven National Laboratory, MASAOKI MATSUDA, SONGXUE CHI, Oak Ridge National Laboratory, GENDA GU, J. M. TRANQUADA, Brookhaven National Laboratory, R.J. BIRGENEAU, UC Berkeley — To study the interplay between magnetism and superconductivity, we have performed neutron scattering and magnetization measurements on a Te vapor annealed single crystal  $\text{Fe}_{1-y}\text{Te}_{0.85}\text{Se}_{0.2}$  ( $T_c \sim 13$ K) sample. Te vapor annealed process is found to reduce/remove the excess Fe in the as-grown sample and make the under-doped originally non-superconducting sample become good superconducting sample. Our neutron scattering studies show both spin gap and spin resonance found in the Te vapor annealed superconducting sample. Comparing to commensurate spin resonance in as-grown optimal-doped sample, the spin resonance of Te annealed sample only shows up at the clearly incommensurate positions. The temperature and energy dependence of low energy magnetic excitations are also measured in the sample. This work is supported by the Office of Basic Energy Sciences, DOE.

**4:42PM H11.00010 Thermal evolution of antiferromagnetic correlations and tetrahedral bond angles in superconducting  $\text{FeTe}_{1-x}\text{Se}_x$** , GUANGYONG XU, Brookhaven National Laboratory, ZHIJUN XU, UC Berkeley, JOHN SCHNEELOCH, Brookhaven National Laboratory, JINSHENG WEN, Nanjing University, EMIL BOZIN, Brookhaven National Laboratory, BARRY WINN, M. FEYGENSON, Oak Ridge National Laboratory, R. J. BIRGENEAU, UC Berkeley, GENDA GU, IGOR ZALIZNYAK, JOHN TRANQUADA, Brookhaven National Laboratory — We will present neutron scattering measurements of low energy magnetic excitations from superconducting  $\text{FeTe}_{1-x}\text{Se}_x$  samples. A model with short-range correlated spin plaquettes characterized by particular antiferromagnetic wave vectors is used to describe the measured magnetic scattering data in the (HK0) plane. We show that the characteristic antiferromagnetic wave vector evolves from that characteristic of the bicollinear structure characteristic of  $\text{FeTe}_{1-x}\text{Se}_x$  (at high temperature) to that associated with the stripe structure of antiferromagnetic iron arsenides (at low temperature). We also present powder neutron diffraction results for lattice parameters in  $\text{FeTe}_{1-x}\text{Se}_x$  indicating that the tetrahedral bond angle tends to increase towards the ideal value on cooling, with a corresponding reduction in crystal-field splitting of the Fe 3d orbitals. We suggest that the thermal change in spin correlations implies a relative change among the exchange couplings, and that this is associated with changes in orbital occupancies. Finally, while the magnitude of the low energy magnetic spectral weight is substantial at all temperatures, it actually weakens somewhat at low temperature, where the charge carriers become more itinerant.

**4:54PM H11.00011 Physical properties of superconducting single crystal iron sulfide**, EFRAIN E. RODRIGUEZ, CHRISTOPHER K. H. BORG, XIUQUAN ZHOU, JOHNPierre PAGLIONE, University of Maryland, UNIVERSITY OF MARYLAND COLLABORATION — Recently, the simple binary tetragonal iron sulfide, FeS, was found to be a superconductor with a  $T_c = 5\text{K}$ . [1] We have prepared single crystals of tetragonal iron sulfide through hydrothermal de-intercalation of  $\text{K}_x\text{Fe}_{2-y}\text{S}_2$ . The  $\text{K}_x\text{Fe}_{2-y}\text{S}_2$  single crystal precursors were grown by slow cooling of stoichiometric melts of K, Fe and S. The silver, plate-like FeS single crystals were highly crystalline with a superconducting transition temperature ( $T_c$ ) of 4 K. The high quality of the FeS crystals revealed highly anisotropic nature of the magnetic and electronic properties intrinsic to FeS. The physical properties and thermal stability of single crystal FeS will be discussed in detail. [1] Lai X, et al., *JACS* **2015** 137 (32)

**5:06PM H11.00012 Structure and Magnetic Interactions in FeS: A low- $T_c$  superconductor**, S. J. KUHN, University of Notre Dame and Oak Ridge National Laboratory, M. R. ESKILDSEN, University of Notre Dame, L. DEBEER-SCHMITT, L. LI, C. DE LA CRUZ, A. S. SEFAT, Oak Ridge National Laboratory (ORNL) — Tetragonal-phase iron sulfide (FeS), with the same structure as the well-known superconductor FeSe ( $T_c \sim 8\text{K}$ ), was recently discovered as a superconductor with a  $T_c$  of  $\sim 5\text{K}$  [1]. Although it has been difficult to synthesize this binary in pure tetragonal, crystalline, and superconducting form by various methods (e.g. [2]), the simple low-temperature hydrothermal method yields pure FeS products. Careful composition and particle size analyses, in addition to the results of neutron diffraction and magnetization across transition temperature(s), will be presented. Preliminary results show high sensitivity of pure products to synthesis procedure, particle sizes of  $\sim 40\text{nm}$ , and phase transitions in addition to  $T_c$ . We explain reasons for superconductivity. [1] Lai, X. et al, *Jour. Amer. Chem. Soc.*, 137, 10148 (2015). [2] Sines, I. T. et al. *Jour. Sol. Stat. Chem.*, 196, 17 (2012). The work of AS, LL, and SJK is supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES); SJK is supported by the DOE, Office of Science Graduate Student Research (SCGSR) Award. MRE is funded by the Office of BES (DE-FG02-10ER46783). The work at ORNLs High Flux Isotope Reactor (HFIR) was sponsored by the Scientific User Facilities Div., BES (LDS, CC)

### Session H12 FIAP GMAG: Beyond STT-MRAM: Future Perspective for Spintronics Devices

308 - Ernesto E. Marinero, Supriyo Datta, Purdue University

**2:30PM H12.00001 Magnetic skyrmions : new solitons on the track for future memories and logic applications.**, VINCENT CROS, Unit Mixte de Physique CNRS/Thales — Magnetic skyrmions are arguably the smallest topologically non-trivial magnetic configurations [1]. These solitons are nanoscale spin configurations that hold promise as information carriers in ultra-dense memory and logic devices owing to the extremely low threshold currents densities for initiating their dynamics [2]. Up to now however magnetic skyrmions have been observed mostly at very low temperature in a few exotic materials and ultra-thin films. Here, I will illustrate the wealth of skyrmions with some of our recent experimental and numerical results stabilized at room temperature in magnetic multilayers due to interfacial chiral interaction. This discovery of stable sub-100 nm individual skyrmions at room temperature [3,4] in a technologically relevant material opens the way for the development of several concepts of skyrmion based memory devices going from race-track memory type to MRAMS, rf devices, logic gates, transistors. **3:06PM H12.00002 Novel spintronics devices for memory and logic: prospects and challenges for room temperature all spin computing**, JIAN-PING WANG, Electrical and Computer Engineering Dept., Univ of Minnesota — An energy efficient memory and logic device for the post-CMOS era has been the goal of a variety of research fields. The limits of scaling, which we expect to reach by the year 2025, demand that future advances in computational power will not be realized from ever-shrinking device sizes, but rather by innovative designs and new materials and physics. Magnetoresistive based devices have been a promising candidate for future integrated magnetic computation because of its unique non-volatility and functionalities. The application of perpendicular magnetic anisotropy for potential STT-RAM application was demonstrated and later has been intensively investigated by both academia and industry groups, but there is no clear path way how scaling will eventually work for both memory and logic applications. One of main reasons is that there is no demonstrated material stack candidate that could lead to a scaling scheme down to sub 10 nm. Another challenge for the usage of magnetoresistive based devices for logic application is its available switching speed and writing energy. Although a good progress has been made to demonstrate the fast switching of a thermally stable magnetic tunnel junction (MTJ) down to 165 ps, it is still several times slower than its CMOS counterpart. In this talk, I will review the recent progress by my research group and my C-SPIN colleagues, then discuss the opportunities, challenges and some potential path ways for magnetoresistive based devices for memory and logic applications and their integration for room temperature all spin computing system.

**3:42PM H12.00003 In Search of New Spintronic Devices Using the Modular Approach<sup>1</sup>**, KEREM YUNUS CAMSARI, Purdue University — There has been enormous progress in the last two decades, effectively combining spintronics and magnetism into a powerful force that is shaping the field of memory devices. At the same time, new materials and phenomena continue to be discovered at a very fast pace, providing an ever-increasing set of building blocks that could be exploited in designing functional devices of the future. Through careful benchmarking against available theory and experiment we recently established a set of “elemental” circuit modules representing a diverse range of materials and phenomena [1], which are continually updated [2]. We will first show how these elemental modules can be integrated seamlessly to model both spintronic transport and nanomagnetic dynamics, starting from basic spin-valves and extending to complex experimental structures. We will then show how this framework can be used to design transistor-like spintronic devices to provide novel functionality compared to a standard complementary metal oxide semiconductor (CMOS) device. This approach allows us to incorporate the detailed physics of diverse sophisticated phenomena accurately into detailed circuit-level simulations to provide reliable estimates for the switching energy and delay of carefully designed devices.

**4:18PM H12.00004 Spin Orbit Interaction Engineering for beyond Spin Transfer Torque memory**, KANG L. WANG, Electrical Engineering Dept., Univ of California, Los Angeles, CA 90095 — Spin transfer torque memory uses electron current to transfer the spin torque of electrons to switch a magnetic free layer. This talk will address an alternative approach to energy efficient non-volatile spintronics through engineering of spin orbit interaction (SOC) and the use of spin orbit torque (SOT) by the use of electric field to improve further the energy efficiency of switching. I will first discuss the engineering of interface SOC, which results in the electric field control of magnetic moment or magneto-electric (ME) effect. Magnetic memory bits based on this ME effect, referred to as magnetoelectric RAM (MeRAM), is shown to have orders of magnitude lower energy dissipation compared with spin transfer torque memory (STTRAM). Likewise, interests in spin Hall as a result of SOC have led to many advances. Recent demonstrations of magnetization switching induced by in-plane current in heavy metal/ferromagnetic heterostructures have been shown to arise from the large SOC. The large SOC is also shown to give rise to the large SOT. Due to the presence of an intrinsic extraordinarily strong SOC and spin-momentum lock, topological insulators (TIs) are expected to be promising candidates for exploring spin-orbit torque (SOT)-related physics. In particular, we will show the magnetization switching in a chromium-doped magnetic TI bilayer heterostructure by charge current. A giant SOT of more than three orders of magnitude larger than those reported in heavy metals is also obtained. This large SOT is shown to come from the spin-momentum locked surface states of TI, which may further lead to innovative low power applications. I will also describe other related physics of SOC at the interface of anti-ferromagnetism/ferromagnetic structure and show the control exchange bias by electric field for high speed memory switching. The work was in part supported by ERFC-SHINES, NSF, ARO, TANMS, and FAME

**4:54PM H12.00005 Rise of Racetrack Memory! Domain Wall Spin-Orbitronics**, STUART PARKIN, Max Planck Institute for Microstructure Physics & IBM Research - Almaden — Memory-storage devices based on the current controlled motion of a series of domain walls (DWs) in magnetic racetracks promise performance and reliability beyond that of conventional magnetic disk drives and solid state storage devices (1). Racetracks that are formed from atomically thin, perpendicularly magnetized nano-wires, interfaced with adjacent metal layers with high spin-orbit coupling, give rise to domain walls that exhibit a chiral Néel structure (2). These DWs can be moved very efficiently with current via chiral spin-orbit torques (2,3). Record-breaking current-induced DW speeds exceeding 1,000 m/sec are found in synthetic antiferromagnetic structures (3) in which the net magnetization of the DWs is tuned to almost zero, making them “invisible”. Based on these recent discoveries, Racetrack Memory devices have the potential to operate on picosecond timescales and at densities more than 100 times greater than other memory technologies. **Tuesday, March 15, 2016 2:30PM - 5:30PM –**  
**Session H13 DCOMP: Rahman Prize Lecture and Computational Design of New Topological Materials** 309 - Bluegel Stefan, Forschungszentrum Jülich GmbH

**2:30PM H13.00001 Designing topologicality using oxides<sup>1</sup>**, VICTOR PARDO, University of Santiago de Compostela — In this talk we will describe a series of ab initio calculations carried out on different oxide-based systems and their nanostructures that show emerging non-trivial topological properties or nodal Fermi surfaces. We will show that various well-known oxide structures with the appropriate filling host Dirac points at the Fermi level that could eventually respond to spin-orbit coupling. In particular, we will focus on the results obtained in rutile multilayers[1], perovskite bilayers[2] grown along the polar (111) direction and corundum-based multilayers[3]. Topologically non-trivial phases occur in various limits of spin-orbit coupling strength and on-site Coulomb repulsion, using different fillings of the d-shell for various 3d and 5d elements in the active layers. The different systems will be discussed and compared to try to understand the key ingredients that lead to non-trivial topological properties in oxides and how these can be enhanced or tuned. [1] V. Pardo, W.E. Pickett, Phys. Rev. Lett. 102, 166803 (2010). [2] J.L. Lado, V. Pardo, D. Baldomir, Phys. Rev. B 88, 155119 (2013). [3] J.F. Afonso, V. Pardo, arxiv/1507.08813 (2015).

**3:06PM H13.00002 Designing topological states by pressure, strain, and functionalization**, UDO SCHWINGENSCHLOGL, PSE Division, KAUST, Thuwal 23955, Saudi Arabia — Various examples of the design of topological states by means of first-principles calculations are discussed. The presentation focusses on the design parameters (1) pressure, (2) strain, and (3) functionalization.  $\text{TiTe}_2$  is found to be unusually accessible to strain effects and the first compound that under hydrostatic pressure (up to experimentally reasonable 30 GPa) is subject to a series of four topological phase transitions, which are related to band inversions at different points of the Brillouin zone. Therefore,  $\text{TiTe}_2$  enables experimental access to all these transitions in a single compound. Phase transitions in  $\text{TiBiS}_2$  and  $\text{TiSbS}_2$  are identified by parity analysis and by calculating the surface states. Zero, one, and four Dirac cones are found for the (111) surfaces of both  $\text{TiBiS}_2$  and  $\text{TiSbS}_2$  when the pressure grows, which confirms trivial-nontrivial-trivial phase transitions. The Dirac cones at the  $\bar{M}$  points are anisotropic with large out-of-plane component.  $\text{TiBiS}_2$  shows normal, topological, and topological crystalline insulator phases under hydrostatic pressure, thus being the first compound to exhibit a phase transition from a topological to a topological crystalline insulator. While monolayer arsenic and arsenic antimonide are semiconductors (direct band gap at the  $\Gamma$  point), fluorination results for both compounds in Dirac cones at the K points. Fluorinated monolayer arsenic shows a band gap of 0.16 eV due to spin-orbit coupling and fluorinated arsenic antimonide a larger band gap of 0.37 eV due to inversion symmetry breaking. Spin-orbit coupling induces spin splitting similar to monolayer  $\text{MoS}_2$ . Phonon calculations confirm that both materials are dynamically stable. Calculations of the edge states of nanoribbons by the tight-binding method demonstrate that fluorinated arsenic is topologically nontrivial in contrast to fluorinated arsenic antimonide.

**3:42PM H13.00003 High-Throughput Computational Design of Advanced Functional Materials: Topological Insulators and Two-Dimensional Electron Gas Systems**, KESONG YANG, Univ of California - San Diego — As a rapidly growing area of materials science, high-throughput (HT) computational materials design is playing a crucial role in accelerating the discovery and development of novel functional materials. In this presentation, I will first introduce the strategy of HT computational materials design, and take the HT discovery of topological insulators (TIs) as a practical example to show the usage of such an approach. Topological insulators are one of the most studied classes of novel materials because of their great potential for applications ranging from spintronics to quantum computers. Here I will show that, by defining a reliable and accessible descriptor, which represents the topological robustness or feasibility of the candidate, and by searching the quantum materials repository aflowlib.org, we have automatically discovered 28 TIs (some of them already known) in five different symmetry families. Next, I will talk about our recent research work on the HT computational design of the perovskite-based two-dimensional electron gas (2DEG) systems. The 2DEG formed on the perovskite oxide heterostructure (HS) has potential applications in next-generation nanoelectronic devices. In order to achieve practical implementation of the 2DEG in the device design, desired physical properties such as high charge carrier density and mobility are necessary. Here I show that, using the same strategy with the HT discovery of TIs, by introducing a series of combinatorial descriptors, we have successfully identified a series of candidate 2DEG systems based on the perovskite oxides. This work provides another exemplar of applying HT computational design approach for the discovery of advanced functional materials.

**4:18PM H13.00004 Materials discovery guided by data-driven insights**, MATTIAS KLINTENBERG, Uppsala University — As the computational power continues to grow systematic computational exploration has become an important tool for materials discovery. In this presentation the Electronic Structure Project (ESP/ELSA)[1-3] will be discussed and a number of examples presented that show some of the capabilities of a data-driven methodology for guiding materials discovery. These examples include topological insulators [4], detector materials and 2D materials. ESP/ELSA is an initiative that dates back to 2001 [5,6] and today contain many tens of thousands of materials that have been investigated using a robust and high accuracy electronic structure method (all-electron FP-LMTO [7]) thus providing basic materials first-principles data for most inorganic compounds that have been structurally characterized. The web-site containing the ESP/ELSA [1] data has as of today been accessed from more than 4,000 unique computers from all around the world.

**4:54PM H13.00005 Rahman Prize Talk: Pushing the frontier in the simulation of correlated quantum many body systems**, MATTHIAS TROYER, ETH Zurich — Amazing progress in the simulation of correlated quantum many body systems has been achieved in the past two decades by combining significant advances in new algorithms with efficient implementations on ever faster supercomputers. This has enabled the accurate simulation of an increasing number of problems and helped settle many open questions. I will review a selection of results that my collaborators and I have worked on, from quantum phase transitions in quantum magnets, over supersolidity of bosons in lattice models and Helium-4 to recent simulations of correlated fermions and quantum gases. I will then provide an outlook to the future and discuss how in the short term analog quantum simulators can help tackle problems for which no efficient simulation algorithms exist and how in the longer term quantum computers can be used to solve many of the still open questions in the field. I will finally connect to the topic of the remainder of this symposium by touching on how the design of new topological materials will help in the construction of these quantum computers.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**

**Session H14 FEd: Reichert Award** 310 - Tim Stelzer, Univ of Illinois - Urbana

**2:30PM H14.00001 Jonathan F. Reichert and Barbara Wolff-Reichert Award for Excellence in Advanced Laboratory Instruction: Advanced Instructional Labs: Why Bother?**, VAN BISTROW, University of Chicago — What are we teaching about physics in the traditional lecture course? Plenty! By offering the Advanced Laboratory Course, we hope to shed light on the following questions: How do we develop a systematic process of doing experiments? How do we record procedures and results? How should we interpret theoretical concepts in the real world? What experimental and computational techniques are available for producing and analyzing data? With what degree of confidence can we trust our measurements and interpretations? How well does a theory represent physical reality? How do we collaborate with experimental partners? How do we best communicate our findings to others? These questions are of fundamental importance to experimental physics, yet are not generally addressed by reading textbooks, attending lectures or doing homework problems. Thus, to provide a more complete understanding of physics, we offer laboratory exercises as a supplement to the other modes of learning. The speaker will describe some examples of experiments, and outline the history, structure and student impressions of the Advanced Lab course at the University of Chicago Department of Physics.

**3:06PM H14.00002 Investigating Student Ownership of Projects in Upper-Division Physics Laboratory Courses<sup>1</sup>**, JACOB STANLEY, University of Colorado - Boulder — In undergraduate research experiences, student development of an identity as a scientist is coupled to their sense of ownership of their research projects. As a first step towards studying similar connections in physics laboratory courses, we investigate student ownership of projects in a lasers-based upper-division course. Students spent the final seven weeks of the semester working in groups on final projects of their choosing. Using data from the Project Ownership Survey and weekly student reflections, we investigate student ownership as it relates to students' personal agency, self-efficacy, peer interactions, and complex affective responses to challenges and successes. We present evidence of students' project ownership in an upper-division physics lab. Additionally, we propose a model for student development of ownership through cycles of frustration and excitement as students progress on their projects.

<sup>1</sup>This work was supported by NSF grant nos. DUE-1323101 and DUE-1334170.

**3:42PM H14.00003 8 Years of ALPhA's Impacts / 45 Years of Developing Experimentalists with Few Resources: A Talk in Two Parts<sup>1</sup>**, LOWELL MCCANN, Univ. of Wisconsin - River Falls — In 2007, faculty with a shared interest in the health of advanced physics laboratory courses (those offered beyond the first year of college) created ALPhA, the Advanced Laboratory Physics Association. Over the past 8 years, ALPhA activities have involved faculty from a sizeable fraction of the physics departments in the United States. In the first part of this talk, I will overview ALPhA's efforts and its impact. In the second part of the talk I will discuss the advanced laboratory curricula at the University of Wisconsin - River Falls, which was developed over several decades using minimal resources for maximum impact.

<sup>1</sup>Supported by NSF grant DUE-1122993.

**4:18PM H14.00004 Student-Driven Engagement: An Interdisciplinary-Team Research-Learning Renewable Energy Laboratory Experience for Undergraduates**, MARK TUOMINEN, University of Massachusetts Amherst — How does engagement and deep learning happen? Every science department seeks to cultivate an excellent level of scientific skills and knowledge in its undergraduate students. Yet, this is not sufficient to thrive as a professional. Engaging directly in real-world challenges can foster a professional attitude: a high level of self-efficacy, a genuine sense of relevance, and proactivity. This talk will describe pedagogical developments of a junior-year renewable energy laboratory course at the University of Massachusetts Amherst that is part of a four-year Integrated Concentration in Science (iCons) program. Over the four years, the interdisciplinary iCons students—from 24 various majors—work through case studies, selection and analysis of real-world problems, inception and development of potential solutions, integrative communication, experimental practice, and capstone research. The team dynamic is a central aspect of the experience, yielding significant educational and developmental benefits. The third-year energy course uses adopts a culture of a small vibrant R and D company (I3E – “Energy, Powered By Intelligence”), in which every person in the course has a vital responsibility and creative resourcefulness must be employed in the project work. The course emphasizes the practice of using reflection and redesign, as a means of generating better solutions and embedding the practice of learning in a real-world context. This work is supported in part by NSF grant DUE-1140805.

**4:54PM H14.00005 Open-ended projects in undergraduate optics and lasers courses**, CHAD HOYT, Bethel University — This talk will describe the format and experience of undergraduate Lasers and Optics courses at Bethel University. The courses, which include a rigorous lecture portion, are built on open-ended research projects that have a novel aspect. They begin with four weeks of small student groups rotating between several standard laser and optics laboratory exercises. These may include, for example, alignment and characterization of a helium neon laser and measurements with a Michelson interferometer or a scanning Fabry-Pérot optical cavity. During the following seven weeks of the course, student groups (2-4 people) choose and pursue research questions in the lab. Their work culminates in a group manuscript typeset in L<sup>A</sup>T<sub>E</sub>X and a twenty-minute presentation to the class. Projects in the spring, 2014 Optics course included experiments with ultracold lithium atoms in a magneto-optical trap, optical tweezers, digital holography and adaptive optics. Projects in the spring, 2015 Lasers course included ultrafast optics with a mode-locked erbium fiber laser, quantum optics, surface plasmon lasers (led by Nathan Lindquist) and a low-cost, near-infrared spectrometer. Several of these projects are related to larger scale, funded research in the physics department. The format and experience in Lasers and Optics is representative of other upper-level courses at Bethel, including Fluid Mechanics and Computer Methods. A physics education research group from the University of Colorado evaluated the spring, 2015 Lasers course. They focused on student experimental attitudes and measurements of student project ownership.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**  
**Session H15 DMP: 2D and Graphene - Electronic and Atomic Structure** 314 -

**2:30PM H15.00001 One-dimensional metallic wires at phase-engineered boundaries in two-dimensional materials**, MARCO GIBERTINI, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne, Switzerland — At the interfaces between systems with different electric polarization, free carriers appear in order to screen the resulting polarization charges associated with the resulting polar discontinuity. This mechanism is believed to be at the origin of the two-dimensional electron gas emerging at oxide interfaces and provides the basis for manifold exciting novel phenomena. Recently, it has been shown that similar processes take place also in two-dimensional materials, where one-dimensional wires of free carriers are induced at planar interfaces between materials with different in-plane polarization or at the edges of polar nanoribbons. Here we show by first-principles simulations that some two-dimensional polar materials can display a metastable non-polar phase, so that boundaries between the stable and metastable phases support a polar discontinuity and the resulting one-dimensional metallic wires. We provide several approaches to engineer such phase boundaries by locally inducing metastable phases in a single parent crystal. We finally show how this novel strategy to engineer polar discontinuities in two dimensions offers unprecedented opportunities to efficiently manipulate and reconfigure the emerging one-dimensional metallic wires or switch their conducting state.

**2:42PM H15.00002 First-principles study of structural properties of SiO<sub>2</sub> bilayers**, ANDREI MALASHEVICH, SOHRAB ISMAIL-BEIGI, ERIC I. ALTMAN, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University — Two dimensional (2D) materials draw a tremendous amount of interest because they exhibit unique physical properties due to reduced dimensionality. Recently, SiO<sub>2</sub> 2D bilayer systems were discovered. The structure of these bilayers is formed by two mirror-image planes of corner-sharing SiO<sub>4</sub> tetrahedra and does not have a direct relation to bulk SiO<sub>2</sub> systems. SiO<sub>2</sub> bilayers may be obtained in crystalline or amorphous forms. In the crystalline form, the bilayers are constructed from six-membered rings of corner-sharing SiO<sub>4</sub> tetrahedra. The amorphous form has rings of various sizes typically in the range from four to nine Si atoms in the ring. These structures may be of practical interest as atomically thin membranes and molecular sieves. In our work, we study the effect of strain and doping on the crystalline structure of SiO<sub>2</sub> bilayers using density functional theory. We analyze the stability of structures depending on the ring size and establish strain and doping conditions that may render the structures with large ring sizes stable. This work is supported by the National Science Foundation through grants MRSEC NSF DMR-1119826 and NSF DMR-1506800.

**2:54PM H15.00003 The Pyrite Structure of PdS<sub>2</sub> and PdSe<sub>2</sub> Monolayers**, ARUNIMA K. SINGH, National Institute of Standards and Technology, RICHARD G. HENNIG, University of Florida, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY COLLABORATION, UNIVERSITY OF FLORIDA COLLABORATION — There has been a rising interest in two-dimensional (2D) materials due to a range of extraordinary electronic, optical and mechanical properties which are different from their bulk counterparts. The structure, stability and electronic properties of 2D PdS<sub>2</sub> and PdSe<sub>2</sub> have been investigated in the past in the well-known hexagonal 1T and 2H structures. However, bulk PdS<sub>2</sub> and PdSe<sub>2</sub> are layered compounds with individual rhombohedral pyrite-type monolayers vertically stacked with van-der Waals forces. Using density functional theory simulations, and five different functionals, we compare the energetic stability of 2D PdS<sub>2</sub> and PdSe<sub>2</sub> pyrite structure with the 1T and 2H structures. We find that the PdS<sub>2</sub> is most stable in the pyrite structure, whereas the PdSe<sub>2</sub> is most stable in the 1T structure with the pyrite structure closely competing in energy. The fundamental band gap of these compounds as a function of the structure, number of layers, the stacking arrangement and in-layer strain has been investigated. The pyrite structures of PdS<sub>2</sub> and PdSe<sub>2</sub> are found to be semi-conducting with indirect band gaps, and effective masses comparable to that of monolayer MoS<sub>2</sub>; thus are potential candidates for nano-electronic applications.

**3:06PM H15.00004 Electronic and Mechanical Properties of Hydrogenated Irradiated and Amorphous Graphene**, ASANKA WEERASINGHE, Department of Physics, University of Massachusetts - Amherst, ASHWIN RAMASUBRAMANIAM, Department of Mechanical and Industrial Engineering, University of Massachusetts - Amherst, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts - Amherst — Defect engineering and chemical functionalization of graphene are promising routes for fabrication of carbon nanostructures and 2D metamaterials with unique properties and function. Here, we use hydrogenation of irradiated, including irradiation-induced amorphous, graphene as a means of studying chemical functionalization effects on its electronic structure and mechanical response. We use molecular-dynamics simulations based on a reliable bond-order potential to prepare the hydrogenated configurations and carry out dynamic deformation tests at constant strain rate and temperature. Our mechanical tests show that hydrogenation does not affect the ultimate tensile strength (UTS) of the irradiated graphene sheet if the hydrogenated C atoms remain sp<sup>2</sup>-hybridized; however, upon inducing sp<sup>3</sup> hybridization of these C atoms, UTS decreases by about 10 GPa. Furthermore, the fracture strain of the irradiated structure decreases by up to 30% upon hydrogenation independent of the hybridization type. We also report results for the electronic structure of hydrogenated configurations based on a density-functional tight-binding approach and assess the potential for tuning the electronic properties of these defective, functionalized graphenes.

**3:18PM H15.00005 Effect of radial stretch on vibration characteristics of single-layered circular graphene sheets**, GUNJAN PAHLANI, Mechanical Engineering, Indian Institute of Tech Hyderabad, DEEPTI VERMA, CEMS, University of Minnesota, SHAKTI GUPTA, Mechanical Engineering, Indian Institute of Tech Kanpur — Vibrations of single-layered circular graphene sheets are studied using molecular mechanics (MM) simulations. Interactions between bonded and non-bonded atoms are prescribed using MM3 potential. Frequencies of different modes of vibration are computed from the eigenvalues and eigen vectors of mass weighted Hessian of the system. This study is performed on graphene sheets of various diameters. A linear continuum membrane model for predicting vibrational frequencies is studied using finite element (FE) method. Frequencies for several modes computed from continuum and molecular model matched well for moderate values of radial stretch, however, with increased stretch those deviated from each other significantly. In particular for higher values of stretch the MM simulations predict considerably lower values of frequencies compared to that found from FE simulations. Also, at higher values of stretch the frequency vs. stretch curve obtained from MM simulations showed a hardening behavior which could not be captured by the linear continuum model. We have also found a similar behavior in two-layered graphene sheets using MM simulations.

**3:30PM H15.00006 A Tight Binding Approach to Strain in Monolayer Transition-Metal Dichalcogenides**, ALEXANDER PEARCE, GUIDO BURKARD, University of Konstanz, Germany — We present a model of the electronic properties of the monolayer transition-metal dichalcogenides based on a tight binding approach which includes the effects of strain and curvature of the crystal lattice. Mechanical deformations of the lattice change bond lengths leading directly to corrections in the electronic Hamiltonian, while curvature of the crystal lattice mixes the orbital structure of the electronic Bloch bands. We first present an effective low energy Hamiltonian describing the electronic properties near the K point in the Brillouin zone, then present the corrections to this Hamiltonian due to arbitrary mechanical deformations and curvature in a way which treats both effects on an equal footing. This analysis finds that local area variations of the lattice allow for tuning of the band gap and effective masses, where the application of uniaxial strain decreases the magnitude of the direct band gap at the K point. Additionally, strain induced bond length modifications create a fictitious gauge field but with a coupling that is smaller than seen in related materials like graphene. Whereas curvature of the lattice leads to appearance of both an effective in-plane magnetic field which couples to spin degrees of freedom and a Rashba-like spin-orbit coupling.

**3:42PM H15.00007 Effective tight-binding model for transition metal dichalcogenides<sup>1</sup>**, YEN-HUNG HO, MIGUEL CAZALILLA, National Tsing Hua University, TAIWAN, HECTOR OCHOA, University of California, Los Angeles, USA — For transition metal dichalcogenides, various band models have been developed to describe the novel subband features. In this work, we propose a new effective minimum-band model by preforming a canonical transformation on the full-band Hamiltonian. We found that, depending on the form of transformation, both the  $\Gamma$ - and  $K$ -valley electrons can be well captured, including the frequency and band effective mass. And, for the full-band parameters used, starting from Wannier function basis set leads to a better result than from Slater-Koster basis set. A close inspection of the transformation projection also enables us to extract the modification on the site energy, as well as the orbital hopping between several nearest neighboring atoms. Instead of pure empirical fitting, our effective models preserve rich orbital physics inside, which is shown to be versatile in studying a variety of fundamental physical properties.

**3:54PM H15.00008 Structural and electronic properties of a single layered  $\alpha$ -tetragonal B<sub>50</sub> sheet.**, CHERNO KAH, MING YU, CHAKRAM S JAYANTHI, SHIYU WU, Univ of Louisville — Ultrathin single-crystalline boron nanosheets with  $\alpha$ -tetragonal B<sub>50</sub> symmetry ( $\alpha$ -t-B<sub>50</sub>) have recently been synthesized [1]. In this presentation, the relaxed structure of this new type of boron sheet is determined using a robust self-consistent and environment-dependent semi-empirical Hamiltonian developed within the LCAO framework that includes MD and power quenching schemes. Upon relaxation, the sheet symmetry is broken and the icosahedral B<sub>12</sub> units in the sheet are found to be distorted. This stability of the sheet was investigated through a calculation of the vibrational frequencies. The sheet electronic density of states exhibits no energy gap at the Fermi level, suggesting a metallic character similar to that of the bulk  $\alpha$ -t-B<sub>50</sub>. Finally, the cohesive energy of the  $\alpha$ -t-B<sub>50</sub> sheet is found to be higher than that of the recently reported icosahedral B<sub>12</sub>-O<sub>6</sub> sheet [2]. [1] Adv. Sci. 2, 1500023 (2015) [2] Nanotechnology 26, 405701 (2015)

**4:06PM H15.00009 Ab Initio Based 2D Continuum Mechanics – Sensitivity Prediction for Contact Resonance Atomic Force Microscopy Based Structure Fingerprints**, QING TU, BJÖRN LANGE, MEMS Department, Duke University, Durham, NC 27708, J. MARCELO J. LOPES, Paul-Drude-Institut für Festkörperelektronik, D-10117 Berlin, Germany, STEFAN ZAUSCHER, VOLKER BLUM, MEMS Department, Duke University, Durham, NC 27708 — Contact resonance AFM is demonstrated as a powerful tool for mapping differences in the mechanical properties of 2D materials and heterostructures, permitting to resolve surface and subsurface structural differences of different domains. Measured contact resonance frequencies are related to the contact stiffness of the combined tip-sample system. Based on first principles predicted elastic properties and a continuum approach to model the mechanical impedance, we find contact stiffness ratios between different domains of few-layer graphene on 3C-SiC(111) in excellent agreement with experiment. We next demonstrate that the approach is able to quantitatively resolve differences between other 2D materials domains, e.g., for h-BN, MoS<sub>2</sub> and MoO<sub>3</sub> on graphene on SiC. We show that the combined effect of several materials parameters, especially the in-plane elastic properties and the layer thickness, determines the contact stiffness, therefore boosting the sensitivity even if the out-of-plane elastic properties are similar.

**4:18PM H15.00010 Substrate induced phase transformation of monolayer transition metal dichalcogenides**, SHUDUN LIU, University of Louisville, XIAOJUN FU, WENGUANG ZHU, University of Science and Technology of China — Using density functional theory calculations, we investigate the effects of a metal substrate on the structural and electronic properties of a monolayer of transition metal dichalcogenide (TMD). We find that a suitable choice of substrate can induce a transformation of the phase of the monolayer from 2H to 1T. We will discuss the impact of the results on some earlier studies of TMD/metal contacts as well as potential applications of our system in catalysis.

**4:30PM H15.00011 DFT calculation of Landau levels in 2D crystals: from black phosphorus to dichalcogenides<sup>1</sup>**, JOSE LADO, JOAQUIN FERNANDEZ ROSSIER, International Iberian Nanotechnology Laboratory — We present a method to calculate the Landau levels and the corresponding edge states of two dimensional (2D) crystals using as a starting point their electronic structure as obtained from standard density functional theory (DFT). The DFT Hamiltonian is represented in the basis of maximally localized Wannier functions [1]. This defines a tight-binding Hamiltonian for the bulk that can be readily used to describe other structures, such as ribbons, provided that atomic scale details of the edges are ignored. The effect of the orbital magnetic field is described using the Peierls substitution. By implementing this approach in a ribbon geometry we recover known results for graphene, MoS<sub>2</sub> [2] and black phosphorous [3]. We apply this method to predict the Landau level spectrum of MoSSe. Our procedure can readily be used in any other 2D crystal, and provides an alternative to effective mass descriptions. [1] A. A. Mostofi, J. R. Yates, Y.-S. Lee, I. Souza, D. Vanderbilt and N. Marzari Comput. Phys. Commun. 178, 685 (2008) [2] Habib Rostami and Reza Asgari, Phys. Rev. B 91, 075433 (2015) [3] J. M. Pereira, Jr. and M. I. Katsnelson, Phys. Rev. B 92, 075437 (2015)

**4:42PM H15.00012 A tight-binding model for MoS<sub>2</sub> monolayers<sup>1</sup>**, EMILIA RIDOLFI, Universidade Federal Fluminense, DUY LE, TALAT RAHMAN, EDUARDO MUCCIOLO, University of Central Florida, CAIO LEWENKOPF, Universidade Federal Fluminense — We propose an accurate tight-binding parametrization for the band structure of MoS<sub>2</sub> monolayers near the main energy gap. We introduce a generic and straightforward derivation for the band energies equations that could be employed for other monolayer dichalcogenides. A parametrization that includes spinorbit coupling is also provided. The proposed set of model parameters reproduce both the correct orbital compositions and location of valence and conduction band in comparison with ab initio calculations. The model gives a suitable starting point for realistic large-scale atomistic electronic transport calculations.

**4:54PM H15.00013 Probing the uniaxial strains in MoS<sub>2</sub> using polarized Raman spectroscopy: A first-principles study<sup>1</sup>**, DANNA DORATOTAJ, JEFFREY R. SIMPSON, JIA-AN YAN, Towson University — Characterization of strain in two-dimensional crystals is important for understanding their properties and performance. Using first-principles calculations, we study the effects of uniaxial strain on the Raman-active modes in monolayer MoS<sub>2</sub>. We show that the in-plane  $E'$  mode at 384 cm<sup>-1</sup> and the out-of-plane  $A'_1$  mode at 403 cm<sup>-1</sup> can serve as fingerprints for the uniaxial strain in this material. Specifically, under a uniaxial strain, the doubly degenerate  $E'$  mode splits into two non-degenerate modes: the  $E'_{||}$  and  $E'_{\perp}$  modes. The frequency of the  $E'_{||}$  mode blue-shifts for a compressive strain, but red-shifts for a tensile strain. In addition, due to the strain-induced anisotropy in the MoS<sub>2</sub> lattice, the polarized Raman spectra of the  $E'_{||}$  and  $E'_{\perp}$  modes exhibit distinct angular dependence for specific laser polarization setups, allowing for a precise determination of the direction of the strain with respect to the crystallographic orientation. Furthermore, we find that the polarized Raman intensity of the  $A'_1$  mode also shows evident dependence on the applied strain, providing additional effective clues for determining the direction of the strain even without knowledge of the crystallographic orientation. Thus, polarized Raman spectroscopy offers an efficient non-destructive way to characterize the uniaxial strains in monolayer MoS<sub>2</sub>.

**5:06PM H15.00014 Computational study of electronic and thermal properties of single-layer molybdenum disulphide folded nanostructure**, JIE PENG, PETER CHUNG, Univ of Maryland-College Park — Single-layer Molybdenum disulphide (*SLMoS<sub>2</sub>*), a two-dimensional transition-metal dichalcogenide with a large band gap and high mobility, is considered to be a next generation material for transistors and optoelectronic devices. We present recent results on the electronic and thermal behavior of *SLMoS<sub>2</sub>* folded nanostructures. Through an approach that uses both molecular dynamics (MD) and density functional theory (DFT), we estimate the stable equilibrium structure of folded sheets as well as the related phonon and electronic band structures. The MD simulations are based on a Stillinger-Weber potential and the DFT simulations employ projector augmented wave (PAW) pseudopotentials using generalized gradient approximation (GGA) and local density approximation (LDA). The structure is examined as a function of folding orientation, layer number and system size. Mechanisms of the phonon transport and electronic band gap properties in such a mechanically distorted atomic-layer nanostructure will be discussed.

**5:18PM H15.00015 Tight binding approach to study electronic properties of MoS<sub>2</sub>/WS<sub>2</sub> heterostructure**, NAMITA NARENDRA, KI WOOK KIM, North Carolina State University — The heterostructure interface of MoS<sub>2</sub>/WS<sub>2</sub> is being increasingly studied in recent years for its electronic and optical properties. The ability to tune properties of few-layer transition metal dichalcogenides (TMDs) by strain engineering provides a significant incentive to further explore these material interfaces. It has been shown that misorientation in bulk MoS<sub>2</sub> and WS<sub>2</sub> can also alter the electronic properties. Tight binding allows us to calculate the transport properties of MoS<sub>2</sub>/WS<sub>2</sub> interface for all the angles of misorientation, unlike the computationally limited first principles approach. In this work, the tight binding parameters for the bulk are extracted from first principles and the heterostructure model is verified. A detailed study of variation of electronic properties of MoS<sub>2</sub>/WS<sub>2</sub> interface with respect to addition of strain and number of layers of MoS<sub>2</sub> and WS<sub>2</sub> is carried out. The extension of tight binding model to misoriented MoS<sub>2</sub>/WS<sub>2</sub> interface is demonstrated.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**

**Session H16 DMP: 2D Devices: Electronics and Optoelectronics** 315 - Jonathan Bird, University at Buffalo

**2:30PM H16.00001 Nano-scale electronic and optoelectronic devices based on 2D crystals**, WENJUAN ZHU, University of Illinois at Urbana-Champaign — In the last few years, the research community has been rapidly growing interests in two-dimensional (2D) crystals and their applications. The properties of these 2D crystals are diverse — ranging from semi-metal such as graphene, semiconductors such as MoS<sub>2</sub>, to insulator such as boron nitride. These 2D crystals have many unique properties as compared to their bulk counterparts due to their reduced dimensionality and symmetry. A key difference is the band structures, which lead to distinct electronic and photonic properties. The 2D nature of the material also plays an important role in defining their exceptional properties of mechanical strength, surface sensitivity, thermal conductivity, tunable band-gap and their interaction with light. These unique properties of 2D crystals open up a broad territory of applications in computing, communication, energy, and medicine. In this talk, I will present our work on understanding the electrical properties of graphene and MoS<sub>2</sub>, in particular current transport and band-gap engineering in graphene, interface between gate dielectrics and graphene, and gap states in MoS<sub>2</sub>. I will also present our work on the nano-scale electronic devices (RF and logic devices) and photonic devices (plasmonic devices and photo-detectors) based on these 2D crystals.

**3:06PM H16.00002 Direct Visualization of Edge States and Electrical Inhomogeneity in MoS<sub>2</sub> Field Effect Transistors**, DI WU, LAN LUAN, ZHAODONG CHU, XIAOYU WU, KEJI LAI, Department of Physics, University of Texas at Austin — Ultrathin transition metal dichalcogenides (TMDs) with layer-dependent bandgaps, relatively high carrier mobilities, and valley pseudospins are promising material platforms for novel electronics. It is of great importance to microscopically probe the TMD-based electronic devices for understanding and improving their performances in relation to metal contacts, interfaces, and defects. Here, we report the electrical imaging of the channel conductance of few-layer MoS<sub>2</sub> field-effect transistors by microwave impedance microscopy (MIM). A systematic evolution of the local conductance of exfoliated MoS<sub>2</sub> back-gated devices was captured during the insulator-to-metal transition induced by electrostatic gating. Interestingly, when the transistors were gradually turned on, the carriers were first accumulated at the edges of MoS<sub>2</sub> flakes, as indicated by the higher local conductivity in MIM images. At the same time, we have also observed strong local conductance fluctuation, which are presumably due to the charged impurities in the flakes or defects at the interfaces. The MIM images can thus provide us the microscopic understanding of how the device performance is influenced by the local defects and edge states.

**3:18PM H16.00003 Tunnelling in van der Waals heterostructures**, ARTEM MISHCHENKO, KOSTYA NOVOSELOV, ANDRE GEIM, School of Physics And Astronomy, The University of Manchester, LAURENCE EAVES, The University of Nottingham, VLADIMIR FALKO, School of Physics And Astronomy, The University of Manchester — When graphene and other conductive two-dimensional (2D) materials are separated by an atomically thin insulating 2D crystal, quantum mechanical tunnelling leads to appreciable current between two 2D conductors due to the overlap of their wavefunctions. These tunnel devices demonstrate interesting physics and potential for applications: such effects as resonant tunnelling, negative differential conductance, light emission and detection have already been demonstrated. In this presentation we will outline the current status and perspectives of tunnelling transistors based on 2D materials assembled into van der Waals heterostructures. Particularly, we will present results on mono- and bilayer graphene tunnelling, tunnelling in 2D crystal-based quantum wells, and tunnelling in superconducting 2D materials. Such effects as momentum and chirality conservation, phonon- and impurity-assisted tunnelling will also be discussed. Finally, we will ponder the implications of discovered effects for practical applications.

**3:30PM H16.00004 Fabrication and characterization of graphene PN junctions<sup>1</sup>**, DENNIS WANG, XIAODONG ZHOU, ALI DADGAR, Columbia Univ, PRATIK AGNIHOTRI, JI UNG LEE, The State University of New York, Albany, MARK REUTER, FRANCES ROSS, IBM T.J. Watson Research Center, ABHAY PASUPATHY, Columbia Univ — Theoretical predictions of relativistic Klein tunneling and Veselago lensing in graphene have inspired efforts to fabricate graphene p-n junctions where such phenomena could be realized and studied via electronic transport or scanning tunneling microscopy (STM). Here we will discuss the interplay between device geometry and our measurements in a 4-probe STM, which allows for simultaneous back gating, biasing, and scanning of a micromechanically exfoliated graphene sample. A sharp p-n junction is essential to the manifestation of these aforementioned effects, and we examine the benefits and drawbacks of several routes toward this goal from a fabrication standpoint. These methods include lithographically pre-patterned substrates and the stacking of vertical heterostructures. Finally, we will describe our subsequent characterization results for each, including information about topography and spatial mapping of the density of states.

**3:42PM H16.00005 Graphene – ferroelectric and MoS<sub>2</sub> – ferroelectric heterostructures for memory applications.**, ALEXEY LIPATOV, PANKAJ SHARMA, ALEXEI GRUVERMAN, ALEXANDER SINITSKII, University of Nebraska - Lincoln — In recent years there has been an unprecedented interest in two-dimensional (2D) materials with unique physical and chemical properties that cannot be found in their three-dimensional (3D) counterparts. One of the important advantages of 2D materials is that they can be easily integrated with other 2D materials and functional films, resulting in multilayered structures with new properties. We fabricated and tested electronic and memory properties of field-effect transistors (FETs) based on a single-layer graphene combined with lead zirconium titanate (PZT) substrate. Previously studied graphene-PZT devices exhibited an unusual electronic behavior such as clockwise hysteresis of electronic transport, in contradiction with counterclockwise polarization dependence of PZT. We investigated how the interplay of polarization and interfacial phenomena affects the electronic behavior and memory characteristics of graphene-PZT FETs, explain the origin of unusual clockwise hysteresis and experimentally demonstrate a reversed polarization-dependent hysteresis of electronic transport. In addition we fabricated and tested properties of MoS<sub>2</sub>-PZT FETs which exhibit a large hysteresis of electronic transport with high ON/OFF ratios. We demonstrate that MoS<sub>2</sub>-PZT memories have a number of advantages over commercial FeRAMs, such as nondestructive data readout, low operation voltage, wide memory window and the possibility to write and erase them both electrically and optically.

**3:54PM H16.00006 Programmable Schottky Junctions Based on Ferroelectric Gated MoS<sub>2</sub> Transistors.**, ZHIYONG XIAO, JINGFENG SONG, STEPHEN DRCHARME, XIA HONG, Univ of Nebraska-Lincoln — We report a programmable Schottky junction based on MoS<sub>2</sub> field effect transistors with a SiO<sub>2</sub> back gate and a ferroelectric copolymer poly(vinylidene-fluoride-trifluoroethylene) (PVDF) top gate. We fabricated mechanically exfoliated single layer MoS<sub>2</sub> flakes into two point devices via e-beam lithography, and deposited on the top of the devices ~20 nm PVDF thin films. The polarization of the PVDF layer is controlled locally by conducting atomic force microscopy. The devices exhibit linear  $I_D$ - $V_D$  characteristics when the ferroelectric gate is uniformly polarized in one direction. We then polarized the gate into two domains with opposite polarization directions, and observed that the  $I_D$ - $V_D$  characteristics of the MoS<sub>2</sub> channel can be modulated between linear and rectified behaviors depending on the back gate voltage. The nonlinear  $I_D$ - $V_D$  relation emerges when half of the channel is in the semiconductor phase while the other half is in the metallic phase, and it can be well described by the thermionic emission model with a Schottky barrier of ~0.5 eV. The Schottky junction can be erased by re-write the entire channel in the uniform polarization state. Our study facilitates the development of programmable, multifunctional nanoelectronics based on layered 2D TMDs..

**4:06PM H16.00007 Control of Rewriteable Doping Patterns in Graphene/Boron Nitride Heterostructures**, SALMAN KAHN, JAIRO VELASCO JR., DILLON WONG, JUWON LEE, HSIN ZON TSAI, University of California - Berkeley, LONG JU, Cornell University, LILI JIANG, ZHIWEN SHI, University of California - Berkeley, PAUL ASHBY, Molecular Foundry, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ALEX ZETTL, FENG WANG, MICHAEL CROMMIE, University of California - Berkeley — Spatial control of charge doping in 2D materials is a promising technique for designing future electronic devices and understanding novel physics. Electrostatic gating and chemical doping are common methods to achieve control of charge doping in 2D materials. However, these approaches suffer from complicated fabrication processes that introduce impurities, change material properties irreversibly, and lack flexibility. Here, we introduce a new method for patterning rewriteable doping profiles with local interface charge transfer from defects in a tunable BN substrate into an adjacent layer of graphene. We characterize these spatial doping patterns through local probe and transport techniques. This technique enables many novel device designs for 2D materials, including atomically thin p-n junctions and rewriteable memory devices.

**4:18PM H16.00008 Spatially inhomogeneous barrier height in graphene/MoS<sub>2</sub> Schottky junctions<sup>1</sup>**, DUSHYANT TOMER, SHIVANI RAJPUT, LIAN LI, University of Wisconsin, Milwaukee — Graphene interfaced with a semiconductor forms a Schottky junction with rectifying properties. In this study, graphene Schottky junctions are fabricated by transferring CVD monolayer graphene on mechanically exfoliated MoS<sub>2</sub> multilayers. The forward bias current-voltage characteristics are measured in the temperature range of 210–300 K. An increase in the zero bias barrier height and decrease in the ideality factor are observed with increasing temperature. Such behavior is attributed to Schottky barrier inhomogeneities possibly due to graphene ripples and ridges at the junction interface as suggested by atomic force microscopy. Assuming a Gaussian distribution of the barrier height, mean barrier of 0.970.10 eV is found for the graphene MoS<sub>2</sub> junction. Our findings provide significant insight on the barrier height inhomogeneities in graphene/two dimensional semiconductor Schottky junctions.

**4:30PM H16.00009 Phase change memory devices formed by using 2 dimensional layered Graphene-In<sub>2</sub>Se<sub>3</sub> van der Waals heterostructure.**<sup>1</sup>, MIN SUP CHOI, CHENXI YANG, CHANG HO RA, WON JONG YOO<sup>2</sup>, Sungkyunkwan Univ., SKKU Advanced Institute of Nano-Technology — Indium selenide (In<sub>2</sub>Se<sub>3</sub>) is one of the unique materials which have both a layered structure and phase change property. One of the advantages of using 2 dimensional (2D) materials is their potential to form van der Waals heterostructures which enable unique physical properties and novel quantum device functions, which cannot be achieved in 2D material alone. In this study, we fabricated vertically stacked graphene-In<sub>2</sub>Se<sub>3</sub> heterostructured memory devices. The fabricated devices showed a rapid increase of current conduction, which is attributed to the phase transition of In<sub>2</sub>Se<sub>3</sub>. The TEM images demonstrated that In<sub>2</sub>Se<sub>3</sub> transformed from polycrystalline to layered structure thanks to the effective thermal confinement effect between graphene and In<sub>2</sub>Se<sub>3</sub>, attributed to the low thermal conductivity of layered materials in vertical direction. In addition, the current conduction could be controlled effectively by applying different pulse voltages, showing stable retention and endurance characteristics. It is thought that the differently bonded states contribute to this control process. This study demonstrates the possibility of Graphene-In<sub>2</sub>Se<sub>3</sub> van der Waals heterostructure as 2D based future memory electronics.

**4:42PM H16.00010 Optoelectronic devices based on MoTe<sub>2</sub> p-n junction.**, YA-QING BIE, Condensed Matter Physics, MIT, MIKKEL HEUCK, EECS, MIT, MARCO FURCHI, Condensed Matter Physics, MIT, GABRIELE GROSSO, EECS, MIT, JIABAO ZHENG, Columbia University, YUAN CAO, Condensed Matter Physics, EECS, MIT, EFREN NAVARRO-MORATALLA, Condensed Matter Physics, MIT, DIRK ENGLUND, EECS, MIT, PABLO JARILLO-HERRERO, Condensed Matter Physics, MIT — 2D transition metal dichalcogenides (2D-TMD), such as MoS<sub>2</sub>, have been verified with many remarkable physical properties, which include an indirect to direct band transition as a function of thickness and a valley dependent spin polarization. One of the 2D-TMD family members, 2H-MoTe<sub>2</sub> has been shown to be a direct bandgap semiconductor as a monolayer and bilayer with a near infrared (NIR) bandgap of about 1.1eV. However, optoelectronic devices based on MoTe<sub>2</sub> were so far not experimentally demonstrated. Here, we will present a high on-off ratio MoTe<sub>2</sub> p-n junction enabled by a hexagonal boron nitride encapsulation technique. Our study of the MoTe<sub>2</sub> p-n junction devices sheds light on designing efficient NIR optoelectronic devices such as photodetectors and energy harvesting cells and light emitters.

**4:54PM H16.00011 Polarization and resistive switching behavior of ferroelectric tunnel junctions with transition metal dichalcogenides**, TAO LI, ALEXEY LIPATOV, University of Nebraska-Lincoln, PANKAJ SHARMA, University of New South Wales, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, ALEXANDER SINITSKII, ALEXEI GRUVERMAN, University of Nebraska-Lincoln, ALEXEI GRUVERMAN TEAM, ALEXANDER SINITSKII TEAM, CHANG-BEOM EOM TEAM — Transition metal dichalcogenides (TMDs) are emerging 2-dimensional (2D) materials of the MX<sub>2</sub> type, where M is a transition metal atom (Mo, W, Ti, Sn, Zr, etc.) and X is a chalcogen atom (S, Se, or Te.). Comparing to graphene, TMDs have a sizable band gap and can be metal, half-metal, semiconductor or superconductor. Their band structures can be tuned by external bias voltage, mechanical force, or light illumination. Their rich physical properties make TMDs potential candidates for a variety of applications in nanoelectronics and optoelectronics. Ferroelectric tunnel junctions (FTJs) are actively studied as a next-generation of non-volatile memory elements. An FTJ comprises a ferroelectric tunnel barrier sandwiched between two electrodes. In this work, we investigate the resistive switching behavior of MoS<sub>2</sub>/BaTiO<sub>3</sub>-based FTJs. The ON/OFF ratio can be modulated via electric or mechanical control of the switched polarization fraction opening a possibility of tunable electroresistance effect. Effect of optical illumination on the polarization reversal dynamics has been observed and analyzed based on the polarization-induced modulation of the MoS<sub>2</sub> layered electronic properties.

**5:06PM H16.00012 Atomic-scaled characterization of graphene PN junctions**, XIAODONG ZHOU, Department of Physics, Columbia University, New York, New York 10027, USA, DENNIS WANG, Department of Applied Physics and Mathematics, Columbia University, New York, New York 10027, USA, ALI DADGAR, Department of Physics, Columbia University, New York, New York 10027, USA, PRATIK AGNIHOTRI, JI UNG LEE, College of Nanoscale Science and Engineering, The State University of New York, Albany, New York 12203, USA, MARK C. REUTER, FRANCES M. ROSS, IBM T.J. Watson Research Center, Yorktown Heights, New York 10598, USA, ABHAY N. PASUPATHY, Department of Physics, Columbia University, New York, New York 10027, USA — Graphene p-n junctions are essential devices for studying relativistic Klein tunneling and the Veselago lensing effect in graphene. We have successfully fabricated graphene p-n junctions using both lithographically pre-patterned substrates and the stacking of vertical heterostructures. We then use our 4-probe STM system to characterize the junctions. The ability to carry out scanning electron microscopy (SEM) in our STM instrument is essential for us to locate and measure the junction interface. We obtain both the topography and *dI/dV* spectra at the junction area, from which we track the shift of the graphene chemical potential with position across the junction interface. This allows us to directly measure the spatial width and roughness of the junction and its potential barrier height. We will compare the junction properties of devices fabricated by the aforementioned two methods and discuss their effects on the performance as a Veselago lens.

**5:18PM H16.00013 Two-dimensional transition metal dichalcogenides based magnetic tunneling junctions**, ZHENG YANG, BO HSU, University of Illinois at Chicago, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING TEAM — The transport properties of magnetic tunneling junctions (MTJ) using two-dimensional (2D) transition metal dichalcogenide monolayers MX<sub>2</sub> (M=Mo, W; X=S, Se) as tunnel layer are reported. The 2D MX<sub>2</sub> were grown using chemical vapor deposition. As-grown 2D MX<sub>2</sub> were transferred and lithographic fabricated into MTJ devices with MX<sub>2</sub> sandwiched within two ferromagnetic material layers. The magnetoresistance of the MTJs were studied at different temperatures.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**

**Session H17 DMP: Transition Metal Dichalcogenides: Defects and Degradation** 316 - Chongwu Zhou, University of Southern California

**2:30PM H17.00001 TMD 2D Materials: Defects, Passivation, Functionalization and Device Impact**<sup>1</sup>, ROBERT WALLACE, Depts. of Materials Science and Engineering and Physics, The University of Texas at Dallas, Richardson, TX — Transition metal dichalcogenides (TMDs) such as MoS<sub>2</sub> have become popular in "beyond CMOS" device concepts and research due to their band structure in two-dimensional layers – viz. a significant band gap. Various device demonstrations have been reported utilizing exfoliated and synthesized single/few layer TMDs for possible electronic and photonic applications. The performance of such devices will also necessarily depend upon the TMD layer quality. The impact of defects and impurities on device transport characteristics is of interest, as well as methods to passivate and minimize their effects. The interaction of the TMDs with component materials, such as dielectrics and contacts, is also an important aspect. This talk will present our recent work using in-situ and ex-situ methods to understand the physics and chemistry of TMDs and their associated interfaces.

**3:06PM H17.00002 Effects of High-Energy X-Ray Radiation on MoS<sub>2</sub> FETs**, AMRITESH RAI, Univ of Texas, Austin, LAXMAN THOUTAM, WEI ZHANG, Materials Science Division, Argonne National Laboratory, Argonne, IL, KIRAN KOVI, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL, SANJAY BANERJEE, Univ of Texas, Austin, SAPTARSHI DAS, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL — FETs based on semiconducting MoS<sub>2</sub> nanosheets are currently being extensively explored for various nanoelectronic device applications. In real-life, several of these applications mandate the exposure of devices to X-ray radiation. In this study, we investigate the effects of high-energy X-ray radiation on few-layer MoS<sub>2</sub> transistors. Back-gated MoS<sub>2</sub> FETs on SiO<sub>2</sub> substrates were fabricated and exposed to X-ray radiation in an enclosed X-ray tube utilizing tungsten as the X-ray source. The devices were exposed to successive radiation doses up to a cumulative dose of 1500 kilorads (Krad). Even after high radiation doses, the devices maintained acceptable electrical performance with high  $I_{ON}/I_{OFF}$  ratios and good current saturation. The subthreshold swing remained similar to initial values. There was, however, a slight reduction in the ON-currents after each successive radiation, concomitant with a positive threshold voltage shift that can be attributed to the formation of negative-fixed charges in the substrate. Moreover, the maximum transconductance ( $g_m$ ) of the devices decreased slightly with increasing radiation dose. Finally, Raman spectroscopy revealed practically no change in the in-plane and out-of-plane Raman modes of MoS<sub>2</sub> after radiation.

**3:18PM H17.00003 Raman shifts and in situ TEM electrical degradation of electron-irradiated monolayer MoS<sub>2</sub>**<sup>1</sup>, WILLIAM M. PARKIN, ADRIAN BALAN, Univ of Pennsylvania, LIANGBO LIANG, Rensselaer Polytechnic Institute, PAUL MASIH DAS, Univ of Pennsylvania, MICHAEL LAMPARSKI, Rensselaer Polytechnic Institute, CARL NAYLOR, JULIO A. RODRIGUEZ-MANZO, ALAN T. JOHNSON, Univ of Pennsylvania, VINCENT MEUNIER, Rensselaer Polytechnic Institute, MARIJA DRNDIC, Univ of Pennsylvania — We report how the presence of electron-beam-induced vacancies affects first-order Raman modes and correlate this effect with the evolution of in situ TEM two-terminal conductivity of monolayer MoS<sub>2</sub> under electron irradiation. We observe a redshift in the E' Raman peak and a less pronounced blueshift in the A'1 peak with increasing electron dose. Using energy-dispersive X-ray spectroscopy, we show that irradiation causes partial removal of sulfur and correlate the dependence of the Raman peak shifts with S vacancy density (a few percent), which is confirmed by first-principles density functional theory calculations. *In situ* device current measurements show exponential decrease in channel current upon irradiation. Our analysis demonstrates that the observed frequency shifts are intrinsic properties of the defective systems and that Raman spectroscopy can be used as a quantitative diagnostic tool to accurately characterize MoS<sub>2</sub>-based transport channels.

**3:30PM H17.00004 Spin- and Valley-Polarized Transport across Line Defects in Monolayer MoS<sub>2</sub>**<sup>1</sup>, ARTEM PULKIN, OLEG YAZYEV, Institute of Theoretical Physics, Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland — We address ballistic transmission of charge carriers across ordered line defects in monolayer transition metal dichalcogenides. Our study reveals the presence of a transport gap driven by spin-orbit interactions, spin and valley filtering, both stemming from a simple picture of spin and momentum conservation, as well as the electron-hole asymmetry of charge-carrier transmission. Electronic transport properties of experimentally observed ordered line defects in monolayer MoS<sub>2</sub>, in particular the vacancy lines and inversion domain boundaries, are further investigated using first-principles Green's function methodology. Our calculations demonstrate the possibility of achieving nearly complete spin polarization of charge carriers in nanoelectronic devices based on engineered periodic line defects in monolayer transition metal dichalcogenides, thus suggesting a novel practical scheme for all-electric control of spin transport.

<sup>1</sup>We acknowledge support from ERC project "TopoMat" (grant No. 306504) and the Swiss NSF (grant No. PP00P2\_133552).

**3:42PM H17.00005 Electronic and Optical properties of Vacancy Defects in two dimensional monolayer Transition metal Dichalcogenides**, MAHTAB KHAN, MIKHAIL EREMENTCHOUK, MICHAEL LEUENBERGER, University of Central Florida — Defects play an important role in tailoring electronic and optical properties of two-dimensional monolayer transition metal dichalcogenides (TMDCs). Recently it has been shown that the presence of vacancy defects (VDs) in two-dimensional monolayer MoS<sub>2</sub> induces localized states which give rise to extra resonance peaks in both in-plane  $\chi_{||}$  and out-of-plane  $\chi_{\perp}$  susceptibilities.<sup>1</sup> In-plane  $\chi_{||}$  and out-of-plane  $\chi_{\perp}$  susceptibilities are related to the presence of even and odd states with respect to the Mo plane, respectively<sup>1</sup>. Moreover, monolayer TMDCs have a large spin orbit coupling (SOC), originating from d-orbitals of heavy transition metals and being of the order of a few 100 meV. We present a more general picture of the electronic and optical properties of defected monolayer TMDCs. In particular, we consider MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub> and WSe<sub>2</sub> with three types of VDs (i) Mo, W vacancy, (ii) S<sub>2</sub>, Se<sub>2</sub> vacancy, and (iii) S, Se vacancy. In addition, we investigate the effects of SOC on the band structures and the optical susceptibilities of VDs in TMDCs. 1. Mikhail Erementchouk, M. A. Khan, and Michael N. Leuenberger, Phys. Rev. B 92, 121401(R) (2015).

**3:54PM H17.00006 Ab-initio study of gold nanoparticles supported on defect-laden single-layer MoS<sub>2</sub>**<sup>1</sup>, TAKAT B. RAWAL, DUY LE, TALAT S. RAHMAN, University of Central Florida — We have investigated the geometry, electronic structure, and catalytic properties of gold nanoparticles on defect-laden single-layer MoS<sub>2</sub> using density functional theory (DFT) based calculations with semi-empirical van der Waals interaction (DFT-D3). Our results show that the two-dimensional planar structure, the most favorable one for unsupported Au<sub>13</sub> nanoparticle, transforms into a distorted three-dimensional (3D) structure when supported on single-layer MoS<sub>2</sub> with single S-vacancy which is more favorable than the icosahedral, decahedron and cuboctahedron forms. The MoS<sub>2</sub> support substantially alters the electronic structure of Au<sub>13</sub> nanoparticle near the Fermi level, owing to the strong interaction of MoS<sub>2</sub> support with Au<sub>13</sub> in the presence of an S-vacancy. The modified electronic structure remarkably affects the catalytic activity of the MoS<sub>2</sub>-supported Au<sub>13</sub>, offering enhanced activity towards methanol synthesis reaction via CO hydrogenation reaction - a contrast from that of titania-supported Au<sub>13</sub> nanoparticle [1] which promotes methanol decomposition. [1] S. Hong and T. S. Rahman, JACS, 135, 7629 (2013)

**4:06PM H17.00007 Growth and optical characterization of distorted octahedral (T') WTe<sub>2</sub> and MoTe<sub>2</sub>**, SHAO-YU CHEN, THOMAS GOLDSTEIN, JUN YAN, Univ of Mass - Amherst, UNIV OF MASS - AMHERST TEAM — The polymorph of transition metal dichalcogenide (TMDC) has recently attracted great attention due to its novel physical properties. We grow distorted octahedral (T') WTe<sub>2</sub> and MoTe<sub>2</sub> by chemical vapor transport and rapid thermal quenching methods. The bulk and few layer samples exhibit distinct optical properties as compared with the well-investigated semiconducting hexagonal (H) TMDCs. We observe sharp intralayer, as well as interlayer optical phonon modes, that display angular dependent intensities consistent with the estimation by Raman tensor calculation. We also demonstrate *in-situ* phase transition of MoTe<sub>2</sub> from H to T' via rapid annealing in an electrically heated microfurnace. This enables ramping of the temperature from above 900C to room temperature within seconds. This well-controlled annealing process is promising for innovative fabrication of novel 2D materials devices.

**4:18PM H17.00008 Alloy Engineering of Defect Properties in Semiconductors: Suppression of Deep Levels in Transition-Metal Dichalcogenides**, BING HUANG, Beijing Computational Science Research Center, MINA YOON, BOBBY SUMPTER, Oak Ridge National Lab, SUHUI WEI, Beijing Computational Science Research Center, FENG LIU, University of Utah — Developing practical approaches to effectively reduce the amount of deep defect levels in semiconductors is critical for their use in electronic and optoelectronic devices, but this still remains a very challenging task. In this talk, we propose that specific alloying can provide an effective means to suppress the deep defect levels in semiconductors while maintaining their basic electronic properties. Specifically, we demonstrate that for transition-metal dichalcogenides, such as MoSe<sub>2</sub> and WSe<sub>2</sub>, where anion vacancies are the most abundant defects that can induce deep levels, the deep levels can be effectively suppressed in MoWSe<sub>2</sub> alloys at low W concentrations. This surprising phenomenon is associated with the fact that the band edge energies can be substantially tuned by the global alloy concentration, whereas the defect level is controlled locally by the preferred locations of Se vacancies around W atoms. Our findings illustrate a concept of alloy engineering and provide a promising approach to control the defect properties of semiconductors.

**4:30PM H17.00009 Focused helium-ion beam irradiation effects on electrical properties of multi-layer WSe<sub>2</sub>**, PUSHPA RAJ PUDASAINI, MICHAEL STANFORD, NICK CROSS, GERD DUSCHER, DAVID MANDRUS<sup>1</sup>, PHILIP RACK<sup>2</sup>, The University of Tennessee — Atomically thin transition metal dichalcogenides (TMDs) are currently receiving great attention due to their excellent opto-electronic properties. Tuning optical and electrical properties of mono and few layers TMDs, such as Tungsten diselenide (WSe<sub>2</sub>), by controlling the defects, is an intriguing opportunity to fabricate the next generation opto-electronic devices. Here, we report the effects of focused helium ion beam irradiation on structural, optical and electrical properties of few layer WSe<sub>2</sub>, via high resolution scanning transmission electron microscopy, Raman spectroscopy and electrical measurements. By controlling the ion irradiation dose, we selectively introduced precise defects in few layer WSe<sub>2</sub> thereby locally tuning the electrically resistivity of the material. Hole transport in the few layer WSe<sub>2</sub> is severely affected compared to electron transport for the same dose of helium ion beam irradiation studied. Furthermore, by selectively exposing the ion beams, we demonstrate the lateral p-n junction in few layer WSe<sub>2</sub> flakes, which constitute an important advance towards two dimensional opto-electronic devices.

**4:42PM H17.00010 Interplay of magnetic order and defect modulation in monolayer FeSe<sup>1</sup>**, JUNQIANG LU, University of Puerto Rico at Mayaguez, PENGFEI ZHANG, JIAN WU, Tsinghua University — We investigate the role of the defects (vacancy and anti-site) at the Fe-site on the magnetic order in monolayer FeSe. Experimental STM studies of defect states reveal that two type dumbbell-like dimers are formed at the surface of monolayer FeSe. We perform first-principles calculations of the magnetic structure of FeSe monolayer in the presence of defects in order to identify the origin of the STM observations. We consider various distribution of the defects and compare the checkerboard and collinear antiferromagnetic orders. Our results show that a single defect can give a dimer in STM image. A preliminary analysis show that both dimers are centered at the defects with their bright ends positioned on two adjacent Se atoms. We show that the two magnetic orders give rise to two distinct dimers types, in agreement with experiments.

**4:54PM H17.00011 Spatially Correlated Disorder in Epitaxial van der Waals Heterostructures<sup>1</sup>**, NOUAMANE LAANAIT, Center for Nanophase Materials Sciences, Oak Ridge National Lab, ZHAN ZHANG, Argonne National Lab, CHRISTIAN SCHLEPUTZ, Paul Sherrer Institute, YING LIU, University of Wisconsin, Milwaukee, MICHAEL WOJCIK, Argonne National Lab, RACHAEL MYERS-WARD, D. KURT GASKILL, U.S Naval Research Lab, PAUL FENTER, Argonne National Lab, LIAN LI, University of Wisconsin, Milwaukee — The structural cohesion of van der Waals (vdW) heterostructures relies upon a cooperative balance between strong intra-layer bonded interactions and weak inter-layer coupling. The confinement of extended defects to within a single vdW layer and competing interactions introduced by epitaxial constraints could generate fundamentally new structural disorders. Here we report on the presence of spatially correlated and localized disorder states that coexist with the near perfect crystallographic order along the growth direction of epitaxial vdW heterostructure of Bi<sub>2</sub>Se<sub>3</sub>/graphene/SiC grown by molecular beam epitaxy. With the depth penetration of hard X-ray diffraction microscopy and high-resolution surface scattering, we imaged local structural configurations from the atomic to mesoscopic length scales, and found that these disorder states result as a confluence of atomic scale modulations in the strength of vdW layer-layer interactions and nanoscale boundary conditions imposed by the substrate. These findings reveal a vast landscape of novel disorder states that can be manifested in epitaxial vdW heterostructures.

**5:06PM H17.00012 Defect-induced multiphoton absorption and photoluminescence in BN for bio-imaging**, MEHMET KARAKAYA, YONGCHANG DONG, RAMAKRISHNA PODILA, APPARAO RAO, Clemson Univ — Emerging two-dimensional materials are known for their excellent optical properties. Boron nitride (BN) is the only 2D material which exhibits multi-photon absorption. This combined with tunable defect-induced photoluminescence in BN could be used for multi-photon bio-imaging. Previously, a two-photon absorption process was proposed for explaining non-linear optical absorption in BN. However, as discussed in this talk, we show that defects (such as C and O) in BN result in mid-gap states that enable three-photon absorption in addition to tunable emission. The non-linear optical properties of BN could be used for bio-imaging at longer wavelengths which facilitate higher penetration depth and the resolution in vivo.

**5:18PM H17.00013 Impurity-mediated early charge density wave condensation in the oxygen-adsorbed In/Si(111)-(4×1)/(8×2) nanowire array**, STEFAN WIPPERMANN, Max-Planck-Institut fuer Eisenforschung, ANDREAS LUECKE, WOLF GERO SCHMIDT, Paderborn University, DEOK MAHN OH, HAN WOONG YEOM, Pohang University — The self-assembled In/Si(111)-(4×1) nanowire array is an extremely popular model system for one-dimensional electronic systems and features a reversible temperature-induced phase transition into a charge density wave (CDW) ordered ground state. While impurities have been widely known to affect this phase transition, the atomistic mechanisms have rarely been elucidated. Here we present a joint experimental and *first principles* study, demonstrating oxygen impurity atoms to condense the In/Si(111) nanowire array locally into its CDW ground state, even above the transition temperature. Interestingly, CDW ordering is induced only by a concerted effect of multiple impurities. The mechanism is explained as a subtle interplay between coherent superposition of local impurity-induced lattice strain, a strong coupling between electronic and lattice degrees of freedom, and phononic effects on the free energy. Funding from DFG FOR1700 is gratefully acknowledged.

**2:42PM H18.00002 Spin-orbit interaction in monolayer (group-III) metal-monochalcogenides**, PENGKE LI, IAN APPELBAUM, Univ of Maryland-College Park, PHYSICS DEPARTMENT TEAM — Beginning with an analysis of the fundamental symmetries of monolayer (group-III) metal-monochalcogenides (such as GaSe), we examine various spin-dependent properties of this new series of 2D semiconductors. Interesting features resulting from spin-orbit interaction include broken valence band degeneracy, cubic Dresselhaus spin splitting, and eigenstate spin-mixing. The latter two control the type and magnitude of dominant spin relaxation pathways and influence the 'caldera' shape valence band edge. Further phenomena endowed by spin-orbit interaction include a modest orbital contribution to the Lande g-factors and the possibility of optical orientation via band-edge photoexcitation spectroscopy, which shows an energy-dependent reversal of conduction electron spin polarization. Based on this analysis, we propose an experiment to use optically-driven spin dynamics to quantify different spin lifetimes for electron and holes. Reference: arXiv:1508.06963

**2:54PM H18.00003 Controlling spin lifetime with Dresselhaus and Rashba fields in the 2D semiconductor  $MX^1$** , IAN APPELBAUM, PENGKE LI, Univ of Maryland-College Park — It is widely believed that whenever spin encodes logic state in a semiconductor device, transport channel materials with the longest spin lifetime are the most suitable choice. However, once a logic operation is completed, residual spins can and will interfere with those involved in future operations. We propose to solve this problem by utilizing the unique properties of spin-orbit effects in the electronic structure of monolayer of group-III metal-monochalcogenide ( $MX$ ) semiconductors. The interplay of Dresselhaus and Rashba effective magnetic fields in these materials will be shown to provide effective external control over spin polarization lifetime, potentially useful for future spin-enabled digital devices.

<sup>1</sup>Based upon: Pengke Li and Ian Appelbaum, arxiv:1508.06963 (to appear in Phys. Rev. B). We acknowledge support from NSF, DTRA, and ONR.

**3:06PM H18.00004 Long-lived Spin Relaxation and Spin Coherence of Electrons in Monolayer  $MoS_2^1$** , LUYI YANG, National High Magnetic Field Laboratory, Los Alamos — Monolayer  $MoS_2$  and related transition metal dichalcogenides (TMDs) are direct-gap semiconductors in which strong spin-orbit coupling and a lack of structural inversion symmetry give rise to new coupled spin-valley physics. Although robust spin and valley degrees of freedom have been inferred from polarized photoluminescence (PL) studies of *excitons*, PL timescales are necessarily constrained by short (3–100 ps) electron-hole recombination. Direct probes of spin/valley dynamics of resident carriers in electron (or hole)-doped TMDs, which may persist long after recombination ceases, are still at an early stage. Here we directly measure the coupled spin-valley dynamics of *resident* electrons in *n*-type monolayer  $MoS_2$  using optical Kerr-rotation spectroscopy [1], and reveal very long spin lifetimes exceeding 3ns at 5K (orders of magnitude longer than typical exciton lifetimes). In contrast with conventional III-V or II-VI semiconductors, spin relaxation accelerates rapidly in small transverse magnetic fields. This suggests a novel mechanism of electron spin dephasing in monolayer TMDs, driven by rapidly-fluctuating internal spin-orbit fields due to fast intervalley scattering. Additionally, a small but very long-lived oscillatory signal is observed, indicating spin coherence of localized states [2]. These studies provide direct insight into the physics underpinning the spin and valley dynamics of electrons in monolayer TMDs. [1] L. Yang *et al.*, *Nature Physics* **11**, 830 (2015). [2] L. Yang *et al.*, *submitted*.

**3:42PM H18.00005 Spin Transport in Single Layer Transition Metal Dichalcogenides<sup>1</sup>**, MICHAEL PHILLIPS, VIVEK AJI<sup>2</sup>, Univ of California - Riverside — Inversion symmetry breaking and strong spin orbit coupling in two dimensional transition metal dichalcogenides leads to interesting new phenomena such as the valley hall and spin hall effects. The nontrivial Berry curvature of the bands yields transverse spin currents in applied field. In this talk we characterize the spin transport in hole-doped systems. Due to the large spin-splitting, time-reversal invariance, and the large separation of hole pockets in momentum space, spin flip scattering involves inter-valley processes with large momentum. As such, one expects large spin life times and a large spin hall angle. We analyze the robustness of the phenomena to various scattering processes and explore the viability of transition metal dichalcogenides for spintronic applications.

<sup>1</sup>We acknowledge the support of the NSF via grant NSF DMR-1506707.

**3:54PM H18.00006 Spin polarized transport in  $MoS_2$** , ANDRÉ DANKERT, PARHAM PASHAEI, VENKATA KAMALAKAR MUTTA, SAROJ PRASAD DASH, Chalmers University of Technology, SPINTRONIC SPD TEAM — The two-dimensional (2D) semiconductor  $MoS_2$  possesses a high potential for spintronic devices due to a rich spin-valley physics and large spin-orbit coupling. While there have been significant advances in studying the spin and valley dynamics in  $MoS_2$  using optical spectroscopy techniques, electronic spin transport in semiconducting  $MoS_2$  or its heterostructures have not yet been demonstrated. Here we report the electronic and spin transport properties in  $MoS_2$  employing ferromagnetic electrodes in a vertical device geometry. Such vertical devices with  $MoS_2$  channel length defined by the thickness of the 2D layer allow to investigate the spin injection, transport and detection. We observe a magnetoresistance effect over a large temperature range up to 300 K and investigate the temperature and bias dependence behavior. Using magnetotransport data and calculations we extract spin parameters in the  $MoS_2$  spin valve devices. These findings can open new avenues for exploring spin functionalities in 2D semiconductor heterostructures for spin logic applications.

**4:06PM H18.00007 Novel valley depolarization dynamics and valley Hall effect of exciton in mono- and bilayer  $MoS_2$** , T. YU, M. W. WU, University of Science and Technology of China, Physics Department — We investigate the valley depolarization dynamics and valley Hall effect of exciton due to the electron-hole exchange interaction in mono- and bilayer  $MoS_2$ . For the valley depolarization dynamics, in the monolayer  $MoS_2$ , it is found that in the strong scattering regime, the conventional motional narrowing picture is no longer valid, and a novel valley depolarization channel is opened. For the valley Hall effect of exciton, in both the mono- and bilayer  $MoS_2$ , with the exciton equally pumped in the K and K' valleys, the system can evolve into the equilibrium state with the valley polarization parallel to the effective magnetic field due to the exchange interaction. With the drift of this equilibrium state by applied uniaxial strain, the *momentum-dependent* valley/photoluminescence polarization is induced by the exchange interaction, which leads to the valley/photoluminescence Hall current. Specifically, the disorder strength dependence of the valley Hall conductivity is revealed. In the strong scattering regime, the valley Hall conductivity decreases with the increase of the disorder strength; whereas in the weak scattering regime, it saturates to a constant, which can be much larger than the one in Fermi system due to the absence of the Pauli blocking.

**4:18PM H18.00008 Spin-orbit coupling and spin relaxation in phosphorene**, MARCIN KURPAS, MARTIN GMITRA, JAROSLAV FABIAN, Physics Department, University of Regensburg, 93040 Regensburg, Germany — We employ first principles density functional theory calculations to study intrinsic and extrinsic spin-orbit coupling in monolayer phosphorene. We also extract the spin-mixing amplitudes of the Bloch wave functions to give realistic estimates of the Elliott-Yafet spin relaxation rate. The most remarkable result is the striking anisotropy in both spin-orbit coupling and spin relaxation rates, which could be tested experimentally in spin injection experiments. We also identify spin hot spots in the electronic structure of phosphorene at accidental bands anticrossings. We compare the Elliott-Yafet with Dyakonov-Perel spin relaxation times, obtained from extrinsic couplings in an applied electric field. We also compare the results in phosphorene with those of black phosphorous. This work is supported by the DFG SPP 1538, SFB 689, and by the EU Seventh Framework Programme under Grant Agreement No. 604391 Graphene Flagship.

**4:30PM H18.00009 Probing Hole Spins in an InAs/GaAs Quantum Dot Molecule subject to Lateral Electric Fields**, XIANGYU MA, Univ of Delaware, GARNETT BRYANT, National Institute of Standards and Technology, MATTHEW DOTY, Univ of Delaware — Quantum dot molecules (QDMs) are structures in which coherent interactions between two or more adjacent quantum dots (QDs) can lead to unique, tunable electronic and spin properties. We explore computationally spin-mixing interactions in the molecular states of single holes confined in vertically-stacked InAs/GaAs self-assembled QDMs. We consider the spin properties of the hole states subject to electric fields that have components both parallel and perpendicular to the molecular stacking axis. We compute the energies of the QDM hole states under various electric and magnetic fields with a combination of full tight binding atomistic calculations and approximate atomistic results using eigenstates found at particular fields as a basis to extrapolate to other fields. We observe a relatively large Stark shift in hole states with the application of lateral electric fields, as well as a quenching of the Zeeman splitting. Most importantly, we observe that lateral electric fields induce hole spin mixing with a magnitude that increases with increasing lateral electric field over a moderate range. These results suggest that applied lateral electric fields provide an opportunity to fine-tune and manipulate, in situ, the energy levels and spin properties of single holes confined in QDMs.

**4:42PM H18.00010 Spin Dynamics of Tellurium Isoelectronic Centers Bound Excitons in Zn-Se-Te Nanostructures**<sup>1</sup>, VASILIOS DELIGIANNAKIS, The City College of New York of CUNY, SIDDHARTH DHOMKAR, Queens College of CUNY, DANIELA PAGLIERO, The City College of New York of CUNY, HAOJIE JI, Queens College of CUNY, MARIA TAMARGO, The City College of New York of CUNY, IGOR KUSKOVSKY, Queens College of CUNY, CARLOS MERILES, The City College of New York of CUNY — Three-dimensionally confined structures such as quantum dots (QDs) have been of considerable interest due to their ability to closely imitate isolated atoms on mesoscopic length scales. Recently, single impurity states in bulk semiconductors have also attracted attention due to their ability to optically address quantum states. Here we show results pertaining to the optical and spin properties of Te isoelectronic centers present in type-II sub-monolayer QDs within a ZnSe matrix. Time resolved Kerr rotation (TRKR) measurements were performed using a degenerate pump-and-probe setup. Attempts to probe the QDs by direct optical excitation did not show any results most likely due to the weak oscillator strength of this transition resulting from their type-II nature. Centering the pump and probe pulses around the band edge of ZnSe and performing TRKR vs energy measurements we were able to address the spin dynamics of Te-isoelectronic centers present in the spacer layer. Results show that the  $\tau^2$  lifetimes exhibit a bi-exponential decay and persist up to 1 ns. Further measurements will be done on samples with varying Te concentration, as well as a function of the applied magnetic-field to understand the spin properties of this defect.

**4:54PM H18.00011 Self-consistent Theory of Magnetic Polarons in Semiconductor Quantum Dots**<sup>1</sup>, DAN REDERTH, RAFAL OSZWALDOWSKI, SDSMT Physics, A. G. PETUKHOV, NASA Ames Research Center — Nanostructures based on dilute magnetic semiconductors indicate paths towards novel devices that could employ carrier spin [1-2]. Magnetic quantum dots (QDs) are an example of such structures. We use a robust numerical method, based on the Luttinger-Kohn Hamiltonian and suitable for realistic self-assembled QD geometries [3], to study electronic structure and magnetism of p-type II-VI quantum dots doped with Mn magnetic ions. Our method relies on self-consistent treatment of exchange coupling of holes and magnetic ions within the mean-field approximation [4]. It explicitly takes into account multi-band character of the hole kinetic energy operator. We demonstrate formation of the hole magnetic polarons, which manifests itself in self-induced splitting of the hole levels in absence of an external magnetic field [5]. Furthermore, we conduct detailed studies of the magnetically-ordered QD ground state. The structure of the ground state reveals highly anisotropic, as well as, position- and temperature-dependent self-induced magnetization. [1] Semiconductor spintronics and quantum computation, D.D. Awschalom, D. Loss, and N. Samarth eds., (Springer, Berlin, 2002). [2] J. Fabian, A. Matos-Abiad, C. Ertler, et al., Acta Phys. Slov 57, 565 (2007). [3] H. Kirmse, R. Schneider, M. **5:06PM H18.00012 Modeling of magnetic polaron properties in (Zn,Mn)Te quantum dots**<sup>1</sup>, JAMES PIENKA, St. Bonaventure University, B. BARMAN, L. SCHWEIDENBACK, A.H. RUSS, Y. TSAI, J.R. MURPHY, A.N. CARTWRIGHT, I. ZUTIC, B.D. MCCOMBE, A. PETROU, SUNY Buffalo, W-C. CHOU, W. C. FAN, National Chiao Tung University, I.R. SELLERS, University of Oklahoma, A.G. PETUKHOV, R. OSZWALDOWSKI, South Dakota School of Mines and Technology — Magnetic polarons in (Zn,Mn)Te quantum dots (QD) show unconventional behavior [1]. These structures exhibit a small red shift of the photoluminescence peak energy in the presence of a magnetic field  $B$  and they also have a weak dependence of the polaron energy  $E_{MP}$  on temperature  $T$  and  $B$ . We attribute these properties to a large molecular field  $B_m$  that is proportional to the heavy holes spin density [2]. We have calculated  $B_m$  using the QD diameter and height as adjustable parameters. Assuming hole localization, this calculation yields values of  $B_m > 20$  T. The assumption that the hole localization diameter can be smaller than the QD diameter is justified due to alloy and spin disorder scattering [3]. Using the magnetic polaron free energy, we calculate  $E_{MP}$  as function of  $T$  and  $B$  for a variety of  $B_m$  values. To get a weak dependence of  $E_{MP}$  on  $T$  and  $B$  we must assume that the polaron temperature is higher than  $T$ . [1] B. Barman et al., Phys. Rev. B 92, 035430 (2015). [2] J. M. Pientka et al., Phys. Rev. B 92, 155402 (2015). [3] K. V. Kavokin et al., Phys. Rev. B 60, 16499 (1999).

**5:18PM H18.00013 Gate-tuned spin to charge conversion in semiconducting single-walled carbon nanotubes**, EI SHIGEMATSU, HIROSHI NAGANO, Kyoto Univ, SERGEY DUSHENKO, Osaka Univ, YUICHIRO ANDO, Kyoto Univ, TETSUYA TSUDA, SUSUMU KUWABATA, Osaka Univ, TAISHI TAKENOBU, Waseda Univ, TAKESHI TANAKA, HIROMICHI KATAURA, AIST, TERUYA SHINJO, MASASHI SHIRAIISHI, Kyoto Univ — Interconversion of spin and charge current is a hot topic in the molecular spintronics. It was achieved for the first time in a conducting conjugated polymer<sup>1</sup>, and shortly followed by spin-charge conversion in graphene. However, control over carrier type has not been shown yet. In this study we focused on single-walled carbon nanotubes (SWNT). Spin injection into semiconductor from metal ferromagnet is challenging due to the presence of Schottky barrier and conductance mismatch problem. To bypass it, we used ionic liquid electric gate and ferrimagnetic insulator. We prepared SWNT layer on top of ferrimagnetic yttrium iron garnet substrate. Using spin pumping we successfully observed spin-charge conversion in metallic SWNT. As for a semiconducting SWNT, we applied a top gate using ionic liquid. The drain-source current vs. gate voltage dependence showed tuning of the Fermi level and changing of carrier type. Under gate voltage application we measured electromotive force induced by spin pumping. Detected voltage changed its sign together with carrier type. This is first evidence of spin-charge conversion in carbon nanotubes<sup>2</sup>.

**2:30PM H19.00001 Influence of interstitial Mn on spin order and dynamics in the room-temperature ferromagnet  $\text{Mn}_{1+\delta}\text{Sb}$** , ALICE TAYLOR, Oak Ridge National Laboratory —  $\text{Mn}_{1+\delta}\text{Sb}$  is a well-known, high Curie temperature, ferromagnetic metal. It has particular importance because it, and closely related MnBi, show promise as alternatives to rare-earth-containing permanent magnets, and as magneto-optic media. To exploit these materials useful properties, it is desirable to tune and optimize the magnetic properties [1]. To achieve this, the magnetic interactions, and the effects of doping and defects must be understood. In  $\text{Mn}_{1+\delta}\text{Sb}$  the magnetic order is highly sensitive to the interstitial Mn ion content,  $\delta$ , suggesting a route to tune the properties [2]. However, detailed theoretical and experimental investigations of the effect of the interstitial ion, Mn2, have been lacking, probably due to a prevailing view in the literature that the Mn2 site is nonmagnetic [3,4]. We examine the magnetic state of Mn2, and its influence on the magnetic properties of  $\text{Mn}_{1+\delta}\text{Sb}$ . We use a combination of neutron scattering techniques alongside detailed calculations to show that the Mn2 site is in-fact magnetic, and has a dramatic impact on the magnetic dynamics in  $\text{Mn}_{1+\delta}\text{Sb}$ . An unusual, broad, intense feature is identified in the magnetic dynamics which cannot be explained by the long-range symmetry of the material. This reveals an area in which current theoretical/modeling techniques limit our ability to understand the magnetic excitations revealed by neutron scattering. This investigation elucidates important aspects of the behavior of  $\text{Mn}_{1+\delta}\text{Sb}$ , whilst highlighting requirements for future research to understand the major influence of the interstitial ion on the magnetic properties. Reimers et al., J. Phys. Chem. Solids 44, 195 (1983).

**3:06PM H19.00002 Magnetic Structure and Dynamics in the Itinerant High-Temperature Ferromagnet MnBi**, TRAVIS WILLIAMS, ALICE TAYLOR, ANDREW CHRISTIANSON, STEVEN HAHN, RANDY FISHMAN, MICHAEL MCGUIRE, BRIAN SALES, MARK LUMSDEN, Oak Ridge National Laboratory — The high-temperature ferromagnet MnBi has been receiving much attention as a rare-earth-free permanent magnet to replace more costly rare-earth-containing magnets in applications above room temperature. This is due to MnBi containing strong Mn moments and large energy products. The synthesis of MnBi also allows for crystals that are free from interstitial Mn, allowing for the study of a more fundamental member of this family of binary Mn-based ferromagnets. In this work, we use polarized neutron diffraction to measure the magnetic moments of Mn and Bi, and find that the Bi atoms also have a magnetic moment, but 2 orders of magnitude smaller than Mn. We study their behavior through the spin reorientation that occurs at  $T_S \approx 100$  K, finding that both moments reorient simultaneously. We also use inelastic neutron scattering to measure the spin waves of MnBi in order to determine the magnetic exchange at low temperatures. Consistent with the strongly temperature-dependent magnetic anisotropy, we find that the spin gap is very small, and so the magnetic order arises from the strongly ferromagnetic nearest-neighbor term, but interactions up to sixth nearest neighbor are required to fully characterize the spin waves, suggesting that the Mn moments are strongly itinerant.

**3:18PM H19.00003 Electronic and magnetic properties of ferromagnetic interfaces for spin injection applications: metallic and semiconducting cases<sup>1</sup>**, E. A. ALBANESI, IFIS-CONICET-UNL and FI-UNER, Santa Fe, Argentina, L. MAKINISTIAN, INFAP-CONICET-UNSL, San Luis, Argentina, C. I. ZANDALAZINI, IFIS-CONICET-UNL, Santa Fe, Argentina, R. M. OSZWALDOWSKI, SDSMT, Rapid City, SD, A. G. PETUKHOV, NASA Ames Research Center, Moffett Field, CA 94035 — Robust and reliable operation of spintronic devices is determined by the quality of interfaces between magnetic and nonmagnetic materials. In order to get insights in the tuning of the magnetic properties of such interfaces we present comparative studies of two important cases relevant to applications in spin injection devices. We performed ab-initio calculations of the electronic and magnetic properties, of the ferromagnetic metallic interface of  $\text{Co}_2\text{MnAl}$  and gold, and of the interfaces of non- and of magnetic II-VI semiconductors and their quantum wells. In the case of the Heusler alloy  $\text{Co}_2\text{MnAl-Au}$ , two structural models are implemented: one with the ferromagnet slab terminated in a pure cobalt plane ( $\text{Co}_2\text{-t}$ ), and the other with it terminated with a plane of MnAl ( $\text{MnAl-t}$ ). The electric in-plane and averaged potential are resolved and analyzed layer by layer through the interface. We predict that both terminations are to be expected to display sensibly different spin injection performances. On the example of magnetic quantum wells of  $\text{ZnSe/Zn}_x\text{Mn}_{1-x}\text{Te/ZnSe}$ , we study the variations in the spin resolved density of states, and the potential energy along the junctions.

**3:30PM H19.00004 Structural and magnetic properties of a prospective spin gapless semiconductor MnCrVAL<sup>1</sup>**, Y HUH, S GILBERT, P KHAREL, Department of Physics, South Dakota State University, Brookings, SD 57007, Y JIN, Department of Physics and Astronomy, University of Nebraska, Lincoln, NE 68588, P LUKASHEV, Department of Physics, University of Northern Iowa, Cedar Falls, IA 50614, S VALLOPILLY, D. J. SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE 68588 — Recently a new class of material, spin gapless semiconductors (SGS), has attracted much attention because of their potential for spintronic devices. We have synthesized a Heusler compound, MnCrVAL, which is theoretically predicted to exhibit SGS by arc melting, rapid quenching and thermal annealing. First principles calculations are employed to describe its structural, electronic and magnetic properties. X-ray diffraction indicates that the rapidly quenched samples crystallize in the disordered cubic structure. The crystal structure is stable against heat treatment up to 650°C. The samples show very small saturation magnetization, 0.3 emu/g, at room temperature under high magnetic field, 30 kOe. Above room temperature, the magnetization increases with increasing temperature undergoing a magnetic transition at 560°C, similar to an antiferromagnetic-to-paramagnetic transition. The prospect of this material for spintronic applications will be discussed.

**3:42PM H19.00005 Enhancement of ferromagnetism by Ag doping in Ni-Mn-In-Ag Heusler alloys**, SUDIP PANDEY, ABDIEL QUETZ, ANIL ARYAL, IGOR DUBENKO, DIPANJAN MAZUMDAR, Southern Illinois University, SHANE STADLER, Louisiana State University, NAUSHAD ALI, Southern Illinois University — The effect of Ag on the structural, magnetocaloric, and thermomagnetic properties of  $\text{Ni}_{50}\text{Mn}_{35}\text{In}_{15-x}\text{Ag}_x$  ( $x=0.1, 0.2, 0.5$ , and 1) Heusler alloys was studied. The magnitude of the magnetization change at martensitic transition temperature ( $T_M$ ) decreases with increasing Ag concentration. A smaller magnetic entropy changes ( $\Delta S_M$ ) for the alloys with higher Ag concentration is observed. A shift of  $T_M$  by about 25 K to a higher temperature was detected for  $P = 6.6$  kbar with respect to ambient pressure. Large drop of resistivity is observed with the increase of Ag concentration. The magnetoresistance is dramatically suppressed with increasing Ag concentration due to the weakening of the antiferromagnetic interactions in the martensitic phase. The experimental results demonstrate that Ag substitution in  $\text{Ni}_{50}\text{Mn}_{35}\text{In}_{15-x}\text{Ag}_x$  Heusler alloys suppresses the AFM interactions and enhances the FM interactions in the alloys. The possible mechanisms responsible for the observed behavior are discussed. Acknowledgement: This work was supported by the Office of Basic Energy Sciences, Material Science Division of the U.S. Department of Energy (DOE Grant No. DE-FG02-06ER46291 and DE-FG02-13ER46946).

**3:54PM H19.00006 Probing the magnetic structure of  $\text{Co}_2\text{Fe}_x\text{Mn}_{1-x}\text{Si}$  thin films by XAS/XMCD**, ADAM J. HAUSER, JOSHUA PHILLIPS, Department of Physics, The University of Alabama, MIHIR PENDHARKAR, SAHILL J. PATEL, CHRIS J. PALMSTROM, Materials Department, University of California-Santa Barbara, Santa Barbara, California 93106, USA — We have analyzed the magnetic configuration for highly ordered epitaxial thin films across the  $\text{Co}_2\text{Fe}_x\text{Mn}_{1-x}\text{Si}$  compositional series ( $x = 0, 0.3, 0.7, 1$ ) by x-ray circular magnetic dichroism (XMCD) and x-ray absorption spectroscopy (XAS). These measurements give the element-specific electronic structure of each film, as well as the spin and orbital moments. We will present our observations at the Co, Mn, and Fe L-edges to explain the significant changes in intermediate stoichiometries as compared with the parent  $\text{Co}_2\text{MnSi}$  and  $\text{Co}_2\text{FeSi}$  systems.

**4:06PM H19.00007 Growth of Cr<sub>2</sub>CoGa and inverse Heusler thin films using Molecular Beam Epitaxy<sup>1</sup>**, MICHELLE JAMER, MATTHEW DECAPIUA, GABRIEL PLAYER, DON HEIMAN, Northeastern University — Theoretical calculations have predicted the existence of inverse Heusler compounds that exhibit zero-moment magnetization while retaining their half-metallicity. These unique compounds have been labeled spin gapless semiconductors (SGS), where the density of states (DOS) can behave as a half-metal or gapless semiconductor.[1] There is a special interest for zero-moment SGS compounds since traditional antiferromagnets cannot be spin-polarized.[2] Such compounds are experimentally attractive for future spintronic devices due to their large magnetic transition temperature (400-800 K).[3] This work focuses on zero-moment inverse Heusler compounds including Cr<sub>2</sub>CoGa and Mn<sub>3</sub>Al. Thin films have been grown using MBE and their magnetic, structural, and electrical properties of these compounds have been characterized by various techniques, including XMCD and magnetometry. The atomic moments are found to be large, but significant cancellations lead to small average moments. [1] M.E. Jamer, B.A. Assaf, T. Devakul and D. Heiman, Appl. Phys. Lett. **103**, 142403 (2013). **4:18PM H19.00008 Large magnetoresistance induced by crystallographic defects in Fe<sub>x</sub>TaS<sub>2</sub> single crystals<sup>1</sup>**, CHIH-WEI CHEN, EMILIA MOROSAN, Rice University, MOROSAN'S GROUP TEAM — The search for the materials that show large magnetoresistance and the mechanisms that induce it remains challenging in both experimental and theoretical aspects. The giant magnetoresistance in one class of materials, ferromagnetic conductors, is generally attributed to the misalignments of magnetic moments, which cause spin disorder scattering. Recently, very large magnetoresistance (>60%) was discovered in the ferromagnetic Fe-intercalated transition metal dichalcogenide, Fe<sub>0.28</sub>TaS<sub>2</sub> [Phys. Rev. B **91**, 054426(2015)]. The mechanism that led to this large magnetoresistance was suggested to be due to the deviation of Fe concentration from commensurate values (1/4 or 1/3), which caused magnetic moments misalignments. Here we report a study of Fe<sub>x</sub>TaS<sub>2</sub> crystals with *x* close to the commensurate values. Our results qualitatively demonstrate that crystallographic defects significantly affect magnetoresistance in Fe<sub>x</sub>TaS<sub>2</sub>. This provides a way to search for large magnetoresistance in more intercalated transition metal dichalcogenides.

**4:30PM H19.00009 Development of spin-gapless semiconductivity and half metallicity in Ti<sub>2</sub>MnAl by substitutions for Al<sup>1</sup>**, PAVEL LUKASHEV, University of Northern Iowa, SIMEON GILBERT, South Dakota State University, BRADLEY STATEN, NOAH HURLEY, University of Northern Iowa, RYAN FUGLSBY, PARASHU KHAREL, YUNG HUH, South Dakota State University, SHAH VALLOPILLY, WENYONG ZHANG, University of Nebraska, Lincoln, K. YANG, Hohai University, DAVID J. SELLMYER, University of Nebraska, Lincoln — In recent years, ever increasing interest in spin-based electronics has resulted in the search for a new class of materials that can provide a high degree of spin polarized electron transport. An ideal candidate would act like insulator for one spin channel and a conductor or semiconductor for the opposite spin channel (e.g., half metal (HM), spin-gapless semiconductor (SGS)). Here, we present the combined computational, theoretical, and experimental study of Ti<sub>2</sub>MnAl, a Heusler compound with potential application in the field of spintronics. We show that in the ground state this material is metallic, however it becomes a SGS when 50% of Al is substituted with In (e.g., Ti<sub>2</sub>MnAl<sub>0.5</sub>In<sub>0.5</sub>), and a HM when 50% of Al is substituted with Sn (e.g., Ti<sub>2</sub>MnAl<sub>0.5</sub>Sn<sub>0.5</sub>). Detailed study of the structural, electronic, and magnetic properties of these materials is presented.

<sup>1</sup>Financial support: DOE/BES (DE-FG02-04ER46152); NSF NNCI: 1542182; NRI; Academic and Scholarly Excellence Funds, Office of Academic Affairs, SDSU; UNI Faculty Summer Fellowship; Program for Outstanding Innovative Talents in Hohai University.

**4:42PM H19.00010 Antiferromagnetic-domain-dependent magnetoresistance in Pt/Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> interface**, TOSHIYA IDEUE, University of Tokyo, TAKASHI KURUMAJI, RIKEN Center for Emergent Matter Science (CEMS), SHINTARO ISHIWATA, University of Tokyo, YOSHINORI TOKURA, University of Tokyo, RIKEN Center for Emergent Matter Science (CEMS), UNIVERSITY OF TOKYO TEAM, RIKEN CENTER FOR EMERGENT MATTER SCIENCE (CEMS) TEAM — Interface between nonmagnetic metal and magnetic insulator has been extensively studied, exploiting a variety of new exotic spin transports. Among them, magnetoresistance in Pt/YIG interface attracts intense experimental and theoretical interest. The resistance of Pt layer reflects the magnetization of YIG in spite of the insulating nature of YIG, which has been explained by the spin current across the Pt/YIG interface or the magnetic proximity effect. So far, such anomalous magnetoresistance have been reported only in the interface between nonmagnetic metal and ferrimagnetic insulator. In this work, we have studied the transport properties of Pt on the antiferromagnetic insulator Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub>. Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> shows the metamagnetic phase transition under the magnetic field by which we can control the two different antiferromagnetic domains. Interestingly, transverse magnetoresistance in Pt/Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> interface shows the distinct behaviors depending on the field cooling process which result in the different antiferromagnetic domains. This implies that the spin transport or proximity effect at the interface is different between two domains and can be probed by the resistance of nonmagnetic Pt.

**4:54PM H19.00011 Magnetic properties of Cr<sub>3</sub>Te<sub>4</sub> doped with transition metals: An *ab initio* study**, NABIL AL-AQTASH, The Hashemite University, RENAT SABIRIANOV, University of Nebraska at Omaha — We report density functional theory (DFT) study of the magnetic properties of Cr<sub>3</sub>Te<sub>4</sub> doped with transition metals (TM) (Co, Fe, Ni, V and Mn), TM ions doped in Cr sites, Cr<sub>3-x</sub>(TM)<sub>x</sub>Te<sub>4</sub> (*x* = 0.5 and 1). We performed screening of the exchange coupling interaction and magnetization modifications upon the substitution of Cr by 3d-transition metals at various Cr sites in the Cr<sub>3</sub>Te<sub>4</sub> structure. Our calculation show that Cr<sub>3</sub>Te<sub>4</sub> has ferromagnetic coupling and large magnetization (Magnetization per unit cell is 18.24μB). Magnetocrystalline anisotropy (MAE) of this material is also large (MAE= 1.67MJ/m<sup>3</sup>). Our calculations show that the increase in interlayer spacing strengthen ferromagnetism of Cr<sub>3</sub>Te<sub>4</sub>. Doping with Mn increases Cr<sub>3</sub>Te<sub>4</sub> magnetization, but reduces the exchange coupling energy which means reducing Curie temperature (T<sub>c</sub>). We find that doping with 3d-TM elements decreases the magnetocrystalline anisotropy energies (MAE) of Cr<sub>3</sub>Te<sub>4</sub>.

**5:06PM H19.00012 Magnetic properties and stability of the atomic laminate Mn<sub>2</sub>GaC.**, MARTIN DAHLQVIST, ÅRNI INGASON, Linköping University, Sweden, GUNNAR PÁLSSON, Uppsala University, Sweden, BJÖRN ALLING, IGOR ABRIKOSOV, JOHANNA ROSEN, Linköping University, Sweden — Using first-principles calculations, we predicted the thermodynamically stable magnetic Mn<sub>2</sub>GaC and subsequently synthesized it as a heteroepitaxial thin film. It belongs to a class of atomically laminated compounds with a unique combination of metallic and ceramic properties. They have a common formula *M*<sub>*n*+1</sub>*A*X<sub>*n*</sub>M<sub>*n*+1</sub>S<sub>*n*</sub> (n = 1-3), where M is an early transition metal, A is an A-group element, and X is carbon or nitrogen. Using density functional theory (DFT) and Heisenberg Monte Carlo (HMC) for a magnetic ground state search, several collinear and noncollinear low energy magnetic spin configurations have been identified, some with different symmetries compared to the non-magnetic crystal structure. Around 240 K X-ray diffraction and magnetic measurements display a sharp contraction of the lattice in the c-direction coinciding with a sharp magnetic transition. Neutron diffraction measurements displays diffraction peaks consistent with long-ranged antiferromagnetic order with a repetition distance of two structural unit cells (25 Å). This is consistent with theoretically predicted structural changes between different, close to degenerate, magnetic ground states, and it is the first unambiguous evidence of long ranged AFM order in MAX phase materials.

**Session H20 GSCCM DCOMP DMP: Materials in Extremes: Novel Energetic Materials 319 -**

Elissaios Stavrou, Lawrence Livermore National Laboratory

**2:30PM H20.00001 The Promise and Challenge of Extended Solids of Nitrogen**, JENNIFER CIEZAK-JENKINS, US Army Research Laboratory — The extended solids of nitrogen are of considerable interest as high-energy-density materials, as it has been projected a transformation from a single-bonded polymeric-like material back to the more stable triply-bonded diatomic phase would release over 2.3 eV/atom, which is significantly higher than conventional energetic materials. Although a transformation to the single bonded cubic gauche structure was experimentally confirmed in 2005, efforts to recover this material to ambient conditions have been challenging and unsuccessful to date. In an effort to increase the metastability of the extended solid, recent studies have focused on mixing, or doping, the nitrogen with small amounts of secondary gases, such as hydrogen or carbon monoxide. It was been postulated the secondary gas would passivate the terminal ends thus increasing the stability of the nitrogen extended solid. Our group was the first to demonstrate such an approach could be used successfully to decrease the transition pressure for the formation of the nitrogen extended solid through doping with hydrogen. Although recent studies on nitrogen/hydrogen mixtures by other research groups have also observed several non-molecular nitrogen/hydrogen structures, recovery of these materials to ambient conditions has not yet been demonstrated. In this talk, I will describe our progress in the study of the synthesis, characterization, and recovery of extended solids of nitrogen from high pressure conditions from nitrogen/carbon monoxide mixtures. I will also detail results from our closely coupled modeling and simulation efforts and discuss how these results help guide our experimental efforts. New opportunities and challenges that have arisen in the course of our studies that will be pursued in the future will also be presented.

**3:06PM H20.00002 Sodium Pentazolate: a Nitrogen Rich Energetic Material**, IVAN OLEJNIK, BRAD STEELE, University of South Florida — Sodium pentazolates  $\text{NaN}_5$  and  $\text{Na}_2\text{N}_5$ , new energetic materials, are discovered using first principles crystal structure search for the compounds of varying amounts of elemental sodium and nitrogen. The pentazole anion ( $\text{N}_5^-$ ) is stabilized in the condensed phase by sodium  $\text{Na}^+$  cations at pressures exceeding 20 GPa, and becomes metastable upon release of pressure, i.e. at ambient conditions. The sodium azide ( $\text{NaN}_3$ ) precursor for the new compounds is predicted to undergo a chemical transformation above 50 GPa into sodium pentazolates  $\text{NaN}_5$  and  $\text{Na}_2\text{N}_5$ . The calculated Raman spectrum of  $\text{NaN}_5$  is in agreement with the experimental Raman spectrum of a previously unidentified substance appearing upon compression and heating of  $\text{NaN}_3$  precursor, thus confirming the appearance of the new compound.

**3:18PM H20.00003 Modeling of formation of extended NH solids under high pressure.**, ISKANDER G. BATYREV, US Army Research Laboratory — Structure of N-H extended network under high pressure was modelled using the evolutionary algorithm program USPEX based on plane wave DFT calculations (VASP). Concentration ratio of  $\text{N}_2$  to  $\text{H}_2$  gases was 3:1, 4:1, and 9:1. Range of the studied pressures was 10 – 50 GPa on compression, and from 50 to 1 GPa on isotropic decompression of the extended network. Formation of an extended network with covalent bonds occurs between 30-50 GPa. Higher concentration of N requires higher pressure to form a covalent bond network. New structure of NH extended solids with covalent bonds are predicted: with P-1(CI-1) symmetry group for 9:1 ratio, with PBAM ( $\text{D}_{2\text{H}+9}$ ) symmetry group for 4:1 ratio, and with P-1(CI-1) for 3:1 ratio of  $\text{N}_2$  to  $\text{H}_2$  gas. Calculations of the mixtures of  $\text{N}_2$  and  $\text{H}_2$  gases at pressures in the range of 10-20 GPa resulted in a variety of structures without a covalent network, but consisting of nitrogen-containing molecules. For example, the lowest energy structure for a 3:1 ratio of N to H atoms consists of tetrazene and  $\text{N}_2$  molecules. At 10 GPa the lowest energy structure appears to be a combination of protonated ammonia and  $\text{N}_2$  molecules.

**3:30PM H20.00004 Computational design of fused heterocyclic energetic materials<sup>1</sup>**, ROMAN TSYSHEVSKIY, University of Maryland College Park, PHILIP PAGORIA, Lawrence Livermore National Laboratory, ISKANDER BATYREV, US Army Research Laboratory, MAIJA KUKLJA, University of Maryland College Park — A continuous traditional search for effective energetic materials is often based on a trial and error approach. Understanding of fundamental correlations between the structure and sensitivity of the materials remains the main challenge for design of novel energetics due to the complexity of the behavior of energetic materials. State of the art methods of computational chemistry and solid state physics open new compelling opportunities in simulating and predicting a response of the energetic material to various external stimuli. Hence, theoretical and computational studies can be effectively used not only for an interpretation of sensitivity mechanisms of widely used explosives, but also for identifying criteria for material design prior to its synthesis and experimental characterization. We report here, how knowledge on thermal stability of recently synthesized materials of LLM series is used for design of novel fused heterocyclic energetic materials, including DNBTT (2,7-dinitro-4H,9H-bis([1,2,4]triazolo)[1,5-b:1',5'-e][1,2,4,5]tetrazine), compound with high thermal stability, which is on par or better than that of TATB.

**3:42PM H20.00005 Metalloid Clusters as Novel Energetic Materials: Progress and Challenges.**, SUFIAN ALNEMRAT, JOSEPH HOOPER, Naval Postgraduate School — Integration of combustible metals is a standard route for increasing the energy density of explosive and propellant formulations. Bulk metals, however, have well-known limitations. As a rather different route, we have been studying molecular scale metalloid clusters that contain a core of low-valence metal surrounded by a layer of organic ligands. These materials may retain the high energy density of bulk metals but offer substantially faster reaction kinetics. In this talk we present recent computational results on the stability and decomposition of these clusters. We compare molecular dynamics simulations of the oxidation of a prototype aluminum metalloid cluster to recent experimental thermally programmed reaction data; both show that oxygen reacts with the metal core and not the ligands. As a route to larger-scale fabrication of these clusters, we present simulations of the nucleation and growth of small metalloid systems on functionalized graphene layers. The simulations demonstrate that spontaneous cluster nucleation and growth is favorable on many graphene defects, suggesting a means of templated growth of clusters and nanoparticles.

**3:54PM H20.00006 Novel LLM series high density energy materials: Synthesis, characterization, and thermal stability<sup>1</sup>**, PHILIP PAGORIA, MAOXI ZHANG, Lawrence Livermore National Laboratory, ROMAN TSYSHEVSKIY, MAIJA KUKLJA, University of Maryland College Park — Novel high density energy materials must satisfy specific requirements, such as an increased performance, reliably high stability to external stimuli, cost-efficiency and ease of synthesis, be environmentally benign, and be safe for handling and transportation. During the last decade, the attention of researchers has drifted from widely used nitroester-, nitramine-, and nitroaromatic-based explosives to nitrogen-rich heterocyclic compounds. Good thermal stability, the low melting point, high density, and moderate sensitivity make heterocycle materials attractive candidates for use as oxidizers in rocket propellants and fuels, secondary explosives, and possibly as melt-castable ingredients of high explosive formulations. In this report, the synthesis, characterization, and results of quantum-chemical DFT study of thermal stability of LLM-191, LLM-192 and LLM-200 high density energy materials are presented.

**4:06PM H20.00007 ABSTRACT WITHDRAWN —**

**4:18PM H20.00008 Mixed Nitrogen-Methane Solids at High Density**, SERGE DESGRENIERS, Laboratoire de physique des solides denses, University of Ottawa — Mixing different molecular species may yield weakly bound compounds or van der Waals solids upon the application of high pressure. Van der Waals solids differ in physical properties from solids formed by pure molecular species at comparable thermodynamic conditions. In this contribution, we present results of the formation of binary methane-nitrogen compounds at high density. Methane and nitrogen, with similar potentials and molecular size, are expected to be partly miscible in the condensed state. Using single crystal and powder X-ray diffraction with synchrotron radiation and vibrational spectroscopy, the pressure-concentration phase diagram for this system has been explored from 1 to 16 GPa, at room temperature. The existence of van der Waals solid phases for samples with concentrations above 10% (methane per volume) is demonstrated. For example, at 7.6 GPa and at room temperature, whereas pure nitrogen and methane exist in cubic and in rhombohedral structures, respectively, our study indicates that a methane-nitrogen sample with 60% nitrogen by volume exhibits, under the same conditions, a novel phase with a tetragonal symmetry. Other novel structures in methane-nitrogen samples with different concentrations under varying pressure conditions have also been observed and will be discussed.

**4:30PM H20.00009 High Pressure Structures and Equations of State of HIO3 and HIO3O8<sup>1</sup>**, JOSEPH ZAUG, ELISSAIO STAVROU, Lawrence Livermore National Laboratory, BRIAN LITTLE, AFRL/RWM, SORIN BASTEA, JONATHAN CROWHURST, Lawrence Livermore National Laboratory, CHEMICAL ENERGETICS COLLABORATION — Knowledge of high-pressure thermodynamic properties of iodine containing oxides and acids is important toward improving the accuracy of semi-empirical predictions of extreme condition explosive and combusive chemistry of iodine containing formulations. Here we report on the synthesis of explosive chemical products HIO3 and HIO3O8 and on the structures and isotropic equations of state up to 35 and 45 GPa respectively. EOS model parameters are provided including parametrized exponential-6 interatomic potential values used to conduct thermochemical calculations of iodine containing reactants.

**4:42PM H20.00010 Harvesting materials formed under extreme conditions: Synthesis and isolation of nanocarbons derived from detonation of high explosives**, MILLICENT FIRESTONE, BRYAN RINGSTRAND, RACHEL HUBER, DANA DATTELBAUM, RICHARD GUSTAVSON, DAVID PODLESÁK, Los Alamos Natl Lab — High explosive detonation products are primarily composed of molecular gases and solid carbon products. Recent studies have shown that the solid carbon condensate morphologies can vary depending on the high explosive and / or the pressure, temperature, or environment of the detonation. These studies have revealed, for example, unique carbon nanoparticles possessing novel morphologies, such as ones composed of hollow cores surrounded by lamellar structured graphitic shells. Despite these observations little work has been done to isolate these particles from the recovered post-detonation soot. This lack of effort to isolate and purify these products limits our understanding of their materials properties and, ultimately our ability to adapt them for useful materials. Herein, we report our recent studies directed at the production of nano-carbons through the detonation of a high explosive (e.g., composition B) under a range of experimental conditions. We further describe work directed at isolation and purification of the carbon nanoparticles.

**4:54PM H20.00011 Simulation of Initiation in Hexanitrostilbene<sup>1</sup>**, AIDAN THOMPSON, TZU-RAY SHAN, COLE YARRINGTON, RYAN WIXOM, Sandia National Laboratories — We report on the effect of isolated voids and pairs of nearby voids on hot spot formation, growth and chemical reaction initiation in hexanitrostilbene (HNS) crystals subjected to shock loading. Large-scale, reactive molecular dynamics simulations are performed using the reactive force field (ReaxFF) as implemented in the LAMMPS software. The ReaxFF force field description for HNS has been validated previously by comparing the isothermal equation of state to available diamond anvil cell (DAC) measurements and density function theory (DFT) calculations. Micron-scale molecular dynamics simulations of a supported shockwave propagating in HNS crystal along the [010] orientation are performed ( $u_p = 1.25$  km/s,  $U_s = 4.0$  km/s,  $P = 11$  GPa.) We compare the effect on hot spot formation and growth rate of isolated cylindrical voids up to 0.1  $\mu$ m in size with that of two 50nm voids set 100nm apart. Results from the micron-scale atomistic simulations are compared with hydrodynamics simulations.

**5:06PM H20.00012 Large-Amplitude Deformation and Bond Breakage in Shock-Induced Reactions of Explosive Molecules**, JEFFREY KAY, Sandia National Laboratories — The response of explosive molecules to large-amplitude mechanical deformation plays an important role in shock-induced reactions and the initiation of detonation in explosive materials. In this presentation, the response of a series of explosive molecules (nitromethane, 2,4,6-trinitrotoluene [TNT], and 2,4,6-triamino-1,3,5-trinitrobenzene [TATB]) to a variety of large-amplitude deformations are examined using ab initio quantum chemical calculations. Large-amplitude motions that result in bond breakage are described, and the insights these results provide into both previous experimental observations and previous theoretical predictions of shock-induced reactions are discussed.

**5:18PM H20.00013 Reactive Force Field for Liquid Hydrazoic Acid with Applications to Detonation Chemistry<sup>1</sup>**, DAVID FURMAN, Hebrew University of Jerusalem and NRCN, Israel, FAINA DUBNIKOVA, Hebrew University of Jerusalem, Israel, ADRI VAN DUIN, Penn. State University, Pennsylvania, USA, YEHUDA ZEIRI, Ben Gurion University, Israel and NRCN, Israel, RONNIE KOSLOFF, Hebrew University of Jerusalem, Israel — The development of a reactive force field (ReaxFF formalism) for hydrazoic acid (HN3), a highly sensitive liquid energetic material, is reported. The force field accurately reproduces results of density functional theory (DFT) calculations. The quality and performance of the force field are examined by detailed comparison with DFT calculations related to uni, bi and trimolecular thermal decomposition routes. Reactive molecular dynamics (RMD) simulations are performed to reveal the initial chemical events governing the detonation chemistry of liquid HN3. The outcome of these simulations compares very well with recent results of tight-binding DFT molecular dynamics and thermodynamic calculations. Based on our RMD simulations, predictions were made for the activation energies and volumes in a broad range of temperatures and initial material compressions.

**2:30PM H21.00001 Spectroscopic Investigation of the Origin of Magnetic Bistability in Molecular Nanomagnets<sup>1</sup>**, JORIS VAN SLAGEREN, University of Stuttgart — Molecular nanomagnets (MNM)s are coordination complexes consisting of one or more transition metal and/or f-element ions bridged and surrounded by organic ligands. Some of these can be magnetized in a magnetic field, and remain magnetized after the field is switched off. Because of this, MNMs have been proposed for magnetic data storage applications, where up to 1000 times higher data densities than currently possible can be obtained. Other MNMs were shown to display quantum coherence, and, as a consequence, are suitable as quantum bits. Quantum bits are the building blocks of a quantum computer, which will be able to carry out calculations that will never be possible with a conventional computer. The magnetic bistability of MNMs originates from the magnetic anisotropy of the magnetic ions, which creates an energy barrier between up and down orientations of the magnetic moment. Currently, most work in the area focuses on complexes of either lanthanide ions or low-coordinate transition metal ions. Synthetic chemical efforts have led to a large number of novel materials, but the rate of improvement has been slow. Therefore a better understanding of the origin of the magnetic anisotropy is clearly necessary. To this end we have applied a wide range of advanced spectroscopic techniques, ranging from different electron spin resonance techniques at frequencies up to the terahertz domain to optical techniques, including luminescence and magnetic circular dichroism spectroscopy. We will discuss two examples, one from the area of lanthanide MNMs [1], one a transition metal MNM (unpublished). [1] . Rechkemmer, J.E. Fischer, R. Marx, M. Dörfel, P. Neugebauer, S. Horvath, M. **3:06PM H21.00002 Conditions for the appearance of boundary modes in topological phases of Heisenberg spin ladders**, NEIL ROBINSON, Brookhaven Natl Lab, ALEXANDER ATLAND, Universität zu Köln, REINHOLD EGGER, HHU Düsseldorf, NKILAS GERGS, Utrecht University, ROBERT KONIK, Brookhaven Natl Lab, WEI LI, LMU München, DIRK SCHURICHT, Utrecht University, ALEXEI TSVELIK, Brookhaven Natl Lab, ANDREAS WEICHSELBAUM, LMU München — We consider the problem of delineating the necessary conditions for the appearance of boundary modes in extended  $SU(2)$  Heisenberg spin ladders. Specifically, we study Heisenberg ladders with rung exchange,  $J_{\perp}$ , and ring exchange,  $J_{\chi}$ , that admit a field theoretic description in terms of Majorana fermions in the continuum limit. In this description there are four Majorana fermions, arranged in a triplet and a singlet. This suggests there are four distinct phases, corresponding to the configurations of the signs of the triplet  $m_t$  and singlet  $m_s$  masses. We label these phases as: Haldane ( $m_t > 0, m_s < 0$ ), rung singlet ( $m_t < 0, m_s > 0$ ),  $VBS_+$  ( $m_t, m_s > 0$ ) and  $VBS_-$  ( $m_t, m_s < 0$ ). Topologically, we find two of these phases support gapless boundary modes: the Haldane phase (the triplet forms a spin-1/2 degree of freedom at the ends of the ladder) and the  $VBS_+$  phase, where all the Majorana fermions have gapless boundary modes. The absence of a gapless boundary mode in the rung singlet phase is surprising; we find that the singlet mode can become gapless if open boundary conditions are replaced with a continuous change in lattice parameters. We suggest a symmetry-allowed modification to the low-energy effective theory which may be responsible for this behavior.

**3:18PM H21.00003 The pressure effects on the antiferromagnetic orders in iron-based ladder compounds  $BaFe_2S_3$** , SONGXUE CHI, Quantum Condensed Matter Division, Oak Ridge National Laboratory, YOSHIYA UWATOKO, None, YASUYUKI HIRATA, KENYA OHGUSHI, Institute for Solid State Physics (ISSP), University of Tokyo — The ladder compounds have recently become a new test ground for the studies on Fe-based superconductors. The building block for such materials, the two-leg Fe ladder surrounded by edge-sharing chalcogen tetrahedra, has provided a quasi-one-dimensional channel for the remaining critical issues in this field. Recently, superconductivity was successfully induced by pressure in one of such compounds,  $BaFe_2S_3$ . The knowledge of the pressure effect on its antiferromagnetic order is crucial in understanding the superconductivity in the low-dimensional system. I will present the results of our neutron diffraction studies on the evolution of the magnetic phase under hydraulic pressure in single crystalline  $BaFe_2S_3$ .

**3:30PM H21.00004 Neutron scattering study of magnetic structure in triangle spin tube  $CsCrF_4$** , MASATO HAGIHALA, ISSP, Univ. of Tokyo, MAXIM AVDEEV, Bragg Institute, ANSTO, HIROTAKA MANAKA, Kagoshima Univ., TAKAT-SUGU MASUDA, ISSP, Univ. of Tokyo — Triangle spin tube viewed from tube direction is topologically equivalent to kagom lattice. The rung ( $J_1$ ) and inter-tube ( $J_2$ ) interactions on triangle spin tube correspond respectively to the next nearest neighbor and the nearest neighbor interactions on kagom lattice. In the case of  $J_1 > 0$  (Antiferromagnetic) and  $J_1 \gg |J_2|$ , the ground state is  $q = 0, 120^\circ$  structure with  $J_2 > 0$  or Cuboc state that represented multi- $q$  ( $q = 2\pi(1/2, 0)$  and two symmetric-equivalent vectors) with  $J_2 < 0$  [1].  $CsCrF_4$  is a perfect triangle spin tube material with antiferromagnetic intra-tube and rung interactions [2]. Neutron diffraction measurement revealed magnetic long-range order at  $T = 1.5$  K. Contrary to the expectation, the magnetic structure was determined  $q = 2\pi(1/2, 0, 1/2)$ ,  $120^\circ$  structure by Rietveld refinement. We also confirmed that this structure was stabilized by Dzyaloshinskii-Moriya interaction and small anisotropy that obeyed the three-fold symmetry at Cr sites by calculation. [1] H. Ishikawa et al., JPSJ 83, 043703 (2014). [2] H. Manaka et al., JPSJ 78, 093701 (2009).

**3:42PM H21.00005 Dielectric effects at a magnetic Bose-Einstein condensation<sup>1</sup>**, KIRILL POVAROV, AARON REICHERT, ERIK WULF, ANDREY ZHELUDEV, Neutron Scattering and Magnetism Group, ETH Zürich, Switzerland — In the presence of magnetoelectric coupling one can expect non-trivial dielectric properties at a magnetic quantum phase transition. A "toy model" here is a spin spiral undergoing a field-induced transition into a quantum-disordered phase. In the incommensurate phase the in-plane spin rotational symmetry is protected, making the analogy between the magnetic long-range ordering and BEC exact, but the spin spiral may also host an electric polarization complicating the picture. We have experimentally studied this transition in the spin tube material  $Sr_{1-x}Cu_2Cl_4$  [1] to understand if it can be described as a magnetic BEC. We have found that indeed it can. Dielectric spectroscopy results combined with calorimetric measurements, clearly show the absence of polarization fluctuations in the disordered phase down to the very critical point. At the same time the ordered phase shows a huge nonlinearity in dielectric permittivity even for small electric fields. The phase boundary shows beautiful consistency with the 3D BEC universality class. We conclude, that although magnetoelectric coupling does not alter the nature of the transition, it gives rise to complex magnetoelectric effects in the helimagnetically ordered phase.

**3:54PM H21.00006 Optical spin excitations in quantum spin ladders**, GEDIMINAS SIMUTIS, SEVERIAN GVASALIYA, NSM laboratory, ETH Zurich, FAN XIAO, Department of Physics, Durham University, CHRISTOPHER LANDEE, Department of Physics, Clark University, ANDREY ZHELUDEV, NSM laboratory, ETH Zurich — We present a Raman spectroscopy study of magnetic excitations in quantum spin ladders. We start with a strong-rung ladder  $Cu(Qnx)(Cl_{1-x}Br_x)_2$ . It has recently attracted attention due to proposal that the ratio of leg to rung exchange can be varied continuously by substituting Br for Cl. We have measured the Raman spectra for the hole doping series and report on the scattering from two magnons [1]. We extract the onset and cutoff of the scattering for the whole series and compare it to the estimates from previous bulk measurements as well as numerical calculations. We find that the magnetic spectrum indeed varies continuously as the halogen ions are exchanged. The general behavior is found to be consistent with expectations, however small systematic deviations persist. The difference can potentially be explained by the existence of three-dimensional coupling, however more systematic computational studies are needed to ascertain the origin of the inconsistencies. Having established the analysis using the strong rung case, we then turn our attention to other ladder systems. Unusual magnetic signal is found in a strong leg spin ladder, which is discussed in terms of selection rules and an unexpected energy scale. [1] G. Simutis *et al.* arXiv:1510.06360

**4:06PM H21.00007 ESR modes in a Strong-Leg Ladder in the Tomonaga-Luttinger Liquid Phase<sup>1</sup>**, S. ZVYAGIN, HLD-HZDR, D-01328 Dresden, Germany, M. OZEROV, Radboud University, 6525 ED Nijmegen, The Netherlands, M. MAKSYMENKO, Weizmann Institute of Science, Rehovot 76100, Israel, J. WOSNITZA, HLD-HZDR, D-01328 Dresden, Germany, A. HONECKER, Université de Cergy-Pontoise, F-95302 Cergy-Pontoise Cedex, France, C.P. LANDEE, M. TURNBULL, Clark University, Worcester, MA 01060, USA, S.C. FURUYA, T. GIAMARCHI, University of Geneva, CH-1211 Geneva, Switzerland — Magnetic excitations in the strong-leg quantum spin ladder compound  $(\text{C}_7\text{H}_{10}\text{N})_2\text{CuBr}_4$  (known as DIMPY) in the field-induced Tomonaga-Luttinger spin liquid phase are studied by means of high-field electron spin resonance (ESR) spectroscopy. The presence of a gapped ESR mode with unusual non-linear frequency-field dependence is revealed experimentally. Using a combination of analytic and exact diagonalization methods, we compute the dynamical structure factor and identify this mode with longitudinal excitations in the antisymmetric channel. We argue that these excitations constitute a fingerprint of the spin dynamics in a strong-leg spin-1/2 Heisenberg antiferromagnetic ladder and owe its ESR observability to the uniform Dzyaloshinskii-Moriya interaction.

**4:18PM H21.00008 Field-induced spontaneous magnon decay in a spin-1/2 coupled two-leg ladder antiferromagnet  $\text{C}_9\text{H}_{18}\text{N}_2\text{CuBr}_4$  with small Ising anisotropy**, TAO HONG, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Y. QIU, National Institute of Standards and Technology, D. A. TENNANT, Quantum Condensed Matter Division, Oak Ridge National Laboratory, K. COESTER, K. P. SCHMIDT, Lehrstuhl für Theoretische Physik I, TU Dortmund, F. F. AWWADI, Department of Chemistry, The University of Jordan, M. M. TURNBULL, Carlson School of Chemistry, Clark University — We present the high-resolution neutron scattering study in magnetic fields applied perpendicular to an easy-axis (Ising type) on the  $S = 1/2$  coupled two-leg ladder antiferromagnet (dimethylammonium)(3,5-dimethylpyridinium) $\text{CuBr}_4$ . At finite fields, the magnetic structure becomes noncollinear canted and the observed intriguing spontaneous magnon decays over a large region of Brillouin Zone in the excitation spectra can be well explained by the mechanism where the process of one-magnon decays into two-magnon continuum is kinematically allowed [1]. [1] M. E. Zhitomirsky and A. L. Chernyshev, Rev. Mod. Phys. **85**, 219 (2013).

**4:30PM H21.00009 Local structure of spin Peierls compound  $\text{TiPO}_4$ :  $^{47/49}\text{Ti}$  and  $^{31}\text{P}$  NMR study<sup>1</sup>**, RAIVO STERN<sup>2</sup>, IVO HEINMAA, ALEXANDER LEITME, ENNO JOON, ALEXANDER TSIRLIN, Natl Inst of Chem Phy & Bio, REINHARD KREMER, MPI Stuttgart, ROBERT GLAUM, Universitt Bonn —  $\text{TiPO}_4$  structure is made of slightly corrugated  $\text{TiO}_2$  ribbon chains of edge-sharing  $\text{TiO}_6$  octahedra. The almost perfect 1D spin  $\text{Ti}^{3+}$  chains are well separated by  $\text{PO}_4$  tetrahedra. By magnetic susceptibility and MAS-NMR measurements [1] it was shown that  $\text{TiPO}_4$  has nonmagnetic singlet ground state with remarkably high Spin-Peierls (SP) transition temperature. The high-T magnetic susceptibility of  $\text{TiPO}_4$  follows well that of a  $S = 1/2$  Heisenberg chain with very strong nearest-neighbor AF spin-exchange coupling constant of  $J = 965\text{K}$ . On cooling  $\text{TiPO}_4$  shows two successive phase transitions at 111K and 74K, with incommensurate (IC) SP phase between them. We studied local structure and dynamics in  $\text{TiPO}_4$  single crystal using  $^{47/49}\text{Ti}$  and  $^{31}\text{P}$  NMR in the temperature range 40K to 300K, and determined the principal values and orientation of the magnetic shift tensors for  $^{31}\text{P}$  and  $^{47,49}\text{Ti}$  nuclei. Since  $^{47,49}\text{Ti}$  ( $S = 5/2$  and  $S = 7/2$ , respectively) have quadrupolar moments, we also found the principal axis values and orientations of the electric field gradient (efg) tensor in SP phase and at 295K. In SP phase the structure contains 2 magnetically inequivalent P sites and only one Ti site. From the T-dependence of the relaxation rate of  $^{31}\text{P}$  and  $^{47}\text{Ti}$  nuclei we determined activation energy  $E_a = 550\text{K}$  for spin excitations in SP phase.

**4:42PM H21.00010 Pressure-Induced Order in the Gapped Quantum Magnet DTN**, ALEXANDRA MANNIG, JOHANNES MOELLER, ANDREY ZHELUDEV, ETH Zurich, Neutron Scattering and Magnetism Group, Laboratory for Solid State Physics, Zurich, Switzerland, V. OVIDIU GARLEA, CLARINA DELA CRUZ, Oak Ridge National Laboratory, Quantum Condensed Matter Division, Oak Ridge, Tennessee, USA, ZURAB GUGUCHIA, RUSTEM KHASANOV, ELVEZIO MORENZONI, Paul Scherrer Institute, Laboratory for Muon Spin Spectroscopy, Villigen-PSI, Switzerland — We present muon-spin relaxation, neutron diffraction and magnetic susceptibility data under applied hydrostatic pressure on the organometallic  $S = 1$  quantum magnet  $\text{NiCl}_2 \cdot 4[\text{SC}(\text{NH}_2)_2]$ . The material consists of weakly coupled antiferromagnetic chains and has a spin gap resulting from a large single-ion anisotropy. Our muon spin rotation experiments provide local field dependencies on temperature as well as pressure and allow for the mapping of a detailed phase diagram up to 22 kbar. Thus, we demonstrate that the compound may be driven through two subsequent pressure-induced transitions into apparently distinct magnetically ordered phases. Neutron diffraction and susceptibility measurements support those results and show the potential of low-pressure transitions to be investigated by various techniques.

**4:54PM H21.00011 Unusual Magnetic-Pressure Response of an  $S = 1$  Antiferromagnetic Linear-Chain near the  $D/J \approx 1$  Critical Point.<sup>1</sup>**, M. K. PEPRAH, P. A. QUINTERO, J. S. XIA, J. M. PÉREZ, M. W. MEISEL, Dept. of Physics and NHMFL, Univ. of Florida, A. GARCIA, S. E. BROWN, Dept. of Physics, UCLA, J. L. MANSON, Dept. of Chemistry, Eastern Washington Univ. — An  $S = 1$  chain,  $[\text{Ni}(\text{HF}_2)(3\text{-Cpy})_4]\text{BF}_4$  (py = pyridine), has been identified to have nearest-neighbor antiferromagnetic interaction  $J/k_B = 4.86\text{K}$  and single-ion anisotropy  $D/k_B = 4.3\text{K}$ , while avoiding long-range order to 25 mK.<sup>2</sup> With  $D/J = 0.88$ , this system is close to the  $D/J \approx 1$  gapless quantum critical point between the Haldane and Large- $D$  phases. The magnetization was studied at  $50\text{mK} \leq T \leq 1\text{K}$  and with  $B \leq 10\text{T}$ .<sup>3</sup> Using a magnetometer equipped with a pressure cell, the low-field (0.1 T), high temperature ( $T \geq 2\text{K}$ ) magnetic susceptibility was studied to 1.47 GPa. These data suggest the response at ambient pressure<sup>2</sup> changes between 0.24 GPa and 0.35 GPa. These studies are being extended by  $^1\text{H}$  NMR experiments capable of varying the pressure and of spanning from 300 K to below 100 mK.

**5:06PM H21.00012 High-pressure neutron scattering of Prussian blue analogue magnets**, DANIEL PAJEROWSKI, Oak Ridge National Laboratory — Pressure sensitive magnetism is known to be useful in sensors, and while applications tend to use metallic alloys, molecule based magnets (MBMs) have been shown to have large inverse magnetostrictive (IMS) response. A promising group of MBMs are the Prussian blue analogues (PBAs), in which magnetic ordering can be tuned by external stimuli such as light, electric field, and pressure. Previously, high pressure neutron scattering of nickel hexacyanochromate hydrate has shown direct evidence for isomerization of the cyanide linkage with applied pressure. Other probes have suggested a similar effect in iron hexacyanochromate hydrate, although there has yet to be direct crystallographic evidence. Neutron diffraction is sensitive to organic elements, even while in the presence of metals, and we have performed experiments above 1 GPa to look for linkage isomerism in iron hexacyanochromate. These results are supported by bulk probes and calculations.

**5:18PM H21.00013 Changes in the unoccupied electronic structure of the spin crossover molecule [Co(dpzca)<sub>2</sub>]**, YANG LIU, XIN ZHANG, AXEL ENDERS, PETER DOWBEN, JIAN LUO, JIAN ZHANG, Univ of Nebraska - Lincoln, ALPHA NDIAYE, LBNL, Advanced Light Source — We have investigated the changes in the unoccupied electronic structure of the spin crossover molecule - [Co(dpzca)<sub>2</sub>] using X-ray absorption spectroscopy (XAS) and have compared the results with magnetometry (SQUID) measurements. The studies of the variable temperature of the electronic structure of this cobalt complex with symmetric pyrazine imide ligands, -(2-pyrazylcarbonyl)-2-pyrazinecarboxamide, i.e. [Co(dpzca)<sub>2</sub>], are consistent with density functional theory (DFT). The temperature dependence of the occupancy of the high-spin state and low-spin state molecular orbital states, the unoccupied  $e_g/t_{2g}$  ratio from XAS and high spin state to low spin state ratio from molecular magnetic susceptibility  $\chi_M T$  indicates that the low spin state is not a zero spin state, but simply a lower moment state that would occur below the spin crossover transition of [Co(dpzca)<sub>2</sub>].

**Tuesday, March 15, 2016 2:30PM - 5:18PM –**

**Session H22 DCOMP: Theory and Simulations of Novel Superconductors** 321 - Barry Klein, University of California, Davis

**2:30PM H22.00001 Computational search of novel superconductors**, ZHIPING YIN, The Center of Advanced Quantum Studies, Beijing Normal University — The recently discovered 200 K high temperature superconductivity in the hydrogen sulfur material under high pressure was first successfully predicted by first-principles computation in a quantitative fashion, demonstrating the power of computation in the search of new superconductors. With the rapid advancement of theory, algorithm, and computer power, computation will play an increasingly important role. In this talk, I will first summarize the key features of different families of high temperature superconductors, including the iron pnictide and chalcogenide superconductors, the transition metal chloronitrides, and Bi-based superconductors. Then I will show how to use the key features as guidance to design novel candidate materials of high temperature superconductivity by utilizing a combination of different computational methods and tools, including evolutionary structural search method, density functional theory and dynamical mean field theory. A few candidate materials will be given towards the end of the talk for interested experimentalists and theorists to test and explore

**3:06PM H22.00002 Superconductivity in compressed sulfur hydride: Dependences on pressure, composition, and crystal structure from first principles**, RYOSUKE AKASHI, The University of Tokyo — The recent discovery of high-temperature superconductivity in sulfur hydride under extreme pressure has broken the long-standing record of superconducting transition temperature ( $T_c$ ) in the Hg-cuprate. According to the isotope effect measurement and theoretical calculations, the superconducting transition is mainly ascribed to the conventional phonon-mediated pairing interaction. It is, however, not enough for understanding the high- $T_c$  superconductivity in the sulfur hydride. To elucidate various possible effects on  $T_c$  with accuracy, we have analyzed  $T_c$  with first-principles methods without any empirical parameters. First, for various pressures and theoretically proposed crystal structures, we calculated  $T_c$  with the density functional theory for superconductors (SCDFT) to examine which structure(s) can explain experimentally measured  $T_c$  data [Akashi et al., PRB 91, 224513(2015)]. We next solved the Eliashberg equations without introducing the renormalized Coulomb parameter  $\mu^*$ , which is the Green-function-based counterpart of the SCDFT, and evaluated the effects of rapidly varying electron density of states, atomic zero-point motion, and phonon anharmonic corrections on  $T_c$  [Sano et al, in preparation]. In the talk, we review these results and discuss the dominant factors for the  $T_c$  and their relation to the experimental results. We also report some crystal structures that we recently found with first-principles calculations, which could have a key role for the pressure-induced transformation to the high- $T_c$  phase.

**3:42PM H22.00003 van Hove Singularities and Spectral Smearing in High Temperature Superconducting H<sub>3</sub>S<sup>1</sup>**, YUNDI QUAN, Physics Department, UC Davis & CAQS, Beijing Normal Univ., WARREN E. PICKETT, Physics Department, UC Davis — The superconducting phase of hydrogen sulfide at  $T_c=200$  K observed by Drozdov and collaborators at pressures around 200 GPa is simple bcc  $Im\bar{3}m$  H<sub>3</sub>S reopens questions about what is achievable in high  $T_c$ . The various "extremes" that are involved – pressure, implying extreme reduction of volume, extremely high H phonon energy scale around 1400K, extremely high temperature for a superconductor – necessitate a close look at new issues raised by these characteristics in relation to high  $T_c$ . We have applied first principles methods to analyze the H<sub>3</sub>S electronic structure, particularly the van Hove singularities (vHs) and the effect of sulfur. Focusing on the two closely spaced vHs near the Fermi level that give rise to the impressively sharp peak in the density of states, the implications of strong coupling Migdal-Eliashberg theory are assessed. The electron spectral density smearing due to virtual phonon emission and absorption, as done in earlier days for A15 superconductors, must be included explicitly to obtain accurate theoretical predictions and a correct understanding. Means for increasing  $T_c$  in H<sub>3</sub>S-like materials will be mentioned.

<sup>1</sup>NSF DMR Grant 1207622

**3:54PM H22.00004 Structure, lattice dynamics, and high- $T_c$  superconductivity in hydrogen sulfide under high pressure**, LINDA HUNG, TANER YILDIRIM, NIST Center for Neutron Research — The recent discovery of superconductivity near 200 K in hydrogen sulfide under pressures 200 GPa has sparked interest in the search for hydrogen-rich superconducting materials. The observed large isotope effect and earlier first-principles calculations convincingly suggest that the high  $T_c$  is due to strong electron-phonon coupling, i.e., that hydrogen sulfide is a conventional superconductor. Hence, first-principles predictions of phonon properties can be used in the search for new phases that can superconduct at even higher temperatures and lower pressures. In this talk, we present structural and lattice dynamics calculations of various phases of H<sub>2</sub>S/H<sub>3</sub>S, examining the electron-phonon coupling and superconductivity in each phase using the finite-displacement and frozen-phonon approaches. The effect of anharmonicity on electron-phonon coupling, isotope effect, and superconducting temperature is discussed. Finally, we explore the properties of potential new hydrogen-sulfide-based materials.

**4:06PM H22.00005 Hydrogen bond symmetrization by proton quantum motion and high  $T_c$  superconductivity in Sulfur hydrides at high pressure.**, ION ERREA, University of the Basque Country and Donostia International Physics Center, MATTEO CALANDRA, CNRS and Université P. et M. Curie, CHRIS PICKARD, University College London, JOSEPH NELSON, RICHARD NEEDS, Cavendish Laboratory Cambridge, Y LI, HANYU LIU, University of Saskatchewan, YUNWEY ZHANG, YAMMING MA, State Key Laboratory of Superhard Materials,, FRANCESCO MAURI, CNRS and Université P. et M. Curie — Atoms in a crystal are quantum particles differing substantial from classical particles. The vibrational energy associated to the quantum oscillations can strongly modify the static energy landscape, even changing the ground state derived from the Born-Oppenheimer energy surface (BOES) minimum. Here, making use of density-functional theory and of the Stochastic Self-consistent Harmonic Approximation, we show that the ground state of the high  $T_c$  superconductor hydrogen sulfide at 155 GPa is completely determined by quantum fluctuations. Indeed, despite the minimum of the BOES is obtained for a rhombohedral structure with covalently bonded H<sub>3</sub>S units and hydrogen bonds between them, quantum fluctuations favor a fully symmetric cubic structure in which the covalent and hydrogen bonds equalize. The quantum hydrogen-bond symmetrization and the large anharmonic effects are crucial to understand the pressure dependence of the observed extraordinary  $T_c=205$  K at 155 GPa. We finally show how, the dependence of  $T_c$  as a function of pressure can be completely explained in the framework of a phonon mediated pairing mechanism in the presence of large anharmonic effects.

**4:18PM H22.00006 Novel properties of Tungsten ditelluride**, HUIMEI LIU, Nanjing Univ, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES, SCHOOL OF PHYSICS, COLLABORATIVE INNOVATION CENT COLLABORATION — Tungsten ditelluride has attracted intense research interest due to the recent discovery of its large unsaturated magnetoresistance up to 60 Tesla. By using density functional theory calculations, we qualitatively reproduced the observed spin texture. Since the spin texture would forbid back scatterings that are directly involved in the resistivity, we suggest that the SOC and the related spin and orbital angular momentum textures may play an important role in the anomalously large magnetoresistance of WTe<sub>2</sub>. Motivated by the presence of a small, sensitive Fermi surface of 5d electronic orbitals, we also boost the electronic properties by applying a high pressure, and introduce superconductivity successfully.

**4:30PM H22.00007 Superconductivity in organic conductors: ab-initio results from parallel DMRG**, ADRIAN KANTIAN, Nordita, KTH Stockholm, MICHELE DOLFI, MATTHIAS TROYER, ETH Zurich, THIERRY GIAMARCHI, Université de Genève — The U-V model at quarter filling is considered the canonical minimal model to explain unconventional superconductivity in the organic Bechgaard and Fabre salts [1]. Yet it has so far resisted solution to show that it actually can support superconducting order. Here, we use a heavily parallelized version of the density-matrix renormalization group (DMRG) to provide the first ab-initio solutions for the U-V model in the regime suspected to support superconducting order. Our results support the existence of a phase marked by spin-singlet pairing, thus ruling out antiferromagnetic order (the usual close competitor to unconventional superconductivity). In this phase we will extend our analysis by studying the response to explicit bias fields. Our work is complemented by analysis of the two-leg U-V ladder through a combination of DMRG and analytical RG of a bosonized low-energy theory. [1] C. Bourbonnais, D. Jerome, The Physics of Organic Superconductors and Conductors (ed. Lebed, A.) pp. 358 (Springer, 2007).

**4:42PM H22.00008 Exchange and correlation effects on the superconducting transition of two-dimensional multivalley semiconductors<sup>1</sup>**, BETUL PAMUK, CNRS and Université Pierre et Marie Curie, JACOPO BAIMA, ROBERTO DOVESI, Università di Torio, MATTEO CALANDRA, FRANCESCO MAURI, CNRS and Université Pierre et Marie Curie — It has recently been shown that the enhancement in the superconducting temperature of two-dimensional semiconductors at low doping is linked to the electron-electron interaction enhancing the response to the valley polarization that is due to the electron-phonon coupling [1]. In this work, we extend this study to analyze the exchange and correlation effects on the electronic, magnetic, and vibrational properties of Li-doped ZrNCI and HfNCI - typical examples of two-dimensional two-valley semiconductors. We show that these properties can be calculated by *ab initio* density functional theory only by using approximations beyond the generalized gradient approximation. Finally, we present the link between the enhancement of the spin susceptibility and superconducting temperature by demonstrating that the electron-phonon coupling is acting as a pseudo-magnetic field causing the valley polarization. [2] [1] M. Calandra, P. Zocante and F. Mauri, Phys. Rev. Lett. 114, 077001 (2015) [2] B. Pamuk *et al.*, in preparation

**4:54PM H22.00009 Correlated properties of the doped Hubbard model on a honeycomb lattice**, TIANXING MA, LUFENG ZHANG, Beijing Normal University, HAI-QING LIN, Beijing Computational Science Research Center — Low doped graphene has a finite density of state, while heavily doped graphene have a Van Hove singularity in the density of states, in combination with pronounced antiferromagnetic spin fluctuations close to half filling, and strong ferromagnetic correlation as doping is below the location of Van Hove singularity, which may lead to different unconventional superconductivity. We performed a systematic quantum Monte Carlo study of the pairing correlation in the Hubbard model on a honeycomb lattice. Close to half filling, we find that pairing with d+id symmetry dominates over pairing with extended-s symmetry. When the next-nearest-neighbor  $t'$  is larger than  $t/6$ , the single-particle spectrum is featured by the continuously distributed Van Hove saddle points at the band bottom, where the density of states diverges in a power law. We investigate possible unconventional superconductivity in such systems with the Fermi level close to the band bottom by employing both random-phase-approximation and determinant quantum Monte Carlo approaches. Our study reveals a possible triplet p+ip superconductivity with appropriate interactions in low-filled graphene. We also explore the effect of the disorder and spin-orbit coupling on the magnetic correlation in doped graphene.

**5:06PM H22.00010 Helical Majorana fermions in d+id'-wave topological superconductivity of doped correlated quantum spin Hall insulators<sup>1</sup>**, CHUNG-HOU CHUNG, National Chiao-Tung University, Taiwan, SHIH-JYE SUN, National University of Kaohsiung, Taiwan, YUNG-YEH CHANG, National Chiao-Tung University, Taiwan, WEI-FENG TSAI, National Sun Yat-Sen University, Taiwan, FUCHUN ZHANG, Zhejiang University, China — Large Hubbard  $U$  limit of the Kane-Mele model on a zigzag ribbon of honeycomb lattice near half-filling is studied via a renormalized mean-field theory. The ground state exhibits time-reversal symmetry (TRS) breaking  $d_{x^2-y^2} + id_{xy}$ -wave superconductivity. At large spin-orbit coupling, the  $Z_2$  topological phase with non-trivial spin Chern number in the pure Kane-Mele model is persistent into the TRS broken state (called "spin-Chern phase"), and has two pairs of counter-propagating helical Majorana modes at the edges. As the spin-orbit coupling is reduced, the system undergoes a topological quantum phase transition from the spin-Chern to chiral superconducting states. Possible relevance of our results to adatom-doped graphene and iridate compounds is discussed. Ref.: Shih-Jye Sun, Chung-Hou Chung, Yung-Yeh Chang, Wei-Feng Tsai, and Fu-Chun Zhang, arXiv:1506.02584.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**  
**Session H23 DMP DCOMP: Computational Materials Discovery and Design - Materials for Catalysis** 322 - David Strubbe, Massachusetts Institute of Technology

**2:30PM H23.00001 First-principles data-driven discovery of transition metal oxides for artificial photosynthesis**, QIMIN YAN, Molecular Foundry, Lawrence Berkeley National Laboratory; Department of Physics, University of California, Berkeley — We develop a first-principles data-driven approach for rapid identification of transition metal oxide (TMO) light absorbers and photocatalysts for artificial photosynthesis using the Materials Project. Initially focusing on Cr, V, and Mn-based ternary TMOs in the database, we design a broadly-applicable multiple-layer screening workflow automating density functional theory (DFT) and hybrid functional calculations of bulk and surface electronic and magnetic structures. We further assess the electrochemical stability of TMOs in aqueous environments from computed Pourbaix diagrams. Several promising earth-abundant low band-gap TMO compounds with desirable band edge energies and electrochemical stability are identified by our computational efforts and then synergistically evaluated using high-throughput synthesis and photoelectrochemical screening techniques by our experimental collaborators at Caltech. Our joint theory-experiment effort has successfully identified new earth-abundant copper and manganese vanadate complex oxides that meet highly demanding requirements for photoanodes, substantially expanding the known space of such materials. By integrating theory and experiment, we validate our approach and develop important new insights into structure-property relationships for TMOs for oxygen evolution photocatalysts, paving the way for use of first-principles data-driven techniques in future applications. This work is supported by the Materials Project Predictive Modeling Center and the Joint Center for Artificial Photosynthesis through the U.S. Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract No. DE-AC02-05CH11231. Computational resources also provided by the Department of Energy through the National Energy Supercomputing Center.

**3:06PM H23.00002 Computational Nano-materials Design for Spinodal Nanotechnology as a New Class of Bottom-up Nanotechnology**, HIROSHI KATAYAMA-YOSHIDA, TETSUYA FUKUSHIMA, Graduate School of Engineering Science, Osaka University, KAZUNORI SATO, Graduate School of Engineering, Osaka University — Based on the spinodal nano-decomposition (SND) of dilute magnetic semiconductors (DMS) [1,2], we generalized the SND to the application of catalysis [3,4] and photovoltaic solar-cells [5], where nano-scale particle formation in catalysis and nano-scale separation of electrons and holes are essential in order to enhance the efficiency. First, we summarize the shape control (Konbu- & Dairiseki-Phases) and dimensionality dependence of crystal growth condition on SND in DMS. Second, we discuss the application of SND for the formation of nano-particles and the self-regeneration in three-way catalysis for automotive emission control by Perovskite  $\text{La}(\text{Fe}, \text{Pd} \text{ or } \text{Rh})\text{O}_3$ . Third, we propose (i) self-regeneration mechanism and (ii) self-organized nano-structures by SND in chalcopyrite  $\text{Cu}(\text{In}, \text{Ga})\text{Se}_2$ , Kesterite  $\text{Cu}_2\text{ZnSnSe}_4$ , and Perovskite  $\text{CsSnI}_3$  for the low-cost, environment-friendly and high-efficiency photovoltaic solar cells using first-principles calculations. Chem. Soc. 133, 18506 (2011). [5] Y. Tani et al., Appl. Phys. Express, 3, 101201 (2010).

**3:18PM H23.00003 Simulation of Photo-isomerization of Functionalized Azobenzene Derivatives**, PEDRAM TAVAZOHI, ZACHARY HERBERGER, JAMES LEWIS, West Virginia Univ — Photo-isomerization is the process of changing the isomer (*cis*, *trans*) of a molecule using light. In azobenzene this process can be utilized in a Metal Organic Framework (MOF) for adsorption of  $\text{CO}_2$ . MOFs are created by two major components, metal ions, and organic molecules which are called linkers. The metal ions and linkers can be coordinated in a way that they form a porous material. In the *cis* isomer of azobenzene, the MOFs pore is available to be filled by  $\text{CO}_2$ , but in the *trans* isomer the pore is filled with a benzene ring. The change from *cis* to *trans* will evacuate the pore if  $\text{CO}_2$  is present. The important considerations in using azobenzene photo-isomerization as a photo-switch in MOFs are, the quantum yield of the process, and the wavelength of the light which triggers photo-isomerization. By substitution of the functional groups of azobenzene and using the fewest switches surface-hopping algorithm in FIREBALL to simulate the photo-isomerization process we can tune the properties of the molecule as we desire and predict the best substitution sites for azobenzene functional groups. We studied the effects of functionalizing the molecule with OH,  $\text{CH}_3$ ,  $\text{NH}_2$ ,  $\text{NO}_2$  and COOH on isomerization quantum yield.

**3:30PM H23.00004 Computational Design of Metal–Organic Frameworks with High Methane Deliverable Capacity**<sup>1</sup>, YI BAO, Rice University, RICHARD MARTIN, Lawrence Berkeley National Laboratory, CORY SIMON, University of California, Berkeley, MACIEJ HARANCZYK, Lawrence Berkeley National Laboratory, BEREND SMIT, University of California, Berkeley, MICHAEL DEEM, Rice University, DEEM TEAM, HARANCZYK TEAM, SMIT TEAM — Metal–organic frameworks (MOFs) are a rapidly emerging class of nanoporous materials with largely tunable chemistry and diverse applications in gas storage, gas purification, catalysis, etc. Intensive efforts are being made to develop new MOFs with desirable properties both experimentally and computationally in the past decades. To guide experimental synthesis with limited throughput, we develop a computational methodology to explore MOFs with high methane deliverable capacity. This *de novo* design procedure applies known chemical reactions, considers synthesizability and geometric requirements of organic linkers, and evolves a population of MOFs with desirable property efficiently. We identify about 500 MOFs with higher deliverable capacity than MOF-5 in 10 networks. We also investigate the relationship between deliverable capacity and internal surface area of MOFs. This methodology can be extended to MOFs with multiple types of linkers and multiple SBUs.

**3:42PM H23.00005 Computational design of materials for solar hydrogen generation**, NAOTO UMEZAWA, National Institute for Materials Science — Photocatalysis has a great potential for the production of hydrogen from aqueous solution under solar light [1]. In this talk, two different approaches toward the computational materials design for solar hydrogen generation will be presented. Tin (Sn), which has two major oxidation states,  $\text{Sn}^{2+}$  and  $\text{Sn}^{4+}$ , is abundant on the earth's crust. Recently, visible-light responsive photocatalytic  $\text{H}_2$  evolution reaction was identified over a mixed valence tin oxide  $\text{Sn}_3\text{O}_4$  [2]. We have carried out crystal structure prediction for mixed valence tin oxides in different atomic compositions under ambient pressure condition using advanced computational methods based on the evolutionary crystal-structure search and density-functional theory. The predicted novel crystal structures realize the desirable band gaps and band edge positions for  $\text{H}_2$  evolution under visible light irradiation. It is concluded that multivalent tin oxides have a great potential as an abundant, cheap and environmentally-benign solar-energy conversion photofunctional materials [3]. Transition metal doping is effective for sensitizing  $\text{SrTiO}_3$  under visible light. We have theoretically investigated the roles of the doped Cr in STO based on hybrid density-functional calculations [4]. Cr atoms are preferably substituting for Ti under any equilibrium growth conditions. The lower oxidation state  $\text{Cr}^{3+}$ , which is stabilized under an n-type condition of STO, is found to be advantageous for the photocatalytic performance. It is further predicted that lanthanum is the best codopant for stabilizing the favorable oxidation state,  $\text{Cr}^{3+}$ . The prediction was validated by our experiments that La and Cr co-doped STO shows the best performance among examined samples [5]. This work was supported by the Japan Science and Technology Agency (JST) Precursory Research for Embryonic Science and Technology (PRESTO) and International Research Fellow program of Japan Society for the Promotion of Science (JSPS) through project P14207. Ye, Journal of Materials Chemistry A, 1, 4221 (2013).

**4:18PM H23.00006 Understanding and controlling the water stability of MOF-74**<sup>1</sup>, SEBASTIAN ZULUAGA, Wake Forest University, ERIKA FUENTES, KUI TAN, University of Texas at Dallas, FENG XU, JING LI, Rutgers University, YVES CHABAL, University of Texas at Dallas, TIMO THONHAUSER, Wake Forest University — Metal organic framework (MOF) materials in general, and MOF-74 in particular, have promising properties for many technologically important processes. However, their instability under humid conditions severely restricts their practical use. In this work, we show that this instability and the accompanying reduction of the  $\text{CO}_2$  uptake capacity of MOF-74 under humid conditions originate in the dissociation of water molecules at the metal centers. In turn, the reduction in the  $\text{CO}_2$  uptake capacity occurs as the metal centers are occupied by the remaining OH groups after the water molecules dissociate. It follows that the reduction in  $\text{CO}_2$  uptake depends on the catalytic activity of MOF-74 towards the water dissociation reaction  $\text{H}_2\text{O} \rightarrow \text{OH} + \text{H}$ . On the other hand, we show that—while the water molecules themselves do only have a negligible effect on the crystal structure of MOF-74—the OH and H products of the dissociation reaction can significantly weaken the MOF framework and lead to the observed crystal structure breakdown. With this knowledge, we can now propose a way to suppress this particular reaction and therefore control the stability of the system under humid conditions.

**4:30PM H23.00007 High-throughput discovery of electrochemically stable photocatalysts for oxygen evolution.** , JIE YU, JCAP, Lawrence Berkeley National Laboratory, QIMIN YAN, WEI CHEN, ANUBHAV JAIN, Lawrence Berkeley National Laboratory, JOHN GREGOIRE, JCAP, California Institute of Technology, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, KRISTIN PERSSON, EETD, Lawrence Berkeley National Laboratory — Widespread use of artificial photosynthesis hinges upon development of photocatalysts and light absorbers with excellent electrochemical stability in aqueous solution. The poor stability of most semiconductors in the highly oxidizing environment of a solar fuels photoanode has been a key factor limiting the use of many candidates light absorbers. We assess the stability of candidate transition metal oxides (TMOs) in alkaline aqueous environments from calculated Pourbaix diagrams. Our analysis reveals interesting trends in the electrochemical stability of TMOs containing elements which have not traditionally been explored for photocatalysts. Utilizing the Pourbaix diagram analysis as the first screen-layer in a high-throughput workflow that incorporates automating density functional theory and hybrid functional calculations, we screen for electrochemically stable TMO compounds with low band gaps and optimal band edge energies. Applying our new data-driven approach, we successfully identify several new TMOs with promising band gaps and edges that are predicted to resist corrosion under aqueous conditions relevant to solar water splitting. Materials synthesis and electrochemical measurements confirm several predictions and demonstrate the utility of computational screening for identifying new solar fuels materials.

**4:42PM H23.00008 Rational Co-Design of Polymer Dielectrics for Energy Storage** , ARUN MANNODI-KANAKKITHODI, HUAN TRAN, University of Connecticut, GHANSHYAM PILANIA, TURAB LOOKMAN, Los Alamos National Laboratory, RAMPI RAM-PRASAD, University of Connecticut — While intuition-driven experiments and serendipity have guided traditional materials discovery, computational strategies have become increasingly important and a powerful complement to experiments in modern day materials research. With the example of polymer dielectrics for electrostatic energy storage applications, we demonstrate how a rational co-design approach—involving synergies between high-throughput computational screening and experimental synthesis and testing—can be harnessed for quick and efficient discovery. We highlight recent co-design efforts that can potentially lead to replacement of present-day “standard” polymer dielectrics (such as biaxially oriented polypropylene) not only by new organic polymer candidates within known generic polymer subclasses (e.g., polyurea, polythiourea, polyimide), but also by organometallic polymers, a hitherto untapped but promising chemical subspace. We also discuss the utilization of vast computational data (generated in the aforementioned process) towards the development of statistical learning models for relevant properties of dielectric polymers, which can further accelerate the guidance to experiments and thus the successful discovery of new materials.

**4:54PM H23.00009 Simulated synthesis of lithium manganese oxide nanostructures and their characterisation.**<sup>1</sup> , PHUTI NGOEPE, SYLVIA LEDWABA, University of Limpopo, Sovenga, 0727, South Africa., DEAN SAYLE, University of Kent, Canterbury, CT2 7NZ, UK — Simulated amorphisation/recrystallization methods, are now routinely used to generate models of various nano-architectures for metal oxides with complex microstructural details [1]. Nano-architectures, i.e. nano- sphere, sheet, porous and bulk, associated with the Li-Mn-O ternary were synthesised from amorphous spinel nanosphere. The resulting crystallised nanostructures are characterised from visual images, radial distribution functions, XRDs and simulated microstructures. An analysis of microstructures and simulated X-ray diffractions reveals the presence of the layered  $\text{Li}_2\text{MnO}_3$  and spinel  $\text{LiMn}_2\text{O}_4$  together with a wide variety of defects, including grain boundaries and ion vacancies. [1] T.X.T. Sayle, R.R. Maphanga, P. E. Ngoepe and D. C. Sayle, J. Am. Chem. Soc., **131** (2009), 6161-6173

**5:06PM H23.00010 Study of Hydrogen Adsorption in Titanium, Nickel and Pd Cluster Supported on Graphene Monovacancies** , CARLOS MANUEL RAMOS CASTILLO, ROMEO DE COSS GMEZ, Departament of Applied Physics Centro de Investigacion y Estudios Avanzados del Instituto Politecnico Nacional, Mexico, JOSE ULISES REVELES, Departament of Applied Physics Virginia Commonwealth University , VA USA — A detailed description of the atomic structure and the energetics of  $\text{H}_2$  adsorption on  $\text{Ti}_4$ ,  $\text{Ni}_4$ , and  $\text{Pd}_4$  clusters on graphene monovacancies is presented. The large binding energy of that clusters on vacancies is a result of strong hybridization between the unsaturated carbon. We found that the binding energy of a single  $\text{H}_2$  is strongly dependent on the specific cluster. In particular, the  $\text{H}_2$  bond cleavage is favored by titanium clusters. On the other hand, the Ni and Pd clusters favours the formation of Kubas complexes. The analysis of the adsorption energies and  $\text{H}_2$  average bond lengths suggests that supported  $\text{Ti}_4$  cluster is a potential hydrogen storage candidate, being able to hold up to 6 molecules covalently with moderate average binding energy within the optimal range for an efficient cyclic adsorption/desorption process at room temperature and moderate pressures. These results give physical insights about how the interaction between graphene monovacancies and metal clusters can be used to enhanced the hydrogen uptake, towards of design of new graphene-based material for hydrogen storage.

**5:18PM H23.00011 Using Cluster Expansions to Model Diffusion in Pt-Ni Nanoparticles** , THOMAS NILSON, TIM MUELLER, LIANG CAO, Johns Hopkins Univ — Pt-Ni alloys have been shown to have excellent catalytic activity for the oxygen reduction reaction. However in practice these particles suffer from Ni dissolution, degrading the performance of the catalyst over time. The exact mechanism by which this occurs is unknown and difficult to determine experimentally. Using density functional theory, we have calculated the energies of formation of several dozen  $\text{Pt}_x\text{Ni}_{1-x}$  nanoparticles with included vacancies and used this data to parametrize a cluster expansion. Because the activation energies for diffusion are included in the model, we are able to use the cluster expansion to rapidly predict the transition rates in a Pt-Ni nanoparticle as a function of particle shape, size, and local atomic order. By using the cluster expansion model in a kinetic Monte Carlo algorithm we are able to model the diffusion of Pt and Ni and provide insights into the dissolution of Ni from Pt-Ni nanoparticles.

**Session H24 DMP: Many-Body Perturbation Theory for Electronic Excitations: Excitonic Phenomena** 323 - Serdar Ogut, University of Illinois at Chicago

### **2:30PM H24.00001 A direct approach to the calculation of many-body Green's functions: quasi-particles and more<sup>1</sup>**

**LUCIA REINING, CNRS-Ecole Polytechnique** — Many-body perturbation theory is a powerful approach to describe many properties of materials. Most often one uses Dyson equations with self-energy kernels that are approximated to low order in the interaction. In Hedin's GW approximation, for example, the self-energy is a product of the one-body Green's function and the screened Coulomb interaction. This is the state-of-the-art method for bandstructure calculations in a wide range of materials. However, sometimes the GW approximation and related approaches are not sufficient, for example when one is interested in satellite structure beyond the quasi-particle peaks in the spectral function, or in the case of strong coupling, where the quasi-particle picture is no longer adequate. We explore an alternative route to the calculation of interacting electron Green's functions. It is based on a set of functional differential equations relating the one-body Green's function to its functional derivative with respect to an external perturbing potential [1]. This set of equations can be used to generate the perturbation series. Here we will show that working directly with the differential equations yields precious insight concerning some fundamental questions, guidelines for practical calculations, and methods that lead to an improved description of spectra, in particular advanced versions of the cumulant expansion. Results will be illustrated on various levels of approximation starting from simple models [2], but with a focus on full ab initio calculations [3] and comparison with, and interpretation of, experiment. In particular, we will discuss various kinds of photoemission satellites, and also address questions linked to strong correlation. [1] L.P. Kadanoff and G. Baym, Quantum Statistical Mechanics (New York: Benjamin, 1962) [2] A. Stan et al., New J. Phys. 17, 093045 (2015) [3] M. Guzzo et al., Phys. Rev. Lett. 107, 166401 (2011); Phys. Rev. B 89, 085425 (2014)

### **3:06PM H24.00002 Multiple Exciton Generation in Semiconductor Nanostructures: DFT-based Computation**

**DEYAN MIHAYLOV, ANDREI KRYJEVSKI, DMITRI KILIN, SVETLANA KILINA, North Dakota State Univ, DAYTON VOGEL, University of South Dakota** — Multiple exciton generation (MEG) in nm-sized H-passivated Si nanowires (NWs), and quasi 2D nanofilms depends strongly on the degree of the core structural disorder as shown by the perturbation theory calculations based on the DFT simulations. In perturbation theory, we work to the 2<sup>nd</sup> order in the electron-photon coupling and in the (approximate) RPA-screened Coulomb interaction. We also include the effect of excitons for which we solve Bethe-Salpeter Equation. To describe MEG we calculate exciton-to-biexciton as well as biexciton-to-exciton rates and quantum efficiency (QE). We consider 3D arrays of Si<sub>29</sub>H<sub>36</sub> quantum dots, NWs, and quasi 2D silicon nanofilms, all with both crystalline and amorphous core structures. Efficient MEG with QE of 1.3 up to 1.8 at the photon energy of about  $3E_{gap}$  is predicted in these nanoparticles except for the crystalline NW and film where  $QE \simeq 1$ . MEG in the amorphous nanoparticles is enhanced by the electron localization due to structural disorder. The exciton effects significantly red-shift QE vs. photon energy curves. Nm-sized a-Si NWs and films are predicted to have effective MEG within the solar spectrum range. Also, we find efficient MEG in the chiral single-wall Carbon nanotubes and in a perovskite nanostructure.

### **3:18PM H24.00003 Excitons in solids with time-dependent density-functional theory: the bootstrap kernel and beyond<sup>1</sup>**

**YOUNG-MOO BYUN, Univ of Missouri - Columbia, ZENG-HUI YANG, Temple University, CARSTEN ULLRICH, Univ of Missouri - Columbia** — Time-dependent density-functional theory (TDDFT) is an efficient method to describe the optical properties of solids. Lately, a series of bootstrap-type exchange-correlation (xc) kernels have been reported to produce accurate excitons in solids, but different bootstrap-type kernels exist in the literature, with mixed results. In this presentation, we reveal the origin of the confusion and show a new empirical TDDFT xc kernel to compute excitonic properties of semiconductors and insulators efficiently and accurately. Our method can be used for high-throughput screening calculations and large unit cell calculations.

### **3:30PM H24.00004 Stability of excitonic complexes in a multi-valley/band semiconductor**

**HIROKI KATOW, University of Tokyo, JUNKO USUKURA, Tokyo University of Science, RYOSUKE AKASHI, University of Tokyo, KALMAN VARGA, Vanderbilt University, SHINJI TSUNEYUKI, University of Tokyo** — Whether bound states are present for few-particle quantum systems is far from axiomatic and has been a hot topic for decades. For example, three-positronium and -/hydrogen bound states are not present in the vacuum. On the other hand, it has also been proposed that three excitons can be bound with each other in multi-valley/band semiconductors [J. S. Wang & C. Kittel, Phys. Lett. 42A, No. 3 (1972)]. Indeed, an array of photoluminescence peaks have been recently observed in diamond [J. Omachi et al., Phys. Rev. Lett. 111, 026402(2013)], which could suggest the existence of possible multi-exciton bound states. We theoretically examine if such bound states are possible by a variational method. For the electron-hole Hamiltonian including the valley and band degrees of freedom, we expressed trial many-body wave function with the correlated Gaussian bases and optimized it with the stochastic variational method [J. Mitroy et al., Rev. of Mod. Phys., 85, 2013]. We have shown bound states for N-exciton systems with N more than two. In the talk, we discuss the dependence of the bound states on the model settings and its relation to the experimental observation.

### **3:42PM H24.00005 Exploring the nature of low-lying excited-states in molecular crystals from many-body perturbation theory beyond the Tamm-Dancoff Approximation<sup>1</sup>**

**TONATIUH RANGEL, Lawrence Berkeley Natl Lab; UC Berkeley, SAHAR SHARIFZADEH, Boston University, ANDRE RINN, Philipps-Universitt Marburg, FELIPE H. DA JORNADA, UC Berkeley; Lawrence Berkeley Natl Lab, MEIYUE SHAO, Lawrence Berkeley Natl Lab, GREGOR WITTE, Philipps-Universitt Marburg, CHAO YANG, Lawrence Berkeley Natl Lab, STEVEN G. LOUIE, UC Berkeley; Lawrence Berkeley Natl Lab, SANGAAM CHATTERJEE, Philipps-Universitt Marburg, LEEOR KRONIK, Weizmann Institute of Science, JEFFREY B. NEATON, Lawrence Berkeley Natl Lab; UC Berkeley** — Organic semiconductors have attracted attention due to their potential for optoelectronics and novel phenomena, such as singlet fission. Here, we use many-body perturbation theory to simulate neutral excitations in acene and perylene crystals. By diagonalizing the full Bethe-Salpeter (BSE) Hamiltonian beyond the Tamm-Dancoff approximation (TDA) [1], we find that both low-lying excitation energies and oscillator strengths are in improved agreement with experiments relative to the TDA. We characterize the low-lying excitons, focusing in the degree of charge-transfer and spatial delocalization, connecting their relevance to singlet fission. [2] For perylene, we find overall good agreement with absorption measurements, and we see evidence for the formation of an exciton-polariton band in  $\beta$ -perylene. 1. da Jornada, F. H. et al., to be submitted. 2. Sharifzadeh, S. et al., J. Phys. Chem. Lett. 4, 2197 (2013).

### **3:54PM H24.00006 ABSTRACT WITHDRAWN —**

**4:06PM H24.00007 Effect of Crystal Packing on the Excitonic Properties of Rubrene Polymorphs**, XIAOPENG WANG, Tulane University, TAYLOR GARCIA, STEPHEN MONACO, Pennsylvania State University, BOHDAN SCHATTSCHNEIDER, California State Polytechnic University, Pomona, NOA MAROM, Tulane University — Singlet fission, the down-conversion of one singlet exciton into two triplet excitons, has been recently observed in molecular crystals of rubrene. The orthorhombic form of rubrene is the most stable in ambient conditions. However, rubrene has two additional known polymorphs, a triclinic form and a monoclinic form. To investigate the relative stability of the three polymorphs under different temperature and pressure conditions we use dispersion-inclusive density functional theory (DFT) with the pairwise Tkatchenko-Scheffler (TS) method and the many-body dispersion (MBD) method. Many-body perturbation theory is then employed to study the effect of crystal structure on the electronic and excitonic properties. Band structures are calculated within the GW approximation, where G is the one-particle Green's function and W is the screened Coulomb interaction, and optical properties are calculated by solving the Bethe-Salpeter equation (BSE). We find that crystal packing affects the band gaps, band dispersion, optical gaps, singlet-triplet gaps, and exciton localization in the three polymorphs of rubrene. Singlet fission efficiency may thus be improved by modulating the crystal packing.

**4:18PM H24.00008 Multiscale modeling of excitation dynamics in molecular materials with GW-BSE/MM**, BJOERN BAUMEIER, Department of Mathematics and Computer Science & Institute for Complex Molecular Systems, Eindhoven University of Technology — Processes involving electronic excitations govern the functionality of molecular materials in which the dynamics of excitons and charges is determined by an interplay of molecular electronic structure and morphological order. To understand, e.g., charge separation and recombination at donor-acceptor heterojunctions in organic solar cells, knowledge about the microscopic details influencing these dynamics in the bulk and across the interface is required. For heterojunctions of small-molecule donor materials with C60, we employ a hybrid QM/MM approach [JCTC 7, 3335 (2011)] linking density-functional and many-body Green's functions theory [JCTC 8, 2790 (2012)] (DFT/GW-BSE) to polarizable force-fields [JCTC 10, 3140 (2014)] and analyze the charged and neutral electronic excitations therein. We develop models for both static and dynamic properties of the excitations, including (a) the diffusion of Frenkel excitons and (b) the relative energies of Frenkel and charge-transfer excitations at the donor-acceptor interface and the resulting charge separation dynamics. Our simulations allow linking the molecular architecture of the donor material, its orientation on the fullerene substrate as well as mesoscale order [Nat. Mater. 14, 434 (2015)] to the solar cell performance.

**4:30PM H24.00009 Excited Biexcitons in Transition Metal Dichalcogenides**, DAVID ZHANG, Vanderbilt University — Recently, experimental measurements and theoretical modeling have been in a disagreement concerning the binding energy of biexcitons in transition metal dichalcogenides.<sup>1</sup> While theory predicts a smaller binding energy ( $\sim 20$  meV) that is, as logically expected, lower than that of the trion, experiment finds values much larger ( $\sim 60$  meV), actually exceeding those for the trion. In this work, we show that there exists an excited state of the biexciton which yields binding energies that match well with experimental findings and thus gives a plausible explanation for the apparent discrepancy. Furthermore, it is shown that the electron-hole correlation functions of the ground state biexciton and trion are remarkably similar, possibly explaining why a distinct signature of ground state biexcitons would not have been noticed experimentally.<sup>2</sup>

**4:42PM H24.00010 Exciton band structure in two-dimensional materials**, PIER LUIGI CUDAZZO, LSI Ecole Polytechnique France, LORENZO SPONZA, Kings College London UK, CHRISTINE GIORGETTI, LUCIA REINING, FRANCESCO SOTTILE, MATTEO GATTI, LSI Ecole Polytechnique France — In low-dimensional materials the screening of the Coulomb interaction is strongly reduced[1,2]. As a consequence, the binding energy of both Wannier and Frenkel excitons in the optical spectra is large and comparable in size. Therefore, contrarily to bulk materials, it cannot serve as a criterion to distinguish different kinds of excitons. Here we demonstrate that the exciton band structure, which can be accessed experimentally, instead provides a powerful way to identify the exciton character. By comparing the *ab initio* solution of the many-body Bethe-Salpeter equation for graphene and single-layer hexagonal BN, we draw a general picture of the exciton dispersion in two-dimensional materials, highlighting the different role played by the exchange electron-hole interaction and by the hopping terms related to the electronic band structure. 1 Pierluigi Cudazzo et. al. *Phys. Rev. Letter* 104 226804 (2010) 2 Pierluigi Cudazzo et. al. *Phys. Rev. B* 84, 085406 (2011)

**4:54PM H24.00011 Effect of Lattice Screening on Excitonic and Optical Properties in CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> Solar Cell Materials**<sup>1</sup>, JOSHUA LEVEILLE, ANDRE SCHLEIFE, Univ of Illinois - Urbana, ANDRE SCHLEIFE RESEARCH GROUP TEAM — Hybrid Organo-Metallic Perovskites have made great strides towards becoming a next generation solar cell material. Though high performing experimental devices have been constructed from these perovskites, the fundamental optical and electronic physics of these systems remains an active area of research. A large lattice dielectric constant in the Methylammonium(CH<sub>3</sub>NH<sub>3</sub>)-Lead(Pb)-Iodide(I<sub>3</sub>) system potentially contributes to the screening of the electron-hole interaction. The strongly increased dielectric screening due to lattice contributions has been suggested to reduce the exciton binding energy and strongly effects the optical band gap. In this study, we seek to understand, from first principles, the interplay between lattice screening and exciton binding energy. We use density functional theory for ground state calculations and the Bethe-Salpeter equation for the optical polarization function, from which we calculate optical spectra and excitonic properties. We will discuss differences between lattice and electronic screening and the effect on the optical properties of multiple CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> phases.

**5:06PM H24.00012 Substrate-induced renormalization of the quasiparticle and optical gaps in monolayer transition metal dichalcogenides from GW and GW-BSE calculations.**, FELIPE H. DA JORNADA, CHIN SHEN ONG, DIANA Y. QIU, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Lab — There has been a considerable effort to experimentally characterize the electronic and optical properties of novel atomically thin 2D semiconductors, such as mono- and few-layer transition metal dichalcogenides (TMDs). However, the role that different substrates play in these experiments still remains unclear. From a theoretical perspective, it is hard to include the substrate in an *ab initio* framework, while in experiments, it is often difficult to suspend these samples. Here, we present a new method to compute the substrate effect on the quasiparticle and optical properties of quasi-2D materials based on state-of-the-art *ab initio* GW and GW plus Bethe-Salpeter equation (GW-BSE) methods. We compute the effects of different metallic and semiconducting substrates, and show that the quasiparticle gap and exciton binding energy can be dramatically reduced even with semiconducting substrates. This work was supported by the National Science Foundation under Grant No. DMR15-1508412 and the DOE under Contract No. DE-AC02-05CH11231.

**5:18PM H24.00013 Nonanalyticity, Valley Quantum Phases, and Massless Excitons in Monolayer Transition Metal Dichalcogenides<sup>1</sup>**, DIANA Y. QIU, TING CAO, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory — Exciton dispersion as a function of center-of-mass momentum  $\mathbf{Q}$  is essential to the understanding of exciton dynamics, relaxation, and condensation. We use the *ab initio* GW-Bethe-Salpeter equation (GW-BSE) method to calculate the dispersion of excitons in monolayer MoS<sub>2</sub> and find a nonanalytic lightlike dispersion. This behavior arises from the interplay of an unusual  $|\mathbf{Q}|$ -term in both the intra- and intervalley exchange of the electron-hole interaction, which concurrently gives rise to a valley quantum phase of winding number two. We have derived a simple, effective Hamiltonian and analytic solutions, which quantitatively describe this physics, and we predict that signatures of this unusual dispersion can be measured with a linearly polarized optical beam tilted away from normal incidence. The existence of a nonanalytic exciton dispersion can be generalized to other 2D semiconductors with excitons whose amplitudes are localized in a small region of the Brillouin zone.

**Session H25 DCMP: Josephson Tunneling: SQUIDS and Superconductor-ferromagnetic Interactions** 324 - Steven Anlage, University of Maryland

**2:30PM H25.00001 Controlling Hysteresis in Superconducting Weak Links and  $\mu$ -Superconducting Quantum Interference Devices.<sup>1</sup>**, NIKHIL KUMAR, Department of Physics, Indian Institute of Technology, Kanpur, India-208016, C.B. WINKELMANN, Institute Neel, CNRS and University Joseph Fourier, 25 Avenue des Martyrs, BP 166, 38042, Grenoble, France, SOURAV BISWAS, Department of Physics, Indian Institute of Technology, Kanpur, India-208016, H. COURTOIS, Institute Neel, CNRS and University Joseph Fourier, 25 Avenue des Martyrs, BP 166, 38042, Grenoble, France, ANJAN K. GUPTA, Department of Physics, Indian Institute of Technology, Kanpur, India-208016 — We have fabricated and studied the current-voltage characteristics of a number of niobium film based weak-link devices and  $\mu$ -SQUIDS showing a critical current and two re-trapping currents. We have proposed a new understanding for the re-trapping currents in terms of thermal instabilities in different portions of the device. We also find that the superconducting proximity effect and the phase-slip processes play an important role in dictating the temperature dependence of the critical current in the non-hysteretic regime. The proximity effect helps in widening the temperature range of hysteresis-free characteristics. Finally we demonstrate control on temperature-range with hysteresis-free characteristics in two ways: 1) By using a parallel shunt resistor in close vicinity of the device, and 2) by reducing the weak-link width. Thus we get non-hysteretic behavior down to 1.3 K temperature in some of the studied devices.

**2:42PM H25.00002 Phase-engineering artificial topology in a three-terminal Josephson interferometer.**, SOPHIE D'AMBROSIO, FRANCESCO VISCHI, ELIA STRAMBINI, FRANCESCO GIAZOTTO, NEST laboratory, GIAZOTTO GROUP TEAM — The fundamental aspects of Majoranas with their non-Abelian statistics offer great applications for the future of quantum computation. Current theories on multi-terminal Josephson junctions emphasize the possibility of engineering non trivial states in the spectrum of a proximized normal metal giving rise to an artificial topological superconductor which is able to support Majorana bound states, and points out the importance of a first experimental agreement with the theoretical speculations [1,2]. Here we report on the realization of a three-terminal Josephson interferometer based on proximity effect and fully controlled by phase-coherence. Our device shows a non trivial phase-tunable switch from a regime where the normal metal spectrum shows a gap in the density of states to a gapless regime in full agreement with recent predictions [1,2,3,4], and represents the first essential step towards phase engineering of an artificial topological superconductor hosting Majorana bound states. [1] arXiv:1508.00146. [2] arXiv:1503.06862. [3] Phys. Rev. B 90, 155450 (2014). [4] arXiv:1508.03289.

**2:54PM H25.00003 Tunable microstrip SQUID amplifiers for the Gen 2 Axion Dark Matter eXperiment (ADMX)**, SEAN O'KELLEY, UC Berkeley, GENE HILTON, NIST Boulder, JOHN CLARKE, UC Berkeley — We present a series of tunable microstrip SQUID amplifiers (MSAs) for installation in ADMX. The axion dark matter candidate is detected via Primakoff conversion to a microwave photon in a high-Q ( $\approx 100,000$ ) tunable microwave cavity cooled with a dilution refrigerator in the presence of a 7-tesla magnetic field. The microwave photon frequency  $\nu$  is a function of the unknown axion mass, so both the cavity and amplifier must be scanned over a wide frequency range. An MSA is a linear, phase-preserving amplifier consisting of a superconducting, resonant microstrip flux-coupled to a resistively-shunted dc SQUID biased into the voltage state. Tunability is achieved by terminating the microstrip with low inductance GaAs varactor diodes that operate below 100 mK. By varying the bias voltage of the varactors we vary their capacitance, allowing a reflected phase varying from nearly 0 to  $\pi$ , thus achieving a tunability close to a factor of 2. We demonstrate several devices operating below 100 mK, matched to the discrete operating bands of ADMX at frequencies ranging from 560 MHz to 1 GHz, that exhibit gains exceeding 20 dB. The associated noise temperatures, measured with a hot/cold load, approach the standard quantum limit ( $h\nu/k_B$ ) for a linear phase-preserving amplifier.

**3:06PM H25.00004 Transparency and Coherence in rf SQUID Metamaterials<sup>1</sup>**, STEVEN ANLAGE, MELISSA TREPANIER, DAIMENG ZHANG, University of Maryland — We have developed active metamaterials capable of quickly tuning their electrical and magnetic responses over a wide frequency range [1]. These metamaterials are based on superconducting elements to form low loss, physically and electrically small, highly tunable structures for fundamental studies of extraordinarily nonlinear media. The meta-atoms are rf superconducting quantum interference devices (SQUIDs) that incorporate the Josephson effect. RF SQUIDs have an inductance which is strongly tunable with dc and rf magnetic fields and currents. The rf SQUID metamaterial is a richly nonlinear effective medium introducing qualitatively new macroscopic quantum phenomena into the metamaterials community, namely magnetic flux quantization and the Josephson effect. The coherent oscillation of the meta-atoms is strongly sensitive to the environment and measurement conditions, and we have developed several strategies to improve the coherence experimentally by exploiting ideas from nonlinear dynamics [2]. The metamaterials also display a unique form of transparency whose development can be manipulated through multiple parametric dependences [3]. We discuss these qualitatively new metamaterial phenomena. [1] Melissa Trepanier, *et al.*, Phys. Rev. X 3, 041029 (2013). [2] Melissa Trepanier, *et al.*, in preparation. **3:18PM H25.00005 Multi-tone response of Nonlinear rf-SQUID metamaterials<sup>1</sup>**, DAIMENG ZHANG, MELISSA TREPANIER, Univ of Maryland-College Park, OLEG MUKHANOV, Hypres Inc., THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, Univ of Maryland-College Park — We study the multi-tone response over a broad microwave frequency range of a nonlinear superconducting meta-atom and a metamaterial composed of Radio Frequency Superconducting QUantum Interference Devices (rf-SQUIDs). Nonlinearity in the SQUID metamaterial gives rise to large-range tunable resonance via dc/rf magnetic field and temperature [1] [2], it also results in signal mixing through intermodulation distortion (IMD). Our metamaterial responds to multi-frequency signals and generates strong higher order intermodulation signals in a certain range of applied rf power. However, our meta-atom and metamaterial show a reduced third-order IMD generation around the resonance, which is unusual for typical nonlinear systems. The numerical simulation predicts the same IMD gap feature as in experiment. A comprehensive analytical model is applied to explain the phenomena, and methods to enhance, or reduce, intermodulation levels are explored. [1] M. Trepanier, Daimeng Zhang, Oleg Mukhanov, Steven M. Anlage, Phys. Rev. X 3, 041029 (2013). [2] Daimeng Zhang, M. Trepanier, Oleg Mukhanov, Steven. M. Anlage, Anlage, arXiv:1504.08301 (2015).

<sup>1</sup>This work is supported by the NSF-GOALI and OISE programs through grant ECCS-1158644, and CNAM.

**3:30PM H25.00006 Stochastic Resonance Magnetic Force Microscopy imaging of Josephson Arrays**, TYLER NAIBERT, HRYHORIY POLSHYN, BRIAN WOLIN, MALCOLM DURKIN, RITA GARRIDO MENACHO, IAN MONDRAGON SHEM, VICTOR CHUA, TAYLOR HUGHES, NADYA MASON, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign — Vortex interactions are key to explaining the behavior of many two dimensional superconducting systems. We report on the development of a technique to locally probe vortex interactions in a 2D array of Josephson junctions. Scanning a magnetic tip attached to an ultra-soft cantilever over the array produces changes in the frequency of the cantilever along certain lines, forming geometric patterns in the scans. Different tip-surface separations and external magnetic fields produce a number of different patterns. These patterns correspond to tip locations in which two configurations of vortices in the lattice have degenerate energies. By imaging the locations of these degeneracies, information on the local vortex interactions may be obtained.

**3:42PM H25.00007 Phase-coherent engineering of electronic heat currents with a Josephson modulator.**, ANTONIO FORNIERI, CHRISTOPHE BLANC, RICCARDO BOSISIO, SOPHIE D'AMBROSIO, FRANCESCO GIAZZOTTO, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore — In this contribution we report the realization of the first balanced Josephson heat modulator designed to offer full control at the nanoscale over the phase-coherent component of electronic thermal currents.<sup>1</sup> The ability to master the amount of heat transferred through two tunnel-coupled superconductors by tuning their phase difference<sup>2</sup> is the core of coherent caloritronics, and is expected to be a key tool in a number of nanoscience fields, including solid state cooling, thermal isolation, radiation detection, quantum information and thermal logic. Our device provides magnetic-flux-dependent temperature modulations up to 40 mK in amplitude with a maximum of the flux-to-temperature transfer coefficient reaching 200 mK per flux quantum at a bath temperature of 25 mK. Foremost, it demonstrates the exact correspondence in the phase-engineering of charge and heat currents, breaking ground for advanced caloritronic nanodevices such as thermal splitters, heat pumps and time-dependent electronic engines.

**3:54PM H25.00008 Josephson current in parallel SFS junctions**, PAVEL IOSELEVICH, PAVEL OSTROVSKY, Max Planck Institute for Solid State Research, Stuttgart, Germany, YAKOV FOMINOV, MIKHAIL FEIGELMAN, Landau Institute for Theoretical Physics — We study a Josephson junction between superconductors connected by two parallel ferromagnetic arms. If the ferromagnets are fully polarised, supercurrent can only flow via Cooper pair splitting between the differently polarised arms. The disorder-average current is suppressed, but mesoscopic fluctuations lead to a significant typical current. We extract the typical current from a current-current correlator. The current is proportional to  $\sin^2 \alpha/2$ , where  $\alpha$  is the angle between the polarisations of the two arms, revealing the spin dependence of crossed Andreev reflection. Compared to an SNS device of the same geometry, the typical SFS current is small by a factor determined by the properties of the superconducting leads alone. The current is insensitive to the flux threading the area between the ferromagnetic arms of the junction. However, if the ferromagnetic arms are replaced by metal with magnetic impurities, or partially polarised ferromagnets, the Josephson current starts depending on the flux with a period of  $h/e$ , i.e. twice the superconducting flux quantum.

**4:06PM H25.00009 Critical Current Oscillations of Josephson Junctions with Ferromagnetic Layers<sup>1</sup>**, JOSEPH A. GLICK, MAZIN A. KHASAWNEH, BETHANY M. NIEDZIELSKI, REZA LOLOEE, W. P. PRATT JR., NORMAN O. BIRGE, Dept. of Physics and Astronomy, Michigan State University — Josephson junctions containing ferromagnetic layers are of considerable interest for the development of practical cryogenic memory and superconducting qubits. Such junctions exhibit a phase shift of  $\pi$  for certain ranges of ferromagnetic layer thickness. We present studies of Nb based micron-scale Josephson junctions using ferromagnetic layers of Ni, Ni<sub>81</sub>Fe<sub>19</sub>, or Ni<sub>65</sub>Co<sub>20</sub>Fe<sub>15</sub>. By applying an external magnetic field, the critical current of the junctions containing Ni<sub>81</sub>Fe<sub>19</sub> and Ni<sub>65</sub>Co<sub>20</sub>Fe<sub>15</sub> is found to follow a characteristic Fraunhofer pattern, and displays the clear switching behavior expected of single-domain magnets. However, the junctions containing Ni exhibit more complex behaviors. The maximum value of the critical current, extracted from the Fraunhofer patterns, oscillates as a function of the ferromagnetic layer thickness, indicating transitions in the phase difference across the junction between values of zero and  $\pi$ . We compare the data to previous work and to models of the  $0-\pi$  transitions based on existing clean and dirty limit theories.

<sup>1</sup>This work was supported by IARPA via ARO contract W911NF-14-C-0115.

**4:18PM H25.00010 Controlling the Phase of Ferromagnetic Josephson Junctions for Cryogenic Memory Applications<sup>1</sup>**, BETHANY NIEDZIELSKI, Michigan State University, ERIC GINGRICH, Northrop Grumman Systems Corporation, JOSEPH GLICK, Michigan State University, YIXING WANG, Seagate Technology, DON MILLER, Northrop Grumman Systems Corporation, REZA LOLOEE, WILLIAM PRATT JR., NORMAN BIRGE, Michigan State University — Josephson junctions containing ferromagnetic layers are currently of interest for use in cryogenic memory where either the phase or critical current can be switched between two distinct states. We present the first direct phase measurements of such a junction demonstrating control of the phase [1]. If a junction contains one ferromagnetic layer, the thickness of that layer dictates the ground state phase between the superconducting electrodes, which can be either 0 or  $\pi$ . If the junction contains two ferromagnetic layers and the layer thicknesses are carefully chosen, then the phase of a single junction can be switched between 0 and  $\pi$  by changing the relative magnetization directions of the two layers from antiparallel to parallel. We have successfully fabricated and directly measured the relative phase of two such spin valve junctions in a SQUID loop to confirm the phase change from  $\pi$  to 0 and back again of each junction. We report our continued progress in optimizing the control of such systems. [1] E. C. Gingrich, B. M. Niedzielski, J. A. Glick, Y. Wang, D. L. Miller, R. Loloee, W. P. Pratt Jr., and N. O. **4:30PM H25.00011 Effects of a rotating magnetization on pair correlations in a ballistic regime Josephson Junction<sup>1</sup>**, ANDREAS BILL, LUIS LEAL, California State University Long Beach — Pair correlations in clean superconducting-magnetic proximity systems are studied with a focus on the singlet-triplet mixing resulting from magnetic inhomogeneities. The system is modeled in the clean limit using a tight-binding Hamiltonian and the Bogoliubov–de Gennes equations are solved to determine the Gor'kov functions of the system. Three different magnetic configurations are considered: an exchange spring, a helical magnet, and misaligned homogeneous ferromagnetic layers; each is sandwiched between two superconductors to form a Josephson junction. The goal of the study is to revisit how pair correlations are affected by different magnetization configurations and magnitudes in the clean limit. We discuss our results in the light of those obtained in the diffusive regime [1,2].

**4:42PM H25.00012 Nanoscale investigation of mesoscopic phenomena in superconductor/ferromagnet hybrid structures using low-temperature scanning tunneling microscopy and spectroscopy<sup>1</sup>**, C. DI GIORGIO<sup>2</sup>, S. A. MOORE, A. PUTILOV<sup>3</sup>, E. LECHNER, Department of Physics, Temple University, Philadelphia, PA 19122, J. E. PEARSON, V. NOVOSAD, Materials Science Division, Argonne National Laboratory, Argonne, IL, G. KARAPETROV, Department of Physics, Drexel University, Philadelphia, PA 19104, M. IAVARONE, Department of Physics, Temple University, Philadelphia, PA 19122 — Superconductor/ferromagnet (S/F) heterostructures exhibit unique electronic phenomena which strongly depend on the nature of the constituent materials and the coupling between the layers. Using low-temperature scanning tunneling microscopy and spectroscopy we have investigated S/F structures in the regimes of magnetic and proximity coupling. Here, in the case of S/F systems made of conventional low- $T_c$  lead films with different ferromagnet materials, the spatial and temperature dependent effects on the local density of states which emerge at the nanoscale will be discussed.

**4:54PM H25.00013 Josephson critical current of long SNS junctions in the presence of a magnetic field**, HENDRIK MEIER, Department of Physics, Yale University, VLADIMIR I. FAL'KO, National Graphene Institute, University of Manchester, United Kingdom, LEONID I. GLAZMAN, Department of Physics, Yale University — We evaluate the Josephson critical current of a long and wide two-dimensional superconductor-normal metal-superconductor (SNS) junction, taking into account the effect of electron reflection off the side edges of the junction. Considering clean junctions, we find that the effect of edges alters the usual Fraunhofer-like dependence of the Josephson critical current  $I_c$  on the magnetic flux  $\Phi$ . At relatively weak fields,  $B\Phi_0/W^2$ , the edge effect lifts zeros of the  $I_c(\Phi)$  dependence and gradually shifts the maxima of that function by  $\Phi_0/2$ . (Here  $W$  is the width of the junction and  $\Phi_0$  the magnetic flux quantum.) At higher fields,  $B\Phi_0/W^2$ , the edge effect leads to an accelerated decay of the critical current  $I_c(\Phi)$  with increasing  $\Phi$ . Our results are robust with respect to the roughness of realistic boundaries. Finally, we discuss the role of mesoscopic fluctuations of  $I_c(\Phi)$  originating from the scattering off the edges, and compare our findings to recent experiments.

**Session H26 DCMP DMP: Graphene: Plasmons and Fluorescence** 325 - Abdel El Fatimy, Georgetown University

**2:30PM H26.00001 Plasmon damping in graphene out of equilibrium**, ZHIYUAN SUN, DIMITRI BASOV, MICHAEL FOGLER, Univ of California - San Diego — Motivated by recent experiments with graphene under high photoexcitation, we study theoretically plasmons of graphene in the two-temperature regime, i.e., the regime where electrons are much hotter than the lattice. We calculate the plasmon damping due to scattering of electrons by acoustic phonons, which is the dominant intrinsic contribution in clean graphene. As the system relaxes to equilibrium, the plasmon frequency adiabatically changes with time. We show that this causes a partial compensation of the plasmon damping. A similar mechanism may apply to another collective mode (the energy wave) predicted to exist in graphene in the low-frequency hydrodynamic regime. Implications for infrared and THz pump-probe experiments are discussed.

**2:42PM H26.00002 Plasmonics of graphene laced stratified media.**, UPALI APARAJITA, United States Military Academy:Department of Physics and Nuclear Engineering,753 Cullum Rd, West Point, NY 10996, OLEKSIY ROSLYAK, Physics and Engineering Physics Fordham University Freeman Hall 208 Bronx, NY 10458 - 5198 — Strong overlap of fields of graphene physics and photonics drawn a lot of attention recently. Not only graphene possesses intrinsic highly tunable plasmons but a combination of graphene with noble metal nano structures promises a variety of existing applications for conventional plasmonics, such as novel optical devices working in a broad range from THz to visible spectra. We report simulations of those devices using combination of discrete dipole approximation (DDA) and boundary element methods (BEM). While DDA is an essential tool for modeling large molecule polarizabilities and scattering the BEM provides necessary Green's function tensors when those molecules are in close proximity to the nano-structures. As an example of that technique we study electron energy loss and Raman spectra for complex molecules in presence of metal plasmon active nano particles embedded into a stratified graphene laced medium.

**2:54PM H26.00003 Nano-plasmonic phenomena in graphene nanoribbons**, ZHE FEI, Iowa State University, MICHAEL GOLDFLAM, JIHI-SHENG WU, SIYUAN DAI, MARTIN WAGNER, ALEX MCLEOD, University of California, San Diego, MENGKUN LIU, Stony Brook University, KIRK POST, University of California, San Diego, SHOU-EN ZHU, GUIDO JANSSEN, Delft University of Technology, MICHAEL FOGLER, DIMITRI BASOV, University of California, San Diego — We report on infrared nano-imaging studies of confined plasmon modes inside patterned graphene nanoribbons. The confined geometry of these ribbons leads to distinct mode patterns and strong field enhancement, both of which evolve systematically with the ribbon width and excitation laser frequency. In addition, broadband nano-imaging in a wide mid-infrared region allowed us to evaluate in real space the effect of the plasmon-phonon coupling. Our data and modeling show that the plasmon damping rate increases significantly when approaching the substrate phonon. Furthermore, we observed one-dimensional edge plasmons that propagate strictly along the edges of our patterned graphene nanostructures. These edge modes appear to have a relatively shorter wavelength compared to two-dimensional plasmons.

**3:06PM H26.00004 Resonantly Enhanced Nonlinear Response of Graphene Plasmons**, MOHAMMAD M. JADIDI, Univ of Maryland-College Park, JACOB KNIG-OTTO, STEPHAN WINNERL, Helmholtz-Zentrum Dresden-Rossendorf, Germany, ANDREI B. SUSHKOV, H. DENNIS DREW, THOMAS E. MURPHY, MARTIN MITTENDORFF, Univ of Maryland-College Park — Sub-wavelength graphene structures support plasmonic resonances in terahertz and mid-infrared part of the spectrum. The strong field confinement at plasmon resonance significantly enhances the light-graphene interaction and can lead to a very strong nonlinear optical response. This feature of graphene plasmons can enable nonlinear optics with low field intensity in miniaturized sub-wavelength devices. However, to date, the nonlinear response of graphene plasmons and their energy loss dynamics have not been studied experimentally. Here we present an experimental and theoretical study of the nonlinear terahertz response of plasmon resonances and their energy relaxation dynamics in graphene nanoribbons. Using THz pump-THz probe measurements at the plasmon frequency (9.4 THz), we observe a strong saturation of plasmon absorption followed by a 10 ps relaxation time. The observed nonlinearity is found to be significantly higher than that of graphene with no plasmon resonance. We further present a thermal model for nonlinear plasmonic absorption in graphene nanoribbons that supports the experimental results.

**3:18PM H26.00005 Fluorescence Intermittency and Nanodot Evolution in Graphene Oxide<sup>1</sup>**, ANTHONY RUTH, Univ of Notre Dame, HAYASHI MICHITOSHI, National Taiwan University, MATTHEW MCDONALD, JIXIN SI, YURI MOROZOV, Univ of Notre Dame, PETER ZAPOL, Argonne National Laboratory, MASARU KUNO, BOLDIZSAR JANKO, Univ of Notre Dame — In recent experiments, micron-sized reduced graphene oxide (rGO) flakes were observed to exhibit strong photoluminescence intensity fluctuations, or blinking. Although blinking has been observed in a wide variety of nanoscale emitters, and striking universalities exist across these very different systems, rGO is the first quasi-two dimensional emitter that shows blinking. Despite the widespread presence of blinking at nanoscale, a microscopic mechanism behind this phenomenon remains elusive. Here we provide density functional theory results, analytical calculations, and Monte Carlo simulations to connect the fluorescence trajectories observed in the experiment to microscopic processes. Through Monte Carlo simulations of chemical processes occurring on the graphene oxide surface, we observe the formation and destruction of carbon nanodots. Finally, we use emission characteristics of carbon nanodots from Ab Initio methods to reconstruct the photoluminescence of the macroscopic flake. In particular, we are investigating whether fluorescence intermittency in reduced graphene oxide is an intrinsic optoelectronic property of the nanodot constituents or the result of reversible chemical processes capable of changing the size and number of graphene nanodots.

**3:30PM H26.00006 Heterogeneous fluorescence intermittency in single layer reduced graphene oxide<sup>1</sup>**, JIXIN SI, Univ of Notre Dame, SANDOR VOLKAN-KACSO, California Institute of Technology, AHMED ELTOM, Oliver Wyman, YURII MOROZOV, Univ of Notre Dame, MATTHEW P. MCDONALD, Max Planck Institute for the Science of Light, ANTHONY RUTH, MASARU KUNO, BOLDIZSAR JANKO, Univ of Notre Dame — Fluorescence intermittency, or blinking, has been observed in a wide range of systems, including quantum dots, nanorods, and nanowires. Striking similarities have been documented in the optical response of these nanoscale emitters. However, the mechanism behind blinking still remains elusive. For the first time, blinking has been observed in a two-dimensional system in recent experiments on reduced graphene oxide (rGO). Here we reveal the power spectral density (PSD) of the blinking in rGO shares the same 1/f-like behavior of previously known blinking systems; meanwhile, the heterogeneous dynamic evolution and spatial correlation make rGO a unique blinking system. To investigate the origin of blinking, we self-consistently explain the evolution of rGO blinking using the phenomenological multiple recombination center (MRC) model that captures common features of nanoscale blinking. Furthermore, tight binding method and ab-initio method calculations of carbon nanodots are utilized to look for the microscopic structure corresponding to the RCs in the MRC model.

**3:42PM H26.00007 Photoemission from Graphene on Copper and Cesium Antimonide: Theory and Experiment<sup>1</sup>**, DANIEL FINKENSTADT, US Naval Academy, KEVIN L. JENSEN, SAMUEL G. LAMBRAKOS, US Naval Research Laboratory, ANDREW SHABAEV, George Mason University, NATHAN A. MOODY, Los Alamos National Laboratory — The work function is calculated using DFT for a substrate of flat copper on which a single layer of graphene is deposited. These calculations show a reduced work function, compared to bare copper, when graphene is deposited on a cathode. Based on our DFT-calculated results, a simple model using the transfer matrix approach gives the transmission probability near and above the barrier maximum. An important element of our model is the DFT-calculated, macroscopically-averaged electrostatic potential. Using this potential, graphene behaves as a resonant well for electrons transmitted between the substrate and vacuum regions. Another system to be discussed is graphene atop cesium antimonide, which has very low work function making it technologically useful, in particular for the development of an x-ray free electron laser. On cesium antimonide, we examine whether graphene may allow for the retention of an underlying cesium layer that is often damaged in high-field applications. A discussion of these results in light of recent experimental characterization at LANL will be given.

<sup>1</sup>Funding and support provide by ONR and DOE.

**3:54PM H26.00008 Optical properties of graphene nanoribbons<sup>1</sup>**, FARHAD KARIMI, IRENA KNEZEVIC, Univ of Wisconsin, Madison — We calculate the dielectric function and optical conductivity of ultra-narrow armchair graphene nanoribbons (AGNRs) and zigzag graphene nanoribbons (ZGNRs) by a self-consistent-field approach within a Markovian master-equation formalism (SCF-MMEF) coupled with full-wave electromagnetic equations. Based on third-nearest-neighbor tight-binding, with appropriate modifications for AGNRs and ZGNRs, we calculate electron dispersions and Bloch wave functions in excellent agreement with the local spin-density approximation (LSDA) results. A generalized Markovian master equation of the Lindblad form, which maintains the positivity of the density matrix, is derived to describe the interaction of the electronic system with an external electromagnetic field (to first order) and with a dissipative environment (to second order). Not only does the SCF-MMEF capture the interband electron-hole-pair generation, but it also accurately accounts for concurrent interband and intraband electron scattering with phonons and impurities. We employ the SCF-MMEF to calculate the dielectric function, complex conductivity, and loss function for both suspended and supported AGNRs and ZGNRs with different widths. Then, we obtain the plasmon dispersion and propagation length from the loss-function maximum.

**4:06PM H26.00009 Thermally managed *f*s Z-scan methods investigation of the size-dependent nonlinearity of Graphene Oxide in different solvents**, PAUL BURKINS, ISAAC BASALDUA, ROBINSON KUIS, ANTHONY JOHNSON, University of Maryland, Baltimore County, SIVA RAM SWAMINATHAN, DAIJE ZHANG, SUDHIR TRIVEDI, Brimrose Corporation, UNIVERSITY OF MARYLAND, BALTIMORE MARYLAND TEAM, BRIMROSE CORPORATION OF AMERICA COLLABORATION — Acoustic and thermal diffusion effects are often ignored in Z-scan measurements resulting in misinterpretation of the nonlinear index of refraction and nonlinear absorption. Thermally managed Z-scan using a modified chopper was compared to utilizing a pulsepicker with the common calibration material CS<sub>2</sub> and then extended to Graphene Oxide (GO) in different solvents. The chopper reveals properties of the material in time and is an inexpensive alternative to changing the repetition rate with a pulsepicker. The pulsepicker allows for much faster rise-times and therefore measurements can be taken before thermal effects have overwhelmed the nonlinear electronic response. GO in DI water using pulsepicked *f*s laser excitation yielded a value of  $(-1.79 \pm .6) \times 10^{-15} \text{ cm}^2/\text{W}$  for nanometer particles and  $(-1.09 \pm .6) \times 10^{-15} \text{ cm}^2/\text{W}$  for micrometer sized particles. Open aperture Z-scan of GO in THF using the modified chopper shows a flip from reverse saturable absorption to saturable absorption in time, previously shown to be intensity dependent, potentially resulting from thermal effects. Both measurements indicate smaller particles have larger negative nonlinearities originating from thermal effects or from defects in lattice structure at the edges.

**4:18PM H26.00010 Infrared spectroscopy of vertical heterostructures of graphene and hexagonal boron nitride<sup>1</sup>**, MARCIN MUCHA-KRUCZYŃSKI, University of Bath, DAVID ABERGEL, NORDITA — We suggest that optical absorption of monolayer and bilayer graphene on hexagonal boron nitride will provide meaningful information about the moiré characteristics. In particular, study of the absorption spectrum as a function of the doping for an almost completely full first miniband will distinguish between various theoretical proposals for the physically realistic interaction. Also, for bilayer graphene, the ability to compare spectra for the opposite signs of the interlayer asymmetry induced by an external electric field might provide additional information about the moiré parameters.

<sup>1</sup>This research was funded by EPSRC Grant No. EP/L013010/1 (MM-K), and ERC project DM-321031 (DSLA),

**4:30PM H26.00011 Quantized beam shifts in graphene<sup>1</sup>**, WILTON KORT-KAMP, NIKOLAI SINITSYN, DIEGO DALVIT, Los Alamos National Laboratory — We show that the magneto-optical response of a graphene-on-substrate system in the presence of an external magnetic field strongly affects light beam shifts. In the quantum Hall regime, we predict quantized Imbert-Fedorov, Goos-Hänchen, and photonic spin Hall shifts. The Imbert-Fedorov and photonic spin Hall shifts are given in integer multiples of the fine structure constant  $\alpha$ , while the Goos-Hänchen ones in discrete multiples of  $\alpha^2$ . Due to time-reversal symmetry breaking the IF shifts change sign when the direction of the applied magnetic field is reversed, while the other shifts remain unchanged. We investigate the influence on these shifts of magnetic field, temperature, and material dispersion and dissipation. An experimental demonstration of quantized beam shifts could be achieved at terahertz frequencies for moderate values of the magnetic field.

<sup>1</sup>We acknowledge the LANL LDRD program for financial support.

**4:42PM H26.00012 Auger mediated positron sticking on graphene and highly oriented pyrolytic graphite.<sup>1</sup>**, V A CHIRAYATH, M CHRYSLER, A MCDONALD, Z LIM, K SHASTRY, R GLADEN, A FAIRCHILD, A KOYMEN, A WEISS, Univ of Texas, Arlington — Positron annihilation induced Auger electron spectroscopy (PAES) measurements on 6-8 layers graphene grown on polycrystalline copper and the measurements on a highly oriented pyrolytic graphite (HOPG) sample have indicated the presence of a bound surface state for positrons. Measurements carried out with positrons of kinetic energies lower than the electron work function for graphene or HOPG have shown emission of low energy electrons possible only through the Auger mediated positron sticking (AMPS) process. In this process the positron makes a transition from a positive energy scattering state to a bound surface state. The transition energy is coupled to a valence electron which may then have enough energy to get ejected from the sample surface. The positrons which are bound to surface state are highly localized in a direction perpendicular to surface and delocalized parallel to it which makes this process highly surface sensitive and can thus be used for characterizing graphene or graphite surfaces for open volume defects and surface impurities. The measurements have also shown an extremely large low energy tail for the C KVV Auger transition at 263eV indicative of another physical process for low energy emission.

**4:54PM H26.00013 Impurity signatures in two-dimensional materials in atomic-resolution valence-electron-energy-loss spectroscopic maps.<sup>1</sup>**, MYRON KAPETANAKIS, MARK OXLEY, VANDERBILT UNIV. & ORNL, WU ZHOU, JUAN-CARLOS IDROBO, ORNL, SOKRATES PANTELIDES, VANDERBILT UNIV. & ORNL — The local atomic configurations and electronic states of impurities in 2D materials can be probed directly by several microscopy techniques. Probes of electronic excitations, however, lack spatial resolution. Here we demonstrate that valence-electron energy-loss spectroscopy in an aberration-corrected scanning transmission electron microscope yields atomic-resolution maps of electronic excitations that provide unique signatures of distinct bonding configuration impurities in 2D materials. We report simulations of the maps based on density functional theory and dynamical scattering theory, which agree with and provide direct interpretation of the observed features. The maps differentiate between different bonding configurations of impurities in graphene and hexagonal boron nitride. The theoretical analysis yields information on local electronic excitations, corresponding to impurity-induced bound, resonant and antiresonant states. The method stands to benefit from new monochromators and detectors that enhance spatial and energy resolution and constitutes a powerful alternative to optical spectroscopies for probing electronic and magnetic signatures related with impurities and defects.

**Session H28 DMP: Topological Crystalline Insulators and Quantum Hall Effects.** 327 - Vidya Madhavan, University of Illinois, Urbana-Champaign

**2:30PM H28.00001 Identification of odd-parity nematic superconductivity in doped topological insulators**, LIANG FU, MIT, Physics Department — I will review our theoretical proposal [1] that  $\text{Cu}_x\text{Bi}_2\text{Se}_3$ , a doped topological insulator that becomes superconducting below  $T_c = 3.8\text{K}$ , may have an odd-parity superconducting order parameter emerging from a strongly spin-orbit-coupled band structure. I will discuss recent experimental discovery of spontaneously rotational symmetry breaking in the superconducting state of  $\text{Cu}_x\text{Bi}_2\text{Se}_3$  [2], which provides strong evidence for a two-component odd-parity order parameter leading to nematic superconductivity [3]. Our theoretical analysis shows that this nematic superconductor is stabilized by spin-orbit coupling [4], exhibits a variety of novel thermodynamic properties [5], and realizes a time-reversal-invariant topological superconductor. [1] L. Fu and E. Berg, PRL 105, 097001 (2010) [2] K. Matano, M. Kriener, K. Segawa, Y. Ando and G. Zheng, arXiv:1512.07086 [3] L. Fu, PRB, 90, 100509 (2014) [4] J. Venderbos, V. Kozii, and L. Fu, arXiv:1512.04554 [5] J. Venderbos, V. Kozii, and L. Fu, to appear

**3:06PM H28.00002 Two-dimensional Topological Crystalline Insulator Phase in Sb/Bi Planar Honeycomb with Tunable Dirac Gap**, CHIA-HSIU HSU, ZHI-QUAN HUANG, CHRISTIAN CRISOSTOMO, LIANG-ZI YAO, FENG-CHUAN CHUANG, Natl. Sun Yat-sen U., YU-TZU LIU, BAO-KAI WANG, CHUANG-HAN HSU, CHI-CHENG LEE, HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — We predict planar Sb/Bi honeycomb to harbor a two-dimensional (2D) topological crystalline insulator (TCI) phase based on first-principles computations. Although buckled Sb and Bi honeycombs support 2D topological insulator (TI) phases, their structure becomes planar under tensile strain. The planar Sb/Bi honeycomb structure restores the mirror symmetry, and is shown to exhibit non-zero mirror Chern numbers, indicating that the system can host topologically protected edge states. Our computations show that the electronic spectrum of a planar Sb/Bi nanoribbon with armchair or zigzag edges contains two Dirac cones within the band gap and an even number of edge bands crossing the Fermi level. Lattice constant of the planar Sb honeycomb is found to nearly match that of hexagonal-BN. The Sb nanoribbon on hexagonal-BN exhibits gapped edge states, which we show to be tunable by an out-of-the-plane electric field, providing controllable gating of edge state important for device applications.

### 3:18PM H28.00003 Topological crystalline insulators and superconductors with order-two nonsymmorphic symmetry

KEN SHIOZAKI, Department of Physics, University of Illinois at Urbana Champaign, MASATOSHI SATO, Yukawa Institute for Theoretical Physics, Kyoto University, KIYONORI GOMI, Department of Mathematical Sciences, Shinshu University — Topological crystalline insulators (TCIs) and topological crystalline superconductors (TCSCs) are symmetry protected topological phases of free fermions with space group symmetry. Like conventional topological insulators and superconductors, TCIs and TCSCs support stable gapless boundary states associated with bulk topological nontriviality, when the additional symmetry is compatible with the boundary. Using the twisted equivariant K-theory, we complete the classification of TCIs and TCSCs in the presence of additional order-two nonsymmorphic space group (NSG) symmetry, which includes half lattice translation with  $Z_2$  spin flip, glide, two-fold screw rotation, and their magnetic symmetries. From isomorphisms connecting different space dimensions, the K-groups are evaluated by those in one-dimension. The resultant topological table shows several interesting features: (1) The NSGs allow various  $Z_2$  topological phases, even in the absence of time-reversal and/or particle-hole symmetries. Their boundary states are detached from the bulk spectrum in the direction of the non-primitive lattice translation. (2)  $Z_4$  phases are found to be realized. Especially, the TCI with the glide and the time-reversal symmetry in three-dimensions shows the  $Z_4$  phase.

### 3:30PM H28.00004 Anion-Anion Bonding and Topology in Ternary Iridium Tin Selenides<sup>1</sup>

BENJAMIN TRUMP, JAKE TUTMAHER, TYREL MCQUEEN, Johns Hopkins University — Iridium compounds have been under intense scrutiny due to strong relativistic effects (spin-orbit coupling) which have comparable energy scales to crystal field stabilization and electron correlations, which could lead to non-trivial behavior. Here we report the synthesis, characterization, and physical properties of two new, and one known, Ir-Sn-Se compounds. Resistivity, specific heat, and magnetization measurements show that all three have insulating and diamagnetic behavior, indicative of low spin  $5d^6$  Ir<sup>3+</sup>. Furthermore, electronic structures calculations on Ir<sub>2</sub>Sn<sub>3</sub>Se<sub>3</sub> show a single, spherical, non-spin-orbit split valence band that supports mobile p-type carriers, and imply that Ir<sub>2</sub>Sn<sub>3</sub>Se<sub>3</sub> is topologically non-trivial under tensile strain, due to inversion of Ir-*d* and Se-*p* states.

### 3:42PM H28.00005 Helical Quantum Edge Gears in 2D Topological Insulators

YANG-ZHI CHOU, Rice University, ALEX LEVCHENKO, University of Wisconsin - Madison, MATTHEW FOSTER, Rice University — A remarkable and as-yet-unexploited aspect of topological insulator (TI) physics is the topology of the edge states, i.e. the fact that the edge liquid of a 2D TI forms a closed, unbreakable loop in the absence of electrical contacts or magnetic fields. We propose a novel experimental setup in which edge loops rotate as interlocking gears through Coulomb drag, in TIs with Rashba spin-orbit coupling. We show that two-terminal transport can measure the Luttinger liquid parameter  $K$ , a quantity that is otherwise notoriously difficult to measure. In the low-temperature ( $T \rightarrow 0$ ) perfect drag regime, the conductance is  $(e^2/h)(2K+1)/(K+1)$ . At higher  $T$  we predict a conductivity  $\sim T^{-4K+3}$ . Our results should trigger new experiments and may open a new venue for edge gear-based electronic devices.

Ref: Phys. Rev. Lett. 115, 186404 (2015)

### 3:54PM H28.00006 Quantum anomalous Hall effect with field-tunable Chern number near $Z_2$ topological critical point<sup>1</sup>

LE QUY DUONG, HSIN LIN, WEI-FENG TSAI, YUAN PING FENG, National University of Singapore — We study the practicability of achieving quantum anomalous Hall (QAH) effect with field-tunable Chern number in a magnetically doped, topologically trivial insulating thin film. Specifically in a candidate material, TlBi(S<sub>1- $\delta$</sub> Se <sub>$\delta$</sub> )<sub>2</sub>, we demonstrate that the QAH phases with different Chern numbers can be achieved by means of tuning the exchange field strength or the sample thickness near the  $Z_2$  topological critical point. Our physics scenario successfully reduces the necessary exchange coupling strength for a targeted Chern number. This QAH mechanism differs from the traditional QAH picture with a magnetic topological insulating thin film, where the “surface” states must involve and sometimes complicate the realization issue. Furthermore, we find that a given Chern number can also be tuned by a perpendicular electric field, which naturally occurs when a substrate is present.[1] High-Chern number QAH phase obtained from magnetically doped topological crystalline insulator thin films will also be discussed.

### 4:06PM H28.00007 Zero-field Dissipationless Chiral Edge Current in Quantum Anomalous Hall State

CUI-ZU CHANG, Massachusetts Inst of Tech-MIT, WEIWEI ZHAO, DUK Y. KIM, The Center for Nanoscale Science and Department of Physics, The Pennsylvania State University, PENG WEI, Francis Bitter Magnet Lab and Physics Department, Massachusetts Institute of Technology, J. K. JAIN, CHAOXING LIU, MOSES H. W. CHAN, The Center for Nanoscale Science and Department of Physics, The Pennsylvania State University, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab and Physics Department, Massachusetts Institute of Technology — The quantum anomalous Hall (QAH) state is predicted to possess, at zero magnetic field, chiral edge channels that conduct spin polarized current without dissipation, and thus holds great promise for future high-performance information processing. In this talk, we will discuss our transport experiments that probe the QAH state with gate bias and temperature dependences, by local and nonlocal magnetoresistance measurements. This allows us to unambiguously distinguish the dissipationless edge transport from transport via other dissipative channels in the QAH system. Our experiments confirm a fundamental feature of the QAH state, namely the dissipationless transport by edge channels in zero applied fields, which will be crucial for future chiral interconnected electric and spintronic applications. This research is supported by the NSF grants (DMR-1420620, Penn State MRSEC; in MIT by DMR-1207469 and the STC Center for Integrated Quantum Materials under NSF grant DMR-1231319) and by ONR Grant N00014-13-1-0301.

### 4:18PM H28.00008 Anomalous Hall Effect on the surface of topological Kondo insulators

ELIO KÖNIG, University of Wisconsin-Madison, PAVEL OSTROVSKY, Max Planck Institute for Solid State Research, Stuttgart, Germany, MAXIM DZERO, Kent State University, ALEX LEVCHENKO, University of Wisconsin-Madison — We calculate the anomalous Hall conductivity  $\sigma_{xy}$  of surface states on three dimensional topological Kondo insulators with cubic symmetry and multiple Dirac cones. We treat a generic model in which the Fermi velocity, the Fermi momentum and the Zeeman energy in different pockets may be unequal and in which the microscopic impurity potential is short ranged on the scale of the smallest Fermi wavelength. Our calculation of  $\sigma_{xy}$  to the zeroth (i.e. leading) order in impurity concentration is based on the Kubo-Smrcka-Streda diagrammatic approach. It also includes certain extrinsic contributions with a single cross of impurity lines, which are of the same order in impurity concentration and were, to the best of our knowledge, scrutinized in a single band model, only. We discuss various special cases of our result and the experimental relevance of our study in the context of recent hysteretic magnetotransport data in SmB<sub>6</sub> samples.

### 4:30PM H28.00009 Intrinsic Quantum Anomalous Hall Effect in the Kagome Lattice

Cs<sub>2</sub>LiMn<sub>3</sub>F<sub>12</sub>, GANG XU, BIAO LIAN, SHOU-CHENG ZHANG, Stanford Univ, ZHANG'S GROUP TEAM — In a kagome lattice, the time reversal symmetry can be broken by a staggered magnetic flux emerging from the ferromagnetic ordering and intrinsic spin-orbit coupling, leading to several well-separated nontrivial Chern bands and intrinsic quantum anomalous Hall effect. Based on this idea and *ab initio* calculations, we propose the realization of the intrinsic quantum anomalous Hall effect in the single layer Cs<sub>2</sub>Mn<sub>3</sub>F<sub>12</sub> kagome lattice and on the (001) surface of a Cs<sub>2</sub>LiMn<sub>3</sub>F<sub>12</sub> single crystal by modifying the carrier coverage on it, where the band gap is around 20 meV. Moreover, a simplified tight binding model based on the inplane  $dd\sigma$  antibonding states is constructed to understand the topological band structures of the system.

**4:42PM H28.00010 Giant tunneling anomalous Hall conductance in topological insulators<sup>1</sup>**, ALEX MATOS-ABIAGUE, BENEDIKT SCHARF, JONG E. HAN, State University of New York at Buffalo, EWELINA M. HANKIEWICZ, University of Würzburg, IGOR ZUTIC, State University of New York at Buffalo — We theoretically investigate the tunneling transport across a magnetic barrier modulated by a top gate potential on the surface of a three-dimensional topological insulator. In the presence of a magnetization component along the bias direction, a finite tunneling anomalous Hall conductance (TAHC), transverse to the applied bias, develops. Depending on the strengths of the magnetization and gate potential, the system can exhibit a giant anomalous Hall angle, with the TAHC exceeding the longitudinal tunneling conductance. Moreover, we predict the existence of a negative differential TAHC even when the longitudinal differential conductance remains positive.

**4:54PM H28.00011 Effective boundary theory of the quantized thermal Hall effect**, RYOTA NAKAI, Tohoku University, SHINSEI RYU, University of Illinois, KENTARO NOMURA, Tohoku University — We study the effective gravitational field theory that accounts for the quantized thermal Hall effect. The effective theory is microscopically derived from the one-dimensional massless boundary fermion, which is a manifestation of the two-dimensional bulk Dirac fermion with nontrivial energy band topology. The gravitational response of the boundary effective theory explains the bulk quantized thermal Hall effect through the Stréda formula.

**5:06PM H28.00012 Quantum tunneling between Chern states in a Topological Insulator<sup>1</sup>**, MINHAO LIU, WUDI WANG, Princeton Univ, ANTHONY R. RICARDELLA, ABHINAV KANDALA, Pennsylvania State Univ, JIAN LI, ALI YAZDANI, Princeton Univ, NITIN SAMARTH, Pennsylvania State Univ, N. P. ONG, Princeton Univ — The tunneling of a macroscopic object through a barrier is a quintessentially quantum phenomenon important in field theory, low-temperature physics and quantum computing. Progress has been achieved in experiments on Josephson junctions, molecular magnets, and domain wall dynamics. However, a key feature - rapid expansion of the true vacuum triggered by a tunneling event is virtually unexplored. Here we report the detection of large jumps in the Hall resistance  $R_{xy}$  in a magnetized topological insulator which result from tunneling out of a metastable topological state. In the TI, the conducting electrons are confined to surface Dirac states. When magnetized, the TI enters the quantum anomalous Hall insulator state in which  $R_{xy}$  is strictly quantized. If the magnetic field is reversed, the sample is trapped in a metastable state. We find that, below 145 mK,  $R_{xy}$  exhibits abrupt jumps as large as one quantum unit on time-scales under 1 ms. If the temperature is raised, the escape rate is suppressed consistent with tunneling in the presence of dissipation. The jumps involve expansion of the thermodynamically stable state bubble over macroscopic lengths, but dissipation limits the final size. The results uncover novel effects of dissipation on macroscopic tunneling.

**5:18PM H28.00013 Entanglement Spectra of Gapped One-dimensional Field Theories and Symmetry-Protected Topological Phases**, GIL YOUNG CHO, Department of Physics, Korea Advanced Institute of Science and Technology, KEN SHIOZAKI, Department of Physics, University of Illinois at Urbana-Champaign, ANDREAS LUDWIG, Department of Physics, University of California, Santa Barbara., SHINSEI RYU, Department of Physics, University of Illinois at Urbana-Champaign — We discuss the entanglement spectrum (ES) of (1+1)d gapped Lorentz invariant field theories in the vicinity of a conformal field theory (CFT). In particular, for a gapped theory obtained by perturbing a CFT in infinite space by relevant perturbations, we show that the low-lying ES for the half-line is equal to the physical spectrum of the gapless CFT defined on a finite interval of length  $L = \log(\xi/a)$ , which is the spectrum of a boundary CFT. Here  $\xi$  is the correlation length,  $a$  a microscopic lattice scale, and our result applies in the "scaling limit" where  $\xi \gg a$ . A similar property has been known to hold for Baxter's Corner Transfer Matrices of a class of very special, namely integrable lattice models, for the entire ES and independent of the scaling limit. In contrast, our result applies to completely general gapped Lorentz invariant theories in the scaling limit, without the requirement of integrability, for the low-lying ES. As a consequence, while on a finite interval of length  $2R$  the physical spectrum of the gapped theory is known to undergo a dramatic reorganization as  $2R$  crosses  $\xi$ , the bipartite ES remains unchanged up to an overall scale. We apply these to (1+1)d symmetry-protected topological phases and symmetry-protected degeneracy of ES.

**Session H29 DCMP DMP: Two-dimensional Topological Insulators: InAs/GaSb Quantum Wells and Beyond** 328 - Xiao Li, University of Maryland

**2:30PM H29.00001 Topologically nontrivial Fermi regions and their novel electromagnetic response properties**, CHING HUA LEE, Institute of High Performance Computing, Singapore, XIAO ZHANG, Sun Yat-Sen University, China — In the last decade, there has been a surge of interest in the application of topology to condensed matter physics. So far, most studies have been concerned with the novel properties that arise due to nontrivial band topology, i.e Quantum Anomalous Hall and Z2 topological insulators (TIs). In this talk, I shall describe another context where nontrivial topology also leads to interesting, measurable effects. Within the semi-classical Boltzmann approach, it can be shown that a topologically nontrivial Fermi sea region generically exhibits a non-monotonic nonlinear electromagnetic response in the limit of low chemical potential. Such topologically nontrivial regions of filled states can arise in experimentally realized TI heterostructures or materials with large Rashba splitting, i.e. BiTeI, where the Fermi sea is not simply connected. A non-monotonic electromagnetic response implies regimes of negative differential resistance, which have important applications in technologies involving microwave generation, like motion sensing and radio astronomy. We hope that nontrivial Fermi sea topology will hence provide another route for the realization of such technologies.

**2:42PM H29.00002 Response of Helical Luttinger Liquid in InAs/GaSb Edges to a Magnetic Field<sup>1</sup>**, TINGXIN LI, BINGBING TONG, XIAOXUE LIU, ZHONGDONG HAN, CHI ZHANG, ICQM, Peking University, GERARD SULLIVAN, Teledyne Scientific and Imaging, RUI-RUI DU, Rice University — Electron-electron interactions have been shown to play an important role in InAs/GaSb quantum spin Hall (QSH) edge states, leading to power-law behaviors of the helical edge conductance as a function of temperature and bias voltage (Li *et al*, Phys. Rev. Lett. **115** 136804). A variety of inelastic and/or multiparticle backscattering processes could occur in helical edges when taking electron-electron interactions into account. On the other hand, in the presence of an external magnetic field, single-particle elastic backscattering is also allowed in QSH edge due to the breaking of time-reversal symmetry (TRS). It would be interesting to pursue experimental investigations for the combined effect of electron-electron interactions and TRS breaking on QSH edge transport. We report work in progress for low temperature conductance measurements of the helical edge in InAs/GaSb under perpendicular or in-plane magnetic fields. We found that the magnetic field responses are generally correlated with the interaction strength in the edge states.

**2:54PM H29.00003 Mapping the topological-to-normal insulator phase transition in InAs/GaSb bilayers by heterostructure variation<sup>1</sup>**, BORZOYEH SHOJAEI, Materials Department, University of California at Santa Barbara, ANTHONY P. MCFADDEN, Department of Electrical and Computer Engineering, University of California at Santa Barbara, JOON SUE LEE, California NanoSystems Institute, MIHIR PENDHARKAR, Department of Electrical and Computer Engineering, University of California at Santa Barbara, CHRIS J. PALMSTRM, Materials Department, Department of Electrical and Computer Engineering, University of California at Santa Barbara — When 2D electron and hole subbands in InAs/GaSb bilayers are tuned to the inverted regime the system is predicted to exhibit an insulating bulk and counter propagating helical 1D edge states. This work presents a dual-gate mapping of the topological-to-normal insulator phase transition for several InAs/GaSb bilayers wherein the InAs and GaSb layer thicknesses are varied. In-plane and out-of-plane magnetotransport experiments reveal the effect of heterostructure geometry on the magnitudes of the longitudinal and Hall magnetoresistances and on the shape and temperature dependence of the gate-tuned resistance map in the vicinity of the phase transition.

**3:06PM H29.00004 Gate-Tuned Mott Transition in Dilute InAs/GaSb Quantum Wells**, LINGJIE DU, Department of Physics and Astronomy, Rice University, WENKAI LOU, KAI CHANG, Institute of Semiconductors, Chinese Academy of Sciences, GERARD SULLIVAN, Teledyne Scientific and Imaging, RUI-RUI DU, Department of Physics and Astronomy, Rice University — We investigate the origin of the bulk gap in inverted InAs/GaSb quantum wells (QWs) that host spatially-separated electrons and holes using charge-neutral point (CNP) density ( $n_o \sim p_o$ ) in gated devices as a tuning parameter. We find two distinct gap regimes: for I),  $n_o \gg 5 \times 10^{10}/\text{cm}^2$ , a soft gap opens predominately by hybridization, which closes under  $B_{\parallel} > 10\text{T}$ ; for II), approaching the dilute limit  $n_o \sim 5 \times 10^{10}/\text{cm}^2$ , a hard gap opens leading to a true bulk insulator with quantized helical edges, continuously for  $B_{\parallel}$  up to 35T. Our results confirm that hard gap is associated with the Quantum Spin Hall (QSH) effect but cannot be explained by single-particle band theory. Instead it originates from many-body correlations. The data are remarkably consistent with a Mott insulator bulk state in the dilute InAs/GaSb bilayers. Specifically, spontaneous exciton binding is a viable mechanism for driving the Mott transition. Our results point to the importance of charge interactions in properties of QSHE in InAs/GaSb, in addition to single-particle band theories. The work in Rice was supported by DOE (measurements) and NSF (materials).

**3:18PM H29.00005 Spin-orbit interaction in InAs/GaSb heterostructures**, FANMING QU, ARJAN J. A. BEUKMAN, FOKKO K. DE VRIES, JASPER VAN VEEN, STEVAN NADJ-PERGE, MICHAEL WIMMER, RAFAL J. SKOLASINSKI, DAVID DE VRIES, Delft University of Technology, BINH-MINH NGUYEN, WEI YI, JACOB THORP, MARKO SOKOLICH, HRL Laboratories, MICHAEL J. MANFRA, Purdue University, CHARLES M. MARCUS, University of Copenhagen, LEO P. KOUWENHOVEN, Delft University of Technology — We investigated spin-orbit interaction (SOI) in InAs/GaSb double quantum wells. A combination of dual-gating and spatially separated electron and hole gases allows for in situ engineering of the band structure. In both the trivial and inverted band alignment regimes, zero-field spin splitting due to SOI was extracted from the beating of the Shubnikov-de Haas oscillations. Deep in the electron regime, we observed anomalous magnetoresistance that points to a highly anisotropic Fermi surface as a result of the intermixing of Dresselhaus and Rashba SOI. In the inverted regime close to the hybridization gap, we obtained an oscillating spin-splitting as a function of electron density, as expected from the band structure calculation.

**3:30PM H29.00006 Electric control of inverted gap and hybridization gap in type II InAs/GaSb quantum wells**, LUN-HUI HU, Department of Physics, Zhejiang University, Hangzhou 310027, China, CHAO-XING LIU, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, DONG-HUI XU, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China, FU-CHUN ZHANG, YI ZHOU, Department of Physics, Zhejiang University, Hangzhou 310027, China — The quantum spin Hall effect has been predicted theoretically and observed experimentally in InAs/GaSb quantum wells as a result of inverted band structures, for which electron bands in InAs layers are below heavy hole bands in GaSb layers in energy. The hybridization between electron bands and heavy hole bands leads to a hybridization gap away from  $k = 0$ . A recent puzzling observation in experiments is that when the system is tuned to more inverted regime by a gate voltage (a larger inverted gap at  $k = 0$ ), the hybridization gap decreases. Motivated by this experiment [ref. 1], we explore the dependence of hybridization gap as a function of external electric fields based on eight-band Kane model. We identify two regimes when varying electric fields: (1) both inverted and hybridization gaps increase and (2) inverted gap increases while hybridization gap decreases. We analyze the effective model and find that light-hole bands in GaSb layers play an important role in determining hybridization gap. In addition, large external electric field can induce strong Rashba splitting and also influence hybridization gap. Our results are consistent with experimental observations. Reference: [1] Lingjie Du, et.al., arXiv:1508.04509 (2015).

**3:42PM H29.00007 Image potential states in the topological semimetal Sb<sup>1</sup>**, YAU CHUEN YAM, YANG HE, PENGCHENG CHEN, ZHIHUAI ZHU, MOHAMMAD HAMIDIAN, Harvard University, MARCEL FRANZ, University of British Columbia, JENNIFER HOFFMAN, Harvard University, HOFFMAN LAB TEAM, MARCEL FRANZ COLLABORATION — Topological materials host protected surface states with locked spin and momentum degrees of freedom that have been predicted to give rise to several exotic excitations such as Majorana fermions and magnetic monopoles. The topological semimetal antimony (Sb) offers a pristine platform in which to search for these excitations. Here we present scanning tunneling microscopy and spectroscopy studies of Sb at high energy where quantized image potential states form due to the binding between the tunneling electron and the polarized surface. These states allow exploration of the image charge geometry necessary to realize a magnetic monopole.

**3:54PM H29.00008 Two-Dimensional Oxide Topological Insulator With LiFeAs Structure**, QIUNAN XU, ZHIDA SONG, SIMIN NIE, HONGMING WENG, ZHONG FANG, XI DAI, Chinese Academy of Sci (CAS), KEY LABORATORY OF CONDENSED MATTER THEORY AND COMPUTATION, CHINESE ACADEMY OF SCI, T03 GROUP TEAM — Using first-principles calculations, we propose that ZrSiO can be viewed as a three-dimensional (3D) oxide weak topological insulator (TI) with  $Z_2$  invariants (0; 001). Further calculations show that the single layer of such material is a long-sought-after 2D oxide TI with a band gap around 10 meV. Furthermore, we also find that there are many other isostructural compounds, which can host similar electronic structure and form a 'WHM' material family with 'W' being Zr, Hf or La, 'H' being group IV or group V element, and 'M' being group VI one.

**4:06PM H29.00009 ab initio based tight-binding investigation of quantum spin Hall effect in InAs/GaSb quantum wells**, QUANSHENG WU, ALEXEY SOLUYANOV, MATTHIAS TROYER, ETH Zurich — Quantum spin Hall state is a topologically non-trivial quantum state, which can be used for designing various quantum devices including those potentially useful for quantum computing. Type-II InAs/GaSb semiconductor quantum well was predicted to realize this state of matter. In this work, we systematically investigate topological properties of this system using symmetrized Wannier-based tight-binding models. The model parameters are derived from first-principles hybrid functional calculations, which capture the right band gap and effective masses of both InAs and GaSb. By varying the thickness of InAs and GaSb layers, three possible phases are obtained: normal insulator, quantum spin Hall insulator, and semimetal, allowing us to optimize the growth conditions for the quantum spin Hall phase realization. Most importantly, we identify optimal growth directions, showing that a significant increase of the topological gap can be obtained by growing the quantum well in the [111]-direction. Phase diagrams are obtained for different layer thicknesses and growth directions. Effects of strain and applied electric fields are also discussed.

#### 4:18PM H29.00010 Zero bias conductance peak on the surface of topological semimetal Sb.<sup>1</sup>

PENGCHENG CHEN, Department of Physics, Harvard University; Department of Physics & Astronomy, University of British Columbia, YANG HE, Department of Physics, Harvard University, YAU CHUEN YAM, Department of Physics, Harvard University; Department of Physics & Astronomy, University of British Columbia, SHIANG FANG, Department of Physics, Harvard University, MARCEL FRANZ, Department of Physics & Astronomy, University of British Columbia, MOHAMMAD HAMIDIAN, Department of Physics, Harvard University; Department of Physics & Astronomy, University of British Columbia; LASSP, Department of Physics, Cornell U, JENNIFER HOFFMAN, Department of Physics, Harvard University; Department of Physics & Astronomy, University of British Columbia, HOFFMAN'S LAB TEAM, MARCEL FRANZ COLLABORATION, SHIANG FANG COLLABORATION — Topological materials host protected surface states with locked spin and momentum degrees of freedom that have been predicted to give rise to several exotic excitations such as Majorana fermions and magnetic monopoles. The topological semimetal antimony (Sb) offers a pristine platform in which to search for these excitations. Sb has a bilayer crystal structure; here we obtained both inter-bilayer cleaved and intra-bilayer cleaved terminations. Using scanning tunneling spectroscopy techniques, we observed a robust zero bias conductance peak on the rarer intra-bilayer cleaved surface.

#### 4:30PM H29.00011 Understanding Magnetic Proximity in Topological Insulators with Raman<sup>1</sup>

GAVIN OSTERHOUDT, KENNETH BURCH, Boston Coll, JAGADEESH MOODERA COLLABORATION, FERHAT KATMIS COLLABORATION — The magnetic proximity effect in Topological Insulators has been extensively studied due to predictions of quantum anomalous Hall effect and numerous applications in spintronics. Nonetheless, the origin of the proximity effect remains unclear. To uncover the role of the lattice we have used Raman scattering to investigate the magnetic proximity effect of thin film ferromagnetic insulator EuS grown by MBE on the topological insulator Bi<sub>2</sub>Se<sub>3</sub>. Through these measurements we are able to probe the magnetic fluctuations in the EuS. We will discuss the results of our measurements and their implications for the role of strain in ferromagnetic/topological insulator heterostructures.

#### 4:42PM H29.00012 Visualization of superparamagnetic dynamics in magnetic topological insulators

E. LACHMAN, Weizmann Institute of Science, A. F. YOUNG, University of California Santa Barbara, A. RICHARDELLA, The Pennsylvania State University, J. CUPPENS, N. HR, Y. ANAHORY, A. Y MELTZER, Weizmann Institute of Science, A. KANDALA, S. KEMPINGER, The Pennsylvania State University, Y. MYASOEDOV, Weizmann Institute of Science, M. E. HUBER, University of Colorado Denver, N. SAMARTH, The Pennsylvania State University, E. ZELDOV, Weizmann Institute of Science — Magnetically doped topological insulators have recently been shown to host a quantum anomalous Hall (QAH) state at low temperatures. Using scanning nanoSQUID magnetic imaging on a Cr-doped (Bi,Sb)<sub>2</sub>Te<sub>3</sub> thin film<sup>[1]</sup>, we reveal that the magnetic structure of magnetically doped topological insulators is not ferromagnetic as assumed so far. In fact it is superparamagnetic, formed by weakly interacting magnetic domains. These domains have a characteristic size of a few tens of nanometers, and undergo random reversals which drive the electronic state from one Hall plateau to the other. The superparamagnetic state is metastable, with small energy barriers to relaxation. We observe magnetic relaxation even at 300 mK, evident also in transport measurements. Unexpectedly, magnetic relaxation can also be induced by varying the gate voltage, and we propose a mechanism for the influence of the electronic phase on the magnetic relaxation. We speculate that the dynamic nature of magnetic disorder in QAH systems may contribute to the observed fragility of the QAH state at elevated temperatures. [1] Lachman *et al*, *arXiv:1506.05114*

#### 4:54PM H29.00013 1-D Modes on Step-edges of the Putative Weak Topological Insulator

BI<sub>2</sub>TeI, NURIT AVRAHAM, ANDREW NORRIS, Weizmann Atomic Scale Physics Lab / Weizmann Institute of Science, Israel, LIN PAN, SHU-CHUN WU, CLAUDIA FELSER, BINGHAI YAN, Max Planck Institute for Chemical Physics of Solids, Dresden Germany, HAIM BEIDENKOPF, Weizmann Atomic Scale Physics Lab / Weizmann Institute of Science, Israel — Weak topological insulators are layered materials that possess surfaces with an even number of Dirac cones and surfaces that are fully gapped. This inherent anisotropy provides them with unique properties such as sensitivity to the parity of the number of layers and absence of localization of their surface states. We use scanning tunneling microscopy to study the topological properties of stacked Bi<sub>2</sub>TeI, a promising candidate for weak topological insulator. We report the observation of the bulk energy gap on terraces perpendicular to the stacking direction and signatures of 1D intra-gap topological edge states along step-edges. The rich structure of quasi 2D terraces and Islands obtained on such cleaved Bi<sub>2</sub>TeI surfaces provides an excellent playground to explore some of the most fundamental concepts of TIs such as their Z<sub>2</sub> classification, “partner switching” of Kramer’s degenerate pairs, and helical modes along dislocation lines.

#### 5:06PM H29.00014 Optical conductivity of topological surface states with emergent supersymmetry<sup>1</sup>

JOSEPH MACIEJKO, University of Alberta, WILLIAM WITCZAK-KREMPA, Harvard University — Topological states of electrons present new avenues to explore the rich phenomenology of correlated quantum matter. Topological insulators (TIs) in particular offer an experimental setting to study novel quantum critical points (QCPs) of massless Dirac fermions, which exist on the samples surface. Here, we obtain exact results for the zero- and finite-temperature optical conductivity at the semimetal-superconductor QCP for these topological surface states. This strongly interacting QCP is described by a scale invariant theory with emergent supersymmetry, which is a unique symmetry mixing bosons and fermions. We show that supersymmetry implies exact relations between the optical conductivity and two otherwise unrelated properties: the shear viscosity and the entanglement entropy. We discuss experimental considerations for the observation of these signatures in TIs.

<sup>1</sup>This work was supported by NSERC, CRC, CIFAR, and the University of Alberta.

#### 5:18PM H29.00015 Proximity-induced global time-reversal symmetry (TRS) breaking and enhanced surface ferromagnetism mediated by Dirac fermions in bilayers of magnetic topological insulators (TIs)

C.-C. CHEN, M. L. TEAGUE, W. FAN, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, L. HE, X. KOU, M. LANG, K.-L. WANG, Dept. of Elec. Eng., UCLA, Los Angeles, CA 90095 — Proximity-induced magnetic effects on the surface Dirac spectra of TIs are investigated by scanning tunneling spectroscopic (STS) studies of bilayer structures consisting of an undoped TI layer Bi<sub>2</sub>Se<sub>3</sub> and (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub> on top of a Cr-doped, magnetic TI of 6 quintuple-layer (QL) thickness.<sup>1</sup> For all samples with the top layer thinner than 4-QL, a surface gap  $\Delta$  opens up below  $T_c^{2D}$ , much higher than the bulk Curie temperature  $T_c^{3D}$  derived from the anomalous Hall resistance. The temperature ( $T$ ) evolution of  $\Delta$  shows an initial increase below  $T_c^{2D}$ , followed by a ‘dip’ near  $T_X$ , and then rises again, reaching maximum at  $T \ll T_c^{3D}$ . The gap is spatially inhomogeneous, and its average value and spatial homogeneity at low  $T$  increases with applied magnetic field  $H$  and Cr-doping level  $x$ . The appearance of massive Dirac spectra below  $T_c^{2D}$  is the result of global TRS breaking in the surface state of TIs. The non-monotonic  $T$ -dependence of  $\Delta$  and the finding of  $T_c^{2D} \gg T_c^{3D}$  may be attributed to proximity magnetism induced by a 3D contribution from the bulk magnetism that dominates at low  $T$ , and a 2D contribution from the RKKY interaction mediated by surface Dirac fermions, which dominates at  $T_c^{3D} \ll T_X < T < T_c^{2D}$  and can significantly enhance the surface magnetism due to the long wavelengths of Dirac fermions.

**Session H30 DMP: Novel Behavior at Oxide Interfaces** 329 - Beatriz Noheda, University of Groningen

**2:30PM H30.00001 Interfaces between strongly correlated oxides : controlling charge transfer and induced magnetism by hybridization<sup>1</sup>**, MANUEL BIBES, CNRS/Thales, Univ. Paris-Saclay, Palaiseau (FRANCE) — At interfaces between conventional materials, band bending and alignment are controlled by differences in electrochemical potential. Applying this concept to oxides in which interfaces can be polar and cations may adopt a mixed valence has led to the discovery of novel two-dimensional states between simple band insulators such as  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$ . However, many oxides have a more complex electronic structure, with charge, orbital and/or spin orders arising from correlations between transition metal and oxygen ions. Strong correlations thus offer a rich playground to engineer functional interfaces but their compatibility with the classical band alignment picture remains an open question. In this talk we will show that beyond differences in electron affinities and polar effects, a key parameter determining charge transfer at correlated oxide interfaces is the energy required to alter the covalence of the metal-oxygen bond. Using the perovskite nickelate ( $\text{RNiO}_3$ ) family as a template, we have probed charge reconstruction at interfaces with gadolinium titanate  $\text{GdTiO}_3$  using soft X-ray absorption spectroscopy and hard X-ray photoemission spectroscopy. We show that the charge transfer is thwarted by hybridization effects tuned by the rare-earth (R) size. Charge transfer results in an induced ferromagnetic-like state in the nickelate (observed by XMCD), exemplifying the potential of correlated interfaces to design novel phases. Further, our work clarifies strategies to engineer two-dimensional systems through the control of both doping and covalence.

**3:06PM H30.00002 Electric field effect on magneto-thermopower in oxide interface  $\text{LaAlO}_3/\text{SrTiO}_3$** , TOMOYA ASABA, GANG LI, Univ of Michigan - Ann Arbor, PASCAL WITTLICH, JOCHEN MANNHART, Max Planck Institute for Solid State Research, LU LI, Univ of Michigan - Ann Arbor — Oxide interface  $\text{LaAlO}_3/\text{SrTiO}_3$  has been attracting huge interest as it shows 2-dimensional electron liquid behavior, negative compressibility and coexistence of magnetism and superconductivity. In this study we measured the magneto-thermoelectric effect and report the observation of the quantum oscillation in the thermopower. Backing gating through  $\text{SrTiO}_3$  tunes the carrier density and the oscillation pattern in the thermoelectric signal. At low carrier density, the oscillation frequency decreases when more electrons are populated, which directly indicates the negative capacitance. At high carrier density regime, both of magneto-thermopower and Nernst effect show the nonlinear behavior which suggests a Lifshitz transition. These results point to the unique multiband electronic structure of oxide interface.

**3:18PM H30.00003 Spin transport in  $\text{LaAlO}_3/\text{SrTiO}_3$  heterostructures**, THACH D. N. NGO, Korea Research Institute of Standards and Science, JUNGWON CHANG, Korea University, KYUJOON LEE, Sogang University, SEUNGJU HAN, JOONSUNG LEE, Korea University, YOUNGHEON KIM, Korea Research Institute of Standards and Science, MYUNGHWA JUNG, Sogang University, YONGJOO DOH, MAHNSOO CHOI, Korea University, JONGHYUN SONG, Chungnam National University, JINHEE KIM, Korea Research Institute of Standards and Science — Since the discovery in 2004, the 2-dimensional electron gas at the  $\text{LaAlO}_3/\text{SrTiO}_3$  heterointerfaces has attracted considerable attentions because of the fascinating physical phenomena and their strong tuneability. However, the manipulation of the spin degree of freedom in this oxide structure is still unattainable. Here, we report the spin-dependent electrical transport in hybrid magnetic tunnel junctions based on the ferromagnetism at the oxide interface. The Ohmic spin injection into the  $\text{LaAlO}_3/\text{SrTiO}_3$  heterostructure is feasible due to the insertion of an approximately thin Ti layer between the oxide and ferromagnetic metal (Co). The observed tunnel magnetoresistive effect shows such a strong anisotropy that the magnitude and even sign of the tunneling magnetoresistance ratio are dramatically modulated by a rotational, in-plane magnetic field. This is attributable to the strong Rashba-type spin-orbit coupling in the oxide structure. In addition, the spin transport is also associated with the tetragonal domain configuration of the  $\text{SrTiO}_3$  substrate. These results provide a further support for the existence of the macroscopic ferromagnetism at  $\text{LaAlO}_3/\text{SrTiO}_3$  interface.

**3:30PM H30.00004 Scanning SQUID measurements of magnetism in  $\text{LaAlO}_3/\text{SrTiO}_3$  heterostructures**, H. NOAD, E. M. SPANTON, J. A. BERT, B. KALISKY, K. C. NOWACK, C. BELL, M. KIM, Y. HIKITA, M. HOSODA, H. K. SATO, SIMES, SLAC National Laboratory, Y. XIE, Department of Applied Physics, Stanford University, P. WITTLICH, Max Planck Institute for Solid State Research, Stuttgart, H. Y. HWANG, SIMES, SLAC National Laboratory, J. MANNHART, Max Planck Institute for Solid State Research, Stuttgart, K. A. MOLER, SIMES, SLAC National Laboratory —  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$  are both nonmagnetic band insulators. It is therefore surprising that signatures of magnetism in  $\text{LaAlO}_3/\text{SrTiO}_3$  heterostructures (LAO/STO) have been seen in a wide variety of experiments. Using scanning superconducting quantum interference device (SQUID) microscopy we previously found that, above a critical thickness of three unit cells of LAO, there can be heterogeneous patches of ferromagnetism. The observed ferromagnetic patches are sparse, and many samples show very few ferromagnetic patches. Scanning SQUID observations suggest that, although ferromagnetic patches can arise, the ground state of LAO/STO is not strongly ferromagnetic. In the few samples studied at millikelvin temperatures, we also observed a relatively homogeneous paramagnetic response with a  $1/T$ -like dependence, suggesting a landscape of localized spins. Theoretical proposals for the origin of magnetism in LAO/STO include intrinsic spin polarization near the interface and cation or oxygen vacancy defects. Measurements on samples with deliberately tuned oxygen content will help us to evaluate these proposals.

**3:42PM H30.00005 Correlations between magnetic and piezoelectric response at gated  $\text{LaAlO}_3/\text{SrTiO}_3$  interfaces<sup>1</sup>**, QING GUO, JIANAN LI, MENGCHEN HUANG, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — The interface between perovskite oxide semiconductors  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$  exhibits remarkable conducting, superconducting, magnetic, and spintronic properties that are strongly influenced by electron density. Scanning probe methods have the ability to probe local properties of interest. For example, magnetic force microscopy (MFM) has been used to measure magnetism at the  $\text{LaAlO}_3/\text{SrTiO}_3$  interface<sup>2</sup>, while piezoelectric force microscopy has been used to measure the local electron density<sup>3</sup>. Here we directly compare these two methods to provide further insight into the relationship between electron density and magnetic properties.

**3:54PM H30.00006 Magneto-optical Kerr probing of LAO/STO interface ferromagnetism<sup>1</sup>**, JIANAN LI, QING GUO, FENG BI, MENGCHEN HUANG, Univ of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, Univ of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Interfacial ferromagnetism in  $\text{LaAlO}_3/\text{SrTiO}_3$  (LAO/STO) heterostructures has been probed by a variety of techniques. Recently, magnetic force microscopy (MFM) was used to image ferromagnetic domains that are electrically tunable at room temperature<sup>2</sup> when the samples were grown in certain conditions. Optical techniques provide powerful tools for probing magnetic phenomena, and recently magnetic circular dichroism has been observed in reduced bulk STO crystals<sup>3</sup>. Here we describe a scanning magneto-optical Kerr imaging system that could achieve sub-micrometer precision and  $10^{-4}$  rad/ $\sqrt{\text{Hz}}$  sensitivity with a 150 fs pulsed-laser centered at 425 nm. Such capability would make pump and probe measurement on the gate-tunable LAO/STO ferromagnetism and ultrafast imaging of domain dynamics possible.

<sup>1</sup>We gratefully acknowledge support from NSF DMR-1104191 (JL, CBE), AFOSR FA9550-12-1-0057 (JL, CBE).

**4:06PM H30.00007 Surface chemically-switchable ultraviolet luminescence from interfacial two-dimensional electron gas**, JONATHAN E SPANIER, MOHAMMAD I ISLAM, Drexel University, DIOMEDES SALDANA-GRECO, University of Pennsylvania, ZONGQUAN GU, Drexel University, FENG GONG WANG, University of Pennsylvania, ERIC BRECKENFELD, University of Illinois at Urbana-Champaign, QINGYU LEI, Temple University, RUIJUAN XU, University of California at Berkeley, CHRISTOPHER J HAWLEY, Drexel University, XIAOXING XI, Temple University, LANE W MARTIN, University of California at Berkeley, ANDREW M RAPPE, University of Pennsylvania — We report intense, narrow-linewidth, surface chemisorption-activated and reversible ultraviolet (UV) photoluminescence from radiative recombination of the two-dimensional electron liquid with photo-excited holes at the  $\text{LaAlO}_3/\text{SrTiO}_3$  interface. The switchable luminescence arises from an electron transfer-driven modification of the electronic structure via H-chemisorption onto  $\text{AlO}_2$ -terminated  $\text{LaAlO}_3$ , at least 2 nm away from the interface. Control of the onset of emission and its intensity are functionalities that go beyond the luminescence of compound semiconductor quantum wells. Connections between reversible chemisorption, fast electron transfer, and quantum-well luminescence suggest a new model for surface chemically reconfigurable solid-state UV optoelectronics and molecular sensing. Work supported by NSF under DMR 1124696, DoE BES under DE-FG02-07ER46453, DE-FG-2-07ER15920, and DE-SC0004764, and by ONR under N00014-12-1-1033 and N00014-11-1-0664.

**4:18PM H30.00008 Ferroelectric Tunnel Junction with a Semiconductor Electrode**, XIAOHUI LIU, J.D. BURTON, EVGENY TSYMBAL, University of Nebraska-Lincoln — Realizing a large tunneling electroresistance (TER) is crucial for the application of ferroelectric tunnel junctions (FTJs) for device applications. FTJs are typically composed of a thin ferroelectric layer sandwiched by two metallic electrodes, where TER generally results from the dependence of the effective tunneling barrier height on the ferroelectric polarization. Since the resistance depends exponentially not only on barrier height but also on barrier width, TER is expected to be greatly enhanced when one of the electrodes is a semiconductor where the depletion region near the interface can be controlled via ferroelectric polarization. To explore this possibility, we perform studies on a  $\text{SrRuO}_3/\text{BaTiO}_3/n\text{-SrTiO}_3$  FTJ using first-principles density functional theory (DFT). We analyze the effect of ferroelectric polarization on the barrier width and transport properties. Our studies show that, in addition to modulation of the depletion region in  $n\text{-SrTiO}_3$ , layers in the  $\text{BaTiO}_3$  barrier near the interface become conducting for one polarization orientation leading to a large TER effect. Additional DFT+U calculations reveal that this effect is insensitive to the bandgap of the barrier, indicating that this should be a robust mechanism to realize large TER in FTJs.

**4:30PM H30.00009 Effect of epitaxial strain on tunneling electroresistance in ferroelectric tunnel junctions<sup>1</sup>**, ANDREI SOKOLOV, OHHEUM BAK, HAIDONG LU, EVGENY TSYMBAL, ALEXEI GRUVERMAN, University of Nebraska at Lincoln — We present the effect of compressive strain on the tunneling electroresistance (TER) effect in  $\text{BaTiO}_3/\text{SrRuO}_3$  (BTO/SRO) heterostructures. The films were prepared using PLD technique and characterized by XRD and RHEED methods. We performed comprehensive study of ferroelectric and transport properties of obtained structure and find that epitaxial strain imposed by the mismatch of  $\text{NdGaO}_3$  and  $\text{SrTiO}_3$  lattice parameters with the BTO and SRO layers improves ferroelectric polarization of BTO and concurrently promotes the metallicity of the SRO films. While the enhanced polarization is beneficial for the TER magnitude, the reduced asymmetry in the tunneling barrier due to the shortened screening length of SRO is detrimental for the effect. Thus, a combined effect of strain on the polarization of the ferroelectric barrier and the screening properties of the electrodes needs to be taken into account when considering and predicting the TER effect in ferroelectric tunnel junctions

**4:42PM H30.00010 Reversible Magnetoelectric Control of Exchange Coupling in Monodomain  $\text{BiFeO}_3$  Heterostructures<sup>1</sup>**, J IRWIN, W SAENRANG, Univ of Wisconsin, Madison, B.A. DAVIDSON, CNR-Istituto Officina dei Materiali, Trieste, Italy, J.E. PODKAMINER, KJ REIERSON, Univ of Wisconsin, Madison, F MACCHEROZZI, S DHESI, Diamond Light Source, Harwell Campus, Didcot, UK, J. W. FREELAND, Advanced Photon Source, Argonne National Laboratory, US, M.S. RZCHOWSKI, C. B. EOM, Univ of Wisconsin, Madison — The electric field control of ferromagnetism has exciting applications in spintronic devices such as magnetic tunnel junctions. We investigate reversible rotation of the magnetization of a Co overlayer on a heterostructure with a monodomain thin film of the multiferroic  $\text{BiFeO}_3$  (BFO). For different electric polarization directions of the BFO film we observe a rotation in Co magnetization direction by photoelectron emission microscopy (PEEM). This effect is robust over at least 100 cycles of the BFO electric polarization. According to anisotropic magnetoresistance (AMR) and magneto-optic Kerr effect (MOKE) measurements performed at room temperature, the easy magnetic direction for the Co layer rotates in plane when the electric polarization of the BFO is switched. Additionally, X-ray linear dichroism (XLD) measurements verify the presence of a magnetoelectric effect in the BFO and suggest magnetic coupling between the BFO and Co layers.

**4:54PM H30.00011 Rashba type band splittings in ferroelectric semiconductor  $\alpha\text{-GeTe}(111)$** , BEOMYOUNG KIM, HYUNGJU OH, YEONGKWAN KIM, JONATHAN DENLINGER, Lawrence Berkeley Natl Lab, CHANGYOUNG KIM, Department of Physics and Astronomy, Seoul National University, Seoul 151747, Republic of Korea — There has been significant increase in the research of spin orbit coupling (SOC) induced exotic phenomena. The Rashba effect, theoretically predicted to exist, is one of the SOC related phenomena. The phenomenon was later experimentally observed in the surface states of metals and topological insulators as well as interfaces of hetero structures that have inversion symmetry breaking (ISB). Even bulk states with intrinsic ISB such as  $\text{BiTeI}$  is found to have Rashba split bands. It was very recently proposed that ferroelectric GeTe has Rashba effect in the bulk. This is a unique situation where ISB is provided not by the structure ISB but by an electrical polarization. We have performed angle-resolved photoemission spectroscopy (ARPES) on GeTe single crystals to investigate the unique bulk Rashba state. Our results indeed show the existence of a Rashba-type band splitting as theoretically predicted. We discuss various aspect of the Rashba states in ferroelectric semiconductor  $\alpha\text{-GeTe}(111)$ .

### 5:06PM H30.00012 Effect of charge on the ferroelectric field effect in strongly correlated oxides

XUEGANG CHEN, ZHIYONG XIAO, XIAOZHE ZHANG, LE ZHANG, WEIWEI ZHAO, Department of Physics & Astronomy, University of Nebraska-Lincoln, NE 68588, XIAOSHAN XU, XIA HONG, Department of Physics & Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, NE 68588 — We present a systematic study of the effect of charge on the ferroelectric field effect modulation of various strongly correlated oxide materials. We have fabricated high quality epitaxial heterostructures composed of a ferroelectric  $\text{Pb}(\text{Zr,Ti})\text{O}_3$  (PZT) gate and a correlated oxide channel, including  $\text{Sm}_{0.5}\text{Nd}_{0.5}\text{NiO}_3$  (SNNNO),  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  (LSMO), SNNNO/LSMO bilayers, and  $\text{NiCo}_2\text{O}_4$  (NCO). The Hall effect measurements reveal a carrier density of  $\sim 4$  holes/u.c. ( $0.4 \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ ) for SNNNO to  $\sim 2$  holes/u.c. ( $27 \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ ) for NCO. We find the magnitude of the field effect is closely related to both the intrinsic carrier density and carrier mobility of the channel material. For devices employing the SNNNO/LSMO bilayer channel, we believe the charge transfer between the two correlated oxides play an important role in the observed resistance modulation. The screening capacitor of the channel materials and the interfacial defect states also have significant impact on the retention characteristics of the field effect. Our study reveals the critical role of charge in determining the interfacial coupling between ferroelectric and magnetic oxides, and has important implications in developing ferroelectric-controlled Mott memory devices.

### 5:18PM H30.00013 Band offset measurement of oxygen annealed $\text{SrTiO}_3/\text{Si}$

ERIC JIN, LIOR KORNBLUM, CHARLES AHN, FRED WALKER, Yale Univ — Integration of the perovskite oxide  $\text{SrTiO}_3$  (STO) with silicon by molecular beam epitaxy (MBE) was initially developed for new high-K gate dielectrics, and more recently as a means to combine the multifunctional properties of oxide heterostructures with the well-established silicon platform. The band alignment at an oxide-semiconductor junction is critical in determining its electrical properties, and control over the conduction band offset is a fundamental goal of materials science. Density functional theory calculations have shown that an interface dipole forms at the STO-Si interface, with the magnitude of this dipole determined by the exact composition of the interface. If the interface is oxygen deficient, the band alignment is type II. If the interface is modified via the addition of a monolayer of oxygen atoms, the predicted heterojunction becomes type-I. We characterize the band alignment of MBE-grown STO-Si films by x-ray photoemission spectroscopy and show that the conduction band offset is negative between STO and Si. We demonstrate an experimental  $\sim 0.5$  eV increase in the conduction band offset for in-situ oxygen-annealed films, in close agreement with theoretical predictions. By careful control of the interface atomic structure, we show an approach toward tuning the band offset of the STO-Si system to modify electronic transport for a variety of device applications.

Session H31 DCP: Advances in Density Functional Theory IV 331 - Adam Wasserman, Purdue University

### 2:30PM H31.00001 Extensions of time density functional theory to QED: QED-Chemistry

ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — In this talk we will review the recent advances within density-functional and many-body based schemes to describe spectroscopic properties of complex systems with special emphasis to modelling time and spatially resolved electron spectroscopies. We will discuss the theoretical approaches developed in the group for the characterisation of matter out of equilibrium, the control material processes at the electronic level and tailor material properties, and master energy and information on the nanoscale to propose new devices with capabilities. We will focus on examples linked to the efficient conversion of light into electricity or chemical fuels ("artificial photosynthesis") and the design on new nanostructured based optoelectronic devices based on inorganic nanotubes, among others. The goal is to provide a detailed, efficient, and at the same time accurate microscopic approach for the ab-initio description and control of the dynamics of decoherence and dissipation in quantum many-body systems. With the help of quantum optimal control (QOC) theory and the mastery over spectroscopy we could direct the movement of electrons, selectively trigger chemical reactions and processes, and create new materials

### 3:06PM H31.00002 Advances in time-dependent current-density functional theory<sup>1</sup>

ARJAN BERGER, University of Toulouse III - Paul Sabatier — In this work we solve the problem of the gauge dependence of molecular magnetic properties (magnetizabilities, circular dichroism) using time-dependent current-density functional theory [1]. We also present a new functional that accurately describes the optical absorption spectra of insulators, semiconductors and metals [2]

N. Raimbault, P.L. de Boeij, P. Romaniello, and J.A. Berger Phys. Rev. Lett. 114, 066404 (2015)

J.A. Berger, Phys. Rev. Lett. 115, 137402 (2015)

### 3:18PM H31.00003 The particle-particle random phase approximation and beyond – insight from the superconductive Gorkov perspective and implications of an efficient truncation scheme

DU ZHANG, WEITAO YANG, Duke University, WEITAO YANG GROUP TEAM — As an excited-state electronic structure method, the particle-particle random phase approximation (ppRPA) satisfactorily resolves many challenges for the time-dependent density functional theory (TDDFT)/particle-hole (ph) RPA, e.g. absence of double excitations, diradicals, singlet-to-triplet instability, etc. Given that the ppRPA equation has been derived from the pairing potential linear response, we derive it using the propagator approach using the superconductive Gorkov formalism. Systematic higher-order contributions are added to the ppRPA, yielding the pp Bethe-Salpeter equation (BSE). This development can be combined with our recently proposed truncation scheme, which makes typical ppRPA calculations up to 100 times faster than the Davidson's algorithm. Since the electron correlation is important in yielding good excitation energies for the ppRPA (the superiority of DFT reference states over Hartree-Fock ones, esp. for large systems), combining the two developments allows us to add the electron correlation into the ppRPA calculation at a modest formal scaling of  $O(N^4)$ , pushing the excitation energy calculations towards both larger systems and higher accuracy.

### 3:30PM H31.00004 Calculating excitation energies with particle-particle and particle-hole random phase approximation using accurate optimized effective potentials

YE JIN, YANG YANG, DEGAO PENG, WEITAO YANG, Duke University — With an accurate electron density, one can calculate the optimized effective potential (OEP) which gives Kohn-Sham energies and eigenvectors accurately. Such Kohn-Sham energies and eigenvectors are developed here for applications in excited state calculations. In this work, Kohn-Sham results from OEP with an accurate input electron density, i.e. CCSD density, are used in excitation energy calculations, within the particle-particle and particle-hole random phase approximation (pp-, ph-RPA). Tests on small molecules, for example, BH and  $\text{CH}^+$ , matches well with the EOM-CCSD calculation for low energy excited states. For  $\text{N}_2$ , CO and  $\text{H}_2\text{O}$ , our method describes the lower excitations well compared with the experimental data and improves the results from pp- and ph-RPA based on approximate density functional approximations. This approach is thus promising for applications in calculating accurate excitation energies.

**3:42PM H31.00005 Singlet–Triplet Energy Gaps for Diradicals from Particle–Particle Random Phase Approximation**, YANG YANG, DEGAO PENG, Duke Univ, ERNEST DAVIDSON, University of Washington, WEITAO YANG, Duke Univ — The particle–particle random phase approximation (pp-RPA) has been applied to the calculation of vertical and adiabatic singlet–triplet energy gaps for a variety of categories of diradicals, including diatomic diradicals, carbene-like diradicals, disjoint diradicals, four- $\pi$ -electron diradicals, and benzynes are calculated. Except for some excitations in four- $\pi$ -electron diradicals, where four-electron correlation may play an important role, the singlet–triplet gaps are generally well predicted by pp-RPA. With a relatively low  $O(r^4)$  scaling, the pp-RPA with DFT references outperforms spin-flip configuration interaction singles. It is similar to or better than the (variational) fractional-spin method. For small diradicals such as diatomic and carbene-like ones, the error of pp-RPA is slightly larger than noncollinear spin-flip time-dependent density functional theory (NC-SF-TDDFT) with LDA or PBE functional. However, for disjoint diradicals and benzynes, the pp-RPA performs much better and is comparable to NC-SF-TDDFT with long-range corrected  $\omega$ PBEh functional and spin-flip configuration interaction singles with perturbative doubles (SF-CIS(D)). In particular, with a correct asymptotic behavior and being almost free from static correlation error, the pp-RPA with DFT references can well describe the challenging ground state and charge transfer excitations of disjoint diradicals in which almost all other DFT-based methods fail. Therefore, the pp-RPA could be a promising theoretical method for general diradical problems.

**3:54PM H31.00006 Thermal connection formula and linear response time-dependent density functional theory for thermal ensembles**, AURORA PRIBRAM-JONES, Lawrence Livermore National Lab and Department of Chemistry, University of California, Berkeley, PAUL GRABOWSKI, Department of Chemistry, University of California, Irvine, KIERON BURKE, Departments of Physics and Chemistry, University of California, Irvine — The finite-temperature adiabatic connection formula is cast as an integral over the temperature and used to write new relations between correlation components in terms of temperature and the coupling constant. Next, the van Leeuwen proof of time-dependent density functional theory is generalized to thermal ensembles, along with the Gross-Kohn relation and the fluctuation-dissipation theorem. These results are combined with the thermal connection formula to produce a method for generating new exchange-correlation approximations.

**4:06PM H31.00007 Solid-state optical absorption from optimally tuned time-dependent range-separated hybrid density functional theory<sup>1</sup>**, SIVAN REFAELY-ABRAMSON, Molecular Foundry, LBNL and Dept. of Physics, UC-Berkeley, MANISH JAIN, Dept. of Physics, IISc, Bangalore, India, SAHAR SHARIFZADEH, Dept. of Electrical and Computer Engineering and Physics Division of MSE, Boston University, JEFFREY B. NEATON, Molecular Foundry, LBNL, Dept. of Physics, UC-Berkeley and Kavli ESNi at Berkeley, LEEOR KRONIK, Dept. of Materials and Interfaces, Weizmann Institute — We present a framework for obtaining solid-state charge and optical excitations and spectra from optimally tuned range-separated hybrid density functional theory, which allows for the accurate prediction of exciton binding energies. We demonstrate our approach through calculations of one- and two-particle excitations in pentacene, a molecular semiconducting crystal, where we find excellent agreement with experiments and prior computations. We show that with one adjustable parameter, our method accurately predicts band structures and optical spectra of Si and LiF, prototypical covalent and ionic solids. For a range of extended bulk systems, this method may provide a computationally inexpensive alternative to many-body perturbation theory, opening the door to studies of materials of increasing size and complexity [Phys. Rev. B 92, 081204(R), 2015].

<sup>1</sup>This work was supported by DOE

**4:18PM H31.00008 Exploring Level Alignment in Molecule-Metal Interfaces with Optimally-Tuned Range-Separated Hybrid Functionals**, ZHENFEI LIU, Lawrence Berkeley National Lab, DAVID A. EGGER, Weizmann Institute of Science, SIVAN REFAELY-ABRAMSON, Lawrence Berkeley National Lab, LEEOR KRONIK, Weizmann Institute of Science, JEFFREY B. NEATON, Lawrence Berkeley National Lab — Molecule-metal interfaces are ubiquitous in nanoscale functional materials and energy related applications. Characterizing the electronic structure at molecule-metal interfaces, especially the level alignment between molecular frontier orbitals and the Fermi level of the combined system, is crucial for understanding charge dynamics. Density functional theory (DFT) has been successful in computing binding geometries and adsorption energies, but much less successful in predicting level alignment. This is because the latter depends on quasiparticle excitation energies, typically believed to be outside the reach of DFT. In this work, we apply the recently developed optimally-tuned range-separated hybrid functional to the electronic structure of a model molecule-metal interface - benzene on graphite - and elucidate parameters leading to agreement with experiment and with many-body perturbation theory.

**4:30PM H31.00009 Chemically accurate description of aromatic rings interaction using quantum Monte Carlo**, SAM AZADI, Department of Physics and Thomas Young Centre, University College London — We present an accurate study of interactions between benzene molecules using wave function based quantum Monte Carlo (QMC) methods [1]. We compare our QMC results with density functional theory (DFT) using various van der Waals (vdW) functionals. This comparison enables us to tune vdW functionals. We show that highly optimizing the wave function and introducing more dynamical correlation into the wave function are crucial to calculate the weak chemical binding energy between benzene molecules. The good agreement among our results, experiments and quantum chemistry methods, is an important sign of the capability of the wave function based QMC methods to provide accurate description of very weak intermolecular interactions based on vdW dispersive forces. [References:1] Sam Azadi, and R. E. Cohen, J. Chem. Phys. **143**, 104301 (2015).

**4:42PM H31.00010 Study of a Quantum Dot in an Excited State**, MARLINA SLAMET, Sacred Heart University, VIRAH T SAHNI, CUNY-Brooklyn Coll — We have studied the first excited singlet state of a quantum dot via quantum density functional theory (QDFT). The quantum dot is represented by a 2D Hooke's atom in an external magnetostatic field. The QDFT mapping is from an excited singlet state of this interacting system to one of noninteracting fermions in a singlet ground state. The results of the study will be compared to (a) the corresponding mapping<sup>1</sup> from a ground state of the quantum dot and (b) to the similar mapping<sup>2</sup> from an excited singlet state of the 3D Hooke's atom. <sup>1</sup> T. Yang, X.-Y. Pan, and V. Sahni, PRA **83**, 042518 (2011) <sup>2</sup> M. Slamet and V. Sahni, IJQC **85**, 436 (2001)

**4:54PM H31.00011 First-principles photoemission spectroscopy in DNA and RNA nucleobases from Koopmans-compliant functionals**, NGOC LINH NGUYEN, Theory and Simulations of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), EPFL, GIOVANNI BORGHI, ANDREA FERRETTI, Centro S3, CNR-Istituto Nanoscienze, 41125 Modena, Italy, NICOLA MARZARI, Theory and Simulations of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), EPFL — The determination of spectral properties of the DNA and RNA nucleobases from first principles can provide theoretical interpretation for experimental data, but requires complex electronic-structure formulations that fall outside the domain of applicability of common approaches such as density-functional theory. In this work, we show that Koopmans-compliant functionals [1], constructed to enforce piecewise linearity in energy functionals with respect to fractional occupation-i.e., with respect to charged excitations-can predict not only frontier ionization potentials and electron affinities of the nucleobases with accuracy comparable or superior with that of many-body perturbation theory and high-accuracy quantum chemistry methods, but also the molecular photoemission spectra are shown to be in excellent agreement with experimental ultraviolet photoemission spectroscopy data. The results highlight the role of Koopmans-compliant functionals as accurate and inexpensive quasiparticle approximations to the spectral potential, which transform DFT into a novel dynamical formalism where electronic properties, and not only total energies, can be correctly accounted for. Reference [1] N.L. Nguyen et al., PRL (2015).

**5:06PM H31.00012 van der Waals Density Functional Theory vdW-DFq for Semihard Materials<sup>1</sup>**, QING PENG, SUVVANU DE, Rensselaer Polytechnic Institute — There are a large number of materials with mild stiffness, which are not as soft as tissues and not as strong as metals. These semihard materials includes energetic materials, molecular crystals, layered materials, and van der Waals crystals. The integrity and mechanical stability are mainly determined by the interactions between instantaneously induced dipoles, the so called London dispersion force or van der Waals force. It is challenging to accurately model the structural and mechanical properties of these semihard materials in the frame of density functional theory where the non-local correlation functionals are not well known. Here we propose a van der Waals density functional named *vdW-DFq* to accurately model the density and geometry of semihard materials. Using  $\beta$ -cyclotetramethylene tetranitramine as a prototype, we adjust the enhancement factor of the exchange energy functional with generalized gradient approximations. We find this method to be simple and robust over a wide tuning range when calibrating the functional on-demand with experimental data. With a calibrated value  $q = 1.05$ , the proposed *vdW-DFq* method shows good performance in predicting the geometries of 11 common energetic material molecular crystals and 3 typical layered van der Waals crystals.

<sup>1</sup>The authors would like to acknowledge the generous financial support from the Defense Threat Reduction Agency (DTRA) Grant HDTRA1-13-1-0025

**5:18PM H31.00013 A non-empirical, parameter-free, hybrid functional for accurate calculations of optoelectronic properties of finite systems<sup>1</sup>**, NICHOLAS BRAWAND, Institute for Molecular Engineering, University of Chicago, MÁRTON VÖRÖS, Materials Science Division, Argonne National Laboratory and Institute for Molecular Engineering, University of Chicago, MARCO GOVONI, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — The accurate prediction of optoelectronic properties of molecules and solids is a persisting challenge for current density functional theory (DFT) based methods. We propose a hybrid functional where the mixing fraction of exact and local exchange is determined by a non-empirical, system dependent function. This functional yields ionization potentials, fundamental and optical gaps of many, diverse systems in excellent agreement with experiments, including organic and inorganic molecules and nanocrystals. We further demonstrate that the newly defined hybrid functional gives the correct alignment between the energy level of the exemplary TTF-TCNQ donor-acceptor system.

**Tuesday, March 15, 2016 2:30PM - 5:30PM –**  
**Session H32 DCP: Theoretical Modeling of Materials for Solar Energy Conversion** 332 - Giulia Galli, University of Chicago

**2:30PM H32.00001 Predicting materials for solar energy conversion: ab-initio spectroscopy of heterogeneous interfaces**, GIULIA GALLI, University of Chicago — We will discuss some progress in predicting materials for solar energy conversion using ab initio calculations, in particular we will focus on heterogeneous interfaces between photo-electrodes and water and between nanocomposites. We will also address the problem of building much needed tighter connections between computational and laboratory experiments.

**3:06PM H32.00002 Ultrafast carrier dynamics in BiVO<sub>4</sub> thin film photoanode material: time-resolved THz spectroscopic study.**, WESLEY BELLEMAN, Department of Physics, Worcester Polytechnic Institute, L. ZHOU, B. GIRI, Department of Mechanical Engineering, Worcester Polytechnic Institute, B.J. DRINGOLI, Department of Physics, Worcester Polytechnic Institute, P.M. RAO, Department of Mechanical Engineering, Worcester Polytechnic Institute, L.V. TITOVA, Department of Physics, Worcester Polytechnic Institute — Recent demonstrations of 3% solar conversion efficiency in thin film BiVO<sub>4</sub> make it a promising photoanode material for photoelectrochemical water oxidation [1]. With a bandgap of 2.4 eV, it strongly absorbs UV and visible light up to 520 nm. However, its efficiency is limited by extremely poor carrier mobility, with values from 0.01 to 1 cm<sup>2</sup>/Vs reported in the literature, and often attributed to formation of small polarons [2]. The precise nature of conductivity in BiVO<sub>4</sub> is, however, not well-established. We use time-resolved terahertz (THz) spectroscopy as a non-contact probe of microscopic photoconductivity of a 100 nm-thick BiVO<sub>4</sub> film. THz spectroscopy allows probing the dynamics of photo-injected carriers over nanometer length scales, and thus provides insight about transport of carriers inside the 100-200 nm grains. We find that intra-grain mobility may be as much as several orders of magnitude higher than macroscopic mobility that is affected by the grain boundaries. References [1] P. M. Rao et al., Nano Lett. 14, 1099 (2014) [2] A.J.E. Rettie et al., Appl. Phys. Lett. 106, 022106 (2015).

**3:18PM H32.00003 Emerging materials with novel electronic properties for solar light harvesting and conversion**, IFFAT NAYYAR, TIFFANY KASPAR, MARTIN MCBRIARTY, SARA CHAMBERLIN, NIRANJAN GOVIND, SCOTT CHAMBERS, PETER SUSHKO, Pacific Northwest National Laboratory, Richland, WA — The optical absorption and electronic transport in complex oxides can be tuned by judicious selection of the lattice structure and control of chemical composition and prevalent oxidation state of the transition metal species. Optical spectra for solid solutions of metal oxides are complex; we focus on revealing the electronic structure and orbital nature of the transitions, which is crucial for rational materials design. We applied state-of-the-art *ab initio* methods, including time-dependent DFT, to screen thermodynamically favorable configurations and determine the effects of the local environment on the transition energies and relative intensities. Here we focus on the magnetite-type Fe<sub>3-x</sub>Cr<sub>x</sub>O<sub>4</sub> mixed spinel solid-solutions, which can only be doped to  $x \leq 2$ , since Cr strongly prefers to occupy octahedral sites. In the interval of  $0 \leq x \leq 2$ , the electronic structure of Fe<sub>3-x</sub>Cr<sub>x</sub>O<sub>4</sub> undergoes transformations resulting in several qualitatively different types of optical transitions sensitive to the Cr concentration. We find the lowest band gap and high room-temperature conductivity, in agreement with experiment, for  $x=1$  (Fe<sub>2</sub>CrO<sub>4</sub>), and attribute this conductivity to the thermally-driven electron hopping between the octahedral-site Fe<sup>2+</sup> and tetrahedral-site Fe<sup>3+</sup>. We compare Fe<sub>3-x</sub>Cr<sub>x</sub>O<sub>4</sub> with the corundum  $\alpha$ -(Fe<sub>1-x</sub>Cr<sub>x</sub>)<sub>2</sub>O<sub>3</sub> and  $\alpha$ -(Fe<sub>1-x</sub>V<sub>x</sub>)<sub>2</sub>O<sub>3</sub>, where electron transfer from the Cr and V 3d to the unoccupied Fe 3d\* orbitals reduces the band gap to 1.6 and 0.6 eV (from 2.1 eV in  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>).

**3:30PM H32.00004 New quaternary semiconductor Cu<sub>2</sub>MgSnS<sub>4</sub> and Cu<sub>2</sub>MgSnSe<sub>4</sub> for photovoltaics<sup>1</sup>**, KINFAL TSE, Chinese Univ of Hong Kong, GUOHUA ZHONG, Chinese Academy of Sciences, Shenzhen, YIYOU ZHANG, Chinese Univ of Hong Kong, XIAO GUANG LI, CHUNLEI YANG, Chinese Academy of Sciences, Shenzhen, JUNYI ZHU, Chinese Univ of Hong Kong, ZHI ZENG, Chinese Academy of Sciences, Hefei, ZHENYU ZHANG, University of Science and Technology of China, Hefei, XUDONG XIAO, Chinese Univ of Hong Kong — Element substitution of Zn by Mg and Ca is attempted to overcome the problem of potential fluctuation in Cu<sub>2</sub>ZnSnS<sub>4</sub> and Cu<sub>2</sub>ZnSnSe<sub>4</sub> (CZTSs) due to prevalence of Cu<sub>Zn</sub>+Zn<sub>Cu</sub> defect complex. Through density function theory calculation with hybrid functional, we have shown that Cu<sub>2</sub>MgSnS<sub>4</sub> and Cu<sub>2</sub>MgSnSe<sub>4</sub> (CMTSs) are stable with respect to secondary phases considered under suitable chemical potential. Stannite CMTSs is thermodynamically more favorable over the kesterite structure. The alternating Cu and Mg/Sn cation layer of stannite structure may suppress the formation of Mg<sub>Cu</sub> antisite due to large stress induced. The electronic and optical properties of CMTSs are similar to that of CZTSs with comparable absorption coefficient at the band-edge suggests CMTSs to be a promising photovoltaic material.

<sup>1</sup>The work was supported by the National Major Science Research Program of China under Grant no. 2012CB933700, the Natural Science Foundation of China (Grant nos. 61274093, 61574157, 11274335, 11504398, 51302303, and 51474132), and the Shenzhen Basic Research

**3:42PM H32.00005 Controlling defects and secondary phases of CZTS by surfactant Potassium<sup>1</sup>**, JUNYI ZHU, YIOU ZHANG, KINFAT TSE, XUDONG XIAO, Department of Physics, Chinese University of Hong Kong — Cu<sub>2</sub>ZnSnS<sub>4</sub> (CZTS) is a promising photovoltaic absorber material with earth abundant and nontoxic elements. However, the detrimental native defects and secondary phases of CZTS will largely reduce the energy conversion efficiencies. To understand the origin of these problems during the growth of CZTS, we investigated the kinetic processes on CZTS (-1-1-2) surface, using first principles calculations. A surface Zn atom was found to occupy the subsurface Cu site easily due to a low reaction barrier, which may lead to a high ZnCu concentration and a secondary phase of ZnS. These n-type defects may create deep electron traps near the interface and become detrimental to device performance. To reduce the population of ZnCu and the secondary phase, we propose to use K as a surfactant to alter surface kinetic processes. Improvements on crystal quality and device performance based on this surfactant are consistent with early experimental observations.

**3:54PM H32.00006 Metal Disorder in Cu<sub>2</sub>ZnSnS<sub>4</sub> (CZTS) Solar Cells from Multi-Scale Simulations**, SUZANNE WALLACE, JARVIST FROST, ARON WALSH, University of Bath — Kesterite-structured Cu<sub>2</sub>ZnSnS<sub>4</sub> (CZTS) is a promising earth-abundant and non-toxic material for the active layer of thin-film solar cells due to its high optical absorption coefficient of  $> 10^4 \text{ cm}^{-1}$  and sunlight matched band gap of 1.5 eV. Device efficiencies are hampered by low open circuit voltage ( $V_{OC}$ ) compared to the optical band gap. One possible origin of this is disorder amongst the Cu and Zn ions. Such disorder could lead to sub band-gap recombination centres due to fluctuations in electrostatic potential from the presence of charged defects. Understanding the origin of these sub-gap states, and the resulting impediment on device performance, is essential to discover design and processing rules for high efficiency kesterite, and other multi-component semiconductor, devices. We investigate this by writing custom Monte-Carlo codes to simulate the on-lattice disorder. A generalised Ising Hamiltonian is parameterised with hybrid density functional theory (DFT) total-energy calculations on defect pairs. The resulting disorder is simulated as a function of temperature, and the order-disorder behaviour and resulting local and long-range electrostatic potential variation due to Cu-Zn disorder is quantified.

**4:06PM H32.00007 First principles investigations on the stability and catalytic reactivity of Cu<sub>2</sub>O surfaces**, LIANG LI, YIMIN WU, TIJANA RAJH, IAN MCNULTY, ZHONGHOU CAI, JEFF GUEST, YUZI LIU, MARIA CHAN, Argonne National Laboratory — Cu<sub>2</sub>O is an attractive candidate as a next-generation photocatalyst for CO<sub>2</sub> reduction because of its high solar spectrum absorption coefficient and small electron affinity. It is observed experimentally, by Electron Paramagnetic Resonance (EPR) and Scanning x-ray fluorescence microscopy (SXFEM), that the surface Cu atoms have various oxidation states, and different sites have different affinities for CO<sub>2</sub> and intermediate products. In this work, we employ first principles density functional theory (DFT) calculations to calculate the free energies of various low-index Cu<sub>2</sub>O surfaces and further identify the change of surface Cu oxidation states upon the creation of surface defects and during the photocatalytic process. The reactivity of Cu<sub>2</sub>O surfaces with various defect types and concentrations are also predicted.

**4:18PM H32.00008 *Ab initio* electron paramagnetic resonance study of 3C-SiC/SiO<sub>2</sub> interfaces in SiC-nanofiber based solar cells<sup>1</sup>**, TAUFIK ADI NUGRAHA, Max-Planck-Institut fuer Eisenforschung, UWE GERSTMANN, WOLFGANG GERO SCHMIDT, University of Paderborn, STEFAN WIPPERMANN, Max-Planck-Institut fuer Eisenforschung — Semiconducting nanocomposites, e. g. hybrid materials based on inorganic semiconducting 3C-SiC nanofibers and organic surfactants, provide genuinely novel pathways to exceed the Shockley-Queisser limit for solar energy conversion. The synthesis of such functionalized fibers can be performed completely using only inexpensive wet chemical solution processing. During synthesis a thin passivation layer is introduced between the SiC-fiber and surfactants, e. g. the native oxide, whose atomistic details are poorly understood. In this study, we utilize unpaired spins in interfacial defects to probe the local chemical environment with *ab initio* EPR (Electron Paramagnetic Resonance) calculations, which can be directly compared to experiment. Considering a wide variety of possible interfacial structures, a grand canonical approach is used to generate a phase diagram of the 3C-SiC/SiO<sub>2</sub> interface as a function of the chemical potentials of Si, O and H, to provide favorable interfacial structures for *g*-tensor calculations. This study provides directions about specific types of interfacial defects and their impact on the electronic properties of the interface. The authors wish to thank S. Greulich-Weber for helpful discussions.

**4:30PM H32.00009 Porphyrin-based polymeric nanostructures for light harvesting applications: *Ab initio* calculations**, WALTER ORELLANA<sup>1</sup>, Universidad Andres Bello — The capture and conversion of solar energy into electricity is one of the most important challenges to the sustainable development of mankind. Among the large variety of materials available for this purpose, porphyrins concentrate great attention due to their well-known absorption properties in the visible range. However, extended materials like polymers with similar absorption properties are highly desirable. In this work, we investigate the stability, electronic and optical properties of polymeric nanostructures based on free-base porphyrins and phthalocyanines (H<sub>2</sub>P, H<sub>2</sub>Pc), within the framework of the time-dependent density functional perturbation theory. The aim of this work is the stability, electronic, and optical characterization of polymeric sheets and nanotubes obtained from H<sub>2</sub>P and H<sub>2</sub>Pc monomers. Our results show that H<sub>2</sub>P and H<sub>2</sub>Pc sheets exhibit absorption bands between 350 and 400 nm, slightly different than the isolated molecules. However, the H<sub>2</sub>P and H<sub>2</sub>Pc nanotubes exhibit a wide absorption in the visible and near-UV range, with larger peaks at 600 and 700 nm, respectively, suggesting good characteristic for light harvesting. The stability and absorption properties of similar structures obtained from ZnP and ZnPc molecules is also discussed.

**4:42PM H32.00010 Fundamental Insights into Aqueous Electrochemical Reduction of CO<sub>2</sub> on the Ligand-Protected Charged Au<sub>25</sub> Clusters**, DOMINIC ALFONSO, DOUGLAS KAUFFMAN, CHRISTOPHER MATRANGA, National Energy Technology Laboratory - Department of Energy, MATERIALS FUNDAMENTAL TEAM — Recent breakthroughs in electrochemical studies in our group showed aqueous CO<sub>2</sub> reduction to CO on atomically precise, inherently charged Au<sub>25</sub> clusters occurring at low overpotentials. Using first-principles density functional theory and continuum solvation models, the role of the cluster in the reduction process was examined. Free energies of species that were proposed as intermediates in its mechanism were determined. Contrary to previous assumptions, our results show that the fully ligand protected version of the cluster can be ruled out as an active participant. In particular, COOH species on the intact cluster should not be expected to form unless very high potentials are applied. Instead, the calculations suggest that the reduction process would likely occur on a dehiolated gold site. These findings point to the crucial role of such reaction center on the Au<sub>25</sub> clusters in facilitating the CO<sub>2</sub> conversion via the formation of low energy COOH intermediates.

**4:54PM H32.00011 First principle simulations of a bias-dependent electrochemical cell<sup>1</sup>**, LUANA PEDROZA, Univ Federal do ABC, Brazil, PEDRO BRANDIMARTE, CFM CSIC-UPV/EHU and DIPC, Spain, MARIVI FERNANDEZ-SERRA, Stony Brook University, USA, ALEXANDRE R. ROCHA, IFT-UNESP, Brazil — Understanding the local structure of water molecules at the interfaces of metallic electrodes is a key problem in many electrochemical problems. Notably the system is under an external potential bias, which makes the task of simulating this setup difficult. To correctly compute the effect of an external bias potential applied to electrodes, we combine density functional theory and non-equilibrium Green's functions methods, with and without van der Waals interactions. In this work, we apply this methodology to study the electronic properties and forces of water molecules at the interface of different metallic electrodes. We find that the water molecule is sensitive to the sign and magnitude of the applied bias. We also show that it changes the position and orientation of the most stable configuration indicating that the external bias plays an important role in the structural properties of the interface.

**5:06PM H32.00012 Photoemission spectra of aqueous solutions of salts from many-body perturbation theory<sup>1</sup>**, ALEX P. GAIDUK, JONATHAN H. SKONE, MARCO GOVONI, GIULIA GALLI, University of Chicago — The computational design of electrode materials for energy conversion and storage processes requires an accurate description of the energy levels of the electrolyte and of electrolyte/electrode interfaces. Conventional density-functional approximations are in general not well suited for this task as they yield inaccurate orbital energies. Many-body perturbation theory (MBPT) predicts vertical ionization potentials and energy gaps in better agreement with experiments, providing the possibility for an accurate description of the electronic properties of electrolytes. We coupled *ab initio* molecular dynamics [1] with MBPT calculations [2] to investigate the photoemission spectra of a 1 M aqueous solution of NaCl. For the first time we were able to determine the absolute positions of the spectra peaks, with excellent agreement with experiments for both the solute and solvent peak positions. The best results were obtained using wavefunctions obtained from dielectric-dependent [3] hybrid calculations as a starting point for MBPT.

**5:18PM H32.00013 Coupled experimental and theoretical study of photon absorption and charge transport in BiVO<sub>4</sub> photoanodes for solar water splitting<sup>1</sup>**, YUAN PING, California Institute of Technology, TAE WOO KIM, University of Wisconsin, Madison, GIULIA GALLI, University of Chicago, KYOUNG-SHIN CHOI, University of Wisconsin, Madison — Bismuth vanadate (BiVO<sub>4</sub>) has been identified as one of the most promising photoanode materials for water-splitting photoelectrochemical cells. The major limitations of BiVO<sub>4</sub> are its relatively wide bandgap ( 2.5 eV) and low electron mobility ( 0.2 cm<sup>2</sup>V<sup>-1</sup>S<sup>-1</sup>), which limit its solar-to-hydrogen conversion efficiency. In this talk we will present the results of a coupled experimental and *ab initio* theoretical study showing that nitrogen doping together with extra oxygen vacancies lead to both a reduction of BiVO<sub>4</sub> band gap and to an increase of the majority carrier density and mobility. In turn these improvements lead to the applied bias photon-to-current efficiency over 2%, a record for a single oxide photon absorber, to the best of our knowledge[1]. The codoping method adopted in our work could also be applied to simultaneously enhance photon absorption and charge transport in other oxides, providing new possibilities for photocatalytic materials. **2:30PM H33.00001 Simulation of chain diffusion in diblock copolymer microstructures using dynamical self-consistent mean-field theory**, DOUGLAS GRZETIC, ROBERT WICKHAM, University of Guelph — We simulate chain diffusion in ordered phases of a diblock copolymer melt, using our recently-developed dynamical self-consistent mean-field theory [*J. Chem. Phys.* **140**, 244907 (2014)]. This theory enables us to study large length and time scales in these dense systems, while remaining connected, in a self-consistent manner, to the microscopic physics of Brownian chains whose beads interact via a species-dependent modified Lennard-Jones potential. In the LAM and HEX phases, chain diffusion perpendicular to the microdomain interface is exponentially suppressed with increasing segregation, while parallel diffusion is unaffected. In the BCC phase, diffusion is isotropic and is gradually suppressed with increasing segregation. Chain diffusion is also isotropic in the gyroid phase, but does not vanish with increasing segregation. Instead, the diffusion constant asymptotes to a value consistent with chain diffusion being restricted to the interface of the three-dimensional gyroid network of struts, characterized by a network tortuosity value of 1.72. Finally, we measure the out-of-equilibrium evolution of the anisotropy in the chain diffusion as metastable LAM transforms to stable HEX over long times.

**2:42PM H33.00002 Effects of Structured Ionomer Interfaces on Water Diffusion: Molecular Dynamics Simulation Insight<sup>1</sup>**, DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY GRETT, Sandia National Laboratory — The dynamics of solvent molecules across structured ionomers interfaces is crucial to innovative technologies with selective controlled transport. These polymers consist of ionizable blocks facilitating transport tethered to mechanical stability enhancing ones, where their incompatibility drives compounded interfaces. Here water penetration through the interface of an A-B-C-B-A co-polymer is probed by atomistic molecular dynamics simulations where C is a randomly sulfonated polystyrene with sulfonation fractions  $f = 0$  to 0.55, B is poly (ethylene-r-propylene) and A is poly (t-butyl styrene). For  $f > 0$ , a two-step process with slow diffusion at the early stages is observed where water molecules transverse the hydrophobic rich surface before reaching the hydrophilic regime. Water molecules then diffuse along the percolating network of the ionic center block. Increasing the temperature and sulfonation fraction enhances both the rate of diffusion and the overall water uptake.

**2:54PM H33.00003 Towards a Modeling Framework for Thermodynamics and Transport Coefficients in Polyelectrolyte Assemblies**, RONALD LARSON, ALI SALEHI, University of Michigan — A continuum description of polyelectrolyte (PE) equilibrium gelation, and the kinetics of assembly is developed, accounting for PE chain diffusion, complexation, network relaxation is reported here. Using a combination of Flory-Huggins and Flory-Rehner free energy model, an upper-convected Maxwell model to describe polyelectrolyte gel stress and relaxation, and a Poisson equation for the electrostatic potential profiles, we develop a model that can account for both equilibrium properties of PE gels and for transport of PE's and ions during layer-by-layer assembly. As PE chains diffuse, counterions readjust themselves to minimize the net local charge, but fail to do so completely as they would have to pay a significant entropic penalty. Diffusion of PE chains predominantly driven by the electrostatic field induced by the entropy of counterions is characterized by pulse-like PE composition profiles. Even without considering chain complexation, we demonstrate that it is possible to at least qualitatively explain the non-monotonic variation of PEM growth kinetics versus salt concentration, observed experimentally.

**3:06PM H33.00004 Topological Constraints in Directed Polymer Melts**, ADAM NAHUM<sup>1</sup>, Massachusetts Institute of Technology, PABLO SERNA, University of Oxford, GUY BUNIN, Massachusetts Institute of Technology — Polymers in a melt may be subject to topological constraints, as in the example of unlinked polymer rings. How to do statistical mechanics in the presence of such constraints remains a fundamental open problem. We study the effect of topological constraints on a melt of directed polymers, using simulations of a simple quasi-2D model. We find that fixing the global topology of the melt to be trivial drastically changes both the static and dynamic properties. Polymers wander in the transverse direction by a distance which is only logarithmic in their length, and monomers subdiffuse logarithmically slowly. This is in sharp contrast to expectations from existing theories. To cast light on the suppression of the strands' wandering, we also analyse the topological complexity of subregions of the melt, finding it is also logarithmically small. We comment on insights the results give for 3D melts, directed and non-directed.

**3:18PM H33.00005 Scaling of viscosity with rate, pressure, and temperature: Linking simulations to experiments**<sup>1</sup>, VIKRAM JADHAO, MARK ROBBINS, The Johns Hopkins University — Elastohydrodynamic lubrication (EHL) is important in many practical devices and produces extreme pressures ( $> 1$  GPa) and shear rates ( $10^5 - 10^7$  s<sup>-1</sup>). This makes EHL fluids ideal candidates for bridging the gap between experimental and simulation studies of viscosity. There is an ongoing debate about whether the high-rate response of simple molecules like squalane follows a power-law Carreau model or a thermal activation based Eyring model. We use molecular dynamics simulations to investigate the rheological response of squalane for a wide range of rates ( $10^5 - 10^{10}$  s<sup>-1</sup>), pressures (0.1 MPa to 3 GPa), and temperatures (100 – 313 K). We find that experimental and theoretical results can be collapsed onto a master curve consistent with Eyring theory over more than 20 orders of magnitude in rate. Extrapolating Eyring fits to simulations at  $10^7$  s<sup>-1</sup> and above yields Newtonian viscosities  $\eta_0$  that are consistent with available low-rate experiments, and allows predictions to much higher pressures and lower temperatures. There is no indication of a diverging viscosity at finite stress, since  $\log \eta_0$  rises sublinearly with pressure up to 6 GPa and  $\eta_0 > 10^{12}$  Pa-s. Correlations between chain conformations and Eyring parameters are also presented.

**3:30PM H33.00006 Unified force-level theory of multiscale transient localization and emergent elasticity in polymer solutions and melts**, ZACHARY E. DELL, KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign — A unified, microscopic, theoretical understanding of polymer dynamics in concentrated liquids from segmental to macromolecular scales remains an open problem. We have formulated a statistical mechanical theory for this problem that explicitly accounts for intra- and inter-molecular forces at the Kuhn segment level. The theory is self-consistently closed at the level of a matrix of dynamical second moments of a tagged chain. Two distinct regimes of isotropic transient localization are predicted. In semidilute solutions, weak localization is predicted on a mesoscopic length scale between segment and chain scales which is a power law function of the invariant packing length. This is consistent with the breakdown of Rouse dynamics and the emergence of entanglements. The chain structural correlations in the dynamically arrested state are also computed. In dense melts, strong localization is predicted on a scale much smaller than the segment size which is weakly dependent on chain connectivity and signals the onset of glassy dynamics. Predictions of the dynamic plateau shear modulus are consistent with the known features of emergent rubbery and glassy elasticity. Generalizations to treat the effects of chemical crosslinking and physical bond formation in polymer gels are possible.

**3:42PM H33.00007 Failure of Tube Models to Predict the Linear Rheology of Star/Linear Blends**, RYAN HALL, PRIYANKA DESAI, University of Michigan, BEOMGOO KANG, University of Tennessee, MARIA KATZAROVA, Illinois Institute of Technology, QIFAN HUANG, University of Michigan, SANGHOON LEE, TAIHYUN CHANG, Pohang University of Science and Technology, DAVID VENERUS, Illinois Institute of Technology, JIMMY MAYS, University of Tennessee, JAY SCHIEBER, Illinois Institute of Technology, RONALD LARSON, University of Michigan — We compare predictions of two of the most advanced versions of the tube model, namely the Hierarchical model by Wang et al. (J. Rheol. 54:223, 2010) and the BOB (branch-on-branch) model by Das et al. (J. Rheol. 50:207-234, 2006), against linear viscoelastic data on blends of monodisperse star and monodisperse linear polybutadiene polymers. The star was carefully synthesized/characterized by temperature gradient interaction chromatography, and rheological data in the high frequency region were obtained through time-temperature superposition. We found massive failures of both the Hierarchical and BOB models to predict the terminal relaxation behavior of the star/linear blends, despite their success in predicting the rheology of the pure star and pure linear. This failure occurred regardless of the choices made concerning constraint release, such as assuming arm retraction in fat or skinny tubes, or allowing for disentanglement relaxation to cut off the constraint release Rouse process at long times. The failures call into question whether constraint release can be described as a combination of constraint release Rouse processes and dynamic tube dilation within a canonical tube model of entanglement interactions.

**3:54PM H33.00008 Challenging Slip-Link Models: Predicting the Linear Rheology of 1,4-Polybutadiene Blends of Well-Characterized Star and Linear 1,4-Polybutadienes**, MARIA KATZAROVA, Illinois Institute of Technology, PRIYANKA DESAI, University of Michigan, BEOMGOO KANG, University of Tennessee, RYAN HALL, QIFAN HUANG, University of Michigan, SANGHOON LEE, TAIHYUN CHANG, Pohang University of Science and Technology, DAVID VENERUS, Illinois Institute of Technology, JIMMY MAYS, University of Tennessee, JAY SCHIEBER, Illinois Institute of Technology, RONALD LARSON, University of Michigan — The discrete slip-link model (DSM) is a single-chain mean-field model for entanglement-dominated polymer dynamics. The model has been used successfully to make predictions about the linear and nonlinear rheology of monodisperse homopolymer melts, polydisperse melts, or blends. By using recent advances in coarse-graining, hierarchical modeling, and graphics processors, the model is amenable to predictions of well-entangled branched polymers. Here, the parameters of the most coarse-grained member of the hierarchy are fit to the dynamic modulus of monodisperse linear chains and applied to symmetric 4-arm polybutadiene (PBd) star-linear blends with roughly 20 entanglements per star arm, but with no parameter adjustment. Agreement with data is quantitative. This detailed model is further used to examine assumptions and approximations typically made in tube models for blending, including factorization in the time domain. Failure of these assumptions point towards possible fixes to tube models.

**4:06PM H33.00009 Multiscale simulations of polymer melt flow in an abrupt contraction and expansion channel<sup>1</sup>**, TAKASHI TANIGUCHI, KOHEI HARADA, Department of Chemical Engineering, Kyoto University, T.TANIGUCHI TEAM — We investigated a flow of a polymer melt with a molecular weight distribution in a channel with 4:1:4 contraction and expansion geometry by using a multi-scale simulation (MSS) method here a macroscopic model and microscopic molecular model are directly connected through the velocity gradient field and stress field. In the MSS method, we introduced Lagrangian particles which contain many chains to precisely maintain the microscopic states. As the microscopic polymer model, a slip-link model is used. As a result, we clarified the relation between the macroscopic flow behavior and molecular level information such as a local polymer configuration and spatial distribution of number of entanglements per chain.

**4:18PM H33.00010 Modeling Structure Property Relations and Failure Mechanisms of PPTA Fibers using Reactive Molecular Dynamics<sup>1</sup>**, DUNDAR YILMAZ, Zirve University — Failure mechanisms of poly(p-phenylene terephthalamide (PPTA) under extreme tensile deformation has been studied using reactive potentials with molecular dynamics simulations. Amorphous PPTA systems with different molecular weights generated using an in-house developed amorphous builder. Tensile modulus of amorphous PPTA has been calculated as up to 6.7 GPa. Nitrogen and carbon vacancy defects were introduced to both crystalline and amorphous systems. The tensile modulus of defects-free crystalline PPTA calculated as 350 GPa. Introduction of 5% nitrogen vacancy defects reduced the tensile modulus to 197 GPa. PPTA fibers generated with skin core structure where skin region composed of PPTA chains in crystalline order and core region was composed of unordered PPTA chains vice versa. Relation between ratios of skin and core regions and mechanical properties of the fiber studied. Tensile load was mostly accommodated through stretching of bonds between amide group and phenyl groups. Under extreme tensile deformation PPTA chains failed at these C-N bonds.

<sup>1</sup>TUBITAK GRANT NO: 113F358

**4:30PM H33.00011 Chain Ends and the Ultimate Tensile Strength of Polyethylene Fibers<sup>1</sup>**, THOMAS C. O'CONNOR, MARK O. ROBBINS, Johns Hopkins University — Determining the tensile yield mechanisms of oriented polymer fibers remains a challenging problem in polymer mechanics. By maximizing the alignment and crystallinity of polyethylene (PE) fibers, tensile strengths  $\sigma \sim 6 - 7$  GPa have been achieved. While impressive, first-principal calculations predict carbon backbone bonds would allow strengths four times higher ( $\sigma \sim 20$  GPa) before breaking. The reduction in strength is caused by crystal defects like chain ends, which allow fibers to yield by chain slip in addition to bond breaking. We use large scale molecular dynamics (MD) simulations to determine the tensile yield mechanism of orthorhombic PE crystals with finite chains spanning  $10^2 - 10^4$  carbons in length. The yield stress  $\sigma_y$  saturates for long chains at  $\sim 6.3$  GPa, agreeing well with experiments. Chains do not break but always yield by slip, after nucleation of 1D dislocations at chain ends. Dislocations are accurately described by a Frenkel-Kontorova model, parametrized by the mechanical properties of an ideal crystal. We compute a dislocation core size  $\xi = 25.24 \text{ \AA}$  and determine the high and low strain rate limits of  $\sigma_y$ . Our results suggest characterizing such 1D dislocations is an efficient method for predicting fiber strength.

<sup>1</sup>This research was performed within the Center for Materials in Extreme Dynamic Environments (CMEDE) under the Hopkins Extreme Materials Institute at Johns Hopkins University. Financial support was provided by grant W911NF-12-2-0022.

**4:42PM H33.00012 Microscopic deformation mechanisms in model thermoplastic elastomers by molecular dynamics simulation**, AMANDA PARKER, JÖRG RÖTTLER, University of British Columbia — Thermoplastic elastomers (TPEs) can be formed by exploiting the nanostructured morphology of triblock copolymers. Glassy end-blocks phase separate to form spherical regions which act as physical cross-links for the soft rubbery phase. Molecular dynamics simulations of TPEs allow us to relate the microscopic mechanisms active during plastic deformation to the macroscopic stress response. A coarse-grained bead-spring model of linear ABA triblock copolymers which forms the desired spherical morphology is used for pure stress and pure strain uniaxial deformations. The systems are first equilibrated using a soft pair potential. We observe increased strain hardening in triblocks when compared to homopolymers of the same chain length in accordance with experiments. We connect variations in the stress response for systems of different chain lengths to the non-affine deformation of chains and to the scale of phase separated regions. The stress response is also compared to rubbery elasticity models, taking into account the evolution of chain entanglements during deformation. We observe void formation at the interfaces of glassy regions or where these regions have broken up at large strain.

**4:54PM H33.00013 Computer-Aided Design of Photocured Polymer Networks**, SWARNAVO SARKAR, SHENG LIN-GIBSON, MARTIN CHIANG, NIST - Natl Inst of Stds & Tech — Light-initiated free radical polymerization is widely used for manufacturing biomaterials, scaffolds for micromolding, and is being developed as a method for fast 3D fabrication. This process has a large set of control parameters in the composition of the photocurable matrix and the photocuring conditions. But a quantitative map between the choice of parameters and the properties of the resultant polymer is currently unavailable. We present a computational approach to simulate the growth of a polymer network using the stochastic differential equations of reactions and diffusion for a photocuring system. This method allows us to sample trajectories of a growing polymer network in silico. Thus, we provide a computational alternative to synthesize and probe a polymer network for properties like the degree of conversion, structure factor, density of states, and viscosity. We present simulation results that agree with the universal features observed in photopolymerization. Our proposed method enables a thorough and systematic search over the entire parameter space to discover interesting combinations for synthesis.

**5:06PM H33.00014 Molecular Description of Yield in Densely Crosslinked Epoxy Thermosets**, SANDIPAN CHATTARAJ, Centre for Research in Nanotechnology and Science, Indian Inst of Tech-Bombay, PRITA PANT, Metallurgical Engineering and Materials Science, Indian Inst of Tech-Bombay, DNYANESH PAWASKAR, Department of Mechanical Engineering, Indian Inst of Tech-Bombay, HEMANT NANAVATI, Department of Chemical Engineering, Indian Inst of Tech-Bombay — In densely crosslinked networks, macroscopic yield is a transition from deformations of bond lengths and angles, to cooperative deformation of multiple effective network chains via bond torsions. In this work, we examine this yield in terms of the "activation number",  $\nu$ , of microscopic effective chains between crosslinks.  $\nu$  is the number of effective network chains, in one Eyring activation volume,  $V^*$ . It is thus a measure of the number of network chains activated at yield, for cooperative deformation. Microcompression experiments have been performed on SU-8 micropillars, to determine its  $V^*$  value. SU-8 is an important epoxy thermoset, which is used extensively in the microelectronics industry, in microfluidics and microelectromechanical systems (MEMS). The effective chain length based on Arruda and Boyce's 8-chain model, compares well with the rms length, obtained by chain conformer analyses. We find that  $\nu \sim 2-4$ , at room temperature, for DGEBA-based epoxies including SU-8 and DGEBA-amine networks, over a range of network junction functionalities and  $V^*$ . That  $\nu$  corresponds very well with the reduced temperature,  $T/T_g$ , also demonstrates its viability as a molecular descriptor of yield in densely crosslinked thermosets.

**5:18PM H33.00015 Toward a predictive model for elastomer seals.** , NICOLA MOLINARI, MUSAB KHAWAJA, ADRIAN SUTTON, ARASH MOSTOFI, Department of Physics and the Thomas Young Centre for Theory and Simulation of Materials, Imperial College London, UK — Nitrile butadiene rubber (NBR) and hydrogenated-NBR (HNBR) are widely used elastomers, especially as seals in oil and gas applications. During exposure to well-hole conditions, ingress of gases causes degradation of performance, including mechanical failure. We use computer simulations to investigate this problem at two different length and time-scales. First, we study the solubility of gases in the elastomer using a chemically-inspired description of HNBR based on the OPLS all-atom force-field. Starting with a model of NBR, C=C double bonds are saturated with either hydrogen or intramolecular cross-links, mimicking the hydrogenation of NBR to form HNBR. We validate against trends for the mass density and glass transition temperature for HNBR as a function of cross-link density, and for NBR as a function of the fraction of acrylonitrile in the copolymer. Second, we study mechanical behaviour using a coarse-grained model that overcomes some of the length and time-scale limitations of an all-atom approach. Nanoparticle fillers added to the elastomer matrix to enhance mechanical response are also included. Our initial focus is on understanding the mechanical properties at the elevated temperatures and pressures experienced in well-hole conditions.

**Session H34 GSOFD DBIO GSNP/DFD: Active Matter V** 337 - Erik Luijten, Northwestern University

**2:30PM H34.00001 Active colloids propelled by induced-charge electrophoresis** , MING HAN, ERIK LUIJTEN, Northwestern University — Populations of motile organisms exhibit a variety of collective behaviors, ranging from bacterial colony formation to the flocking of birds. Current understanding of these active motions, which are typically far from equilibrium and based on the collective behavior of self-propelled entities, is far from complete. One approach is to reproduce these observations in systems of synthetic active colloids. However, one of the standard self-propulsion mechanisms, induced-charge electrophoresis (ICEP) of a dielectric Janus colloid remains not fully understood by itself, especially the strong dependence of the resultant particle motion on the frequency of the external field. Resolution of this outstanding problem requires detailed study of the time-resolved dielectric response of the colloid and the dynamics of the electric double layer. Through molecular dynamics simulations coupled with an efficient dielectric solver, we elucidate the underlying mechanism of the frequency dependence of ICEP and the polarization of a metalodielectric Janus colloid.

**2:42PM H34.00002 Driving magnetic colloidal polymers<sup>1</sup>** , JOSHUA DEMPSTER, Northwestern University, MONICA OLVERA DE LA CRUZ, Northwestern University Department of Materials Science — Magnetic colloids are of growing interest for applications such as drug delivery and in vitro tissue growth. Recent experiments have synthesized 1D chains of magnetic colloids into permanent colloidal polymers. We study magnetic colloidal polymers theoretically and computationally under the influence of time-varying external fields and find a rich set of controllable, dynamic conformations. By iterating through a sequence of conformations, these polymers can perform mechanical functions. We discuss possible roles for these polymers beyond those considered for single colloids.

<sup>1</sup>This work was supported as part of the Center for Bio-Inspired Energy Science, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0000989

**2:54PM H34.00003 Broken detailed balance observed for hydrodynamically coupled colloidal particles in two optical traps** , CHRISTOPH F. SCHMIDT, JANNES GLADROW, Universitt Gttingen, NIKTA FAKHRI, Massachusetts Institute of Technology, CHASE P. BROEDERSZ, Ludwig-Maximilians-Universitt Mnchen — Optical traps can be approximated as harmonic potentials for refractile colloidal particles. If two particles are trapped by two optical traps at close distance, particles remain hydrodynamically coupled. With two traps at different laser powers, one can create a non-equilibrium situation, where one particle can feed energy to the other particle. We show that this situation leads to the breaking of detailed balance that can be visualized as finite flux in a coarse-grained phase space spanned by the displacements of the two particles. We test if the slight temperature difference caused by different laser powers drives the flux or if it is due to energy dissipation associated with scattered light, a second-order effect for non-absorbing particles.

**3:06PM H34.00004 Collective motion in populations of colloidal bots** , DENIS BARTOLO, ENS Lyon — One of the origins of active matter physics was the idea that flocks, herds, swarms and shoals could be quantitatively described as emergent ordered phases in self-driven materials. From a somehow dual perspective, I will show how to engineer active materials out of colloidal flocks. I will show how to motorize colloidal particles capable of sensing the orientation of their neighbors and how to handle them in microfluidic chips. These populations of colloidal bots display a non-equilibrium transition toward collective motion. A special attention will be paid to the robustness of the resulting colloidal flocks with respect to geometrical frustration and to quenched disorder.

**3:42PM H34.00005 Self-similarity in active colloid motion** , COLIN CONSTANT, SERGEY SUKHOV, ARISTIDE DOGARIU, Univ of Central Florida - CREOL — The self-similarity of displacements among randomly evolving systems has been used to describe the foraging patterns of animals and predict the growth of financial systems. At micron scales, the motion of colloidal particles can be analyzed by sampling their spatial displacement in time. For self-similar systems in equilibrium, the mean squared displacement increases linearly in time. However, external forces can take the system out of equilibrium, creating active colloidal systems, and making this evolution more complex. A moment scaling spectrum of the distribution of particle displacements quantifies the degree of self-similarity in the colloid motion. We will demonstrate that, by varying the temporal and spatial characteristics of the external forces, one can control the degree of self-similarity in active colloid motion.

**3:54PM H34.00006 Paramagnetic colloids in rotating fields: from chains through chaos to clusters.<sup>1</sup>** , HAMED ABDI, RASAM SOHEILIAN, RANDALL ERB, CRAIG MALONEY, Northeastern — We present computer simulations and experiments on dilute suspensions of superparamagnetic particles subject to rotating magnetic fields. We focus on short chains of particles and their decay routes to stable structures. At low rate, the chains track the external field. At intermediate rate, the short chains break up but perform a periodic (albeit complex) motion. At sufficiently high rates, the chains generally undergo chaotic motion at short times and decay to either close-packed clusters or more dispersed colloidal “molecules” at long times. We show that the transition out of the chaotic states follows a first order reaction kinetics.

#### **4:06PM H34.00007 Hydrodynamic self-organization and mixing in suspensions of micro-rotors<sup>1</sup>**

, KYONGMIN YEO, IBM Research, ENKELEIDA LUSHI, PETIA VLAHOVSKA, Brown University — Self-organization of active objects has attracted considerable attention recently, especially in the context of living systems. Hydrodynamic interactions can play a crucial role in the emerging behavior when the objects are immersed in fluid, especially in the low Reynolds number regime. While self-propelled active objects have been extensively investigated, the collective behavior of rotating active particle has received limited attention. To elucidate the transition to collective behavior and especially the role of multi-body hydrodynamic interactions, we numerically study systems of co- and counter-rotating spheres by varying the mixture ratio as well as the total volume fraction. With increasing volume fraction, we observe the emergence of intriguing patterns such as lanes, vortices of same-spin rotors as well as dynamic crystals composed of both types of rotors. We consider how the motion of the rotating particles and fluid they collectively generate affects the dispersion or clustering of passive sphere particles or mixing of passive scalar fields in the system.

<sup>1</sup>We acknowledge support from NSF CBET 1437545 and NSF CBET 1544196.

#### **4:18PM H34.00008 Collective dynamics of rotating colloidal particles**

, SOFIA MAGKIRIADOU, VISHAL SONI, University of Chicago, BENNY VAN ZUIDEN, Leiden University, DENIS BARTOLO, Ecole Normale Supérieure de Lyon, VINCENZO VITELLI, Leiden University, WILLIAM T.M. IRVINE, University of Chicago — We study magnetic colloidal particles in suspension under the influence of a rotating magnetic field. When in aggregates, these particles show rich dynamics that are governed by magnetic and hydrodynamic interactions. By tuning these interactions, we probe the phase diagram of this system and study the emergent collective dynamics. Finally, we begin to investigate whether we can control this phase diagram with geometry.

#### **4:30PM H34.00009 Helical motion of chiral liquid crystal droplets<sup>1</sup>**

, TAKAKI YAMAMOTO, MASAKI SANO, Department of Physics, Graduate School of Science, the University of Tokyo — Artificial swimmers have been intensively studied to understand the mechanism of the locomotion and collective behaviors of cells and microorganisms. Among them, most of the artificial swimmers are designed to move along the straight path. However, in biological systems, chiral dynamics such as circular and helical motion are quite common because of the chirality of their bodies, which are made of chiral biomolecules. To understand the role of the chirality in the physics of microswimmers, we designed chiral artificial swimmers and the theoretical model for the chiral motion. We found that chiral liquid crystal droplets, when dispersed in surfactant solutions, swim in the helical path induced by the Marangoni effect. We will discuss the mechanism of the helical motion with our phenomenological model.

#### **4:42PM H34.00010 Rolling and spinning swimmers**

, MICHELLE DRISCOLL, MELISSA FERRARI, MENA YOUSSEF, PAUL CHAIKIN, STEFANO SACANNA, New York Univ NYU — We study the dynamics and collective interactions that occur in a system of rotating active matter: an oscillating, externally applied magnetic field is used to drive motion in a system of confined, magnetic colloids. By adjusting the orientation, frequency, and amplitude of the applied field we can drive a wide range of particle motions, from rolling to spinning. These rotations lead to a large variety of collective behaviors, which are driven both by particle-particle magnetic interactions as well as long-range hydrodynamic flows. We observe that the clustering which results from in-plane spinning can be strongly modulated by changing inter-particle magnetic interactions. We explore the strength of this clustering as a function of particle interaction, and can isolate the effect of magnetic and hydrodynamic interactions. We also observe that particle rotation can lead to complex and large-scale flows for both the case of rolling and spinning particles.

#### **4:54PM H34.00011 Emergent order in ensembles of active spinners**

, BENJAMIN C. VAN ZUIDEN, JAYSON PAULOSE, Lorentz Institute, Leiden University, WILLIAM T. M. IRVINE, James Franck Institute, University of Chicago, DENIS BARTOLO, Ecole Normale Supérieure de Lyon, VINCENZO VITELLI, Lorentz Institute, Leiden University — Interacting self-propelled particles is proxy to model many living systems from cytoskeletal motors to bird flocks, while also providing a framework to investigate fundamental questions in non equilibrium statistical mechanics. A surge of recent studies have shown that self-propulsion significantly modifies the phase behavior of particles interacting via potential interactions. A prototypical example is the so-called Motility Induced Phase Separation occurring in ensembles of self-propelled hard spheres. In stark contrast, our understanding of active spinning, as opposed to self-propulsion, remains very scarce. Here, we study a system of self-spinning dimers, interacting via soft repulsive forces. Upon varying the density and activity, we observe a range of emergent phases characterized by different degrees of spatiotemporal order in the position and orientation of the dimers. Changes in bulk properties, including crystallization, melting, and freezing, are reflected in the collective motion of the particles. We rationalize our numerical findings theoretically and demonstrate some of these concepts in a active granular experiment.

#### **5:06PM H34.00012 Emergent collective dynamics in ensembles of magnetic colloidal rollers**

, ALEXEY SNEZHKO, Argonne National Laboratory — Strongly interacting colloids driven out-of-equilibrium by an external periodic forcing often develop nontrivial collective dynamics. Ferromagnetic micro-particles immersed in water and sediment on the bottom surface of the flat cell are energized by a single-axis homogeneous alternating magnetic field applied perpendicular to the surface supporting the particles. Upon application of the alternating magnetic field the magnetic torque on each particle is transferred to the mechanical torque giving rise to a rolling motion of the particle. Experiments reveal a rich collective dynamics of magnetic rollers in a certain range of excitation parameters. Flocking and spontaneous formation of steady vortex motion have been observed. The effects are fine-tuned and controlled by the parameters of the driving magnetic field. Formation of the self-organized collective states spontaneously breaking the symmetry of the underlying interactions has been attributed to the interplay of inelastic inter-particle collisions and self-induced hydrodynamic flows in the system. The research was supported by the U.S. DOE, Office of Basic Energy Sciences, Division of Materials Science and Engineering.

#### **2:30PM H35.00001 Standing variation in spatially growing populations**

, DIANA FUSCO, MATTI GRALKA, JONA KAYSER, OSKAR HALLATSCHEK, Univ of California - Berkeley — Patterns of genetic diversity not only reflect the evolutionary history of a species but they can also determine the evolutionary response to environmental change. For instance, the standing genetic diversity of a microbial population can be key to rescue in the face of an antibiotic attack. While genetic diversity is in general shaped by both demography and evolution, very little is understood when both factors matter, as e.g. for biofilms with pronounced spatial organization. Here, we quantitatively explore patterns of genetic diversity by using microbial colonies and well-mixed test tube populations as antipodal model systems with extreme and very little spatial structure, respectively. We find that Eden model simulations and KPZ theory can remarkably reproduce the genetic diversity in microbial colonies obtained via population sequencing. The excellent agreement allows to draw conclusions on the resilience of spatially-organized populations and to uncover new strategies to contain antibiotic resistance.

**2:42PM H35.00002 Crowds as an Excitable Medium for Spiral Wave Dynamics<sup>1</sup>**, ANDREA WELSH, EDWIN GRECO, FLAVIO FENTON, Georgia Institute of Technology — Spiral wave (SW) patterns are studied in many physical, biological, and chemical excitable systems. Of particular importance are SW of electrical activity that develop in the heart and give rise to arrhythmias such as tachycardia (single SW) and fibrillation (multiple SWs). We investigate if a crowd of people given simple rules for activation and deactivation, modeled on cardiac cells, can act as a living simulation for SW dynamics. For group sizes ranging from 50 to 650 people we demonstrate, experimentally, the existence of stable spiral waves and of spiral wave breakup leading to chaotic dynamics. Numerical simulation predicts the simple rules lead to well defined wave fronts. People, however, respond with various degrees of anticipation and misinformation. This human behavior can lead to smoothed fronts or even lead to spiral wave breakup and chaos. We present a new cell model that includes variations in reaction to account for the observed behavior in crowds. This model may be useful in the study of coupling and decoupling of cardiac cells that lead to arrhythmic behavior.

**2:54PM H35.00003 Adapting populations in space: clonal interference and genetic diversity**, DANIEL WEISSMAN, Emory University, NICK BARTON, IST Austria — Most species inhabit ranges much larger than the scales over which individuals interact. How does this spatial structure interact with adaptive evolution? We consider a simple model of a spatially-extended, adapting population and show that, while clonal interference severely limits the adaptation of purely asexual populations, even rare recombination is enough to allow adaptation at rates approaching those of well-mixed populations. We also find that the genetic hitchhiking produced by the adaptive alleles sweeping through the population has strange effects on the patterns of genetic diversity. In large spatial ranges, even low rates of adaptation cause all individuals in the population to rapidly trace their ancestry back to individuals living in a small region in the center of the range. The probability of fixation of an allele is thus strongly dependent on the alleles spatial location, with alleles from the center favored. Surprisingly, these effects are seen genome-wide (instead of being localized to the regions of the genome undergoing the sweeps). The spatial concentration of ancestry produces a power-law dependence of relatedness on distance, so that even individuals sampled far apart are likely to be fairly closely related, masking the underlying spatial structure.

**3:06PM H35.00004 3-D Technology Approaches for Biological Ecologies<sup>1</sup>**, LIYU LIU, Chongqing University/Institute of Physics, Chinese Academy of Sciences, ROBERT AUSTIN, Princeton University, U.S-CHINA PHYSICAL-ONCOLOGY SCIENCES ALLIANCE (PS-OA) TEAM — Constructing three dimensional (3-D) landscapes is an inevitable issue in deep study of biological ecologies, because in whatever scales in nature, all of the ecosystems are composed by complex 3-D environments and biological behaviors. Just imagine if a 3-D technology could help complex ecosystems be built easily and mimic in vivo microenvironment realistically with flexible environmental controls, it will be a fantastic and powerful thrust to assist researchers for explorations. For years, we have been utilizing and developing different technologies for constructing 3-D micro landscapes for biophysics studies in vitro. Here, I will review our past efforts, including probing cancer cell invasiveness with 3-D silicon based Trepis, constructing 3-D microenvironment for cell invasion and metastasis through polydimethylsiloxane (PDMS) soft lithography, as well as explorations of optimized stenting positions for coronary bifurcation disease with 3-D wax printing and the latest home designed 3-D bio-printer. Although 3-D technologies is currently considered not mature enough for arbitrary 3-D micro-ecological models with easy design and fabrication, I hope through my talk, the audiences will be able to sense its significance and predictable breakthroughs in the near future.

**3:42PM H35.00005 Population Dynamics of Viral Inactivation<sup>1</sup>**, KRISTA FREEMAN, DONG LI, Carnegie Mellon University, MANJA BEHRENS, Lund University, KIRIL STRELETZKY, Cleveland State University, ULF OLSSON, Lund University, ALEX EVILEVITCH, Carnegie Mellon University — We have investigated the population dynamics of viral inactivation *in vitro* using time-resolved cryo electron microscopy combined with light and X-ray scattering techniques. Using bacteriophage  $\lambda$  as a model system for pressurized double-stranded DNA viruses, we found that virions incubated with their cell receptor eject their genome in a stochastic triggering process. The triggering of DNA ejection occurs in a non synchronized manner after the receptor addition, resulting in an exponential decay of the number of genome-filled viruses with time. We have explored the characteristic time constant of this triggering process at different temperatures, salt conditions, and packaged genome lengths. Furthermore, using the temperature dependence we determined an activation energy for DNA ejections. The dependences of the time constant and activation energy on internal DNA pressure, affected by salt conditions and encapsidated genome length, suggest that the triggering process is directly dependent on the conformational state of the encapsidated DNA. The results of this work provide insight into how the *in vivo* kinetics of the spread of viral infection are influenced by intra- and extra cellular environmental conditions.

**3:54PM H35.00006 Coalescent Theory Analysis of Population Collapse and Recovery in a Neutral Evolution Model<sup>1</sup>**, DAWN KING, SONYA BAHAR, University of Missouri at Saint Louis — As we move through the Anthropocene Epoch, human-driven climate change is predicted to accelerate extinction risk in the near future. Therefore, understanding basic underlying mechanisms of population loss and recovery could be paramount to saving key species in changing ecosystems. Here, we present an evolutionary model that investigates the dynamics of population collapse and recovery following a simulated mass extinction. Previously, we have shown that nonequilibrium, continuous phase transitions of the directed percolation universality class occur as a function of two different control parameters: the mutability,  $\mu$ , which dictates how phenotypically different an offspring can be from its parent, and the death probability,  $\delta$ , which probabilistically removes organisms within each generation. Here, we characterize the phylogenetic tree structures at two levels of biological organization—the organism and species level. Using methods from coalescent theory, we examine the phylogenetic tree structures at, and above, criticality, by considering common descent. The times to most recent common ancestor show phase transition behavior, as well as scale-free branching behavior at both levels of organization. We further examine these genealogical structures pre- and post-extinction.

**4:06PM H35.00007 Confirming Time-reversal Symmetry of a Directed Percolation Phase Transition in a Model of Neutral Evolutionary Dynamics<sup>1</sup>**, STEPHEN ORDWAY, DAWN KING, SONYA BAHAR, University of Missouri at Saint Louis — Reaction-diffusion processes, such as branching-coalescing random walks, can be used to describe the underlying dynamics of nonequilibrium phase transitions. In an agent-based, neutral model of evolutionary dynamics, we have previously shown that our system undergoes a continuous, nonequilibrium phase transition, from extinction to survival, as various system parameters were tuned. This model was shown to belong to the directed percolation (DP) universality class, by measuring the critical exponents corresponding to correlation length  $\xi_{\perp}$ , correlation time  $\xi_{\parallel}$ , and particle density  $\beta$ . The fourth critical exponent that defines the DP universality class is  $\beta'$ , which measures the survival probability of growth from a single seed organism. Since DP universality is theorized to have time-reversal symmetry, it is assumed that  $\beta = \beta'$ . In order to confirm the existence of time-reversal symmetry in our model, we evaluate the system growth from a single asexually reproducing organism. Importantly, the critical exponent  $\beta'$  could be useful for comparison to experimental studies of phase transitions in biological systems, since observing growth of microbial populations is significantly easier than observing death.

**4:18PM H35.00008 Holes influence the mutation spectrum of human mitochondrial DNA.** , MARTHA VILLAGRAN, JOHN MILLER, University of Houston, Dept. of Physics & Texas Ctr. for Superconductivity — Mutations drive evolution and disease, showing highly non-random patterns of variant frequency vs. nucleotide position. We use computational DNA hole spectroscopy [M.Y. Suarez-Villagran & J.H. Miller, *Sci. Rep.* 5, 13571 (2015)] to reveal sites of enhanced hole probability in selected regions of human mitochondrial DNA. A hole is a mobile site of positive charge created when an electron is removed, for example by radiation or contact with a mutagenic agent. The hole spectra are quantum mechanically computed using a two-stranded tight binding model of DNA. We observe significant correlation between spectra of hole probabilities and of genetic variation frequencies from the MITOMAP database. These results suggest that hole-enhanced mutation mechanisms exert a substantial, perhaps dominant, influence on mutation patterns in DNA. One example is where a trapped hole induces a hydrogen bond shift, known as tautomerization, which then triggers a base-pair mismatch during replication. Our results deepen overall understanding of sequence specific mutation rates, encompassing both hotspots and cold spots, which drive molecular evolution.

**4:30PM H35.00009 A kinetic theory for age-structured stochastic birth-death processes<sup>1</sup>** , TOM CHOU, Univ of California - Los Angeles, CHRIS GREENMAN, University of East Anglia — Classical age-structured mass-action models such as the McKendrick-von Foerster equation have been extensively studied but they are structurally unable to describe stochastic fluctuations or population-size-dependent birth and death rates. Conversely, current theories that include size-dependent population dynamics (e.g., carrying capacity) cannot be easily extended to take into account age-dependent birth and death rates. In this paper, we present a systematic derivation of a new fully stochastic kinetic theory for interacting age-structured populations. By defining multiparticle probability density functions, we derive a hierarchy of kinetic equations for the stochastic evolution of an aging population undergoing birth and death. We show that the fully stochastic age-dependent birth-death process precludes factorization of the corresponding probability densities, which then must be solved by using a BBGKY-like hierarchy. Our results generalize both deterministic models and existing master equation approaches by providing an intuitive and efficient way to simultaneously model age- and population-dependent stochastic dynamics applicable to the study of demography, stem cell dynamics, and disease evolution.

**4:42PM H35.00010 Theoretical ecology without species** , MIKHAIL TIKHONOV<sup>1</sup>, Harvard University — The sequencing-driven revolution in microbial ecology demonstrated that discrete “species” are an inadequate description of the vast majority of life on our planet. Developing a novel theoretical language that, unlike classical ecology, would not require postulating the existence of species, is a challenge of tremendous medical and environmental significance, and an exciting direction for theoretical physics. Here, it is proposed that community dynamics can be described in a naturally hierarchical way in terms of population fluctuation eigenmodes. The approach is applied to a simple model of division of labor in a multi-species community. In one regime, effective species with a core and accessory genome are shown to naturally appear as emergent concepts. However, the same model allows a transition into a regime where the species formalism becomes inadequate, but the eigenmode description remains well-defined. Treating a community as a black box that expresses enzymes in response to resources reveals mathematically exact parallels between a community and a single coherent organism with its own fitness function. This coherence is a generic consequence of division of labor, requires no cooperative interactions, and can be expected to be widespread in microbial ecosystems.

**4:54PM H35.00011 A new model for biological effects of radiation and the driven force of molecular evolution.** , TAKAHIRO WADA, Department of Pure and Applied Physics, Kansai University, YUICHIRO MANABE, Division of Sustainable Energy and Environmental Engineering, Osaka University, HIROO NAKAJIMA, Department of Radiation Biology and Medical Genetics, Osaka University, YUICHI TSUNOYAMA, Radioisotope Research Center, Kyoto University, MASAKO BANDO, RCNP, Osaka University — We proposed a new mathematical model to estimate biological effects of radiation, which we call Whack-A-Mole (WAM) model. A special feature of WAM model is that it involves the dose rate of radiation as a key ingredient. We succeeded to reproduce the experimental data of various species concerning the radiation induced mutation frequencies. From the analysis of the mega-mouse experiments, we obtained the mutation rate per base-pair per year for mice which is consistent with the so-called molecular clock in evolution genetics,  $10^{-9}$  mutation/base-pair/year. Another important quantity is the equivalent dose rate for the whole spontaneous mutation,  $d_{\text{eff}}$ . The value of  $d_{\text{eff}}$  for mice is  $1.1 \times 10^{-3}$  Gy/hour which is much larger than the dose rate of natural radiation ( $10^{-(6-7)}$  Gy/hour) by several orders of magnitude. We also analyzed *Drosophila* data and obtained essentially the same numbers. This clearly indicates that the natural radiation is not the dominant driving force of the molecular evolution, but we should look for other factors, such as miscopy of DNA in duplication process. We believe this is the first quantitative proof of the small contribution of the natural radiation in the molecular evolution.

**5:06PM H35.00012 Scaling of expected survival time in a stochastic harvesting model** , HAROLD HASTINGS, Hofstra University and Bard College at Simon's Rock, MICHAEL RADIN, TAMAS WIANDT, Rochester Institute of Technology — We explore the dynamics of modified version of a standard fishery model (Gordon-Schaefer-Munro [1]), with additive and multiplicative noise, under a quota-based harvest. A harvest quota induces an effective strong Allee effect (a positive unstable steady state population level, below which populations die out), with expected survival time following generalized Ornstein-Uhlenbeck dynamics [2]. In particular, for additive noise, the expected survival time is exponential in  $s^3/\sigma^2$ , where  $s$  is the difference between stable and unstable steady state populations and  $\sigma$  the noise level. Thus survival time depends sensitively upon harvest quota (which determines steady state population), perhaps a warning to avoid future collapses such as that of the Atlantic cod fishery [3]. 1. **5:18PM H35.00013 Computational design of hepatitis C vaccines using maximum entropy models and population dynamics** , GREGORY HART, ANDREW FERGUSON, Univ of Illinois - Urbana — Hepatitis C virus (HCV) afflicts 170 million people and kills 350,000 annually. Vaccination offers the most realistic and cost effective hope of controlling this epidemic. Despite 20 years of research, no vaccine is available. A major obstacle is the virus' extreme genetic variability and rapid mutational escape from immune pressure. Improvements in the vaccine design process are urgently needed. Coupling data mining with spin glass models and maximum entropy inference, we have developed a computational approach to translate sequence databases into empirical fitness landscapes. These landscapes explicitly connect viral genotype to phenotypic fitness and reveal vulnerable targets that can be exploited to rationally design immunogens. Viewing these landscapes as the mutational “playing field” over which the virus is constrained to evolve, we have integrated them with agent-based models of the viral mutational and host immune response dynamics, establishing a data-driven immune simulator of HCV infection. We have employed this simulator to perform in silico screening of HCV immunogens. By systematically identifying a small number of promising vaccine candidates, these models can accelerate the search for a vaccine by massively reducing the experimental search space.

**Session H36 GSOFT: Soft Matter at Interfaces (Surfactants)** 339 - Jonathan Whitmer, Notre Dame

**2:30PM H36.00001 Stretching and ordering of amyloid fibrils at liquid interfaces** , EMANUELA DEL GADO, Georgetown University, KONRAD SCHWENKE, SOPHIA JORDENS, IVAN USOV, RAFFAELE MEZZENGA, ETH Zurich, GEORGETOWN UNIVERSITY TEAM, ETH ZURICH TEAM — We investigate the formation of nematic domains, which might be precursor of plaque formation, in the adsorption of amyloid fibrils at liquid interfaces. Combining experiments and computer simulations we analyse spatial correlations in the nematic order and in apparent persistence length. Non-equilibrium numerical simulations provide new insight into the coupling between those quantities. The emerging scenario is that the out-of-equilibrium adsorption favors the formation of spatial heterogeneities due to the presence of local nematic order that tend to persist upon increasing the surface coverage. Such structural heterogeneities are directly coupled to the apparent straightening of the fibrils and might affect the density and the mechanical properties of the final self-assembled material.

**2:42PM H36.00002 Effect of headgroup-substrate interactions on the thermal behavior of long-chain amphiphiles** , SARANSHU SINGLA, HE ZHU, Graduate Student, ALI DHINOJWALA, Professor — The structure of amphiphilic molecules at liquid/solid and solid/solid interfaces is relevant in understanding lubrication, colloid stabilization, chromatography, and nucleation. Here, we characterize the interfacial structures of long chain amphiphilic molecules with different head groups (OH, COOH, NH<sub>2</sub>) using interface-sensitive sum frequency generation (SFG) spectroscopy. The behavior of these self-assembled monolayers (SAMs) on sapphire substrate is recorded in situ as a function of temperature (above and below bulk  $T_m$ ) using SFG. Previous studies using synchrotron X-ray reflectivity and SFG show that the melting point of an ordered hexadecanol monolayer is around 30C above its bulk  $T_m$ . The thermal stability of the monolayer is explained due to strong hydrogen bonding interactions between the head-group and the sapphire substrate. The strength of these hydrogen-bonding interactions between substrate and different head groups is calculated using the Badger-Bauer equation. Below  $T_m$ , the ordered monolayer influenced the structure of the interfacial crystalline layer, and the transition from monolayer to the bulk crystalline phases. The results with different head groups will be presented.

**2:54PM H36.00003 The role of hydrophobic mismatch in tuning lipid membrane dynamics** , ELIZABETH KELLEY, National Institute of Standards and Technology, RANA ASHKAR, Oak Ridge National Laboratory, ROBERT BRADBURY, National Institute of Standards and Technology, ANDREA WOODKA, United States Military Academy, MICHIOHITO NAGAO, PAUL BUTLER, National Institute of Standards and Technology — Lipid membranes undergo an array of conformational and dynamic transitions, ranging from individual lipid motions to undulations of micron-sized patches of the membrane. However, the collective dynamics at intermediate length scales are largely unexplored due to experimental challenges in accessing the appropriate length and time scales. Here we use neutron spin echo spectroscopy (NSE) to provide unique insights into these elusive dynamics and measure membrane mechanical properties by probing both bending and thickness fluctuations in model lipid bilayers. We show that hydrophobic mismatch between lipids with different acyl chain lengths tunes the dynamics in a way not achievable in single component systems. For example, the thickness fluctuation amplitude is enhanced in the fluid phase of mixed lipid bilayers, reaching approximately 20% of the bilayer thickness. Combining these experimental results with deformation free energy calculations suggests the mixed bilayers are more compressible than single component bilayers and provides new insights into the role of lipid diversity in controlling the rich dynamics of biomembranes.

**3:06PM H36.00004 Interplay Between Hydrophobic Effect and Dipole Interactions in Peptide Aggregation** , SAI GANESAN, SILVINA MATYSIAK, Univ of Maryland-College Park — In the past decade, the development of various coarse-grained models for proteins have provided key insights into the driving forces in folding and aggregation. We recently developed a low resolution Water Explicit Polarizable PROtein coarse-grained Model by adding oppositely charged dummy particles inside protein backbone beads. With this model, we were able to achieve significant  $\alpha/\beta$  secondary structure content, without any added bias. We now extend the model to study peptide aggregation at hydrophobic-hydrophilic interface using elastin-like octapeptides (GV)<sub>4</sub> as a model system. A condensation-ordering mechanism of aggregation is observed in water. Our results suggest that backbone interpeptide dipolar interactions, not hydrophobicity, plays a more significant role in fibril-like peptide aggregation. We observe a cooperative effect in hydrogen bonding or dipolar interactions, with increase in aggregate size in water and interface. Based on this cooperative effect, we provide a potential explanation for the observed nucleus size in peptide aggregation pathways. Without dipolar particles, peptide aggregation is not observed at the hydrophilic-hydrophobic interface. Thus, the presence of dipoles, not hydrophobicity plays a key role in aggregation observed at hydrophobic interfaces.

**3:18PM H36.00005 Theory of Kinetics of Registration and Anti-Registration in Lipid Bilayers** , PETER OLMSTED, JOHN WILLIAMSON, Georgetown University — Lipid bilayer leaflets are often treated as if they are coupled; i.e., that the two leaflets undergo simultaneous transitions between phases, and that domains involve both leaflets together in a registered fashion. We present theory and simulation showing how interleaflet couplings and hydrophobic mismatch can lead to a complex phase diagram with multiple metastable two-phase and three-phase states. Many of these states can be discerned in the experimental literature, and are expected in the early stages of coarsening when domains are sub-micron (and thus perhaps of significance to lipid rafts). We present different kinetic scenarios for transitions between these state, and show how lipid flip flop can surprisingly lead to non-symmetric anti-registered patterns.

**3:30PM H36.00006 The activity of MscL in asymmetric droplet interface bilayers.**<sup>1</sup> , JOSEPH NAJEM, Virginia Polytechnic Institute and State University , SERGEI SUKHAREV, University of Maryland, DONALD LEO, University of Georgia — The ability to host and activate MscL, a large-conductance channel and osmolyte release valve, in a droplet interface bilayer (DIB) has been demonstrated. In previous work, the V23T mutant of MscL produced a reliable activation when axial compression is applied to the droplets supporting the lipid bilayer. Near maximal compression, the aqueous droplets deform and the resulting increase in surface area leads to an increase in tension in the water-lipid-oil interface. This increase in tension is the product of the relative change in the droplet surface area and the elastic modulus of the DPhPC monolayer (120 mN/m). However, a relatively high potential (~100 mV) is also needed to be applied in order to activate the channels. Here, we use two different types of lipids to form asymmetric DIBs. As a result of an asymmetric interface, a transmembrane potential is created across the membrane (~130 mV) due to the difference in the dipole potentials of both lipids. When MscL channels are incorporated in the bilayer, they are activated upon mechanical stimulation, without the need to apply a high external potential. We also observed that the channels became more susceptible to gating upon the application of a negative potential, compared to when a positive potential is applied, proving their sensitivity to voltage polarity.

**3:42PM H36.00007 Dynamic surface tension measurements with maximum bubble pressure tensiometry** , NORMAN MORENO, THEODORE WALKER, ADAM BURSHAN, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — Dynamic surface tension refers to the time dependent variation in surface tension, and is intimately linked with the rate of mass transfer of a surfactant from liquid sub-phase to the interface. The diffusion- or adsorption-limited kinetics of mass transfer to interfaces is said to impact the so-called foamability and the Gibbs-Marangoni elasticity of surfaces. Dynamic surface tension measurements carried out with conventional methods like pendant drop analysis, Wilhelmy plate, etc are limited in their temporal resolution (>50 ms). In this study, we describe design and application of maximum bubble pressure tensiometry for the measurement of dynamic surface tension effects at extremely short (1-50 ms) timescales. Using experiments and theory, we discuss the challenges and experimental constraints related with the maximum bubble pressure tensiometry measurement.

**3:54PM H36.00008 Compression-Induced Fusion of Glassy Core Polymer Micelles at the Air-Water Interface**, HYUN CHANG KIM, YOU-YEON WON, Purdue Univ — The surface mechanical and morphological properties of glassy core polymer micelles at the air-water interface were investigated. Asymmetric PS-PEG and PtBMA-PEG block copolymers with PEG weight fractions larger than 0.5 were formulated in the form of aqueous micelles and spread onto water. Compressed films of PS-PEG and PtBMA-PEG micelles reach high dynamic surface pressures. On the detailed level, however, PS-PEG and PtBMA-PEG micelles exhibit different surface pressure-area profiles. The PtBMA-PEG isotherm shows a transition to a plateau around a surface pressure of 24 mN/m, which is attributed to the PtBMA block as it forms a continuous film; this interpretation is supported by the fact that the surface pressure at the plateau transition is identical to the value of the spreading coefficient for PtBMA. This presents evidence that the core domains of PtBMA-PEG micelles melt and merge into a film when the micellar monolayer is laterally compressed. Such behavior was not observed with PS-PEG micelles. We suspect that under lateral compression, PtBMA-PEG micelles undergo fusion into a continuous film because PtBMA has the natural tendency to spread on the water surface, whereas PS-PEG micelles does not because the dewetting tendency of PS preventing formation of a uniform layer.

**4:06PM H36.00009 Temperature Dependent Rotational Correlation in Lipids**, CHRISTINA OTHON, NEDA DADASHVAND, EDUARDO VEGA LOZADA, Wesleyan University — The lateral heterogeneity of lipid dynamics is explored in free standing lipid monolayers. As the temperature is lowered the lipids exhibit increasingly broad and heterogeneous rotational correlation. This increase in heterogeneity appears to exhibit a critical onset, similar to those observed for glass forming fluids. We explore this heterogeneous relaxation by measuring the rotational diffusion of a fluorescent probe (NBD-PC) using wide-field time-resolved fluorescence anisotropy microscopy, in single constituent lipid monolayer of DMPC. The observed relaxation exhibits a narrow, liquid-like distribution at high temperatures ( $\tau \sim 2.4$  ns), consistent with previous experimental measures by different methods. However, as the temperature is quenched, the distribution broadens, and we observe the appearance of a long relaxation population (16.5 ns). This demonstrates that the nanoscale diffusion and reorganization in lipid structures can be significantly complex, even in the simplest unstructured architectures. This result can have a significant impact on the organization, permeability and energetics of natural membrane structures.

**4:18PM H36.00010 Interfacial microrheology study of layer formation by staphylococcal nuclease protein and its disordered variant**, BILYANA TZOLOVA, Johns Hopkins University, DANIEL ALLAN, Brookhaven National Lab, DANIEL FIRESTER, BERTRAND GARCIA-MORENO, DANIEL REICH, ROBERT LEHENY, Johns Hopkins University — We study the formation of layers of staphylococcal nuclease protein adsorbing at the air-water interface. In a series of experiments, we follow the evolution of the rheological response of the layer using an active microrheology technique that involves tracking the rotational motion of magnetic nanowires at the interface in response to time-dependent external magnetic fields. At early stages of layer formation, the wire mobility can be interpreted using a model for viscous drag with an interfacial viscosity that increases rapidly with layer age; however, at later ages deviations from a simple viscous response indicating non-Newtonian behavior are observed. We compare the evolution in microrheology of layers forming from wild-type protein that assumes a folded conformation in solution with a variant that is disordered due to substitution of a single amino acid, thereby gaining a perspective on the impact of initial protein state on the layer formation and rheology.

**4:30PM H36.00011 Interaction of water with melittin inserted in a single-supported lipid bilayer<sup>1</sup>**, ZACHARY BUCK, MENGJUN BAI, JAMES TORRES, HELMUT KAISER, HASKELL TAUB, Univ. of Missouri - Columbia, FLEMMING Y. HANSEN, Technical University of Denmark, ANDREW MISKOWIEC, Oak Ridge National Lab, MADHUSUDAN TYAGI, NIST Center for Neutron Research — The insertion mechanism, conformation, and the function of transmembrane proteins are strongly influenced by both the lipid molecules and the hydration water of a cell membrane. Previously, we have fabricated samples of single-supported lipid bilayers of zwitterionic DMPC and studied extensively their influence on the freezing behavior and diffusion of water in their vicinity [2]. We have recently extended these studies to a more biologically relevant system by depositing melittin proteins onto single-supported DMPC bilayers. By monitoring the elastically-scattered neutron intensity as a function of temperature from such samples, we observe an abrupt freezing transition of the associated water not seen in the bare membrane case. Moreover, the change in elastic intensity of this freezing step increases proportionally with melittin concentration. For a particular peptide concentration, a small increase of the elastically-scattered neutron intensity is measured while annealing the sample at 328 K. We tentatively interpret this increase of the elastic intensity to anchoring and/or insertion of the melittin peptides within the membrane. <sup>2</sup>M. Bai *et al.*, Europhys. Lett. **98**, 48006 (2012).

**4:42PM H36.00012 Formation, disruption and mechanical properties of a rigid hydrophobin film at an air-water interface<sup>1</sup>**, LYNN WALKER, STEPHANIE KIRBY, SHELLEY ANNA, Carnegie Mellon Univ, CMU TEAM — Hydrophobins are small, globular proteins with distinct hydrophilic and hydrophobic regions that make them extremely surface active. The behavior of hydrophobins at surfaces has raised interest in their potential industrial applications, including use in surface coatings, food foams and emulsions, and as dispersants. Practical use of hydrophobins requires an improved understanding of the interfacial behavior of these proteins, both individually and in the presence of surfactants. Cerato-ulmin (CU) is a hydrophobin that has been shown to strongly stabilize air bubbles and oil droplets through the formation of a persistent protein film at the interface. In this work, we characterize the adsorption behavior of CU at air/water interfaces by measuring the surface tension and interfacial rheology as a function of adsorption time. CU is found to strongly, irreversibly adsorb at air/water interfaces; the magnitude of the dilatational modulus increases with adsorption time and surface pressure, until the CU eventually forms a rigid film. The persistence of this film is tested through the addition of SDS, a strong surfactant, to the bulk. SDS is found to co-adsorb to interfaces pre-coated with a CU film. At high concentrations, the addition of SDS significantly decreases the dilatational modulus, indicating disruption and displacement of CU. These results lend insight into the complex interfacial interactions between hydrophobins and surfactants.

**4:54PM H36.00013 Boundary condition in liquid thin films revealed through the thermal fluctuations of their free surfaces**, BASILE POTTIER<sup>1</sup>, LAURENCE TALINI, CHRISTIAN FRTIGNY, SIMM — We investigate the properties of liquids confined at nanometric scales from a solid wall with a new noninvasive technique. The optical technique used consists of measuring the height of fluctuations of the free surface, using the reflection of a laser beam on that surface. We hence measure the spontaneous thermal fluctuations of the free surfaces of liquids to probe their hydrodynamic boundary condition at a solid wall. The surface fluctuations of a silicon oil film could be described with a no-slip boundary condition for film thicknesses down to 20 nm. Oppositely, a 4 nm negative slip length had to be introduced to describe the behavior of n-hexadecane, consistently with previous surface force apparatus data on the same system. Our results demonstrate that at vanishing flow, a nanometric solid-like layer close to the wall may exist according to the nature of the liquid.

**5:06PM H36.00014 Charge Effects on Surfactant Membrane Thickness Fluctuations**, ROBERT BRADBURY, MICHIOHRO NAGAO, Indiana University — The mechanical properties of surfactant bilayer membranes have been measured over a range of surface charge densities using small-angle neutron scattering and neutron spin echo spectroscopy. An increase in the surface charge density leads to a stiffening of the membrane, which is consistent with classical theory of charge effects on membranes. The fluctuations in the membrane thickness, however, become slower with increasing charge density, which can be explained by an increase in the membrane viscosity as predicted by Bingham *et al.* We suggest that an increase in the repulsive interactions between the charged headgroups is responsible for this increased membrane viscosity. Furthermore, the amplitude of the thickness fluctuations is observed to remain almost constant with variation in surface charge density which suggests almost constant values for the total compressibility modulus of the bilayer and the optimum fluctuation wavelength. This indicates that the time scale and amplitude of membrane thickness fluctuations are controlled by different membrane effects. This work demonstrates that charge stabilization of lamellar bilayers is not merely affected by inter-membrane interactions but that intra-membrane dynamics also have a significant contribution.

**5:18PM H36.00015 Branching mechanisms in surfactant micelles.**<sup>1</sup>, SUBAS DHAKAL, Department of Biomedical and Chemical Engineering, Syracuse University, Syracuse, NY, RADHAKRISHNA SURESHKUMAR, Department of Biomedical and Chemical Engineering and Department of Physics, Syracuse University, Syracuse, NY — The mechanisms of branch formation in surfactant micelles of cetyltrimethylammonium chloride (CTAC) in presence of sodium salicylate (NaSal) counter ions in water are studied using molecular dynamics simulations. The curvature energy associated with the formation of micelle branches and the effect of branching on the solution viscosity are quantified. Highly curved surfaces are energetically stabilized by a higher density of binding counter ions near the branch points. Simulations show that micellar branches result in a significant reduction in the solution viscosity as observed in experiments [Dhakal & Sureshkumar, J. Chem. Phys. 143, 024905 (2015)]. This reduction in viscosity has long been attributed to the sliding motion of micelle branches across the main chain. However, to date, such dynamics of micelle branches have never been visualized in either experiments or simulations. Here, we explicitly illustrate and quantify, for the first time, how branches slide along the micelle contour to facilitate stress relaxation.

**2:30PM H37.00001 Implicit depletion of anisotropic particles**, JENS GLASER, ANDREW KARAS, SHARON GLOTZER, Univ of Michigan - Ann Arbor — Entropy mediates depletion interactions between particles with excluded volume. We implement a novel algorithm [1] to simulate this emergent attraction between hard anisotropic particles in the presence of penetrable hard spheres. Our algorithm is efficient because it integrates out the degrees of freedom of the ideal depletant gas in parallel, which makes it well suited for high-performance computing. The algorithm can achieve several orders of magnitude speed-up over explicit algorithms. As an application we study the interplay between phase separation and kinetic arrest in the anisotropic clustering of colloidal discoids [2]. We also discuss applications of the algorithm for the assembly of hemispheres [1] and of cuboctahedra [3]. [1] J. Glaser, A. S. Karas, and S. C. Glotzer, arXiv:1508.07077. [2] L. C. Hsiao, B. A. Schultz, J. Glaser, M. Engel, M. E. Szakasits, S. C. Glotzer, and M. J. Solomon, Nat. Commun. 6, 8507 (2015). [3] A. S. Karas, J. Glaser, and S. C. Glotzer, arXiv:1510.04236.

**2:42PM H37.00002 Interplay of directional and isotropic interactions in self-assembly**, DEBRA AUDUS, National Institute of Standards and Technology, FRANCIS STARR, Wesleyan University, JACK DOUGLAS, National Institute of Standards and Technology — Patchy particle models, composed of hard spheres with decorated with attractive patches, have been introduced as models of micron-sized particles with anisotropic interactions, as well as solutions of globular proteins. Here, we extend the canonical model of the patchy particles to include a short-ranged isotropic interaction in order to probe of the coupling of the directional and isotropic interactions on the self-assembly process. In particular, we evaluate basic properties characterizing self-assembly including average cluster mass and the fraction of particles in the clustered state using both Monte Carlo simulation and analytic Wertheim theory. This combination allows for validation of the theory and for insight into analyzing experimental data. We also find that Flory-Stockmayer theory describes the cluster size distribution data found in our simulations remarkably well, despite its erroneous mass-scaling exponent. This result, coupled with Wertheim theory, predicts both a master curve for the average cluster mass and a method to parameterize patchy particle models using experimental data.

**2:54PM H37.00003 Effective potentials in concentrated colloid-polymer mixtures with competing interactions**, MARCO LAURATI, NESTOR VALADEZ PEREZ, Universidad de Guanajuato, RONJA CAPELLMANN, STEFAN EGELHAAF, University of Düsseldorf, RAMON CASTAÑEDA-PRIEGO, Universidad de Guanajuato — We determine the effective potentials describing the interactions between colloidal particles in concentrated colloid-polymer mixtures in which depletion attraction competes with electrostatic repulsion. To obtain the potentials, the method of Monte-Carlo inversion is applied to experimental pair distribution functions obtained by confocal microscopy. Both fluid and gel states are investigated. We compare the results of the inversion method with those obtained by describing the interactions using a combination of a square well potential for the attractive component and a Yukawa potential for the repulsive component. This allows us to test the validity range of the one-component pair-potential.

**3:06PM H37.00004 Short-time dynamics in dispersions with competing short-range attraction and long-range repulsion**, RIEST JONAS, GERHARD NAEGELE, Institute of Complex Systems (ICS-3), Forschungszentrum Juelich GmbH, 52425 Juelich, Germany — The dynamic clustering of globular particles in suspensions exhibiting competing short-range attraction and long-range repulsion such as in protein solutions has gained a lot of interest over the past years. We investigate theoretically the influence of clustering on the dynamics of globular particle dispersions [1]. To this end, we systematically explore various pair potential models by a combination of state-of-the-art analytic methods in conjunction with computer simulations where the solvent-mediated hydrodynamic interactions are likewise included. Our theoretical results show that the cluster peak (intermediate-range-order peak) is present also in the hydrodynamic function characterizing the short-time dynamics, in accord with new experimental data [2]. Enhanced short-range attraction leads to a smaller self-diffusion coefficient and a larger dispersion viscosity. The behavior of the (generalized) sedimentation coefficient is more intricate, e.g. showing a non-monotonic interaction strength dependence.

**3:18PM H37.00005 Rheology of clustering protein solutions**, STEVEN HUDSON, NIST, VISHNU DHARMARAJ, Montgomery Blair High School, P. DOUGLAS GODFRIN, MIT, YUN LIU, NIST — Here we explore the rheology of low-salt lysozyme solutions, with special interest in the extremes of high concentration and low temperature. Under these conditions, reversible clustering of protein governed by their competing short-range attraction and long-range repulsion markedly enhances viscosity. Even in these conditions, the solutions exhibit Newtonian behavior over a wide range of shear rates. To test for departures from Newtonian behavior, we examined still higher shear rates. At shear rates in excess of 10,000 /s, we find reversible shear thinning at 40 % mass fraction. These results reveal dynamics of the protein clusters and are compared with other measurements of solution dynamics by neutron spin echo scattering and dynamic light scattering.

**3:30PM H37.00006 Monte Carlo simulation studies of diffusion in crowded environments**, PRITHVIRAJ NANDIGRAMI, Kent State University, BRANDY GROVE, Case Western Reserve University, ANDREW KONYA, ROBIN SELINGER, Kent State University — Anomalous diffusion has been observed in protein solutions and other multi-component systems due to macromolecular crowding. Using Monte Carlo simulations, we investigate mechanisms that govern anomalous diffusive transport and pattern formation in a crowded mixture. We consider a multi-component lattice gas model with “tracer” molecules diffusing across a density gradient in a solution containing sticky “crowder” molecules that cluster to form dynamically evolving obstacles. The dependence of tracer flux on crowder density shows an intriguing re-entrant behavior as a function of temperature with three distinct temperature regimes. At high temperature, crowders segregate near the tracer sink but, for low enough overall crowder density, remain sufficiently disordered to allow continuous tracer flux. At intermediate temperature, crowders segregate and block tracer flux entirely, giving rise to complex pattern formation. At low temperature, crowders aggregate to form small, slowly diffusing obstacles. The resulting tracer flux shows scaling behavior near the percolation threshold, analogous to the scenario when the obstacles are fixed and randomly distributed. Our simulations predict distinct quantitative dependence of tracer flux on crowder density in these temperature limits.

**3:42PM H37.00007 On shape and charges in colloidal dispersions**, EMMANUEL TRIZAC, Univ. Paris-Sud — Coulomb interactions are paramount in determining structural and dynamical properties for a wealth of anisotropic soft matter systems (clays, mineral crystallites, exfoliated nanosheets, patchy colloids, cement etc). The interplay between screening effects and anisotropy leads to distinctive yet often overlooked features, that will be discussed. In turn, the competition between the resulting effective potential and hard core constraints will be addressed. This competition can lead to non trivial structures, or impose strong dynamical slowing down. A distinction will be operated between weak and strong Coulomb coupling regimes.

**4:18PM H37.00008 Wetting-induced clustering and phoretic motions of colloidal particles**, THEYENCHERI NARAYANAN, ENRICO SEMERARO, RAJIV DATTANI, ESRF The European Synchrotron, F-38043, Grenoble — In recent years, self-propelled colloidal systems have received considerable attention as models for active matter. Most commonly used synthetic self-propelled systems involve Janus particles with asymmetric chemical composition in a catalytic medium. An analogous behavior can be obtained when particles are suspended in a phase separating binary liquid mixture due to preferential adsorption of one of the liquid species on the colloidal particles. Above an aggregation temperature ( $T_A$ ), particles become attractive and aggregate to form compact colloidal clusters. In the two phase region of the binary mixture, particles partition into the phase rich in adsorbed component. We have used silica colloids suspended in a binary mixture of 3-methyl pyridine and heavy water to probe this adsorption-induced phoretic motion of particles. Using ultra small-angle X-ray scattering and photon correlation spectroscopy, we investigated the static and dynamic behavior of this system. In the one phase region below  $T_A$ , particles display a repulsive structure factor with diffusive dynamics. In the two-phase region of the host liquid, the static structure is similar but the dynamics is strongly enhanced with the onset of phase separation reminiscent of self-propelled motion.

**4:30PM H37.00009 Multiscale simulations of nanoribbon structures from chromophore amphiphile self-assemblies**, DONGXU HUANG, ZHENWEI YAO, MONICA OLVERA, SAMUEL STUPP, Northwestern University — Finite-width self-assembled one-dimensional nanostructures have many potential applications as electronically or biologically active materials. Understanding the driving forces for supramolecular self-assembly is essential for the molecular design of new highly functional structures. Here we use multi-scale molecular dynamics simulations to study the self-assembly of chromophore amphiphiles into a nanoribbon previously shown to be useful in photocatalysis [1]. We demonstrate that the nanoribbon structure is a result of the competition between electrostatics and the hydrophobic effect. We incorporate a scaling analysis that correlates the electrostatic strength with the finite width of the ribbon. These results with additional numerical calculations show that anisotropy of the short-range intermolecular interactions and long-range electrostatics can be used to control the dimensionality of these systems. [1] Adam S. Weingarten, Roman V. Kazantsev, Liam C. Palmer, et al. & Samuel I. Stupp, Nature Chemistry, 2014

**4:42PM H37.00010 Self-assembly of Ionic Chromonic Liquid Crystals**, HYTHEM SIDKY, JONATHAN K. WHITMER, University of Notre Dame — Chromonic liquid crystals exhibit a unique self-assembly process which is of both theoretical and practical interest. A characteristic feature of chromonics is the occurrence of molecular association through stacking at extremely low concentrations. Experimental evidence has suggested that this process is approximately isodesmic across a broad concentration range. To date, only a handful of computational studies have managed to reproduce crucial aspects of chromonic phases, using expensive atomistic simulations. Here, we present a minimal model capable of capturing key features of the lyotropic chromonic phase. Molecular simulations of coarse-grained mesogens are used to map out the phase behavior and explore how structural and energetic anisotropies influence their ordering and response.

**4:54PM H37.00011 Lipid domains in zwitterionic-anionic lipid mixtures induced by combined effect of monovalent and divalent ions**, HONGCHENG XU, Biophysics Program, University of Maryland, College Park, SAI GANESAN, Fischell Department of Engineering, University of Maryland, College Park, SILVINA MATYSIAK, Biophysics Program, Fischell Department of Engineering, University of Maryland, College Park — Lipid domain formation is an important process for many cellular processes. In experiment, the effects of  $\text{Ba}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  in inducing lateral phase separation in the binary phosphatidylcholine-phosphatidylserine (PC-PS) bilayer are quite different, of which the molecular mechanism remains to be understood. We have explored the effect of monovalent (MI) and divalent (MII) cationic radii on lipid domain formation in mixed zwitterionic-anionic lipid bilayers. We propose a mechanism for the formation of divalent-cation-induced lipid domains based on MD simulations with our Water-Explicit Polarizable MEMbrane (WEPMEM) coarse-grained model, which uses PC as the model for zwitterionic and PS for anionic lipids. Lipid aggregation only occurs with limited range of monovalent and divalent ion sizes in agreement with experimental observations. More ordering and closer packing of the lipids are noted within the domains, which correlate with bilayer thickness, curvature and lipid asymmetry. The results of the simulations reveal that the lipid domain consists of MII-mediated anionic lipid dimer/trimer complexes bridged by monovalent ions MI and provide a stereochemical insight in understanding the experimentally observed calcium-induced phase separation.

**5:06PM H37.00012 The morphology of small sized clusters in a system with the competing interactions**, YUN LIU, NIST Center for Neutron Research, Gaithersburg, MD, USA, NSTOR VALADEZ-PREZ, RAMON CASTAEDA-PRIEGO, Department of Physical Engineering, University of Guanajuato, Mexico — We have systematically investigated the morphological changes of clusters in a system with both a short-ranged attraction and long-ranged repulsion, which is ubiquitous for protein solutions. Interestingly, even though the delicate balance between the attraction and repulsion controls the fractal dimension of the large clusters, the overall sizes of small clusters seem to be sensitive only to the short-ranged attraction. This microscopic structure change is thus consistent with and provides a microscopic physical picture of the recently proposed general phase diagram where the attractive interaction controls the formation of clustered fluid in the one phase region.

**5:18PM H37.00013 Viscoelastic properties of DNA coated colloid suspensions**, CHRISTINE MIDDLETON, DAVID PINE, New York University — DNA coated colloids are a unique gel forming system because of their tunable short range attraction. The interparticle potential can be varied through the chosen DNA sticky end, the particle coating density, and the temperature. We present studies of how these parameters affect the viscoelastic properties of suspensions of DNA coated colloids around the gel transition.

**Tuesday, March 15, 2016 2:30PM - 5:30PM —**

**Session H38 DPOLY FIAP: Polymer Nanocomposites: Dynamics** 341 - Laura Clarke, NC State University

**2:30PM H38.00001 Dynamics in Polymer Melts and Nanocomposites**, GERALD SCHNEIDER, Louisiana State Univ - Baton Rouge — Intense research has led to substantial progress in the field of polymer melts and nanocomposites, both regarding the fundamental understanding and the relationship to applications. From a fundamental point of view, knowing the microscopic single chain dynamics is important. It may even lead to optimized materials ranging from the classical car tire to battery or fuel cell applications. In polymer melts, different processes, such as diffusion, reptation, contour length fluctuations, etc. occur and determine the macroscopic results, e.g. obtained by rheology. In nanocomposites confinement effects and interactions of chains with surfaces play an important role. High resolution techniques, such as small-angle neutron scattering or neutron spin echo spectroscopy are suited to explore the structure and dynamics of chains. The presentation illuminates the fundamental relationship between the microscopic dynamics and the mesoscopic properties, exploiting different experimental techniques, such as dielectric spectroscopy, rheology, neutron scattering and neutron spin echo spectroscopy.

**2:42PM H38.00002 Phase Stability and Dynamics of nanoparticles in Polymer Nanocomposites**, RAHUL MANGAL, Cornell University, SAMANVAYA SRIVASTAVA, The University of Chicago, LYNDEN ARCHER, Cornell University — In polymer nanocomposites, polymer grafted nanoparticles, where the tethered polymer chains are chemically identical to the host chains, have been reported to irreversibly aggregate if the length of host chains (P) become 5 or more times larger than the length tethered chains (N) due to the autophobic dewetting of the polymer brush. Utilizing Small Angle X-ray scattering as a tool, here we show that by choosing appropriate chemistry one can utilize the enthalpic attractions between the tethered chains and host chains to facilitate uniform nanoparticle dispersion in very large  $M_w$  hosts ( $P/N \sim 140$ ). A generic phase diagram has also been proposed. X-ray Photon Correlation Spectroscopy (XPCS) is employed as a sensitive probe of nanoparticle relaxation dynamics to investigate particle dynamics in these model PNCs. Remarkably, we find that for nanoparticle size  $D$ , slightly larger than the tube diameter of the host polymer ( $a$ ), particles undergo a transition from normal diffusion to hyperdiffusive relaxation dynamics. In contrast, for unentangled hosts, diffusive particle relaxation are observed. Our experimental observations are rationalized by finding that nanoparticle motion in entangled melts only disturb sub-chain entangled segments of size comparable to the particle diameter.

**2:54PM H38.00003 Nanoparticle effect on polymer chain dynamics and entanglement network<sup>1</sup>**, YING LI<sup>2</sup>, University of Connecticut, MARTIN KROGER, ETH Zurich — We investigated structure and dynamics of polymer nanocomposites through molecular modeling, by considering different molecular weights of polymers chains, and volume fractions of fillers. The dynamics of unentangled chains can be separated into two phases, a bulk polymer phase and a confined polymer phase between fillers. The dynamics of a confined polymer is slower than that of a bulk polymer, while still exhibiting high mobility. The amount of the bulk polymer phase is found to exponentially decay with increasing volume fraction of fillers. When highly entangled polymer chains are confined between fillers, their conformation and entanglement network are dramatically changed, in district with their unentangled counterparts. The entangled polymer chains are found to be significantly disentangled and flattened during increment of the volume fractions of spherical nonattractive fillers. A critical volume fraction is found to control the crossover from polymer chain entanglements to 'nanoparticle entanglements', below which the polymer chain relaxation accelerates upon filling. These results provide a microscopic understanding of the dynamics of entangled polymer chains inside their composites, and offer an explanation for the unusual rheological properties of polymer composites.

**3:06PM H38.00004 Thermally induced infiltration of polymer into nanoparticle packings**, JYO LYN HOR, University of Pennsylvania, Department of Chemical and Biomolecular Engineering, YIJIE JIANG, KEVIN T. TURNER, University of Pennsylvania, Department of Mechanical Engineering and Applied Mechanics, DAEYEON LEE, University of Pennsylvania, Department of Chemical and Biomolecular Engineering — We present a novel approach in generating three-phase polymer nanocomposites via capillary rise infiltration (CaRI) of polymer into a dense nanoparticle packing, which we have previously utilized to generate dense nanocomposites with extremely high filler fraction. The CaRI process involves first generating a bilayer film of porous nanoparticle layer on a polymer layer, followed by annealing of the bilayer above the  $T_g$  of the polymer to induce polymer infiltration into the voids of the nanoparticle layer. By tuning the amount of polymer to be less than the void volume of the nanoparticle layer, we demonstrate that CaRI is capable of generating spatially homogeneous porous composite. We utilize spectroscopic ellipsometry to characterize and monitor the polystyrene infiltration process into the titania nanoparticle packing in-situ. The infiltration process occurs in two stages. Upon annealing, we observe that the polymer layer is depleted rapidly via capillary-induced infiltration to form a dense composite at the base of the nanoparticle packing. Eventually, the front of this composite layer propagates throughout the nanoparticle packing, just as the composite refractive index decreases, indicating the redistribution of polymer throughout the nanoparticle matrix.

**3:18PM H38.00005 The effect of chain rigidity on the interfacial layer thickness and dynamics of polymer nanocomposites.**, SHIWANG CHENG, JAN-MICHAEL Y. CARRILLO, Oak Ridge National Laboratory, BOBBY CARROLL, Department of Physics and Astronomy, University of Tennessee, BOBBY G. SUMPTER, Oak Ridge National Laboratory, ALEXEI P. SOKOLOV, Department of Chemistry, University of Tennessee — There are growing experimental evidences showing the existence of an interfacial layer that has a finite thickness with slowing down dynamics in polymer nanocomposites (PNCs). Moreover, it is believed that the interfacial layer plays a significant role on various macroscopic properties of PNCs. A thicker interfacial layer is found to have more pronounced effect on the macroscopic properties such as the mechanical enhancement. However, it is not clear what molecular parameter controls the interfacial layer thickness. Inspired by our recent computer simulations that showed the chain rigidity correlated well with the interfacial layer thickness,[1] we performed systematic experimental studies on different polymer nanocomposites by varying the chain stiffness. Combining small-angle X-ray scattering, broadband dielectric spectroscopy and temperature modulated differential scanning calorimetry, we find a good correlation between the polymer Kuhn length and the thickness of the interfacial layer, confirming the earlier computer simulations results. Our findings provide a direct guidance for the design of new PNCs with desired properties. [1] Carrillo, J.-M. Y. *et al*; *Macromolecules* **2015**, *48*, (12), 4207-4219.

**3:30PM H38.00006 Fragility-Controllable Polymer Grafted Nanoparticles.**<sup>1</sup> , MAKOTO ASAI, SANAT KUMAR, ANGELO CACCIUTO, Columbia Univ — 20 years ago, the concept of 'Fragility' has been suggested to categorize glass-forming liquids. Currently, we know there are two kinds of glass-forming liquids group. One is Arrhenius type liquids called as Strong glass (large Fragility). Another one is non-Arrhenius liquid called as Fragile glass (small Fragility). The physical meaning of Fragility is unknown yet, but people believe that to understand the physical meaning of Fragility leads to understand glass transition. Recently we found Polymer Grafted Nanoparticles (PGNPs) could behave like glass-forming liquids depending on their grafting density in MD simulations. Surprisingly, their Fragility can be controlled by grafting density and we can obtain both 'Strong' and 'Fragile' glass using this system.

**3:42PM H38.00007 Activated Dynamics in Dense Model Nanocomposites** , SHIJIE XIE, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — The nonlinear Langevin equation approach is applied to investigate the ensemble-averaged activated dynamics of small molecule liquids (or disconnected segments in a polymer melt) in dense nanocomposites under model isobaric conditions where the spherical nanoparticles are dynamically fixed. Fully thermalized and quenched-replica integral equation theory methods are employed to investigate the influence on matrix dynamics of the equilibrium and nonequilibrium nanocomposite structure, respectively. In equilibrium, the miscibility window can be narrow due to depletion and bridging attraction induced phase separation which limits the study of activated dynamics to regimes where the barriers are relatively low. In contrast, by using replica integral equation theory, macroscopic demixing is suppressed, and the addition of nanoparticles can induce much slower activated matrix dynamics which can be studied over a wide range of pure liquid alpha relaxation times, interfacial attraction strengths and ranges, particle sizes and loadings, and mixture microstructures. Numerical results for the mean activated relaxation time, transient localization length, matrix elasticity and kinetic vitrification in the nanocomposite will be presented.

**3:54PM H38.00008 Effect of polymer-nanoparticle interactions on the capillary rise infiltration of polymers into nanoporous media**<sup>1</sup> , DAVID RING, AMIT SHAVIT<sup>2</sup>, ROB RIGGLEMAN, DAEYEON LEE, Univ of Pennsylvania — By wicking a polymer into a porous packing of nanoparticles, it is possible to generate polymer nanocomposites with extremely high filler fractions. Although capillary rise of simple fluids in porous media is fairly well understood based on the Lucas-Washburn model, there remain many unanswered questions related to the infiltration of high molecular weight polymer melts in nanoporous media. In this work, we probe the thermally induced infiltration of polymers into packings of nanoparticles using molecular dynamics (MD) simulations. In particular, we investigate the effect of polymer-nanoparticle interactions on the three phase contact angle of the polymer on the nanoparticle surface, and probe how the infiltration process is affected by changes in these interactions. We also study the effect of molecular weight on the capillary rise behavior of polymers in nanoparticle packings.

**4:06PM H38.00009 Effects of Attractive Interactions on Nanoparticle Diffusion in Entangled Polymer Melts** , PHILIP GRIFFIN, University of Pennsylvania, NIGEL CLARKE, University of Sheffield, RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — Developing a complete picture for the mechanism of nanoparticle diffusion in model polymer nanocomposites remains a great challenge, especially experimentally. Using Rutherford backscattering spectroscopy, we have measured the translational diffusion coefficient of spherical nanoparticles (diameter = 20 nm) infiltrated into poly(2-vinylpyridine) melts across a range of molecular weights (35-300 kg/mol). Our results reveal that the diffusion coefficient of nanoparticles in attractive nanocomposites is several times slower than what is predicted from the melt viscosity according to the Stokes-Einstein (SE) relation. This runs contrary to recent theoretical studies of non-attractive systems, where it is predicted that nanoparticle diffusion can be many orders of magnitude faster than SE predictions. Potential explanations for this unusual slowing of nanoparticle diffusion are discussed.

**4:18PM H38.00010 Understanding the interfacial layer dynamics of polymer nanocomposites from broadband dielectric spectroscopy** , ROBERT CARROLL, SHIWANG CHENG, ALEXEI SOKOLOV, Univ of Tennessee, Knoxville — Polymer nanocomposites show many advanced mechanical, thermal, optical, and transport properties mainly due to the vast interfacial area between the polymer matrix and nanoparticles. Recent studies show that there is an interfacial polymer layer with structure and dynamics that are different from the bulk polymer, and that contributes to the advanced macroscopic properties. It has been shown that broadband dielectric spectroscopy provides good method to study the interfacial dynamics in nanocomposites. However, current dielectric spectroscopy studies ignore the heterogeneous nature of polymer nanocomposites. Models based on a simple superposition of bulk polymer and interfacial layer spectra, or those that assume the interfacial layer is dynamically dead are inaccurate. In this talk, the prevailing methods in the literature will be compared with an accurate method accounting for the heterogeneity of the nanocomposites. Different nanocomposites with well-dispersed nanoparticles will be used as examples. The analysis clearly shows that the width and the amplitude of the relaxation peaks are affected by the data analysis. Thus accurate quantitative conclusions on properties and thickness of the interfacial layer can be achieved only using heterogeneous models.

**4:30PM H38.00011 Interfacial Effect on Confined Crystallization of Poly(ethylene oxide)/Silica Composites**<sup>1</sup> , YUNLAN SU, WEIWEI ZHAO, XIA GAO, Institute of Chemistry, Chinese Academy of Sciences, JIANJUN XU, 2DSM Resolve, P.O. Box 18, the Netherlands , DUJIN WANG, Institute of Chemistry, Chinese Academy of Sciences — The impact of nanoconfinement introduced by nanoparticles on polymer crystallization has attracted extensive attention because it plays the decisive role in the ultimate properties of polymer nanocomposites. In this study, interfacial and spatial confinement effects of silica (SiO<sub>2</sub>) nanoparticles on the crystallization behaviors of poly(ethylene oxide) (PEO)/SiO<sub>2</sub> composites were systematically investigated by changing the size and concentration of SiO<sub>2</sub> in PEO matrix. The composites with high silica loadings exhibit two crystallization peaks of PEO as determined by differential scanning calorimetry (DSC). The first peak at 7–43 C is related to the bulk PEO, while the second peak at –20 to –30 C is attributed to the restricted PEO segments. Three-layer (amorphous, interfacial and bulk) model is proposed to interpret the confined crystallization of PEO/SiO<sub>2</sub> composites, which is supported by the results of thermogravimetric analysis (TGA) and solid-state <sup>1</sup>H nuclear magnetic resonance (NMR). In amorphous layer, most PEO segments are directly adsorbed on SiO<sub>2</sub> surface via hydrogen bonding. The interfacial PEO layer, which is nonuniform, is composed of crystallizable loops and tails extending from amorphous layer.

**4:42PM H38.00012 Molecular Dynamics Simulations of Silica-Filled Copolymers with Variable Sequence for Applications in Tire Treads**, ALEX J. TRAZKOVICH, The Ohio State University and The Cooper Tire and Rubber Company, LISA M. HALL, The Ohio State University — We simulate a simple nanocomposite relevant to tire tread compounds consisting of a single spherical nanoparticle surrounded by coarse-grained polymer chains. The polymers are composed of two different monomer types, which have different interaction strengths with the nanoparticle. The monomer sequence can be varied to model different copolymer configurations. We study the polymer end-to-end vector autocorrelation functions to obtain relaxation times of adsorbed and bulk polymer, showing how the interphase is affected by the polymer type and the monomer-nanoparticle interaction strengths. An understanding of the effect of copolymer sequence on the range of the polymer interphase and the magnitude of the effect on chain dynamics is critical to tire tread material design since the primary polymer component of modern tire tread is styrene-butadiene rubber (SBR) copolymer, which may be synthesized in primarily random or in various blocky copolymer configurations. Macromolecular adsorption to and desorption from filler surfaces has a significant effect on hysteresis, and in tire treads, hysteresis must be controlled to optimize the tradeoff between traction and rolling resistance. Superior tire tread materials must have high hysteresis under the operating conditions of traction while maintaining low hysteresis under the operating conditions of rolling resistance. An opportunity exists to control hysteresis through the use of SBR with specific monomer sequences.

**4:54PM H38.00013 Distortion of chain conformation and reduced entanglement in polymer-graphene oxide nanocomposites**, MICHAEL WEIR, Department of Physics and Astronomy, University of Sheffield, STEPHEN BOOTHROYD, DAVID JOHNSON, RICHARD THOMPSON, KARL COLEMAN, Durham University, NIGEL CLARKE, University of Sheffield — Graphene and related two-dimensional materials are excellent candidates as filler materials in polymer nanocomposites due to their extraordinary physical properties and high aspect ratio. To explore the mechanism by which the filler affects the bulk properties of these unique systems, and to build understanding from the macromolecular level upwards, we use a combination of small-angle neutron scattering (SANS) and oscillatory rheology. Where a good dispersion is achieved in poly(methyl methacrylate)-graphene oxide (PMMA-GO) nanocomposites, we observe a reduction in the polymer radius of gyration with increasing GO concentration that is consistent with the predicted behavior of polymer melt chains at a solid interface. We use concepts from thin-film polymer physics to formulate a scaling relation for the reduction in entanglements caused by the GO interfaces. Using these scaling arguments, we utilize SANS results to directly estimate the changes to the elastic plateau modulus of the network of entangled polymer chains, and find a correlation with the measured bulk rheology. We present a direct link between interfacial confinement effects and the bulk polymer nanocomposite properties, whilst demonstrating a model system for measuring thin film polymer physics in the bulk.

**5:06PM H38.00014 Thin Film Deformation Behavior of Polystyrene Grafted Nanoparticle Assemblies**, YANG JIAO, MING-SIAO HSIAO, LAWRENCE DRUMMY, RICHARD VAIA, Air Force Research Laboratory, WPAFB — Assemblies of polymer-grafted “hairy” nanoparticles (HNPs) are of current interest for a wide array of mechanical, photonic and electrical applications. In contrast to nanoparticles dispersed in a free polymer matrix, the grafted polymer determines particle spacing and circumvents nanoparticle agglomeration. The extent to which these grafted polymers are entangled determines the robustness and strength of the HNP assembly. Here in, we investigate the correlations between grafted polymer conformation, entanglements and deformation mechanisms of thin film assemblies of polystyrene-grafted HNPs by controlling the HNP architecture (grafting density and molecular weight). HNPs with varied corona structures are synthesized with surface-initiated controlled/living radical polymerization. Thin films with controlled thickness are prepared by flow coating. Plastic deformation of thin films are examined using static (bright field, HAADF-STEM, tomography) and AFM techniques. Results show a decrease of void density in craze as grafted polymer length increases for semi-dilute polymer brushes. These correlations between HNP architecture and assembly deformation and failure modes refine the HNP design space for the synthesis and fabrication of assemblies with excellent mechanical properties.

**5:18PM H38.00015 Tuning mechanical properties of polymer-grafted nanoparticle networks by using biomimetic catch bonds**, BADEL L. MBANGA, BALAJI V. S. IYER, VICTOR V. YASHIN, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh, Pennsylvania 15261, USA — Cross-linked networks of polymer-grafted nanoparticles (PGNs) constitute a class of composites with tunable mechanical properties that exhibit a self-healing behavior. A PGN network consists of nanoparticles that are decorated with end-grafted polymer chains. Reactive groups on the free ends of these grafted chains can form bonds with the chain ends on the nearby particles. We study these materials using a 3D computational model that encompasses the particle-particle interactions, the kinetics of bond formation and rupture, and the external forces applied to the network. In our model, a fraction of cross-links is formed through biomimetic catch bonds. In contrast to conventional slip bonds, catch bonds can effectively become stronger under a deformation. We show that by varying the fraction of these catch bonds in the network, the toughness, ductility, and tensile strength of the material could be tuned to desired levels.

**2:30PM H39.00001 Expulsion of swimming bacteria by a circular flow.**<sup>1</sup>, ANDREY SOKOLOV, IGOR ARONSON, Argonne National Laboratory — Macroscopic shear flow alters swimming trajectories in a highly nontrivial way and results in dramatic reduction of viscosity and heterogeneous bacterial distributions. We report on experimental and theoretical studies of rapid expulsion of microswimmers, such as motile bacteria, by a circular flow created by a rotating microparticle. We observed a formation of a macroscopic depletion area in a high-shear region, in the vicinity of a microparticle. The rapid migration of bacteria from the shear-rich area is caused by a circular structure of the flow rather than intrinsic random fluctuations of bacteria orientations, in stark contrast to planar shear flow. Our mathematical model revealed that expulsion is a combined effect of motility and alignment by a vortical flow. Our findings offer a novel approach for manipulation of motile microorganisms and shed new light on bacteria-flow interactions.

**2:42PM H39.00002 Bacterial haptotaxis: Effect of auto-attraction and bacterial motility on microcolony formation**, BERNARD BECKERMAN, Northwestern University, KUN ZHAO, Tianjin University, GERARD C. L. WONG, University of California, Los Angeles, ERIK LUIJTEN, Northwestern University — Recent work<sup>1</sup> has demonstrated that surface-adhered *Pseudomonas aeruginosa* tend to self-organize into microcolonies using a positive-feedback mechanism mediated by the exopolysaccharide Psl, which the bacteria secrete as they traverse the surface. We elucidate this colony-nucleation process and explore how it is influenced by the deposition rate of Psl and by bacterial motility. A detailed analysis of the data presented in our earlier study, in combination with additional simulations, provides further insight into the exploratory strategy of *P. aeruginosa*. Specifically, the isogenic bacterial population is found to exhibit polyphenic motility. As a result, the bacterial population splits into two distinct subpopulations when depositing Psl, those that become trapped in their self-deposited Psl and those that move sufficiently quickly to escape their Psl beds and explore the surface. We perform computer simulations in which we adjust the relative prevalence of these subpopulations by varying the Psl deposition rate and find that there is a trade-off between surface exploration, microcolony diversity and microcolony fortification.

**3:06PM H39.00004 Tethered motion of unflagellated bacteria at the liquid-solid surface**, JORDAN BELL, JAY TANG, Brown University — Direct evidence of the bacterial flagellar motors rotation was first noted when multiflagellated bacterial cells were observed (under the optical microscope) to rotate when tethered to glass by a single flagellum. The tethered cell assay has continued to play a significant role throughout the subsequent studies of motor characteristics and behavior. Such studies have expanded to include unflagellated bacteria, such as *Vibrio alginolyticus*, *Pseudomonas aeruginosa*, and *Caulobacter crescentus*. Here we show that such cells are not necessarily tethered by their flagellum, but rather elsewhere on the cell body. The observed cell body rotation is actually due to the flagellum either rolling against the glass surface, or pushing the cell body at the flagellar base. These motions are directly observed for *Vibrio alginolyticus* with darkfield microscopy. Additionally, our recently measured distributions of intervals between motor switches for tethered *Caulobacter crescentus* also confirm this more complicated mode of tethering. Therefore, the rotational speed of tethered unflagellated bacteria may not equate to that of the motor itself, as is commonly assumed.

**3:18PM H39.00005 Two-dimensional swimming behavior of bacteria**, YE L

The Chinese University of Hong Kong, SANDRA SANCHEZ, DANIEL KEARNS, Department of Biology, Indiana University, The Chinese University of Hong Kong; Department of Physics, The Chinese University of Hong Kong — Many motile bacteria use flagella, which is essential for bacterial dispersal, chemotaxis, and pathogenesis. Here we combined single-cell tracking, theoretical analysis, and experiments to investigate two-dimensional swimming behavior of a well-characterized flagellated bacterium *Bacillus subtilis* at the single-cell motion pattern of *B. subtilis* in confined space and studied how cells interact with each other. Our findings shed light on bacterial collective motion environments, and will serve as the ground for building more accurate models to understand bacterial collective motion.

**3:30PM H39.00006 Swimming of bacteria under dielectrophoresis**, NGOC PHU TRAN, MARCOS MARCOS<sup>1</sup>, School of Mechanical and Aerospace Engineering, Nanyang Technological University, Singapore — In this work, we present a model to predict the response of a swimming helically flagellated bacterium to a unidirectional dielectrophoretic (DEP) force with its strength varying linearly in space. We employ resistive force theory to compute the hydrodynamic force on the flagellar bundle, and the effects of DEP force and rotational diffusion are examined using the Fokker-Planck equation. The DEP force greatly contributes to the reorientation of the bacterium such that the bacterium's primary axis is aligned with the direction of the force. Interestingly, when the DEP strength varies perpendicularly to the direction of the force, the bacterium's primary axis is no longer aligned with the DEP force, which results in a translation of the bacterium perpendicular to its primary axis. Finally, we show the feasibility to utilize this phenomenon to achieve bacterial focusing.

<sup>1</sup>The full name of the second author is MARCOS.

**3:42PM H39.00007 The bacterial gliding machinery**, ABHISHEK SHRIVASTAVA, Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA — Cells of *Flavobacterium johnsoniae*, a rod-shaped bacterium, glide over surfaces with speeds reaching up to 2 micrometer's. Gliding is powered by a protonmotive force. The adhesin SprB forms filaments about 160 nm long that move on the cell-surface along a looped track. Interaction of SprB filaments with a surface produces gliding. We tethered *F. johnsoniae* cells to glass by adding anti-SprB antibody. Tethered cells spun about fixed points, rotating at speeds of about 1 Hz. The torques required to sustain such speeds were large, comparable to those generated by the flagellar rotary motor. Using a flow cell apparatus, we changed load on the gliding motor by adding the viscous agent Ficoll to tethered cells. We found that a gliding motor runs at constant speed rather than constant torque. We attached gold nanoparticles to the SprB filament and tracked its motion. We fluorescently tagged a bacterial Type IX secretion system (T9SS) protein and imaged its dynamics. Fluorescently tagged T9SS protein localized near the point of tether, indicating that T9SS localizes with the gliding motor. Based on our results, we propose a model to explain bacterial gliding.

**4:18PM H39.00008 Coordinated Beating of Algal Flagella is Mediated by Basal Coupling**, KIRSTY WAN, RAYMOND GOLDSTEIN, Univ of Cambridge — Cilia or flagella often exhibit synchronized behavior. This includes phase-locking, as seen in *Chlamydomonas*, and metachronal wave formation in the respiratory cilia of higher organisms. Since the observations by Gray and Rothschild of phase synchrony of nearby swimming spermatozoa, it has been a working hypothesis that synchrony arises from hydrodynamic interactions between beating filaments. Recent work on the dynamics of physically separated pairs of flagella isolated from the multicellular alga *Volvox* has shown that hydrodynamic coupling alone is sufficient for synchrony. However, the situation is more complex when considering multiple flagella on a single cell. We suggest that a mechanism, internal to the cell, provides an additional flagellar coupling. For instance, flagella of *Chlamydomonas* mutants deficient in filamentary connections between basal bodies are found to display markedly different synchronization from the wildtype. Diverse flagellar coordination strategies found in quadri-, octo- and hexadecaflagellates reveal further evidence that intracellular couplings between flagellar basal bodies compete with hydrodynamic interactions to determine the precise form of flagellar synchronization in unicellular algae.

**4:30PM H39.00009 Non-Poissonian run-and-turn motions**, FRANCOIS DETCHEVERRY, University of Lyon, CNRS — Swimming bacteria exhibit a variety of motion patterns (run-and-tumble, run-reverse, run-reverse-flick), in which persistent runs are punctuated by sudden turning events. What are the properties of such random motions? If a complete answer has been given when the turning events follow a Poisson process, it has remained elusive outside this particular case. We present a generic framework for such non-Poissonian run-and-turn random motions. We obtain the generating function of moments by building on the framework of continuous time random walks and using non-commutative calculus. The approach is applied to a bimodal model of persistent motion that is directly applicable to swimming patterns and cell motility.

**4:42PM H39.00010 Directionality Time - New Analytical Treatment of Directionally Biased, Crawling Motility** , JAY TANG, ALEXANDER LOOSLEY, Brown University — Insights on crucial biological functions often emerge from measuring how animal cells crawl on surfaces, particularly in response to gradients of external cues that cause directionally biased motion. Most existing metrics commonly used to characterize directional migration, such as straightness index (or chemotactic index), persistence time, and turning angle distribution, tend to be sensitive to relatively large errors at short sampling times. In contrast, we recently introduced a new metric, called directionality time, to define the onset time by which a seemingly random motion becomes directionally biased (OBrien et al., J Leukocyte Biol, 2014, 95:9931004; Loosley et al., PLOS ONE, 2015, 10.1371). Directionality time is obtained by fitting the mean squared displacement as a function of time interval, in log-log coordinates, to a fit function based on biased and persistent random walk processes. We show that the fit function is approximately model invariant and is applicable to a variety of directionally biased motions. Simulations are performed to show the robustness of the directionality time model and its decoupling from measurement errors. Finally, we demonstrate as an example how to usefully apply the directionality time fit to trajectories of chemotactic neutrophils.

**4:54PM H39.00011 Paramagnetic ellipsoidal microswimmer in a magnetic field** , MARIO SANDOVAL, Metropolitan Autonomous University, LOUIS FAN, University of Wisconsin, Madison, ON SHUN PAK, University of Santa Clara — We study the two-dimensional Brownian dynamics of an ellipsoidal paramagnetic microswimmer moving at low-Reynolds-number and subject to a magnetic field. Its corresponding mean-square displacement tensor showing the effect of particles's shape, activity and magnetic field, on the microswimmer's diffusion is analytically obtained. A comparison among analytical and computational results is also made and we obtain excellent agreement.

**2:30PM H40.00001 Wave Manipulation in Metamaterials: A LEGO® Bricks Enabled Platform<sup>1</sup>** , PAOLO CELLI, STEFANO GONELLA, University of Minnesota — In this work, we show how simple, reconfigurable arrangements of LEGO® bricks can be turned into the building blocks of an experimental platform for the investigation of wave phenomena in metamaterial architectures. The approach involves the assembly of reconfigurable specimens consisting of patterns of bricks on a baseplate and the use of a 3D laser vibrometer to reconstruct global and local wave features. The ability to seamlessly transition between different topologies makes this an effective approach for rapid experimental verification and proof of concept in the arena of mechanical metamaterials engineering. The intuitive nature of the brick-and-baseplate assembly paradigm can also be leveraged to implement families of intuitive lab demonstrations with significant didactic and scientific outreach potential. The versatility of the platform is tested through a series of experiments that illustrate a variety of wave manipulation effects, such as waveguiding and seismic isolation, both in periodic and disordered topologies.

**2:42PM H40.00002 Transformable topological mechanical metamaterials<sup>1</sup>** , D. ZEB ROCKLIN, SHANGNAN ZHOU, KAI SUN, XIAOMING MAO, University of Michigan, Department of Physics — We present a class of mechanical metamaterials characterized by a *uniform soft deformation*—a large, zero-energy homogeneous elastic deformation mode of the structure—that may be used to induce topological transitions and dramatically change mechanical and acoustic properties of the structure. We show that the *existence* of such a mode determines certain exotic mechanical and acoustic properties of the structure and its *activation* can reversibly alter and tune these properties. This serves as the basis for a design principle for mechanical metamaterials with tunable properties. When the structure's uniform mode is primarily dilational (shearing) its surface (bulk) possesses phonon modes with vanishing speed of sound. Maxwell lattices comprise a subclass of such material which, owing to their critical coordination number (four, in 2D), necessarily possess such a uniform zero mode, often termed a Guest mode, and which may be *topologically polarized*, such that zero modes are moved from one edge to another. We show that activating the deformation can alter the shear/dilational character of the mode and topologically polarize the structure, thereby altering the bulk and surface properties at no significant energy cost. arXiv:1510.06389 [cond-mat.soft]

**2:54PM H40.00003 Tuning the Response in Disordered Networks** , NIDHI PASHINE, Department of Physics, The University of Chicago, Chicago, IL, JASON W. ROCKS, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA, IRMGARD BISCHOFBERGER, Department of Physics, The University of Chicago, Chicago, IL, CARL P. GOODRICH, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, SIDNEY R. NAGEL, Department of Physics, The University of Chicago, Chicago, IL, ANDREA J. LIU, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA — The fact that amorphous materials are structurally different from crystals has important consequences for how the properties of a disordered structure can be tuned. We have used jamming as a method to create spring networks in both two and three dimensions. By selectively removing a small percentage of bonds, we can tune the network to have a desired response. For example, we can tune the network's Poisson ratio anywhere between the auxetic and incompressible limits. We can also produce a targeted response at a local scale; by perturbing the positions of pair of particles at one point we can tune in a desired response a large distance away. This response is similar to the allosteric regulation in proteins where a reaction at one site activates another site of the protein molecule. Experimentally, we have successfully demonstrated such mechanical networks in 2D (by laser cutting) or in 3D (3D printing).

**3:06PM H40.00004 The breakdown of breathers in the Fermi-Pasta-Ulam-Tsingou system<sup>1</sup>** , ALEXANDRA WESTLEY, RAHUL KASHYAP, SURAJIT SEN, State Univ of NY - Buffalo — It is well known that in many nonlinear lattices, remarkably stable and localized disturbances known as breathers may form. Here we discuss in short the properties of these objects in the context of the Fermi-Pasta-Ulam-Tsingou (FPUT) system which consists of a mass-spring chain, with spring potentials containing both quadratic and quartic terms. These breathers, though long-lasting, inevitably decay and eventually break apart with sudden violence. This talk in particular will focus on recent numerical work studying the lead-up to the breakdown in which the breather emits at (seemingly) random intervals solitary and anti-solitary waves in the highly nonlinear limit. Furthermore, a possible method to predict the times at which these waves are emitted by examining the frequency structure of the breather will be discussed.

**3:18PM H40.00005 Multifunctional Lattices with Low Thermal Expansion and Low Thermal Conductivity** , HANG XU, LU LIU, DAMIANO PASINI<sup>1</sup>, Mechanical Engineering, McGill University — Systems in space are vulnerable to large temperature changes when travelling into and out of the Earth's shadow. Variations in temperature can lead to undesired geometric changes in susceptible applications requiring very fine precision. In addition, temperature-sensitive electronic equipment hosted in a satellite needs adequate thermal-control to guarantee a moderate ambient temperature. To address these specifications, materials with low coefficient of thermal expansion (CTE) and low coefficient of thermal conductivity (CTC) over a wide range of temperatures are often sought, especially for bearing components in satellites. Besides low CTE and low CTC, these materials should also provide desirable stiffness, strength and extraordinarily low mass. This work presents ultralightweight bi-material lattices with tunable CTE and CTC, besides high stiffness and strength. We show that the compensation of the thermal expansion and joint rotation at the lattice joints can be used as an effective strategy to tailor thermomechanical performance. Proof-of-concept lattices are fabricated from Al and Ti alloy sheets via a simple snap-fit technique and vacuum brazing, and their CTE and CTC are assessed via a combination of experiments and theory.

**3:30PM H40.00006 Finite-temperature twisted-untwisted transition of the kagome lattice** , DESHPREET BEDI, D. ZEB ROCKLIN, XIAOMING MAO, University of Michigan — Mechanical instability governs many fascinating phenomena in nature, including jamming, glass transitions, and structural phase transitions. Although mechanical instability in athermal systems is well understood, how thermal fluctuations modify such transitions remains largely unexplored. Recent studies reveal that, due to the large number of floppy modes that emerge at mechanical instability, intriguing new phenomena occur, such as fluctuation-driven first-order transitions and order-by-disorder. In this talk, we present an analytic study of the finite-temperature rigidity transition for the kagome lattice. Our model exhibits a zero-temperature continuous twisted-untwisted transition as the sign of the next-nearest-neighbor spring constant changes. At finite temperature, we show that the divergent contribution of floppy modes to the vibrational entropy renormalizes this spring constant, resulting in a first-order transition. We also propose an experimental manifestation of this transition in the system of self-assembling triblock Janus particles.

**3:42PM H40.00007 Topological design of torsional metamaterials** , VINCENZO VITELLI, JAYSON PAULOSE, ANNE MEEUSSEN, Institute Lorentz for Theoretical Physics, Leiden, TOPOLOGICAL MECHANICS LAB TEAM — Frameworks – stiff elements with freely hinged joints – model the mechanics of a wide range of natural and artificial structures, including mechanical metamaterials with auxetic and topological properties. The unusual properties of the structure depend crucially on the balance between degrees of freedom associated with the nodes, and the constraints imposed upon them by the connecting elements. Whereas networks of featureless nodes connected by central-force springs have been well-studied, many real-world systems such as frictional granular packings, gear assemblies, and flexible beam meshes incorporate torsional degrees of freedom on the nodes, coupled together with transverse shear forces exerted by the connecting elements. We study the consequences of such torsional constraints on the mechanics of periodic isostatic networks as a foundation for mechanical metamaterials. We demonstrate the existence of soft modes of topological origin, that are protected against disorder or small perturbations of the structure analogously to their counterparts in electronic topological insulators. We have built a lattice of gears connected by rigid beams that provides a real-world demonstration of a torsional metamaterial with topological edge modes and mechanical Weyl modes.

**3:54PM H40.00008 Surface morphology of pre-stressed bilayer shells for tunable optical transmittance** , RASHED AL-RASHED, FRANCISCO LPEZ JIMNEZ, JOEL MARTHELOT, ANNA LEE, PEDRO REIS, Massachusetts Institute of Technology — We introduce a new class of pre-stressed bilayer shells, whose surface morphology can be used to smoothly tune their optical transmittance by pneumatic actuation. Each sample is fabricated by pressurizing a disk made out of an optically clear silicone-based rubber to bulge it into a nearly hemispherical pre-strained shell. The surface of this shell is then taken as a substrate and coated with a thin layer of a polymer suspension with black micron-sized dye particles, which, upon curing, can make the samples opaque. The sample becomes planar when it is depressurized to remove the pre-strain, and its surface develops a complex topography that significantly affects its optical transmittance (i.e. the amount of light that passes through the sample). Re-pressurization of the samples allow for their transmittance to be smoothly tuned in a reversible manner. We explore the parameter space of the system by systematically varying its geometric and material properties. A phase diagram is then constructed where we characterize the transmittance of each of the surface patterns at varying levels of pre-strain.

**4:06PM H40.00009 Elastic theory of origami-based metamaterials<sup>1</sup>** , FREDERIC LECHENAULT, Laboratoire de Physique Statistique, ENS, Paris, V. BRUNCK, Lab. de Physique Statistique, Ecole Normale Supérieure, UPMC, Univ. Paris 06, Univ. Paris-Diderot, CNRS, Paris, France, A. REID, Lab. de Physique Statistique, Ecole Normale Supérieure, UPMC, Univ. Paris 06, Univ. Paris-Diderot, CNRS, Paris, France & NC State Univ, M. ADDA-BEDIA, Lab. de Physique Statistique, Ecole Normale Supérieure, UPMC, Univ. Paris 06, Univ. Paris-Diderot, CNRS, Paris, France — Origami offers the possibility for new metamaterials whose overall mechanical properties can be programmed by acting locally on each crease. Starting from a thin plate and having knowledge about the properties of the material and the folding procedure, one would aim to determine the shape taken by the structure at rest and its mechanical response. We introduce a vector deformation field acting on the imprinted network of creases, that allows to express the geometrical constraints of rigid origami structures in a simple and systematic way. This formalism is then used to write a general covariant expression of the elastic energy of  $n$ -creases meeting at a single vertex, and then extended to origami tessellations. The generalized waterbomb base and the Miura-Ori are treated within this formalism. For the Miura folding, we uncover a phase transition from monostable to two metastable states, that explains the efficient deployability of this structure for a given range of geometrical and mechanical parameters.

**4:18PM H40.00010 Self-Folding With Graphene Bimorphs** , MARC MISKIN, KYLE DORSEY, PETER ROSE, ITAI COHEN, PAUL MCEUEN, Cornell University — We have developed a new technique that let us program two layer stacks, or bimorphs, made of graphene and ultra-thin films to self-fold via differential stress. Our approach works in the extreme regime of bimorph folding: we construct bimorphs that optimize folding efficiency when one layer is atomically thin. The resulting devices controllably fold to micron sized radii of curvature. By applying this technique in concert with lithographic patterning, we have produced a powerful platform to build three dimensional structures at the nanoscale. We demonstrate that this this approach is intrinsically scalable and facilitates the construction of both fixed 3d structures and actuation.

**4:30PM H40.00011 The role of geometry in 4-vertex origami mechanics** , SCOTT WAITUKAITIS, PETER DIELEMAN, MARTIN VAN HECKE, Leiden University, AMOLF — Origami offers an interesting design platform metamaterials because it strongly couples mechanics with geometry. Even so, most research carried out so far has been limited to one or two particular patterns. I will discuss the full geometrical space of the most common origami building block, the 4-vertex, and show how exotic geometries can have dramatic effects on the mechanics.

**4:42PM H40.00012 Generalized Bistability in Origami Cylinders** , AUSTIN REID, North Carolina State University, MOKHTAR ADDA-BEDIA, FREDERIC LECHENAULT, Laboratoire de Physique Statistique de l'ENS — Origami folded cylinders (origami bellows) have found increasingly sophisticated applications in space flight, medicine, and even experimental nuclear physics. In spite of this interest, a general understanding of the dynamics of an origami folded cylinder has been elusive. By solving the fully constrained behavior of a periodic fundamental origami cell defined by unit vectors, we have found an analytic solution for all possible rigid-face states accessible from a cylindrical Miura-ori pattern. Although an idealized bellows has two rigid-face configurations over a well-defined region, a physical device, limited by nonzero material thickness and forced to balance hinge with plate-bending energy, often cannot stably maintain a stowed configuration. We have identified and measured the parameters which control this emergent bistability, and have demonstrated the ability to fabricate bellows with tunable deployability.

**4:54PM H40.00013 Origami Optimization: Role of Symmetry in Accelerating Design<sup>1</sup>**, PHILIP BUSKOHL, Air Force Research Laboratory, KAZUKO FUCHI, Wright State Research Institute, GIORGIO BAZZAN, UES, Inc, MICHAEL DURSTOCK, GREGORY REICH, JAMES JOO, RICHARD VAIA, Air Force Research Laboratory — Origami structures morph between 2D and 3D conformations along predetermined fold lines that efficiently program the form, function and mobility of the structure. Design optimization tools have recently been developed to predict optimal fold patterns with mechanics-based metrics, such as the maximal energy storage, auxetic response and actuation. Origami actuator design problems possess inherent symmetries associated with the grid, mechanical boundary conditions and the objective function, which are often exploited to reduce the design space and computational cost of optimization. However, enforcing symmetry eliminates the prediction of potentially better performing asymmetric designs, which are more likely to exist given the discrete nature of fold line optimization. To better understand this effect, actuator design problems with different combinations of rotation and reflection symmetries were optimized while varying the number of folds allowed in the final design. In each case, the optimal origami patterns transitioned between symmetric and asymmetric solutions depended on the number of folds available for the design, with fewer symmetries present with more fold lines allowed. This study investigates the interplay of symmetry and discrete vs continuous optimization in origami actuators and provides insight into how the symmetries of the reference grid regulate the performance landscape.

**5:06PM H40.00014 How do bendy straws bend? A study of re-configurability of multi-stable corrugated shells<sup>1</sup>**, NAKUL BENDE, SARAH SELDEN, Univ of Mass - Amherst, ARTHUR EVANS, University of Wisconsin–Madison, CHRISTIAN SANTANGELO, RYAN HAYWARD, Univ of Mass - Amherst — Shape programmable systems have evolved to allow for reconfiguration of structures through a variety of mechanisms including swelling, stress-relaxation, and thermal expansion. Particularly, there has been a recent interest in systems that exhibit bi-stability or multi-stability to achieve transformation between two or more pre-programmed states. Here, we study the ubiquitous architecture of corrugated shells, such as drinking straws or bellows, which has been well known for centuries. Some of these structures exhibit almost continuous stability amongst a wide range of reconfigurable shapes, but the underlying mechanisms are not well understood. To understand multi-stability in 'bendy-straw' structures, we study the unit bi-conical segment using experiments and finite element modeling to elucidate the key geometrical and mechanical factors responsible for its multi-stability. The simple transformations of a unit segment – a change in length or angle can impart complex re-configurability of a structure containing many of these units. The fundamental understanding provided of this simple multi-stable building block could yield improvements in shape re-configurability for a wide array of applications such as corrugated medical tubing, robotics, and deployable structures.

**5:18PM H40.00015 Q: How many folded angels can we fit on the head of pin? A: 22+/-5**, ITAI COHEN, Cornell University, TOM HULL, Western New England University, ROBERT LANG, Lang Origami, CHRISTIAN SANTANGELO, University of Massachusetts, Amherst, MARC MISKIN, KYLE DORSEY, PAUL MCEUEN, Cornell University — For centuries, origami, the Japanese art of paper folding, has been a powerful technique for transforming two dimensional sheets into beautiful three dimensional sculptures. Recently, origami has made its foray into a new realm, that of physics, where it has been revolutionizing our concept of materials design. Arguably the greatest strength of this new paradigm is the fact that origami is intrinsically scalable. Thus sculptures built at one size can be shrunk down smaller and smaller. This begs the question: what is the smallest fold one can make? Or in other words how many folded angels can we fit on the head of a pin? This talk takes a deep dive into how origami has been marching smaller and smaller in size. From folding by hand, to self-folding through shape memory alloys and even folding via polymer layers, I will argue that the ultimate limit for scaling down origami is set by folding asheet of atomic dimensions. I will conclude by showing this vision realized in the folds of a single sheet of graphene.

**2:30PM H41.00001 Zero-Mode Waveguide detection of biomolecules transport through artificial nanopores and nuclear pore complexes**, THOMAS AUGER, LOIC AUVRAY, FABIEN MONTEL, Universit Paris Diderot — We have developed a novel single molecule optical observation method using a custom Zero-Mode Waveguide setup to study the translocation of biopolymers through artificial and biological nanopores. Our work focuses on two aspects. First we monitored the flow driven injection of DNA molecules through solid state nanopores and showed that DNA starts translocating over a flow threshold independent of the pore radius, the DNA concentration and length. We demonstrate that the translocation is controlled by an energy barrier as proposed by the de Gennes - Brochard suction model. The height of the energy barrier can be modulated by functionalizing the nanopores with PEG-Thiols. More recently we adapted our setup to the study of transport through the nuclear pore complex (NPC) using extracted nuclear membranes from *Xenopus Laevis* oocytes. We aim at probing the conformation of unstructured proteins – the FG-Nucleoporins – crowding the central channel of the NPC by monitoring the free diffusion of small Dextran molecules (3kDa). We have been able to estimate the radius of the central pore of the NPC. We want to study the effects of transporter molecules, which have a high affinity for the FG-Nups, on the central pore size and correlate it to the conformation of FG-Nups.

**2:42PM H41.00002 A Nanopore with an Internal Cavity to Selectively Translocate Polymers of a Specific Length<sup>1</sup>**, HENDRICK W. DE HAAN, MARTIN MAGILL, University of Ontario Institute of Technology — In the majority of experimental and simulation studies of polymer translocation through a nanopore, the scaling of the translocation time,  $\tau$ , with polymer length,  $N$ , is well described by a single exponent:  $\tau \sim N^\alpha$ . Hence, an increase in  $N$  always yields an increase in  $\tau$ . I will present a nanopore geometry in which there is a large central cavity between narrow nanopores at both the *cis* entrance and the *trans* exit. Results from simulations of this system reveal a complex dependence of  $\tau$  on  $N$ . Most notably, the translocation time is now non-monotonic in polymer length such that  $\tau$  is a minimum for polymers of an intermediate length with both longer and shorter polymers taking a longer time to cross across the membrane. A simple yet effective model for predicting this critical length as a function of the size of the cavity and the magnitude of the external field will be presented. The pore thus can be designed to be optimized for particular lengths with some dynamic tuning being possible by varying the strength of the external field. These results suggest new applications for nanopore-based devices such as the ability to select DNA strands of a specific length from a sample containing both shorter and longer strands.

**2:54PM H41.00003 Effect of excluded volume on the force-extension of wormlike chains in slit confinement**, XIAOLAN LI, KEVIN DORFMAN, University of Minnesota - Twin cities — We will present a quantitative phase diagram for the stretching of a wormlike chain confined in a slit with excluded volume interactions. Using pruned-enriched Rosenbluth method (PERM) simulations, we demonstrate the existence of a “confined Pincus” regime in slit confinement. This regime is similar to the Pincus regime in free solution, where excluded volume effects are sensible. The lower bound for the confined Pincus regime in the force-contour length plane and the dependence of the extension with force and slit size are in agreement with scaling theory. The upper bound of the confined Pincus regime depends on the confinement strength; it ends in strong confinement when the Pincus blobs do not have excluded volume, while it ends in weak confinement when the Pincus blobs do not fit in the slit. We also show the existence of a free-solution Pincus regime in weak confinement that exists before ideal chain behavior sets in under strong forces. We will discuss the implication of our results on the analysis of experiments on the “tug-of-war” stretching of DNA partially confined to a slit.

**3:06PM H41.00004 Visualizing Chemical Interaction Dynamics of Confined DNA Molecules**, GILEAD HENKIN, DANIEL BERARD, FRANK STABILE, SABRINA LESLIE, McGill Univ — We present a novel nanofluidic approach to controllably introducing reagent molecules to interact with confined biopolymers and visualizing the reaction dynamics in real time. By dynamically deforming a flow cell using CLIC (Convex Lens-induced Confinement) microscopy, we are able to tune reaction chamber dimensions from micrometer to nanometer scales. We apply this gentle deformation to load and extend DNA polymers within embedded nanotopographies and visualize their interactions with other molecules in solution. Quantifying the change in configuration of polymers within embedded nanotopographies in response to binding/unbinding of reagent molecules provides new insights into their consequent change in physical properties. CLIC technology enables an ultra sensitive, massively parallel biochemical analysis platform which can access a broader range of interaction parameters than existing devices.

**3:18PM H41.00005 Relaxation dynamics of internal segments of DNA chains in nanochannels**, AASHISH JAIN, ABHIRAM MURALIDHAR, KEVIN DORFMAN, Department of Chemical Engineering and Materials Science, University of Minnesota, DORFMAN GROUP TEAM — We will present relaxation dynamics of internal segments of a DNA chain confined in nanochannel. The results have direct application in genome mapping technology, where long DNA molecules containing sequence-specific fluorescent probes are passed through an array of nanochannels to linearize them, and then the distances between these probes (the so-called DNA barcode) are measured. The relaxation dynamics of internal segments set the experimental error due to dynamic fluctuations. We developed a multi-scale simulation algorithm, combining a Pruned-Enriched Rosenbluth Method (PERM) simulation of a discrete wormlike chain model with hard spheres with Brownian dynamics (BD) simulations of a bead-spring chain. Realistic parameters such as the bead friction coefficient and spring force law parameters are obtained from PERM simulations and then mapped onto the bead-spring model. The BD simulations are carried out to obtain the extension autocorrelation functions of various segments, which furnish their relaxation times. Interestingly, we find that (i) corner segments relax faster than the center segments and (ii) relaxation times of corner segments do not depend on the contour length of DNA chain, whereas the relaxation times of center segments increase linearly with DNA chain size.

**3:30PM H41.00006 Controlling the Motion of Knotted Polymers through Nanopores**, VIVEK NARSIMHAN, C. BENJAMIN RENNER<sup>1</sup>, PATRICK DOYLE, Massachusetts Inst of Tech-MIT — Nanopore sequencing is a technique where DNA moves through a pore and base-pair information is read along the chain as an electric signal. One hurdle facing this technique is that DNA passes too quickly through the pore, rendering the signal to be too noisy. In this talk, we discuss one strategy to control the speed by which polymers move through pores. By tying a knot on a polymer chain, we find that we can jam the polymer at the pore's entrance and halt translocation completely. This idea by itself may not seem useful, but by cycling the field on and off at the relaxation time scale of the knot, we can control the swelling dynamics of the knot at the pore's entrance, and hence ratchet the polymer through the pore. This talk focuses on two parts. First, we will discuss the dynamics of a knot jamming at the pore entrance and determine what sets the critical tension to halt translocation. We will determine how knot topology affects these results and discuss what regimes lead to large fluctuations in the translocation speed. We will then discuss the dynamics of a knot under a time-dependent, periodic force. Lastly, we develop a model to describe the knot's swelling dynamics during relaxation, and use this to explain some of the trends observed in our simulations.

<sup>1</sup>Now at Liquiglide

**3:42PM H41.00007 Confined polymers in the extended de Gennes regime**, BERNHARD MEHLIG, University of Gothenburg — In the “extended de Gennes regime” the problem of describing the conformations of a semiflexible polymer confined to a channel can be mapped onto the weakly self-avoiding random-walk model. For large contour lengths the asymptotically exact solution of this model predicts how the conformational fluctuations of the confined polymer depend upon the channel dimensions and upon the physical properties of the polymer, its effective width and persistence length. The extended de Gennes regime (where the polymer is neither weakly nor strongly confined) has recently been studied intensively experimentally and by means of computer simulations of worm-like chain models. In this talk I explain the mapping, summarise the predictions derived from the exact solution, and compare the predictions to results of computer simulations [Dorfman *et al.*] and experiments [Westerlund *et al.*] of DNA molecules confined to nanochannels. I conclude by summarising open questions. This talk is mainly based on joint work with E. Werner [Phys. Rev. E 90 (2014) 062602].

**4:18PM H41.00008 From stripe to slab confinement for DNA linearization in nanochannels<sup>1</sup>**, PETER CIFRA, ZUZANA BENKOVA, PAVOL NAMER, Polymer Institute, Slovak Academy of Sciences, Bratislava, Slovakia — We investigate suggested advantageous analysis in the linearization experiments with macromolecules confined in a stripe-like channel using Monte Carlo simulations. The enhanced chain extension in a stripe that is due to significant excluded volume interactions between monomers in two dimensions weakens on transition to experimentally feasible slit-like channel. Based on the chain extension-confinement strength dependence and the structure factor behavior for the chain in stripe we infer the excluded volume regime typical for two-dimensional systems. On transition to the slab geometry, the advantageous chain extension decreases and the Gaussian regime is observed for not very long semiflexible chains. The evidence for pseudo-ideality in confined chains is based on indicators such as the extension curves, variation of the extension with the persistence length or the structure factor. The slab behavior is observed when the stripe (originally of monomer thickness) reaches the thickness larger than cca 10nm in the third dimension. This maximum height of the slab to retain the advantage of the stripe is very low and this has implication for DNA linearization experiments. The presented analysis, however, has a broader relevance for confined polymers.

**4:30PM H41.00009 Knotted DNA in Nanofluidic Confinement**, ALEXANDER KLOTZ, PATRICK DOYLE, MIT — The behavior of topologically simple semiflexible polymers such as DNA has become well-understood in the last several years. Recently, several computational analyses have predicted that certain topological features of a polymer, such as the average size of pseudo-knots and the probability of knot formation, are enhanced by confinement. Here, we extend recent work on the stretching of knotted DNA and examine diffusion, relaxation, and chain statistics of topologically complex linear DNA molecules. Topological phenomena are studied both in the bulk and under nanofluidic confinement to examine the interplay between knotting and confinement in semiflexible polymers, as well as to provide a controlled experimental interrogation of the knotted region of the polymer.

**4:42PM H41.00010 DNA Partitioning in Confining Nanofluidic Slits**, MADELINE GREENIER, STEPHEN LEVY, Physics Department, Binghamton University — We measure the partitioning of double stranded DNA molecules in moderately and strongly confining nanofluidic slit-like structures. Using fluorescent microscopy, the free energy penalty of confinement is inferred by comparing the concentration of DNA molecules in adjoining slits of different depths. These depths range in size from several persistence lengths to the DNA molecule's radius of gyration. The partition coefficient is determined as a function of the slit depth, DNA contour length, and DNA topology. We compare our results to theory and Monte Carlo simulations that predict the loss of free energy for ideal and semiflexible excluded volume polymers confined between parallel plates.

**4:54PM H41.00011 To Knot or Not-That is the Question: A Nanofluidic Knot Factory based on Compression of Single DNA Molecules against Slit Barriers in Nanochannels**, SUSAN AMIN, AHMED KHORSHID, LILI ZENG, Department of Physics- McGill University, PHILIP ZIMNY, Department of Biomedical Engineering- McGill University, WALTER REISNER, Department of Physics- McGill University — Knots can form during DNA packaging in chromosome and obstruct mapping of DNA in nanochannels. Studies have focused on theoretical and numerical studies of knots, but an efficient and fully controlled means of knotting has not yet been explored. Here, we introduce a knot factory on chip based on pneumatic compression of single T4 DNA against a slit barrier in a nanochannel. The DNA are compressed to a well-defined fraction of their initial equilibrium extension. The pressure is then released and the DNA molecules relax back to their equilibrium extension; knots are present along the relaxed DNA, visualized as sharply localized regions of high intensity. Via repeated compression and relaxation, we can measure the probabilities of forming single and multiple knot states and the distribution of knot sizes as a function of fractional compression and waiting time in the compressed state. We show that the total probability of knot formation increases with greater compression and waiting time. These findings are well described via a knot formation free energy derived from scaling arguments, suggesting that the enhanced knotting probability at high compression arises from avoiding the free energy cost due to self-exclusion interactions that would arise from contour stored in the knot.

**5:06PM H41.00012 Polymer translocation from a confining tube: the effect of a finite tube length**, DAVID SEAN, GARY W SLATER, Univ of Ottawa — Coarsed-grained Langevin Dynamics simulations of driven polymer translocation are used to study situations where the polymer is initialized inside a confining cylindrical cavity. The latter limits the number of conformations at the onset of translocation, which (in the highly driven limit) should lead to a net reduction in the variance of the mean translocation time. We vary both the confinement volume and the cavity aspect ratio to minimize the coefficient of variation of the translocation time. We also use a tension-propagation model and find that its predictions are in good agreement with our simulation results: both yield a minimum in the coefficient of variation for a tube having an aspect ratio corresponding to a diameter which is roughly twice the tube length. Moreover, fluctuations in the translocation coordinate  $s(t)$  do not generally follow a power law with time  $\langle \Delta s^2 \rangle \sim t^\beta$ ; for some of the geometries we actually observed non-monotonic fluctuations. We attribute this result to conformations containing hairpins, which are an outcome of having a polymer initially confined in a tube with a finite volume.

**5:18PM H41.00013 Experimental Evidence of Weak Excluded Volume Effects for Nanochannel Confined DNA**, DAMINI GUPTA, JEREMY J. MILLER, ABHIRAM MURALIDHAR, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA, SARA MAHSHID, WALTER REISNER, Physics Department, McGill University, Montreal QC, Canada, KEVIN D. DORFMAN, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA — In the classical de Gennes picture of weak polymer nanochannel confinement, the polymer contour is envisioned as divided into a series of isometric blobs. Strong excluded volume interactions are present both within a blob and between blobs. In contrast, for semiflexible polymers like DNA, excluded volume interactions are of borderline strength within a blob but appreciable between blobs, giving rise to a chain description consisting of a string of anisometric blobs. We present experimental validation of this subtle effect of excluded volume for DNA nanochannel confinement by performing measurements of variance in chain extension of T4 DNA molecules as a function of effective nanochannel size (305-453 nm).<sup>1</sup> Additionally, we show an approach to systematically reduce the effect of molecular weight dispersity of DNA samples, a typical experimental artifact, by combining confinement spectroscopy with simulations.

**2:30PM H42.00001 Phase Behavior and Micellar Packing of Impurity-Free Pluronic Block Copolymers in Water**<sup>1</sup>, CHANG YEOL RYU, HANJIN PARK, Rensselaer Polytechnic Institute — We have investigated the impacts of the non-micellizable polymeric impurities on the micellar packing and solution phase behavior of Pluronic block copolymers in water. In particular, small angle x-ray scattering, rheology and dynamic light scattering techniques have been employed to elucidate how the low MW impurities affect the micellar packing and solution phase diagram in water, when ordered cubic structures of spherical micelles are formed. A silica slurry method has been developed using the competitive adsorption of the PEO-PPO-PEO triblock copolymers over the low MW polymeric impurities for a large scale purification of Pluronics and its purity of Pluronics has been assessed by interaction chromatography. Based on the comparative studies on micellar packing between As-Received (AR) and Purified (Pure) Pluronic F108 solutions, we found experimental evidence to support the hypothesis that the inter-micellar distance of Pluronic cubic structures in aqueous solution is governed by the effective polymer concentration in terms of PEO-PPO-PEO triblock copolymers. Removal of the impurities in AR F108 offers an important clue on window into the onset of BCC ordering via hydrodynamic contact between micelles in solution.

**2:42PM H42.00002 Controlled Solution Self-Assembly of a Midblock-Sulfonated Pentablock Copolymer**<sup>1</sup>, KENNETH MINEART, North Carolina State University, MICHAEL GRADZIELSKI, Technische Universität Berlin, RICHARD SPONTAK, North Carolina State University — The solution self-assembly of midblock-sulfonated block ionomers (SBIs) has been shown to translate to their bulk, solution-cast morphology, which can further impact their function in applications such as desalination, fuel cell, and photovoltaic membranes. Previous studies have identified that increasing the degree of sulfonation (DOS) in SBIs dispersed in a nonpolar solvent results in the growth of micellar aggregates due to increased interfacial energy. However, these works have not attempted to control the assembly at a given DOS by tuning the solvent environment. The current study probes the tunability of SBI aggregation behavior using a nonpolar/polar solvent mixture varying in composition. A combination of light scattering (SLS and DLS) and small angle X-ray scattering (SAXS) independently confirm that SBI micelles grow larger, both in core and corona, as the solvent environment becomes more nonpolar. The increases in both core and corona size will be explained using polymer thermodynamics and further supported through presentation of small angle neutron scattering (SANS) data. In addition, these results will be compared with SBI self-assembly in a single solvent, which is expected to distribute between the micelle cores and bulk solvent environment.

**2:54PM H42.00003 Self-Assembly of Soft Colloids with Multi-scale Phase-Separated Structures<sup>1</sup>**, CHRIS SOSA, ROBERT K. PRUD'HOMME, RODNEY D. PRIESTLEY, Princeton Univ — The ability of polymers and block co-polymers to self-assemble into highly-ordered structures in bulk two-dimensional films under specific environmental conditions has allowed in recent years for the fabrication of nano-porous membranes, nano-structured surfaces, and sacrificial templates for the preparation of inorganic nanomaterials with well-defined geometries. Extending these fairly specific fabrication techniques to the creation of similar three-dimensional colloidal structures in bulk solutions, however, has proven quite challenging despite the significant need for heterogeneously-structured colloidal materials in medicine and industry. Here we present a strategy for controlling the structural heterogeneity of soft polymer particles along multiple length scales by inducing the rapid phase-separation of polymer mixtures through a continuous nanoprecipitation process.

**3:06PM H42.00004 Solution assembly behaviors of 3-hexylthiophene polymer based rod-coil graft copolymer**, YOUNGKWON KIM, JIN-SUNG KIM, HYEONG JUN KIM, BUMJOON KIM, KAIST — Solution assembly of conjugated polymer based block copolymers (BCPs) is an attractive approach for achieving conducting nanowires (NWs) with nanometer-scale cross-sectional dimensions. In particular, conjugated block offers one-dimensional self-growth of crystalline NWs, and secondary block gives rise to stable dispersion of NWs and additional tuning parameter for the structures of NWs. Herein, we developed a series of poly(3-hexylthiophene)-graft-poly(2-vinylpyridine) (P3HT-g-P2VP) rod-coil copolymers with systematically controlled crystallinity by modifying both grafting density and molecular weight (Mn) of coil block, and their solution assembly behaviors were carefully examined. As increasing the volume fraction and grafting density of the secondary blocks, melting temperatures, crystallization temperatures, and the crystallinity were gradually decreased by hindering rod-rod interaction between P3HT backbones, resulting in the formation of short NWs. Furthermore, the length of NMs was relatively shorter for the densely grafted copolymer despite same volume fraction of secondary block. These results suggested that controlling Mn and the number of branched coil block was critical to regulate the crystalline properties and new approach for determining the NWs growth.

**3:18PM H42.00005 Tuning nanoscale viscoelasticity of polyelectrolyte complexes with multiple types of cross-links**, TIANZHU MA, BIAO HAN, Drexel University, School of Biomedical Eng, Sci and Health Systems, DAEYEON LEE, University of Pennsylvania, School of Engineering and Applied Science, LIN HAN, Drexel University, School of Biomedical Engineering, Science, and Health Systems — Mechanical properties of hydrogels are manifestation of cross-link type and density, fixed charges and water-polymer interactions. In this study, we revealed how different types of cross-links regulate the nanoscale viscoelasticity of polyelectrolyte networks. Ionically cross-linked PAH/PAA layer-by-layer complexes were modified to include covalent cross-links using EDC. AFM-nanoindentation and force relaxation were performed at various ionic strength (0.01-1M) and pH (1.5-5.5). As-assembled networks, held only by ionic cross-links, underwent >95% relaxation, dominated by cross-link breaking and re-formation. Addition of covalent cross-links increased the instantaneous modulus by 1.6-fold and attenuated relaxation to ≈80% of net neutral states (pH≥3.5), as covalent cross-links provide additional elastic components. The network remained stabilized when all ionic cross-links were dissociated at pH≤1.5, whereby further attenuation to 31% in relaxation could be due to viscoelastic polymer conformational changes and fluid flow-induced poroelasticity. Taken together, this study demonstrates the potential of using multiple cross-linking types to tune the viscoelastic mechanisms in polyelectrolyte complexes.

**3:30PM H42.00006 Coarse-grained Simulation of Complexation between Small Interfering RNA and Polycations**, ZONGHUI WEI, Northwestern University, YONG REN, JOHN-MICHAEL WILLIFORD, HAI-QUAN MAO, Johns Hopkins University, ERIK LUIJTEN, Northwestern University, NORTHWESTERN UNIVERSITY COLLABORATION, JOHNS HOPKINS UNIVERSITY COLLABORATION — Nanoparticles formed through self-assembly of polycations and nucleic acids are promising systems for gene delivery. A full understanding of the behavior of these particles in physiological context requires detailed knowledge of their physical properties. All-atom molecular dynamics simulations can provide insight into the interaction of polymeric carriers with genomic material, but only at limited time and length scales. To overcome these limitations and explore the full complexation process, a reliable coarse-grained model is needed. Here, we systematically develop such a model for a system comprised of small interfering RNA (siRNA) and polyethyleneimine-based carriers, and evaluate the quality of the coarse-grained model through comparison with all-atom simulations. We show that our coarse-grained model provides a reliable description of detailed binding pictures, charge characteristics, and water dynamics, while accelerating the simulations by two orders of magnitude. This makes it possible to quantitatively investigate nanoparticle formation involving multiple siRNA molecules and cationic copolymers.

**3:42PM H42.00007 Mesoscale Lattices Assembled from Charge-Tunable Block Copolymer Blends in Selective Solvents**, SEYOUNG KIM, JEWON CHOI, Seoul Natl Univ, SOO-HYUNG CHOI, Hongik Univ, KOOKHEON CHAR, Seoul Natl Univ — Recent studies revealed that block copolymer (BCP) microdomains are capable of being organized into unusual symmetries such as the Frank-Casper phases. These unique structures result from a compromise between domain geometry and space-filling constraint; in other words, the deformability of soft matter. Our mesoscale micellar lattices co-assembled from the blends of oppositely charged BCPs demonstrate the nature of deformable soft materials in a distinctive way. The micellar structures and interactions of BCPs in selective solvents can be finely tuned by controlling the charge density such that the spherical micelles further assemble into hexagonal arrays. The micellar lattices show unconventional symmetry and sub-10 nm clean facet formation compared to hard-sphere counterparts reported so far. We attribute these novel phenomena to multi-compartment intrastructure of the micelles assembled and their strong interactions, since the crystalline symmetry disappears with a subtle control of solvency, mixing ratio of BCP blends, and micellar interactions. Analysis on the nucleation condition reveals that such deviation in the micellar lattices arises from the soft nature of BCP assemblies which can be readily deformed upon swelling.

**3:54PM H42.00008 The Sheet Trapped in a Plumber's Nightmare**, CHRISTOPHER O'BRYAN, TAPOMOY BHATTACHARJEE, W. GREGORY SAWYER, THOMAS ANGELINI, Univ of Florida - Gainesville — Block co-polymer systems offer exquisite control in the molecular-level design of self-assembled structures. The application of block copolymer phases has been generally limited to their use as bulk stabilizing agents in mass produced commodity chemicals and plastics. Recently, we have found the complex phase structures of self-assembled styrene ethylene/propylene diblock and styrene ethylene/butylene triblock co-polymers useful in 3D printing of other soft materials; the co-polymer structure yields around a writing nozzle as it moves through space while leaving material (polymers or colloids) trapped in the form of programmed structures. However, the relationship between the structural phase of the co-polymer self-assembly and its ability to support printed soft matter materials is not understood. In this study, we explore how different block co-polymer assemblies interact with and support soft matter materials once localized yielding has occurred.

**4:06PM H42.00009 Structural transformation of peptide amphiphile self-assembly induced by headgroup charge and size regulation**, CHANGRUI GAO, Northwestern University, MICHAEL BEDZYK, MONICA OLVERA, SUMIT KEWALRAMANI, Northwestern University, Materials Science and Engineering, LIAM PALMER, Northwestern University, Chemistry — The ability to control the nano and the meso-scale architecture of molecular assemblies is one of the major challenges in nanoscience. Significantly, structural transformations of amphiphilic aggregates induced by variations in environmental conditions have attracted attention due to their biotechnological relevance. Here, we study the assembly in aqueous solution for a modular series of peptide amphiphiles with 3, 2 or 1 lysine groups conjugated to a C<sub>16</sub> carbon tail (C<sub>16</sub>K<sub>3</sub>, C<sub>16</sub>K<sub>2</sub>, and C<sub>16</sub>K<sub>1</sub>). This system design allow us to probe how the equilibrium structure of the self-assembly can be tuned by controlling the coupling between steric (via choice of headgroup: K<sub>3</sub>, K<sub>2</sub>, or K<sub>1</sub>) and electrostatic (via solution pH) interactions. Solution small- and wide-angle X-ray scattering (SAXS/WAXS) and transmission electron microscopy (TEM) studies reveal that depending on pH and number of lysines in the lipid headgroup, amphiphiles can assemble into a range of structures: spherical micelles, bilayer ribbons and vesicles. We also perform detailed phase space mapping of pH-and headgroup size dependency of the structures of assembly over 0.1-100 nm length scales via SAXS/WAXS. The experimental results in conjunction with molecular dynamics (MD) simulations deduce quantitative relations between pH-dependent molecular charges, steric constraints and self-assembly morphologies, which is significant for developing experimental routes to obtain assembly structures with specific nano- and meso-scale features through controlled external stimuli.

**4:18PM H42.00010 Multibody Interactions, Phase Behavior and Clustering in Nanoparticle-Polyelectrolyte Mixtures**, VENKATRAGHAVAN GANESAN, GUNJA PANDAV, VICTOR PRYAMITSYN, Univ of Texas, Austin, JEFFREY ERRINGTON, SUNY Buffalo — We present the results of a computational study of the interactions, phase-behavior and aggregation characteristics of charged nanoparticles (CNPs) suspended in solution of oppositely charged polyelectrolytes (PEs). We used an extension of the mean-field polymer self-consistent field theory (SCFT) model to explicitly characterize the multibody interactions in such systems. For dilute-moderate particle volume fractions, the magnitudes of three and higher multibody interactions were seen to be weak relative to the contributions from pair interactions. We embedded the pair-interaction potentials within a thermodynamic perturbation theory approach to identify the phase behavior of such systems. The results of such a framework suggested that the gas and FCC crystal phases were thermodynamically stable, whereas the fluid-like phase was metastable in such systems. To complement the parameters studied, we used a recently developed simulation approach to study the aggregation and cluster morphologies in CNP-PE mixtures. For low particle charges, such systems mainly exhibited clusters arising from direct contact aggregation between CNPs. However, for higher particle and PE charges and low PE concentrations, large regions of PE-bridged clusters were seen to form.

**4:30PM H42.00011 Early Stage Kinetics in Polyelectrolyte Complexation Studied in a Stopped-Flow Configuration**, XIAOQING LIU, MARIE HADDOU, JOANNA GIERMANSKA, Centre de Recherche Paul Pascal (CRPP), UPR CNRS 8641, Universit Bordeaux, 33600 Pessac, France, CHRISTOPHE SCHATZ, Laboratoire de Chimie des Polymres Organiques, Ecole Nationale Suprieure de Chimie de Biologie et de Physique, 33600 Pessac, France, JEAN-PAUL CHAPEL, Centre de Recherche Paul Pascal (CRPP), UPR CNRS 8641, Universit Bordeaux, 33600 Pessac, France — Polyelectrolyte complexes (PECs) are the association complexes formed between oppositely charged macromolecules. A large body of work has been devoted to the preparation and morphology characterizations of PECs. Much less attention was paid on formation kinetics of PECs, which often occurs under non-equilibrium conditions. Stopped-flow technique combined with light scattering was used to investigate the early stage complexation kinetics in the poly(acrylic acid) and poly(diallyldimethylammonium chloride) system. It was found that initial complexes form within a few ms. Depending on the PEs molar charge ratio  $z$ , initial complexes followed different evolution pathways. For  $z > 0.7$ , a large complex aggregation ascribed to the onset of coacervation was identified by an increase of the scattered intensity while an unexpected decay was observed for  $z < 0.7$  where small PECs are formed. The appearance of characteristic bell-shaped curves in the presence of different ionic strengths ( $I$ ) highlighted the strong influence of the interaction intensity on the complexation/reorganization kinetics. The results revealed distinct assembly and ageing mechanisms as a function of  $z$ ,  $I$  and molecular weights.

**4:42PM H42.00012 Supramolecular Assemblies of Poly(propyleneimine) Dendrimers Driven by Simple Monovalent Counterions**, SEYED ALI EGHTESADI, FADI HASO, MARJAN ALSADAT KASHFIPOUR, DR. ROBERT LILLARD, DR. TIANBO LIU, University of Akron, DR. TIANBO LIU'S GROUP TEAM, DR. LILLARD'S GROUP COLLABORATION — Polyelectrolytes (PE) are fascinating class of polymers carrying dissociative ionic groups which give them unique properties in solutions and at charged surfaces. The properties of these polymers in solution are mainly depending on the fraction of dissociated ionic groups, the quality of solvent and salt concentration. Describing the solution properties of polyelectrolytes have always been an obstacle for polymer scientists due to their different behavior as a result of their dual character of being highly charged electrolytes and at macromolecular size. The question we tried to address was what happens to solution behavior of charged polyelectrolytes when they reach to the nano-scale size which can neither be considered as point charges nor colloids. Second generation of poly(propyleneimine) dendrimer in different solvent qualities, salt concentrations, pH and temperatures were studied using techniques such as LLS, TEM, AFM and zeta-potential, and dominant controlling factors over their self-assembly into hollow spherical "Blackberry" like nanoparticles was investigated.

**4:54PM H42.00013 Self-Assembly of Polyoxometalate and Polyelectrolyte Macroions into Mechanically Strong Supramolecular Hydrogels**, BENXIN JING, Y. ELAINE ZHU, Department of Chemical Engineering and Materials Science, Wayne State University, Detroit, MI 48202 — Polyoxometalate (POM) macroions are the nanoclusters of transition metal oxide with size 1-10 nm and well-defined structure at the atom level. Because of their stoichiometric surface groups and high solubility in polar solvents to form thermodynamically stable solution, POMs are studied as excellent model macroions at nanoscale. In this work, we explore the electrostatic controlled self-assembly of anionic POMs and cationic or zwitterionic polyelectrolytes (PEs) in aqueous solution. Specifically we examine the complex formation of zwitterionic poly(3-(methacryloylamino)propyl]dimethyl(3-sulfopropyl)ammonium hydroxide) (PSBMA) and cationic poly(diallyldimethylammonium chloride) (PDADMAC) with tungstate based POMs of varied valence. The phase diagram of POM/polyelectrolyte complexes is determined with varied POM/PE charge ratios. It is interesting to observe the coacervation of POMs with PSBMA. With cationic PDADMAC, hybrid POM-PDADMAC hydrogels can be formed. Nevertheless, POM-PDADMAC complexes exhibit much enhanced mechanical properties in comparison to polymer hydrogel. The viscoelastic properties of hybrid macroion complexes strongly depend on PDADMAC concentration, POM-to-PDADMAC molar ratio, the size and valence of POMs. At the intermediate range of POM-to-PDADMAC concentration ratio, shear thickening and strain hardening are observed with soft supramolecular hydrogels, which is resulted from the non-Gaussian stretching of polymer chains.

**5:06PM H42.00014 Polyelectrolyte Complex Hydrogels: Self-assembly and the Influence of Charged and Neutral Blocks**, SAMANVAYA SRIVASTAVA, DAVID GOLDFELD, ADAM LEVI, JUN MAO, Univ of Chicago, WEI CHEN, Argonne National Laboratory, MATTHEW TIRRELL, Univ of Chicago — Polyelectrolyte complexes (PEC) form when oppositely charged polyelectrolyte chains spontaneously associate and phase separate in aqueous mediums. Bulk phase separation of the PECs can be evaded by combining one or both of the polyelectrolytes with a neutral polymer, thus engineering pathways for self-assembled PEC micelles and hydrogels. The PEC domains in these assemblies can encapsulate therapeutics as well as genetic materials and thus have tremendous potential in drug delivery and tissue engineering applications. We will present insights on the equilibrium structure and self-assembly kinetics of PEC hydrogels with large-scale ordering of the nanoscale PEC domains through detailed structure characterization and rheology studies of self-assembled materials comprising of functionalized polyallyl glycidyl ethers (PAGE) connected to either single poly(ethylene glycol) (PEG) chain to form diblock copolymers or as functionalized end-groups on a triblock copolymer with a PEG midblock. The effect of key parameters such as polymer concentration, polymer block lengths, salt, ionic strength, and degree of charge mismatch on the equilibrium materials properties will be discussed, with a special emphasis on the structure-defining role of the charged blocks and the structure-directing role of neutral blocks. Additionally, interesting similarities, and differences between structures and dynamics of hydrogels comprising diblock and corresponding triblock polyelectrolytes, respectively, will be discussed.

**5:18PM H42.00015 Thermo-reversible morphology and conductivity of a conjugated polymer network embedded in polymeric self-assembly.**<sup>1</sup>, YOUNGKYU HAN, JAN-MICHAEL Y. CARRILLO, ZHE ZHANG, YUNCHAO LI, KUNLUN HONG, BOBBY G. SUMPTER, Oak Ridge National Laboratory, MICHAEL OHL, Jlich Center for Neutron Science, MARIAPPAN PARANS PARANTHAMAN, GREGORY S. SMITH, CHANGWOO DO, Oak Ridge National Laboratory — Self-assembly of block copolymers provides opportunities to create nano hybrid materials, utilizing self-assembled micro-domains with a variety of morphology and periodic architectures as templates for functional nano-fillers. Here we report new progress towards the fabrication of a thermally responsive conducting polymer self-assembly made from a water-soluble poly(thiophene) derivative with short PEO side chains and Pluronic L62 solution in water. The structural and electrical properties of conjugated polymer-embedded nanostructures were investigated by combining SANS, SAXS, CGMD simulations, and impedance spectroscopy. The L62 solution template organizes the conjugated polymers by stably incorporating them into the hydrophilic domains thus inhibiting aggregation. The changing morphology of L62 during the micellar-to-lamellar phase transition defines the embedded conjugated polymer network. The conductivity is strongly coupled to the structural change of the templating L62 phase and exhibits thermally reversible behavior with no signs of quenching of the conductivity at high temperature.

**Session H43 GSNP GSOF: Aging in the Jammed State** 346 - Stefan Boettcher, Emory University

**2:30PM H43.00001 A Time-Temperature Transistor - An Application of Aging Dynamics**, GREGORY KENNING, Indiana University of Pennsylvania — Aging dynamics occur as systems far from thermodynamic equilibrium evolve towards equilibrium. We have produced a magnetic nanoparticle system composed of Co nanoparticles, which self-assemble during Co deposition on Sb. At a particular time in the formation of the nanoparticles, they are encased in a layer of Sb producing a system far from equilibrium. Magnetization vs. temperature measurements as well as Magnetic Force Microscopy (MFM) indicates that the nanoparticles initially have a large magnetic moment. We observe, as a function of time, an approximately 80% decay in the sample magnetization and an approximately 50% decay in the DC electrical resistivity. MFM suggests that the magnetization decay proceeds from the magnetic nanoparticles losing their net moments possibly due to spin rearrangement. Evidence also suggests that the initial magnetic moments, drive the Sb layer semiconducting. As the net moments of the magnetic nanoparticles decrease, the Sb reverts back to its semi-metal behavior with the accompanying decrease in the electrical resistivity. The magnetization and resistance decays follow the same Arrhenius type behavior. By varying the Co layer thickness, the Arrhenius parameters can be tuned. We have been able to tune the parameters making these materials excellent candidates for sensors for electronically monitoring the age and lifetime of perishable foods.

**2:42PM H43.00002 Density variations of plastic carriers in metallic glasses during aging.**, YUE FAN, Oak Ridge National Lab, TAKUYA IWASHITA, University of Tennessee, TAKESHI EGAMI, University of Tennessee; Oak Ridge National Lab — Thermally induced deformation in metallic glasses was investigated by sampling the potential energy landscape (PEL) and probing the changes in the atomic properties (e.g. energy, displacement, stress). We demonstrate that there exists a universal plastic carrier in amorphous materials, which corresponds to the hopping between local minima on PEL. However very interestingly, the density of plastic carrier is largely affected by the aging history of the glasses. The higher fictive temperature (*i.e.* fast cooling rate), the larger density of plastic carrier is contained in the system. In particular, we observe a scaling of  $\rho \sim \exp(-\alpha/T_{fic})$ , which is consistent with the prediction of shear transformation zone theory. The work is supported by U.S. Department of Energy.

**2:54PM H43.00003 Aging and memory effects in the spin jam states of densely populated frustrated magnets**, ANJANA SAMARAKOON, SEUNG-HUN LEE, University of Virginia, TAKU SATO, Tohoku University, Katahira, Sendai, Japan, HAIDONG ZHOU, RYAN SINCLAIR, University of Tennessee, JUNJIE YANG, TIANRAN CHEN, GIA-WEI CHERN, ISRAEL KLICH, University of Virginia — Defects and randomness has been largely studied as the key mechanism of glassiness find in a dilute magnetic system. Even though the same argument has also been made to explain the spin glass like properties in dense frustrated magnets, the existence of a glassy state arise intrinsically from a defect free spin system, far from the conventional dilute limit with different mechanisms such as quantum fluctuations and topological features, has been theoretically proposed recently. We have studied field effects on zero-field cooled and field cooled susceptibility bifurcation and memory effects below freezing transition, of three different densely populated frustrated magnets which glassy states we call spin jam, and a conventional dilute spin glass. Our data show common behaviors among the spin jam states, which is distinct from that of the conventional spin glass. We have also performed Monte Carlo simulations to understand the nature of their energy landscapes.

**3:06PM H43.00004 Time Dependence of the freezing temperature for thin film spin glasses**<sup>1</sup>, RAYMOND ORBACH, The University of Texas at Austin — There have been many measurements of the dependence of the “freezing temperature”,  $T_f$ , on the thickness  $\mathcal{L}$  of thin film spin glasses.  $T_f$  decreases with decreasing  $\mathcal{L}$ , but never vanishes. This contribution suggests that the dependence of  $T_f$  on  $\mathcal{L}$  is a time dependent relationship. Because the lower critical dimension of a spin glass,  $d_\ell \approx 2.5$ , when the spin glass correlation length  $\xi(t, T)$  grows to  $\mathcal{L}$ , the spin glass dimensionality crosses over from  $d = 3$  to  $d = 2$ . What remains are spin glass correlations for length scales  $\leq \mathcal{L}$ . The time dependence of the magnetization dynamics are then activated, with activation energy equal to a largest barrier  $\Delta_{max}(\mathcal{L})$ , and an associated activation time  $\tau$ . For measurements at time scales such that  $\xi(t, T) < \mathcal{L}$ , the effective dimension  $d = 3$ , and the characteristic cusp and knee of a spin glass is observed. For experimental time scales greater than  $\tau$ , with  $\xi(t, T) \approx \mathcal{L}$ , the zero-field cooled magnetization has grown to the field-cooled value of the magnetization, leading to the identification of  $T_f$ . Quantitative agreement with experiment is exhibited.

**3:18PM H43.00005 Intermittent Aging Dynamics in a Metallic Glass Studied by X-ray Photon Correlation Spectroscopy**, ZACH EVENSON, Technical University Munich / Maier-Leibnitz Zentrum (MLZ), BEATRICE RUTA, ESRF - The European Synchrotron, SIMON HECHLER, MORITZ STOLPE, Saarland University, ELOI PINEDA, Universitat Politècnica de Catalunya-BarcelonaTech, ISABELLA GALLINO, RALF BUSCH, Saarland University — Although physical aging is a universal feature of glasses and other non-equilibrium matter, the atomic-level processes involved still remain a puzzling mystery. Here we study the microscopic aging dynamics of a metallic glass using coherent X-rays. Contrary to the common assumption of a steady slowing down of the dynamics usually observed in macroscopic studies, we show that the structural relaxation processes underlying aging in this metallic glass are intermittent and highly heterogeneous at the atomic scale. Moreover, physical aging is triggered by cooperative atomic rearrangements, driven by the relaxation of internal stresses. These results strengthen the similarities between metallic glasses and non-equilibrium soft materials and suggest a common microscopic origin stemming from a complex energy landscape.

**3:30PM H43.00006 Record Dynamics and the Parking Lot Model for granular dynamics<sup>1</sup>**, PAOLO SIBANI, University of Southern Denmark, STEFAN BOETTCHER, Emory University — Also known for its application to granular compaction (E. Ben-Naim et al., *Physica D*, 1998), the Parking Lot Model (PLM) describes the random parking of identical cars in a strip with no marked bays. In the thermally activated version considered, cars can be removed at an energy cost and, in thermal equilibrium, their average density increases as temperature decreases. However, equilibration at high density becomes exceedingly slow and the system enters an aging regime induced by a kinematic constraint, the fact that parked cars may not overlap. As parking an extra car reduces the available free space, the next parking event is even harder to achieve. Records in the number of parked cars mark the salient features of the dynamics and are shown to be well described by the log-Poisson statistics known from other glassy systems with record dynamics. Clusters of cars whose positions must be rearranged to make the next insertion possible have a length scale which grows logarithmically with age, while their life-time grows exponentially with size. The implications for a recent cluster model of colloidal dynamics, (S. Boettcher and P. Sibani, *J. Phys.: Cond. Matter*, 2011 N. Becker et al., *J. Phys.: Cond. Matter*, 2014) are discussed.

**3:42PM H43.00007 Non-equilibrium phenomena in disordered colloidal solids**, PETER YUNKER, Georgia Institute of Technology — Colloidal particles are a convenient tool for studying a variety of non-equilibrium phenomena. I will discuss experiments that investigate the aging and non-equilibrium growth of disordered solids. In the first set of experiments, colloidal glasses are rapidly formed to study aging in jammed packings. A colloidal fluid, composed of micron-sized temperature-sensitive pNIPAM particles, is rapidly quenched into a colloidal glass. After the glass is formed, collective rearrangements occur as the glass ages. Particles that undergo irreversible rearrangements, which break nearest-neighbor pairings and allow the glass to relax, are identified. These irreversible rearrangements are accompanied by large clusters of fast moving particles; the number of particles involved in these clusters increases as the glass ages, leading to the slowing of dynamics that is characteristic of aging. In the second set of experiments, we study the role particle shape, and thus, interparticle interaction, plays in the formation of disordered solids with different structural and mechanical properties. Aqueous suspensions of colloidal particles with different shapes evaporate on glass slides. Convective flows during evaporation carry particles from drop center to drop edge, where they accumulate. The resulting particle deposits grow heterogeneously from the edge on the air-water interface. Three distinct growth processes were discovered in the evaporating colloidal suspensions by tuning particle shape-dependent capillary interactions and thus varying the microscopic rules of deposition. Mechanical testing of these particulate deposits reveals that the deposit bending rigidity increases as particles become more anisotropic in shape.

**4:18PM H43.00008 Correlated Clusters in Aging Colloidal Glass<sup>1</sup>**, DOMINIC ROBE, STEFAN BOETTCHER<sup>2</sup>, Emory University, PETER YUNKER<sup>3</sup>, Georgia Tech — A numerical model of correlated domains in glassy colloids is recreated, following its development by Becker, et. al.<sup>4</sup>. The model is a coarse grained representation of 2D colloidal systems inspired by record dynamics, and produces emergent dynamic heterogeneity and aging. Results from the original development are reproduced, and compared to the same observables in an experimental system of bidisperse microgel spheres studied by Yunker, et. al.<sup>5</sup>. Basic observables such as particle persistence and mean square displacement are measured at different waiting times to observe aging. Four-point correlation lengths are also examined for signs of dynamic heterogeneity. Results from both the numerical and experimental systems are consistent with the predictions of record dynamics, that aging systems evolve on a logarithmic time scale.

**4:30PM H43.00009 Universal Scaling in the Aging of the Strong Glass Former SiO<sub>2</sub><sup>1</sup>**, KATHARINA VOLLMAIR-LEE, Bucknell University, HORACIO CASTILLO, Department of Physics and Astronomy and Nanoscale and Quantum Phenomena Institute, CHRISTOPHER GORMAN, University of California, Santa Barbara — We show that the aging dynamics of a strong glass former displays a strikingly simple scaling behavior. Using molecular dynamics simulations, we quench the system from high temperature to 2500 K, below the glass transition and investigate dynamic heterogeneities as function of waiting time, the time elapsed since the quench. We find that both the dynamic susceptibility and the probability distribution of the local incoherent intermediate scattering function can be described by simple scaling forms in terms of the global incoherent intermediate scattering function. The scaling forms are the same that have been found to describe the aging of several fragile glass formers. Furthermore we find that the aging dynamics is controlled by a unique aging clock which is the same for Si and O atoms.

**4:42PM H43.00010 Aging near the wall in colloidal glasses**, CONG CAO, XINRU HUANG, ERIC WEEKS, Emory University — In a colloidal glass system, particles move slower as sample ages. In addition, their motions may be affected by their local structure, and this structure will be different near a wall. We examine how the aging process near a wall differs from that in the bulk of the sample. In particular, we use a confocal microscope to observe 3D motion in a bidisperse colloidal glass sample. We find that flat walls induce the particles to organize into layers. The aging process behaves differently near the boundary, especially within the first three layers. Particle motion near the wall is noticeably slower but also changes less dramatically with age. We compare and contrast aging seen in samples with flat and rough walls.

**4:54PM H43.00011 Thermal fluctuations and elastic relaxation in the compressed exponential dynamics of colloidal gels**, MEHDI BOUZID, JADER COLOMBO, EMANUELA DEL GADO, Georgetown University — Colloidal gels belong to the class of amorphous systems, they are disordered elastic solids that can form at very low volume fraction, via aggregation into a rich variety of networks. They exhibit a slow relaxation process in the aging regime similar to the glassy dynamics. A wide range of experiments on colloidal gels show unusual compressed exponential of the relaxation dynamical properties. We use molecular dynamics simulation to investigate how the dynamic change with the age of the system. Upon breaking and reorganization of the network structure, the system may display stretched or compressed exponential relaxation. We show that the transition between these two regimes is associated to the interplay between thermally activated rearrangements and the elastic relaxation of internal stresses. In particular, ballistic-like displacements emerge from the non local relaxation of internal stresses mediated by a series of "micro-collapses". When thermal fluctuations dominate, the gel restructuring involves instead more homogeneous displacements across the heterogeneous gel network, leading to a stretched exponential type of relaxation.

**5:06PM H43.00012 Power-law creep and residual stresses in carbopol microgels** , PIERRE LIDON, SEBASTIEN MANNEVILLE, Physics Laboratory - Ecole Normale Supérieure de Lyon - France — We report on the interplay between creep and residual stresses in carbopol microgels. When a constant shear stress  $\sigma$  is applied below the yield stress  $\sigma_c$ , the strain is shown to increase as a power law of time,  $\gamma(t) = \gamma_0 + (t/\tau)^\alpha$ , with an exponent  $\alpha \simeq 0.38$  that is strongly reminiscent of Andrade creep in hard solids. For applied shear stresses lower than some characteristic value of about  $\sigma_c/10$ , the microgels experience a more complex creep behavior that we link to the existence of residual stresses and to weak aging of the system after preshear. The influence of the preshear protocol, of boundary conditions and of microgel concentration on residual stresses is investigated. We discuss our results in light of previous works on colloidal glasses and other soft glassy systems.

**5:18PM H43.00013 Creep and aging in jammed granular materials** , ISHAN SRIVASTAVA, TIMOTHY FISHER, Purdue Univ — Granular materials flow (or unjam) when stressed above the Coulomb yield stress, but a slow creep is observed when the applied stresses are low. In this work, using a recently introduced enthalpy-based variable-cell simulation method, we will present results on the creep and slow aging dynamics in granular systems comprised of soft particles of varying shape that are hydrostatically jammed and subjected to an external stress. We observe a two-stage creep with an initial fast exponential evolution followed by a slow logarithmic evolution over long time scales. We correlate the slow creeping dynamics with micromechanical evolution at the grain scale, such as increasing dynamical heterogeneity and force-chain rearrangements. Results will also be presented on the effect of grain shape (faceted vs. spherical) on the creep and aging dynamics. Finally, a continuum granular fluidity model is developed to rationalize these observations.

Session H44 GQI: Quantum Algorithms 347 - Kenneth Rudinger, Sandia National Labs

**2:30PM H44.00001 Quantum linear systems algorithm with exponentially improved dependence on precision**<sup>1</sup> , ROLANDO SOMMA, Los Alamos National Laboratory, ANDREW CHILDS, University of Maryland, ROBIN KOTHARI, Massachusetts Institute of Technology — Harrow, Hassidim, and Lloyd showed that for a suitably specified  $N \times N$  matrix  $A$  and  $N$ -dimensional vector  $\vec{b}$ , there is a quantum algorithm that outputs a quantum state proportional to the solution of the linear system of equations  $A\vec{x} = \vec{b}$ . If  $A$  is sparse and well-conditioned, their algorithm runs in time polynomial in  $\log N$  and  $1/\epsilon$ , where  $\epsilon$  is the desired precision in the output state. We improve this to an algorithm whose running time is polynomial in  $\log(1/\epsilon)$ , exponentially improving the dependence on precision while keeping essentially the same dependence on other parameters. Our algorithm is based on a general technique for implementing any operator with a suitable Fourier or Chebyshev series representation. This allows us to bypass the quantum phase estimation algorithm, whose dependence on  $\epsilon$  is prohibitive.

<sup>1</sup>The authors acknowledge support from AFOSR, ARO, CIFAR, IARPA, NRO, and NSF

**2:42PM H44.00002 QUANTUM ALGORITHM FOR LINEAR PROGRAMMING PROBLEMS** , PRAMOD JOAG, Professor, DHANANJAY MEHENDALE, Associate Professor — The quantum algorithm (PRL 103, 150502, 2009) solves a system of linear equations with exponential speedup over existing classical algorithms. We show that the above algorithm can be readily adopted in the iterative algorithms for solving linear programming (LP) problems. The first iterative algorithm that we suggest for LP problem follows from duality theory. It consists of finding nonnegative solution of the equation for duality condition; for constraints imposed by the given primal problem and for constraints imposed by its corresponding dual problem. This problem is called the problem of nonnegative least squares, or simply the NNLS problem. We use a well known method for solving the problem of NNLS due to Lawson and Hanson. This algorithm essentially consists of solving in each iterative step a new system of linear equations. The other iterative algorithms that can be used are those based on interior point methods. The same technique can be adopted for solving network flow problems as these problems can be readily formulated as LP problems. The suggested quantum algorithm can solve LP problems and Network Flow problems of very large size involving millions of variables.

**2:54PM H44.00003 A quantum Algorithm for the Moebius Function** , PETER LOVE, Tufts Univ — We give an efficient quantum algorithm for the Moebius function from the natural numbers to  $-1, 0, 1$ . The cost of the algorithm is asymptotically quadratic in  $\log n$  and does not require the computation of the prime factorization of  $n$  as an intermediate step.

**3:06PM H44.00004 The Deutsch-Jozsa algorithm as a suitable framework for MapReduce in a quantum computer** , SAMIR LIPOVACA, None — The essence of the MapReduce paradigm [1] is a parallel, distributed algorithm across hundreds or thousands of machines. In crude fashion this parallelism reminds us of the method of computation by quantum parallelism which is possible only with quantum computers. Deutsch and Jozsa [2] showed that there is a class of problems which can be solved more efficiently by quantum computer than by any classical or stochastic method. The method of computation by quantum parallelism solves the problem with certainty in exponentially less time than any classical computation. This leads to the question: would it be possible to implement the MapReduce paradigm in a quantum computer and harness this incredible speedup over the classical computation performed by the current computers. Although present quantum computers are not robust enough for code writing and execution, it is worth exploring this question from a theoretical point of view. We will show from a theoretical point of view that the Deutsch-Jozsa algorithm is a suitable framework to implement the MapReduce paradigm in a quantum computer. References: [1] Chuck Lam, *Hadoop in Action*, (Manning Publications Co. Greenwich, CT, USA ©2010). [2] Deutsch, D., Jozsa, R. 1992 *Proc. R. Soc. Lond. A* 439, 553-558.

**3:18PM H44.00005 Optimizing Qubit Resources for Quantum Chemistry Simulations in Second Quantization on a Quantum Computer** , NIKOLAJ MOLL, ANDREAS FUHRER, PETER STAAR, IVANO TAVERNELLI, IBM Research - Zurich — Quantum chemistry simulations on a quantum computer suffer from the overhead needed for encoding the fermionic problem in a bosonic system of qubits. By exploiting the block diagonality of a fermionic Hamiltonian, we show that the number of required qubits can be reduced by a factor of two or more. There is no need to go into the basis of the Hilbert space for this reduction because all operations can be performed in the operator space. The scheme is conceived as a pre-computational step that would be performed on a classical computer prior to the actual quantum simulation. We apply this scheme to reduce the number of qubits necessary to simulate both the Hamiltonian of the two-site Fermi-Hubbard model and the hydrogen molecule. Both quantum systems can then be simulated with a two-qubit quantum computer.

**3:30PM H44.00006 Modelling Quantum Subsystem Dynamics<sup>1</sup>**, JASON DOMINY, University of Southern California, ALIREZA SHABANI, Google Research, DANIEL LIDAR, University of Southern California — We describe a general and consistent mathematical model for linear subsystem quantum dynamical maps, developed from a minimal set of postulates, primary among which is a relaxation of the usual, restrictive assumption of uncorrelated initial system-bath states. The resulting space of physically realizable dynamical maps, far from being limited to only completely positive (CP) maps, comprises essentially all  $C$ -linear, Hermiticity-preserving, trace-preserving subsystem maps. We will discuss some implications for the standard theory of open quantum systems and the search for necessary and sufficient conditions for complete positivity. See [1], [2] for additional details. [1] Jason M. Dominy, Alireza Shabani, and Daniel A. Lidar. A general framework for complete positivity. *Quantum Inf. Proc.*, 2015. (To appear). URL: <http://dx.doi.org/10.1007/s11128-015-1148-0>. **3:42PM H44.00007 Hybrid quantum-classical approach to correlated materials**, BELA BAUER, DAVE WECKER, Microsoft Research, ANDREW J. MILLIS, Columbia University, MATTHEW B. HASTINGS, Microsoft Research, MATTHIAS TROYER, ETH Zurich — Recent improvements in control of quantum systems make it seem feasible to finally build a programmable general-purpose quantum computer within a decade. While it has been shown that such a quantum computer can in principle solve certain small electronic structure problems and idealized model Hamiltonians, the highly relevant problem of directly solving a complex correlated material appears to require a prohibitive amount of resources. Here, we show that by using a hybrid quantum-classical algorithm that incorporates the power of a small quantum computer into a framework of classical embedding algorithms, the electronic structure of complex correlated materials can be efficiently tackled using a quantum computer. In our approach, the quantum computer solves a small effective quantum impurity problem that is self-consistently determined via a feedback loop between the quantum and classical computation. Use of a quantum computer enables much larger and more accurate simulations than with any known classical algorithm, and will allow many open questions in quantum materials to be resolved once a small quantum computer with around one hundred logical qubits becomes available.

**3:54PM H44.00008 A method to efficiently simulate the thermodynamic properties of the Fermi-Hubbard model on a quantum computer**, PIERRE-LUC DALLAIRE-DEMERS, FRANK WILHELM-MAUCH, Saarland University — Many phenomena of strongly correlated materials are encapsulated in the Fermi-Hubbard model whose thermodynamic properties can be computed from its grand canonical potential. In general, there is no closed form expression of the grand canonical potential for lattices of more than one spatial dimension, but solutions can be approximated with cluster perturbation theory. To model long-range effects such as order parameters, a powerful method to compute the cluster's Green's function consists in finding its self-energy through a variational principle. This opens the possibility of studying various phase transitions at finite temperature in the Fermi-Hubbard model. However, a classical cluster solver quickly hits an exponential wall in the memory (or computation time) required to store the computation variables. Here it is shown theoretically that the cluster solver can be mapped to a subroutine on a quantum computer whose quantum memory scales as the number of orbitals in the simulated cluster. A quantum computer with a few tens of qubits could therefore simulate the thermodynamic properties of complex fermionic lattices inaccessible to classical supercomputers.

**4:06PM H44.00009 Efficient Simulation of Dissipative Dynamics**, KYUNGJOO NOH, VICTOR V. ALBERT, CHAO SHEN, LIANG JIANG, Yale University — Open quantum systems with engineered dissipations may have more than one steady states. These steady states may form a non-trivial decoherence free subspace (DFS) that can store quantum information against major decoherences. Besides unitary operations within DFS, it is also useful to have dissipative/cooling operations within the DFS. We investigate the possibility of using Hamiltonian perturbation to the engineered dissipation to induce an effective dissipative dynamics within the DFS in a controlled manner. The major challenge is to simulate all the Lindblad jump operators in the master equation. By designing the dissipation within the subspace complementary to the DFS, we can simply use the Hamiltonian perturbation to the designed dissipation with a *single* jump operator to produce an effective dissipation with *multiple* Lindblad jump operators.

**4:18PM H44.00010 Racing in parallel: Quantum versus Classical**, DAMIAN S. STEIGER, MATTHIAS TROYER, ETH Zurich — In a fair comparison of the performance of a quantum algorithm to a classical one it is important to treat them on equal footing, both regarding resource usage and parallelism. We show how one may otherwise mistakenly attribute speedup due to parallelism as quantum speedup. We apply such an analysis both to analog quantum devices (quantum annealers) and gate model algorithms and give several examples where a careful analysis of parallelism makes a significant difference in the comparison between classical and quantum algorithms.

**4:30PM H44.00011 How far can we push quantum variational algorithms without error correction?**, RYAN BABBUSH, Google — Recent work has shown that parameterized short quantum circuits can generate powerful variational ansatzes for ground states of classically intractable fermionic models. This talk will present numerical and experimental evidence that quantum variational algorithms are also robust to certain errors which plague the gate model. As the number of qubits in superconducting devices keeps increasing, their dynamics are becoming prohibitively expensive to simulate classically. Accordingly, our observations should inspire hope that quantum computers could provide useful insight into important problems in the near future. This talk will conclude by discussing future research directions which could elucidate the viability of executing quantum variational algorithms on classically intractable problems without error correction.

**4:42PM H44.00012 A Quantum Algorithm for Estimating Hitting Times of Markov Chains<sup>1</sup>**, ANIRBAN NARAYAN CHOWDHURY, University of New Mexico, ROLANDO SOMMA, Los Alamos National Laboratory — We present a quantum algorithm to estimate the hitting time of a reversible Markov chain faster than classically possible. To this end, we show that the hitting time is given by an expected value of the inverse of a Hermitian matrix. To obtain this expected value, our algorithm combines three important techniques developed in the literature. One such a technique is called spectral gap amplification and we use it to amplify the gap of the Hermitian matrix or reduce its condition number. We then use a new algorithm by Childs, Kothari, and Somma to implement the inverse of a matrix, and finally use methods developed in the context of quantum metrology to reduce the complexity of expected-value estimation for a given precision.

<sup>1</sup>The authors acknowledge support from AFOSR grant number FA9550-12-1-0057 and the Google Research Award.

**4:54PM H44.00013 Continuous Time Quantum Walks in finite Dimensions<sup>1</sup>**, SHANSHAN LI, STEFAN BOETTCHER, Emory University — Continuous time quantum walk (CTQW) provides optimal quadratic speedup for spatial search on complete graphs, hypercubes, and connected random graphs compared to classical algorithms. Instead of these high dimensional graphs, we consider the performance of CTQW on the finite dimensional Migdal-Kadanoff lattices. We relate the critical point for the walk Hamiltonian to the lattice Laplacian. Using renormalization group analysis<sup>2</sup>, we calculate the critical point and derive the search performance on instances of different spectral dimension. For those with integer dimension, we reproduce the known algorithmic efficiency on regular lattices. In particular, we show that on these finite dimensional graphs, the algorithmic efficiency of quantum walk is entirely determined by the spectral dimension of the Laplacian. Quadratic speedup can only be achieved when the spectral dimension is larger than four.

**5:06PM H44.00014 Spatial search by quantum walk is optimal for almost all graphs**, SHANTANAV CHAKRABORTY, LEONARDO NOVO, University of Lisbon, ANDRIS AMBAINIS, University of Latvia, YASSER OMAR, Instituto de Telecomunicaes, Lisbon — The problem of finding a marked node in a graph can be solved by the spatial search algorithm based on continuous-time quantum walks (CTQW). However, this algorithm is known to run in optimal time only for a handful of graphs. In this work, we prove that for Erds-Renyi random graphs, i.e. graphs of  $n$  vertices where each edge exists with probability  $p$ , search by CTQW is almost surely optimal as long as  $p \geq \log^{3/2}(n)/n$ . Consequently, we show that quantum spatial search is in fact optimal for almost all graphs, meaning that the fraction of graphs of  $n$  vertices for which this optimality holds tends to one in the asymptotic limit. We obtain this result by proving that search is optimal on graphs where the ratio between the second largest and the largest eigenvalue is bounded by a constant smaller than 1. Finally, we show that we can extend our results on search to establish high fidelity quantum communication between two arbitrary nodes of a random network of interacting qubits, namely to perform quantum state transfer, as well as entanglement generation. Our work shows that quantum information tasks typically designed for structured systems retain performance in very disordered structures.

**5:18PM H44.00015 Connecting the Discrete-time and Continuous-time Quantum Walks**, ALBERT SCHMITZ, University of North Dakota — Much work has gone into connecting the discrete-time and continuous-time versions of the quantum walk. This talk will demonstrate a method for finding an appropriate coin operator to simulate the continuous-time dynamics generated by a graph Hamiltonian for any arbitrary bigraph. This method draws a connection between a continuous-time model on the standard 1D and 2D lattice and the Hadamard walk. Furthermore, some extensions will be discussed with applications to algorithm design.

**Tuesday, March 15, 2016 2:30PM - 5:18PM –**  
**Session H45 GQI DAMOP: Quantum Information with Ions, Photons and Spins** 348 - Philipp Schindler, Innsbruck University

**2:30PM H45.00001 Parallel transport gates in a mixed-species ion trap processor<sup>1</sup>**, JONATHAN HOME, ETH Zurich — Scaled up quantum information processors will require large numbers of parallel gate operations. For ion trap quantum processing, a promising approach is to perform these operations in separated regions of a multi-zone processing chip between which quantum information is transported either by distributed photonic entanglement or by deterministic shuttling of the ions through the array. However scaling the technology for controlling pulsed laser beams which address each of multiple regions appears challenging. I will describe recent work on the control of both beryllium and calcium ions by transporting ions through static laser beams <sup>2, 3</sup>. We have demonstrated both parallel individually addressed operations as well as sequences of operations. Work is in progress towards multi-qubit gates, which requires good control of the ion transport velocity. We have developed a number of techniques for measuring and optimizing velocities in our trap, enabling significant improvements in performance <sup>4</sup>. In addition to direct results, I will give an overview of our multi-species apparatus, including recent results on high fidelity multi-qubit gates.

**3:06PM H45.00002 Quantum information processing with long-wavelength radiation**, DAVID MURGIA, Imperial College London, SEBASTIAN WEIDT, University of Sussex, JOSEPH RANDALL, Imperial College London, BJOERN LEKITSCH, SIMON WEBSTER, TOMAS NAVICKAS, ANTON GROUNDS, ANDREA RODRIGUEZ, ANNA WEBB, EAMON STANDING, University of Sussex, STUART PEARCE, IBRAHIM SARI, KIAN KIANG, HWANJIT RATTANASONTI, MICHAEL KRAFT, University of Southampton, WINFRIED HENSINGER, University of Sussex — To this point, the entanglement of ions has predominantly been performed using lasers. Using long wavelength radiation with static magnetic field gradients provides an architecture to simplify construction of a large scale quantum computer. The use of microwave-dressed states protects against decoherence from fluctuating magnetic fields, with radio-frequency fields used for qubit manipulation. I will report the realisation of spin-motion entanglement using long-wavelength radiation, and a new method to efficiently prepare dressed-state qubits and qutrits, reducing experimental complexity of gate operations. I will also report demonstration of ground state cooling using long wavelength radiation, which may increase two-qubit entanglement fidelity. I will then report demonstration of a high-fidelity long-wavelength two-ion quantum gate using dressed states. Combining these results with microfabricated ion traps allows for scaling towards a large scale ion trap quantum computer, and provides a platform for quantum simulations of fundamental physics. I will report progress towards the operation of microchip ion traps with extremely high magnetic field gradients for multi-ion quantum gates.

**3:18PM H45.00003 Controlled-phase gate for photons based on stationary light**, IVAN IAKOUPOV, Niels Bohr Institute, JOHANNES BORREGAARD, Harvard University, ANDERS S. SØRENSEN, Niels Bohr Institute — We propose a controlled-phase gate for optical photons based on an atomic ensemble coupled to a one-dimensional waveguide. When an ensemble of  $\Lambda$ -type atoms is subject to a standing wave control field, it creates a *stationary light* [1] effect where the ensemble develops a band gap for light propagation. For frequencies close to the band gap, the light-matter interactions are enhanced due to the reduced group velocity of the light pulses. Changing the internal state of one of the atoms, such that it behaves as an absorbing two-level atom instead of a transparent  $\Lambda$ -type atom, can change the scattering properties of the whole ensemble, switching it from being completely transmissive to being completely reflective. To realize a controlled-phase gate between photons, we store one of the photons inside the atomic ensemble (thereby changing the internal state of one of the atoms), scatter a second photon off the ensemble, and retrieve the first photon. Finally, we consider an application of the proposed controlled-phase gate – a quantum repeater.

### 3:30PM H45.00004 Photonic Quantum Logic with Narrowband Light from Single Atoms

ALLISON RUBENOK, University of Bristol, ANNEMARIE HOLLECZEK, OLIVER BARTER, JEROME DILLEY, PETER B. R. NISBET-JONES<sup>1</sup>, GUNNAR LANGFAHL-KLABES, AXEL KUHN, University of Oxford, CHRIS SPARROW, University of Bristol, Imperial College London, GRAHAM D. MARSHALL, JEREMY L. O'BRIEN, KONSTANTINOS POULIOS<sup>2</sup>, JONATHAN C. F. MATTHEWS, University of Bristol — Atom-cavity sources of narrowband photons are a promising candidate for the future development of quantum technologies. Likewise, integrated photonic circuits have established themselves as a fore-running contender in quantum computing, security, and communication. Here we report on recent achievements to interface these two technologies: Atom-cavity sources coupled to integrated photonic circuits. Using narrow linewidth photons emitted from a single <sup>87</sup>Rb atom strongly coupled to a high-finesse cavity we demonstrate the successful operation of an integrated control-not gate. Furthermore, we are able to verify the generation of post-selected entanglement upon successful operation of the gate. We are able to see non-classical correlations in detection events that are up to three orders of magnitude farther apart than the time needed for light to travel across the chip. Our hybrid approach will facilitate the future development of technologies that benefit from the advantages of both integrated quantum circuits and atom-cavity photon sources.

### 3:42PM H45.00005 Scalable Boson Sampling with Noisy Components

TYLER KEATING, University of New Mexico, JOSEPH SLOTE, Carleton College, GOPIKRISHNAN MURALEEDHARAN, EZEQUIEL CARRASCO, IVAN DEUTSCH, University of New Mexico — The goal of a Boson Sampler is to efficiently and scalably sample from a probability distribution that cannot be simulated efficiently on a classical computer, thus violating the Extended Church-Turing Thesis (ECTT). To properly falsify the ECTT, the physical device must do so even in the face of realistic noise. Scaling a Boson Sampler requires increasing quantities of a set of fixed-size components (beamsplitters, detectors, etc.), so it is natural to consider noise models that act on each component independently. We show that for any such model, the per-component noise need only decrease polynomially to keep the sampling problem hard. In this sense, Boson Sampling with noise is scalable. However, the same result applies to a number of other quantum information systems, including universal circuit-model quantum computers. Such devices are widely believed to require error correction in order to be truly scalable, even though polynomial reduction of per-component errors would allow them to work without error correction. This belief is consistent with the stricter requirement that error rates should be not just polynomially small, but constant in problem size. We conclude that a more precise definition of scalability with noise is needed to properly evaluate Boson Samplers.

### 3:54PM H45.00006 Spin models and boson sampling<sup>1</sup>

JUAN JOSE GARCIA RIPOLL, Institute of Fundamental Physics, IFF-CSIC, Spain, BORJA PEROPADRE, ALAN ASPURU-GUZI, Department of Chemistry and Chemical Biology, Harvard University — Aaronson & Arkhipov showed that predicting the measurement statistics of random linear optics circuits (i.e. boson sampling) is a classically hard problem for highly non-classical input states [1]. A typical boson-sampling circuit requires N single photon emitters and M photodetectors, and it is a natural idea to rely on few-level systems for both tasks. Indeed, we show that 2M two-level emitters at the input and output ports of a general M-port interferometer interact via an XY-model with collective dissipation and a large number of dark states that could be used for quantum information storage. More important is the fact that, when we neglect dissipation, the resulting long-range XY spin-spin interaction is equivalent [2] to boson sampling under the same conditions that make boson sampling efficient. This allows efficient implementations of boson sampling using quantum simulators & quantum computers. [1] S. Aaronson, A. Arkhipov, Proc. of the 43rd annual ACM symposium on Theory of computing (ACM, 2011) 333-342 [2] arXiv:1509.02703

### 4:06PM H45.00007 Experimental fault tolerant universal quantum gates with solid-state spins under ambient conditions.<sup>1</sup>

XING RONG, University of Science and Technology of China — Quantum computation provides great speedup over classical counterpart for certain problems, such as quantum simulations, prime factoring and database searching. One of the challenges for realizing quantum computation is to execute precise control of the quantum system in the presence of noise. Recently, high fidelity control of spin-qubits has been achieved in several quantum systems. However, control of the spin-qubits with the accuracy required by the fault tolerant quantum computation under ambient conditions remains exclusive. Here we demonstrate a universal set of logic gates in nitrogen-vacancy centers with an average single-qubit gate fidelity of 0.99995 and two qubit gate fidelity of 0.992. These high control fidelities have been achieved in the C naturally abundant diamonds at room temperature via composite pulses and optimal control method. This experimental implementation of quantum gates with fault tolerant control fidelity sets an important step towards the fault-tolerant quantum computation under ambient conditions.

### 4:18PM H45.00008 Universal Superadiabatic Geometric Quantum Gates in Nitrogen-Vacancy Centers

HUI YAN, ZHENGTAO LIANG, South China Normal University, SHILIANG ZHU, Nan Jing University — We propose a scheme to implement a universal set of quantum gates based on geometric phases and superadiabatic quantum control. The proposed quantum gates consolidate the advantages of both strategies for robust and fast. The diamond nitrogen-vacancy center system is adopted as a typical example to illustrate the scheme. We show those gates can be realized in a simple two-level configuration by appropriately controlling the amplitude, phase and frequency of just one microwave field. The robust and fast features are confirmed by comparing the fidelities of the proposed superadiabatic geometric phase gate with three other kinds of phase gates.

replacing MAR16-2015-000077.

### 4:30PM H45.00009 Nonlinear opti- tum electrodynamics

IMRAN M. MIRZA, D. Center for Optics, Department of Physics, University of Oregon — We propose a scheme to perform linear optics quantum computation (LOQC). The Heisenberg-Wigner (HW) [18], 2044-2046 (1987)] i.e. complete destructive interference of two 50/50 beam splitter, is a well-known example in this context. In particular and by applying quantum jump/trajectory formalism, we show that the HW is produced by two-level emitter and spectral filtering due to the HW [18], 2044-2046 (1987)]. Along with LOQC, this work [18], 2044-2046 (1987)] (without altering their temporal and spectral traits) [Imran M.

And this abstract can also go in the sorting categories 6.9 and 6.11.

**4:42PM H45.00010 Saving entangled photons from sudden death in a single-mode fiber — Interplay of decoherence and dynamical decoupling.** , MANISH K. GUPTA, CHENGLONG YOU, HWANG LEE, JONATHAN P. DOWLING, Hearne Institute of Theoretical Physics, Louisiana State Univ - Baton Rouge — We study the dynamics of decoherence in an optical fiber for the case of entangled photons. Such a study will allow us to increase the physical length of fiber for the transmission of entangled photon from the sources such as SPDC. We analytically derive the model for decoherence of entangled state photons in a single-mode fiber. We also show that entanglement lifetime can be increased with open loop control technique called dynamical decoupling.

**4:54PM H45.00011 Restoring photon indistinguishability via pulse and continuous-wave control of solid-state quantum emitters.**<sup>1</sup> , HERBERT F. FOTSO, Ames Laboratory, ADRIAN E. FEIGUIN, Northeastern University, DAVID D. AWSCHALOM, University of Chicago, VIATCHESLAV V. DOBROVITSKI, Ames Laboratory — Interference of indistinguishable photons is a central element of many protocols for entangling distant qubits in quantum networks. In spite of great progress [1,2,3] in development and applications of solid-state quantum emitters, the entanglement rate remains severely limited. One of the major obstacles is the photon indistinguishability which is greatly reduced by the uncontrollable slow drift of the qubit emission frequency. We investigate several pulse-based and continuous-wave control protocols which suppress the spectral diffusion. We confirm, using both analytics and direct numerical simulations, that these protocols effectively keep the emission at a set target frequency, and explicitly show that the indistinguishability of the emitted photons is restored by the control. We also compare several pulse-based protocols with different pulse timings, and discuss how they affect the emission line and the photon properties. Considering the nitrogen-vacancy centers in diamonds as a convenient example, we demonstrate that both pulse-based and continuous-wave controls can boost the success rate of the long-range entanglement. [1]B. Hensen et al., Nature 526, 682 (2015). [2]B. B. Buckley et al., Science 330, 1212 (2010). [3]W. B. Gao et al., Nature Comm. 4, 2744 (2013).

**5:06PM H45.00012 Optimizing Adiabaticity in NMR** , JONATHAN VANDERMAUSE, CHANDRASEKHAR RAMANATHAN, Dartmouth College — We demonstrate the utility of Berry's superadiabatic formalism for numerically finding control sequences that implement quasi-adiabatic unitary transformations. Using an iterative interaction picture, we design a shortcut to adiabaticity that reduces the time required to perform an adiabatic inversion pulse in liquid state NMR. We also show that it is possible to extend our scheme to two or more qubits to find adiabatic quantum transformations that are allowed by the control algebra, and demonstrate a two-qubit entangling operation in liquid state NMR. We examine the pulse lengths at which the fidelity of these adiabatic transitions break down and compare with the quantum speed limit.

## Tuesday, March 15, 2016 2:30PM - 5:30PM – Session H46 DCMP: Metals I 311 - Duane Johnson, Ames Laboratory

**2:30PM H46.00001 Multiscale modelling of gallium induced embrittlement in aluminium** , VENKATA SAI PAVAN KUMAR BHOGIREDDY, MIRA TODOROVA, Max Planck Inst für Eisenforschung GmbH, ROBERT SPATSCHEK, Research Center Jülich and Max Planck Inst für Eisenforschung GmbH, JÖRG NEUGEBAUER, Max Planck Inst für Eisenforschung GmbH — Liquid metal embrittlement is a degradation phenomenon in which a solid metal undergoes brittle failure when it is stressed while in contact with a liquid metal. The transition from ductile to brittle metal failure manifests itself by rapid crack propagations which reduces the elongation to failure ratio. Combining density functional theory calculations with continuum methods, we study the liquid metal embrittlement of aluminium in contact with gallium. Comparing ab initio calculated energies for a  $\Sigma 3$  and a  $\Sigma 5$  Al grain boundary and their corresponding surface energies in the presence and absence of Ga, we identify critical Ga concentrations which result in a weakening of the mechanical strength of aluminium. Parametrising the DFT results in continuum model we obtain the concentration as a function of the strain in the system. In a final step we extend this approach and compute the stress field induced by cracks in bulk and at grain boundaries. The stress field explains the large segregation of gallium atoms at the crack tip and the crack tips subsequent propagation.

**2:42PM H46.00002 Corrosion Thermodynamics of Magnesium and Alloys from First Principles as a Function of Solvation** , KRISTA LIMMER, US Army Rsch Lab - Aberdeen, KRISTEN WILLIAMS, Boeing, JAN ANDZELM, US Army Rsch Lab - Aberdeen — Thermodynamics of corrosion processes occurring on magnesium surfaces, such as hydrogen evolution and water dissociation, have been examined with density functional theory (DFT) to evaluate the effect of impurities and dilute alloying additions. The modeling of corrosion thermodynamics requires examination of species in a variety of chemical and electronic states in order to accurately represent the complex electrochemical corrosion process. In this study, DFT calculations for magnesium corrosion thermodynamics were performed with two DFT codes (VASP and DMol3), with multiple exchange-correlation functionals for chemical accuracy, as well as with various levels of implicit and explicit solvation for surfaces and solvated ions. The accuracy of the first principles calculations has been validated against Pourbaix diagrams constructed from solid, gas and solvated charged ion calculations. For aqueous corrosion, it is shown that a well parameterized implicit solvent is capable of accurately representing all but the first coordinating layer of explicit water for charged ions.

**2:54PM H46.00003 Role of defect coordination environment on point defects formation energies in Ni–Al intermetallic alloys** , EMRYS TENNESSEN, JAMES RONDINELLI, Northwestern Univ — We present a relationship among the point defect formation energies and the bond strengths, lengths, and local coordination environment for Ni–Al intermetallic alloys based on density functional calculations, including  $\text{Ni}_3\text{Al}$ ,  $\text{Ni}_5\text{Al}_3$ ,  $\text{NiAl}$ ,  $\text{Ni}_3\text{Al}_4$ ,  $\text{Ni}_2\text{Al}_3$  and  $\text{NiAl}_3$ . We find the energetic stability of vacancy and anti-site defects for the entire family can be attributed primarily to changes in interactions among first nearest neighbors, owing to spatially localized charge density reconstructions in the vicinity of the defect site. We also compare our interpretation of the local coordination environment with a DFT-based cluster expansion and discuss the performance of each approach in predicting defect stability in the Ni–Al system.

**3:06PM H46.00004 A high-throughput search for new ternary superalloys**<sup>1</sup> , CHANDRAMOULI NYSHADHAM, JACOB HANSEN, Department of Physics and Astronomy, Brigham Young University, Provo, Utah 84602, USA., COREY OSES, Center for Materials Genomics, Duke University, Durham, North Carolina 27708, USA., STEFANO CURTAROLO, Center for Materials Genomics, Department of Mechanical Engineering and Materials Science and Department of Physics, Duke University, Durham, North Ca, GUS HART, Department of Physics and Astronomy, Brigham Young University, Provo, Utah 84602, USA. — In 2006 an unexpected new superalloy,  $\text{Co}_3[\text{Al,W}]$ , was discovered[1]. This new alloy is cobalt-based, in contrast to conventional superalloys, which are nickel-based. Inspired by this new discovery, we performed first-principles calculations, searching through 2224 ternary metallic systems of the form  $\text{A}_3[\text{B}_{0.5}\text{C}_{0.5}]$ , where  $\text{A} = \text{Ni/Co/Fe}$  and  $[\text{B}, \text{C}] = \text{all binary combinations of 40 different elements chosen from the periodic table}$ . We found 175 new systems that are better than the  $\text{Co}_3[\text{Al}, \text{W}]$  superalloy. 75 of these systems are brand new—they have never been reported in experimental literature. These 75 new potential superalloys are good candidates for further experiments. Our calculations are consistent with current experimental literature where data exists.

**3:18PM H46.00005 High-throughput study of crystal structures and stability of strengthening precipitates in Mg alloys**, DONGSHU WANG, MAXMILIAN AMSLER, VINAY HEGDE, JAMES SAAL, AHMED ISSA, Northwestern University, XIAOQIN ZENG, Shanghai Jiao Tong University, CHRISTOPHER WOLVERTON, Northwestern University — Age hardening, in which precipitates form and impede the movement of dislocations, can be applied to magnesium alloys in order to increase their limited strengthening behavior. To help clarify the energetics of precipitation hardening of Mg alloys, we employed first principles density functional theory calculations to elucidate both crystal structures and energetics of a very large set of precipitates in Mg alloys. We find the enthalpy changes of (stable and metastable) observed precipitates during the age hardening process are consistent with the experimental sequence of formation for many Mg binary alloys (Mg- {Nd, Gd, Y, Sn, Al, Zn}). For cases where the metastable precipitate crystal structure is unavailable, we search over several prototypes and predict structures/stoichiometries for several ternary precipitates. In addition, high-throughput calculations are performed to construct hcp-based based convex hulls, which assist the identification of coherent GP zones and new metastable phases in age-hardened hcp systems.

**3:30PM H46.00006 High hardness and superlative oxidation resistance in a pseudo-icosahedral Cr-Al binary**, J. W. SIMONSON, R. ROSA, A. K. ANTONACCI, Department of Physics, Farmingdale State College, H. HE, Department of Physics and Astronomy, Stony Brook University, A. D. BENDER, J. PABLA, W. ADRIAP, Department of Physics, Farmingdale State College, D. E. MCNALLY, A. ZEBRO, P. KAMENOV, G. GESCHWIND, Department of Physics and Astronomy, Stony Brook University, S. GHOSE, E. DOORYHEE, National Synchrotron Light Source II, Brookhaven National Laboratory, A. IBRAHIM, Department of Mechanical Engineering Technology, Farmingdale State College, M. C. ARONSON, Department of Physics and Astronomy, Stony Brook University — Improving the efficiency of fossil fuel plants is a practical option for decreasing carbon dioxide emissions from electrical power generation. Present limits on the operating temperatures of exposed steel components, however, restrict steam temperatures and therefore energy efficiency. Even as a new generation of creep-resistant, high strength steels retain long term structural stability to temperatures as high as  $\sim 973$  K, the low Cr-content of these alloys hinders their oxidation resistance, necessitating the development of new corrosion resistant coatings. We report here the nearly ideal properties of potential coating material  $\text{Cr}_{55}\text{Al}_{229}$ , which exhibits high hardness at room temperature as well as low thermal conductivity and superlative oxidation resistance at 973 K, with an oxidation rate at least three times smaller than those of benchmark materials. These properties originate from a pseudo-icosahedral crystal structure, suggesting new criteria for future research.

**3:42PM H46.00007 Ordering Transformations in High-Entropy Alloys<sup>1</sup>**, PRASHANT SINGH, Ames Laboratory, DUANE D. JOHNSON, Ames Laboratory and Iowa State University — The high-temperature disordered phase of multi-component alloys, including high-entropy alloys (HEA), generally must experience segregation or else passes through partially-ordered phases to reach the low-temperature, fully-ordered phase. Our first-principles KKR-CPA-based atomic short-range ordering (SRO) calculations (analyzed as concentration-waves) reveal the competing partially and fully ordered phases in HEA, and these phases can be then directly assessed from KKR-CPA results in larger unit cells [Phys. Rev. B 91, 224204 (2015)]. For  $\text{Al}_x\text{CrFeNiTi}_{0.25}$ , Liu et al. [J Alloys Compd 619, 610 (2015)] experimentally find FCC+BCC coexistence that changes to BCC with increasing Al ( $x$  from 0-to-1), which then exhibits a partially-ordered B2 at low temperatures. CALPHAD (Calculation of Phase Diagrams) predicts a region with  $\text{L}_{21}+\text{B}_2$  coexistence. From KKR-CPA calculations, we find crossover versus Al from FCC+BCC coexistence to BCC, as observed, and regions for partially-order  $\text{B}_2+\text{L}_{21}$  coexistence, as suggest by CALPHAD. Our combined first-principles KKR-CPA method provides a powerful approach in predicting SRO and completing long-range order in HEA and other complex alloys.

<sup>1</sup>Supported by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. Work was performed at Ames Laboratory, which is operated by Iowa State University for the U.S. DOE under contract #DE-AC02-07CH11358.

**3:54PM H46.00008 KKR-DCA Thermodynamics for Cluster Short-Range Order with Full Charge Self-Consistency**, DOMINIC A. BIAVA, University of Illinois - Urbana, DUANE D. JOHNSON, Ames Laboratory, Ames, Iowa — The Dynamical Cluster Approximation (DCA) implemented in the Korringa-Kohn-Rostoker (KKR) electronic-structure method gives a systematically exact, *course-grained* theory of the electronic states of substitutionally disordered alloys, including the effects of chemical short-ranged order (SRO). We implement the KKR-DCA within density functional theory (DFT) to calculate directly the charge self-consistent electronic contributions to the alloy grand potential. The KKR-DCA is combined with the chemical entropy from the Cluster Variation Method (CVM), which when minimized predicts the SRO directly. The calculated SRO has been tested in several metallic systems with agreement to measured values. For very large clusters, the KKR-DCA can be sampled, as done within Quantum Monte Carlo, and provides the charge self-consistent thermodynamic grand potential in complex alloys with SRO at finite temperature, at the same level as done for perfect ordered alloys in other electronic-structure methods at zero Kelvin.

**4:06PM H46.00009 The Effect of Disorder on Lattice Thermal Transport in Solid Solution Alloys**, RAINA OLSEN, Oak Ridge National Laboratory, BISWANATH DUTTA, Max-Planck-Institut für Eisenforschung GmbH, GERMAN SAMOLYUK, BRIAN SALES, BEN LARSON, HONGBIN BEI, ELIOT SPECHT, MALCOLM STOCKS, Oak Ridge National Laboratory, THE ENERGY DISSIPATION TO DEFECT EVOLUTION ENERGY FRONTIER RESEARCH CENTER COLLABORATION — Dramatic decreases in radiation damage for 3- and 4-component equiatomic single phase solid solution Ni-based alloys have been recently observed. The strongly decreased damage retention in these highly disordered materials is attributed to severe disruption of the pathways of energy dissipation away from atomic displacement cascades. Because the energy of an irradiating ion is primarily deposited into the lattice degrees of freedom, it is the lattice thermal conductivity that is most important to the dissipation of heat from damage events. Here we report measurements of phonon linewidths in NiCo, NiFe, and NiFeCoCr using inelastic neutron and X-ray scattering, showing a dramatic increase in phonon linewidth by a factor of 4 with increasing disorder. Measured phonon linewidths are shown in comparison to theoretical phonon linewidths originating from disorder calculated using the itinerant coherent potential approximation (I-CPA). Lattice thermal conductivity is calculated from the phonon properties, and compared to measurements of bulk thermal and electrical properties. The impact of the observed decrease in lattice thermal conductivity on damage resistance is discussed.

**4:18PM H46.00010 Extreme Chemical Disorder and the Electrical Transport Properties of Concentrated Solid Solution Alloys: From Binaries to High Entropy Alloys Replace this text with your abstract title**, G. MALCOLM STOCKS, GERMAN SAMOLYUK, SUFFIAN KHAN, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37830, USA, MARKUS DAENE, Physical and Life Sciences, Lawrence Livermore National Laboratory, Livermore CA 94551, USA, SEBASTIAN WIMMER, Department Chemie, Ludwig-Maximilians-Universität München, 81377 München, Germany, BRIAN SALES, HONGBIN BEI, KE JIN, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37830, USA — We present the results of experimental and theoretical studies of electrical transport properties of a family of 2, 3, 4 and 5-component concentrated solid solution alloys (CSA) comprising subsets of the 3d- and 4d-transition metal elements Cr, Mn, Fe, Co, Ni and Pd. Many of this family of CSA show unusual mechanical, magnetic and transport properties as well as indications of increased radiation resistance that are clearly related to the underlying chemical disorder. Here we show the results of calculations of the electrical transport properties that are based on the *ab initio* Korringa-Kohn-Rostoker coherent-potential-approximation (KKR-CPA) method for treating the effect of substitutional disorder, and necessary configurational averaging, on the underlying electronic structure. We compare calculated residual ( $T=0\text{K}$ ) resistivities to corresponding experimental measurements and relate the variations in residual resistivity, which span almost two orders of magnitude, to the underlying electron structure.

**4:30PM H46.00011 Electronic origin of atomic-level stresses in High-Entropy Alloys**, KHOR-GOLKHUU ODBADRAKH, JICS at ORNL, University of Tennessee, TAKESHI EGAMI, MADHU OJHA, UTK, DON NICHOLSON, UNCA, MALCOLM STOCKS, ORNL — High-entropy alloys are multi-component solid solutions in which four or more elements occupy the same crystallographic lattice sites with roughly equal compositions. The underlying chemical disorder gives rise to small local lattice distortions and atomic-level stresses, which are also disorders on their own. These disorders lead to radiation resistance and mechanical strength in high temperature environment, making HEAs alloys attractive candidates as nuclear materials. We report electronic origin of the atomic-level stresses based upon first-principles calculations using Locally Self-consistent Multiple Scattering theory method. Strong atomic-level stresses are present in HEAs due not only to the differences in the intrinsic atomic sizes but due to charge transfer among the elements. We suggest that the improved properties of HEAs originate mainly from the high magnitudes of atomic-level stresses in these complex disordered alloys.

**4:54PM H46.00013 Ab Initio Investigation of He Bubbles at the  $Y_2Ti_2O_7$ -Fe Interface in Nanostructured Ferritic Alloys**, THOMAS DANIELSON, ERIC TEA, CELINE HIN, Virginia Tech — Nanostructured ferritic alloys are promising materials candidates for the next generation of nuclear reactors due to their ability to withstand high temperatures, high pressures, high neutron flux and especially, the presence of high concentrations of transmutation product helium. As helium diffuses through the matrix, large number densities of complex oxide nanoclusters, namely  $Y_2Ti_2O_7$ ,  $Y_2O_3$  and  $Y_2TiO_5$ , act as trapping sites for individual helium atoms and helium clusters. Consequently, there is a significant decrease in the amount of helium that reaches grain boundaries, mitigating the threat of pressurized bubble formation and embrittlement. In order to understand the helium trapping mechanisms of the oxides at a fundamental level, the interface between the nanoclusters and the iron matrix must be modeled. We present results obtained using density functional theory on the  $Y_2Ti_2O_7$ -Fe interface where the structure has been modeled based on experimental observations. Helium has been added along the interface in order to investigate the influence of helium on the structure and to obtain thermodynamic and kinetic parameters of helium along the interface.

**5:06PM H46.00014 The impact of short-range forces on high-energy atom collisions in displacement cascades.**<sup>1</sup>, GERMAN SAMOLYUK, ROGER STOLLER, Oak Ridge National Lab, USA, ARTUR TAMM, Institute of Technology, University of Tartu, Estonia, LAURENT BELAND, G. MALCOLM STOCKS, Oak Ridge National Lab, USA, ALFREDO CARO, Los Alamos National Laboratory, USA, LYUDMILA SLIPCHENKO4, Purdue University, USA, YURY OSETSKIY, Oak Ridge National Lab, USA, ALVO AABLOO, Institute of Technology, University of Tartu, Estonia, MATTIAS KLINTENBERG, Uppsala University, Sweden, YANG WANG, Pittsburgh Supercomputer Center, Carnegie-Mellon University, US — Simulation of primary radiation damage formation in solid materials involves collisions between atoms with a few hundred keV of kinetic energy. As a result, during these collisions, the distance between two colliding atoms can approach 0.05 nm. For such small atomic separations, interatomic potentials significantly underestimate the potential energy. The common practice involves using a screened Coulomb pair potential to describe the high-energy interactions and to smoothly join this to the equilibrium potential. However, there is no standard method for choosing the joining parameters and defect production during cascade evolution has been shown to be sensitive to how the joining is done. We developed a new procedure, which includes the use of ab initio, calculations to determine the pair interactions at intermediate distances, together with systematic criteria for choosing the joining parameters. Results are presented for the case of nickel.

**2:30PM H47.00001 Adsorption Characteristics of Binary Mixtures of Two Halomethanes on Graphite Surface**<sup>1</sup>, KIRAN KHANAL, Department of Polymer Science, The University of Akron, Akron, Ohio, GARY LEUTY, Air Force Research Lab, Dayton, Ohio, MESFIN TSIGE, Department of Polymer Science, The University of Akron, Akron, Ohio — Understanding the physisorption mechanism of mixtures of small molecules on graphite substrate has been a growing interest in materials science in order to investigate the changes in adsorption behavior of mixtures near interfaces vs. the individual components. Using atomic-scale molecular dynamics simulations, we have studied the structure and dynamics of multilayer adsorption of binary mixtures of two halomethanes (CF<sub>4</sub> and CF<sub>3</sub>Cl) on graphite substrates for different bulk compositions of CF<sub>4</sub>. Simulations were performed in the temperature range 60-120K. The goal of this study is to explore how the compositions of individual components as well as temperature, affect the structure of films near the interface, the mobility of molecules, the molecular orientation and the substrate affinity. Preliminary results suggest a strong influence of the concentration of CF<sub>4</sub> and temperature on the structure and mobility of molecules in first adsorbed layer on the graphite surface. In agreement with the recent experimental results, CF<sub>4</sub> displaces CF<sub>3</sub>Cl from the first adsorbed layer at all temperatures in our range and becomes the leading component in the mixture at high temperature for large CF<sub>4</sub> concentrations in the mixture.

**2:42PM H47.00002 Exfoliation and Dispersion of 2-Dimensional Materials by Elevating Temperature**<sup>1</sup>, SANGHYUK KWON, School of Mechanical Engineering, Sungkyunkwan University, 2066 Seobu-ro, Jangan-gu, Suwon 440-746, Korea, JINSEON KIM, Mechanical Test & Analysis Section, Korea Electric Power Corporation Nuclear Fuel, Daedeok-daero 989 beon-gil, Yuseong-gu, Daejeon 305-353, Korea, HYUKJOON KWON, SKKU Advanced Institute of Nanotechnology, Sungkyunkwan University, 2066 Seobu-ro, Jangan-gu, Suwon 440-746, Korea, CHANGGU LEE, School of Mechanical Engineering, Sungkyunkwan University, 2066 Seobu-ro, Jangan-gu, Suwon 440-746, Korea, GRAPHENE ENGINEERING LAB TEAM — It is known that graphene and other 2-dimensional materials are hard to dissolve in water without using chemicals or surfactants. Here, we present a facile method to exfoliate and disperse those materials in water by simply controlling temperature. Graphene, when sonicated in water at high temperature (60C), was edge-functionalized due to the extremely high temperature and pressure locally induced by ultrasonic cavitation, and dissolved in water stably even for longer than 1 month. However, it was not dispersed at low temperature(30C) because of less cavitation and reduced sonochemical reaction. Other 2-dimensional materials, such as h-BN, MoS<sub>2</sub>, and other layered metal chalcogenides, were also well dissolved in water as graphene, but even at low temperature. Their stable solution is from the electric double layer because their relatively high insulating property. Also elevated storage temperature (60C) improved the long-term dispersion stability compared to lower storage temperature (20C)

**3:06PM H47.00004 Role of edge dehydrogenation in magnetization and spin transport of zigzag graphene nanoribbons with line defects<sup>1</sup>**, BIN CUI, DESHENG LIU, School of Physics, Shandong University, Jinan 250100, China — We investigate the effects of edge dehydrogenation on magnetism and spin transport of zigzag graphene nanoribbons (ZGNRs) with line defects (558defect and 57defect) by the first-principles calculations. Results show that magnetization can be induced or strengthened obviously in 558defect-ZGNRs underterminated by hydrogen, but not for 57defect-ZGNRs. This is because a spin-polarized  $\sigma$  edge state appears near the Fermi level and strengthens spin-splitting of energy bands at bare edges of the 558defect-ZGNRs. Moreover, compared with pristine ZGNRs, the 558defect-ZGNRs with bare edges can realize a transition from antiferromagnetic coupling to ferromagnetic coupling between both edges. In addition, the spin-filter efficiency can be effectively improved in our proposed devices by edge dehydrogenation. Our results demonstrate that the presence of  $\sigma$  edge state near the Fermi level plays an important role in controlling spin transport of the graphene-based spintronic devices.

**3:18PM H47.00005 New insights into the opening band gap of graphene oxides**, NGOC THANH THUY TRAN, SHIH-YANG LIN, MING-FA LIN, National Cheng Kung University — Electronic properties of oxygen absorbed few-layer graphenes are investigated using first-principle calculations. They are very sensitive to the changes in the oxygen concentration, number of graphene layer, and stacking configuration. The feature-rich band structures exhibit the destruction or distortion of the Dirac cone, opening of band gap, anisotropic energy dispersions, O- and (C,O)-dominated energy dispersions, and extra critical points. The band decomposed charge distributions reveal the  $\pi$ -bonding dominated energy gap. The orbital-projected density of states (DOS) have many special structures mainly coming from a composite energy band, the parabolic and partially flat ones. The DOS and spatial charge distributions clearly indicate the critical orbital hybridizations in O-O, C-O and C-C bonds, being responsible for the diversified properties. All of the few-layer graphene oxides are semi-metals except for the semiconducting monolayer ones.

**3:30PM H47.00006 Raman Spectra Study and the Corresponding Strain Dependence of Graphyne and Graphdiyne**, SHUQING ZHANG, Peking University, COLLEGE OF CHEMISTRY AND MOLECULAR ENGINEERING TEAM — Graphynes, composed of  $sp$ - $sp^2$  carbon atoms, have attracted increasing interest of research due to particular optical, electrical and mechanical properties they might have. According to recent theoretical studies prediction, the synthesis of graphyne and graphdiyne are difficult but offer more possible compared to other graphynes, and they have been tried to form and got initial achievement<sup>1</sup>. For new materials, their widespread application is impossible without a convenient, fast, non-destructive characterization tool. Raman spectroscopy has performed remarkable ability for studying the properties of  $sp^2$  and  $sp^3$  carbon materials, such as diamond, graphite, carbon fibers and nanotubes. Naturally, we may expect it is also work in  $sp$ - $sp^2$  carbon materials<sup>2</sup>. In our work, the Raman features of graphyne and graphdiyne are studied systematically and their variations versus mechanical strain are also investigated by group theory and first-principles calculations. 1. Guoxing Li, et al. *Chem. Commun.* 2010, 46: 3256 2. Jinying Wang\*, Shuqing Zhang\*, et al. *Phys. Chem. Chem. Phys.* 2014, 16 (23): 11303

**3:42PM H47.00007 Complete Wetting of Graphene by Biological Membrane**, BINQUAN LUAN, RUHONG ZHOU, IBM T J Watson Research Center — In a very recent study, we found that surprisingly graphene nanosheets can extract large amount of lipid molecules directly out of cell membranes thus causing serious damage in cell's integrity (Nat. Nanotechnol. 8, 594, 2013). Here through extensive molecular dynamics simulations and theoretical analyses, we show that this novel phenomenon can be categorized as a complete wetting of graphene by membrane lipids in the medium of water. A wetting-based theory was developed to associate the free energy change during the extraction with the macroscopic spreading parameter. With a customer-designed thermodynamic cycle for detailed energetics, we demonstrated that the dispersive adhesion between graphene and lipids plays a dominant role during this extraction as manifested by the curved graphene.

**3:54PM H47.00008 Electrical conductivity of graphite oxide nanoplatelets obtained from bamboo: Effect of the deoxidation degree.**, K. GROSS, CENM, Universidad del Valle, Cali, Colombia, J. J. PRIAS-BARRAGAN, IS Institute and Electronic IT Program, Universidad del Quindío, Armenia, Colombia, S. SANGIAO, LMA, INA and DFMC, Universidad de Zaragoza, 50009 Zaragoza, Spain, J. M. DE TERESA, DFMC and ICMA, CSIC, Universidad de Zaragoza, 50009 Zaragoza, Spain, L. LAJAUNIE, R. ARENAL, LMA, Instituto de Nanociencia de Aragon (INA), Universidad de Zaragoza, Spain, H. ARIZA-CALDERN, IS Institute, Universidad del Quindío, Armenia, Colombia, P. PRIETO, CENM, Universidad del Valle, Cali, Colombia — Given the high interest in the fabrication and application of carbon-based materials, we present a new and cost-effective method for the synthesis of graphite oxide nanoplatelets (GONP) using bamboo pyrolytic acid (BPA) as source. GONP-BPA present lateral dimensions of 5-100 micro-meter and thickness less than 80 nm, as confirmed by TEM. EEL spectra show that locally the carbon is mainly in  $sp^2$  bonding configuration and confirm a short/medium range crystalline order. Elemental analysis by EDX confirms the presence of oxygen in an atomic percentage ranging from 17 to 5%. For electrical characterization, single platelets were contacted by focused-ion-beam-induced deposition of Pt nanowires. The four-point probe electrical conductivity shows a direct correlation with the oxygen percentage. Three orders of magnitude conductivity rise is observed by the oxygen reduction, reaching a value of  $2.3 \times 10^3$  S/m at the final deoxidation degree. The results suggest that GONP-BPA could be used in the development of advanced devices and sensors.

**4:06PM H47.00009 Simulation of Adsorption of Carbon Dioxide and Methane on Graphene Sheet.**<sup>1</sup>, SIDI MAIGA, Student, SILVINA GATICA<sup>2</sup>, None — Carbon dioxide (CO<sub>2</sub>) and Methane (CH<sub>4</sub>) constitute 90% of the annual greenhouse emission. These gases are emitted from multitude of sources such as: power station, transportation fuels, industrial processes, and agricultural byproducts. Scientists around the globe are looking for materials capable of capturing, separating, and storing these gases. Graphene with its high specific surface area provides a great platform for gas adsorption and separation. Adsorption is defined as the attachment of atoms, or molecules of a gas, liquid or dissolved solid onto a surface, creating a film or monolayer of material onto the adsorbing surface. Using the Method of Grand Canonical Monte Carlo, we computed the adsorption of carbon dioxide (CO<sub>2</sub>) and methane (CH<sub>4</sub>) on a monolayer graphene sheet, at various temperatures for each gas. For each temperature, we compute the adsorption isotherm, Energy gas-surface and Energy gas-gas. We compare the uptake pressures of CO<sub>2</sub> and CH<sub>4</sub>. Using the Ideal Adsorbed Solution Theory (IAST), we predict the selectivity of a mixture CO<sub>2</sub>/CH<sub>4</sub>.

**4:18PM H47.00010 Structural and Compositional Study of Graphene grown on SrTiO<sub>3</sub> by Chemical Vapour Deposition**, SHUMAILA KARAMAT, Middle East Technical University (ODTU), Ankara, Turkey, UMIT CELIK, 3Nano-magnetics Instruments, Ankara Turkey, AHMET ORAL, Middle East Technical University (ODTU), Ankara, Turkey — Graphene, a monolayer of sp<sup>2</sup> bonded carbon atom, is considered as one of the most promising candidate materials for future electronics. The most critical step in graphene research is its transfer from the growth catalyst to the dielectric substrate, many unavoidable issues in the transfer process are: contamination from etchants, photoresist residues, wrinkles, and mechanical breakage. The direct growth of graphene on the substrates without using catalyst offer new opportunities in device fabrication without any transfer process. But till now, the field of direct graphene growth on dielectrics or insulating substrates is not mature like growth on metallic catalysts using CVD. We used chemical vapour deposition to grow graphene on SrTiO<sub>3</sub> (110) substrates. The growth was carried out in presence of methane, argon and hydrogen. Raman Spectrum clearly showed the D and G peaks which were absent in bare substrate. XPS was used to get information about the presence of necessary elements, their bonding with STO substrates. AFM imaging clearly showed graphene island formation on substrates.

**4:30PM H47.00011 Surface and Compositional Study of Graphene grown on Lithium Niobate (LiNbO<sub>3</sub>) substrates by Chemical Vapour Deposition**, SHUMAILA KARAMAT, Middle East Technical University (ODTU), Ankara, Turkey, UMIT CELIK, Nanomagnetics Instruments, Ankara Turkey, AHMET ORAL, Middle East Technical University (ODTU), Ankara, Turkey — The diversity required in the designing of electronic devices motivated the community to always attempt for new functional materials and device structures. Graphene is considered as one of the most promising candidate materials for future electronics and carbon based devices. It is very exciting to combine graphene with new dielectric materials which exhibit multifunctional properties. Lithium Niobate exhibits ferro-, pyro-, and piezoelectric properties with large electro-optic, acousto-optic, and photoelastic coefficients as well as strong photorefractive and photovoltaic effects which made it one of the most extensively studied materials over the last 50 years. We used ambient pressure chemical vapour deposition to grow graphene on LiNbO<sub>3</sub> substrates without any catalyst. The growth was carried out in presence of methane, argon and hydrogen. AFM imaging showed very unique structures on the surface which contains triangular domains. X-ray photoelectron spectroscopy (XPS) was used to get information about the presence of necessary elements, their bonding with LiNbO<sub>3</sub> substrates. Detailed characterization is under process which will be presented later.

**4:42PM H47.00012 Atomically precise nitrogen-doped graphene nanoribbons<sup>1</sup>**, ALEXANDER SINITSKII, University of Nebraska - Lincoln — There is a considerable interest in graphene nanoribbons (GNRs), few-nm-wide strips of graphene with high aspect ratios, because of their intriguing physical properties. For example, GNRs with zigzag edges are predicted to exhibit low-dimensional magnetism, while GNRs with armchair edges can possess large energy band gaps, making them promising materials for future electronics and photovoltaics. The ability to control structural parameters of GNRs, such as their width, edge structure and termination, with atomic precision is the key for practical realization of these intriguing nanoscale properties. Physical properties of GNRs can also be modified by their doping with heteroatoms, such nitrogen, resulting in nitrogen-doped GNRs or N-GNRs. In this talk I will discuss several types of N-GNRs with different doping levels that have been synthesized and systematically studied by spectroscopic, microscopic and transport methods. Incorporation of nitrogen atoms in graphene lattice is shown to be an effective route to affect GNRs' band gap, doping level as well as aggregation behavior.

<sup>1</sup>The support from NSF CHE-1455330 is gratefully acknowledged.

**4:54PM H47.00013 CVD films of narrow atomically precise graphene nanoribbons**, MIKHAIL SHEKHIREV, ALEXEY LIPATOV, University of Nebraska-Lincoln, ASHLEY HARKLERoad, University of Missouri - Kansas City, ALEXANDER SINITSKII, University of Nebraska-Lincoln — Atomically precise graphene nanoribbons (GNRs) is a promising material for the next-generation electronics and optoelectronics. So far, solution-based and surface-assisted approaches have been the two main routes to synthesize GNRs with atomically smooth armchair edges. However, efficient processing of the resulting GNRs into uniform thin films to fabricate GNR-based functional devices remains a formidable challenge. In this presentation we will report the synthesis of narrow armchair GNRs using an alternative approach – a radical polymerization of rationally designed molecular precursors. The technique allows fabrication of thin, transparent and conductive films of GNRs on almost any substrate. Microscopic structure and electrical properties of the fabricated GNR films will also be discussed.

**5:06PM H47.00014 Analysis of vibrational response in graphite oxide nanoplatelets.**, JHON JAIRO PRIAS BARRAGAN, IS Institute and Electronic IT Program of the Universidad del Quindío, KATHERINE GROSS, CENM of the Universidad del Valle, LUC LAJAUNIE, RAUL ARENAL, LMA, Instituto de Nanociencia de Aragón (INA), Universidad de Zaragoza, Spain, HERNANDO ARIZA CALDERON, PEDRO PRIETO, CENM of the Universidad del Valle, Colombia — In this work, we present a new low-cost fabrication process to obtain graphite oxide nanoplatelets from bamboo pyrolytic acid (GO-BPA) by thermal decomposition method using a pyrolysis system for different carbonization temperatures from 673 to 973 K. The GO-BPA samples were characterized by using Raman, FTIR, XRD, SEM and TEM techniques, whose results suggest that increased carbonization temperature increases graphite conversion, boundary defects, desorption of some organic compounds and phonon response, respectively. We discuss potential applications of the GO-BPA samples involving phonon response that would benefit from a fully scaled technology, advanced electronic sensors and devices.

**5:18PM H47.00015 Surface aging phenomena in multidimensional *sp*<sup>2</sup> carbon allotropes**, YUN-HSIANG CHANG, SERGIO SANTOS, MATTEO CHIESA, Laboratory for Energy and NanoScience, Masdar Institute — Despite the current interest in the scientific community in exploiting divergent surface properties of graphitic carbon allotropes, conclusive differentiation remains elusive even when dealing with parameters as fundamental as adhesion. Here we set out to provide conclusive experimental evidence on the time evolution of the surface properties of highly oriented pyrolytic graphite (HOPG), graphene monolayer (GML) and multiwalled carbon nanotubes (MWCNTs) as we expose these materials to airborne contaminants, by providing 1) statistically significant results based on large data-sets, i.e. thousands of force measurements, and 2) errors sufficiently self-consistent to treat the comparison between data-sets in atomic force microscopy measurements. We first consider HOPG as a model system and then employ our results to draw conclusions from the GML and MWCNT samples. We find that, in terms of surface properties and thus regarding surface functionality, aged HOPG and GML are more similar than aged HOPG and cleaved HOPG. The state of the HOPG samples is also as relevant for the comparison between HOPG and MWCNTs.

## 2:30PM H48.00001 Entanglement of remote transmon qubits by concurrent photon detection

**- Part 1<sup>1</sup>**, S. SHANKAR, A. NARLA, M. HATRIDGE, W. PFAFF, Z. LEGHTAS, K.M. SLIWA, E. ZALYS-GELLER, L. FRUNZIO, M.H. DEVORET, Department of Applied Physics, Yale University — One proposed realization for a quantum computer is the modular architecture, which consists of error-corrected quantum memories that are connected via a quantum router. A fundamental requirement for this modular quantum computer is the ability to entangle arbitrary, distant qubits on demand. This can be realized in circuit QED using a protocol inspired by recent experiments based on trapped ions and nitrogen-vacancy centers. First, each qubit is entangled with a single cavity photon (Fock state  $n=1$ ) using sideband pulses. On their way out of the cavity, the now flying photons interfere on a beam-splitter and are concurrently detected by a novel microwave photo-multiplier that employs a third qubit-cavity system. In this protocol, the presence of losses in the photon flight path only affect the success probability of creating an entangled state but not its fidelity. In this talk, we present the experimental realization of this protocol for entangling two transmon qubits, focusing on the implementation and optimization of the microwave photo-multiplier.

## 2:54PM H48.00003 Using a Superconducting Resonator with Frequency-Compensated Tunable Coupling to Transfer a Quantum State Deterministically and Directly

, JAMES WENNER, C. NEILL, C. QUINTANA, B. CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, P. O'MALLEY, A. VAINSENER, University of California, Santa Barbara, T. WHITE, R. BARENDT, Y. CHEN, A. FOWLER, E. JEFFREY, J. KELLY, E. LUCERO, A. MEGRANT, J. MUTUS, M. NEELEY, P. ROUSHAN, D. SANK, Google, Santa Barbara, JOHN M. MARTINIS, University of California and Google, Santa Barbara — Deterministic direct quantum state transfer between devices on different chips requires the ability to transfer quantum states between traveling qubits and fixed logic qubits. Reflections must be minimized to avoid energy loss and phase interference; this requires tunable coupling to an inter-chip line while the two devices are at equal frequencies. To achieve this, we use a 6GHz superconducting coplanar resonator with tunable coupling to a 50 Ohm transmission line. We compensate for the resulting shift in resonator frequency by simultaneously tuning a second SQUID. We measure the device coherence and demonstrate the ability to release a single-frequency shaped pulse into the transmission line, efficiently capture a shaped pulse, and deterministically and directly transfer a quantum state.

## 3:06PM H48.00004 Controlled release of cavity states into propagating modes induced via a single qubit

, WOLFGANG PFAFF, MARIUS CONSTANTIN, MATTHEW REAGOR, CHRISTOPHER AXLINE, JACOB BLUMOFF, KEVIN CHOU, ZAKI LEGHTAS, STEVEN TOUZARD, REINIER HEERES, PHILIP REINHOLD, NISSIM OFEK, KATRINA SLIWA, LUIGI FRUNZIO, Yale University, MAZYAR MIRRAHIMI, Yale University & INRIA, KONRAD LEHNERT, University of Colorado, LIANG JIANG, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University — Photonic states stored in long-lived cavities are a promising platform for scalable quantum computing and for the realization of quantum networks. An important aspect in such a cavity-based architecture will be the controlled conversion of stored photonic states into propagating ones. This will allow, for instance, quantum state transfer between remote cavities. We demonstrate the controlled release of quantum states from a microwave resonator with millisecond lifetime in a 3D circuit QED system. Dispersive coupling of the cavity to a transmon qubit allows us to enable a four-wave mixing process that transfers the stored state into a second resonator from which it can leave the system through a transmission line. This permits us to evacuate the cavity on time scales that are orders of magnitude faster than the intrinsic lifetime. This Q-switching process can in principle be fully coherent, making our system highly promising for quantum state transfer between nodes in a quantum network of high-Q cavities.

## 3:18PM H48.00005 Concurrent remote entanglement with continuous variables<sup>1</sup>

, E. ZALYS-GELLER, A. NARLA, S. SHANKAR, M. HATRIDGE, M. SILVERI, K.M. SLIWA, S.O. MUNDHADA, S.M. GIRVIN, M.H. DEVORET, Department of Applied Physics, Yale University — A necessary ingredient for large scale quantum information processing is the ability to entangle distant qubits on demand. In the field of superconducting quantum information, this process can be achieved by entangling stationary superconducting qubits with flying coherent states of microwave light, which are then co-amplified by a Josephson Parametric Converter (JPC). The JPC also serves as a which-path information eraser, causing the probabilistic continuous measurement process to concurrently entangle the qubits. We discuss the sensitivity of the experiment to the loss of quantum information during the flight of the coherent states, as well as strategies to improve which-path information erasure and reduce information loss to the degree required for entanglement generation.

## 3:30PM H48.00006 Preparation of a narrowband, itinerant microwave qubit for quantum information transfer<sup>1</sup>

, XIZHENG MA, ADAM REED, LUCAS SLETTEN, Department of Physics, University of Colorado, Boulder, Colorado, USA, MATTHEW REAGOR, LUKE BURKHART, WOLFGANG PFAFF, R.J. SCHOELKOPF, Departments of Applied Physics and Physics, Yale University, New Haven, Connecticut, USA., K.W. LEHNERT, JILA, University of Colorado and NIST, Boulder, Colorado, USA; Department of Physics, University of Colorado, Boulder, Colorado, USA — Narrowband microwave-frequency signals are compatible with many quantum information processing technologies and can coherently transfer quantum information between devices. The creation of itinerant, microwave single photon states has been successfully demonstrated. Here, we show progress towards generating a narrowband, itinerant microwave qubit in a coherent superposition of zero and one Fock states. Specifically, we use the red-sideband transition of a transmon to map a superposition of qubit states onto a propagating microwave signal. This signal should have a bandwidth sufficiently narrow to be absorbed by a quantum-enabled electro-optic converter [1], potentially enabling the transfer of quantum information from a transmon qubit to the optical domain.

<sup>1</sup>[1] R.W. Andrews, *et al.*, Nature Phys. **10**, 321–326 (2014).

**3:42PM H48.00007 Characterizing an itinerant microwave Fock state compatible with transfer to a macroscopic mechanical oscillator<sup>1</sup>**, L.R. SLETTEN, A.P. REED, XIZHENG MA, JILA, University of Colorado, Boulder, Colorado, L.D. BURKHART, M. REAGOR, W. PFAFF, R.J. SCHEOLKOPF, Department of Physics and Applied Physics, Yale University, New Haven, Connecticut, K.W. LEHNERT, JILA and National Institute of Standards and Technology, Boulder, Colorado — Transferring propagating single-photon signals generated by a qubit to a mechanical oscillator offers a way to prepare non-classical motional states of a macroscopic object. In this concept, a highly coherent transmon qubit in a cavity is used to create single itinerant microwave photons. These photons can then be directed towards a tunable electromechanical circuit where they can be converted into single phonons. In this talk, we present measurements of itinerant single photons engineered to realize this concept. In particular, we characterize their quantum state tomographically, demonstrate that they have sufficiently narrow bandwidth for capture by an electromechanical circuit, and measure the efficiency with which they travel between microwave cavities.

**3:54PM H48.00008 Entangled Schrodinger cats in circuit QED: Experimental Architecture**, CHEN WANG, YVONNE Y. GAO, PHILIP REINHOLD, REINIER W. HEERES, NISSIM OFEK, KEVIN CHOU, CHRISTOPHER AXLINE, LUIGI FRUNZIO, MICHEL H. DEVORET, ROBERT J. SCHEOLKOPF, Yale University — The development of quantum information technology relies on creating and controlling entanglement over an increasingly large Hilbert space. Superconducting cavities offer high-dimensional spaces for quantum states in a low-loss and hardware-efficient fashion, making it an ideal memory of quantum information and an important element towards fault-tolerant quantum computation. In this talk we present a cQED architecture that allows quantum control over the coherent state basis of two superconducting cavities with millisecond coherence. In particular, we show deterministic entanglement of coherent-state microwave fields in two superconducting cavities of the form:  $\frac{1}{\sqrt{2}}(|\beta_a\rangle|\beta_a\rangle \pm |-\beta_a\rangle|-\beta_a\rangle)$ . We engineer the capability to measure the joint photon number parity to achieve complete state tomography of the two-cavity state. Following widespread efforts of realizing “Schrodinger’s cat”-like mesoscopic superposition in various physical systems, this experiment demonstrates mesoscopic entanglement between two “Schrodinger’s cats”.

**4:06PM H48.00009 Entangled Schrodinger cats in circuit QED: Joint Wigner Tomography**, YVONNE Y. GAO, CHEN WANG, PHILIP REINHOLD, REINIER W. HEERES, NISSIM OFEK, KEVIN CHOU, CHRISTOPHER AXLINE, LUIGI FRUNZIO, MICHEL H. DEVORET, ROBERT J. SCHEOLKOPF, Yale University — Creating and controlling entanglement of quantum states over large Hilbert space is an important element of quantum information processing. Using the cQED architecture consisting of two long-lived superconducting cavities dispersively coupled to a transmon qubit, we successfully created an entangled coherent-state microwave fields in two superconducting cavities. In this talk, we will present the full joint Wigner tomography of the state, measured using the method of joint photon number parity measurement introduced in the previous talk. Furthermore, we will show the redundant encoding and efficient read-out of two logical bits of information in such entangled state and hence demonstrating that the entangled “Schrodinger cats” is a viable candidate as an error-correctable quantum memory as well as a valuable platform for implementation of two-qubit logical operations.

**4:18PM H48.00010 Generating entanglement via symmetry-selective bath engineering in superconducting qubits<sup>1</sup>**, IRFAN SIDDIQI, MOLLIE SCHWARTZ, LEIGH MARTIN, EMMANUEL FLURIN, Quantum Nanoelectronics Laboratory, UC Berkeley, CAMILLE ARON, Laboratoire de Physique Thorique, cole Normale Suprieure; Instituut voor Theoretische Fysica, KU Leven, MANAS KULKARNI, Department of Physics, New York City College of Technology, City University of New York, HAKAN TURECI, Department of Electrical Engineering, Princeton University — Bath engineering, which utilizes coupling to lossy modes in a quantum system to generate non-trivial steady states, is a potential alternative to gate- and measurement-based quantum science. In this talk, we discuss autonomous stabilization of entanglement between two superconducting transmon qubits in a symmetry-selective manner. Our experiments are implemented using two 3D transmons housed in separate copper cavities. The cavities are coupled via an aperture, and hybridize into nondegenerate symmetric and antisymmetric bath modes. We utilize the engineered symmetries of the dissipative environment to stabilize a target Bell state  $\frac{1}{\sqrt{2}}(|ge\rangle \pm |eg\rangle)$  in the qubit sector; we further demonstrate suppression of the Bell state of opposite symmetry due to parity selection rules. This implementation is resource-efficient, achieves a steady-state fidelity  $\mathcal{F} = 0.70$ , and is scalable to multiple qubits. <http://arxiv.org/abs/1511.00702>

**4:30PM H48.00011 Multimode Entanglement Generation in a Parametric Superconducting Cavity**, C.W.S. CHANG, University of Waterloo, M. SIMOEN, Chalmers University of Technolog, A.M. VADIRAJ, University of Waterloo, P. DELSING, Chalmers University of Technolog, C.M. WILSON, University of Waterloo — Parametric microwave resonators implemented with superconducting circuits have become increasingly important in various application within quantum information processing. For example, quantum-limited parametric amplifiers based on these devices have now become commonplace as first-stage amplifiers for qubit experiments. Here we study the generation of multimode entangled states of propagating microwave photons, which can be used a resource in quantum computing and communication applications. We use a CPW resonator with a low fundamental resonance frequency that than has a number of modes in the common frequency band of 4-12 GHz. These modes are all parametrically coupled by a single SQUID that terminates the resonator. When parametrically pumping the system at the sum of two mode frequencies, we observe parametric downconversion and two-mode squeezing. By pumping at the difference frequency, we observe a beamsplitter-like mode conversion. By using multiple pump tones that combine these different processes, theory predicts we can construct multimode entangled states with a well-controlled entanglement structure, e.g., cluster states. Preliminary measurements will be presented.

**4:42PM H48.00012 Simultaneous measurement of non-commuting observables in circuit QED: Theory<sup>1</sup>**, LEIGH MARTIN, SHAY HACOEN-GOURGY, EMMANUEL FLURIN, Quantum Nanoelectronics Laboratory, UC Berkeley, BIRGITTA WHALEY, Berkeley Quantum Information and Computation Center, UC Berkeley, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — We describe the theory of a novel technique for simultaneously and continuously measuring a pair of non-commuting qubit observables, which has until now not been realized experimentally. Our proposed experimental platform consists of a qubit dispersively coupled to two linear cavity modes. Driving the qubit on resonance realizes an effective two-level system with energy splitting given by the Rabi frequency. Non-commuting measurements are performed on this system by application of sideband tones detuned from the cavity resonance frequencies by the Rabi frequency. We show that this realizes cooling and back-action free measurements constituting destructive and QND measurements, respectively, along an arbitrary axis of the Bloch sphere. Simultaneous application of a distinct pair of measurements may then be achieved by choosing a different axis for each cavity mode. We show that existing high quantum efficiency homodyne measurement techniques will enable the reconstruction of quantum trajectories of the qubit. Finally, we describe methods for characterizing the system’s dynamics and verifying that the scheme does enable access to incommensurate, competing degrees of freedom.

<sup>1</sup>This research is supported by the ARO.

**4:54PM H48.00013 Simultaneous measurement of non-commuting observables in circuit QED: Experiment<sup>1</sup>**, SHAY HACOEN-GOURGY, LEIGH MARTIN, EMMANUEL FLURIN, Quantum Nanoelectronics Laboratory, UC Berkeley, BRIGITTA WHALEY, Berkeley Quantum Information Center, UC Berkeley, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — The existence of incompatible measurements lies at the heart of numerous fundamental concepts in quantum mechanics, such as entanglement, contextuality and measurement-disturbance tradeoffs. We implement a novel technique for simultaneously and continuously measuring a pair of non-commuting observables in a circuit-QED architecture, which features a transmon qubit coupled to two modes of an electromagnetic cavity. By driving the transmon on resonance, we form an effective, low-frequency two-level system on which we perform the non-commuting measurements. To this end, we use microwave tones near the cavity's resonances to implement cooling and backaction-evading measurements familiar from optomechanics. Control of the relative amplitude and phase of these sideband tones enables qubit state measurement along an arbitrary axis of the Bloch sphere. We apply this technique to both modes of the cavity simultaneously, with distinct axes chosen for each mode. This realizes a continuous and simultaneous measurement of two non-commuting observables. We use high quantum-efficiency parametric amplifiers to track the resulting quantum trajectories of the qubit, enabling a measurement of the mutual disturbance of the two observables.

<sup>1</sup>This research is supported by the ARO

**5:06PM H48.00014 Optimized entanglement purification schemes for modular based quantum computers**, STEFAN KRASTANOV, LIANG JIANG, Yale University — The choice of entanglement purification scheme strongly depends on the fidelities of quantum gates and measurements, as well as the imperfection of initial entanglement. For instance, the purification scheme optimal at low gate fidelities may not necessarily be the optimal scheme at higher gate fidelities. We employ an evolutionary algorithm that efficiently optimizes the entanglement purification circuit for given system parameters. Such optimized purification schemes will boost the performance of entanglement purification, and consequently enhance the fidelity of teleportation-based non-local coupling gates, which is an indispensable building block for modular-based quantum computers. In addition, we study how these optimized purification schemes affect the resource overhead caused by error correction in modular based quantum computers.

**5:18PM H48.00015 Entanglement distillation in circuit quantum electrodynamics**, MARKUS OPPLIGER, JOHANNES HEINSOO, YVES SALATHE, ANTON POTOCNIK, MINTU MONDAL, ANDREAS WALLRAFF, ETH Zurich, GHEORGHE SORIN PAROANU, Aalto University School of Science — Entanglement is an essential resource for quantum information processing, such as quantum error correction, quantum teleportation and quantum communication. Such algorithms perform optimally with maximally entangled states. In practice entangled quantum states are very fragile due to a wide range of decoherence mechanisms. When two parties share degraded entangled states they are still able to generate an entangled state with higher fidelity using local operations and classical communication. This process is commonly referred to as entanglement distillation. Here we demonstrate distillation of highly entangled Bell states from two copies of less entangled states on a four transmon qubit device realized in the circuit-QED architecture. We characterize the output state for different degrees of entanglement at the input with quantum state tomography. A clear improvement of the entanglement measures is observed at the output.

**2:30PM H50.00001 Characterizing eigenstate thermalization via measures in the Fock space of operators**, XIAO-LIANG QI, PAVAN HOSUR, Stanford Univ — The eigenstate thermalization hypothesis (ETH) attempts to bridge the gap between quantum mechanical and statistical mechanical descriptions of isolated quantum systems. Here, we define unbiased measures for how well the ETH works in various regimes, by mapping general interacting quantum systems on regular lattices onto a single particle living on a high-dimensional graph. By numerically analyzing deviations from ETH behavior in the non-integrable Ising model, we propose quantities that we call the "n-weight" and the "n-distinguishability" to democratically characterize the average and the maximum deviations, respectively, for all operators residing on  $n$  sites. Along the way, we discover that complicated operators on average are worse than simple ones at distinguishing between neighboring eigenstates, contrary to the naive intuition created by the usual statements of the ETH that few-body (many-body) operators acquire the same (different) expectation values in nearby eigenstates at finite energy density.

**2:42PM H50.00002 Dynamical Many-Body Localization in a System of Coupled Relativistic Kicked Rotors**, EFIM ROZENBAUM, VICTOR GALITSKI, University of Maryland, College Park — A periodically-driven rotor is a prototypical model that exhibits a transition to chaos in the classical regime and dynamical localization (related to Anderson localization) in the quantum regime. In a recent preprint, arXiv:1506.05455, Keser *et al.* considered a many-body generalization of coupled quantum kicked rotors, and showed that in the special integrable linear case, the dynamical localization survives interactions. By analogy with many-body localization, the phenomenon was dubbed dynamical many-body localization (DMBL). In the present work, we study a non-integrable model of coupled quantum relativistic kicked rotors. Our analysis of such coupled "kicked" Dirac equations indicates that DMBL can exist for generic, non-integrable systems. We also analyze quantum dynamics of the model, which for certain select values of model's parameters exhibits highly unusual behavior – e.g., superballistic transport and peculiar spin dynamics.

**2:54PM H50.00003 A renormalization group approach to identifying the local quantum numbers in a many-body localized system<sup>1</sup>**, DAVID PEKKER, University of Pittsburgh, BRYAN K. CLARK, UIUC, VADIM OGANESYAN, College of Staten Island and the Graduate Center, CUNY, GIL REFAEL, Caltech, BINBIN TIAN, University of Pittsburgh — Many-body localization is a dynamical phase of matter that is characterized by the absence of thermalization. One of the key characteristics of many-body localized systems is the emergence of a large (possibly maximal) number of local integrals of motion (local quantum numbers) and corresponding conserved quantities. We formulate a robust algorithm for identifying these conserved quantities, based on Wegner's flow equations – a form of the renormalization group that works by disentangling the degrees of freedom of the system as opposed to integrating them out. We test our algorithm by explicit numerical comparison with more engineering based algorithms – Jacobi rotations and bi-partite matching. We find that the Wegner flow algorithm indeed produces the more local conserved quantities and is therefore more optimal. A preliminary analysis of the conserved quantities produced by the Wegner flow algorithm reveals the existence of at least two different localization lengthscales.

### 3:06PM H50.00004 Many-body localization and thermalization in disordered Hubbard chains

, RUBEN MONDAINI, MARCOS RIGOL, The Pennsylvania State University — Recently, a lot of attention has been given to the aspects that lead isolated interacting quantum systems to thermalize. In the presence of disorder, however, the thermalization process fails resulting in a phenomena where transport is suppressed known as many-body localization. Unlike the standard Anderson localization for non-interacting systems, the delocalized (ergodic) phase is very robust against disorder even for moderate values of interaction. Another interesting aspect of the many-body localization phase is that under the time evolution of the quenched disorder, information present in the initial state may survive for arbitrarily long times. This was recently used as a probe of many-body localization of ultracold fermions in optical lattices with quasi-periodic disorder<sup>1</sup>. Here, we will use numerical results in one-dimensional Hubbard chains to show that this analysis may suffer from substantial finite-size effects. We will also compare different types of disorder to see how the ergodicity is affected.<sup>2</sup>

### 3:18PM H50.00005 Particle-hole symmetry, many-body localization, and topological edge

**modes**<sup>1</sup>, ROMAIN VASSEUR, UC Berkeley and Lawrence Berkeley National Laboratory, AARON J. FRIEDMAN, S.A. PARAMESWARAN, University of California, Irvine, ANDREW C. POTTER, UC Berkeley — We study the excited states of interacting fermions in one dimension with particle-hole symmetric disorder (equivalently, random-bond XXZ chains) using a combination of renormalization group methods and exact diagonalization. Absent interactions, the entire many-body spectrum exhibits infinite-randomness quantum critical behavior with highly degenerate excited states. We show that though interactions are an irrelevant perturbation in the ground state, they drastically affect the structure of excited states: even arbitrarily weak interactions split the degeneracies in favor of thermalization (weak disorder) or spontaneously broken particle-hole symmetry, driving the system into a many-body localized spin glass phase (strong disorder). In both cases, the quantum critical properties of the non-interacting model are destroyed, either by thermal decoherence or spontaneous symmetry breaking. This system then has the interesting and counterintuitive property that edges of the many-body spectrum are less localized than the center of the spectrum. We argue that our results rule out the existence of certain excited state symmetry-protected topological orders.

### 3:30PM H50.00006 Dynamical many-body localization in an integrable model

, AYIN C. KESER, Condensed Matter Theory Center, University of Maryland, College Park, SRIRAM GANESHAN, Simon Center for Geometry and Physics, GIL REFAEL, Institute of Quantum Information and Matter, Caltech, VICTOR GALITSKI, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We investigate dynamical many-body localization and delocalization in an integrable system of periodically-kicked, interacting linear rotors. The linear-in-momentum Hamiltonian makes the Floquet evolution operator analytically tractable for arbitrary interactions. One of the hallmarks of this model is that depending on certain parameters, it manifest both localization and delocalization in momentum space. We explicitly show that, for this model, the energy being bounded at long times is neither a necessary nor a sufficient condition for dynamical localization. We present a set of integrals of motion, which can serve as a fundamental diagnostic of dynamical localization. We also propose an experimental scheme, involving voltage-biased Josephson junctions, to realize such many-body kicked models.

### 3:42PM H50.00007 Dynamics of Hubbard-Band Quasiparticles in Disordered Optical Lattices<sup>1</sup>

, VITO SCAROLA, Virginia Tech, BRIAN DEMARCO, University of Illinois, Urbana-Champaign — Recent experiments use transport of degenerate Fermi gases in optical lattices (Kondov et al. Phys. Rev. Lett. **114**, 083002 (2015)) to probe the interplay of disorder and strong interactions. These experiments find evidence for an intriguing insulating phase where quantum diffusion is completely suppressed by strong disorder. Quantitative interpretation of these experiments remains an open problem that requires inclusion of non-zero entropy, strong interaction, and trapping in an Anderson-Hubbard model. We construct a theory of dynamics of Hubbard-band quasiparticles tailored to trapped optical lattice experiments. We compare the theory directly with center-of-mass transport experiments of Kondov et al. with no fitting parameters. The close agreement between theory and experiments shows that the suppression of transport is only partly due to finite entropy effects. We argue that the complete suppression of transport is consistent with short-time, finite size precursors of Anderson localization of Hubbard-band quasiparticles. The combination of our theoretical framework and optical lattice experiments offers an important platform for studying localization in isolated many-body quantum systems.

### 3:54PM H50.00008 Many-body localization and symmetry protected topology with ultracold

**Rydberg atoms**, IONUT-DRAGOS POTIRNICHE, Univ of California - Berkeley, MONIKA SCHLEIER-SMITH, Stanford University, ASHVIN VISHWANATH, NORMAN YAO, Univ of California - Berkeley — The interplay between quantum entanglement and symmetry-protected topological order has led to the classification of gapped, interacting, one dimensional quantum phases. A consequence of this classification is the existence of a diverse set of exactly solvable models, which serve as paradigmatic examples of various SPT orders. The experimental realization of such models has been hampered by the challenge of implementing tunable multi-body interactions. Recently, an alternate strategy has arisen: periodic driving. Indeed, it has been shown that the dynamics of a simple Floquet transverse-field Ising model can mirror that of the celebrated Haldane chain. However, as SPT order is expected only in the ground state while a driven system is expected to heat to infinite temperature, the ability to observe such Floquet SPT phases remains an open question. Here, we demonstrate that strong disorder, leading to many-body localization, stabilizes SPT order at finite energy densities while also preventing arbitrary heating of the system. Moreover, we propose a natural experimental implementation in a 1D optical lattice of ultracold Rydberg atoms.

### 4:06PM H50.00009 Probing Anderson localization of light via decay rate statistics in aperiodic

**Vogel spirals**<sup>1</sup>, ARISTI CHRISTOFI, Department of Electrical and Computer Engineering, Boston University, 8 Saint Marys street, Boston, MA 02215 USA, FELIPE A. PINHEIRO, Universidade Federal do Rio de Janeiro, Rio de Janeiro-RJ, 21941-972, Brazil & University of Southampton, Highfield, Southampton SO17 1BJ, UK, LUCA DAL NEGRO, Department of Electrical and Computer Engineering & Photonics Center, Boston University, 8 Saint Marys street, Boston, MA 02215 USA — We systematically investigate the spectral properties of different types of two-dimensional aperiodic Vogel spiral arrays of pointlike scatterers and three-dimensional metamaterials with Vogel spiral chirality using rigorous Greens function spectral method. We considered an efficient T-matrix approach to analyze multiple-scattering effects, including all scattering orders, and to understand localization properties through the statistics of the Greens matrix eigenvalues. The knowledge of the spectrum of the Green matrix of multi-particle scattering systems provides important information on the character of light propagation and localization in chiral media with deterministic aperiodic geometry. In particular, we analyze for the first time the statistics of the eigenvalues and eigenvectors of the Green matrix and extract the decay rates of the eigenmodes, their inverse participation ratio (IPR), the Wigner delay times and their quality factors. We emphasize the unique properties of aperiodic Vogel spirals with respect to random scattering media, which have been investigated so far.

**4:18PM H50.00010 Anomalous transport in ergodic lattice systems<sup>1</sup>** , YEVGENY BAR LEV, DAVID R. REICHMAN, Columbia University — Many-body localization transition is a peculiar dynamical transition between ergodic and non-ergodic phases, which may occur at any temperature and in any dimension. For temperatures below the transition the system is nonergodic and localized, such that conductivity strictly vanishes at the thermodynamic limit, while for temperatures above the transition the system is thermal and conductive. In this talk I will present a comprehensive study of the dynamical properties of the ergodic phase in one and two dimensional generic disordered and interacting systems, conducted using a combination of nonequilibrium diagrammatic techniques and numerically exact methods. I will show that the ergodic phase, which was expected to be diffusive, exhibits anomalous transport regime for nontrivial times and explain how our findings settle with phenomenological theoretical models.

<sup>1</sup>NSF-CHE-1644802

**4:30PM H50.00011 Eigenstate Order in Floquet Systems** , CURT VON KEYSERLINGK, SHIVAJI SONDHAI, Princeton Univ — Recent work has introduced the notion of eigenstate order for many body systems and extended it to periodically driven, or Floquet, systems. I will discuss a set of results on possible phases in Floquet systems. These involve generalisations of topological insulators and superconductors as well as generalisations of interacting symmetry protected and topological phases of matter. Many body localisation plays an essential role in their realisation.

**4:42PM H50.00012 Localization in systems with long-range interactions<sup>1</sup>** , LEA SANTOS, Yeshiva University, USA, FRANCISCO PEREZ-BERNAL, Universidad de Huelva, Spain, FAUSTO BROGONÓVI, GIUSEPPE CELARDO, Università Cattolica del Sacro Cuore, Italy — In recent experiments with ion traps, long-range interactions were associated with the very fast propagation of excitations. Here, we show that, depending on the initial state, the evolution of these systems may actually be exceedingly slow. This is justified with the analysis of the density of states and structures of the eigenstates, and confirmed with numerical simulations of quench dynamics. The two sources of restricted dynamics that we discuss are: the presence of an excited state quantum phase transition and the onset of subspaces shielded from the effects of long-range interactions. Both scenarios can be tested experimentally.

**4:54PM H50.00013 Dynamics of a Many-Body-Localized System Coupled to a Bath** , MARK FISCHER, MYKOLA MAKSYMENKO, EHUD ALTMAN, Weizmann Institute of Science — Coupling a many-body localized system to a dissipative bath necessarily leads to delocalization. Here we investigate the nature of the ensuing relaxation dynamics and the information it holds on the many-body localized state. To solve for the time evolution, we formulate the relevant Lindblad equation in terms of the local integrals of motion of the underlying localized Hamiltonian. This allows to map the quantum evolution deep in the localized state to tractable classical rate equations. We consider two different types of dissipation relevant to systems of ultra-cold atoms: particle loss and dephasing due to inelastic scattering on the lattice lasers. Only the first mechanism shows a pronounced effect of interactions on the relaxation of observables.

**5:06PM H50.00014 Extended slow dynamical regime near the many-body localization transition** , DAVID J. LUITZ, University of Illinois at Urbana-Champaign, NICOLAS LAFLORENCIE, FABIEN ALET, Laboratoire de Physique Théorique, IRSAMC, Université de Toulouse, CNRS — Many-body localization is characterized by a slow logarithmic growth of entanglement entropy after a global quantum quench while the local memory of an initial spin imbalance remains at infinite time. We address the dynamics in the delocalized ergodic regime, where thermalization is expected. Using an exact Krylov space technique, the out-of-equilibrium dynamics of the random-field Heisenberg chain is studied up to  $L = 28$  sites, starting from an initially unentangled high-energy product state. With such a global quench protocol, we study the time evolution of the entanglement entropy, as well as the spin density imbalance in order to make contact with recent cold atom experiments. Within most of the delocalized phase, we unambiguously find a sub-ballistic entanglement growth  $S(t) \propto t^{1/z}$  with a disorder-dependent exponent  $z \geq 1$ , in contrast with the pure ballistic growth  $z = 1$  of clean systems. At the same time, anomalous relaxation is also observed for the spin imbalance  $I(t) \propto t^{-\zeta}$  with a continuously varying disorder-dependent exponent  $\zeta$ , vanishing at the transition. This provides a clear experimental signature for detecting this non-conventional metallic state where transport is sub-diffusive.

**5:18PM H50.00015 Effective localization potential of quantum states in disordered media<sup>1</sup>** , FILOCHE MARCEL, Ecole Polytechnique, DOUGLAS N. ARNOLD, University of Minnesota, GUY DAVID, Université Paris-Sud, DAVID JERISON, Massachusetts Institute of Technology, SVITLANA MAYBORODA, University of Minnesota — The amplitude of localized quantum states in random or disordered media may exhibit long range exponential decay. We present here a theory that unveils the existence of a localization landscape that controls the amplitude of the eigenstates in any quantum system. For second order operators such as the Schrödinger operator, this localization landscape is simply the solution of a Dirichlet problem with uniform right-hand side [1]. Moreover, we show that the reciprocal of this landscape plays the role of an effective potential which finely governs the confinement of the quantum states. In this picture, the boundaries of the localization subregions for low energy eigenfunctions correspond to the barriers of this effective potential, and the long range exponential decay characteristic of Anderson localization is explained as the consequence of multiple tunneling in the dense network of barriers created by this effective potential. Finally, we show that the Weyl's formula based on this potential turns out to be a remarkable approximation of the density of states for a large variety of systems, periodic or random, 1D, 2D, or 3D. [1] M. Filoche and S. Mayboroda, Proceedings of the National Academy of Sciences of the USA 109, 14761 (2012).

Session H51 GPC DFD GSNP: Climate as a Non-equilibrium and Stochastic System Hilton Baltimore Holiday Ballroom 2 - Juan Restrepo, Oregon State University

**2:30PM H51.00001 Fluctuations and Response in Geophysical Fluid Dynamics** , VALERIO LUCARINI, University of Hamburg — The climate is a complex, chaotic, non-equilibrium system featuring a limited horizon of predictability, variability on a vast range of temporal and spatial scales, instabilities resulting into energy transformations, and mixing and dissipative processes resulting into entropy production. Despite great progresses, we still do not have a complete theory of climate dynamics able to account for instabilities, equilibration processes, response to changing parameters of the system, and multiscale effects. We will outline some possible applications of the response theory developed by Ruelle for non-equilibrium statistical mechanical systems, showing how it allows for setting on firm ground and on a coherent framework concepts like climate sensitivity, climate response, and climate tipping points, and to construct parametrizations for unresolved processes. We will show results for comprehensive global climate models. The results are promising in terms of suggesting new ways for approaching the problem of climate change prediction and for using more efficiently the enormous amounts of data produced by modeling groups around the world. Ref: V. Lucarini, R. Blender, C. Herbert, F. Ragone, S. Pascale, J. Wouters, Mathematical and Physical Ideas for Climate Science, Reviews of Geophysics 52, 809-859 (2014)

**3:06PM H51.00002 Balanced Dynamics in the Madden-Julian Oscillation<sup>1</sup>**, SHARON SESSIONS, STIPO SENTIC, New Mexico Tech, ZELJKA FUCHS, University of Split, Croatia, and New Mexico Tech, DAVID RAYMOND, New Mexico Tech — Balanced dynamics describes the response of the tropical thermodynamic environment to changes in the atmospheric vorticity patterns. Observations and numerical simulations have demonstrated that positive mid-tropospheric vorticity anomalies produce a more stable thermodynamic environment with cool anomalies at low levels and warm anomalies aloft. The increase in atmospheric stability creates more bottom-heavy convective profiles which are highly conducive for developing tropical cyclones. Balanced dynamics may also play a role in other varieties of tropical convection, including the most significant source of intraseasonal variability: the Madden-Julian Oscillation (MJO). Using data from DYNAMO—a field program aimed to investigate the dynamics of the MJO—we investigate the role of balanced dynamics in the Madden-Julian Oscillation.

**3:18PM H51.00003 Stochastic dynamics of melt ponds and sea ice-albedo climate feedback**, IVAN SUDAKOV, Department of Physics, University of Dayton — Evolution of melt ponds on the Arctic sea surface is a complicated stochastic process. We suggest a low-order model with ice-albedo feedback which describes stochastic dynamics of melt ponds geometrical characteristics. The model is a stochastic dynamical system model of energy balance in the climate system. We describe the equilibria in this model. We conclude the transition in fractal dimension of melt ponds affects the shape of the sea ice albedo curve.

**3:30PM H51.00004 A Novel Method to Unravelling Energy Pathways in the Ocean**, HUSSEIN ALUIE, University of Rochester — Large-scale currents and eddies pervade the ocean and play a prime role in the general circulation and climate. The coupling between scales ranging from  $10^4$  km down to  $10^1$  mm presents a major difficulty in understanding, modeling, and predicting oceanic circulation and mixing, where the energy budget is uncertain within a factor possibly as large as ten. Identifying the energy sources and sinks at various scales can reduce such uncertainty and yield insight into new parameterizations. To this end, we refine a novel coarse-graining framework, which accounts for the spherical geometry of the problem, to directly analyze the coupling between scales. We apply these tools to strongly eddying high-resolution simulations using LANL's Parallel Ocean Program (POP).

**4:06PM H51.00005 The impact of the diurnal insolation cycle on the tropical cyclone heat engine**, MORGAN E. O'NEILL, Department of Earth and Planetary Sciences, Weizmann Institute of Science, DIAMILET PEREZ-BETANCOURT, Program in Atmospheres, Oceans and Climate, Massachusetts Institute of Technology, ALLISON A. WING, Lamont-Doherty Earth Observatory, Columbia University — A hurricane, or tropical cyclone, is understood as a heat engine that moves heat from the warm sea surface to the cold tropopause. The efficiency of this engine depends in part on the strength and duration of solar heating. Over land, peak rainfall associated with individual thunderstorms occurs in the late afternoon. Over ocean, with its markedly higher surface heat capacity, deep convection responds more to radiational cooling than daytime surface heating. However, the role of daily varying solar forcing on the dynamics of tropical cyclones is poorly understood. Recently, Dunion et al. (2014) reported significant, repeating diurnal behavior propagating outward from tropical cyclone centers, using infrared imagery from nine years of North Atlantic tropical cyclones. We study the impact of the diurnal cycle on tropical cyclones using a high resolution 3D numerical model, the System for Atmospheric Modeling (Khairoutdinov and Randall 2003). Simulations are run with and without variable sunlight. We are able to reproduce the observational finding of Dunion et al. (2014), and further identify a diurnally-varying residual circulation in the tropical cyclone at midlevels. The impact of the diurnal cycle on the equilibrium dynamics of tropical cyclones is also discussed.

**4:18PM H51.00006 Towards a General Turbulence Model for Planetary Boundary Layers Based on Direct Statistical Simulation<sup>1</sup>**, BRAD MARSTON, BAYLOR FOX-KEMPER, JOE SKITKA, Brown University — Sub-grid turbulence models for planetary boundary layers are typically constructed additively, starting with local flow properties and including non-local (KPP) or higher order (Mellor-Yamada) parameters until a desired level of predictive capacity is achieved or a manageable threshold of complexity is surpassed. Such approaches are necessarily limited in general circumstances, like global circulation models, by their being optimized for particular flow phenomena. By using direct statistical simulation (DSS) that is based upon expansion in equal-time cumulants we offer the prospect of a turbulence model and an investigative tool that is equally applicable to all flow types and able to take advantage of the wealth of nonlocal information in any flow. We investigate the feasibility of a second-order closure (CE2) by performing simulations of the ocean boundary layer in a quasi-linear approximation for which CE2 is exact. As oceanographic examples, wind-driven Langmuir turbulence and thermal convection are studied by comparison of the statistics of quasi-linear and fully nonlinear simulations. We also characterize the computational advantages and physical uncertainties of CE2 defined on a reduced basis determined via proper orthogonal decomposition (POD) of the flow fields.

**4:30PM H51.00007 Non-equilibrium Statistical Mechanics and the Sea Ice Thickness Distribution<sup>1</sup>**, JOHN WETTLAUER, SRIKANTH TOPPALADODDI, Yale University — We use concepts from non-equilibrium statistical physics to transform the original evolution equation for the sea ice thickness distribution  $g(h)$  due to Thorndike et al., (1975) into a Fokker-Planck like conservation law. The steady solution is  $g(h) = \mathcal{N}(q)h^q e^{-h/H}$ , where  $q$  and  $H$  are expressible in terms of moments over the transition probabilities between thickness categories. The solution exhibits the functional form used in observational fits and shows that for  $h \ll 1$ ,  $g(h)$  is controlled by both thermodynamics and mechanics, whereas for  $h \gg 1$  only mechanics controls  $g(h)$ . Finally, we derive the underlying Langevin equation governing the dynamics of the ice thickness  $h$ , from which we predict the observed  $g(h)$ . This allows us to demonstrate that the ice thickness field is ergodic. The genericity of our approach provides a framework for studying the geophysical scale structure of the ice pack using methods of broad relevance in statistical mechanics.

**4:42PM H51.00008 Large-eddy simulation of the transient and near-equilibrium behavior of precipitating shallow convection**, THIJS HEUS, Cleveland State University, AXEL SEIFERT, Deutscher Wetter Dienst, Offenbach, Germany, ROBERT PINCUS, University of Colorado, BJORN STEVENS, Max Planck Institute for Meteorology, Hamburg, Germany — Cloud-aerosol remain one of the largest uncertainties in climate modeling. Many of the postulated cloud-aerosol interactions involve precipitation to limit cloud size and life time, in particular for barely precipitating shallow cumulus clouds. If the precipitation exceeds a certain threshold, it will create feedback on the cloud field through cold pools and mesoscale organization. Such mesoscale responses have mostly been ignored so far in the discussion of aerosol indirect effects. We study the sensitivity of trade wind cumulus clouds to perturbations in cloud droplet number concentrations. Over time, the cloud system approaches a radiative-convective equilibrium state. The transient behavior and the properties of the near-equilibrium cloud field depend on the microphysical state and therefore on the cloud droplet number density. The primary response of the cloud field to changes in the cloud droplet number density is deepening of the cloud layer, and results in a shorter cloud life time. If the atmospheric time scales are long enough compared to the microphysical time scales, the cloud field may reach a near-equilibrium regime. In this regime, the decrease in cloud cover compensates much of the brightening of the clouds, and the overall effect on the albedo is small.

#### **4:54PM H51.00009 Statistical state dynamics of jet/wave coexistence in beta-plane turbulence**

, NAVID CONSTANTINOU, Scripps Inst. of Oceanography, Univ of California - San Diego, BRIAN FARRELL, Department of Earth and Planetary Sciences, Harvard University, PETROS IOANNOU, Physics Department, National and Kapodistrian University of Athens — Jets are commonly observed to coexist in the turbulence of planetary atmospheres with planetary scale waves and embedded vortices. These large-scale coherent structures arise and are maintained in the turbulence on time scales long compared to dissipation or advective time scales. The emergence, equilibration at finite amplitude, maintenance and stability of these structures pose fundamental theoretical problems. The emergence of jets and vortices from turbulence is not associated with an instability of the mean flow and their equilibration and stability at finite amplitude does not arise solely from the linear or nonlinear dynamics of these structures in isolation from the turbulence surrounding them. Rather the dynamics of these large-scale structures arises essentially from their cooperative interaction with the small-scale turbulence in which they are embedded. It follows that fundamental theoretical understanding of the dynamics of jets and vortices in turbulence requires adopting the perspective of the statistical state dynamics (SSD) of the entire turbulent state. In this work a theory for the jet/wave coexistence regime is developed using the SSD perspective.

#### **5:06PM H51.00010 A stochastic shallow cumulus ensemble model as a scale-aware parameterization of convective fluctuations<sup>1</sup>**

, MIRIANA SAKRADZIJIA, Max Planck Institute for Meteorology, AXEL SEIFERT, Deutscher Wetterdienst, THIJS HEUS, Cleveland State University, ANURAG DIPANKAR, Max Planck Institute for Meteorology — Numerical models are approaching the high-resolution limit where some aspects of deep convection and mesoscale convective systems can be explicitly modeled, while shallow cumuli are still a subgrid process that requires a parameterization. The classical assumption of a sufficiently large cloud sample within a model grid column breaks down in this regime, so it is crucial to develop scale-aware parameterizations. Therefore, we propose an approach to represent the variability of subgrid shallow cumuli about the ensemble average convective response. The shallow clouds are studied using Large Eddy Simulation (LES), where the original cloud field modeled on the grid of 25 m resolution is coarse-grained to mimic resolutions from 1 to 50 km. A canonical statistical ensemble is developed based on theoretical and LES findings and fluctuations of shallow convection are modeled by random subsampling of microstates from the convective ensemble distribution. The resulting distribution of subgrid convective states is scale-aware, and it represents stochastic fluctuations that increase with grid resolution and become substantial on the kilometre-scale grids. We find that the local cloud memory plays an important role in defining the convective ensemble statistics in a steady cumulus regime.

### **Session H52 DAMOP: Optomechanics and Hybrid Systems II: Metrology and Other Topics**

Hilton Baltimore Holiday Ballroom 3 - Mukund Vengalatorre, Cornell University

#### **2:30PM H52.00001 Hybrid atom-membrane optomechanics**

, PHILIPP TREUTLEIN, University of Basel, Department of Physics — We have realized a hybrid mechanical system in which ultracold atoms and a micromechanical membrane are coupled by radiation pressure forces. The atoms are trapped in an optical lattice, formed by retro-reflection of a laser beam from an optical cavity that contains the membrane as mechanical element. When we laser cool the atoms, we observe that the membrane is sympathetically cooled from ambient to millikelvin temperatures through its interaction with the atoms. Sympathetic cooling with ultracold atoms or ions has previously been used to cool other microscopic systems such as atoms of a different species or molecular ions up to the size of proteins. Here we use it to efficiently cool the fundamental vibrational mode of a macroscopic solid-state system, whose mass exceeds that of the atomic ensemble by ten orders of magnitude. Our hybrid system operates in a regime of large atom-membrane cooperativity. With technical improvements such as cryogenic pre-cooling of the membrane, it enables ground-state cooling and quantum control of mechanical oscillators in a regime where purely optomechanical techniques cannot reach the ground state. #### **3:06PM H52.00002 Detecting continuous gravitational waves with a jug of superfluid**

, SWATI SINGH, University of Arizona, LAURA DELORENZO, ADAM PEARLMAN, Caltech, IGOR PIKOVSKI, ITAMP, MILES BLENCOWE, Dartmouth College, KEITH SCHWAB, Caltech — We investigate the sensitivity to narrow band, continuous-wave strain fields of a kg-scale optomechanical system formed by the acoustic motion of superfluid helium-4 parametrically coupled to a super-conducting microwave cavity. This narrowband detection scheme is tunable through pressurization of the helium, thereby making both doppler tracking of astrophysical sources and tuning the detector on/off from the source possible. For reasonable experimental parameters, we find that gravitational metric strain fields from nearby pulsars could be detected with a few weeks of integration time.

#### **3:18PM H52.00003 Measurement and Applications of Radiation Pressure<sup>1</sup>**

, DAKANG MA, JOSEPH GARRETT, JOSEPH MURRAY, JEREMY MUNDAY, University of Maryland, College Park, MUNDAY LAB TEAM — Light reflected off a material or absorbed within it exerts radiation pressure through the transfer of momentum. Measuring and utilizing radiation pressure have aroused growing interest in a wide spectrum of research fields. Micromechanical transducers and oscillators are good candidates for measuring radiation pressure, but accompanying photothermal effects often obscure the measurement. In this work, we investigate the accurate measurement of the radiation force on microcantilevers in ambient conditions and ways to separate radiation pressure and photothermal effects. Further, we investigate an optically broadband switchable device based on polymer dispersed liquid crystal which has potential applications in solar sails and maneuvering spacecraft without moving parts.

#### **3:30PM H52.00004 Real-time Measurement of Mechanical Fluctuations in Carbon Nanotube Resonators**

, IOANNIS TSIOUTSIOS, ALEXANDROS TAVERNARAKIS, JOHANN OSMOND, ICFO, Institut de Cincies Fotniques, Mediterranean Technology Park, 08860 Castelldefels, Barcelona, Spain, PIERRE VERLOT<sup>1</sup>, Universit Claude Bernard Lyon 1, UCBL, Domaine Scientifique de La Doua, 69622 Villeurbanne, France, ADRIAN BACHTOLD, ICFO, Institut de Cincies Fotniques, Mediterranean Technology Park, 08860 Castelldefels, Barcelona, Spain — Carbon nanotube resonators have been recently shown to hold an exceptional sensing potential, relying on their extremely low mass. As a consequence, they are also expected to transduce the fundamental thermal force into very large motion fluctuations. Recently, an increasing number of theoretical proposals have suggested that this property may strongly affect the vibrational behaviour of carbon nanotube resonators, which has so far remained unobserved. Here we report the first, real-time detection of the thermally-induced vibrations in carbon nanotube resonators with masses in the 10 *ag* range. We show that coupling singly-clamped carbon nanotubes to a focused electron beam enables the full access to their mechanical trajectories. Our detailed analysis demonstrates that our devices behave as linear harmonic oscillators undergoing thermally-driven Brownian motion. Our result establishes the viability of carbon nanotube resonator technology at room temperature and paves the way towards the observing novel thermodynamics regimes in nanomechanics.

<sup>1</sup>ICFO, Institut de Cincies Fotniques, Mediterranean Technology Park, 08860 Castelldefels, Barcelona, Spain

**3:42PM H52.00005 Testing quantum mechanics and quantum gravity with cavity optomechanics**, DAVID VITALI, Physics Division, School of Science and Technology, University of Camerino — Cavity optomechanical setups represents a promising platform for testing quantum mechanics and its validity at a macroscopic scale. Here we present two different examples. We first show the result of an experiment which, by a high sensitive measurement of the free evolution of the nanomechanical resonator probed by an optical field, has improved by many orders of magnitude the bounds on commutator deformation parameters which characterize a wide class of approaches to quantum gravity. In the second case we propose an experiment able to discriminate unambiguously collapse models, postulating the existence of intrinsic noise which modifies quantum mechanics and is responsible for the emergence of macroscopic classicality, from standard environmental sources of decoherence. In particular, we show that the stationary state of a trapped nanosphere is particularly sensitive, under specific experimental conditions, to the interplay between the cavity size, the trapping frequency and the momentum diffusion induced by the collapse models, allowing to detect them even in the presence of standard environmental noises.

**3:54PM H52.00006 Torque Magnetometry and Susceptometry using Split-Beam Optomechanical Nanocavities**, TAYYABA FIRDOUS, Department of Physics and National Institute for Nanotechnology, University of Alberta, Canada, NATHANAEL WU, MARCELO WU, Department of Physics and Astronomy and Institute for Quantum Science and Technology, University of Calgary, Canada, FATEMEH FANI SANI, JOSEPH LOSBY, Department of Physics and National Institute for Nanotechnology, University of Alberta, Canada, PAUL BARCLAY, Department of Physics and Astronomy and Institute for Quantum Science and Technology, University of Calgary, Canada, MARK FREEMAN, Department of Physics and National Institute for Nanotechnology, University of Alberta, Canada — A large number of sensitive magnetometry methods are limited to cryogenic operation. We present a highly sensitive torque magnetometer using a photonic crystal optomechanical split-beam nanocavity operating in air at room temperature. The chip-based magnetometer is proficient for probing both the net magnetization and AC susceptibility of individual magnetic microstructures. This is demonstrated through the observation of nanoscale Barkhausen transitions in the magnetic hysteresis of a permalloy thin-film element. Control of the vector direction of the radio frequency drive allows detection of accompanying AC susceptibility terms.

**4:06PM H52.00007 Appearance and disappearance of motional sideband asymmetry in measurement-based control of a mechanical oscillator**, VIVISHEK SUDHIR, DALZIEL WILSON, RYAN SCHILLING, HENDRIK SCHUETZ, Ecole Polytechnique Federale de Lausanne, ANDREAS NUNNENKAMP, University of Cambridge, TOBIAS KIPPENBERG, Ecole Polytechnique Federale de Lausanne — Measurement-based feedback provides an avenue to study the delicate interplay between the quantum correlations established during the process of measurement, and their progressive obfuscation when exposed to uncorrelated noise in the form of fundamental quantum fluctuations in the feedback path. Here we demonstrate this tradeoff using a feedback strategy whose objective is to cool a nano-mechanical oscillator close to its ground state. The correlations established due to the measurement are revealed in the appearance of motional sideband asymmetry. The latter, faithfully measured using an optical heterodyne interferometer with an imprecision  $\sim 17$  dB below that at the standard quantum limit, increases to 6% as the oscillator is feedback cooled to an occupation of 15 phonons. Further increase in the gain of the feedback loop leads to a decrease in the asymmetry. This is due to the addition of unavoidable quantum fluctuations in a feedback amplifier – photon shot-noise amplified by a homodyne detector in our case.

**4:18PM H52.00008 Enhanced nonlinear interactions in quantum optomechanics via mechanical amplification**, NICOLAS DIDIER, Quantic team, INRIA Paris, MARC-ANTOINE LEMONDE, Atominstut, Vienna University of Technology, AASHISH A. CLERK, Department of Physics, McGill University — A key challenge limiting truly quantum behaviour in optomechanical systems is the typically small value of the optomechanical coupling at the single-photon, single-phonon level. We present an approach for exponentially enhancing the single-photon coupling strength in an optomechanical system using only additional linear resources. It allows one to reach the quantum nonlinear regime of optomechanics, where nonlinear effects are observed at the single photon level, even if the bare coupling strength is much smaller than the mechanical frequency and cavity damping rate. Our method is based on using a large amplitude, strongly detuned mechanical parametric drive to amplify mechanical zero-point fluctuations and hence enhance the radiation pressure interaction. It has the further benefit of allowing time-dependent control, enabling pulsed schemes. For a two-cavity optomechanical setup, we show that our scheme generates photon blockade for experimentally accessible parameters, and even makes the production of photonic states with negative Wigner functions possible. We discuss how our method is an example of a more general strategy for enhancing boson-mediated two-particle interactions and nonlinearities. Preprint: arXiv:1509.09238.

**4:30PM H52.00009 Quantum squeezing of a mechanical resonator**, CHAN U LEI, AARON WEINSTEIN, California Institute of Technology, JUNHO SUH, Korea Research Institute of Standards and Science, EMMA WOLLMAN, KEITH SCHWAB, California Institute of Technology — Generating nonclassical states of a macroscopic object has been a subject of considerable interest. It offers a route toward fundamental test of quantum mechanics in an unexplored regime. However, a macroscopic quantum state is very susceptible to decoherence due to the environment. One way to generate robust quantum states is quantum reservoir engineering. In this work, we utilize the reservoir engineering scheme developed by Kronwald et al. [1] to generate a steady quantum squeezed state of a micron-scale mechanical oscillator in an electromechanical system. Together with the backaction evading measurement technique [2], we demonstrate a quantum nondemolition measurement of the mechanical quadratures to characterize the quantum squeezed state. By measuring the quadrature variances of the mechanical motion, more than 3dB squeezing below the zero-point level has been achieved. [1] A. Kronwald, F. Marquardt, and A. A. Clerk, Phys. Rev. A 88, 063833 (2013). [2] J. Suh, A. J. Weinstein, C. U. Lei, E. E. Wollman, S. K. Steinke, P. Meystre, A. A. Clerk, and K. C. Schwab, Science 344, 1262 (2014).

**4:42PM H52.00010 Quantum nondemolition measurement of a nonclassical state of a massive object**, FLORENT LECOCQ, JEREMY CLARK, RAYMOND SIMMONDS, JOSE AUMENTADO, JOHN TEUFEL, NIST - Boulder — By coupling a macroscopic mechanical oscillator to two microwave cavities, we simultaneously prepare and monitor a nonclassical steady state of mechanical motion [1]. In each cavity, correlated radiation pressure forces induced by two coherent drives engineer the coupling between the quadratures of light and motion. We first demonstrate the ability to perform a continuous quantum nondemolition measurement of a single mechanical quadrature at a rate that exceeds the mechanical decoherence rate, while avoiding measurement backaction by more than 13dB. Second, we apply this measurement technique to independently verify the preparation of a squeezed state in the mechanical oscillator, resolving quadrature fluctuations 20% below the quantum noise. [1] F.Lecocq, et al, ArXiv 1509.01629 (2015)

**4:54PM H52.00011 Observation of Nonclassical Radiation Pressure Forces on a Mechanical Oscillator<sup>1</sup>**, JEREMY CLARK, FLORENT LECOCQ, RAYMOND SIMMONDS, JOSE AUMENTADO, JOHN TEUFEL, NIST Boulder — Squeezed states of light are known to be useful for enhancing mechanical displacement sensing since they can be tailored to reduce the “photon counting noise” that limits the measurement’s noise floor. On the other hand, recent experiments in cavity optomechanics have reached measurement regimes where an interrogating light field exerts radiation pressure noise on a mechanical oscillator. One outstanding challenge has been to explore the intersection between such experiments. I will present data obtained using a superconducting cavity optomechanical system wherein a mechanical oscillator is driven by nonclassical radiation pressure imparted by squeezed microwave fields.

**5:06PM H52.00012 Complex squeezing for force measurement beyond the standard quantum limit**, SYDNEY SCHREPLER, University of California, Berkeley, LUKAS BUCHMANN, Aarhus Universitet, JONATHAN KOHLER, University of California, Berkeley, NICOLAS SPETHMANN, University of California, Berkeley, Technische Universitt Kaiserslautern, DAN STAMPER-KURN, University of California, Berkeley, Lawrence Berkeley National Laboratory — Squeezed quantum states are popular theoretical and experimental means of overcoming precision limits set by quantum mechanics. We identify "complex squeezing" as time delayed correlations that can in general not be measured using homodyne or heterodyne detection schemes, but nonetheless arise naturally in measurement devices such as optomechanical systems. In this case, the dispersive coupling between a mechanical element and an electromagnetic resonator causes real ponderomotive squeezing at frequencies away from mechanical resonance, but that squeezing becomes complex closer to resonance, where the system can be operated more sensitively for force detection. We describe a measurement protocol sensitive to complex squeezing and show how it can lead to enhanced sensitivity of force measurements using optomechanical oscillators.

**5:18PM H52.00013 Frequency stabilization of single layer graphene oscillators through optical injection locking**, SAMER HOURI<sup>1</sup>, SANTIAGO CARTAMIL BUENO, Delft University of Technology, WARNER VENSTRA<sup>2</sup>, Quantified Air — Single layer graphene (SLG) drum resonators offer exciting prospects as experimental testbeds for nonlinear dynamics. Recently, photo-thermal induced feedback effects leading to self-oscillations in graphene have been demonstrated [1]. In this paper we examine the phase jitter of self-oscillating SLG, and the means to improve the frequency stability through optical injection locking. The resonator consists of an SLG on top of a 10 micron diameter circular cavity with a cavity depth of 750 nm. By shining a 10 mW He-Ne laser the drum enters a regime of photo-thermally induced self-oscillation. The oscillating SLG suffers from a significant phase noise that can be directly observed in the time domain as random walk of the oscillation period. By applying a lock tone to the oscillator through the application of a modulated blue laser (405 nm), the SLG motion is then phase locked to the applied tone with more than an order of magnitude improvement in its coherence time. The injection locking is also studied as a function of lock signal detuning and power. [1] Barton, Robert A., et al. "Photothermal self-oscillation and laser cooling of graphene optomechanical systems." *Nano letters* 12.9 (2012): 4681-4686.

**2:30PM H53.00001 Pushing the lipid envelope: using bio-inspired nanocomposites to understand and exploit lipid membrane limitations**, GABRIEL MONTANO, Los Alamos National Laboratory — Lipids serve as the organizing matrix material for biological membranes, the site of interaction of cells with the external environment. . As such, lipids play a critical role in structure/function relationships of an extraordinary number of critical biological processes. In this talk, we will look at bio-inspired membrane assemblies to better understand the roles of lipids in biological systems as well as attempt to generate materials that can mimic and potentially advance upon biological membrane processes. First, we will investigate the response of lipids to adverse conditions. In particular, I will present data that demonstrates the response of lipids to harsh conditions and how such responses can be exploited to generate nanocomposite rearrangements. I will also show the effect of adding the endotoxin lipopolysaccharide (LPS) to lipid bilayer assemblies and describe implications on our understanding of LPS organization in biological systems as well as describe induced lipid modifications that can be exploited to organize membrane composites with precise, two-dimensional geometric control. Lastly, I will describe the use of amphiphilic block copolymers to create membrane nanocomposites capable of mimicking biological systems. In particular, I will describe the use of our polymer-based membranes in creating artificial photosynthetic assemblies that rival biological systems in function in a more flexible, dynamic matrix.

**3:06PM H53.00002 Expanding the versatility of silicon carbide thin films and nanowires<sup>1</sup>**, LUNET LUNA, Univ of California - Berkeley — Silicon carbide (SiC) based electronics and sensors hold promise for pushing past the limits of current technology to achieve small, durable devices that can function in high-temperature, high-voltage, corrosive, and biological environments. SiC is an ideal material for such conditions due to its high mechanical strength, excellent chemical stability, and its biocompatibility. Consequently, SiC thin films and nanowires have attracted interest in applications such as micro- and nano-electromechanical systems, biological sensors, field emission cathodes, and energy storage devices. However to fully realize SiC in such technologies, the reliability of metal contacts to SiC at high temperatures must be improved and the nanowire growth mechanism must be understood to enable strict control of nanowire crystal structure and orientation. Here, we present a novel metallization scheme, utilizing solid-state graphitization of SiC, to improve the long-term reliability of Pt/Ti contacts to polycrystalline n-type SiC films at high temperature. The metallization scheme includes an alumina protection layer and exhibits low, stable contact resistivity even after long-term (500 hr) testing in air at 450 °C. We also report the crystal structure and growth mechanism of Ni-assisted silicon carbide nanowires using single-source precursor, methyltrichlorosilane. The effects of growth parameters, such as substrate and temperature, on the structure and morphology of the resulting nanowires will also be presented. Overall, this study provides new insights towards the realization of novel SiC technologies, enabled by advanced electron microscopy techniques located in the user facilities at the Molecular Foundry in Berkeley, California.

**3:42PM H53.00003 Graphene Oxide/ Ruthenium Oxide Composites for Supercapacitors Electrodes<sup>1</sup>**, FATIMA AMIR, Winthrop University — Supercapacitors are electrical energy storage devices with high power density, high rate capability, low maintenance cost, and long life cycle. They complement or replace batteries in harvesting applications when high power delivery is needed. An important improvement in performance of supercapacitors has been achieved through recent advances in the development of new nanostructured materials. Here we will discuss the fabrication of graphene oxide/ ruthenium oxide supercapacitors electrodes including electrophoretic deposition. The morphology and structure of the fabricated electrodes were investigated and will be discussed. The electrochemical properties were determined using cyclic voltammetry and galvanostatic charge/discharge techniques and the experiments that demonstrate the excellent capacitive properties of the obtained supercapacitors will also be discussed. The fabrication and characterization of the samples were performed at the Center of Functional Nanomaterials at Brookhaven National Lab. The developed approaches in our study represent an exciting direction for designing the next generation of energy storage devices.

**4:18PM H53.00004 Pushing the limits of nanolithography outside the box<sup>1</sup>**, LEONIDAS OCOLA, Argonne Natl Lab — The Center for Nanoscale Materials (CNM) at Argonne National Laboratory was constructed in 2006, and opened its doors to serve the user community in 2007 with the objective to provide research opportunities in Nanoscience for the scientific community worldwide. Currently, the CNM hosts over 400 user proposals a year. There are six research groups at the CNM that do work in nanophotonics, electronic and magnetic materials and devices, nanobio interfaces, nanofabrication and devices, x-ray nanoscale microscopy and theory and modeling. At the CNM Nanofabrication and Devices Group we have been able to push the limits of electron beam lithography to make plasmonic nanostructures obtain sharp corners with less than 6 nm radius of curvature and expand the use of ion beams to 3D large area nanofabrication in microfluidics by novel design methodologies, among other accomplishments. None of these accomplishments are possible without detailed understanding of the physics and chemistry mechanisms involved during fabrication. During my talk I will discuss a few clear cases where lithography and fabrication are used in ways not commonly found in current nanofabrication facilities and what make our facility unique.

**4:54PM H53.00005 The USER: Utilizing Scientific Environments for Research<sup>1</sup>**, LAKEISHA WALKER, Oak Ridge National Lab — A lot of hard work goes into submitting a proposal for access to equipment in our nation's top science research facilities. It seems the biggest focus for a facility USER should be on the acceptance of the proposal, however, the job of a facility USER actually begins after the acceptance letter arrives. In order to make the most of the awarded experiment time and cultivate collaborations for the future, facility USERS need to look beyond the proposal. From experiment scheduling to arrival to data analysis the entire USER experience is valuable and worth doing well. This presentation will discuss best practices for facility USERS and highlight successful USER collaborations at ORNL's High Flux Isotope Reactor.

<sup>1</sup>Funded by the Office of Basic Energy Sciences, U.S. DOE. ORNL is managed by UT-Battelle, LLC for US DOE.

**2:30PM H54.00001 Dual Electrospray Pyrolysis for Mixed Metal Oxide (and Carbon) Composite Nanoparticle Synthesis with Applications in Energy Storage**, JUSTIN TANG, WEN LIU, HAILIANG WANG, ALESSANDRO GOMEZ, Yale University — We present a novel approach to synthesizing mixed metal oxide nanoparticles with a continuous, scalable aerosol flow process using the electrospray. The electrospray is a liquid atomization technique that generates a monodisperse population of highly charged liquid droplets over a broad size range (nanometric to tens of microns). Each liquid droplet serves as a micro-reactor, containing a payload of suitable precursors (such as metal nitrides), allowing for precise control over particle composition and size. By using two electrosprays of opposite polarities, the two highly charged droplets plumes are electrostatically mixed to produce a charge-neutral aerosol. Electrostatically driven droplet-droplet collisions can also be used to control morphology to some degree. This aerosol is passed through a tubular furnace via carrier gas, pyrolyzing the precursors to synthesize nanomaterials. We apply this approach to manganese oxide, cobalt oxide, and carbon composite nanoparticles for use in energy storage applications.

**2:42PM H54.00002 The Basic Understanding of Lithium Superoxide in Li-O<sub>2</sub> Battery<sup>1</sup>**, KAH CHUN LAU, Argonne National Lab, DENG YUN ZHAI, Graduate School at Shenzhen, Tsinghua University, China, HSIEN-HAU WANG, XIANGYI LUO, JIANGUO WEN, DEAN MILLER, PAUL REDFERN, JUN LU, LARRY CURTISS, KHALIL AMINE, Argonne National Lab — The electrochemical and chemical processes that involved in Li-O<sub>2</sub> battery are complex, and depend heavily on electrode materials, electrolytes, interfaces, and cell operating conditions. In non-aqueous Li-O<sub>2</sub> battery, the main discharge products are commonly known to be lithium peroxide (Li<sub>2</sub>O<sub>2</sub>), and possibly some other parasitic components (i.e. Li<sub>2</sub>CO<sub>3</sub>, LiOH, Li<sub>2</sub>O). However, the superoxide intermediates and lithium superoxide (O<sub>2</sub><sup>-</sup>, LiO<sub>2</sub>) which are commonly known to be metastable can also be found as reported [1, 2]. Relative to these compounds (i.e. Li<sub>2</sub>CO<sub>3</sub>, Li<sub>2</sub>O, LiOH, Li<sub>2</sub>O<sub>2</sub>) in discharge products, little is known about LiO<sub>2</sub>. To have a basic understanding of lithium superoxide, both theoretical studies and experimental characterizations are important. In this presentation, the recent developments, studies and findings of this exotic species will be discussed. References: 1. D. Zhai<sup>+</sup>, K.C. Lau<sup>+</sup>, H. Wang, J. Wen, D. Miller, J. **2:54PM H54.00003 3D strain engineered self-rolled thin-film architecture for high-energy density lithium-ion batteries**, GRIFFIN GODBEY, CHEN GONG, CYNTHIA YU, CLAYTON BLYTHE, MARINA LEITE, Depart. of Materials Science and Eng. & Institute for Research in Electronics and Applied Physics, Univ. of Maryland, College Park, MD — Recently, multiple 3D geometries have been implemented into energy storage devices (e.g. nanowire anodes and arrays of interdigitated rods) in order to better accommodate the large volume expansion experienced by the anode during lithiation and to increase the structure energy density. However, most approached structures are difficult to scale up. Here we show how self-rolled thin-films can maintain a high energy density and can potentially accommodate the volume expansion suffered by the anode. The self-rolled tubes are fabricated by physical deposition of the active layers, creating a stress gradient between thin-film stack due to differences in coefficient of thermal expansion. Upon a sacrificial layer removal, the thin-film rolls to relieve this built-in stress. We predict the final dimension of self-rolled battery tubes using known elastic properties of materials commonly used as the active layers of the device. We will discuss an appropriate figure-of-merit that defines how the winding process can ultimately affect the volumetric capacity of 3D self-rolled batteries.

**3:06PM H54.00004 Electrochemical properties of Li<sub>2</sub>FeSiO<sub>4</sub>/C nanocomposites prepared by sol-gel and hydrothermal methods**, AJAY KUMAR, Wayne State University, O.D. JAYAKUMAR, Bhabha atomic research centre, VAMAN M. NAIK, University of Michigan Dearborn, GHOLAM A. NAZRI, RATNA NAIK, Wayne State University — Li<sub>2</sub>FeSiO<sub>4</sub> is considered as potential cathode material for next generation lithium ion batteries because of its high specific theoretical capacity, low cost, and safety. However, it suffers from poor electronic conductivity and slow lithium ion diffusion in the solid phase. To address these issues, we have studied mesoporous Li<sub>2</sub>FeSiO<sub>4</sub>/C composites synthesized by sol-gel (SG) and hydrothermal (HT) methods using tri-block copolymer (P123) as carbon source and structure directing agent. The structure and morphology of the composites were characterized by XRD, SEM and TEM and the surface area and pore size distribution were measured by using N<sub>2</sub> adsorption/desorption. Galvanostatic cycling, electrochemical impedance spectroscopy, and cyclic voltammetry were used to evaluate the electrochemical performance of the Li<sub>2</sub>FeSiO<sub>4</sub>/C composites. The Li<sub>2</sub>FeSiO<sub>4</sub>/C (HT) composites show a superior electrochemical performance compared to Li<sub>2</sub>FeSiO<sub>4</sub>/C (SG). At C/30 rate, the discharge capacity of Li<sub>2</sub>FeSiO<sub>4</sub>/C (HT) reached ~276 mAh/g in the 1.5-4.6 V window and shows better rate capability and stability at high rates. We attribute the improved electrochemical performance of Li<sub>2</sub>FeSiO<sub>4</sub>/C (HT) to its large surface area and reduced particle size. The details of the study will be presented.

**3:18PM H54.00005 Transmission Electron Microscopy and First Principle Studies Investigating Intercalation Phenomenon Of Vanadium Pentoxide( $V_2O_5$ ) nanowire cathode<sup>1</sup>**, ARIJITA MUKHERJEE, UIC, HASTI ASAYESH ARDAKANI, MTU, TANGHONG YI, CHEON JUNG KIM, UIC, JUSTIN ANDREWS, SARBAJIT BANERJEE, Texas AM, JORDI CABANA, REZA S YASSAR, ROBERT F KLIIE, UIC, JCESR COLLABORATION — Vanadium Pentoxide( $V_2O_5$ ) is an attractive intercalation compound due to its characteristic layered structure from weak vanadium-oxygen bonding which enables the intercalation of ions between the layers. Here, we will discuss an in-situ transmission electron microscopy and electron energy-loss spectroscopy approach investigating lithiation of orthorhombic  $\alpha$ - $V_2O_5$  nanowires where the center of the nanowire undergoes a transformation to  $\gamma$ - $Li_2V_2O_5$  phase. Since  $V_2O_5$  has also been predicted as a potential cathode host for magnesium ion intercalation, we also investigate Mg intercalation in  $\alpha$ - $V_2O_5$  nanowire and determine if our reaction pathway leads to the formation of  $\varepsilon$ - $Mg_{0.5}V_2O_5$  phase, as predicted by density functional theory calculations. In-situ Li and Mg intercalation experiments into the new tunnel structured  $\zeta$ - $V_2O_5$  nanowires will also be presented and the resulting phases will be compared with theoretical predictions.

**3:30PM H54.00006 Dry Pressed Holey Graphene Composites for Li-air Battery Cathodes<sup>1</sup>**, STEVEN LACEY, University of Maryland, College Park, YI LIN, National Institute of Aerospace, LIANGBING HU, University of Maryland, College Park — Graphene is considered an “omnipotent” material due to its unique structural characteristics and chemical properties. By heating graphene powder in an open-ended tube furnace, a novel compressible carbon material, holey graphene (hG), can be created with controlled porosity and be further decorated with nanosized catalysts to increase electrocatalytic activity. All hG-based materials were characterized using various microscopic and spectroscopic techniques to obtain morphological, topographical, and chemical information as well as to identify any disordered/crystalline phases. In this work, an additive-free dry press method was employed to press the hG composite materials into high mass loading mixed, sandwich, and double-decker Li-air cathode architectures using a hydraulic press. The sandwich and double-decker (i.e. Big Mac) cathode architectures are the first of its kind and can be discharged for more than 200 hours at a current density of 0.2 mA/cm<sup>2</sup>. The scalable, binderless, and solventless dry press method and unique Li-air cathode architectures presented here greatly advance electrode fabrication possibilities and could promote future energy storage advancements.

**3:42PM H54.00007 Importance of liquid fragility for energy applications of ionic liquids<sup>1</sup>**, PIT SIPPEL, PETER LUNKENHEIMER, STEPHAN KROHNS, ERIK THOMS, ALOIS LOIDL, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany — Ionic liquids (ILs) are salts that are liquid at ambient temperatures. The strong electrostatic forces between their molecular ions result, e.g., in low volatility and high stability for many members of this huge material class [1]. For this reason they bear a high potential for new advancements in applications, e.g., as electrolytes in energy-storage devices such as supercapacitors or batteries, where the ionic conductivity is an essential figure of merit.

Most ILs show dynamic properties typical for glassy matter, which dominate many of their physical properties. An important method to study these dynamical glass-properties is dielectric spectroscopy that can access relaxation times of dynamic processes and the conductivity in a broad frequency and temperature range. In the present contribution, we present results on a large variety of ionic liquids showing that the conductivity of ILs depends in a systematic way not only on their glass temperature but also on the so-called fragility, characterizing the non-canonical super-Arrhenius temperature dependence of their ionic mobility [2].

**3:54PM H54.00008 A joint *first principles* and ATR-IR study of the vibrational properties of interfacial water at semiconductor-water solid-liquid interfaces**, LEI YANG, STEFANIE TECKLENBURG, FANG NIU, ANDREAS ERBE, STEFAN WIPPERMANN, Max-Planck-Institut für Eisenforschung, FRANCOIS GYGI, University of California, Davis, GIULIA GALLI, University of Chicago — Despite the importance of understanding the structural and bonding properties of solid-liquid interfaces for a wide range of (photo-)electrochemical applications, there are presently no experimental techniques available to directly probe the microscopic structure of solid-liquid interfaces. We carried out joint ATR-IR spectroscopy measurements and *ab initio* molecular dynamics simulations of the vibrational properties of interfaces between liquid water and prototypical semiconductor substrates. In particular, the Ge(100)/H<sub>2</sub>O interface is shown to feature a reversible bias potential dependent surface phase transition. Our study highlights the key role of coupled theory-experimental investigations on well controlled and characterized interfaces, in order to develop robust strategies to interpret experiments and validate theory. The authors wish to thank T. A. Pham for helpful discussions. G. G. and F. G. acknowledge DOE-BES Grant No. DE-SS0008939.

**4:06PM H54.00009 Effect of Metal Ion Intercalation on the Structure of MXenes and its Impact on the Dynamics of Water in MXenes**, NARESH OSTI, MICHEAL NAGUIB, Oak Ridge National Laboratory, Oak Ridge, TN, USA, ALIREZA ÖSTADHOSSEIN, ADRI VAN DUIN, The Pennsylvania State University, PA, USA, YURY GOGOTSI, Drexel University PA, USA, DAVID WESOLOWSKI, EUGENE MAMONTOV, Oak Ridge National Laboratory, Oak Ridge, TN, USA — MXenes are two-dimensional materials of sheet-like morphology invented as an alternative to graphene with a potential for energy applications. Because of the heterogeneous bonding between different species and the presence of surface functionalities, MXenes can be intercalated with different chemical species including metal ions and water. The presence of water in MXenes even at ambient conditions impacts their properties relevant to technical applications. Therefore, it is important to understand how intercalants change the structure of MXene and the behavior of water in these materials. Here, using different scattering techniques (x-ray and neutron), we found that intercalation of MXenes with potassium ion increases the c- lattice parameter, yielding a more homogeneous structure with higher water uptake compared to pristine MXenes. In the latter, inhomogeneous structure was observed, with most water residing between the MXenes stacks rather than in between the layers. We found a two orders of magnitude reduction in the diffusion coefficient of water resulting from potassium intercalation, which is in good agreement with the values predicted from ReaxFF simulation. Consequences of improved homogeneity on the water dynamics following metal ion intercalation will be discussed..

**4:18PM H54.00010 Low Temperature Synthesis of Cubic-phase Fast-ionic Conducting Bismuth-doped Garnet Solid State Electrolytes.**, DEREK K. SCHWANZ, ERNESTO MARINERO, School of Materials Engineering, Purdue University — We report on the synthesis of cubic-phase fast ionic conducting garnet solid state electrolytes based on LiLaZrO (LLZO) at unprecedented low synthesis temperatures. Ionic conductivities around  $1.2 \times 10^{-4}$  S/cm are readily achieved. Bismuth aliovalent substitution into LLZO utilizing the Pechini processing method is successfully employed to synthesize LiLaZrBiO compounds. Cubic phase LiLaZrBiO powders are generated in the temperature range 650C to 900C in air. In contrast, in the absence of Bi and under identical synthesis conditions, the cubic phase of LiLaZrO is not formed below 750C and a transformation to the poor ionically conducting tetragonal phase is observed at 800C for the undoped compound. The critical role of Bi in lowering the formation temperature of the garnet cubic phase and the improvements in ionic conductivity are elucidated in this work through microstructural and electrochemical studies.

**4:30PM H54.00011 Electrophoretic deposition of RuO<sub>2</sub>/HRGO composites for flexible supercapacitor electrodes** , FATIMA AMIR, Winthrop University, VIET PHAM, Brookhaven National Laboratory, DAKODA MULLINAX, Winthrop University, JAMES DICKERSON, Brookhaven National Laboratory — Flexible energy storage devices are essential for the development of wearable electronics, such as bendable displays and wearable multi-media systems. A subset of these energy storage devices, flexible supercapacitors have received increased attention because of their long cycle life, low cost, and easy fabrication. Herein, we report an easy and low cost method to fabricate bendable ruthenium oxide (RuO<sub>2</sub>)/holey reduced graphene oxide (HRGO) electrodes using electrophoretic deposition. Analysis of the surface morphology using scanning electron microscopy (SEM) shows a highly nanoporous structure with pores ranging from 2 to 3 nm. The obtained RuO<sub>2</sub>/HRGO supercapacitor exhibited excellent electrochemical capacitive performance in a PVA-H<sub>2</sub>SO<sub>4</sub> gel electrolyte, with a specific capacitance of 418.5F/g. Additionally, a high rate performance with capacitance retention of 85% was observed when the current was increased by a factor of 20 from 1.0 to 20.0 A/g. The supercapacitor exhibited an exceptional cycling stability of 88.5% after 10,000 cycles, indicating excellent long term electrochemical stability.

**4:42PM H54.00012 Li<sup>+</sup> ion diffusion in nanoscale alumina coatings** , MICHELLE JOHANNES, NOAM BERNSTEIN, Naval Research Lab — Nanoscale coatings of alumina are used to stabilize surfaces for a variety of technologies. Diffusion of ions through these coatings is of primary importance: in some cases, diffusion is unwanted (e.g. corrosion) and in others (e.g. electrode materials), it is necessary. In this work DFT and AIMD calculations are used to investigate Li<sup>+</sup> ion diffusion through a nano-layer of alumina, examining the phase (alpha, gamma, and amorphous), ion concentration, and electron count dependence. We look at the role of the surface itself in promoting diffusion. One of our main findings is that as the number of ions or charge increases, the diffusivity rises. We show how our data can explain electrochemical data from coated LiCoO<sub>2</sub> cathodes and may point toward better and more efficient coatings for stabilizing electrodes.

**4:54PM H54.00013 Finding out the optimal boron concentration in BC<sub>x</sub> sheets for high capacity anode material in Li-ion batteries** , DEYA DAS, RAHUL HARDIKAR, Indian Institute of Science, SANG SOO HAN, KWANG RYEOL LEE, Korea Institute of Science and Technology, ABHISHEK KUMAR SINGH, Indian Institute of Science — Boron doped graphene shows better adsorption of Li compared to pristine graphene and has been investigated as a potential anode material for Li-ion batteries. Using first principles density functional theory calculations, we investigate the effect of increasing boron concentration on the gravimetric capacity of mono-layered boron doped graphene sheets, BC<sub>x</sub> (x = 7, 5, 3, 2 and 1). Li storage capacity increases with the increase in boron concentration giving highest capacity for monolayer BC<sub>2</sub> (~ 1400 mAh/g), and is about 1.6 times higher than previously reported capacity of BC<sub>3</sub>. This is due to the more number of available empty states above the Fermi level in BC<sub>2</sub> compared to other sheets. Moreover, owing to a very low Li diffusion barrier, the Li kinetics in BC<sub>2</sub> is also found to be better among all the layered boron doped carbon sheets. Further enhancement of B concentration, as in BC, leads to strong binding of Li, thereby hindering the delithiation processes. Hence, BC<sub>2</sub> with optimal concentration of B among the BC<sub>x</sub> phases, emerges as a promising choice for anode material in rechargeable Li ion battery.

Session H55 DBIO: Theoretical Physics and Networks of Real Neurons Hilton Baltimore Holiday Ballroom 6 - William Bialek, Princeton University

**2:30PM H55.00001 Neural circuit mechanisms of short-term memory<sup>1</sup>** , MARK GOLDMAN, Center for Neuroscience, UC Davis — Memory over time scales of seconds to tens of seconds is thought to be maintained by neural activity that is triggered by a memorized stimulus and persists long after the stimulus is turned off. This presents a challenge to current models of memory-storing mechanisms, because the typical time scales associated with cellular and synaptic dynamics are two orders of magnitude smaller than this. While such long time scales can easily be achieved by bistable processes that toggle like a flip-flop between a baseline and elevated-activity state, many neuronal systems have been observed experimentally to be capable of maintaining a continuum of stable states. For example, in neural integrator networks involved in the accumulation of evidence for decision making and in motor control, individual neurons have been recorded whose activity reflects the mathematical integral of their inputs; in the absence of input, these neurons sustain activity at a level proportional to the running total of their inputs. This represents an analog form of memory whose dynamics can be conceptualized through an energy landscape with a continuum of lowest-energy states. Such continuous attractor landscapes are structurally non-robust, in seeming violation of the relative robustness of biological memory systems. In this talk, I will present and compare different biologically motivated circuit motifs for the accumulation and storage of signals in short-term memory. Challenges to generating robust memory maintenance will be highlighted and potential mechanisms for ameliorating the sensitivity of memory networks to perturbations will be discussed.

**3:06PM H55.00002 Dynamical criticality in the collective activity of a neural population** , THIERRY MORA, CNRS and Ecole normale supérieure, Paris — The past decade has seen a wealth of physiological data suggesting that neural networks may behave like critical branching processes. Concurrently, the collective activity of neurons has been studied using explicit mappings to classic statistical mechanics models such as disordered Ising models, allowing for the study of their thermodynamics, but these efforts have ignored the dynamical nature of neural activity. I will show how to reconcile these two approaches by learning effective statistical mechanics models of the full history of the collective activity of a neuron population directly from physiological data, treating time as an additional dimension. Applying this technique to multi-electrode recordings from retinal ganglion cells, and studying the thermodynamics of the inferred model, reveals a peak in specific heat reminiscent of a second-order phase transition.

**3:42PM H55.00003 Adaptation on multiple time scales** , ADIRENNE FAIRHALL, University of Washington — No abstract available.

**4:18PM H55.00004 A theory of neural dimensionality, dynamics, and measurement.** , SURYA GANGULI<sup>1</sup>, Stanford University — In many experiments, neuroscientists tightly control behavior, record many trials, and obtain trial-averaged firing rates from hundreds of neurons in circuits containing millions of behaviorally relevant neurons. Dimensionality reduction has often shown that such datasets are strikingly simple; they can be described using a much smaller number of dimensions than the number of recorded neurons, and the resulting projections onto these dimensions yield a remarkably insightful dynamical portrait of circuit computation. This ubiquitous simplicity raises several profound and timely conceptual questions. What is the origin of this simplicity and its implications for the complexity of brain dynamics? Would neuronal datasets become more complex if we recorded more neurons? How and when can we trust dynamical portraits obtained from only hundreds of neurons in circuits containing millions of neurons? We present a theory that answers these questions, and test it using neural data recorded from reaching monkeys. Overall, this theory yields a picture of the neural measurement process as a random projection of neural dynamics, conceptual insights into how we can reliably recover dynamical portraits in such under-sampled measurement regimes, and quantitative guidelines for the design of future experiments. Moreover, it reveals the existence of phase transition boundaries in our ability to successfully decode cognition and behavior as a function of the number of recorded neurons, the complexity of the task, and the smoothness of neural dynamics.

<sup>1</sup>membership pending

**4:54PM H55.00005 Understanding vision through the lens of prediction<sup>1</sup>** , STEPHANIE PALMER, Univ of Chicago — Prediction is necessary for long-term planning and decision-making, but prediction is also essential to the short-term calculations necessary to overcome the sensory and motor delays present in all neural systems. In order to interact appropriately with a changing environment, the brain must respond not only to the current state of sensory inputs but to rapid predictions of these inputs' future state. To test whether the visual system performs optimal predictive compression and computation, we compute the past and future stimulus information in populations of retinal ganglion cells, the output cells of the retina, in salamanders and rats. By controlling the motion statistics of the input stimulus presented to the retina, a moving bar with inertia making a random walk in space, we can derive the optimal tradeoff between compressing information about the past stimulus while retaining as much information as possible about the future stimulus. By changing parameters in the equation of motion for the bar, we can explore qualitatively different motion prediction problems. We show that retinal ganglion cells sit near this optimum for some motion types but not others, and compare these results between the two sampled species. Taking the next step towards exploring the predictive capacity of neural systems, we characterize the ensemble of spatiotemporal correlations present in the natural environment. To do so, we construct and analyze a database of natural motion videos. We have made high-speed, high-pixel-depth recordings of natural scenes and have preliminary data quantifying the space-time power spectra and the local motion content of these scenes.

Session K1 DCMP: Visualization of Vorticity in Quantum Fluids Ballroom I - Katepalli Sreenivasan, New York Univ

**8:00AM K1.00001 Three-dimensional nanoparticle dynamics in superfluid helium<sup>1</sup>**, DANIEL LATHROP, University of Maryland — Quantized vortices have been observed in superfluid <sup>4</sup>He and AMO trapped atom systems, and have been inferred in superfluid <sup>3</sup>He and neutron stars. The dynamics of quantum fluids is substantially controlled by the motion of quantized vortices, which are topological phase defects analogous to crystalline dislocations. Long-range quantum order underlies a number of related physical phenomena, including superfluidity, trapped-atom Bose-Einstein condensates, superconductivity, ferromagnetism, antiferromagnetism, lasers, and the Higgs mechanism. While superfluidity in <sup>4</sup>He is one of the first discovered of these, it is one of the least understood, given that the strongly interacting nature of helium makes theory difficult, and that development of local experimental probes is lagging. The advent of three-dimensional flow visualization of particles that trace quantized vortices provides new opportunities to investigate their creation and dynamics. We work to address the following questions using flow visualization in this system: What are field equations that express the coupling of the ordered and disordered parts of the flow? How does vortex reconnection lead to dissipation and breaking of time-reversal invariance? What are the similarities and differences between quantum and classical turbulence at small and large scales? How do quantized vortices form through the lambda transition?

<sup>1</sup>This work is supported by the National Science Foundation DMR CMP 1407472

**8:36AM K1.00002 Imaging of quantum vortices in superfluid helium droplets**, ANDREY VILESOV, University of Southern California — Helium nanodroplets are especially promising for exploring quantum hydrodynamics in self-contained, isolated superfluids. However, until very recently, the dynamic properties of individual droplets, such as vorticity, could not be assessed experimentally. Here we investigate the rotation of single superfluid 4-He droplets ranging from 200 to 2000 nm in diameter at T = 0.4 K via single-shot femtosecond X-ray coherent diffractive imaging. The droplets were produced by free jet expansion of liquid helium into vacuum. The angular velocities of the droplets were estimated from the centrifugal distortion and span a range from vanishing to those close to the disintegration limit. For visualization of vortices, Xe atoms were added to the droplets where they gather in cores forming nm-thin filaments. A newly developed phase retrieval technique enables the reconstruction of the instantaneous positions and shapes of the vortices from the diffraction images with about 20 nm resolution. The vorticity attainable in the nano-droplets was found to be about six orders of magnitude larger than achieved in previous experiments in the bulk. Stationary configurations of vortices are represented by triangular lattice in large (2 μm) droplets and symmetric arrangements of few vortices in smaller (200 nm) droplets. Evidence for non-stationary vortex dynamics comes from observation of asymmetric formations of vortices in some droplets. This collaborative work was performed at Linac Coherent Light Source, the free electron laser within SLAC National Accelerator Laboratory. The experiments and the full list of collaborators are reported in: L. F. Gomez et. al. Science, 345 (2014) 906.

**9:12AM K1.00003 Numerical simulation of quantum turbulence**, MAKOTO TSUBOTA, Osaka City University — Turbulence in quantum fluids has been studied for more than half century, and the recent developments of visualization experiments are so remarkable that they have made significant contributions for understanding the topics. Numerical simulation is also indispensable for this field. Two kinds of formulation are generally available. One is the vortex filament model useful for simulation of dynamics of quantized vortices in superfluid helium. The other is the Gross-Pitaevskii model that addresses the order parameters in Bose-Einstein condensation and is applicable for atomic condensates. We discuss some novel important topics of both simulations. One is inhomogeneous turbulence in superfluid helium, which was recently revealed by the visualization experiments. Another is quantum turbulence in atomic Bose condensates addressing multi-component order parameters.

**9:48AM K1.00004 Turbulent flows of superfluid helium visualized by particle dynamics<sup>1</sup>**, MARCO LA MANTIA, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — The motions of relatively small particles in quantum flows of superfluid helium (He II) are visualized in order to reveal the underlying flow-induced physics. It is specifically shown how the derived flow properties - such as the particle velocity distribution - depend on the length scale probed by the particles, for both thermally and mechanically driven flows of He II. Quantum features may indeed appear at small enough length scales, smaller than the quantum scale of the flow, the average distance between quantized vortices, while, at larger length scales, a classical (viscous-like) picture emerges, reinforcing the idea that quantum turbulence is not only interesting in its own right but may also lead to the deeper understanding of fluid turbulence in general, an open problem of classical physics relevant to many research fields, ranging from fluid dynamics to cosmology.

<sup>1</sup>Support from the Czech Science Foundation is acknowledged.

**10:24AM K1.00005 Flow visualization in superfluid helium-4 using He2 molecular tracers<sup>1</sup>**, WEI GUO, Florida State Univ — Flow visualization in superfluid helium is challenging, yet crucial for attaining a detailed understanding of quantum turbulence. Two problems have impeded progress: finding and introducing suitable tracers that are small yet visible; and unambiguous interpretation of the tracer motion. We show that metastable He<sub>2</sub> triplet molecules are outstanding tracers compared with other particles used in helium. These molecular tracers have small size and relatively simple behavior in superfluid helium: they follow the normal fluid motion at above 1 K and will bind to quantized vortex lines below about 0.6 K. A laser-induced fluorescence technique has been developed for imaging the He<sub>2</sub> tracers. We will present our recent experimental work on studying the normal-fluid motion by tracking thin lines of He<sub>2</sub> tracers created via femtosecond laser-field ionization in helium. We will also discuss a newly launched experiment on visualizing vortex lines in a magnetically levitated superfluid helium drop by imaging the He<sub>2</sub> tracers trapped on the vortex cores. This experiment will enable unprecedented insight into the behavior of a rotating superfluid drop and will untangle several key issues in quantum turbulence research.

**Wednesday, March 16, 2016 8:00AM - 11:00AM —**  
**Session K2 DCMP DMP GMAG: Kitaev Spin Liquid Physics in Honeycomb and Related Lattice Materials** Ballroom II - Stephen Nagler, Oak Ridge National Lab

**8:00AM K2.00001 The magnetic ground state and relationship to Kitaev physics in  $\alpha$ -RuCl<sub>3</sub><sup>1</sup>**, ARNAB BANERJEE, Quantum Condensed Matter Div., Oak Ridge Nat. Lab., Oak Ridge, TN - 37830. — The 2D Kitaev candidate  $\alpha$ -RuCl<sub>3</sub> consists of stacked honeycomb layers weakly coupled by Van der Waals interactions. Here we report the measurements of bulk properties and neutron diffraction in both powder and single crystal samples. Our results show that the full three dimensional magnetic ground state is highly pliable with at least two dominant phases corresponding to two different out-of-plane magnetic orders. They have different Neel temperatures dependent on the stacking of the 2D layers, such as a broad magnetic transition at T<sub>N</sub> = 14 K as observed in phase-pure powder samples, or a sharp magnetic transition at a lower T<sub>N</sub> = 7 K as observed in homogeneous single crystals with no evidence for stacking faults. The magnetic refinements of the neutron scattering data [1] will be discussed, which in all cases shows the in-plane magnetic ground state is the zigzag phase common in Kitaev related materials including the honeycomb lattice Iridates. Inelastic neutron scattering in all cases shows that this material consistently exhibit strong two-dimensional magnetic fluctuations leading to a break-down of the classical spin-wave picture [2]. **8:36AM K2.00002 How to identify and resolve beyond-geometrical frustration**, ITAMAR KIMCHI, Massachusetts Institute of Technology — In this talk, we will discuss recent theoretical developments triggered by the experimental discoveries of iridium oxides  $\alpha, \beta, \gamma$ -Li<sub>2</sub>IrO<sub>3</sub>. In these polytypes, spin-orbit-coupled  $J=1/2$  moments form 2D and 3D lattices (honeycomb, hyperhoneycomb and stripyhoneycomb) which generalize the 2D honeycomb lattice. Scattering experiments on these compounds have uncovered a peculiar non-coplanar incommensurate magnetic order, involving spirals which counter-rotate across neighboring sites. We discuss the emergence of this ordering, and the striking similarities visible across the three Li<sub>2</sub>IrO<sub>3</sub> structures. The model Hamiltonians that capture the materials indicate strong magnetic frustration, which arises from spin-orbit coupling. Tuning the frustration, perhaps by just a 10% Hamiltonian perturbation, exposes a fractionalized phase: Kitaev's three-dimensional quantum spin liquid (QSL). What is its range of stability to the competing Hamiltonian terms which occur in the materials, such as antiferromagnetic Heisenberg exchange? The frustration prohibits direct computations. Instead, we demonstrate a viable approach by numerically solving the model in a fully quantum infinite-dimensional approximation, which captures both the magnetically ordered and the QSL phases. Finally, we discuss the phenomenology of the QSL phase, including the role of its emergent magnetic-like field lines in stabilizing its deconfined fermion excitations to finite temperatures. The resulting phase transition is a signature unique to three-dimensional fractionalization.

**9:12AM K2.00003 3D Kitaev spin liquids**, MARIA HERMANNNS, University of Cologne — The Kitaev honeycomb model has become one of the archetypal spin models exhibiting topological phases of matter, where the magnetic moments fractionalize into Majorana fermions interacting with a  $Z_2$  gauge field. In this talk, we discuss generalizations of this model to three-dimensional lattice structures. Our main focus is the metallic state that the emergent Majorana fermions form. In particular, we discuss the relation of the nature of this Majorana metal to the details of the underlying lattice structure. Besides (almost) conventional metals with a Majorana Fermi surface<sup>1</sup>, one also finds various realizations of Dirac semi-metals, where the gapless modes form Fermi lines or even Weyl nodes<sup>2</sup>. We introduce a general classification of these gapless quantum spin liquids using projective symmetry analysis. Furthermore, we briefly outline why these Majorana metals in 3D Kitaev systems provide an even richer variety of Dirac and Weyl phases than possible for electronic matter and comment on possible experimental signatures. Work done in collaboration with Kevin O'Brien and Simon Trebst.

**9:48AM K2.00004 Hyperhoneycomb iridate beta-Li<sub>2</sub>IrO<sub>3</sub> as a platform for Kitaev spin liquid**, TOMOHIRO TAKAYAMA, Max Planck Inst — Realization of quantum spin liquid has been a long-sought dream in condensed matter physics, where exotic excitations and unconventional superconductivity upon doping are expected. Honeycomb iridates recently emerged as a possible materialization of Kitaev spin liquid with frustrated "*bond-dependent ferromagnetic interaction*". However, the real materials,  $\alpha$ -Na<sub>2</sub>IrO<sub>3</sub> and  $\alpha$ -Li<sub>2</sub>IrO<sub>3</sub>, undergo antiferromagnetic ordering likely due to the presence of other dominant magnetic interactions and lattice distortion. We discovered a new form of Li<sub>2</sub>IrO<sub>3</sub>,  $\beta$ -Li<sub>2</sub>IrO<sub>3</sub>, which comprises a three-dimensional analogue of honeycomb lattice dubbed as "hyperhoneycomb". Each Ir<sup>4+</sup> ion of the hyperhoneycomb lattice has three neighboring like ions rotated by 120° and thus the local structure is identical with 2D honeycomb, indicating that the hyperhoneycomb lattice is a new platform for Kitaev physics.  $\beta$ -Li<sub>2</sub>IrO<sub>3</sub> displays a spiral magnetic order below 38 K, which likely originates from dominance of ferromagnetic Kitaev interaction. We argue that  $\beta$ -Li<sub>2</sub>IrO<sub>3</sub> locates in a close proximity to Kitaev spin liquid. We also discuss the spin liquid behavior observed in a new honeycomb iridate obtained by chemical modulation.

**10:24AM K2.00005 Magnetic "three states of matter" in two and three dimensions: a quantum Monte Carlo study of the extended toric codes**, YOSHITOMO KAMIYA, RIKEN - Saitama — The possibility of quantum spin liquids, characterized by nontrivial entanglement properties or a topological nonlocal order parameter, has long been debated both theoretically and experimentally. Since candidate systems (e.g., frustrated quantum magnets or 5d transition metal oxides) may host other competing phases including conventional magnetic ordered phases, it is natural to ask what types of global phase diagrams can be anticipated depending on coupling constants, temperature, dimensionality, etc. In this talk, by considering an extension of the Kitaev toric code Hamiltonians by Ising interactions on 2D (square) and 3D (cubic) lattices, I will present thermodynamic phase diagrams featuring magnetic "three states of matter," namely, quantum spin liquid, paramagnetic, and magnetically ordered phases (analogous to liquid, gas, and solid, respectively, in conventional matter) obtained by unbiased quantum Monte Carlo simulations [YK, Y. Kato, J. Nasu, and Y. Motome, PRB **92**, 100403(R) (2015)]. We find that the ordered phase borders on the spin liquid around the exactly solvable point by a discontinuous transition line in 3D, while it grows continuously from the quantum critical point in 2D. In both cases, peculiar *proximity effects* to the nearby spin liquid phases are observed at high temperature even when the ground state is magnetically ordered. Such proximity effects include flux-shrinking and a tricritical behavior in 3D and a "fractionalization" of the order parameter field at the quantum critical point in 2D, both of which can be detected by measuring critical exponents. (\*) Work done in collaboration with Yasuyuki Kato, Joji Nasu, and Yukitoshi Motome

**Wednesday, March 16, 2016 8:00AM - 11:00AM**

**Session K3 DCMP DMP: Weyl Topological Semimetals: Theory and Experiment** Ballroom III - Arun Bansil, Northeastern University

**8:00AM K3.00001 Weyl semimetals and topological phase transitions**, SHUICHI MURAKAMI, Tokyo Inst of Tech - Tokyo — Weyl semimetals are semimetals with nondegenerate 3D Dirac cones in the bulk. We showed that in a transition between different  $Z_2$  topological phases, i.e. between the normal insulator (NI) and topological insulator (TI), the Weyl semimetal phase necessarily appears when inversion symmetry is broken. In the presentation we show that this scenario holds for materials with any space groups without inversion symmetry. Namely, let us take any band insulator without inversion symmetry, and assume that the gap is closed by a change of an external parameter. In such cases we found that the system runs either into (i) a Weyl semimetal or (ii) a nodal-line semimetal, but no insulator-to-insulator transition happens. This is confirmed by classifying the gap closing in terms of the space groups and the wavevector. In the case (i), the number of Weyl nodes produced at the gap closing ranges from 2 to 12 depending on the symmetry. In (ii) the nodal line is protected by mirror symmetry. In the presentation, we explain some Weyl semimetal and nodal-line semimetals which we find by using this classification. As an example, we explain our result on ab initio calculation on tellurium (Te). Tellurium consists of helical chains, and therefore lacks inversion and mirror symmetries. At high pressure the band gap of Te decreases and finally it runs into a Weyl semimetal phase, as confirmed by our ab initio calculation. In such chiral systems as tellurium, we also theoretically propose chiral transport in systems with such helical structures; namely, an orbital magnetization is induced by a current along the chiral axis, in analogy with a solenoid. [1] S. Murakami, New J. Phys. **9**, 356 (2007). [2] S. Murakami and S. Kuga, Phys. Rev. B **78**, 165313 (2008). [3] R. Okugawa, and S. Murakami, Phys. Rev. B **89**, 235315 (2014). [4] M. Hirayama, R. Okugawa, S. Ishibashi, S. Murakami, and T. Miyake, Phys. Rev. Lett. **114**, 206401 (2015). [5] T. Yoda, T. Yokoyama, S. Murakami, Sci. Rep. **5**, 12024 (2015).

**8:36AM K3.00002 Topological insulator route to Weyl fermions**, ANTON BURKOV, University of Waterloo — I will describe one of the possible routes to realizing Weyl fermions in condensed matter, which is based on violating either time reversal or spatial inversion symmetry in a system, tuned near a quantum phase transition between a topological and an ordinary insulator. This route is particularly attractive, since it may lead to the simplest possible realization of a Weyl semimetal, with only two opposite-chirality Weyl nodes in the first Brillouin zone, which is yet to be found experimentally. I will describe some of the most important physical properties of such an elemental Weyl semimetal, in particular a negative longitudinal magnetoresistance due to the chiral anomaly and possible exotic superconducting states.

**9:12AM K3.00003 Discovery of Weyl fermion semimetal and topological Fermi arc quasiparticles in TaAs, NbAs, NbP, TaP and related materials** , M. ZAHID HASAN<sup>1</sup>, Princeton Univ — Topological matter can host Dirac, Majorana and Weyl fermions as quasiparticle modes on their boundaries. First, I briefly mention the basic theoretical concepts defining insulators and superconductors where topological surface state modes are robust only in the presence of a gap (Hasan & Kane; Rev. of Mod. Phys. 82, 3045 (2010)). In these systems topological protection is lost once the gap is closed turning the system into a trivial metal. A Weyl semimetal is the rare exception in this scheme which is a topologically robust metal (semimetal) whose low energy emergent excitations are Weyl fermions. In a Weyl fermion semimetal, the chiralities associated with the Weyl nodes can be understood as topological charges, leading to split monopoles and anti-monopoles of Berry curvature in momentum space. This gives a measure of the topological strength of the system. Due to this topology a Weyl semimetal is expected to exhibit 2D Fermi arc quasiparticles on its surface (Wan et.al., 2011). These arcs ("fractional" Fermi surfaces) are discontinuous or disjoint segments of a two dimensional Fermi contour, which are terminated onto the projections of the Weyl fermion nodes on the surface we have observed experimentally in TaAs, NbAs, NbP class of materials (Xu, Belopolski et.al., Science 349, 613 (2015); Xu, Alidoust et.al., Nature Phys. (2015); Xu, Belopolski et.al., Science Adv. (2015), Belopolski, Xu et.al., arXiv (2015)) following our theoretical predictions (Huang, Xu, Belopolski et.al., Nature Commun. 6:7373 (2015), submitted in November 2014). Our theoretical predictions (Nature Commun. 2015) and experimental demonstrations (Science 2015, Nature Physics 2015, Science Advances 2015) reveal that these Fermi arc quasiparticles can only live on the boundary of a 3D crystal which collectively represents the realization of a new state of quantum matter beyond our earlier work on Fermi arcs in topological materials (Xu, Liu, Kushwaha et.al., Science 347, 294 (2015), adv.online (2014)). This work is in collaboration with Su-Yang Xu, Ilya Belopolski, Nasser Alidoust, Madhab Neupane, Chenglong Zhang, Raman Sankar, Shin-Ming Huang, Chi-Cheng Lee, Guoqing Chang, BaoKai Wang, Guang Bian, Hao Zheng, Daniel S. Sanchez, Fangcheng Chou, Hsin Lin, Shuang Jia, Titus Neupert. This work is supported by GBMF and U.S. DOE.

<sup>1</sup>In collaboration with Su-Yang Xu, I. Belopolski, N. Alidoust, M. Neupane, C. Zhang, R. Sankar, S.-M. Huang, C.-C. Lee, G. Chang, B. Wang, G. Bian, H. Zheng, D. Sanchez, F.-C. Chou, T. Neupert, Hsin Lin, Shuang Jia. Work supported by GBMF(Moore) & DOE.

**9:48AM K3.00004 Observation of Weyl fermions in condensed matter** , HONG DING, Institute of Physics, Chinese Academy of Sciences — In 1929, a German mathematician and physicist Hermann Weyl proposed that a massless solution of the Dirac equation represents a pair of new type of particles, the so-called Weyl fermions. However, their existence in particle physics remains elusive after more than eight decades, e.g., neutrino has been regarded as a Weyl fermion in the Standard Model until it was found to have mass. Recently, significant advances in topological materials have provided an alternative way to realize Weyl fermions in condensed matter as an emergent phenomenon. Weyl semimetals are predicted as a class of topological materials that can be regarded as three-dimensional analogs of graphene breaking time reversal or inversion symmetry. Electrons in a Weyl semimetal behave exactly as Weyl fermions, which have many exotic properties, such as chiral anomaly, magnetic monopoles in the crystal momentum space, and open Fermi arcs on the surface. In this talk I will report our experimental discovery of a Weyl semimetal in TaAs by observing Fermi arcs with a characteristic spin texture in the surface states and Weyl nodes in the bulk states using angle-resolved photoemission spectroscopy.

**10:24AM K3.00005 Two Types of Weyl Semimetals** , ANDREI BERNEVIG, Princeton U — No abstract available.

**Wednesday, March 16, 2016 8:00AM - 11:00AM —**

**Session K4 DPOLY FIAP: From Nano to Meso: Assembly, Structure and Dynamics of Polymers and Polymer Nanocomposite Thin Films I - Industry Day** Ballroom IV - Sanat Kumar, Columbia Univ

**8:00AM K4.00001 Directed Assembly of Nanofilled Polymer Thin Films** , ALAMGIR KARIM, University of Akron — Facile directed self-assembly (DSA) of multicomponent thin films is important for potential technological applications. This requires a fine control of a complex interplay of processing parameters that need to be properly optimized for different organized structures. This talk will discuss some of our recent success towards realizing tunable DSA of soft matter multicomponent systems involving a dispersion of polymer-grafted nanoparticles in block copolymer or homopolymer matrices. DSA methods for such multicomponent films will be discussed. These include the use of zone-annealing with soft-shear to create highly anisotropic nanoparticle arrays, while direct immersion annealing (DIA) has been used to order nanoparticle filled films by dipping the films into controlled solvent quality solvent mixtures. A recently observed phenomena of confinement driven entropic order and phase segregation of polymer grafted nanoparticles in similar and dissimilar polymer matrices in melt state will be discussed. A high density of nano particles of different types ranging from metallic to inorganic to organic were patterned almost exclusively into channels via topographical soft confinement using entropic forces. Enthalpic interactions between the nanoparticle grafted layer and the polymer matrix could be used as a further handle to tune the directed assembly of the nanoparticles. The phenomena will be discussed in terms of confinement parameters, partition coefficient, free energy gain and entropic versus enthalpic interactions.

**8:36AM K4.00002 Photothermal heating at the nano and meso scales within polymer nanocomposites<sup>1</sup>** , LAURA CLARKE<sup>2</sup>, North Carolina State University — Metal nanoparticles strongly absorb specific wavelengths of visible/infrared light with no radiative relaxation by which to release this energy. As a result, the absorbed energy is efficiently converted to local heat (a photothermal effect [1]). With an effective cross-section of up to 10 times its physical size, each particle acts as a "super-sized" absorber even when embedded within a material environment, resulting in dramatic heating [2,3] originating at the particles. Polymer nanocomposites containing metal nanoparticles can then be probed [4] and altered by applying internal heat at nano- and meso- length scales. I'll discuss our recent studies [5] utilizing this effect, including internal annealing to increase crystallinity fraction in both films and nanofibers of poly(ethylene oxide) [6], in-situ curing of epoxy, and intentional degradation of starch-poly(ethyl cyanoacrylate) composites. The talk will highlight the unique features of a photothermal approach, such as the ability to couple energy quickly (as light) into low thermal conductivity environments and possible changes in thermal conductivity at the particle-polymer interface. **9:12AM K4.00003 Evaporation-induced Nanoparticle Self-Assembly in a Polymer Matrix**, SHENGFENG CHENG, Virginia Polytechnic Institute and State University — A critical challenge in many applications of polymer nanocomposites is to control the dispersion of nanoparticles in a polymer matrix. We employ large-scale molecular dynamics simulations to study the assembly of nanoparticles as the solvent evaporates from a polymer solution containing nanoparticles. Results show that the organization of nanoparticles can be controlled by varying the strength of the polymer-nanoparticle interactions. When the nanoparticles and polymers strongly attract, as the solvent evaporates, a concentrated polymer film forms at the surface and entraps a layer of nanoparticles, which assemble into a close-packed hexagonal lattice. This dense film of polymers and nanoparticles dramatically reduce the rate of evaporation as the solvent has to transverse the film to reach the surface. If the nanoparticle-polymer interactions are weak, then as the solvent evaporates, the surface layer is almost entirely made of polymers. The nanoparticles are largely excluded from the surface and dispersed randomly in the region below the surface layer. In this case the slowing-down of the evaporation by the surface layer is less dramatic. Also of interest is the case of a nanoparticle solution in contact with polymers that are end grafted to a flat surface to form a polymer brush. For a relatively weak nanoparticle-brush attraction, after evaporation of the solvent the nanoparticles straddle the brush surface and form an ordered lattice. For a strong nanoparticle-polymer attraction, however, the nanoparticles are engulfed inside the brush and the packing quality diminishes because the lateral diffusion of the nanoparticles is suppressed. To better understand the nanoparticle-brush interactions, our calculations to quantify the free energy penalty of inserting a nanoparticle into a polymer brush will also be discussed.

**9:48AM K4.00004 Influence of microstructure and environment on nanoparticle membrane and superlattice mechanical properties**, K. MICHAEL SALERNO, Sandia National Laboratories — Assembly of nanoparticles (NPs) offers a means to tailor materials, incorporating unique nanoscale electro-optical behavior with controllable, responsive mechanical properties. Encoding NPs with organic ligands provides a way to simultaneously drive assembly and control assembly properties. Atomistic molecular dynamics simulations of alkanethiol-coated gold nanoparticles are used to examine how coating chemistry, temperature, and assembly history affect the properties of two-dimensional nanoparticle membranes and three-dimensional nanoparticle superlattices. Specifically, NPs were coated with dodecanethiol and octadecanethiol ligands with COOH or CH<sub>3</sub> end groups and assembled into two-dimensional membranes at water vapor interface. Capping ligands with hydrogen-bond forming carboxyl groups rather than methyl groups more than doubles the membrane Young's modulus from 1.5 to 3.6 GPa. The orientational order of the coating oligomers indicates that ligands strongly bundle and orient within the membrane. This effect inhibits ligand interdigitation, decreasing stiffness. Ligand structure is also highly temperature dependent, causing membranes to lose mechanical stability at about 400K. We observe that the interface asymmetry leads to a measurable stress asymmetry. Due to buckling, stresses in 2D membranes are typically quite small, however 3D superlattices can reversibly reach pressures of 8 GPa. Simulations show that at these pressures the ligand-core bond can be an important failure point, and experiments show that core sintering occurs at high pressure, creating novel 3D and quasi-2D structures.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:24AM K4.00005 Polymer Melt Diffusion inside Nanoscale Cylindrical Pores.**, KAREN WINEY, University of Pennsylvania — Polymers in composites and inside porous media are frequently confined to spaces that are comparable to or even smaller than their mean end-to-end distances in the unconfined bulk state. Understanding the impact of nanoscale confinement on both polymer structure and dynamics is critical during processing and in applications. Anodized aluminum oxide (AAO) membranes with uniform cylindrical pores (diameters 18, 35, 55 or 80 nm) were filled with polystyrene (200 kDa) and then a thin layer of deuterated polystyrene was deposited on top. After annealing the concentration profile of the deuterated polymer was measured using elastic recoil detection and the center-of-mass polymer diffusion coefficient was determined. Melt diffusion is faster in AAO membranes with smaller pore diameters. This experimental finding is corroborated by coarse grain simulations with neutral interactions with the pore walls, although the increase is more pronounced in the simulations. Our simulations previously found that chain conformations slightly elongated parallel to the cylinder axis and compressed perpendicular to the cylinder and the number of entanglements per chain decreases as the cylinder diameter decreases. It is primarily the reduction in polymer entanglements that allows polymers to diffuse faster when the pore diameter is smaller in an athermal or weakly interacting system. Segmental dynamics have been measured using quasielastic neutron scattering. Polymer diffusion in cylindrical pores is now being studied at a fixed pore diameter as a function of molecular weight.

## Wednesday, March 16, 2016 8:00AM - 11:00AM – Session K5 GMAG DMP: Frustrated Magnetism: Spinels 301 - Daniel Khomskii, University of Cologne

**8:00AM K5.00001 From Spin Glass to Spin Liquid Ground States in Pyrochlore Molybdates**, LUCY CLARK, University of St Andrews — Magnetic pyrochlores continue to generate intense interest due to the wealth of interesting behaviours that they can display as a result of their highly frustrated nature. Here we will present our study of the molybdate pyrochlore Lu<sub>2</sub>Mo<sub>2</sub>O<sub>7</sub>, which contains non-magnetic Lu<sup>3+</sup> and an antiferromagnetic network of corner-sharing tetrahedra of Mo<sup>4+</sup>  $4d^2$   $S = 1$  ions [1]. Magnetic susceptibility data show that Lu<sub>2</sub>Mo<sub>2</sub>O<sub>7</sub> enters an unconventional spin glass state at  $T_f \sim 16$  K that displays a quadratic dependence of the low temperature magnetic heat capacity, akin to that observed for its well-studied sister compound Y<sub>2</sub>Mo<sub>2</sub>O<sub>7</sub> [2]. This spin glass transition is also clearly marked in our inelastic (CNCS, SNS) and diffuse elastic magnetic (D7, ILL) neutron scattering data. Furthermore, we will show that it is possible to topochemically substitute the oxide, O<sup>2-</sup>, ions within Lu<sub>2</sub>Mo<sub>2</sub>O<sub>7</sub> for nitride, N<sup>3-</sup>, to produce an oxynitride molybdate pyrochlore of composition Lu<sub>2</sub>Mo<sub>2</sub>O<sub>5</sub>N<sub>2</sub>. Magnetic susceptibility measurements confirm that strong antiferromagnetic correlations persist within the oxynitride, which contains Mo<sup>5+</sup>  $4d^1$   $S = \frac{1}{2}$  ions and is thus a prime candidate to host exotic quantum spin liquid behavior. We will discuss how the enhanced quantum spin fluctuations in Lu<sub>2</sub>Mo<sub>2</sub>O<sub>5</sub>N<sub>2</sub> appear to suppress the spin freezing transition observed in its parent oxide and instead support the formation of a gapless spin liquid phase that displays a linear dependence of the low temperature magnetic heat capacity [3]. [1] L. Clark *et al.*, J. Solid State Chem. **203**, 199 (2013), [2] H. J. Silverstein *et al.*, Phys. Rev. B **89**, 054433 (2014), [3] L. Clark *et al.*, Phys. Rev. Lett. **113**, 117201 (2014).

**8:36AM K5.00002 Observation of a new incommensurate phase in the spinel MnV<sub>2</sub>O<sub>4</sub><sup>1</sup>**, GILBERTO DE LA PENA MUNOZ, SANGJUN LEE, SAMUEL GLEASON, TAYLOR BYRUM, XINYUE FANG, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, SHIH-CHANG WENG, National Synchrotron Radiation Research Center, PETER ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign — Using x-ray scattering, we studied the temperature dependence of a large volume of reciprocal space in a MnV<sub>2</sub>O<sub>4</sub> spinel crystal. In addition to the known cubic to tetragonal phase transition at around 56 K, we observed previously unreported incommensurate modulation peaks at  $\delta q = 0.33$   $0.33$   $-0.16$ . We measured the temperature dependence of these modulations and, while they exhibit a shift or splitting in momentum space analogous to that of the structural phase transition, they do so at higher temperature than the Bragg reflections ( $\sim 100$ K). Our results suggest that MnV<sub>2</sub>O<sub>4</sub> has an additional phase transition that may be a precursor for the V t<sub>2g</sub> orbital ordering, which is closely related to the cubic to tetragonal transition.

**8:48AM K5.00003 Geometric Magnetic Frustration in  $\text{Li}_3\text{Mg}_2\text{OsO}_6$  Studied with Muon Spin Relaxation**<sup>1</sup>, J. P. CARLO, Villanova University, S. DERAKHSHAN, California State University - Long Beach, J. E. GREEDAN, McMaster University — Geometric frustration manifests when the spatial arrangement of ions inhibits magnetic order. Typically associated with antiferromagnetically (AF)-correlated moments on triangular or tetrahedral lattices, frustration occurs in a variety of structures and systems, resulting in rich phase diagrams and exotic ground states. As a window to exotic physics revealed by the cancellation of normally dominant interactions, the research community has taken great interest in frustrated systems. One family of recent interest are the rock-salt ordered oxides  $\text{A}_5\text{BO}_6$ , in which the B sites are occupied by magnetic ions comprising a network of interlocked tetrahedra, and nonmagnetic ions on the A sites control the B oxidation state through charge neutrality. Here we will discuss studies of  $\text{Li}_3\text{Mg}_2\text{OsO}_6$  using muon spin relaxation ( $\mu\text{SR}$ ), a highly sensitive local probe of magnetism. Previous studies of this family included  $\text{Li}_5\text{OsO}_6$ , which exhibits AF order below 50K with minimal evidence for frustration, and  $\text{Li}_4\text{MgReO}_6$ , which exhibits glassy magnetism.  $\text{Li}_3\text{Mg}_2\text{RuO}_6$ , meanwhile, exhibits long-range AF, with the ordering temperature suppressed by frustration. But its isoelectronic twin,  $\text{Li}_3\text{Mg}_2\text{OsO}_6$  ( $5d^3$  vs.  $4d^3$ ) exhibits very different behavior, revealed by  $\mu\text{SR}$  to be a glassy ground state below 12K. Understanding why such similar systems exhibit diverse ground-state behavior is key to understanding the nature of geometric magnetic frustration.

**9:00AM K5.00004 Effects of Zn doping on the A-Site antiferromagnet spinel  $\text{CuRh}_2\text{O}_4$** <sup>1</sup>, ALEXANDER ZAKJEVSKII, DALMAU REIG-I-PLESSIS, University of Illinois, Urbana, IL, ALEXANDER THALER, ASHFIA HUQ, Oak Ridge National Laboratory, Oak Ridge, TN, GREGORY MACDOUGALL, University of Illinois, Urbana, IL — A major recent focus of the correlated electron community has been the investigation of 4d and 5d transition metal oxides, which are predicted to have novel phases arising from relativistic spin-orbit coupling. We have recently synthesized and characterized several compounds of the doped spinel series  $\text{Cu}_{1-x}\text{Zn}_x\text{Rh}_2\text{O}_4$ . The parent compound is a normal spinel which undergoes a cubic-tetragonal structural phase transition at  $T \sim 850\text{K}$ , and further undergoes a suspected antiferromagnetic transition at  $T_N = 22\text{K}$ . We have performed powder x-ray and neutron diffraction, and bulk magnetization measurements on members of the Zn-doping series. Magnetization measurements clearly indicate a monotonic suppression of the Néel temperature with increasing Zn content, to a quantum critical point at  $x \approx 0.42$ . X-ray results indicate a change in structure occurring near the same doping. We will present these data and discuss the results within the context of exotic predictions in the literature. Lastly, we will discuss our recent neutron powder diffraction measurements and insights gleaned about the local spin state.

**9:12AM K5.00005 Magnetic Ordering in  $\text{FeSc}_2\text{S}_4$** <sup>1</sup>, K.W. PLUMB, J.R. MOREY, Johns Hopkins University, J.P.C. RUFF, CHESS, Cornell University, J.A. RODRIGUEZ-RIVERA, NIST, T.M. MCQUEEN, S.M. KOOHPAYEH, C.L. BROHOLM, Johns Hopkins University —  $\text{FeSc}_2\text{S}_4$  is a cubic spinel where orbitally active  $\text{Fe}^{2+}$  ions occupy the A-site diamond sublattice. Despite a high spin ( $S=2$ ) state and Curie Weiss temperature of 45 K thermodynamic measurements show no indication of a phase transition and the material has been proposed as a unique example of a spin-orbital liquid. This ground state might arise from competition between on site spin-orbit coupling and Kugel-Khomskii exchange. We report neutron scattering measurements on polycrystalline samples of  $\text{FeSc}_2\text{S}_4$  which bring this picture into question. They reveal a previously unreported magnetically ordered state below 11 K. No structural distortions are visible with neutron or x-ray scattering. The effect of hydrostatic pressure on the magnetic excitation spectrum was also explored and found to be minimal.

**9:24AM K5.00006 Quantum phase transitions and anomalous Hall effect in a pyrochlore Kondo lattice**, SARAH GREFE, Rice University, WENXIN DING, University of California Santa Cruz, QIMIAO SI, Rice University — The metallic variant of the pyrochlore iridates  $\text{Pr}_2\text{Ir}_2\text{O}_7$  has shown characteristics of a possible chiral spin liquid state [PRL **96** 087204 (2006), PRL **98**, 057203 (2007), Nature **463**, 210 (2010)] and quantum criticality [Nat. Mater. **13**, 356 (2014)]. An important question surrounding the significant anomalous Hall response observed in  $\text{Pr}_2\text{Ir}_2\text{O}_7$  is the nature of the f-electron local moments, including their Kondo coupling with the conduction d-electrons. The heavy effective mass and related thermodynamic characteristics indicate the involvement of the Kondo effect in this system's electronic properties. In this work, we study the effects of Kondo coupling on candidate time-reversal-symmetry-breaking spin liquid states on the pyrochlore lattice. Representing the f-moments as slave fermions Kondo-coupled to conduction electrons, we study the competition between Kondo-singlet formation and chiral spin correlations and determine the zero-temperature phase diagram. We derive an effective chiral interaction between the local moments and the conduction electrons and calculate the anomalous Hall response across the quantum phase transition from the Kondo destroyed phase to the Kondo screened phase. We discuss our results' implications for  $\text{Pr}_2\text{Ir}_2\text{O}_7$  and related frustrated Kondo-lattice systems.

**9:36AM K5.00007 Chemical insights into the synthesis and properties of polycrystalline and single crystal iron scandium sulfide ( $\text{FeSc}_2\text{S}_4$ )**<sup>1</sup>, JENNIFER R. MOREY, KEMP W. PLUMB, SEYED M. KOOHPAYEH, COLLIN L. BROHOLM, TYREL M. MCQUEEN, Institute for Quantum Matter and Johns Hopkins University — Iron scandium sulfide,  $\text{FeSc}_2\text{S}_4$ , has recently attracted significant theoretical and experimental interest as a candidate spin-orbital liquid. An  $\text{AB}_2\text{X}_4$  spinel,  $\text{FeSc}_2\text{S}_4$  (space group  $\text{Fd-3m}$ , No. 227) features a high degree of frustration associated with the  $\text{Fe}^{2+}$ , which occupies the A-site diamond sublattice and is tetrahedrally coordinated by sulfur. The  $\text{Fe}^{2+}$  ion is in a high spin ( $S=2$ ) state, resulting in orbital degeneracy due to a single hole on the  $e$  orbitals. We report the strides we have made to produce material in powder and single crystal form, and the relationship between the chemistry and the structural, magnetic, and thermodynamic properties of  $\text{FeSc}_2\text{S}_4$ .

<sup>1</sup>This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under Grant No. DEFG02-08ER46544.

**9:48AM K5.00008 Weyl Magnon**, FEI-YE LI, Institute of Theoretical Physics, Chinese Academy of Sciences, YAO-DONG LI, Department of Computer Sciences, Fudan Univ, YUE YU, Physics Department, Fudan Univ, YONG BAEK KIM, Physics Department, Univ of Toronto, Ontario; School of Physics, Korea Institute for Advanced Study, Seoul, LEON BALENTS, Kavli Institute for Theoretical Physics, UCSB, California, GANG CHEN<sup>1</sup>, Physics Department, State Key Laboratory of Surface Physics, Fudan Univ; Perimeter Institute for Theoretical Physics — Conventional magnetic orders in Mott insulators are often believed to be trivial as they are simple product states. In this talk, we argue that this belief is not always right. We study a realistic spin model on the breathing pyrochlore lattice. We find that, although the system has a magnetic ordered ground state, the magnetic excitation is rather nontrivial and supports linear band touchings in its spectrum. This linear band touching is a topological property of the magnon band structure and is thus robust against small perturbation. We thus name this magnon band touching as Weyl magnon. Just like the Weyl fermion, the existence of Weyl magnon suggests the presence of chiral magnon surface states. Unlike the surface Fermi arcs for the Weyl fermions, the chiral surface state for Weyl magnon appears at a finite energy due to the bosonic nature of the magnons. Moreover, the external magnetic field only couples to the spins with a Zeeman term and thus can readily shift the Weyl node position. This provides a way to control the Weyl magnon. Our work will inspire a re-examination of the excitation spectrum of many magnetic ordered systems.

<sup>1</sup>chggst@gmail.com

**10:00AM K5.00009 Spin Glass Behavior and Field Induced Anisotropic Magnetic Ordering in  $S = 2$  Frustrated Spinel  $\text{GeFe}_2\text{O}_4$** , TAO ZOU, Michigan State Univ, ZHILING DUN, University of Tennessee, TAO HONG, HUIBO CAO, CLARINA DELA CRUZ, Oak Ridge National Lab, MICHAEL GOTTSCHALK, MENGZE ZHU, Michigan State Univ, HAIDONG ZHOU, University of Tennessee, XIANGLIN KE, Michigan State Univ — We report comprehensive studies of magnetic properties of spinel  $\text{GeFe}_2\text{O}_4$  by means of magnetic susceptibility and heat capacity measurements on both polycrystalline and single crystalline samples as well as neutron powder diffraction measurements. We find that this system shows a spin-glass ground state with the transition temperature around  $T \sim 21$  K, in contrast to the static antiferromagnetic order reported in earlier literature. In addition, we reveal a field-induced magnetic ordering, which displays strong magnetic anisotropy character.

**10:12AM K5.00010 Orbital degeneracy near the itinerant electron limit in  $\text{CoV}_2\text{O}_4$** <sup>1</sup>, D. REIG-IPLESSIS, D. CASAVANT, University of Illinois, V. O. GARLEA, A. A. ACZEL, M. FEYGENSON, J. NEUEFEIND, Oak Ridge National Lab, H. D. ZHOU, University of Tennessee, S. E. NAGLER, Oak Ridge National Lab, G. J. MACDOUGALL, University of Illinois — Vanadium spinels,  $\text{AV}_2\text{O}_4$  have both magnetic frustration and orbital degeneracy on the  $V^{3+}$  sublattice, which lead to strong coupling of the orbital, lattice and spin degrees of freedom. Additionally, upon decreasing the V-V distance, the material is predicted to go from a Mott insulator to a metallic phase. Of all the materials in the  $\text{AV}_2\text{O}_4$  series,  $\text{CoV}_2\text{O}_4$  is closest to the predicted transition, and it's debated whether it may be fully described by either localized or itinerant electrons pictures. In all other studied vanadium spinels, there is a cubic to tetragonal transition associated with ordering of the degenerate  $V^{3+}$  orbitals, consistent with a local orbital picture but, this transition is surprisingly absent from  $\text{CoV}_2\text{O}_4$  despite being an insulator with local spins. In this talk we present recent high resolution neutron diffraction and inelastic scattering measurements by our group on powders of  $\text{CoV}_2\text{O}_4$ . Diffraction data show there is small but clear first order structural transition present which correlates with canting of the  $V^{3+}$  spins, while inelastic data are well described by a local spinwave picture. We discuss how these results contribute evidence of a local orbital ordering phase in the region near electron itinerancy.

**10:24AM K5.00011 Spin Dynamics and Two-Dimensional Correlations in the FCC Antiferromagnetic  $\text{Sr}_2\text{YRuO}_6$** , STEVEN DISSELER, J. W. LYNN, NIST Center for Neutron Research, Gaithersburg, Maryland 20899, USA, R. F. JARDIM, Instituto de Física, Universidade de São Paulo 05315-970, Brazil, M. S. TORIKACHVILI, Department of Physics, San Diego State University, San Diego, California 92182, USA, E. GR, Institute of Physics "Gleb Wataghin," University of Campinas - UNICAMP, Campinas, São Paulo 13083-859, Brazil — The face-centered cubic lattice of  $\text{Ru}^{5+}$  spins in the double perovskite  $\text{Sr}_2\text{YRuO}_6$  shows a delicate three dimensional antiferromagnetic (AFM) ground state composed of stacked square AFM layers. We present new inelastic neutron scattering data taken on this state revealing a gapped low-energy excitation band that may be modeled by a simple  $J_1 - J_2$  interaction scheme allowing quantitative comparison of similar materials. At higher temperatures, the low-energy excitation spectrum is dominated by a quasi-elastic component associated with size fluctuations of two-dimensional AFM clusters that exhibit asymmetric correlations even at low temperatures. Thus, the FCC lattice in general and the double perovskite structure in particular emerge as hosts of both two-dimensional and three-dimensional dynamics resulting from frustration.

**10:36AM K5.00012 Unanticipated spin gap measured in the frustrated quasi-FCC  $d^3$  double perovskites  $\text{La}_2\text{LiXO}_6$  ( $X = \text{Ru, Os}$ )**, DALINI D MAHARAJ, GABRIELE SALA, CASEY A MARJERRISON, JOHN GREEDAN, BRUCE GAULIN, McMaster University, MATTHEW STONE, Spallation Neutron Source, Oak Ridge National Laboratory — There is much current interest in the influence of strong spin-orbit (SO) interactions on exotic ground state selection in new 4d and 5d magnets, particularly involving  $4d^5$  Ir. Here we consider double perovskites of the form  $\text{A}_2\text{BB}'\text{O}_6$  which are based on heavy 4d or 5d magnetic ions, where the SO interaction is expected to be significant as it increases as  $\sim Z^4$ . The double perovskite structure can accommodate a variety of magnetic ions on the B' site, providing a playground for systematic studies of the exotic ground states stabilized by strong SO coupling. Here, we report inelastic neutron scattering (INS) measurements conducted on the frustrated monoclinic magnets,  $\text{La}_2\text{LiXO}_6$  ( $X = \text{Ru, Os}$ ), wherein the magnetic moments decorate a quasi face-centered-cubic lattice. Our results show the development of a spin gap in the spin excitation spectrum of size  $\Delta_{\text{Os}} = 8$  meV and  $\Delta_{\text{Ru}} = 2.5$  meV concomitant with  $T_N$ , which is unexpected for orbitally quenched  $d^3$  systems. We liken these results to INS results obtained for  $\text{Ba}_2\text{YXO}_6$  and  $\text{La}_2\text{NaXO}_6$ , which were also shown to exhibit spin gaps that correlate with  $T_N$ . We shall discuss trends observed in these three  $d^3$  double perovskite families which correlate strong SO coupling, spin gap and  $T_N$ .

**10:48AM K5.00013 Raman spectroscopy study of spin-orbital liquid candidate  $\text{FeSc}_2\text{S}_4$** <sup>1</sup>, STREIT CUNNINGHAM, K.W. PLUMB, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, Maryland, USA, J.R. MOREY, T.M. MCQUEEN, Department of Chemistry, Johns Hopkins University, Baltimore, Maryland, USA, S. KOOHPAYEH, C.L. BROHOLM, NATALIA DRICHKO, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, Maryland, USA — The A-site cubic spinel  $\text{FeSc}_2\text{S}_4$ , containing  $\text{Fe}^{2+}$  ions in a tetrahedral  $\text{S}_4$  environment, represents a rare candidate of a spin-orbital liquid, where spin and orbital order remain suppressed down to the lowest measurable temperature [1]. We studied phonon spectrum and orbital excitations in  $\text{FeSc}_2\text{S}_4$  by Raman spectroscopy on single crystals. At temperatures below 100K we observe widening of sulfur  $330 \text{ cm}^{-1}$   $T_{2g}$  and  $365 \text{ cm}^{-1}$   $A_{1g}$  phonon modes with an additional weak mode emerging at  $400 \text{ cm}^{-1}$ . These changes can indicate weak lattice distortions associated with the sulfur sites. Below 100K we also observe orbital excitations at frequencies of approximately  $2000 \text{ cm}^{-1}$ . We discuss the result in terms of a competition of spin-orbital liquid and a magnetically ordered state. [1] L. Mittelstadt et al., Phys. Rev. B 91 125112 (2015).

## Wednesday, March 16, 2016 8:00AM - 11:00AM – Session K6 GMAG DMP: Ruthenates 302 - Songxue Chi, Oak Ridge National Laboratory

**8:00AM K6.00001 Tuning quantum properties in bilayer ruthenates**, XIANGLIN KE, Michigan State University — The mutual coupling among spin, charge, lattice and orbital degrees of freedom in transition-metal oxide materials often leads to the competition of various types of energetic states. This makes such materials dramatically susceptible to external parameters, giving rise to novel physical properties and rich phase diagrams. In this talk, I shall use a bilayer ruthenate,  $\text{Ca}_3\text{Ru}_2\text{O}_7$ , as an example to discuss the emergent phenomena achieved by systematically tuning materials magnetic and electronic properties via chemical doping, magnetic field, and pressure. I shall show that this system provides a rare opportunity to investigate the interplay between correlated metal and Mott insulator. This work was done in collaboration with M. Zhu, T. Tao, S. D. Mahanti, Z. Q. Mao, J. Peng, T. Hong, W. Tian, H. Cao, C. R. dela Cruz, D. Singh, and K. Prokes.

**8:36AM K6.00002 Metamagnetism and Nonlinear Susceptibilities in the Bilayer Ruthenate  $\text{Sr}_3\text{Ru}_2\text{O}_7$** <sup>1</sup>, D. PHELAN, Argonne National Labs, B. SHIVARAM, Univ of Virginia, A. VECCHIONE, ROSALBA FITTIPALDI, CNR-SPIN and Dipartimento di Fisica, Salerno, Italy — We report measurements of the third and fifth order nonlinear susceptibilities in the correlated oxide metamagnet,  $\text{Sr}_3\text{Ru}_2\text{O}_7$  for both orientations of the magnetic field, H parallel to the c-axis and in the basal plane. In both geometries we observe peaks in the temperature dependence of the higher order susceptibilities. The position in temperature where the peak in the fifth order susceptibility occurs is at half the temperature where a peak in the third order susceptibility is seen. The latter in turn is at half the temperature where the peak in the linear susceptibility is known to occur. This simple scaling is common to both orientations of the magnetic field. These results will be discussed in the context of similar work with heavy fermion metamagnets<sup>1</sup>.

**8:48AM K6.00003 Structure-magnetism correlation induced by Mn substitution in bilayered perovskite  $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$** <sup>1</sup>, QIANG ZHANG, Louisiana State Univ - Baton Rouge, FENG YE, SONGXUE CHI, Oak Ridge National Laboratory, DALGIS MESA, Louisiana State Univ - Baton Rouge, WEI TIAN, Oak Ridge National Laboratory, RONGYING JIN, WARD PLUMMER, JIANDI ZHANG, Louisiana State Univ - Baton Rouge — Elastic neutron scattering technique was employed to investigate the effect of Mn substitution on the structure, magnetism and their correlation in  $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_7$  (x=6%, 12% and 16%) crystals. While parent compound  $\text{Sr}_3\text{Ru}_2\text{O}_7$  is paramagnetic, a small amount of Mn substitution induces an E-type antiferromagnetic order. With the increase of Mn substitution from 6 % to 16%, the ordered moment at Ru/Mn site increases significantly with an enhanced  $T_N$  from 20 K for x=6 % to 80 K for x= 16%, and the in-plane magnetic correlation lengths increase to achieve the maximum for x= 16% as indicated by the resolution-limited linewidth of the H-scans through  $\mathbf{Q}_{\text{AFM}}=(0.5, 0, 0)$ . Accompanied by the enhancement of  $T_N$ , the (Ru/Mn) $\text{O}_6$  octahedron rotation is found to be suppressed simultaneously, suggesting a correlation between (Ru/Mn) $\text{O}_6$  octahedron rotation and magnetism due to Mn substitution. Our findings indicate that Mn substitution on Ru in  $\text{Sr}_3\text{Ru}_2\text{O}_7$  has a significant effect on the microscopic structure and magnetism as well as the correlations between them.

**9:00AM K6.00004 Magnetic phase separation in double layer ruthenates  $\text{Ca}_3(\text{Ru}_{1-x}\text{Ti}_x)_2\text{O}_7$** , JIN PENG, Nanjing University, JINYU LIU, JIN HU, ZHIQIANG MAO, Tulane University, XIAOSHAN WU, Nanjing University — Ti doping of a small concentration in the double-layered ruthenate  $\text{Ca}_3(\text{Ru}_{1-x}\text{Ti}_x)_2\text{O}_7$  was previously found to induce an unusual magnetic phase transition from a metallic antiferromagnetic state formed from anti-parallel stacking of ferromagnetic bilayers (AFM-b) to a nearest-neighbor antiferromagnetic state (G-AFM) with Mott insulating properties; the critical Ti concentration for the transition is near  $x = 0.03$ . In this article, we conducted systematic studies on this magnetic transition near the critical composition through detailed magnetization measurements. We found that no intermediate magnetic phases exist between AFM-b and G-AFM states; this is contrasted with manganites where a similar magnetic phase transition takes place through the presence of several intermediate magnetic phases. The AFM-b-to-G-AFM transition in  $\text{Ca}_3(\text{Ru}_{1-x}\text{Ti}_x)_2\text{O}_7$  happens through a phase separation process; the AFM-b and G-AFM phases coexist in the 2-5

**9:12AM K6.00005 Field-controlled spin-density-wave order and quantum criticality in  $\text{Sr}_3\text{Ru}_2\text{O}_7$** , STEPHEN HAYDEN, University of Bristol — The quasi-2D metamagnetic perovskite metal  $\text{Sr}_3\text{Ru}_2\text{O}_7$  has been an enigma for the last decade. The application of a large magnetic field of 8T parallel to the c-axis creates a new phase at low temperatures. This phase shows "electronic nematic" properties in that strong anisotropy its resistivity can be created by tilting the field away from the c-axis. In addition, measurement of transport and thermodynamic properties suggest that the phase is at the centre of a quantum critical region. Here we use neutron scattering to show that the magnetic field actually induces spin-density-wave magnetic order in the proximity of a metamagnetic critical endpoint. In fact,  $\text{Sr}_3\text{Ru}_2\text{O}_7$  can be tuned through two magnetically-ordered SDW states which exist over relatively small ranges in field ( $\mu_0$  0.4 T). Their origin is probably due to the electronic fine structure near the Fermi energy. The magnetic field direction is shown to control the SDW domain populations which naturally explains the strong resistivity anisotropy or "electronic nematic" behaviour observed in this material. We find that  $\text{Sr}_3\text{Ru}_2\text{O}_7$  is also unique in that its quantum critical region is controlled by overdamped incommensurate low-energy spin fluctuations with a diverging relaxation time. The low-energy electronic properties reflect the presence of these fluctuations and, in particular, the field-dependent low-temperature specific heat is proportional to the spin relaxation rate. [Based on C. Lester, S. Ramos, R. S. Perry at el. Natural Materials 14, 373 (2015).]

**9:48AM K6.00006 Magnetic-field-induced first-order phase transitions in  $\text{Ca}_3(\text{Ru}_{1-x}\text{Fe}_x)_2\text{O}_7$  with unusual irreversible behaviors**, MENGZE ZHU, Michigan State Univ, JIN PENG, Nanjing Univ, China, TAO ZOU, Michigan State Univ, TAO HONG, Oak Ridge National Lab, KAREL PROKES, Helmholtz Zentrum Berlin, Germany, S. D. MAHANTI, Michigan State Univ, ZHIQIANG MAO, Tulane University, XIANGLIN KE, Michigan State Univ — Neutron diffraction measurements reveal a magnetic-field-induced incommensurate-commensurate magnetic structure transition in a bilayer ruthenate  $\text{Ca}_3(\text{Ru}_{1-x}\text{Fe}_x)_2\text{O}_7$  ( $x = 0.05$ ). The transition is of first-order in nature, and exhibits intriguing irreversible behaviors at low temperature, i.e. the zero-field incommensurate state before and after field sweeping showing very distinct magnetic ordering wave vectors. The difference in the wavelength of magnetic ordering is strongly temperature-dependent, and disappears gradually as temperature raises. This unusual irreversibility in magnetic ordering vector is rarely observed, and in disagreement with phase coexistence phenomena that is commonly seen in other irreversible first-order phase transitions. Nevertheless, our results demonstrate that thermal fluctuations also play an essential role in this unusual behavior.

**10:00AM K6.00007 Unconventional Magnetic Domains in Triple-layered  $\text{Sr}_4\text{Ru}_3\text{O}_{10}$** <sup>1</sup>, KAI DU, SEONG JOON LIM, JAE WOOK KIM, Rutgers Univ, GANG CAO, University of Kentucky, SANG WOOK CHEONG, Rutgers Univ, RUTGERS CENTER FOR EMERGENT MATERIAL TEAM, CENTER FOR ADVANCED MATERIALS, UNIVERSITY OF KENTUCKY COLLABORATION — A plethora of fascinating phenomena including p-wave superconductivity in  $\text{Sr}_2\text{RuO}_4$  (n=1) and hybrid improper ferroelectricity in  $\text{Ca}_3\text{Ru}_2\text{O}_7$  (n=2) have been observed in Ruddlesden-Popper ruthenates  $(\text{Ca}, \text{Sr})_{n+1}\text{Ru}_n\text{O}_{3n+1}$ . The triple-layered  $\text{Sr}_4\text{Ru}_3\text{O}_{10}$  (n=3) is believed to have an intriguing complex magnetic state, compared with its neighboring bi-layered meta-magnetic  $\text{Sr}_3\text{Ru}_2\text{O}_7$  (n=2) and ferromagnetic  $\text{SrRuO}_3$  (n= $\infty$ ). The phase competition nature associated with this complexity is considered to be responsible for its novel properties such as coupled anisotropic magnetism and transport, low frequency quantum oscillations and sharp magneto-resistivity steps, which are still not well understood yet. To better understand its microscopic mechanism, we studied the magnetic domain structure on  $\text{Sr}_4\text{Ru}_3\text{O}_{10}$  using low-temperature magnetic force microscopy. The observed unique domain structures in  $\text{Sr}_4\text{Ru}_3\text{O}_{10}$  may shed lights on its microscopic phase competition nature and lead to a deeper understanding on its relations with other layered ruthenates.

**10:12AM K6.00008 Dynamical mean field study of ferromagnetism and correlation strength in cubic barium ruthenate: results and comparison to strontium and calcium ruthenate**, QIANG HAN, Department of Physics, Columbia University, New York, New York 10027, USA, HUNG DANG, Institute for Theoretical Solid State Physics, JARA-FIT and JARA-HPC, RWTH Aachen University, 52056 Aachen, Germany, ANDREW MILLIS, Department of Physics, Columbia University, New York, New York 10027, USA — We present density functional plus dynamical mean field studies of cubic BaRuO<sub>3</sub> using interaction parameters previously found to be appropriate for the related materials CaRuO<sub>3</sub> and SrRuO<sub>3</sub>. The calculated trends in material properties across this family of compounds are in good agreement with experiment and the results provide insights into the origin of magnetism and the role of the van Hove singularity in the physics of Hund's metals.

**10:24AM K6.00009 Ferromagnetic cluster glass state induced by non-magnetic ions in a paramagnetic host**, TAKAFUMI D. YAMAMOTO, Department of Physics, Nagoya University, Nagoya 464-8602, RYUJI OKAZAKI, Department of Physics, Faculty of Science and Technology, Noda 278-8510, HIROKI TANIGUCHI, ICHIRO TERASAKI, Department of Physics, Nagoya University, Nagoya 464-8602 — A paramagnetic metal CaRuO<sub>3</sub> has been known to show unique impurity effects, where a magnetic ordering is induced by a partial substitution of transition metal ions for Ru. Since this phenomenon occurs regardless of the magnetism of the substituted ions, it must reflect a magnetic instability of this ruthenate. Understanding such physical properties is one of intriguing issues in condensed matter physics.

In this talk, we report an unconventional magnetic state induced by substituting non-magnetic Sc<sup>3+</sup> ions. We find that the static magnetic susceptibilities of all Sc-substituted samples show ferromagnetic-like features below 40 K, while the Curie-Weiss temperature dramatically changes with increasing  $x$ . This inconsistency is a sign of *non-uniform magnetic system*. We propose a phenomenological model and show that the static magnetic properties can be described as a volume average of a paramagnetic component originated from Ru<sup>4+</sup> ions and a ferromagnetic one driven by Sc substitution [T. D. Yamamoto *et al.*, JPSJ **84**, 014708 (2015)]. Furthermore our dynamic magnetic measurements reveal a ferromagnetic cluster glass state embedded in the paramagnetic and metallic host of CaRuO<sub>3</sub>.

**10:36AM K6.00010 Suppression of ferromagnetism and observation of quantum well states in epitaxial thin films of the cubic ruthenate BaRuO<sub>3</sub>**, BULAT BURGANOV, Department of Physics, Cornell University, HANJONG PAIK, Department of Materials Science and Engineering, Cornell University, KYLE SHEN, Department of Physics, Cornell University, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University — The pseudocubic perovskite ruthenates ARuO<sub>3</sub>, where A is alkaline earth metal, are correlated materials where Hund's coupling drives correlations and leads to a low coherence scale, large renormalization, and formation of local moments. The ferromagnetic BaRuO<sub>3</sub> has an ideal cubic structure and a larger bandwidth, compared to its GdFeO<sub>3</sub>-distorted counterparts, CaRuO<sub>3</sub> and SrRuO<sub>3</sub>. In stark contrast to SrRuO<sub>3</sub>, which is a Fermi liquid below  $T_C$ , BaRuO<sub>3</sub> exhibits critical fluctuations near  $T_C$  that are enhanced under hydrostatic pressure, which suppresses the Fermi liquid coherence scale and  $T_C$  and drives a crossover into non-FL regime. Here we use ARPES to characterize the momentum-resolved electronic structure of strained ultrathin BaRuO<sub>3</sub> films grown in situ by molecular beam epitaxy. The films on STO (001) are metallic down to 2 u.c. thickness and manifest clearly defined subbands of well-defined quasiparticles which arise due to quantum confinement effects. We observe that the bands are moderately renormalized compared to bare GGA bands and discover that the ferromagnetism can be suppressed in the atomically thin limit. We discuss our results on BaRuO<sub>3</sub> in the context of our recent ARPES studies of the other perovskite ruthenates, SrRuO<sub>3</sub> and CaRuO<sub>3</sub>.

**10:48AM K6.00011 Antiferromagnetism in Bulk Rutile RuO<sub>2</sub>**<sup>1</sup>, T. BERLIJN, Oak Ridge National Laboratory, P. C. SNIJDERS, P. R. C. KENT, T. A. MAIER, Oak Ridge National Laboratory, University of Tennessee, H.-D. ZHOU, University of Tennessee, H.-B. CAO, O. DELAIRE, Y. WANG, Oak Ridge National Laboratory, M. KOEHLER, University of Tennessee, H. H. WEITERING, University of Tennessee, Oak Ridge National Laboratory — While bulk rutile RuO<sub>2</sub> has long been considered to be a Pauli paramagnet, we conclude it to host antiferromagnetism based on our combined theoretical and experimental study. This constitutes an important finding given the large amount of applications of RuO<sub>2</sub> in the electrochemical and electronics industry. Furthermore the high onset temperature of the antiferromagnetism around 1000K together with the high electrical conductivity makes RuO<sub>2</sub> unique among the ruthenates and among oxide materials in general.

**Session K7 DMP FIAP: Dopants and Defects in Semiconductors: Nitrides** 303 - Christopher Van de Walle, UCSB

**8:00AM K7.00001 Point and Extended Defects in GaN-based Materials**, JAMES SPECK, UCSB Materials Department — In this presentation, the origin and evolution of threading dislocations in GaN heteroepitaxy are reviewed. For heteroepitaxial of GaN on most substrates (e.g., sapphire, MgAl<sub>2</sub>O<sub>4</sub>, SiC, ...) high temperature GaN grows in a Volmer-Weber mode. Threading dislocations result from island coalescence. The evolution of threading dislocations has been extensively modeled. Tensile stress generation via threading dislocation inclination is a major ongoing issue in GaN growth. We review older and more recent work on the impact of threading dislocations in GaN materials properties and device performance. Finally, we review recent work from our group on stress relaxation in nonpolar and semipolar GaN. We demonstrate the first GaN-based laser diodes grown on intentionally stress-relaxed buffer layers and we demonstrate control of relaxation in semipolar laser diodes by selective area growth.

**8:36AM K7.00002 Impact of defects on efficiency of nitride devices**<sup>1</sup>, CHRIS VAN DE WALLE, Univ of California - Santa Barbara — Nitride semiconductors are the key materials for solid-state lighting and also increasingly for power electronics. In both bulk crystals and epitaxial layers, point defects may act as compensating centers, charge traps, or radiative or nonradiative recombination centers. Unintentional impurities often play an equally important role; for instance, carbon that is unavoidably incorporated during metal-organic chemical vapor deposition (MOCVD) acts as a source of yellow luminescence [1]. Theoretical advances now enable us to calculate the energetics as well as electronic and optical properties of point defects with unprecedented accuracy [2]. In AlN, we have identified the defects that lead to characteristic luminescence and absorption lines [3]. Both point defects and impurities can affect the radiative efficiency of light emitters. We have developed a first-principles methodology [4] to determine nonradiative carrier capture coefficients. Accurate calculations of electron-phonon coupling, combined with results for defect formation energies and charge-state transition levels [5], enable the calculation of nonradiative capture rates for electrons and holes and the evaluation of Shockley-Read-Hall coefficients. This approach allows us to identify specific defects that play a key role in limiting the efficiency of nitride semiconductor devices.

**9:12AM K7.00003 Saturation Behavior of Eu ion emission in GaN**, NATALIE HERNANDEZ, Lehigh University, BRANDON MITCHELL, University of Mount Union, YASUFUMI FUJIWARA, Osaka University, VOLKMAR DIEROLF, Lehigh University — Europium doped Gallium Nitride (GaN:Eu) has been recognized as a candidate for the red-emitting active layer in nitride-based light emitting diodes. To better comprehend the excitation energy transfer from the excited GaN host to the Eu ion, we performed an extensive analysis of GaN:Eu and GaN co-doped with Eu and other dopants (Silicon and Magnesium). We determined how various growth parameters manipulated site formations and measured the optical accessibility of the Eu ions within the GaN host and the excitation efficiency of the energy transfer between the host material and the Eu ions. Furthermore, we derived a model for the saturation behavior of the emission of Eu ions within GaN. Our results suggest that the saturation behavior is strongly influenced by different crystal growth specifications and co-dopants.

**9:24AM K7.00004 Hydrogen-carbon complexes and the blue luminescence band in GaN**,<sup>1</sup> DENIS DEMCHENKO, Virginia Commonwealth Univ, IBRAHIMA DIALLO, MICHAEL RESHCHIKOV, Virginia Commonwealth University — The blue luminescence band with a maximum at 3.0 eV and the zero-phonon line at 3.33 eV (labeled BL2) is observed in high-resistivity GaN. Under prolonged ultraviolet (UV) light exposure, the BL2 band transforms into the yellow luminescence (YL) band with a maximum at 2.2 eV. Our calculations using hybrid functionals suggest that the BL2 band is related to a hydrogen-carbon defect complex, most likely  $C_N O_N - H_i$ . The complex creates defect transition level close to the valence band, which is responsible for the BL2 band. Under UV illumination the complex dissociates, leaving as byproduct the source of the YL band ( $C_N O_N$  or  $C_N$ ) and interstitial hydrogen.

**9:36AM K7.00005 Impact of point defects on III-nitride tunnel devices**,<sup>1</sup> DARSHANA WICKRAMARATNE, Materials Department, UC Santa Barbara, JOHN LYONS, Center for Functional Nanomaterials, Brookhaven National Laboratory, CHRIS G. VAN DE WALLE, Materials Department, UC Santa Barbara — Heterostructures using GaN and InGaN are being pursued in designs of tunnel field-effect-transistors (TFETs) to enable low-power switching devices. Point defects and impurities in these heterostructures can adversely affect the performance of these devices through Shockley-Read-Hall (SRH) and Trap-Assisted-Tunneling (TAT) processes. Using first-principles calculations based on a hybrid functional, we calculate the thermodynamic and charge-state switching levels as well as nonradiative recombination rates of point defects and impurities in GaN and InGaN. Gallium vacancies and their complexes, in particular, are found to be potentially detrimental centers. We then investigate how these defects can contribute to SRH and TAT processes in a nitride TFET device.

**9:48AM K7.00006 Density Functional Theory Calculations of Activation Energies for Carrier Capture by Defects in Semiconductors**, N. A. MODINE, A. F. WRIGHT, S. R. LEE, Sandia National Laboratories — The rate of defect-induced carrier recombination is determined by both defect levels and carrier capture cross-sections. Density functional theory (DFT) has been widely and successfully used to predict defect levels, but only recently has work begun to focus on using DFT to determine carrier capture cross-sections. Lang and Henry developed the theory of carrier-capture by multiphonon emission in the 1970s and showed that carrier-capture cross-sections differ between defects primarily due to differences in their carrier capture activation energies. We present an approach to using DFT to calculate carrier capture activation energies that does not depend on an assumed configuration coordinate and that fully accounts for anharmonic effects, which can substantially modify carrier activation energies. We demonstrate our approach for intrinsic defects in GaAs and GaN and discuss how our results depend on the choice of exchange-correlation functional and the treatment of spin polarization. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:00AM K7.00007 First-principles identification of optically active  $Er^{3+}$  centers in GaN**, KHANG HOANG, North Dakota State University — Rare-earth (RE) doped III-nitrides are of great interest for optoelectronic and spintronic applications. The identification of optically active RE centers in these materials has however been challenging, both in experimental and theoretical/computational studies. In this talk, we present a hybrid density functional study of the interaction between the erbium (Er) dopant and wurtzite GaN, including intrinsic point defects and other impurities that may be present in the host material. Particularly, we investigate the structure, energetics, and transition levels of the Er impurity and its complexes with N and Ga vacancies, substitutional C and O impurities, and H interstitials. In light of our results, we identify possible luminescent  $Er^{3+}$  centers in Er-doped GaN and discuss the role of these centers in the excitation of the Er 4f-electron core.

**10:12AM K7.00008 Native defects in GaN: a hybrid functional study**<sup>1</sup>, IBRAHIMA CASTILLO DIALLO, DENIS DEMCHENKO, None — Intrinsic defects play an important role in the performance of GaN-based devices. We present hybrid density functional calculations of the electronic and possible optical properties of interstitial N ( $N_i - N_i$ ), N antisite ( $N_{Ga}$ ), interstitial Ga ( $Ga_i$ ), Ga antisite ( $Ga_N$ ), Ga vacancy ( $V_{Ga}$ ), N vacancy ( $V_N$ ) and Ga-N divacancies ( $V_{Ga}V_N$ ) in GaN. Our results show that the vacancies display relatively low formation energies in certain samples, whereas antisites and interstitials are energetically less favorable. However, interstitials can be created by electron irradiation. For instance, in 2.5 MeV electron-irradiated GaN samples, a strong correlation between the frequently observed photoluminescence (PL) band centered around 0.85 eV accompanied with a rich phonon sideband of ~0.88 eV and the theoretical optical behavior of interstitial Ga is discussed. N vacancies are found to likely contribute to the experimentally obtained green luminescence band (GL2) peaking at 2.24 eV in high-resistivity undoped and Mg-doped GaN.

<sup>1</sup>National Science Foundation (DMR-1410125) and the Thomas F. and Kate Miller Jeffress Memorial Trust.

**10:24AM K7.00009 Native point defects and doping in  $ZnGeN_2$** <sup>1</sup>, DMITRY SKACHKOV, WALTER LAMBRECHT, Case Western Reserve University — A computational study within the framework of density functional theory is presented for native defects and doping in  $ZnGeN_2$ . We study the three types of vacancies  $V_{Zn}$ ,  $V_{Ge}$ ,  $V_N$ , cation antisite defects  $Zn_{Ge}$ ,  $Ge_{Zn}$ , and potential n-type ( $O_N$ ,  $Ga_{Zn}$ ) and p-type  $Ga_{Ge}$  dopants. The cation antisite defects are found to have significantly lower formation energy than the cation vacancies. The charge neutrality condition pins the Fermi level close to the crossing of the  $Zn_{Ge}^{-1}$  acceptor with the  $Ge_{Zn}^{2+}$  donor, and intrinsic p-type doping would result. The  $V_N$  is found to be a rather deep donor.  $Ge_{Zn}$  is found to behave as a shallow donor. Oxygen impurities are found to strongly prefer the  $O_N$  substitutional site and are found to be shallow donors with a very low energy of formation. Energies of formation of  $Ga_{Zn}$  and  $Ga_{Ge}$  are lower than those of the cation antisites. Thus good solubility is expected and these impurities can hence pin the Fermi level at the crossing of the donor  $Ga_{Zn}^{+1}$  with the acceptor  $Ga_{Ge}^{-1}$ , and efficient p-type doping should result.

**10:36AM K7.00010 Fluorescent Defects in Hexagonal Boron Nitride<sup>1</sup>**, ANNEMARIE L. EXARHOS, KAMERON OSER, DAVID A. HOPPER, RICHARD R. GROTE, LEE C. BASSETT, University of Pennsylvania — Mono- and few-layer hexagonal boron nitride (h-BN) can host defects whose electronic states lie deep within the bandgap, similar to the nitrogen-vacancy color center in bulk diamond. Here, we study defect creation in h-BN through irradiation and thermal annealing. We employ confocal photoluminescence (PL) imaging and spectroscopy under various excitation energies on both supported and suspended h-BN to identify and characterize the emission of isolated defect centers. Polarization- and temperature-dependent measurements of the observed PL are used to map out the electronic structure of the defects, enabling optical control of fluorescent defects in h-BN. This knowledge, coupled with the spatial confinement to 2D and the unique electrical, optical, and mechanical properties of h-BN, will enable the use of these defects for quantum sensing and other applications in quantum information processing.

<sup>1</sup>Work supported by the ARO (W911NF-15-1-0589) and NSF MRSEC (DMR-1120901).

**10:48AM K7.00011 Unique stability of neutral interstitial hydrogen in cubic BN and diamond<sup>1</sup>**, JOHN L. LYONS, Center for Functional Nanomaterials, Brookhaven National Laboratory, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — In virtually all semiconductors and insulators, hydrogen interstitial impurities act as negative-U centers, implying that hydrogen is never stable in the neutral charge state. Using hybrid density functional calculations, which are crucial for obtaining accurate properties of defects in semiconductors, we find a different behavior for hydrogen interstitials in diamond and cubic BN. In diamond, we find that hydrogen is a very strong positive-U center, and the neutral charge state of the interstitial is stable over a Fermi-level range of more than 2 eV. In cubic BN, a III-V compound semiconductor with properties similar to diamond, we also find positive-U behavior, though over a much smaller Fermi-level range. We will discuss the electronic-structure origins of this negative-U behavior, and compare with the properties of hydrogen in other materials.

<sup>1</sup>Research done in part at the Center for Functional Nanomaterials, which is a U.S. DOE Office of Science Facility, at Brookhaven National Laboratory under Contract No. DE-SC0012704. Work at UCSB was supported by the National Science Foundation.

## Wednesday, March 16, 2016 8:00AM - 11:00AM – Session K8 DCMP: Superconductivity: Cuprates 304 -

**8:00AM K8.00001 FERMIOLOGY OF THE UNDOPED CUPRATE SUPERCONDUCTOR  $\text{Pr}_2\text{CuO}_4$** , ROSS MCDONALD, LANL, NICHOLAS BREZNAY, UC Berkeley, YOSHIHARU KROCKENBERGER, NTT, KIMBERLY MODIC, ZENGWEI ZHU, LANL, IAN HAYES, NITYAN NAIR, TONI HELM, UC Berkeley, HIROSHI IRIE, HIDEKI YAMAMOTO, NTT, JAMES ANALYTIS, UC Berkeley — Unconventional, high temperature superconductivity consistently appears in the vicinity of suppressed phase transitions, leading to the suggestion that quantum criticality is vital to the physics of these systems. A confounding factor in identifying the role of quantum criticality in the electron-doped cuprates is the competing influence of chemical doping and oxygen stoichiometry. Recent advances in molecular beam epitaxy and preparation of cuprate thin films indicate that annealing can be employed to optimize  $T_c$  via the control of apical oxygen occupancy. For  $\text{Pr}_2\text{CuO}_{4\pm\delta}$  the resulting square planar coordinated structure exhibits a 25 K superconducting transition in the absence of Cerium doping. Using these films and ultra high magnetic fields (>90 T) enables measurements of magnetic quantum oscillations – the first observation of their kind for a cuprate thin film. The oscillation frequency is consistent with the reconstructed Fermi surface of the bulk electron-doped cuprate  $\text{Nd}_{2-x}\text{Ce}_x\text{CuO}_4$ . Furthermore, we observe a mass enhancement, suggesting that tuning these materials via oxygen stoichiometry enables exploration of underlying quantum criticality, providing a new axis with which to explore the physics underlying the electron doped side of the cuprate phase diagram.

**8:12AM K8.00002 Single reconstructed Fermi surface pocket in an underdoped single layer cuprate superconductor**, MUN K. CHAN, National High Magnetic Field Laboratory, Los Alamos National Laboratory, R. D. MCDONALD, B. J. RAMSHAW, K. A. MODIC, National High Magnetic Field Laboratory, Los Alamos National Laboratory, N. BARISIC, Technische Universität Wien, M. GREVEN, University of Minnesota, N. HARRISON, National High Magnetic Field Laboratory, Los Alamos National Laboratory — The observation of a small reconstructed Fermi surface with quantum oscillations in bilayer  $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$  opened a path towards identifying broken symmetry states in underdoped cuprates. However, the multi-frequency spectrum of quantum oscillations and complications from bilayer coupling has rendered such an identification inconclusive. Our high resolution quantum oscillation study of the structurally simpler single layer cuprate  $\text{HgBa}_2\text{CuO}_{4+\delta}$  (Hg1201) reveal a single oscillatory component with no signatures of magnetic breakdown tunneling. From this, we conclude that the reconstructed Fermi surface of Hg1201 is comprised of only a single pocket with negligible c-axis warping. Quantitative modeling of these results allow us to determine that biaxial charge-density-wave order is responsible for Fermi surface reconstruction. We find that the characteristic reconstruction gap is a significant fraction of the pseudogap energy. ‘Criss-crossed’ uniaxial charge stripes is ruled out as a viable alternative to biaxial order within a  $\text{CuO}_2$  plane for Hg1201.

**8:24AM K8.00003 Crystal Growth and Electronic Raman Scattering Study of Model High- $T_c$  Cuprate  $\text{HgBa}_2\text{CaCu}_2\text{O}_{6+\delta}$** , LICHEN WANG, YUAN LI, XIANGPENG LUO, JIARUI LI, School of Physics, Peking University, YUAN LI'S GROUP IN ICQM TEAM — In this talk, I will report our recent progress on crystal growth of  $\text{HgBa}_2\text{CaCu}_2\text{O}_{6+x}$  (Hg1212), which possesses a simple tetragonal crystal structure and the highest ambient-pressure  $T_c$  (128 K) among all cuprate superconductors with two  $\text{CuO}_2$  sheets in the primitive cell. Improvement in single-crystal synthesis was made possible by using self-designed high-pressure furnaces and a two-layer encapsulation method, and we demonstrate that the hole concentration can be homogeneously tuned in the underdoped region by post-growth annealing. Our electronic Raman scattering experiments reveal that the maximum of the d-wave superconducting gap increases from single-layer  $\text{HgBa}_2\text{CuO}_{4+x}$  to double-layer Hg1212. In the same spectra, it is found that the characteristic energy of spin excitations, as manifested by the energy of the two-magnon signal, also increases in a nearly proportional fashion. This result is consistent with the idea that magnetic interactions are closely related to the Cooper pairing mechanism.

**8:36AM K8.00004 Effects of pressure and disorder on superconductivity in  $\text{Ti}_2\text{Ba}_2\text{Ca}_{n-1}\text{Cu}_n\text{O}_{2n+4+\delta}$  ( $n=2,3$ )**, JIAN-BO ZHANG, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, VIKTOR STRUZHUKIN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, U.S.A., WENGE YANG, HO-KWANG MAO, Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, HAI-QING LIN, Beijing Computational Science Research Center, Beijing 100089, China, YONG-CHANG MA, School of Materials Science and Engineering, Tianjin University of Technology, Tianjin 300384, China, NAN-LIN WANG, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — The structural, vibrational, and superconducting properties of nearly optimally doped  $\text{Ti}_2\text{Ba}_2\text{Ca}_{n-1}\text{Cu}_n\text{O}_{2n+4+\delta}$  ( $n=2,3$ ) single crystals are studied at high pressures. While the superconducting transition temperature  $T_c$  of the bilayer system exhibits a parabolic behavior with a maximum around an optimal pressure level, its increased path has a kink in the trilayer compound, indicating a joint effect from the inner  $\text{CuO}_2$  plane. The latter is further supported by the appearance of the two additional Raman modes. At higher pressures, we observe the sudden increase of the full width at half maximum of some lattice modes as well as the anomaly of the lattice parameters at certain pressure. These together contribute the enhanced disorder and the  $T_c$  reduction accordingly. We thus are able to distinguish the contribution to  $T_c$  from the intrinsic pressure variables, disorder, and the  $\text{CuO}_2$  plane number and type in this layered family.

**8:48AM K8.00005 Bulk superconductivity at 84 K in the strongly overdoped regime of cuprates**, ANDREA GAUZZI, YANNICK KLEIN, IMPMC-Sorbonne Universities, ELVEZIO MORENZONI, Paul Scherrer Institut, MIKKO NISULA, MAARIT KARP-PINEN, Aalto University, MASSIMO MAREZIO, CRESTA-CNRS, THEODORE H. GEBALLE, Stanford University — By means of magnetic susceptibility, specific heat and muon-spin relaxation ( $\mu$ SR) measurements, we report on bulk superconductivity at 84 K in high-pressure oxidized  $\text{Cu}_{0.75}\text{Mo}_{0.25}\text{Sr}_2\text{YCu}_2\text{O}_{7.54}$ . A record short apical Cu-O distance and a large excess of electronic specific heat at low temperature give evidence of hole overdoping,  $p \approx 0.43$  hole/Cu, well beyond the superconducting dome relating  $T_c$  and  $p$ , considered universally valid for cuprates, where a normal Fermi liquid behavior is expected. On the other hand, the superfluid density measured by means of  $\mu$ SR is similar to that of optimally doped  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ , which indicates that the extra-holes do not contribute to superconductivity, thus leading to a phase separation between superconducting and normal carriers, or that Cooper pairs are strongly localized. In both cases, the unexpected observation of high  $T_c$  in the strongly overdoped regime constitutes a further open issue for the theoretical explanation of superconductivity in cuprates.

**9:00AM K8.00006 Enhanced Surface Superconductivity in Single Crystal  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$** , IVAR MARTIN, Argonne National Laboratory, XIAN YANG TEE, Nanyang Technological University, Singapore, TOSHIMITSU ITO, TOMOHARU USHIYAMA, YASUhide TOMIOKA, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, CHRISTOS PANAGOPOULOS, Nanyang Technological University, Singapore — Surfaces of materials often possess properties which are distinctly different from their bulk. The atomic structure can develop intricate new patterns due to surface reconstruction and the electronic properties can be very distinct, as most dramatically manifested in topological insulators. However, more subtle collective phenomena such as superconductivity are not as strongly affected by the presence of surfaces. Here, we report an unprecedented finding of enhanced superconductivity at the ab-plane surface of high- $T_c$  cuprate  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$ . Spatially-resolved electrical and thermoelectric transport measurements detect a superconducting surface below the transition temperature  $T_{cs}$  which is considerably higher than the bulk  $T_c$ . The effect is pronounced in the region of charge carrier doping ( $x$ ) with strong spin-charge stripe correlations. Notably, for  $x = 0.12$ ,  $T_{cs}$  reaches 36 K, exceeding even the highest reported bulk  $T_c$  in this material for any doping. Possible interpretations for the novel effect are discussed.

**9:12AM K8.00007 Vortex Lattice Formation in High Magnetic Fields in an Underdoped Single Crystal of Hg1201 from  $^{17}\text{O}$  NMR**, JEONGSEOP LEE, YIZHOU XIN, W. P. HALPERIN, Northwestern University, A. P. REYES, P. L. KUHN, National High Magnetic Field Laboratory — The vortex lattice in  $\text{HgBa}_2\text{CuO}_{4+\delta}$  forms at a vortex melting temperature,  $T_v$ , typically  $\sim 40\text{K}$  for underdoped crystals with a hole doping  $\sim 0.11$ . We present our results from  $^{17}\text{O}$  NMR for investigation of the vortex lattice as a function of external magnetic field up to 30 T and temperature as low as 5 K. The vortex contribution to the NMR linewidth can be separated from inhomogeneous broadening by deconvolution of the normal state spectra which was measured separately above,  $T_v$ . The vortex melting temperature was measured for two underdoped samples marked by the onset of extra linewidth broadening due to the inhomogeneous magnetic field distribution from the solid vortex lattice consistent with transverse relaxation measurements. We have found evidence for a change in the vortex lattice symmetry as a function of external fields. This work was supported by the DOE BES under grant No. DE-FG02-05ER46248 and the NHMFL through the NSF and State of Florida. [1] V. F. Mitrovic, *et al.*, Nature, **413**, 501-504 (2001).

**9:24AM K8.00008 Broken bond symmetry assists stripe pinning in superconducting  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$** <sup>1</sup>, JOHN TRANQUADA, Brookhaven Natl Lab, H. JACOBSEN, U. Copenhagen, I.A. ZALIZNYAK, M. HUECKER, G.D. GU, BNL, A.T. SAVICI, B. WINN, ORNL, S. CHANG, NCNR — There has been evidence for quite some time for some degree of charge and spin stripe order in  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  (LSCO). This has been a bit surprising as the crystal structure is supposed to lack the anisotropic Cu-O bonds that lead to robust stripe pinning in  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$ . Using neutron scattering measurements on the HYSPEC instrument at the Spallation Neutron Source, we have discovered evidence for broken bond symmetry and strong associated lattice fluctuations in an LSCO crystal with  $x = 0.07$  [1]. The broken bond symmetry occurs within the orthorhombic phase. We also observe quasielastic incommensurate spin excitations that coexist with the bulk superconductivity, suggesting some degree of pair-density-wave order in the superconducting state. [1] H. Jacobsen *et al.*, Phys. Rev. B (accepted); arXiv:1508.02429.

**9:36AM K8.00009 Neutron scattering study of the antiferromagnetic response of  $\text{HgBa}_2\text{CuO}_{4+\delta}$** <sup>1</sup>, YANG TANG, MUN CHAN, CHELSEY DOROW, MIKE VEIT, YANG GE, MARTIN GREVEN, University of Minnesota, LUCILE MANGIN-THRO, YVAN SIDIS, PHILIPPE BOURGES, Laboratoire Louis Brillouin, France, XUDONG ZHAO, Jilin University, China, PAUL STEFFENS, Institut Laue Langevin, France, ANDREW CHRISTIANSON, DOUGLAS ABERNATHY, Oak Ridge National Laboratory, JITAE PARK, Forschungs-Neutronenquelle Heinz Maier-Leibnitz — Antiferromagnetic correlations have been argued to be the cause of the  $d$ -wave superconductivity and of the pseudogap phenomena exhibited by the cuprates. Although neutron scattering experiments of the antiferromagnetic response have been reported for a number of cuprates, results for structurally simple  $\text{HgBa}_2\text{CuO}_{4+\delta}$  (Hg1201) have begun to emerge only recently. Specifically, we have found for moderately-doped Hg1201 ( $T_c \approx 71\text{ K}$ , pseudogap temperature  $T^* \approx 305\text{ K}$ ) that the two most prominent features of the magnetic spectrum reported for other cuprates are absent: the X-shaped 'hourglass' response and the resonance mode in the superconducting state. Instead, the response of Hg1201 is Y-shaped, gapped, and significantly enhanced below  $T^*$  [1]. Here we will discuss our ongoing efforts to understand the doping dependence of the AF response in Hg1201. [1] M. K. Chan *et al.*, arXiv:1402.4517.

<sup>1</sup>Work supported by the DOE Office of Basic Energy Sciences.

**9:48AM K8.00010 Dynamics of quasiparticles and antiferromagnetic correlations in electron-doped cuprate  $\text{La}_{2-x}\text{Ce}_x\text{CuO}_{4\pm\delta}$  (LCCO)**, I. M. VISHIK, F. MAHMOOD, Z. ALPICHSEV, Massachusetts Institute of Technology, J. S. HIGGINS, R. L. GREENE, University of Maryland, N. GEDIK, Massachusetts Institute of Technology — We studied quasiparticle dynamics in thin films of the electron-doped cuprate  $\text{La}_{2-x}\text{Ce}_x\text{CuO}_4$  (LCCO) via optical pump-probe spectroscopy. In underdoped LCCO, the quasiparticle recombination dynamics imply a nodeless superconducting gap, which can be realized with  $d_{x^2-y^2}$  symmetry if a nodal hole-pocket is absent. Meanwhile, optimally doped LCCO shows recombination dynamics consistent with line nodes. Above  $T_c$ , fluence-dependent dynamics indicate a fully-formed gap in the density of states, which is associated with antiferromagnetic correlations, and limits can be placed on the correlation length and time.

**10:00AM K8.00011 A close look at antiferromagnetic phase boundary in multidimensional phase diagram of electron-doped copper oxide**, HESHAN YU, GE HE, Chinese Academy of Sci (CAS), ZIQUAN LIN, Huazhong University of Science & Technology, JIE YUAN, BEIYI ZHU, YI-FENG YANG, TAO XIANG, Chinese Academy of Sci (CAS), FEO.V. KUSMARTSEV, Department of Physics, Loughborough University, LIANG LI, JUNFENG WANG, Huazhong University of Science & Technology, KUI JIN, Chinese Academy of Sci (CAS) — In copper-oxide superconductors, spin fluctuations play a predominant role in electron pairing with electron dopants yet composite orders veil the nature of superconductivity for hole-doped family. However, in electron-doped ones the ending point of AFM is still in controversy for different probes or its sensitivity to oxygen content. Here, by carefully tuning the oxygen content, a systematic study of Hall signal and magnetoresistivity up to 58 Tesla on optimally doped  $\text{La}_{2-x}\text{Ce}_x\text{CuO}_{4\pm\delta}$  ( $x = 0.10$ ) thin films identifies two characteristic temperatures at 62.5 K (error is 7.5 K) and 25 K (error is 5 K). The former is quite robust whereas the latter becomes flexible with increasing magnetic field, thereby linked to two- and three-dimensional AFM, evident from the multidimensional phase diagram as a function of oxygen as well as Ce dopants. Consequently, the observation of extended AFM phase in contrast to  $\mu\text{SR}$  probe corroborates an elevated critical doping in field, providing an unambiguous picture to understand the interactions between AFM and superconductivity.

**10:12AM K8.00012 Superconductivity and planar hole densities in the cuprates from NMR**, JUERGEN HAASE, MICHAEL JURKUTAT, University of Leipzig, DAMIAN RYBICKI, AGH University of Science and Technology — We show how nuclear magnetic resonance (NMR) of  $^{63}\text{Cu}$  and  $^{17}\text{O}$  provides a quantitative measure of the charge distribution in the ubiquitous  $\text{CuO}_2$  plane, the common structural feature of cuprate physics. The various materials are found to differ significantly in the local charge distribution, while the total charge per  $\text{CuO}_2$  matches expectation from stoichiometry. Using the local charges on Cu and O measured by NMR, a new three-dimensional cuprate phase diagram is drawn that consistently encompasses all cuprate materials. These appear ordered according to their maximum  $T_c$ . It is the sharing of the inherent Cu hole with O that sets an upper limit for  $T_c$ , and it correlates with the superfluid density measured by  $\mu\text{SR}$ , over all cuprate families.

**10:24AM K8.00013 Change of carrier density at the pseudogap critical point of a cuprate superconductor**, LOUIS TAILLEFER, SVEN BADOUX, GAEL GRISSONNANCHE, NICOLAS DOIRON-LEYRAUD, University of Sherbrooke, Sherbrooke, Canada, WOJCIECH TABIS, FRANCIS LALIBERTE, BAPTISTE VIGNOLLE, DAVID VIGNOLLES, JEROME BEARD, CYRIL PROUST, LNCMI, Toulouse, France, DOUG BONN, RUIXING LIANG, WALTER HARDY, University of British Columbia, Vancouver, Canada — The pseudogap is a central puzzle of cuprate superconductors. Its connection to the Mott insulator at low doping  $p$  remains ambiguous and its relation to the charge order that reconstructs the Fermi surface at intermediate  $p$  is still unclear. Here we use measurements of the Hall coefficient in magnetic fields up to 88 T to show that Fermi-surface reconstruction by charge order in  $\text{YBa}_2\text{Cu}_3\text{O}_y$  ends sharply at a critical doping  $p = 0.16$ , distinctly lower than the pseudogap critical point at  $p^* = 0.19$ . This shows that pseudogap and charge order are separate phenomena. We then find that the change of carrier density from  $n = 1 + p$  in the conventional metal at high  $p$  to  $n = p$  in the lightly doped regime at low  $p$  starts at  $p^*$ . This shows that pseudogap and antiferromagnetic Mott insulator are linked.

**10:36AM K8.00014 Charge order and the pseudogap in the underdoped cuprates: a quantum oscillation study**, YU-TE HSU, MATE HARTSTEIN, Cavendish Laboratory, University of Cambridge, NEIL HARRISON, MUN CHAN, KIMBERLY MODIC, Los Alamos National Laboratory, JUAN PORRAS, TOSHINAO LOEW, MATHIEU LE TACON, BERNHARD KEIMER, Max Planck Institute for Solid State Research, SUCHITRA SEBASTIAN, Cavendish Laboratory, University of Cambridge — I will present quantum oscillation results on the underdoped copper-oxide superconductors to address the question of the interplay of the charge ordered ground state with the pseudogap. Specifically we experimentally distinguish between the two cases where charge order reconstructs a large paramagnetic Fermi surface predicted by band structure, or where charge order reconstructs a truncated Fermi surface where the density of states is restricted to the nodal region, as observed in the pseudogap state.

**10:48AM K8.00015 Anomalous suppression of energy gap near the antinode in Bi2212**, ALFRED ZONG, Massachusetts Institute of Technology, SUDI CHEN, YU HE, Stanford University, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, SHIGEYUKI ISHIDA, YOSHIYUKI YOSHIDA, AIST, Japan, ZHI-XUN SHEN, Stanford University — An energy gap holds special importance in the study of high- $T_c$  superconductors (HTSC) as it is often associated with the order parameter of complex phases in these materials. In hole-doped cuprates around optimal doping, past experiments suggest the presence of two momentum-anisotropic energy gaps originating from  $d$ -wave superconductivity and pseudogap. Here we report an anomalous energy gap suppression near the antinode in overdoped Bi2212 that persists from  $T \ll T_c$  to  $T > T_c$ . Our data imply that the suppression may not originate from pair-breaking scattering, but can be phenomenologically described by higher harmonics of a  $d$ -wave gap. It is important to uncover the origin of this suppression, which is instrumental in understanding the complex landscape of interacting order parameters in cuprate HTSCs.

Session K9 DMP: Superlattices & Nanostructures (Wires, Dots, etc): Optical Phenomenona

305 - Andrey Kiselev, HRL Laboratories, LLC

**8:00AM K9.00001 Spin polarization and spatial texture in quantum dots**, GARNETT BRYANT, National Institute of Standards and Technology — Spins in semiconductor quantum dots (QD) are promising qubits. Zeeman-split states form two-level systems with pseudo spin 1/2. Rotations of these qubits typically use magnetic fields B. However, this pseudo spin is not the physical spin of the state. Due to confinement, strain and strong spin-orbit coupling, the physical spin can be strongly mixed and spatially varying in the QD. We use atomistic tight-binding theory for strained InAs/GaAs and strain-free GaAs/AlAs QDs to investigate the influence of strain, QD geometry and magnetic field orientation on spin polarization and spatial texturing. For electrons, with weak spin-orbit coupling, spin is almost fully polarized and nearly aligned with B. For holes, with strong spin-orbit coupling, there can be incomplete spin polarization and spin locked to the QD axis, rather than B, even for B far off the QD axis. Spatial spin texturing occurs on the atomic scale with spin flipping between nearby atoms. In the Voigt configuration, hole spin remains nearly locked locally to the QD axis, but with opposite orientation on opposite sides of the dot, creating a spin-dipole. The influence of this spin polarization and spatial texturing on spin manipulation, exchange interaction and decoherence will be discussed.

**8:12AM K9.00002 Photon Statistics of Quantum Dot Resonance Fluorescence under the Influence of an Above Band-Gap Laser**, DISHENG CHEN, GARY LANDER, KYLE KROWPMAN, West Virginia University, GLENN SOLOMON, Joint Quantum Institute, NIST & University of Maryland, Gaithersburg, MD, EDWARD FLAGG, West Virginia University — We study the statistical behavior of resonance fluorescence from self-assembled InAs quantum dots (QDs) as a function of the density of free charge carriers introduced by an above band-gap laser. Second-order correlation measurements show bunching behavior that changes with above-band laser power and is absent in purely above-band excited emission. Resonant photoluminescence excitation spectra indicate that the QD experiences discrete spectral shifts and continuous drift due to changes in the local charge environment. These spectral changes, combined with tunneling of charges from the environment to the QD, provide an explanation of the bunching observed in the correlations.

**8:24AM K9.00003 Hole spins in quantum dot molecules: novel tuning by GaBiAs barriers**, JACKSON FLOWERS, GARNETT BRYANT, National Institute of Standards and Technology, MATTHEW DOTY, University of Delaware — Hole spins in semiconductor quantum dots (QD) are promising qubits. Tunneling in vertical quantum dot molecules (QDM) provides additional freedom to use fields to manipulate hole g-factors and induce spin mixing. Interdot barriers made from GaBiAs should provide novel opportunities to further engineer these hole spin properties, because heavy- and light-holes in GaBiAs are modified by the Bi concentration without affecting conduction electrons or split off bands. For low Bi concentrations, GaBiAs provides a lower barrier for hole tunneling, allowing hole tunneling more comparable to electron tunneling and enhancing opportunities for g-factor modification. We use atomistic tight-binding theory for InAs QDMs with GaBiAs in the interdot barrier to assess the utility of this barrier material. We model the alloy barrier regions both with the virtual crystal approximation and with random realizations of atomic configurations for the alloy region in the barrier. Results are presented for electron and hole energies in QDMs with GaBiAs barriers as a function of applied electric and magnetic fields. These results allow us to quantify g-factor modification and hole-spin mixing in asymmetric structures to show how different GaBiAs barrier configurations modify hole spin physics in QDMs.

**8:36AM K9.00004 Tunable emission from InAs quantum dots gated with graphene<sup>1</sup>**, LAURA KINNISCHTZE, University of Rochester, Department of Physics & Astronomy, KENNETH GOODFELLOW, University of Rochester, Institute of Optics, CHITRALEEMA CHAKRABORTY, University of Rochester, Materials Science, YIMING LAI, ANTONIO BADOLATO, University of Rochester, Department of Physics & Astronomy, NICK VAMIVAKAS, University of Rochester, Institute of Optics — We demonstrate Stark shifted photo-luminescence from InAs quantum dots (QD) using an n-i-Schottky diode where graphene has been used as the Schottky barrier material. This hybrid photonic device is motivated by the need for tunable single photon sources with high flux and storage capabilities. Photonic crystal nanocavities decorated with a single QD provide a rich environment for coupling spins and photons, in addition to accessing cavity quantum electrodynamic physics. Methods currently used for electrically tuning the QD inside the cavity suffer from a loss of the cavity quality factor, or high leakage currents in the diode which impacts the spin-photon coupling of the device. Our measurements are a first step towards using a graphene flake to electrically tune the emission of a strongly coupled QD-cavity system.

**8:48AM K9.00005 Electronic Structure and Optical Properties of Spectrally Uniform Nanotemplate-Directed InGaAs/GaAs Quantum Dots in Regular Arrays.<sup>1</sup>**, JIEFEI ZHANG, Dept. of Physics and Astronomy, Univ. of Southern California, SIYUAN LU, IBM Thomas J. Watson Research Center, Yorktown Heights, ANUPAM MADHUKAR, Mork Family Dept. of Chemical Engineering and Materials Science — Spectrally uniform single photon emitters in spatially regular arrays are highly sought for their potential use in quantum information processing systems. We have utilized nanotemplate-directed on-site growth of quantum dots (NTQDs) approach[1] that exploits engineered surface stress to provide preferred direction for adatom migration during growth to synthesize regular arrays of single InGaAs/GaAs QDs of controlled flat-top pyramidal shape residing on GaAs(001) nanomesa arrays[2]. The GaAs/In<sub>0.5</sub>Ga<sub>0.5</sub>As/GaAs NTQDs reported here are spectrally uniform within 5nm over 1000um<sup>2</sup>, order of magnitude better than island and colloidal quantum dots. Photoluminescence (PL) and PL excitation studies of individual NTQDs shows that first excited electron state and dense hole states are, respectively, ~40meV and ~10meV higher than ground state. Electrons escape out of QDs through thermally activated tunneling to first excited electron state, which is also manifest in the temperature-dependent behavior of the QD PL decay time. Suitability of such arrays of NTQDs as single photon emitter array will be discussed. [1] A. Konkar, et. al., Jour. Cryst. Growth, 150, 311 (1995) [2] J. Zhang et. al., Jour. Vac. Sc. Tech. B32, 02C106 (2014)

<sup>1</sup>work supported by AFOSR and ARO

**9:00AM K9.00006 Localized magnetoplasmons in quantum dots: Scrutinizing the eligibility of FIR, Raman, and electron energy-loss spectroscopies**, M. KUSHWAHA, Rice University — We report on a one-component, quasi-zero dimensional, quantum plasma exposed to a parabolic potential and an applied magnetic field in the symmetric gauge. If the size of such a system as can be realized in the semiconducting quantum dots is on the order of the de-Broglie wavelength, the electronic and optical properties become highly tunable. Then the quantum size effects challenge the observation of many-particle phenomena such as the magneto-optical absorption, Raman intensity, and electron-energy-loss spectrum. An exact analytical solution of the problem leads us to infer that these many-particle phenomena are, in fact, dictated by the generalized Kohn's theorem in the long-wavelength limit. Maneuvering the confinement and/or the magnetic field furnishes the resonance energy capable of being explored with the FIR, Raman, or electron-energy-loss spectroscopy. This implies that either of these probes should be competent in observing the localized magnetoplasmons in the system. A deeper insight into the physics of quantum dots is paving the way for their implementation in such diverse fields as quantum computing and medical imaging<sup>1</sup>. 1. M.S. Kushwaha, Unpublished.

**9:12AM K9.00007 Influence of Indium Segregation on InGa<sub>N</sub>/Ga<sub>N</sub> QD Band Alignment**, CHRISTIAN GREENHILL, ALEXANDER CHANG, JENNA WALRATH, T. FROST, P.K. BHATTACHARYA, RACHEL GOLDMAN, University of Michigan — InGa<sub>N</sub>/Ga<sub>N</sub> QD systems are promising for optoelectronic devices, such as photovoltaics, light emitters, and lasers due to their high mobility, high absorption coefficient, and direct wide bandgap. However, indium segregation within InGa<sub>N</sub> quantum structures can lead to inefficiencies in device performance and has not been investigated in InGa<sub>N</sub>/Ga<sub>N</sub> QD systems. Using scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS), we have investigated the influence of indium nanostructure on the band structure of single or multi-layered InGa<sub>N</sub>/Ga<sub>N</sub> QDs. We observe a mixture of indium mounds and QDs in the single layered InGa<sub>N</sub>/Ga<sub>N</sub> QD system, where local STS measurements suggest a gradient in indium concentration across the indium mound. Furthermore, STM imaging suggests a higher density of InGa<sub>N</sub>/Ga<sub>N</sub> QDs for multi-layered InGa<sub>N</sub>/Ga<sub>N</sub> QDs compared to that of a single layered InGa<sub>N</sub>/Ga<sub>N</sub> QDs, where STS measurements suggest indium clustering within InGa<sub>N</sub> QDs. We discuss the comparison of the band structure of InGa<sub>N</sub>/Ga<sub>N</sub> mounds vs. QD systems.

**9:24AM K9.00008 Droplet heteroepitaxy of zinc-blende vs. wurtzite Ga<sub>N</sub> quantum dots**, C REESE, S JEON, Department of Materials Science and Engineering - University of Michigan, T HILL, C JONES, Department of Physics - University of Michigan, S SHUSTERMAN, Soreq Nuclear Research Center, Y YACOBY, The Hebrew University of Jerusalem, R CLARKE, H DENG, Department of Physics - University of Michigan, RS GOLDMAN, Department of Materials Science and Engineering - University of Michigan — We have developed a Ga<sub>N</sub> droplet heteroepitaxy process based upon plasma-assisted molecular-beam epitaxy. Using various surface treatments and Ga deposition parameters, we have demonstrated polycrystalline, zinc-blende (ZB), and wurtzite (WZ) Ga<sub>N</sub> quantum dots (QDs) on Si(001), r-Al<sub>2</sub>O<sub>3</sub>, Si(111), and c-GaN substrates. For the polar substrates (i.e. Si(111) and c-GaN), high-resolution transmission electron microscopy and coherent Bragg rod analysis reveals the formation of coherent WZ Ga<sub>N</sub> QDs with nitridation-temperature-dependent sizes and densities. For the non-polar substrates (i.e. Si(001) and r-Al<sub>2</sub>O<sub>3</sub>), QDs with strong near-band photoluminescence emission are observed and ZB Ga<sub>N</sub> QD growth on Si(001) is demonstrated for the first time.

**9:36AM K9.00009 Hydrothermal Synthesis and Photoluminescence of Boron Nitride Quantum Dots**, HONGLING LI, ROLAND YINGJIE TAY, SIU HON TSANG, EDWIN HANG TONG TEO, Nanyang Tech Univ — Boron nitride quantum dots (BNQDs), as a new member of heavy metal-free quantum dots, have attracted great interest owing to its unique structure as well as fascinating physical/chemical properties. However, it is still a challenge to controllably synthesize high quality BNQDs with high quantum yield (QY), uniform size and strong luminescence. Here we present a facile and effective approach to controllably fabricate BNQDs by sputter-solvothermal technique. Encouragingly, the as-prepared BNQDs possess strong blue luminescence with high QY of up to 19.5%, which can be attributed to the synergic effect of size, surface chemistry and edge defects. In addition, the size of the BNQDs could be controlled with a narrow size distribution of 1.32 nm and the smallest average size achieved is 2.62 nm with an average thickness of ~3 atomic layers. Furthermore, the as-prepared BNQDs are non-toxic to cells and show nanosecond-scaled lifetimes and little photobleaching effect. Therefore, it is believed that BNQDs are promising as one of the novel heavy metal-free QDs for multi-purpose applications in a range of fields. Moreover, this synthesis concept is expected to open a new window to controllably prepare other heavy metal-free QDs, as well as to understand their luminescence mechanism.

**9:48AM K9.00010 Insight into Factors Affecting the Presence, Degree, and Temporal Stability of Fluorescence Intensification on ZnO Nanorod Ends**, MANPREET SINGH, Georgetown University, RUIBIN JIANG, The Chinese University of Hong Kong, DANIEL S. CHOI, Georgetown University, JIANFANG WANG, The Chinese University of Hong Kong, JONG-IN HAHM, Georgetown University, GU TEAM, CUHK TEAM — We present a combined experimental and simulation study identifying the key physical and optical parameters affecting the presence and degree of fluorescence intensification measured on zinc oxide nanorod (ZnO NR) ends. We aim to provide an insight into the unique optical phenomenon of fluorescence intensification on NR ends (*FINE*) through experimental and simulation approaches and to elucidate the key factors affecting the occurrence, degree, and temporal stability of *FINE*. Specifically, we examined the effect of the length, width, and growth orientation of single ZnO NRs on the NR-enhanced biomolecular emission profile after decorating the NR surfaces with different amounts and types of fluorophore-coupled protein molecules. We quantitatively and qualitatively profiled the biomolecular fluorescence signal from individual ZnO NRs as a function of both position along the NR long axis and time. Additionally, we employed finite-difference time-domain methods to examine both near- and far-field emission characteristics when considering various scenarios of fluorophore locations, polarizations, spectroscopic characteristics, and NR dimensions. Our efforts may provide a deeper insight into the unique optical phenomenon of *FINE* and further be beneficial to highly miniaturized biodetection favoring the use of single ZnO NRs.

**10:00AM K9.00011 Scattering Intensity and Directionality Probed Along Individual Semiconducting Oxide Nanorods with Precisely Controlled Light Polarization and Nanorod Orientation**, DANIEL S. CHOI, MANPREET SINGH, JONG-IN HAHM, Georgetown University — We elucidate the light-matter interaction properties of individual semiconducting oxide nanorods (NRs) with a monochromatic beam of linearly polarized light that scatters elastically from the NRs by performing forward scattering in a dark-field setting. Specifically, individual NRs of ZnO, SnO<sub>2</sub>, ITO, and ZTO are probed. We precisely control the electric field vector of the incident light and the NR orientation within the plane of light interaction, and spatially resolve the scattering response from different interaction points along the NR long axis. We then discern the effects of light polarization, analyzer angle, and NR orientation on the intensity and directionality of the optical responses both qualitatively and quantitatively along the length of the single NRs. We identify distinctive, forward scattering profiles from individual NRs subject to various incident light polarizations and NR orientations. Fundamental light interaction behavior of the NRs is likely to govern their functional outcomes in photonics, optoelectronics, and sensor devices. Hence, our efforts providing much needed insight into unique optical responses from individual 1D semiconducting oxide nanomaterials can be highly beneficial in developing next-generation optoelectronic systems and optical biodetectors with improved device efficiency and sensitivity.

**10:12AM K9.00012 Exploring the Nature of Exciton Localization in Quasi One-Dimensional GaAs/AlGaAs Quantum Well Tube Nanowires<sup>1</sup>**, HOWARD JACKSON, BEKELE BADADA, TENG SHI, LEIGH SMITH, Department of Physics, University of Cincinnati, CHANGLIN ZHENG, Monash Centre for Electron Microscopy, Monash University, JOANNE ETHERIDGE, Monash Centre for Electron Microscopy and Department of Materials Engineering, Monash University, NIAN JIANG, HOE TAN, CHANNUPATI JAGADISH, Department of Electronic Materials Engineering, Australian National University — We explore the nature of exciton localization in single GaAs/AlGaAs nanowire quantum well tube (QWT) devices using photocurrent (PC) spectroscopy combined with simultaneous photoluminescence (PL) and photoluminescence excitation (PLE) measurements. Excitons confined to GaAs quantum well tubes of 8 and 4 nm widths embedded into an AlGaAs barrier are seen to ionize at high bias. Spectroscopic signatures of the ground and excited states confined to the QWT seen in PL, PLE and PC data are consistent with simple numerical calculations. The demonstration of good electrical contact with the QWTs enables the study of Stark effect shifts in the sharp emission lines of excitons localized to quantum dot-like states within the QWT. Atomic resolution cross-sectional TEM measurements, an analysis of the temperature dependence of PL and time-resolved PL as well as the quantum confined Stark effect of these dots provide insights into the nature of the exciton localization in these nanostructures.

<sup>1</sup>We acknowledge the financial support of NSF DMR 1507844, DMR 151373 and ECCS 1509706 and the Australian Research Council.

**10:24AM K9.00013 Surface sensitivity to dielectric environment of optical and magneto-optical properties in magnetoplasmonic nanodisks**, CÉSAR AURELIO HERREÑO-FIERRO<sup>1</sup>, Universidad Distrital F. J. de C., EDGAR J. PATINO, Universidad de los Andes, GASPAS ARMELLES, ALFONSO CEBOLLADA, Instituto de Microelectrónica de Madrid (CNM-CSIC) — The optical, ellipsometric and magneto-optical surface sensitivity to dielectric environment of magnetoplasmonic nanodisks is experimentally studied. Here the shift of the corresponding spectral structures as a function of the thickness of a coating SiO<sub>2</sub> layer is characterized. Our results reveal that the so called pseudo-Brewster Angle, easily identified in the ellipsometric phase ( $\Delta$ ) spectrum, is up to four times more sensitive than the conventional features used in Surface Plasmon Resonance (SPR) based sensors. These results highlight the need of investigating the factual implementation of this technique to develop improved ellipsometric-phase based transducers for bio-chemical sensing purposes.

**10:36AM K9.00014 Size and Morphology Dependent Raman Scattering**, XIANGHUA ZENG, CHUAN HU, JIEYA CUI, Yangzhou Univ — Through thermal evaporation, ripple-like CdS nanobelts (NBs) and ZnS:Al nanowires (NWs) were prepared. Room-temperature photoluminescence spectra showed two luminescence peaks at approximately 513 and 725 nm from the ripple-like CdS NBs, the two peaks can be ascribed to the near band gap transition and defect emissions, respectively. Raman spectra showed that the intensities of the longitudinal optical (LO) phonon and its replica peaks from the ripple-like CdS NBs are more than 4 times larger than those from the normal CdS NBs. The Huang–Rhys parameter *S* calculated from the intensity ratio of the 2LO to 1LO phonon increases from 3.21 to 3.56 for normal and ripple-like NBs, which is indicative of a strong exciton-phonon coupling interaction dominated mainly by a Fröhlich interaction through the charge transfer. The results from the ZnS:Al NWs exhibited that the morphology of ZnS:Al NWs greatly influences on the Raman scattering, while the Al-dopant concentration has a smaller effect on the Raman scattering. The Raman scattering intensity of the pine leaf-like morphological ZnS:Al NWs displayed more than eight times larger than the bulk one, which can be explained as a polarization dependent behavior and a multiple scattering.

**10:48AM K9.00015 Multiple-pulse superradiance from an optically induced harmonic confinement in a semiconductor microcavity**<sup>1</sup>, CHIH WEI LAI<sup>2</sup>, WEI XIE<sup>3</sup>, FENG-KUO HSU, Michigan State University, YI-SHAN LEE, SHENG-DI LIN, National Chiao Tung University — We report the observation of macroscopic harmonic states in an optically induced confinement in a highly photoexcited semiconductor microcavity at room temperature. The spatially photomodulated refractive index changes result in the visualization of harmonic states in a micrometer-scale optical potential at quantized energies up to 4 meV even in the weak-coupling plasma limit. We characterize the time evolution of the harmonic states directly from the consequent pulse radiation and identify sequential multiple  $\sim 10$  ps pulse lasing with different emitting angles and frequencies. Such multiple-pulse coherent radiation is attributed to superradiance from correlated electron-hole pairs in a high-density plasma.

**Session K11 DMP GMAG: Electronic Structure and Magnetism in Fe-based Superconductors**

**II** 307 - Emilia Morosan, Rice University

**8:00AM K11.00001 Orbital-dependent electron correlation effects in iron-based superconductors**, MING YI, Univ of California - Berkeley — The iron chalcogenide superconductors constitute arguably one of the most intriguing families of the iron-based high temperature superconductors given their ability to superconduct at comparable temperatures as the iron pnictides, despite the lack of similarities in their magnetic structures and Fermi surface topologies. In particular, the lack of hole Fermi pockets at the Brillouin zone center posts a challenge to the previous proposal of spin fluctuation mediated pairing via Fermi surface nesting. In this talk, using angle-resolved photoemission spectroscopy measurements, I will present evidence that show that instead of Fermi surface topology, strong electron correlation observed in electron bandwidth is an important ingredient for superconductivity in the iron chalcogenides. Specifically, I will show i) there exists universal strong orbital-selective renormalization effects and proximity to an orbital-selective Mott phase in  $\text{Fe}_{1+y}\text{Te}_{1-x}\text{Se}_x$ ,  $\text{A}_x\text{Fe}_{2-y}\text{Se}_2$ , and monolayer FeSe film on  $\text{SrTiO}_3$  [1,2], and ii) in  $\text{Rb}_x\text{Fe}_2(\text{Se}_{1-x}\text{S}_x)_2$ , where sulfur substitution for selenium continuously suppresses superconductivity down to zero, little change occurs in the Fermi surface topology while a substantial reduction of electron correlation is observed in an expansion of the overall bandwidth, implying that electron correlation is one of the key tuning parameters for superconductivity in these materials. [1] M. Yi et al. Phys. Rev. Lett. 110, 067003 (2013). [2] M. Yi et al. Nat. Comm. 6, 7777 (2015). [3] M. Yi et al. arXiv: 1505.06636.

**8:36AM K11.00002 Bandwidth-controlled metal-superconductor-insulator phase diagram in iron-chalcogenides**, XIAOHAI NIU, SUDI CHEN, JUAN JIANG, ZIRONG YE, TIANLUN YU, DIFEI XU, MIN XU, YU FENG, YAJUN YAN, BINPING XIE, JUN ZHAO, Fudan University, DACHUN GU, LILING SUN, Institute of Physics, Chinese Academy of Sciences, QIANHUI MAO, HANGDONG WANG, MINGHU FANG, Zhejiang University, C. J. ZHANG, High Magnetic Field Laboratory, Chinese Academy of Sciences and University of Science and Technology of China, J. P. HU, Institute of Physics, Chinese Academy of Sciences, ZHE SUN, National Synchrotron Radiation Laboratory, University of Science and Technology of China, DONGLAI FENG, Fudan University — Using angle-resolved photoemission spectroscopy, we studied isovalently doped  $\text{K}_{x-y}\text{Fe}_{2-z}\text{Se}_{2-z}\text{S}_z$ ,  $\text{Rb}_{x-y}\text{Fe}_{2-z}\text{Te}_{2-z}\text{S}_z$  and  $(\text{Ti,K})_{x-y}\text{Fe}_{2-z}\text{Se}_{2-z}\text{S}_z$ , in which the superconducting transition temperature decreases with either positive or negative chemical pressures. The bandwidths of Fe 3d bands in the energy window of [0, -0.5] eV in these materials change systematically with doping: with the decreasing of bandwidth, the ground state evolves from a metal to a superconductor, and eventually to an insulator. This systematic study of electronic structures discovered the correlation-driven insulator state by tuning the bandwidth, which is independent with carrier density. The results also indicate that moderate correlation strength is beneficial to enhance superconductivity.

**8:48AM K11.00003 ARPES investigation of heavily hole-doped Fe-based superconductor  $(\text{Ba,K})\text{Fe}_2\text{As}_2$** , XUN SHI, PIERRE RICHARD, PENG ZHANG, AMBROISE VAN ROEKEGHEM, TIAN QIAN, JIANGPING HU, HONG DING, Chinese Academy of Sci (CAS), DELONG FANG, HAIHU WEN, Nanjing University, NAN XU, MING SHI, Paul Scherrer Institut, TIMUR KIM, MORITZ HOESCH, Diamond Light Source, XIANHUI CHEN, University of Science and Technology of China, PHOTOELECTRON SPECTROSCOPY RESEARCH TEAM, NANJING UNIVERSITY COLLABORATION, PAUL SCHERRER INSTITUT COLLABORATION, DIAMOND LIGHT SOURCE COLLABORATION, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA COLLABORATION — A Lifshitz transition occurs in the  $(\text{Ba,K})\text{Fe}_2\text{As}_2$  family upon K doping and electron pocket are absent in the heavily doped compounds, including  $\text{KFe}_2\text{As}_2$ . The pairing symmetry is argued to undergoes a phase transition due to the existence of gap node(s) reported in various experiments. In this work we present angle-resolved photoemission spectroscopy and scanning tunneling spectroscopy studies of  $\text{KFe}_2\text{As}_2$ . We observe a van Hove singularity (vHs) in proximity of the Fermi level ( $E_F$ ), which locates in the middle of the principal axes of the first Brillouin zone. The density-of-states at  $E_F$  mainly comes from the vHs whereas it is non-gapped in the superconducting state. Our observation provides natural explanations for many novel behaviors in this material. In particular, it is consistent with our measurements of the gap structure in  $\text{Ba}_{0.1}\text{K}_{0.9}\text{Fe}_2\text{As}_2$ . All these results suggest that Cooper pairing is induced by a strong-coupling mechanism.

**9:00AM K11.00004 Persistence of Dirac Node near Antiferromagnetic-to-Superconducting Phase Boundary in  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$** , HITOSHI TAKITA, NAOYA KISHIMOTO, YOUSUKE NAKASHIMA, Hiroshima University, AKIHIRO INO, MASASHI ARITA, HIROHUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima Synchrotron Radiation Center, YOSHIHIRO AIURA, IZUMI HASE, HIROSHI EISAKI, KUNIHITO KIHOU, CHUL-HO LEE, AKIRA IYO, National Institute of Advanced Industrial Science and Technology, MASAMICHI NAKAJIMA, Osaka University, SHIN-ICHI UCHIDA, University of Tokyo, HIROSHIMA UNIVERSITY TEAM, HIROSHIMA SYNCHROTRON RADIATION CENTER TEAM, NATIONAL INSTITUTE OF INDUSTRIAL SCIENCE AND TECHNOLOGY TEAM, OSAKA UNIVERSITY TEAM, UNIVERSITY OF TOKYO TEAM — Since the ground state of iron-pnictides changes from an antiferromagnetic (AF) phase to a superconducting (SC) phase, the evolution of electronic structure has attracted much attention. However, systematic investigation has been hindered by the intricate multiple bands arising from the orbital degree of freedom of iron 3d states. Here we performed a polarization-dependent ARPES study of  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  across the AF-SC phase boundary. The doping-dependence of ARPES spectra has shown that the Dirac node reported in the AF phase of  $\text{BaFe}_2\text{As}_2$  persists in  $x = 0.04$  near the AF-SC phase boundary, and that it disappears in the SC phase of  $x = 0.05$ . We parametrized the cone-like dispersion in  $x = 0.04$ . The polarization-dependence of our ARPES spectra is consistent with the view that the Dirac node is protected by Berry phase arising from orbital degree of freedom under the inversion symmetry.

**9:12AM K11.00005 orbital selective correlation reduce in collapse tetragonal phase of  $\text{CaFe}_2(\text{As}_{0.935}\text{P}_{0.065})_2$  and electronic structure reconstruction studied by angle resolved photoemission spectroscopy**, LINGKUN ZENG, Chinese Academy of Sci (CAS) — We performed an angle-resolved photoemission spectroscopy (ARPES) study of the  $\text{CaFe}_2(\text{As}_{0.935}\text{P}_{0.065})_2$  in the collapse tetragonal(CT) phase and uncollapse tetragonal(UCT) phase. We find in the CT phase the electronic correlation dramatically reduces respectively to UCT phase. Meanwhile, the reduction of correlation in CT phase show an orbital selective effect: correlation in  $d_{xy}$  reduces the most, and then  $d_{xz/yz}$ , while the one in  $d_{z^2-r^2}$  almost keeps the same. In CT phase, almost all bands sink downwards to higher binding energy, leading to the hole like bands around Brillouin zone(BZ) center sink below  $E_F$  compared with UCT phase. However, the electron pocket around Brillouin Zone(BZ) corner(M) in UCT phase, forms a hole pocket around BZ center(Z point) in CT phase. Moreover, the  $d_{xy}$  exhibits larger movement down to higher binding energy, resulting in farther away from  $d_{yz/xz}$  and closer to  $d_{xy}$ . We propose the electron filling, namely high spin state in UCT phase to low spin state in CT phase(due to competing between crystal structure field and Hund's coupling), other than the Fermi surface nesting might be responsible for the absent of magnetic ordering.

**9:24AM K11.00006 Effect of directional strain on the phase diagram of  $\text{Ca}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$** , A. E. BÖHMER, G. DRACHUK, M. A. TANATAR, S. L. BUD'KO, R. PROZOROV, P. C. CANFIELD, Ames Laboratory and Iowa State University — The iron-based superconductor  $\text{Ca}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  is exceptionally sensitive to directional stress with *ab*-plane compression stabilizing and *c*-axis compression de-stabilizing the orthorhombic antiferromagnetic phase [1]. Due to differential thermal expansion between a sample and a substrate, an effective in-plane compressive strain can be exerted on it upon cooling. We found that this strain induces a phase transition even in overdoped compositions where the usual magneto-structural transition, observed in underdoped compounds, does not occur in the unstrained state. The induced transition has been characterized by 4-probe resistivity, elastoresistivity (the derivative of resistivity with respect to deformations), polarized light microscopy and Mössbauer spectroscopy. We found a pronounced increase of the resistivity and a divergence of the elastoresistivity coefficients, which is a signature of the tetragonal-to-orthorhombic transition in other iron-based superconductors. The polarized light images directly show the formation of a particularly rich domain pattern below the transition in these samples. This work was supported by the Ames Laboratory, US DOE, under Contract No. DE-AC02-07CH11358. [1] Bud'ko et al., PRB 88,064513 (2013).

**9:36AM K11.00007 Quantum fluctuations in iron-pnictide superconductor  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$** , LEI SHU, Z. F. DING, J. ZHANG, C. TAN, K. HUANG, Fudan University, Shanghai, China, L. LIU, S. CHEUNG, Y. J. UEMURA, Columbia University, D. E. MACLAUGHLIN, University of Riverside, O. O. BERNAL, California State University, Los Angeles, P.-C. HO, California State University, Fresno, D. HU, Chinese Academy of Sciences, P.C. DAI, Rice University — Muon-spin-relaxation/rotation ( $\mu\text{SR}$ ) experiments were performed on single crystals of iron-pnictide superconductors  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$  ( $x = 0.28, 0.30$ , and  $0.33$ ). Our preliminary results reveal that the static muon relaxation rate from ZF- $\mu\text{SR}$  measurements is temperature independent through  $T_c$ , suggesting that time reversal symmetry is preserved in the superconducting state. Above  $T_c$ , the field dependence of muon relaxation rate shows NFL behaviors for optimal composition  $x = 0.3$ . A maximum of zero temperature penetration depth at  $x = 0.3$  is also observed.

**9:48AM K11.00008 Soft-mode transitions of alkaline-earth 122 pnictides<sup>1</sup>**, MICHAEL WIDOM, Carnegie Mellon University, KHANDKER QUADER, Kent State University — A-122 pnictides (A=Ca, Sr, Ba) exhibit three pressure-driven transitions: a first order enthalpic transition at  $P_H$  from the striped AFM orthorhombic (OR) to a tetragonal (T) or a collapsed tetragonal (cT) phase; a transition at  $P_M > P_H$  from the metastable AFM OR to a T or cT phase; a Lifshitz transition at  $P_L$  that causes T to collapse to a cT phase. Transitions at  $P_H$  and  $P_L$  were previously examined through total energy and band structure calculations<sup>23</sup>. Here we address the transition at  $P_M$ , beyond which the metastable AFM OR state ceases to exist. We show this transition occurs through a loss of elastic stability caused by softening of a shear mode associated with stretching along the *c*-axis. Simultaneously, magnetism and orthorhombicity approach limiting values with an approximately square-root singularity<sup>4</sup>. Together these suggest a strong magneto-elastic coupling that may be relevant to a further understanding of the A-122-pnictides under pressure.

**10:00AM K11.00009 Correlation driven dimensional reduction in a two orbital Hubbard model**, ANAMITRA MUKHERJEE, University of Tennessee, Knoxville, Tennessee 37996, USA, National Institute of Science Education and Research, India, NIRAVKUMAR D. PATEL, ADRIANNA MOREO, ELBIO DAGOTTO, University of Tennessee, Knoxville, Tennessee 37996, USA — We apply a recently developed many-body technique that allows for the incorporation of thermal effects, to a two orbital Hubbard model of relevance for the pnictides. In this Mean Field-Monte Carlo (MF-MC) approach, we first perform a mean field (MF) decomposition of the Hubbard model and then treat the mean field parameters via the standard finite-temperature classical Monte Carlo (MC). We have earlier established [1] that for the one orbital Hubbard model, this MF-MC approach provides remarkable improvement over simple finite-temperature mean field methods and is in good agreement with Determinantal Quantum Monte Carlo results. In this talk we will discuss our MC-MF results applied to the two orbital Hubbard model with degenerate  $dxz$  and  $dyz$  orbitals for the undoped pnictides [2]. The onsite repulsion strength  $U$  vs. temperature phase diagram is rich and has a narrow window of nematicity above the Neel temperature. Our main result is the discovery of a novel intermediate coupling regime characterized by an unexpected spontaneous dimensional reduction that renders one direction insulating and the other metallic. [1] A. Mukherjee, et. al. Phys. Rev. B 90, 205133 (2014). [2] A. Mukherjee, et. al. arXiv:1510.04902

**10:12AM K11.00010 Testing The Constrained-Path Quantum Monte Carlo Method Using A One Dimensional Three Orbital Hubbard Model.**, GUANGKUN LIU, Univ of Tennessee, Knoxville and Beijing Normal University, NITIN KAUSHAL, Univ of Tennessee, Knoxville, CHRIS BISHOP, SHUHUA LIANG, Univ of Tennessee, Knoxville and ORNL, SHAOZHI LI, STEVE JOHNSTON, Univ of Tennessee, Knoxville, ELBIO DAGOTTO, Univ of Tennessee, Knoxville and ORNL — The “sign problem” usually prevents the large scale quantum Monte Carlo simulations of the multi-orbital Hubbard models. Projecting from a variety of initial states constructed via the Hartree-Fock technique, a constrained-path quantum Monte Carlo [1] (CPQMC) simulation has been carried out for the full one-dimensional three-orbital Hubbard model [2] and also for the same model but neglecting the pair-hopping and spin-flip interactions. The corresponding phase diagrams varying electronic density  $n$  and Hubbard  $U$  are constructed. Extensive comparisons with density matrix renormalization group and determinant quantum Monte Carlo results demonstrate that CPQMC is capable of capturing the physics of the orbital-selective Mott phase [2,3]. Our results also suggest that the spin-flip and pair-hopping interactions only have a limited effect on multi-orbital Hubbard model phase diagrams. [1] Guangkun Liu, Zhongbing Huang, and Yongjun Wang, J. Phys.: Condens. Matter 26, 325601(2014) [2] Julian Rincon, Adriana Moreo, Gonzalo Alvarez, and Elbio Dagotto, Phys. Rev. **10:24AM K11.00011 Density Matrix Renormalization Group Study of a One Dimensional Three-Orbital Hubbard Model: The role of pair hopping and spin-flip interactions.** , NITIN KAUSHAL, GUANGKUN LIU, CHRIS BISHOP, SHUHUA LIANG, SHAOZHI LI, STEVE JOHNSTON, Department of Physics and Astronomy, The University of Tennessee, Knoxville, ELBIO DAGOTTO, Department of Physics and Astronomy, The University of Tennessee, Knoxville and Oak Ridge National Laboratory — Using the Density Matrix Renormalization Group technique, we extensively study a three-orbital Hubbard model in one dimension without pair hopping and spin-flip Hund interactions. The phase diagram varying the electronic density  $n$  and Hubbard  $U$  is constructed and compared against previous results obtained using the full interaction Hamiltonian [1]. Our results suggest that spin-flip and pair hopping terms are not crucially important to address the orbital-selective Mott phase [1]. This analysis paves the way to study multiorbital Hubbard models using techniques such as the Constrained-Path Quantum Monte Carlo (CPQMC) and Determinant Quantum Monte Carlo (DQMC) methods since they perform better, reducing for instance the severity of the “sign problem”, in the absence of pair hopping and spin flip terms in the interaction.

**10:36AM K11.00012 Doping Evolution of Electronic Properties of FeSe/SrTiO<sub>3</sub> Films** , BING SHEN, YONG HU, DEFA LIU, JIANWEI HU, Department of Physics, Chinese Academy of Sciences, LILI WANG, XUCUN MA, QIKUN XUE, Department of Physics, Tsinghua University, CHUANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, ZHOU, Institute of Physics, Chinese Academy of Sciences — The latest discovery of high-temperature superconductivity in FeSe has attracted extensive attention. Our previous ARPES studies on the single-layer and double-layer FeSe/SrTiO<sub>3</sub> films from N-phase to S phase by vacuum annealing and get superconductivity in the S phase. Here we report on the doping evolution of electronic properties of double-layer FeSe/SrTiO<sub>3</sub> films doped and it remains in the semiconducting/insulating state. We will present our new ARPES results on the FeSe/SrTiO<sub>3</sub> films with different layers (1UC, 2UC, 3UC) by potassium deposition, to increase the carrier concentration. As the result, we observed the evolution of electronic properties with different layers. This systematic study will provide insight in understanding the evolution of electronic properties from multiple-layer FeSe film and eventually to the bulk FeSe superconductor.

and MAR16-2015-004498

**10:48AM K11.00013 Electronic structure and lattice dynamics at the interface of single layer FeSe and SrTiO<sub>3</sub>**<sup>1</sup> , TOWFIQ AHMED, Los Alamos Natl Laboratory, ALEXANDER BALATSKY, Los Alamos Natl Lab and Nordita, JIAN-XIN ZHU, Los Alamos National Laboratory — Recent discovery of high-temperature superconductivity with the superconducting energy gap opening at temperatures close to or above the liquid nitrogen boiling point in the single-layer FeSe grown on SrTiO<sub>3</sub> has attracted significant interest. It suggests that the interface effects can be utilized to enhance the superconductivity. It has been shown recently that the coupling between the electrons in FeSe and vibrational modes at the interface play an important role. Here we report on a detailed study of electronic structure and lattice dynamics in the single-layer FeSe/SrTiO<sub>3</sub> interface by using the state-of-art electronic structure method within the density functional theory. The nature of the vibrational modes at the interface and their coupling to the electronic degrees of freedom are analyzed. In addition, the effect of hole and electron doping in SrTiO<sub>3</sub> on the electron-mode coupling strength is also considered. [1] Q. Y. Wang et al., *Chin. Phys. Lett.* **29**, 037402 (2012); [2] Jian-Feng Ge et al., *Nature Mater.* **14**, 285 (2014).

## Wednesday, March 16, 2016 8:00AM - 11:00AM — Session K12 DCMP: Topological Insulators: Towards Applications 308 -

**8:00AM K12.00001 Plasmon-enhanced electron-phonon coupling in Dirac surface states of the thin-film topological insulator Bi<sub>2</sub>Se<sub>3</sub>** , YURI D. GLINKA, SERCAN BABAKIRAY, DAVID LEDERMAN, West Virginia University — Raman measurements of a Fano-type surface phonon mode associated with Dirac surface states (SS) in Bi<sub>2</sub>Se<sub>3</sub> topological insulator thin films allowed an unambiguous determination of the electron-phonon coupling strength in Dirac SS as a function of film thickness ranging from 2 to 40 nm. A non-monotonic enhancement of the electron-phonon coupling strength with maximum for the 8-10 nm thick films was observed. The non-monotonicity is suggested to originate from plasmon-phonon coupling which enhances electron-phonon coupling when free carrier density in Dirac SS increases with decreasing film thickness and becomes suppressed for thinnest films when anharmonic coupling between in-plane and out-of-plane phonon modes occurs. The observed about four-fold enhancement of electron-phonon coupling in Dirac SS of the 8-10 nm thick Bi<sub>2</sub>Se<sub>3</sub> films with respect to the bulk samples may provide new insights into the origin of superconductivity in this-type materials and their applications.

**8:12AM K12.00002 Inverse spin-galvanic effect in topological-insulator graphene heterostructures.**<sup>1</sup> , MARTIN RODRIGUEZ-VEGA, The College of William and Mary , GEORG SCHWIETE, JAIRO SINOVA, Institut für Physik, Johannes Gutenberg Universität Mainz, ENRICO ROSSI, The College of William and Mary — We study theoretically the inverse spin-galvanic effect in heterostructures formed by a layer of a three dimensional strong topological insulator (TI) and a graphenic layer (single layer graphene, and bilayer graphene). We also consider trilayer structures in which a ferromagnetic thin film is added on top of the graphenic layer. We consider the cases of coherent, and random tunneling between states in the TI and the graphenic layer. We obtain the strength of the inverse spin-galvanic effect, taking into account both intraband and interband contributions, as a function of the system's parameters both for the case in which the disorder is short-range and for the case in which the disorder is long-range as when charge impurities are the dominant source of disorder. We find that for a large range of system's parameters the presence of the graphenic layer enhances the strength of the inverse spin-galvanic effect. Finally, we discuss the relevance of our results for recent experiments.

**8:24AM K12.00003 Non-local magnetoelectric effects via Coulomb interaction in TI-FMI heterostructures<sup>1</sup>**, STEFAN REX, Department of Physics, Norwegian University of Science and Technology, FLAVIO S. NOGUEIRA, IFW Dresden, and Ruhr-Universität Bochum, ASLE SUDBØ, Department of Physics, Norwegian University of Science and Technology — Magnetic order on the surface of a 3D topological insulator (TI) has been predicted to evoke a topological magnetoelectric effect (TME) by the breaking of time-reversal invariance. In the TME, an electric field leads to a magnetic polarization in the same direction as the field and vice versa. Here, we consider heterostructures of TI and ferromagnetic insulator (FMI) layers. We show that in the presence of long-range Coulomb interactions the magnetization couples non-locally to the fluctuating electric field (non-local TME) by performing a field-theoretic calculation of the vacuum polarization. In addition, we obtain a Landau-Lifshitz equation for the magnetization dynamics, and find that charged magnetic textures lead to a net magnetization even at a large distance. Such textures can be induced by an external electric field with nonzero in-plane divergence. We apply this effect to a FMI-TI-FMI trilayer heterostructure with two parallel interfaces being well-separated by the bulk TI, where we propose to non-locally control the magnetic texture at one interface by proper gating of the other interface. A preprint can be found at arXiv:1510.04285

**8:36AM K12.00004 Electric field induced quantum anomalous Hall effect in two-dimensional antiferromagnetic triphenyl-lead lattice**, HYUN-JUNG KIM, Korea Inst for Advanced Study, CHAOKAI LI, International Center for Quantum Materials, Peking University, JI FENG, Peking University, ZHENYU ZHANG, University of Science and Technology of China, JUN-HYUNG CHO, Hanyang University — The tuning of topological states is of significant fundamental and practical importance in contemporary condensed matter physics, for which the extension to two-dimensional (2D) organometallic systems is particularly attractive.[1] Using first-principles calculations, we find that a 2D hexagonal triphenyl-lead lattice composed of only main group elements is susceptible to a magnetic instability, characterized by an antiferromagnetic (AFM) insulating state with a renormalized valley gaps with gap difference of 24 meV due to the spin and valley coupling. This AFM state will be subject to a anomalous valley Hall effect under the action of Berry curvature-induced spin and valley currents via, for example, injection of circularly polarized light.[2] Furthermore, such a AFM band insulator can be tuned into a topologically nontrivial quantum anomalous Hall state with a Chern number of one by the application of an out-of-plane electric field. These findings further enrich our understanding of 2D hexagonal organometallic lattices for potential applications in spintronics and valleytronics. [1] M. Z. F. Wang, Z. Liu, and F. Liu, Nat. Comm. 4, 1471 (2013) [2] X. Li, T. Cao, Q. Niu, J. Shi, and J. Feng, Proc. Natl. Acad. Sci. 110, 2738 (2012)

**8:48AM K12.00005 A generalized spin diffusion equation with four electrochemical potentials for channels with spin-orbit coupling<sup>1</sup>**, SHEHRIN SAYED, Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907, SEOKMIN HONG, Intel Corporation, SUPRIYO DATTA, Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907 — We will present a general semiclassical theory for an arbitrary channel with spin-orbit coupling (SOC) [1], that uses four electrochemical potential ( $U+$ ,  $D+$ ,  $U-$ , and  $D-$ ) depending on the sign of  $z$ -component of the spin (up ( $U$ ), down ( $D$ )) and the sign of the  $x$ -component of the group velocity ( $+$ ,  $-$ ). This can be considered as an extension of the standard spin diffusion equation [2] that uses two electrochemical potentials for up and down spin states, allowing us to take into account the unique coupling between charge and spin degrees of freedom in channels with SOC. We will describe applications of this model to answer a number of interesting questions in this field such as: (1) whether topological insulators can switch magnets, (2) how the charge to spin conversion is influenced by the channel resistivity, and (3) how device structures can be designed to enhance spin injection. **9:00AM K12.00006 Measurements of current-induced spin polarizations in topological insulators Bi<sub>2</sub>Te<sub>2</sub>Se and Bi<sub>2</sub>Se<sub>3</sub> thin flakes.**, JIFA TIAN, IRENEUSZ MIOTKOWSKI, Department of Physics and Astronomy, Purdue University, SEOKMIN HONG, SUPRIYO DATTA, Birck Nanotechnology Center, Purdue University, YONG CHEN, Department of Physics and Astronomy, Purdue University — Topological insulators (TIs) possess nontrivial spin-momentum-locked topological surface states (TSS). Real TI can also host trivial surface 2DEG with strong Rashba spin-orbit coupling derived from the bulk states. Both TSS and Rashba 2DEG can generate current induced spin polarization, although the dominant helicities of their spin-momentum locking (SML) are expected to be opposite. Here, we report spin potentiometric measurements in exfoliated bulk-insulating Bi<sub>2</sub>Te<sub>2</sub>Se and bulk-metallic Bi<sub>2</sub>Se<sub>3</sub> thin flakes. In both materials, the voltage measured by a FM electrode shows a hysteretic step-like change when the FM magnetization is switched by an in-plane magnetic field. The trend of the voltage change can be reversed by reversing the direction of the dc current, and the amplitude of the spin signal increases linearly with increasing bias current. Such a spin signal is consistent with a current induced spin polarization arising from a helical SML. However, the observed trend of the voltage change is opposite between Bi<sub>2</sub>Te<sub>2</sub>Se and Bi<sub>2</sub>Se<sub>3</sub>, suggesting opposite signs of dominant spin helicity that we attribute to TSS and Rashba 2DEG respectively.

**9:12AM K12.00007 Spintronics device made of topological materials<sup>1</sup>**, JIANGSHENG WU, ZHANGSHENG SHI, MAOJI WANG, South University of Science and Technology of China — Topological Materials is a new state of matter of which the bulk states are gapped insulator or superconductor while the surface states are gapless metallic states. Such surface states are robust against local disorder and impurities due to its nontrivial topology. It induces unusual transport properties and shows nontrivial topological spin texture in real space. We have made use of these two exotic properties to make application in spintronics. For example, we propose to make spin-filter transistor using of 1D or 2D quantum anomalous Hall insulator or 2D topological Weyl semimetal, we also propose a device to measure the spin-polarization of current, a device to generate entangled electron pairs.

**9:24AM K12.00008 Topological Insulator and Thermoelectric Effects**, YONG XU, Department of Physics, Tsinghua University, Beijing 100084, China — The recent discovery of topological insulator (TI) offers new opportunities for the development of thermoelectricity, because many TIs (like Bi<sub>2</sub>Te<sub>3</sub>) are excellent thermoelectric materials. In this talk, I will first introduce our theoretical predictions of anomalous Seebeck effect and strong size effect in TI [PRL 112, 226801 (2014)]. Then I will report our recent proof experiments, which find in TI thin films that (i) the hole-type Seebeck effect and the electron-type Hall effect coexist in the same TI sample for all the measured temperatures (up to 300 K), and (ii) the thermoelectric properties depend sensitively on the film thickness. The unconventional phenomena are revealed to be closely related to the topological nature of the material. These findings may inspire new ideas for designing TI-based high-efficiency thermoelectric devices.

**9:36AM K12.00009 Electric-field control of spin-orbit torque in magnetically doped topological insulators<sup>1</sup>**, YABIN FAN, QIMING SHAO, XUFENG KOU, PRAMEY UPADHYAYA, KANG WANG, University of California, Los Angeles — Recent advances of spin-orbit torques (SOTs) generated by topological insulators (TIs) [1-2] have drawn increasing interest to the spin-momentum locking feature of TIs' surface states, which can potentially provide a very efficient means to generate SOTs for spintronic applications. In this presentation, we will show the magnetization switching through current-induced giant SOT in both TI/Cr-doped TI bilayer [1] and uniformly Cr-doped TI films [3]. In particular, we show that the current-induced SOT has significant contribution from the spin-momentum locked surface states of TIs. We find that the spin torque efficiency is in general three orders of magnitude larger than those reported in heavy metal/ferromagnetic heterostructures. In the second part, we will present the electric-field control of the giant SOT in magnetically doped TIs [3], which suggests promising gate-controlled spin-torque device applications. The giant SOT and efficient current-induced magnetization switching exhibited by the magnetic TIs may lead to innovative spintronic applications such as ultralow power dissipation memory and logic devices. **9:48AM K12.00010 Optical Control of Ferromagnetism in a Magnetically-Doped Topological Insulator<sup>1</sup>**, ANDREW L. YEATS, PETER J. MINTUN, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637, YU PAN, ANTHONY RICHARDELLA, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park, PA 16802, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637 — Many proposed experiments involving topological insulators (TIs) require spatial control over time-reversal symmetry and chemical potential. We demonstrate micron-scale optical control of both magnetization and chemical potential in thin films of Cr-doped (Bi,Sb)<sub>2</sub>Te<sub>3</sub>. By optically modulating the coercivity of the films, we write and erase arbitrary spatial configurations of their magnetization, which we then image with Kerr microscopy. Additionally, by optically manipulating a space charge layer in the underlying SrTiO<sub>3</sub> substrates, we can control the local chemical potential of the films. This allows us to write and erase *p-n* junctions in the films, which we image with photocurrent microscopy<sup>2</sup>. Both effects persist for > 16 hours. We will present systematic Kerr microscopy, photocurrent microscopy, and electrical transport studies of these materials and various electronic and magnetic structures patterned on them. We will discuss the prospects for using these optical phenomena to study and control the unique physics of TIs, such as edge-state transport in the quantum anomalous Hall regime.

**10:00AM K12.00011 Edge channel transport in a HgTe waveguide modulated by two magnetic barriers<sup>1</sup>**, FENG ZHAI, University of Puerto Rico at Mayaguez, XUANPING JIN, Zhejiang Normal University, JUNQIANG LU, University of Puerto Rico at Mayaguez — we investigate the effects of a magnetic double barrier on the ballistic transport properties of edge-states in a HgTe waveguide with inverted band structures. When its energy is in the bulk gap and close to the bulk conduction band of leads, the electron incident from a quantum spin Hall (QSH) state can be almost totally reflected as the two magnetic barriers are in the antiparallel configuration. For the magnetic double barrier in the parallel configuration, the same electron can transmit nearly perfectly for a proper spin orientation. In the antiparallel configuration, the spin polarization of the output current vanishes. This distinction in the transmission indicates that the proposed edge-state device has two functions: magnetic switching and spin filtering. Our calculations also indicate that nonuniform magnetic fields can break the QSH states more effectively than uniform ones.

**10:12AM K12.00012 Dynamical electron compressibility in the 3D topological insulator Bi<sub>2</sub>Se<sub>3</sub>**, ANDREAS INHOFER, Laboratoire Pierre Aigrain, ENS Paris, BADIH ASSAF, Département de Physique, ENS Paris, QUENTIN WILMART, Laboratoire Pierre Aigrain, ENS Paris, LOUIS VEYRAT, CHRISTIAN NOWKA, JOSEPH DUFOULEUR, ROMAIN GIRAUD, SILKE HAMPEL, BERND BUECHNER, IFW-Dresden, Institute for Solid State Research, GWENDAL FVE, JEAN-MARC BERROIR, BERNARD PLACAIS, Laboratoire Pierre Aigrain, ENS Paris — Measurements of the quantum capacitance  $c_q$ , related to the electron compressibility  $\chi = c_q/e^2$  is a sensitive tool to probe the density of states. In a topological insulator (TI) the situation is enriched by the coexistence and the interplay of topologically protected surface states and massive bulk carriers. We investigate top-gate metal-oxide-TI capacitors using Bi<sub>2</sub>Se<sub>3</sub> thin crystals at GHz frequencies. These measurements provide insight into the compressibility of such a two electron-fluid system. Furthermore, the dynamical response yields information about electron scattering properties in TIs. More specifically, in our measurements we track simultaneously the conductivity  $\sigma$  and the compressibility as a function of a DC-gate voltage. Using the Einstein relation  $\sigma = c_q D$ , we have access to the gate dependence of the electron diffusion constant  $D(V_g)$ , a signature of the peculiar scattering mechanisms in TIs.

**10:24AM K12.00013 Observation of Majorana fermion states in rf-SQUIDs constructed on Pb-Bi<sub>2</sub>Te<sub>3</sub> surface**, LI LU, YUAN PANG, JIE SHEN, FANMING QU, ZHAOZHENG LYU, JUNHUA WANG, JUNYA FENG, JIE FAN, GUANGTONG LIU, ZHONGQING JI, XIUNIAN JING, CHANGLI YANG, Institute of Physics, Chinese Academy of Sciences, QINGFENG SUN, X. C. XIE, Peking University, LIANG FU, Massachusetts Institute of Technology — Recently, much attention has been paid to search for Majorana fermions in solid-state systems. Among various proposals there is one based on radio-frequency superconducting quantum interference devices (rf-SQUIDs), in which a  $4\pi$ -periodic current-phase relation is expected if Majorana fermion states exist. In this talk we report observations of truncated  $4\pi$ -periodic (i.e.,  $2\pi$ -periodic but fully skewed) oscillatory patterns of contact resistance, on rf-SQUIDs constructed on the surface of three-dimensional topological insulator Bi<sub>2</sub>Te<sub>3</sub>. The results reflect the existence of Majorana fermion states in the devices.

**10:36AM K12.00014 Quantum well states in Rashba semiconductor BiTeI<sup>1</sup>**, YANG HE, ZHIHUI ZHU, Harvard University, MOHAMMAD HAMIDIAN, Harvard University; Cornell University, PENGCHENG CHEN, YAU CHUEN YAM, JENNIFER HOFFMAN, Harvard University; The University of British Columbia — BiTeI displays large Rashba-type spin splitting in both valence and conduction bands. In this work, we use scanning tunneling microscopy to reveal the bipolar nature of BiTeI, confirming the previously observed p-n junction electronic structure. We also discover two-dimensional quantum well states both below and above the semiconducting gap on the Te-terminated surface. This work sheds light on the origin of the giant Rashba splitting in the system.

<sup>1</sup>This effort is funded by the NSF grant DMR-1410480.

**10:48AM K12.00015 Kondo and Majorana doublet interactions in quantum dots**, YOUNGHYUN KIM, UC Santa Barbara, DONG E. LIU, Microsoft Research Station Q, ERIKAS GAIDAMAUSKAS, JENS PAASKE, KARSTEN FLENSBERG, Niels Bohr Institute, University of Copenhagen, ROMAN LUTCHYN, Microsoft Research Station Q — We study the properties of a quantum dot coupled to a normal lead and a time-reversal topological superconductor with Majorana Kramers pair at the end. We explore the phase diagram of the system as a function of Kondo and Majorana-induced coupling strengths using perturbative renormalization group study and slave-boson mean-field theory. We find that, in the presence of coupling between a quantum dot and a Majorana doublet, the system flows to a new fixed point controlled by the Majorana doublet, rather than the Kondo coupling, which is characterized by correlations between a localized spin and the fermion parity of each spin sector of the topological superconductor. We find that this fixed point is stable with respect to Gaussian fluctuations. We also investigate the effect of spin-spin interaction between a quantum dot and Majorana doublet and compare the result with a case where a normal lead is directly coupled to Majorana doublet.

**8:00AM K13.00001 Coexistence, Interfacial Energy and the Fate of Microemulsions of 2D Dipolar Bosons**, MASSIMO BONINSEGNI, University of Alberta — The superfluid-crystal quantum phase transition of a system of purely repulsive dipolar bosons in two dimensions has been the subject of a lot of theoretical study, mainly because of some intriguing predictions by Spivak and Kivelson (2004) regarding an exotic, intermediate "microemulsion" that should appear at low temperature between the crystal and the superfluid. We investigated this scenario by means of Quantum Monte Carlo simulations at zero temperature, determined freezing and melting densities, and estimated the energy per unit length of a macroscopic interface separating the coexisting crystal and superfluid phases. The results rule out quantitatively the microemulsion scenario for any physical realization of this system, given the exceedingly large predicted size of the bubbles. Reference: S. Moroni and M. Boninsegni, Phys. Rev. Lett. **113**, 240407 (2014)

**8:36AM K13.00002 Quantum spin dynamics and entanglement in systems with long-range interactions<sup>1</sup>**, ANA M REY, JILA, NIST and University of Colorado at Boulder — One of the fundamental goals of modern quantum sciences is to learn how to control and manipulate non-equilibrium many-body systems and use them to make powerful and improved quantum devices, materials and technologies. However, out-of-equilibrium systems are complex, typically strongly correlated and entangled, and thus to model them we are in an urgent need of new methodologies. In this talk I will discuss new theoretical methods that we have developed to investigate emergent non-equilibrium phenomena in driven-dissipative spin systems interacting via long-range interactions. I will show we can capture the dynamics of correlations and entanglement in close systems and the interplay between dissipation and entanglement in open quantum systems including spin-boson models. As a specific application I will discuss the use of our methods to model the spin dynamics exhibited by arrays of trapped ions with controllable long-range interactions. I will show that our predictions are consistent with recent experimental measurements. I will also discuss new protocols to diagnostic and characterize entanglement based on well-established NMR protocols

**9:12AM K13.00003 Universal scaling of density and momentum distributions in Lieb-Liniger gases<sup>1</sup>**, MARCOS RIGOL, The Pennsylvania State University — We present numerically exact results for the scaling of density and momentum distribution functions of harmonically trapped one-dimensional bosons with repulsive contact interactions. We consider systems in the continuum [1], and in the presence of a lattice [2,3], both in the ground state [1,2] and at finite temperature [1,3]. We use path integral quantum Monte Carlo with worm updates in calculations at finite interaction strengths, and the Bose-Fermi mapping in the Tonks-Girardeau limit. We first discuss the homogeneous case and, within the local density approximation, use it to motivate the scaling in the presence of a harmonic trap. For the momentum distribution function, we pay special attention to the high momentum tails and their  $k^{-4}$  asymptotic behavior. When available, we compare our results to experimental measurements of the momentum distribution function of ultracold bosonic gases in two-dimensional optical lattices.

**9:48AM K13.00004 Cooling Atomic Gases With Disorder<sup>1</sup>**, RICHARD SCALETTAR, University of California, Davis — Cold atomic gases have proven capable of emulating a number of fundamental condensed matter phenomena including Bose-Einstein condensation, the Mott transition, Fulde-Ferrell-Larkin-Ovchinnikov pairing and the quantum Hall effect. Cooling to a low enough temperature to explore magnetism and exotic superconductivity in lattices of fermionic atoms remains a challenge. We propose a method to produce a low temperature gas by preparing it in a disordered potential and following a constant entropy trajectory to deliver the gas into a non-disordered state which exhibits these incompletely understood phases. We show, using quantum Monte Carlo simulations, that we can approach the Neel temperature of the three-dimensional Hubbard model for experimentally achievable parameters. Recent experimental estimates suggest the randomness required lies in a regime where atom transport and equilibration are still robust. **10:24AM K13.00005 Diagrammatic Monte Carlo study of mass-imbalanced Fermi-polaron system**, LOUE POLLET, Department of Physics, LMU Munich — After a brief introduction and review of diagrammatic Monte Carlo, I present our results for the three-dimensional Fermi-polaron system with mass-imbalance, where an impurity interacts resonantly with a noninteracting Fermi sea whose atoms have a different mass. This method allows to go beyond frequently used variational techniques by stochastically summing all relevant impurity Feynman diagrams up to a maximum expansion order limited by the sign problem. The polaron energy and quasiparticle residue can be accurately determined over a broad range of impurity masses. Furthermore, the spectral function of an imbalanced polaron demonstrates the stability of the quasiparticle and allows to locate in addition also the repulsive polaron as an excited state. The quantitative exactness of two-particle-hole wave-functions is investigated, resulting in a relative lowering of polaronic energies in the mass-imbalance phase diagram. The contact coefficient for the mass-balanced polaron system is found in good agreement with variational methods. Mass-imbalanced systems can be studied experimentally by ultracold atom mixtures like  $^6\text{Li}$ - $^{40}\text{K}$ . I will discuss some open questions and links with recent experiments.

**8:00AM K14.00001 Topological mechanics of gyroscopic meta-materials**, WILLIAM IRVINE, University of Chicago — Topological mechanical meta-materials are artificial structures whose unusual properties are protected very much like their electronic and optical counterparts. I will present an experimental and theoretical study<sup>1</sup> of a new kind of active meta-material comprised of coupled gyroscopes on a lattice that breaks time-reversal symmetry. The vibrational spectrum displays a sonic gap populated by topologically protected edge modes which propagate in only one direction and are unaffected by disorder. We observe these edge modes in experiment and verify their robustness to disorder and the insertion of obstacles. Controlled distortions of the underlying lattice can induce a topological phase transition that switches the edge mode chirality. This effect allows the direction of the edge current to be determined on demand.

**8:36AM K14.00002 Kirigami!**, RANDALL KAMIEN, Univ of Pennsylvania — We explore and develop a simple set of rules that apply to cutting, pasting, and folding honeycomb lattices. We consider origami-like structures that are extrinsically flat away from zero dimensional sources of Gaussian curvature and one-dimensional sources of mean curvature, and our cutting and pasting rules maintain the intrinsic bond lengths on both the lattice and its dual lattice. We find that a small set of rules is allowed providing a framework for exploring and building kirigami - folding, cutting, and pasting the edges of paper.

**9:12AM K14.00003 Mechanisms and nonlinear waves from topological modes**, BRYAN CHEN, UMass Amherst — Topological protection can arise in mechanical structures such as linkages, frames, or rigid origami. The key ingredients are a balance of degrees of freedom and constraints away from the boundaries. In this setting certain zero energy modes of the system can be made robust against a broad class of perturbations and noise. However, since there are no restoring forces to these modes to linear order, they result in flexes and mechanisms which must be treated as nonlinear waves. I will discuss several simple and concrete examples which illustrate these ideas.

**9:48AM K14.00004 Topological Toughening of graphene and other 2D materials**, HUAJIAN GAO, Brown University — It has been claimed that graphene, with the elastic modulus of 1TPa and theoretical strength as high as 130 GPa, is the strongest material. However, from an engineering point of view, it is the fracture toughness that determines the actual strength of materials, as crack-like flaws (i.e., cracks, holes, notches, corners, etc.) are inevitable in the design, fabrication, and operation of practical devices and systems. Recently, it has been demonstrated that graphene has very low fracture toughness, in fact close to that of ideally brittle solids. These findings have raised sharp questions and are calling for efforts to explore effective methods to toughen graphene. Recently, we have been exploring the potential use of topological effects to enhance the fracture toughness of graphene. For example, it has been shown that a sinusoidal graphene containing periodically distributed disclination quadrupoles can achieve a mode I fracture toughness nearly twice that of pristine graphene. Here we report working progresses on further studies of topological toughening of graphene and other 2D materials. A phase field crystal method is adopted to generate the atomic coordinates of material with specific topological patterns. We then perform molecular dynamics simulations of fracture in the designed samples, and observe a variety of toughening mechanisms, including crack tip blunting, crack trapping, ligament bridging, crack deflection and daughter crack initiation and coalescence.

**10:24AM K14.00005 Control of defect localization in crystalline wrinkling by curvature and topology**<sup>1</sup>, FRANCISCO LOPEZ JIMENEZ, MIT — We investigate the influence of curvature and topology on crystalline wrinkling patterns in generic elastic bilayers. Our numerical analysis predicts that the total number of defects created by adiabatic compression exhibits universal quadratic scaling for spherical, ellipsoidal and toroidal surfaces over a wide range of system sizes. However, both the localization of individual defects and the orientation of defect chains depend strongly on the local Gaussian curvature and its gradients across a surface. Our results imply that curvature and topology can be utilized to pattern defects in elastic materials, thus promising improved control over hierarchical bending, buckling or folding processes. Generally, this study suggests that bilayer systems provide an inexpensive yet valuable experimental test-bed for exploring the effects of geometrically induced forces on assemblies of topological charges.

**Session K15 DCMP DMP: Transport in Graphene and 1D Structures** 314 - Kurt Gaskill, Naval Research Laboratory

**8:00AM K15.00001 Unconventional 1/f noise in Graphene on SrTiO<sub>3</sub> substrate**, ANINDITA SAHOO, Department of Physics, Indian Institute of Science, Bangalore-560012, India, ROALD RUITER, TAMALIKA BANERJEE, Zernike Institute for Advanced Materials, University of Groningen, Groningen, The Netherlands, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore-560012, India — Electrical transport in graphene has been of great interest in both fundamental and applied research. The impact of the substrate is critical to the operation of graphene field effect transistors (FET), which can modify several transport parameters as well as low frequency 1/f noise. Replacing the usual SiO<sub>2</sub>/Si<sup>++</sup> substrate with SrTiO<sub>3</sub> [STO] having high dielectric constant, has opened up new possibilities, leading to large doping, higher mobility, and also hysteretic transfer characteristics for memory applications. We have studied 1/f noise in dual-gated single layer graphene (SLG) FET sandwiched between STO (substrate) and mechanically exfoliated hexagonal boron-nitride (dielectric for the top gate). The area normalized noise amplitude of SLG on STO followed an unexpected 'W'-shape dependence of gate-bias with the central peak at Dirac point in conflict with the usual 'V', 'M' or 'Λ'-type dependence of SLG noise on SiO<sub>2</sub>. We discuss possible microscopic mechanisms for such behavior, considering the role of puckering of oxygen atoms introducing inward dipole moments that can form a new source of electrostatically tunable scattering mechanism at the graphene-STO interface.

**8:12AM K15.00002 1/f Noise in Gated Epitaxial Graphene Nanoribbons**, OWEN VAIL, JEREMY YANG, ANNA MIETTINEN, JOHN HANKINSON, School of Physics, Georgia Institute of Technology, CLAIRE BERGER, School of Physics, Georgia Institute of Technology, CNRS-Institut Neel, WALTER DE HEER, ZHIGANG JIANG, School of Physics, Georgia Institute of Technology — Epitaxial Graphene Nanoribbons (EGNR) grown on sidewall SiC have gained interest as a high-quality interconnect enabling room temperature ballistic transport over micron lengths. To be useful as an interconnect a proper characterization of the noise level in the EGNR needs to be determined. Toward this end, we fabricated EGNR devices with an Aluminum-Oxide top gate and use field effect to tune the fermi energy in the graphene channel. Our studies of the electronic noise and its dependence on the charge density in the ribbon reveal information about the subband structure of the density of states in addition to the ribbon's spectral density at low frequencies. Comparisons to the widely reported 1/f noise in silicon and other forms of graphene provide strong references for analyzing our results.

**8:24AM K15.00003 Theoretical study of the crossover into hydrodynamic regime in graphene<sup>1</sup>**, DEREK HO, INDRA YUDHISTIRA, National University of Singapore, BEN YU-KUANG HU, University of Akron, SHAFFIQUE ADAM, National University of Singapore and Yale-NUS College — Experiments on graphene have recently succeeded in entering the hydrodynamic regime, as demonstrated by successful observations of strong violation of Wiedemann-Franz law [1], the Gurzhi effect and electronic Poiseuille flow [2]. It is known that electronic systems enter the hydrodynamic regime when electron-electron scattering dominates over electron-impurity and electron-phonon scattering. However, a quantitative study of this transition from the Fermi liquid to hydrodynamic regime is still lacking. In view of this, we quantitatively analyze the electron-electron, electron-impurity and electron-phonon scattering rates as a function of temperature, charge doping and disorder (charge puddle) strength. This yields a quantitative understanding of the onset of hydrodynamic electronic behavior in graphene samples. [1] J. Crossno et al., arXiv: 1509.04713v1 (2015). [2] D. A. Bandurin et al., arXiv: 1509.04165 (2015).

<sup>1</sup>This work is supported by the National Research Foundation of Singapore under its Fellowship program (NRF-NRFF2012-01) and by the Singapore Ministry of Education and Yale-NUS College through Grant No. R-607-265-01312.

**8:36AM K15.00004 Observation of insulating behavior and strong localization in suspended monolayer graphene<sup>1</sup>**, CENK YANIK, YASER VAHEB, ABDULKADIR CANATAR, VAHID SAZGARI, ISMET I. KAYA, Sabanci University, QUANTUM TRANSPORT AND NANOELECTRONICS LABORATORY TEAM — Dirac point of graphene is known to be inaccessible due to the electron hole puddles which screen the neutrality point and makes the minimum conductance limited to the order of  $e^2/h$ . However, in extremely clean suspended graphene samples, there is a possibility to observe a diverging resistance approaching the charge neutrality point via yet to be understood localization or Boltzmann transport mechanism. We observe a resistance in excess of  $10^6 \Omega$  near the charge neutrality point in a very high quality suspended monolayer graphene in the absence of magnetic field. The sample exhibits negative magnetoresistance indicating a strong localization effect at low charge carrier densities. The possible origins of these observations will be discussed in the context of the transport mechanisms mentioned above.

**8:48AM K15.00005 ABSTRACT WITHDRAWN —**

**9:00AM K15.00006 Approaching Collimation with a Graphene-based Quantum Point Contact**, GRACE PAN, Department of Physics, Yale University, MENYOUNG LEE, Department of Physics, Stanford University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, DAVID GOLDBABER-GORDON, Department of Physics, Stanford University — Quantum point contacts (QPCs) are narrow constrictions on the order of the Fermi wavelength that bridge together two electrically conducting regions. QPCs display sensitive conductance quantization and are a classic playing field to illustrate clean, ballistic transport in low-dimensional materials. However, graphene-based QPCs are challenging to fabricate, in part due to two reasons: edge disorder that suppresses conductance quantization and imperfect gate depletion leading to charge puddles. Using graphene-boron nitride heterostructures, we demonstrate improvements over a simple etch and Au-gating method by introducing a protective alumina dielectric layer. We use this method to create two QPCs in series and explore potential electron-beam collimation at low magnetic field, in the spirit of Molenkamp (1990).

**9:12AM K15.00007 Realizing 1-D conducting channel between oppositely gated regions in bilayer graphene.**, JANGHEE LEE, Pohang University of Science and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, HU-JONG LEE, Pohang University of Science and Technology — The band gap of bilayer graphene (BLG) can be tuned by applying an external electric field perpendicular to the plane of a BLG sheet. If direction of the electric fields in two adjacent regions in BLG are opposite, one-dimensional (1-D) conducting channel emerges at the boundary between two regions with chiral nature. In this presentation, we introduce a method for fabricating two pairs of split-gates attached to BLG, which is sandwiched between two atomically clean hexagonal boron nitride (h-BN) single crystals and thus allows ballistic transport of carriers at least within the device size. Current-voltage characteristics show a large transport gap, which is comparable to the results obtained from optical measurements and numerical calculations. Opening the band gap in two adjacent regions of the BLG flake by oppositely gated electric fields, we observed metallic behavior in transport characteristics along the boundary between the two regions although the resistance of two gapped regions are a few hundreds of  $k\Omega$ . These results indicate that a 1-D conducting channel formed between the two regions where the induced band gaps were inverted to each other. The formation of this 1-D conducting channel mimics the topological edge conducting channels emerging at the boundary of a two-dimensional topological insulator and may be utilized for applying BLG to valleytronics

**9:24AM K15.00008 Orientation-independent conductance step of graphene nanoribbons**, JI-HAE CHOI, SANG-HOON LEE, MINSOO KIM, Pohang Univ of Sci & Tech, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, HU-JONG LEE, SEUNG-HOON JHI, Pohang Univ of Sci & Tech, CNPL TEAM, QTS TEAM, ULTRA-HIGH PRESSURE PROCESSES GROUP TEAM — Low-energy electronic structure of graphene is characterized by the states from two inequivalent valleys at K and K' points that have opposite chirality. In graphene nanoribbons (GNRs), the K and K' valleys, when projected into one-dimensional (1D) Brillouin zone, can be mixed due to the edge termination. The degree of mixing determines the electronic property of GNRs. However, non-valley mixing properties have been hardly observed so far. In this work, we made effective 1D transport channels by gate-defined carrier guiding. They exhibit a quantum conductance step of  $4e^2/h$ , which is the characteristic of non-mixed valleys. To verify these experimental results, we performed both first-principles and tight-binding calculations of GNRs with arbitrary axial orientations. Calculated band structures and quantum conductance of GNRs show zero-energy flat bands and a conductance step of  $4e^2/h$  except armchair-edge GNRs. We find that this is a consequence of generic zigzag-type boundary conditions of GNRs with arbitrary axial orientations except armchair-edge cases

**9:36AM K15.00009 Theoretical Study of All-Electrical Quantum Wire Valley Filters in Bilayer Graphene<sup>1</sup>**, YU-SHU WU, National Tsing-Hua University, Taiwan, NING-YUAN LUE, YEN-CHUN CHEN, NTHU, Taiwan, JIA-HUEI JIANG, NTHU, Taiwan, MEI-YIN CHOU, AS, Taiwan — Graphene electrons carry valley pseudospin, due to the double valley degeneracy in graphene band structure.[1] In gapped graphene, the pseudospin is coupled to an in-plane electric field, through the mechanism of valley-orbit interaction (VOI).[2] Based on the VOI, a family of electrically-controlled valleytronic devices have been proposed. Here, we report the theoretical study of a recently proposed valley filter consisting of a Q1D channel in bilayer graphene defined and controlled by electrical gates. We discuss two types of calculations – those of energy subband structure in the channel and electron transmission through a valley valve consisting of two proposed filters. For the former, we have developed a tight binding formulation in the continuum limit. For the latter, we employ the recursive Green's function method. Results from the calculations will be presented. **9:48AM K15.00010 Transport measurements in quasi-one dimensional graphene wires**, VARUN HARBOLA, MENYOUNG LEE, Physics department, Stanford University, DAVID GOLDBABER-GORDON, Physics department, Stanford Univ, TAKASHI TANIGUCHI, KENJI WATANABE, National institute of material science, Japan — ABSTRACT: Recent developments have enabled fabrication of high mobility graphene structures. The elastic mean free path in the 2D bulk of the graphene can be greater than ten microns, whereas the graphene can be patterned to widths of 1 micron or below. Thus, we can make structures for which bulk elastic scattering can be neglected. We experimentally study the role of other length scales, such as electron-electron scattering length, cyclotron length, and the width of the graphene ribbon, on transport properties.

**10:00AM K15.00011 Near-field study of domain walls in bilayer graphene**, LILI JIANG, ZHIWEN SHI, FENG WANG, Univ of California - Berkeley — Domain wall in bilayer graphene is emerging as a fascinating one-dimensional system due to the presence of structural soliton and electrically valley Hall boundary states. They are expected to process unusual electronic and optical properties because of the modification of atomic structures. We systematically study the bilayer graphene domain walls with different configurations including lines, circles and networks using scanning near-field optical microscopy (SNOM). The SNOM technique provides a convenient way to investigate domain walls in ambient condition. Our results suggest that bilayer graphene domain wall is an interesting and rich system for fundamental research about light-matter interactions.

**10:12AM K15.00012 Optical signatures of a hypercritical 1D potential in a 2D Dirac metal**, BOR-YUAN JIANG, GUANGXIN NI, Univ of California - San Diego, CHENG PAN, Univ of California - Riverside, ZHE FEI, Univ of California - San Diego, BIN CHENG, CHUN NING LAU, MARC BOCKRATH, Univ of California - Riverside, DIMITRI BASOV, MICHAEL FOGLER, Univ of California - San Diego — Generation of quasi-bound states in graphene near strong charged perturbations is a solid-state analog of atomic collapse of superheavy elements or particle production by hypothetical cosmic strings. We show, for the case of a linelike perturbation, that as the perturbation grows in strength, quasi-bound states are generated sequentially. Each of these critical events is signaled by a sharp change in the local optical conductivity. Tunable linelike perturbations can be realized in experiment using nanowire or nanotube electrostatic gates. We report measurements of local conductivity for such systems obtained through near-field optical microscopy.

**10:24AM K15.00013 Electronic transport across linear defects in graphene**, ANA L C PEREIRA, CARLOS J PAEZ, State University of Campinas, JOO NUNO B RODRIGUES, National University of Singapore, NUNO M R PERES, Universidade do Minho - Portugal — Graphene is being proposed for a variety of new electronic devices. However, the required high-quality electrical properties are affected by the formation of polycrystalline structures, which are practically unavoidable by the growth methods known so far. As such, the scattering problem of an electron off a grain boundary becomes relevant. We investigate the low-energy electronic transport across grain boundaries in graphene ribbons and in ?nite ?akes. Using the recursive Greens-function method, we compute the electronic transmittance across different types of grain boundaries in graphene ribbons and ?akes. We use the charge and current density spatial distributions to enhance our understanding of their electronic transport properties, and ?nd that electronic transport depends both on the grain boundaries microscopic details and on their orientation. We consider extended linear defects of type 585 and 5757, and also a spatial region where the grain boundary is composed by the superposition of two monolayer domains. In addition, we employ the transfer-matrix formalism to analytically study the electronic transport across a class of zigzag grain boundaries with periodicity 3. We ?nd that these grain boundaries give rise to intervalley scattering.

**10:36AM K15.00014 Theoretical investigation of graphene on STO(111) surface**, DONGHAN SHIN, ALEXANDER A. DEMKOV, Univ of Texas, Austin — Graphene, a two-dimensional electronic system which consists of a single layer of graphite, is considered a possible candidate for nano-electronic applications as it has a very high electron mobility. One of the problems in realizing this in practice is the difficulty of doping. Using density functional theory we explore the possibility of field-doping graphene by placing a graphene sheet on a (111)-oriented SrTiO3 (STO) surface that is highly polar. We investigate the electronic structure of the system. Our results suggest that two conduction channels can form near the Fermi level. One is mainly composed of  $\pi$ -like carbon based orbitals, while the other is localized at the oxide surface.

**10:48AM K15.00015 Critical Delocalization of Chiral Zero Energy Modes in Graphene<sup>1</sup>**, AIRES FERREIRA, Department of Physics, University of York, York YO10 5DD, United Kingdom, EDUARDO MUCCIOLO, Department of Physics, University of Central Florida, Orlando, Florida 32816, USA — Graphene subjected to chiral-symmetric disorder is believed to host zero energy modes (ZEMs) resilient to localization, as suggested by the renormalization group analysis of the underlying nonlinear sigma model. We report accurate quantum transport calculations in honeycomb lattices with in excess of  $10^9$  sites and fine meV resolutions. The Kubo dc conductivity of ZEMs induced by vacancy defects (chiral BDI class) is found to match  $4e^2/(\pi h)$  within 1% accuracy, over a parametrically wide window of energy level broadenings and vacancy concentrations. Our results disclose an unprecedentedly robust metallic regime in graphene, providing strong evidence that the early field-theoretical picture for the BDI class is valid well beyond its controlled weak-coupling regime.

**Session K16 DMP: 2D Devices: Black Phosphorous** 315 - Marija Drndic, University of Pennsylvania

**8:00AM K16.00001 Black phosphorus for future devices**, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Black phosphorus (or phosphorene at the monolayer limit) has attracted significant attention as an emerging 2D material due to its unique properties compared with well-explored graphene and transition metal dichalcogenides such as MoS<sub>2</sub> and WSe<sub>2</sub>. In bulk form, this mono-elemental layered structure is a highly anisotropic semiconductor with a bandgap of 0.3 eV which presents marked distinctions in optical and electronic properties depending on crystalline directions. In addition, black phosphorus possesses a high carrier mobility, making it promising for applications in high frequency electronics. A large number of characterization studies have been performed to understand the intrinsic properties of BP. Here I will present a number of investigations where first-principles modelling was combined with scanning tunneling microscopy (STM) [1], Raman spectroscopy [2], and transmission electron microscopy (TEM) [3] to assist in the design of phosphorene-based devices.<sup>1</sup> I will provide an overview of these studies and position them in the context of the very active research devoted to this material. In particular, I will show how low-frequency Raman spectra provide a unique handle on the physics of multilayered systems and how BP's structural anisotropy weaves its way to its unusual polarization dependent Raman signature. Finally, I will show recent progress where nanopores, nanobridges, and nanogaps have been sculpted directly from a few-layer BP sample using a TEM, and indicate the potential use of these results on the creation of phosphorene-based nanoelectronics. I will conclude this talk with a critical look at the issues of phosphorene stability under ambient conditions. **8:36AM K16.00002 Strain Engineering of Phosphorene via Bending**, DEEPTI VERMA, Department of Chemical Engineering and Materials Science, University of Minnesota, TRAIAN DUMITRICA, Department of Mechanical Engineering, University of Minnesota — Phosphorene (PE) - the newly discovered 2D derivative of Phosphorus - has an inherent band gap and a high current on/off ratio. Manipulating strain in PE films - strain engineering (SE) - will offer the opportunity to further tailor its electronic properties. Using objective boundary conditions (OBC) coupled with density functional tight binding model (DFTB), we calculate bending rigidity of PE and its 2D allotropes by modeling bent PE as large diameter nanotubes (PNTs). OBCs not only allow for drastic reductions in the number of atoms in simulations but also enable simulations of chiral PNTs, which is impossible with periodic boundary conditions. At the same time, the method describes how bending influences the electronic structure. We establish a robust platform for achieving SE for anisotropic 2D films. Using results from our calculations and orthotropic thin shell model we develop equivalent continuum structure (ECS) for PE and its allotropes upon bending. The developed ECS can be used for performing finite element simulations of PE films on substrates.

**8:48AM K16.00003 Quantum Hall Effect in Black Phosphorus/hBN Heterostructures**, FANGYUAN YANG, LIKAI LI, Fudan University, Collaborative Innovation Center of Advanced Microstructures, Nanjing, GUO JUN YE, University of Science and Technology of China, Collaborative Innovation Center of Advanced Microstructures, Nanjing, ZUOCHENG ZHANG, Tsinghua University, ZENGWEI ZHU, Wuhan National High Magnetic Field Center and School of Physics, Huazhong University of Science and Technology, WEN KAI LOU, Chinese Academy of Sciences, University of Science and Technology of China, LIANG LI, Wuhan National High Magnetic Field Center and School of Physics, Huazhong University of Science and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, KAI CHANG, Chinese Academy of Sciences, University of Science and Technology of China, YAYU WANG, Tsinghua University, XIAN HUI CHEN, University of Science and Technology of China, Collaborative Innovation Center of Advanced Microstructures, Nanjing, YUANBO ZHANG, Fudan University, Collaborative Innovation Center of Advanced Microstructures, Nanjing — Black phosphorus field effect transistors have emerged as a new two-dimensional electron system (2DES) with high mobility. We achieved high mobilities by placing black phosphorus thin flakes on atomically flat hBN substrates. The mobility is further improved by placing a graphite back gate very close to the 2DES, which screens charged impurities. In this talk, we will present our observation of the integer quantum Hall effect in high mobility black phosphorus 2DEG. Temperature and angular dependent measurements reveal a wealth of information on the charge carriers in this new 2DES.

**9:00AM K16.00004 Fabrication of suspended few-layer black phosphorus nanopores and nanoribbons via electron beam nanosculpting**, PAUL MASIH DAS, Department of Physics and Astronomy, University of Pennsylvania, GOPINATH DANDA, Department of Electrical and Systems Engineering, University of Pennsylvania, WILLIAM PARKIN, Department of Physics and Astronomy, University of Pennsylvania, ANDREW CUPO, NEERAV KHARCHE, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, XI LING, SHENGXI HUANG, MILDRED DRESSSELHAUS, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, MARIJA DRNDIC, Department of Physics and Astronomy, University of Pennsylvania — We present nanopores, nanoribbons, and nanogaps in suspended few-layer black phosphorus (BP) flakes that have been realized using in situ transmission electron microscope nanosculpting. Few-layer BP flakes were first produced through a liquid exfoliation procedure and suspended on holey SiN<sub>x</sub> membranes. We investigate the structural characteristics of few-layer BP and further show the time-dependent properties of various nanostructures under exposure to an electron beam. It is shown that high-resolution structural modification of nanopores and nanoribbons can be achieved with nanometer-scale precision on timescales of a few minutes. We also used density functional theory to provide a model for the observed anisotropy in edge formation by computing energy barriers for various edge geometries.

**9:12AM K16.00005 Highly Anisotropic intrinsic electronic transport properties of monolayer and bilayer phosphorene from first principles<sup>1</sup>**, ZHENGHE JIN, JEFFREY MULLEN, KI WOOK KIM, North Carolina State University — We present an analysis of the electron(hole)-phonon scattering in monolayer and bilayer phosphorene using first principles. Density Functional Theory (DFT) and Density Functional Perturbation Theory (DFPT) are used to calculate the scattering matrix elements and full band Monte Carlo carrier transport simulation is employed to obtain the intrinsic electron/hole mobility. Room temperature mobility and saturation velocity in monolayer and bilayer phosphorene are extracted and significant layer number dependence in the mobility is revealed which results from the carrier-phonon interaction matrix elements. The transport properties are also varied with the crystal orientation with anisotropy mobility mostly attributed to the anisotropic band structure and effective masses. Our calculation reveals monolayer phosphorene has anisotropic hole transport property with the room temperature mobility in the armchair direction (458 cm<sup>2</sup>/Vs) about five times larger than in the zigzag direction (90 cm<sup>2</sup>/Vs). For bilayer phosphorene, the mobility on both directions increases to 1610 cm<sup>2</sup>/Vs and 760 cm<sup>2</sup>/Vs along armchair and zigzag direction respectively. The increased mobility in bilayer is consistent with the experiments which revealed low field mobility of over one thousand in multiple layer phosphorene structure, which provides optimal material for channel in field-effect transistor and a good opportunity for high-performance p-type device.<sup>1</sup> This work was supported, in part, by SRC/NRI SWAN.

**9:24AM K16.00006 Realize Dirac cones in compressed black phosphorus**, LI YANG, RUIXIANG FEI, VY TRAN, Department of Physics, Washington University — Using the k-p theory and first-principles simulations, we predict that applying a moderate uniaxial or hydrostatic pressure (>0.6GPa) on bulk or multilayer black phosphorus (BP) can diminish its bandgap and produce one-dimensional and even two-dimensional (2D) Dirac cones. Similar to topological insulators, these 2D Dirac cones result from two competing mechanisms: the unique linear band dispersion tends to open a gap via a "pseudo-spin-orbit" coupling, while the band symmetries preserve the material's gapless spectrum. In particular, these Dirac cones in BP are bulk states that do not require time-reversal symmetry, thus they can keep the high carrier mobility even in the presence of surface or magnetic perturbations. Finally, our predictions have been confirmed by recent experiments.

**9:36AM K16.00007 Extraordinary Bending Effects in MoS<sub>2</sub>, Phosphorene, and Graphene Nanoribbons<sup>1</sup>**, LIPING YU, ADRIENN RUZSINSZKY, JOHN PERDEW, Temple University — The two-dimensional (2D) materials show great potential for flexible electronics and energy applications. They have remarkable mechanical, electronic, thermal and optical properties, which are often coupled to each other. In this talk, we shall present our first principles study on the bending effects in the electronic structure of MoS<sub>2</sub>, phosphorene, and graphene nanoribbons. We predict that mechanical bending, as a unique attribute of thin 2D materials, can be used to control conductivity and Fermi-level shift. We find that bending can control the charge localization of top valence bands in both MoS<sub>2</sub> and phosphorene nanoribbons. The donor-like in-gap edge-states of armchair MoS<sub>2</sub> ribbon and their associated Fermi-level pinning can be removed by bending. A bending-controllable new in-gap state and accompanying direct-indirect gap transition are predicted in armchair phosphorene nanoribbon. We demonstrate that such emergent bending effects are realizable in experiment and can be attributed to the highly non-uniform and enormously large local in-plane strains induced by bending. The bending stiffness as well as the effective thickness of 2D materials are also derived from first principles.

**9:48AM K16.00008 Synthesis of black phosphorus films and particles by ultra-fast laser ablation<sup>1</sup>**, GANG QIU, QIONG NIAN, YEXIN DENG, BIWEI DENG, SHENGYU JIN, ADAM CHARNAS, GARY CHENG, PEIDE YE, Purdue University — Few-layer black phosphorus (BP) has become one of top interests among various 2D materials because of its outstanding electrical and optical properties. However, availability of large size BP thin films stands as a major roadblock against further research and its applications. Here we report a method of synthesis BP films and particles by employing ultra-fast laser ablation. We demonstrated that arbitrary BP film patterns can be defined by laser direct writing. BP particles were also achieved as byproduct through manipulating laser power and frequency. Physical mechanism of laser ablation process was investigated, which also provides an optimizing strategy of improving BP thin film quality.

**10:00AM K16.00009 Quasiparticle Band Gap and Band Gap Reduction of Multi-Layer Black Phosphorus in an External Electric Field**, VY TRAN, LI YANG, Washington University in St Louis — Few-layer black phosphorus has emerged as a promising 2D semiconductor due to its highly tunable, direct band gap. In this talk, we examine the tunability of the band gap with respect to the number of layers and the under an external electric field. Using the results of DFT as well as many-body GW calculations, we explore the mechanism for the band gap reduction when increasing the number of layers in black phosphorus. We propose a simple model that describes this behavior, allowing us to calculate the band gap of multi-layer black phosphorus under an external electric field. The results are checked against *ab-initio* calculations, which shows excellent agreement. This allows us to overcome the limitations of DFT and predict the band gap for much larger layer numbers and electric field strength.

**10:12AM K16.00010 An Accurate and Compact Tight-binding Model for Phosphorene**, CARLOS PAEZ, ANA PEREIRA, University of Campinas, EDUARDO MUCCILO, University of Central Florida — In recent years, a variety of tight-binding models have been proposed for phosphorene. Although capturing key features such as the main band gap and the effective masses near the gamma point, they are not sufficiently accurate for the determination of electronic transport properties, particularly when probing states near the vicinity of extreme points of the valence and conduction bands. We propose a new tight-binding model parameterization based on the hybridization of s and p orbitals. For that purpose, we use the Slater-Koster method to construct a four-band model. We optimized the tight-binding parameters to fit the main features of *ab-initio* electronic band structure calculations and to reproduce the correct orbital composition at high-symmetry and low-symmetry points. Using this new tight-binding model, we compute some electronic transport properties of phosphorene ribbons in the presence of disorder.

**10:24AM K16.00011 Weak Localization in few layer Black Phosphorus**, NATHANIEL GILLGREN, YANMENG SHI, TIMOTHY ESPIRITU, University of California Riverside, KENJI WATANABE, TAKAHASHI TANIGUCHI, National Institute for Materials Science, CHUN NING (JEANIE) LAU, University of California Riverside — Few-layer black phosphorus has recently attracted interest from the scientific community due to its high mobility, tunable band gap, and large anisotropy. Recent experiments have demonstrated that black phosphorus provides a promising candidate to explore the physics of 2D semiconductors. In this study we explore the magnetotransport of few-layer black phosphorus-boron nitride heterostructure devices at low magnetic fields. Weak localization is observed at low temperatures. We extract the dephasing length and measure its dependence on temperature, carrier density and electric field.

**10:36AM K16.00012 Chemically Controlling Black Phosphorus Exfoliation to Achieve Variable-Sized Phosphorene<sup>1</sup>**, AMY NG, THOMAS SUTTO, US Naval Research Laboratory, YEXIN DENG, Purdue University, RHONDA STROUD, TODD BRINTLINGER, US Naval Research Laboratory, PEIDE YE, Purdue University, NABIL BASSIM, US Naval Research Laboratory — Phosphorene is the 2-dimensional form of phosphorus and a close relative of graphene. It has a nonzero fundamental band gap that gives rise to semiconductor properties, which makes it highly desirable for numerous applications in optoelectronics and as a replacement channel for conventional semiconductor devices. However, difficulties in isolating large area single-, few-, or multi-layer sheets are an impediment to realizing the aforementioned applications. We are investigating multiple chemical routes for optimal production of phosphorene sheets. Utilizing various solvent systems, ranging from a simple ethanol to dimethylformamide to more viscous ionic liquids, we have obtained flakes of differing thicknesses and sizes. We characterized the structure and composition of the resulting phosphorene sheets with aberration-corrected scanning transmission electron microscopy in addition to optical/macroscopic studies. Flake size, quality, and quantity obtained as a function of the solvent system, where factors such as viscosity, surface tension, chemical behavior, and degree of agitation, will be presented.

<sup>1</sup>This work was supported by the Office of Naval Research.

**10:48AM K16.00013 Negative differential resistance observed from vertical  $p^{+}-n^{+}$  junction device with two-dimensional black phosphorous<sup>1</sup>**, DAEYEONG LEE, YOUNG DAE JANG, JAEHWAN KWEON, JUNGJIN RYU, EUYHEON HWANG, WON JONG YOO<sup>2</sup>, Sungkyunkwan Univ. (SKKU), SAMSUNG-SKKU GRAPHENE/2D CENTER (SSGC) COLLABORATION — A vertical  $p^{+}-n^{+}$  homojunction was fabricated by using black phosphorus (BP) as a van der Waals two-dimensional (2D) material. The top and bottom layers of the materials were doped by chemical dopants of gold chloride ( $AuCl_3$ ) for p-type doping and benzyl viologen (BV) for n-type doping. The negative differential resistance (NDR) effect was clearly observed from the output curves of the fabricated BP vertical devices. The thickness range of the 2D material showing NDR and the peak to valley current ratio of NDR are found to be strongly dependent on doping condition, gate voltage, and BP's degradation level. Furthermore, the carrier transport of the  $p^{+}-n^{+}$  junction was simulated by using density functional theory (DFT) and non-equilibrium Green's function (NEGF). Both the experimental and simulation results confirmed that the NDR is attributed to the band-to-band tunneling (BTBT) across the 2D BP  $p^{+}-n^{+}$  junction, and further quantitative details on the carrier transport in the vertical  $p^{+}-n^{+}$  junction devices were explored, according to the analyses of the measured transfer curves and the DFT simulation results.

**8:00AM K17.00001 Gate-tunable electron focusing across graphene p-n junction**, SHAOWEN CHEN, Columbia University, ZHENG HAN, Institute of Metal Research, Chinese Academy of Sciences, LEI WANG, Cornell University, CORY DEAN, JAMES HONE, Columbia University — Electrons moving across a ballistic semiconductor junction experience a change in trajectory described by an electronic version of Snell's law. In the case of a barrier separating regions of  $n$  and  $p$  type carriers, negative refraction is expected, which theoretically leads to a Veselago type of electron focusing. Being a ballistic bipolar 2D system, hexagonal Boron Nitride-encapsulated graphene is expected to be a model system to realize this effect, however, robust demonstration of veselago lensing has remained limited. We describe novel methods to fabricate high quality graphene p-n junctions with atomically sharp boundaries. Using a magnetic focusing measurement scheme, we demonstrate unambiguous signatures of negative refraction in these devices. Our observations are in good agreement with simulations and shed light on future application for electronic optics in ballistic graphene.

**8:12AM K17.00002 Dynamical polarizability of the 2D pseudospin-1 dice lattice**, JOHN MALCOLM, ELISABETH NICOL, Guelph-Waterloo Physics Institute, University of Guelph — The two-dimensional dice lattice is composed of three triangular sublattices whose low-energy excitation spectrum consists of Dirac-Weyl fermions with pseudospin-1. The energy dispersion has two Dirac cones, like the pseudospin-1/2 two-triangular-sublattice graphene, with an additional third band exactly at zero energy. We present theoretical results for the electronic dynamical polarization function in the material. This is a fundamental entity in many-body physics, renormalizing the Coulomb interaction through the dielectric function. From the polarization function we also obtain the Lindhard function, the plasmon branch, and can discuss other screening effects. These are contrasted with those of graphene.

**8:24AM K17.00003 Dynamical Energy Gap Engineering in Graphene via Oscillating Out-of-Plane Deformations<sup>1</sup>**, NANCY SANDLER, DAWEI ZHAI, Department of Physics and Astronomy, Ohio University — The close relation between electronic properties and mechanical deformations in graphene has been the topic of active research in recent years. Interestingly, the effect of deformations on electronic properties can be understood in terms of pseudo-magnetic fields, whose spatial distribution and intensity are controllable via the deformation geometry. Previous results showed that electromagnetic fields (light) have the potential to induce dynamical gaps in graphene's energy bands, transforming graphene from a semimetal to a semiconductor [1, 2]. However, laser frequencies required to achieve these regimes are in the THz regime, which imposes challenges for practical purposes. In this talk we report a novel method to create dynamical gaps using oscillating mechanical deformations, i.e., via time-dependent pseudo-magnetic fields. Using the Floquet formalism we show the existence of a dynamical gap in the band structure at energies set by the frequency of the oscillation, and with a magnitude tuned by the geometry of the deformation. This dynamical-mechanical manipulation strategy appears as a promising venue to engineer electronic properties of suspended graphene devices. [1] Syzranov et al. Phys. Rev. B 78, 045407 (2008). **8:36AM K17.00004 Hyperfine interaction in hydrogenated graphene**, NOEL GARCIA, International Iberian Laboratory (INL), MANUEL MELLE, Centro Algoritmi, Universidade do Minho, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Laboratory (INL) — We study the hyperfine interaction of Hydrogen chemisorbed in graphene nanostructures with a gap in their spectrum, such as islands and ribbons. Chemisorption of Hydrogen on graphene results in a bound in-gap state that hosts a single electron localized around the adatom. Using both density functional theory and a four-orbital tight-binding model we study the hyperfine interaction between the hydrogen nuclear spin and the conduction electrons in graphene. We find that the strength of the hyperfine interaction decreases for larger nanostructures for which the energy gap is smaller. We then compare the results of the hyperfine interaction for large nanostructures with those of graphene 2D crystal with a periodic arrangement of chemisorbed Hydrogen atoms, obtaining very similar results. The magnitude of the hyperfine interaction is about 150 MHz, in line with that of Si:P. We acknowledge financial support by Marie-Curie-ITN 607904-SPINOGRAPH.

**8:48AM K17.00005 Two-particle vortices in graphene<sup>1</sup>**, MIKHAIL PORTNOI, University of Exeter, CHARLES DOWNING, University of Strasbourg — We show that a pair of two-dimensional massless Dirac-Weyl fermions can form a bound state independently on the sign of the inter-particle interaction potential, as long as this potential decays at large distances faster than Kepler's inverse distance law. The coupling occurs only at the Dirac point, when the charge carriers lose their chirality. These bipartite states must have a non-zero internal angular momentum, meaning that they only exist as stationary vortices. This leads to the emergence of a new type of energetically-favorable quasiparticles: double-charged zero-energy vortices. Their bosonic nature allows condensation and gives rise to Majorana physics without invoking a superconductor. The presence of dark-matter-like silent immobile vortices explains a range of poorly understood experiments in gated graphene structures at low doping.

**9:00AM K17.00006 Local density of states in bilayer graphene with 1D potential well**, AKIHIRO OKAMOTO, TAKEHITO YOKOYAMA, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Monolayer graphene shows anomalous behaviors at the scattering by a 1D potential well due to the massless Dirac fermions, and it is called Klein paradox. In contrast, bilayer graphene shows different behaviors at the scattering by the potential well, and is attributed to the massive chiral fermions with a parabolic dispersion. We then expect that bound states at the 1D potential well for the two cases are different, due to the different effective models and the K and K' points. In the present work, we calculate bound states induced by a 1D potential well, and compare them with the properties of 1D edge states. In particular, in the bilayer graphene, there are two types of bound states, both of which have a parabolic dispersion near K and K' points, and we describe how the dispersion changes by the change of the potential strength. We then calculate the local density of states at various positions, contributed by the scattering states and the bound states by the 1D potential well, and discuss how they depend on the potential strength.

**9:12AM K17.00007 Non-perturbative renormalization group calculation of the quasi-particle velocity and the dielectric function of graphene.**, ANAND SHARMA, CARSTEN BAUER, ANDREAS RUECKRIEGEL, PETER KOPIETZ, Univ Frankfurt — We use a nonperturbative functional renormalization group approach to calculate the renormalized quasiparticle velocity  $v(k)$  and the static dielectric function  $\epsilon(k)$  of suspended graphene as function of an external momentum  $k$ . We fit our numerical result for  $v(k)$  to  $v(k)/v_F = A + B \ln(\Lambda_0/k)$ , where  $v_F$  is the bare Fermi velocity,  $\Lambda_0$  is an ultraviolet cutoff, and  $A = 1.37$ ,  $B = 0.51$  for the physically relevant value ( $e^2/v_F = 2.2$ ) of the coupling constant. In stark contrast to calculations based on the static random-phase approximation, we find that  $\epsilon(k)$  approaches unity for  $k \rightarrow 0$ . Our result for  $v(k)$  agrees very well with a recent measurement by Elias *et al.* [Nat. Phys. **7**, 701 (2011)]. With in the same approximation, we also explore an alternative scheme in order to understand the true nature of the low energy (momentum) behavior in graphene.

**9:24AM K17.00008 Majorana Zero Modes in Graphene**, PABLO SAN-JOSE, CSIC - Madrid, JOSE L. LADO, International Iberian Nanotechnology Laboratory (INL), RAMN AGUADO, CSIC - Madrid, FRANCISCO GUINEA, Instituto Madrileo de Estudios Avanzados en Nanociencia (IMDEA-Nanociencia), JOAQUIN FERNANDEZ-ROSSIER, Departamento de Fisica Aplicada, Universidad de Alicante — A clear demonstration of topological superconductivity (TS) and Majorana zero modes remains one of the major pending goal in the field of topological materials. One common strategy to generate TS is through the coupling of an s-wave superconductor to a helical half-metallic system. Numerous proposals for the latter have been put forward in the literature, most of them based on semiconductors or topological insulators with strong spin-orbit coupling. Here we demonstrate an alternative approach for the creation of TS in graphene/superconductor junctions without the need of spin-orbit coupling. Our prediction stems from the helicity of graphene's zero Landau level edge states in the presence of interactions, and on the possibility, experimentally demonstrated, to tune their magnetic properties with in-plane magnetic fields. We show how canted antiferromagnetic ordering in the graphene bulk close to neutrality induces TS along the junction, and gives rise to isolated, topologically protected Majorana bound states at either end. We also discuss possible strategies to detect their presence. Remarkable progress has recently been reported in the fabrication of the proposed type of junctions, which offers a promising outlook for Majorana physics in graphene systems.

**9:36AM K17.00009 Electron interactions in graphene through an effective Coulomb potential<sup>1</sup>**, JOAO N. B. RODRIGUES, Centre for Advanced 2D Materials and Department of Physics, National University of Singapore, SHAFFIQUE ADAM, Centre for Advanced 2D Materials and Department of Physics, National University of Singapore and Yale-NUS College — A recent numerical work [H.-K. Tang *et al.*, PRL **115**, 186602 (2015)] considering graphene's  $\pi$ -electrons interacting through an effective Coulomb potential that is finite at short-distances, stressed the importance of the  $sp^2$ -electrons in determining the semimetal to Mott insulator phase transition in graphene. Some years ago, I. F. Herbut [PRL **97**, 146401 (2006)] studied such a transition by mapping graphene's  $\pi$ -electrons into a Gross-Neveu model. From a different perspective, D. T. Son [PRB **75**, 235423 (2007)] put the emphasis on the long-range interactions by modelling graphene as Dirac fermions interacting through a bare Coulomb potential. Here we build on these works and explore the phase diagram of Dirac fermions interacting through an effective Coulomb-like potential screened at short-distances. The interaction potential used allows for analytic results that controllably switch between the two perspectives above.

<sup>1</sup>This work was supported by the Singapore National Research Foundation (NRF-NRFF2012-01 and CA2DM medium-sized centre program) and by the Singapore Ministry of Education and Yale-NUS College (R-607-265-01312).

**9:48AM K17.00010 Quasiparticle weight and renormalized Fermi velocity of graphene with long-range Coulomb interactions<sup>1</sup>**, HO-KIN TANG, JIA NING LEAW, J. N. B. RODRIGUES, Department of Physics, National University of Singapore, P. SENGUPTA, School of Physical and Mathematical Sciences, Nanyang Technological University, F. F. ASSAAD, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, S. ADAM, Department of Physics, National University of Singapore — In this work, we study the effects of realistic Coulomb interactions in graphene using a projective quantum Monte Carlo simulation of electrons at half-filling on a honeycomb lattice. We compute the quasiparticle residue, the renormalized Fermi velocity and the antiferromagnetic order parameter as a function of both the long-range and short-range components of the Coulomb potential. We find that the Mott insulator transition is determined mostly by the short-range interaction and is consistent with the Gross-Neveu-Yukawa critical theory. Far from the critical point and in the semi-metallic regime, we find that the Fermi-velocity and quasiparticle residue are influenced by the long-range tail of the Coulomb potential, and for very small interaction strength are consistent with predictions of first order perturbation theory. For experimentally relevant and stronger values of the long-range interaction, our numerical data contradicts prediction from both perturbation theory and the renormalization group approaches.

<sup>1</sup>This work was supported by Singapore National Research Foundation (NRF-NRFF2012-01 and CA2DM mid-size Centre), Singapore Ministry of Education (Yale-NUS College R-607-265-01312 and MOE2014-T2-2-112), and DFG Grant No. AS120/9-1.

**10:00AM K17.00011 Snake states and their symmetries in graphene**, RAKESH TIWARI, University of Basel, YANG LIU, MATEJ BRADA, Loughborough University, C. BRUDER, University of Basel, F. V. KUSMARTSEV, Loughborough University, E. J. MELE, University of Pennsylvania — Snake states are open trajectories for charged particles moving in two dimensions under the influence of a spatially varying perpendicular magnetic field. They can also occur in a constant perpendicular magnetic field when the particle density is made nonuniform as realized at a pn junction in a semiconductor, or in graphene. We examine the correspondence of such trajectories in monolayer graphene in the quantum limit for two families of domain walls: (a) a uniform doped carrier density in an antisymmetric perpendicular magnetic field and (b) antisymmetric carrier density distribution in a uniform perpendicular magnetic field. Although, these families support different internal symmetries, the pattern of the boundary and interface currents is the same in both cases. We demonstrate that these two physically different situations are gauge equivalent when rewritten in a Nambu doubled formulation of the two limiting problems. Using gauge transformations in particle-hole space to connect these two problems, we map the protected interfacial modes to the Bogoliubov quasiparticles of an interfacial one-dimensional p-wave paired state.

**10:12AM K17.00012 A complete set of data to characterize loop braiding statistics in (3+1)-D topological phases**, DOMINIC ELSE, Department of Physics, University of California, Santa Barbara, CHETAN NAYAK, Microsoft Research, Station Q, University of California, Santa Barbara — In (2+1)-D, topological phases of matter can be classified by the braiding statistics of their particle-like excitations. Similarly, in (3+1)-D one expects topological phases to be characterized by the braiding statistics of their excitations, which may be particle-like or loop-like. A “braiding” of loop-like excitations is any continuous deformation of some collection of (possibly linked) loops which eventually returns the loops to their original locations. Here, we identify a finite set of basic data which determines the amplitude for *any* loop braiding in an abelian (3+1)-D topological phase. This includes the “three-loop braiding” recently considered by several authors, but also all other possible braidings. Our basic data are the natural generalization of the  $F$  and  $R$  symbols of (2+1)-D topological phases to (3+1)-D. From a mathematical point of view, we expect them to correspond to a “ribbon 2-category”.

**10:24AM K17.00013 A Bosonic Analogue of a Topological Dirac Semi-Metal<sup>1</sup>**, MATTHEW LAPA, University of Illinois at Urbana-Champaign, GIL YOUNG CHO, Korea Advanced Institute of Science and Technology, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — We construct a bosonic analogue of a two-dimensional topological Dirac Semi-Metal (DSM). The low-energy description of the most basic 2D DSM model consists of two Dirac cones at positions  $\pm \mathbf{k}_0$  in momentum space. The local stability of the Dirac cones is guaranteed by a composite symmetry  $Z_2^{T\mathcal{I}}$ , where  $T$  is time-reversal and  $\mathcal{I}$  is inversion. This model also exhibits interesting time-reversal and inversion symmetry breaking electromagnetic responses. In this work we construct a bosonic analogue of a DSM by replacing each Dirac cone with a copy of the  $O(4)$  Nonlinear Sigma Model (NLSM) with topological theta term and theta angle  $\theta = \pm\pi$ . One copy of this NLSM also describes the gapless surface termination of the 3D Bosonic Topological Insulator (BTI). We compute the time-reversal and inversion symmetry breaking electromagnetic responses for our model and show that they are twice the value one gets in the DSM case. We also investigate the local stability of the individual  $O(4)$  NLSM's in the BSM model. Along the way we clarify many aspects of the surface theory of the BTI including the electromagnetic response, the charges of vortex excitations, and the stability to symmetry-allowed perturbations.

**10:36AM K17.00014 Hydrodynamic & Transport Properties of Dirac Materials in the Quantum Limit**, MATTHEW GOCHAN, KEVIN BEDELL, Boston College — Dirac materials are a versatile class of materials in which an abundance of unique physical phenomena can be observed. Such materials are found in all dimensions, with the shared property that their low-energy fermionic excitations behave as massless Dirac fermions and are therefore governed by the Dirac equation. The most popular Dirac material, its two dimensional version in graphene, is the focus of this work. We seek a deeper understanding of the interactions in the quantum limit within graphene. Specifically, we derive hydrodynamic and transport properties, such as the conductivity, viscosity, and spin diffusion, in the low temperature regime where electron-electron scattering is dominant. To conclude, we look at the so-called universal lower bound conjectured by the anti-de Sitter/conformal field theory (AdS/CFT) correspondence for the ratio of shear viscosity to entropy density ratio. The lower bound, given by  $\eta/s \geq \hbar/(4\pi k_B)$ , is supposedly obeyed by all quantum fluids. This leads us to ask whether or not graphene can be considered a quantum fluid and perhaps a “nearly perfect fluid” (NPF); if this is the case, is it possible to find a violation of this bound at low temperatures.

**10:48AM K17.00015 Matrix Product State approach to quantum Hall quasielectrons**, HANS HANSSON, EDDY ARDONNE, JONAS KJLL, Stockholm University — Matrix product state (MPS) techniques have been successfully used to study quasiholes in different quantum Hall states. In particular it has provided a numerically very efficient way to calculate statistical braiding phases. So far it has been hard to generalize these methods to also describe quasielectrons. Using recently developed techniques for constructing explicit wave functions for the abelian quantum Hall hierarchy, we suggest a new way to construct MPS wave functions for states containing quasielectrons, and also for Abelian hierarchy states.

**8:00AM K18.00001 Anomalous Hall effect in antiferromagnetic GdPtBi**, TAKEHITO SUZUKI, ARAVIND DEVARAKONDA, YU-TING LIU, JOSEPH CHECKELSKY, Massachusetts Inst of Tech-MIT — The Berry phase of the electronic wave function is responsible for a transverse velocity of conducting carriers which results in anomalous Hall conductivity. This effect has been extensively investigated in ferromagnetic systems, but less is known in antiferromagnets. We have synthesized single crystals of GdPtBi, a metallic system which exhibits antiferromagnetic ordering below the transition temperature  $T_N = 9$  K. We have investigated the electrical transport and magnetic properties of these crystals and found a distinct anomalous Hall effect response. We will discuss these observations in the context of the known mechanisms for anomalous velocity in ferromagnets and recent models unique to antiferromagnetic systems.

**8:12AM K18.00002 Spin transport in antiferromagnetic insulator detected by spin pumping**, WEI CAO, YI LI, WILLIAM BAILEY, Columbia Univ — Spin transport in antiferromagnetic insulators has drawn attention recently. Prior work has been done on the spin diffusion length of different antiferromagnetic materials via inverse spin hall effect. In this work, we measure the spin pumping of Py/Cu/CoO to characterize the absorption of spin current in the CoO layer. The series of Py/Cu/CoO (t) with changing the thickness of CoO layer indicates that there is a Gilbert damping enhancement of 0.001 in saturation at about 2 nm at room temperature. The spin mixing conductance obtained from this experimental series and from Py (t)/Cu/CoO series is  $2.4 \text{ nm}^{-2}$  and  $3.2 \text{ nm}^{-2}$ , respectively. We also measured the spin pumping of the Py/Cu/CoO sample at low temperatures. The Gilbert damping exhibits a positive peak at about 280 K, which is close to the  $Nel$  temperature of CoO. Our work shows a finite spin mixing conductance in Py/Cu/CoO and the spin diffusion length of CoO is quite small at room temperature. We also find that its Gilbert damping reaches its maximum value at  $Nel$  temperature.

**8:24AM K18.00003 Spin current control of damping in YIG/Pt nanowires**, CHRISTOPHER SAFRANSKI, IGOR BARSUKOV, HAN KYU LEE, University of California Irvine, TOBIAS SCHNEIDER, Helmholtz-Zentrum Dresden Rossendorf, ALEJANDRO JARA, ANDREW SMITH, University of California Irvine, HOUCHEH CHANG, 3 Colorado State University, YAROSLAV TSEKOVNYAK, University of California Los Angeles, MINGZHONG WU, 3 Colorado State University, ILYA KRIVOROTOV, University of California Irvine — Understanding of spin transport at ferromagnet/normal metal interfaces is of great importance for spintronics applications. We report the effect of pure spin currents in YIG(30 nm)/Pt(6 nm) nanowires. The samples show magneto-resistance from two distinct mechanisms: (i) spin Hall magnetoresistance (SMR) and (ii) inverse spin Hall effect (ISHE) along with spin Seebeck current (SSC) induced by Ohmic heating of the Pt layer. Using the SMR and ISHE effects, we measure the spin wave eigenmodes by spin-torque ferromagnetic resonance (ST-FMR). Direct current applied to the Pt layer results in injection of spin Hall current into YIG that acts as damping or anti-damping spin torque depending on the polarity. In addition, Ohmic heating gives rise to a SSC acting as anti-damping regardless of current polarity. ST-FMR reveals current-induced variation of the spin wave mode linewidth that is asymmetric in the bias current and decreases to zero for anti-damping spin Hall current. Near this current, we observe complex interaction among the spin wave eigenmodes that we assess using micromagnetic simulations. Our results advance understanding of magnetization dynamics driven by pure spin currents.

**8:36AM K18.00004 Spin Circuit Representation of Spin Pumping in Topological Insulators<sup>1</sup>**, KUNTAL ROY, Purdue University — Earlier we developed spin circuit representation of spin pumping and combined it with the spin circuit representation for the inverse spin Hall effect to show that it reproduces the established results in literature [1]. Here we construct the spin circuit representation of spin pumping in topological insulators. The discovery of spin-polarized surface states in three-dimensional (3D) topological insulators (TIs) with strong spin-orbit coupling is promising for the development of spintronics. There is considerable bulk conduction too in 3D TIs (e.g., Bi<sub>2</sub>Se<sub>3</sub>) apart from possessing the surface states. We utilize the spin circuit model for spin orbit torques in topological insulator surface states [2] to develop the equivalent circuit model of spin pumping in topological insulators. Such equivalent circuit model developed here can be utilized to analyze available experimental results and evaluate more complex structures. [1] K. Roy et al., Spin Circuit Representation for Spin Pumping Phenomena, in APS March Meeting, Session Y28.12 (2015). [2] S. Hong, Spin Circuit Model for Spin-Orbit Torque in 2D Channels, in APS March Meeting, Session G52.1 (2015).

**8:48AM K18.00005 Spin pumping from a ferromagnet into a hopping insulator: Role of resonant absorption of magnons<sup>1</sup>**, MIKHAIL RAIKH, YUE ZHANG, DMYTRO PESIN, Univ of Utah — Motivated by recent experiments [1,2,3] on spin pumping from a ferromagnet into organic materials in which the charge transport is due to hopping, we study theoretically the generation and propagation of spin current in a hopping insulator. Unlike metals, the spin polarization at the boundary with ferromagnet is created as a result of magnon absorption within pairs of localized states and it spreads following the current-carrying resistor network (although the charge current is absent). We consider a classic resonant mechanism of the ac absorption in insulators and adapt it to the absorption of magnons. A strong enhancement of pumping efficiency is predicted when the Zeeman splitting of the localized states in external magnetic field is equal to the frequency of ferromagnetic resonance. Under this condition the absorption of a magnon takes place within *individual* sites.

<sup>1</sup>This work was supported by the NSF MRSEC program at the University of Utah under Grant No. DMR 1121252 (Z.Y. and M.E.R.) and by the NSF Grant No. DMR 1409089 (D.A.P.).

**9:00AM K18.00006 Detection of topological surface states by spin pumping at room temperature**, Y. T. FANCHIANG, C. K. CHENG, M. HONG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei 10617, Taiwan, H. Y. LIN, K. H. CHEN, S. R. YANG, C. N. WU, J. KWO, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, S. F. LEE, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan — Spin pumping on heterostructures made of ferrimagnetic YIG film and topological insulator Bi<sub>2</sub>Se<sub>3</sub> films has been performed at room temperature. In the presence of topological interface states, spin pumping induced non-equilibrium spin density caused significant resonance field shifts ( $H_{\text{res}}$  shifts) of YIG/Bi<sub>2</sub>Se<sub>3</sub> with respect to bare YIG. The uncommon  $H_{\text{res}}$  shifts correspond to clearly resolved changes of gyromagnetic ratio of YIG. As the Bi<sub>2</sub>Se<sub>3</sub> thickness varied from 4 nm to 20 nm, increasing  $H_{\text{res}}$  shifts were observed, while the enhancement of damping constant saturated at the spin diffusion length of Bi<sub>2</sub>Se<sub>3</sub>, suggesting the two parameters were of different origins. Bi<sub>2</sub>Se<sub>3</sub> thickness dependence of spin pumping revealed that Rashba-split 2DEG has comparable effects on the magnetization dynamics. From the change of gyromagnetic ratio, we calculated the imaginary part of spin mixing conductance to be one order of magnitude larger than the real part. Our results showed that with clean and well-defined interface, spin pumping may serve as an effective way to detect spin-polarized surface states.

**9:12AM K18.00007 Current-induced spin and orbital magnetizations in tellurium**, TAIKI YODA, MOTOAKI HIRAYAMA, TAKEHITO YOKOYAMA, Department of Physics, Tokyo Institute of Technology, SHOJI ISHIBASHI, TAKASHI MIYAKE, Nanosystem Research Institute, AIST, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology, TIES, Tokyo Institute of Technology — Tellurium has a characteristic helical lattice structure, and lacks inversion and mirror symmetries. Such chiral crystals lead to various novel phenomena. For example, we have shown that spin and orbital magnetizations are induced by an electric current in chiral crystals[1]. In our presentation, we calculate the current-induced spin and orbital magnetization in tellurium by using first-principles calculations. The calculations show that both spin and orbital magnetizations are induced parallel to the electric current. In tellurium we found that the orbital magnetization is larger than the spin magnetization by two orders of magnitude. The spin magnetization is induced by the current via the spin-orbit coupling. Therefore, the induced spin magnetization is limited by the size of the spin-orbit coupling. On the other hand, the orbital magnetization is determined by crystal structure without spin-orbit coupling. By using a chiral crystal, a magnetization can be induced by an electric current without ferromagnets and the spin-orbit coupling. [1]Yoda, T. et al. Sci. Rep. **5**, 12024

**9:24AM K18.00008 Enhanced spin Hall ratios by Al and Hf impurities in Pt thin films<sup>1</sup>**, MINH-HAI NGUYEN, MENGNAO ZHAO, DANIEL C. RALPH, ROBERT A. BUHRMAN, Cornell Univ — The spin Hall effect (SHE) in Pt has been reported to be strong and hence promising for spintronic applications. In the intrinsic SHE mechanism, which has been shown to be dominant in Pt, the spin Hall conductivity  $\sigma_{SH}$  is constant, dependent only on the band structure of the spin Hall material. The spin Hall ratio  $\theta_{SH} = \sigma_{SH} / \rho$ , on the other hand, should be proportional to the electrical resistivity  $\rho$  of the spin Hall layer. This suggests the possibility of enhancing the spin Hall ratio by introducing additional diffusive scattering to increase the electrical resistivity of the spin Hall layer. Our previous work has shown that this could be done by increasing the surface scattering by growing thinner Pt films in contact with higher resistivity materials such as Ta. In this talk, we discuss another approach: to introduce impurities of metals with negligible spin orbit torque into the Pt film. Our PtAl and PtHf alloy samples exhibit strong enhancement of the spin Hall torque efficiency with impurity concentration due to increased electrical resistivity.

**9:36AM K18.00009 Large Spin Hall Angle in Vanadium Film**, TAO WANG, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 USA, XIN FAN, Department of Physics and Astronomy, University of Denver, Denver, CO 80208 USA, WENRUI WANG, Department of Physics, University of Illinois, Urbana, IL 61801 USA, YUNSONG XIE, MUHAMMAD A. WARS, JUN WU, YUNPENG CHEN, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 USA, VIRGINIA O. LORENZ, Department of Physics, University of Illinois, Urbana, IL 61801 USA, JOHN Q. XIAO, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 USA — We report the large spin Hall angle observed in Vanadium film with small grain size and distorted lattice parameter. The spin Hall angle is quantified by measuring current-induced spin-orbit torque in V/CoFeB bilayer using optical spin torque magnetometer based on polar magneto-optical Kerr effect (MOKE). The spin Hall angle as large as  $\theta_{SH} = -0.071$  has been observed in V/CoFeB bilayer Structural analysis, using X-ray diffraction (XRD), transmission electron microscopy (TEM) and selected area electron diffraction (SAED), confirms films grown at room temperature have very small grain size and enlarged lattice parameter. The Vanadium films with distorted crystal structure also have high resistivity ( $>200 \mu\Omega\bullet\text{cm}$ ) and long spin diffusion length ( $\sim 16.3 \text{ nm}$ ) measured via spin pumping experiment. This finding of spin Hall effect enhancement in more disordered structure will provide insights for understanding and exploiting materials with strong spin orbit interaction, especially in light 3d transition metals which promise long spin diffusion length.

**9:48AM K18.00010 Spin-orbit torques and charge pumping in crystalline magnets**, CHIARA CICCARELLI, Univ of Cambridge — In magnetic crystals with an inversion asymmetric unit cell a non-zero global spin-polarization is generated by an electrical current, which acts with a torque on the magnetisation exciting magnetic dynamics [1]. This relativistic non-equilibrium spin phenomenon also has a reciprocal effect in which the excitation of magnons results in the pumping of a charge current [2]. The possibility to manipulate/read magnetism with electrical currents is highly relevant for magnetic memories and other spintronic devices. I will start by reviewing our recent research on spin-orbit torques (SOTs) in crystalline magnets, in particular our very recent measurements of the crystalline SOT at room temperature in half-Heusler NiMnSb thin films. With this experiment we are able to fully characterise magnitude and symmetry of the SOTs [3, 4]. I will then talk about the first demonstration of magnonic charge pumping in crystal magnet GaMnAs [2]. In this effect, which is the reciprocal effect of SOTs, the precessing ferromagnet pumps a charge current. Differently from spin pumping, which is commonly used to electrically detect magnetization dynamics, in charge pumping magnons are converted within the ferromagnet into high-frequency currents via the relativistic spin-orbit interaction, without the need of a secondary spin-charge conversion element, such as heavy metals with large spin Hall angle. Kurebayashi et al., Nature Nanotechnology 9, 211 (2014).

**10:24AM K18.00011 Experiment study on special anisotropy of spin mixing conductance**, XIAOLONG FAN, HENGAN ZHOU, Lanzhou University, LI MA, SHIMING ZHOU, Tongji University, DESHENG XUE, Lanzhou University — Spin pumping, a promising technique for generating pure spin current via ferromagnetic resonance (FMR), can pump nonequilibrium magnetization through the interface between normal metal (NM) and ferromagnetic metal or ferromagnetic insulator. The efficiency of spin current injection is determined by spin mixing conductance (SMC). In this work, we systematically investigate the values of the SMC in NM(Pt, Pd, W, Mo)/YIG systems. By using cavity FMR, we found that the SMC has in-plane isotropy but out-of-plane anisotropy. The values of SMC show maximum when magnetization is along film normal. We also used electrical detection of inverse spin Hall voltage to double check the anisotropy of SMC. We attribute such anisotropy to the interfacial spin orbit coupling.

**10:36AM K18.00012 Moderate Positive Spin Hall Angle in Uranium<sup>1</sup>**, MARTA ANGUERA, SIMRAN SINGH, ENRIQUE DEL BARCO, University of Central Florida, ROSS SPRINGELL, University of Bristol, CASEY W. MILLER, Rochester Institute of Technology — We will present results on FMR and voltage measurements of magnetic damping and the inverse spin Hall effect, respectively, in Ni<sub>80</sub>Fe<sub>20</sub>/Uranium bilayers. A pure spin current is injected into an Uranium film from the ferromagnetic resonance dynamics of the magnetization of an adjacent Ni<sub>80</sub>Fe<sub>20</sub> (permalloy) film. The spin current generated is then converted into an electric field by the inverse spin Hall effect. Our results suggest a spin mixing conductance of order  $2 \times 10^{19} \text{ m}^{-2}$  and a positive spin Hall angle of 0.004, which are both unexpected based on trends in d-electron systems. These results support the idea that materials with unfilled f-electron orbitals may require additional exploration for spin physics.

**10:48AM K18.00013 Thickness dependence of inverse spin Hall effect in Au and W studied using YIG-based spin pumping**, KENG-YUAN MENG, JACK BRANGHAM, JAMES GALLAGHER, SISHENG YU, SHANE WHITE, WILLIAM RUANE, ROHAN ADUR, CHRIS HAMMEL, FENGYUAN YANG, The Ohio State University — Yttrium iron garnet (YIG) is an excellent material for generating pure spin currents due to its narrow ferromagnetic resonance (FMR) linewidth and low damping. High quality YIG thin films are deposited by off-axis magnetron sputtering, followed by in-situ deposition of Au and W layers of varying thicknesses. Using the inverse spin-Hall effect (ISHE) in the Au and W layers, we study FMR-driven spin pumping from YIG thin films (16nm) into each metal at thicknesses of 2-50nm. Gilbert damping of these bilayers are obtained with variable frequency FMR measurements. Spin transport parameters, including the spin diffusion length in metal, spin mixing conductance at the interfaces and spin hall angles, are also determined.

Session K19 GMAG DMP FIAP: III-V Magnetic Semiconductors 318 - Paul Crowell, University of Minnesota

**8:00AM K19.00001 An X-ray standing wave study of the diluted magnetic semiconductor Ga(Mn)As**, SLAVOMIR NEMSAK, Forschungszentrum Juelich, CHENG-TAI KUO, UC Davis, CHRISTOPH SCHLUETER, Diamond Light Source, MATHIAS GEHLMANN, Forschungszentrum Juelich, SHIH-CHIEH LIN, UC Davis, SVEN DOERING, MARKUS ESCHBACH, EWA MLYNCZAK, LUKASZ PLUCINSKI, Forschungszentrum Juelich, STEPHAN BOREK, JAN MINAR, University Muenchen, HIDEO OHNO, Tohoku University, TIEN-LIN LEE, Diamond Light Source, CLAUS M. SCHNEIDER, Forschungszentrum Juelich, CHARLES S. FADLEY, UC Davis — We have combined the recently developed techniques of soft x-ray standing-wave angle-resolved photoemission (SW-ARPES) [Gray et al., EPL 104, 17004 (2013)] and hard x-ray ARPES (HARPES) [Gray et al., Nature Mat. 11, 957 (2012)] so as to be able to use single-crystal Bragg reflection to create the SW [Thiess et al., Sol. St. Comm. 150, 553 (2010)], thus permitting the first measurements of momentum- and element- resolved bulk electronic structure. The strengths of the SW-HARPES method are demonstrated using the dilute magnetic semiconductor Ga<sub>(1-x)</sub>Mn<sub>x</sub>As. A strong SW is generated by Bragg reflection of ca. 3 keV x-rays from the (111) planes of both undoped GaAs and Mn-doped thin films with x=0.05. Due to the uneven occupancy of (111) planes by either Ga(Mn) or As atoms, the element-specific band structure can be obtained with a help of the SW modulation in core levels. Apart from the site specific decomposition of the electronic structure, the SW measurements also confirmed a substitutional presence of Mn atoms at the Ga sites. This technique should be applicable to a broad range of complex materials.

**8:12AM K19.00002 Magnetism and Mn Clustering in (In, Mn)Sb Magnetic Semiconductors.<sup>1</sup>**, BRUCE WESSELS, JINDONG LIU, MICAH HANSON, JOHN PETERS, Northwestern University — Magnetic semiconductors doped with transition metal elements such as (In,Mn)Sb and (Ga,Mn)Sb are considered ideal systems for spintronic devices such as magnetic junction transistors. The magnetic behavior of these semiconductors is largely influenced by magnetic atom distribution, electronic structure, and chemical state. The Mn distribution and phase composition in (In, Mn)Sb films grown by metal-organic vapor phase epitaxy (MOVPE) were determined using X-ray photoelectron spectroscopy (XPS). From XPS the spin-orbit splitting energy of the Mn 2p core-level was found to increase with increasing Mn concentration. The measured magnetic moment per Mn atom decreases with increasing Mn concentration, which is attributed to atomic-scale clusters that are ferromagnetic or ferrimagnetic. The magnetic properties in conjunction with XPS analysis indicate that atomic-scale Mn clusters could be responsible for the high-temperature magnetism of greater than 400 K in (In,Mn)Sb. These results demonstrate the potential of modifying the magnetic properties of (In,Mn)Sb films by controlling Mn concentration or phase composition.

**8:24AM K19.00003 Electronic structure near the Fermi level in the ferromagnetic semiconductor GaMnAs studied by ultrafast time-resolved light-induced reflectivity measurements<sup>1</sup>**, TOMOAKI ISHII, TADASHI KAWAZOE, Univ of Tokyo, YUSUKE HASHIMOTO, Radboud Univ Nijmegen, HIROSHI TERADA, IRIYA MUNETA, MOTOICHI OHTSU, MASAOKI TANAKA, SHINOBU OHYA, Univ of Tokyo — The determination of the Fermi level ( $E_F$ ) position is important to understand the origin of the ferromagnetism in ferromagnetic semiconductor GaMnAs. The recent transient reflectivity (TR) spectroscopy measurement, which is potentially sensitive to the absorption edges, indicated that the  $E_F$  exists in the valence band [1]. However, the pump fluence in this study is rather high, and the accumulation of photo-carriers can shift the absorption edges. Thus, the definition of both the band gap and  $E_F$  is obscure. Here, we have performed TR spectroscopy measurements on GaMnAs films with the pump fluence carefully controlled to suppress the accumulation of photo-carriers. The energy resolution of the TR spectrum was improved to 0.5 meV. The data shows light-induced change in the reflectivity spectra which is attributed to the band-gap renormalization and band filling. We have reproduced the observed TR spectra using the Kramers-Kronig relation and found the Mn-induced electronic states near the  $E_F$  in the band gap. [1] T. de Boer et al., Phys. Rev. B 85, 033202 (2012).

**8:36AM K19.00004 High Field Magnetic Circular Dichroism in Ferromagnetic InMnSb and InMnAs<sup>1</sup>**, M. A. MEEKER, B. A. MAGILL, G. A. KHODAPARAST, Virginia Tech, D. SAHA, C. J. STANTON, University of Florida, S. MCGILL, NHMFL, Florida, B. W. WESSELS, Northwestern Univ. — An understanding of the fundamental interactions in narrow gap ferromagnetic semiconductors such as InMnAs and InMnSb has been developed primarily from static magnetization and electrical transport measurements. In this study, to provide a better understanding of the coupling of the Mn impurities to the conduction and valence bands through the sp-d exchange interactions, we have performed magnetic circular dichroism measurements (MCD) on MOVPE grown InMnAs and InMnSb. In our samples, the Mn content varies from 2% to 10.7% and all the samples have Curie temperatures above 300 K. The samples were photo-excited using a Quartz Tungsten Halogen lamp with energies ranging between 0.92-1.45 eV, and in magnetic fields up to 31 T. The temperatures ranged from 15-190 K. Comparison of the observed MCD with theoretical calculations provides a direct method to probe the band structure including the temperature dependence of the spin-orbit split-off bandgap and g-factors, as well as a means to estimate the sp-d coupling constants.

**8:48AM K19.00005 Spin-dependent transport properties of a GaMnAs-based vertical spin metal-oxide-semiconductor field-effect transistor structure<sup>1</sup>**, TOSHIKI KANAKI, HIROKATSU ASAHARA, SHINOBU OHYA, MASAOKI TANAKA, The University of Tokyo — Spin metal-oxide semiconductor field-effect transistors (spin MOSFETs) [1] are one of the most promising devices for the post-scaling era. In previous studies on spin MOSFETs[2,3], the drain-source current was controlled by the gate-source voltage and magnetization configuration of the source and drain; however, the magnetoresistance (MR) ratios (0.1% [2] and 0.005% [3]) were too small to be put into practical applications, and thus spin MOSFET with a high MR ratio is strongly required. Here, we study a GaMnAs-based vertical spin-MOSFET structure. We successfully modulate the drain-source current  $I_{DS}$  by  $\sim 0.5$  (–0.5) % with a gate-source voltage of  $-10.8$  (+10.8) V and also modulate  $I_{DS}$  by up to 60 % with changing the magnetization configuration of the GaMnAs source/drain at 3.5 K. The MR ratio is more than two orders of magnitude higher than that obtained in the previous studies on spin MOSFETs[2,3][4] [1] S. Sugahara and M. Tanaka, APL 84, 2307 (2004). [2] R. Nakane et al., JJAP 49, 113001 (2010). [3] T. Sasaki et al., Phys. Rev. Appl. 2, 034005 (2014). [4] T. Kanaki et al., submitted; arXiv:1510.07497.

**9:00AM K19.00006 Ferromagnetism in Silicon Single Crystals with Positively Charged Vacancy Clusters<sup>1</sup>**, YU LIU, Helmholtz Zentrum Dresden-Rossendorf, XINGHONG ZHANG, QUAN YUAN, JIECAI HAN, Harbin Institute of Technology, SHENGQIANG ZHOU, Helmholtz Zentrum Dresden-Rossendorf, BO SONG, Harbin Institute of Technology — Defect-induced ferromagnetism provides an alternative for organic and semiconductor spintronics. Here, we investigated the magnetism in Silicon after neutron irradiation and try to correlate the observed magnetism to particular defects in Si. Commercially available p-type Si single crystal wafer is cut into pieces for performing neutron irradiations. The magnetic impurities are ruled out as they can not be detected by secondary ion mass spectroscopy. With positron annihilation lifetime spectroscopy, the positron trapping center corresponding to lifetime 375 ps is assigned to a kind of stable vacancy clusters of hexagonal rings (V6) and its concentration is enhanced by increasing neutron doses. After irradiation, the samples still show strong diamagnetism. The weak ferromagnetic signal in Si after irradiation enhances and then weakens with increasing irradiation doses. The saturation magnetization at room temperature is almost the same as that at 5 K. The X-ray magnetic circular dichroism further provides the direct evidence that Silicon is the origin of this ferromagnetism. Using first-principles calculations, it is found that positively charged V6 brings the spin polarization and the defects have coupling with each other.

### 9:12AM K19.00007 Microscopic understanding of spin current probed by shot noise<sup>1</sup>, TOMONORI

ARAKAWA, Department of Physics, Graduate School of Science, Osaka University, 560-0043, Toyonaka, Osaka — The spin currents is one of key issue in the spintronics field and the generation and detection of those have been intensively studied by using various materials. The analysis of experiments, however, relies on phenomenological parameters such as spin relaxation length and spin flip time. The microscopic nature of the spin current such as energy distribution and energy relaxation mechanism, has not yet well understood. To establish a better microscopic understanding of spin currents, I focused on the shot noise measurement which is well established technique in the field of mesoscopic physics [Y. M. Blanter and M. Büttiker, Phys. Rep. 336, 1 (2000)]. Although there are many theoretically works about shot noise in the presence of spin currents, for example detection of spin accumulation [J. Meair, P. Stano, and P. Jacquod, Phys. Rev. B 84 (2011).], estimation of spin flip currents, and so on, these predictions have never been experimentally confirmed. In this context, we reported the first experimental detection of shot noise in the presence of the spin accumulation in a (Ga,Mn)As/tunnel barrier/n-GaAs based lateral spin valve device [T. Arakawa et al., Phys. Rev. Lett. 114, 016601 (2015)].

Together with this result, we found however that the effective temperature of the spin current drastically increases due to the spin injection process. This heating of electron system could be a big problem to realize future spin current devices by using quantum coherence, because the effective temperature rise directly related to the destruction of the coherence of the spin current. Therefore, then we focused on the mechanism of this heating and the energy relaxation in a diffusive channel. By measuring current noise and the DC offset voltage in the usual non-local spin valve signal as a function of the spin diffusion channel length, we clarified that the electron-electron interaction length, which is the characteristic length for the relaxation of the electron system, is much longer than the spin relaxation length. In other words, the spin currents in such a semiconducting material can be strongly out of equilibrium. In this invited talk, I will present a series of experimental work on the spin current in a (Ga,Mn)As/tunnel barrier/n-GaAs based lateral spin valve device, mainly probed by the current noise measurement. Finally I hope I will mention about our future plan to cool down the effective temperature of the spin current by using superconductivity.

### 9:48AM K19.00008 Physical Properties of Fe-doped Ba(Mn<sub>1-x</sub>Fe<sub>x</sub>)<sub>2</sub>Sb<sub>2</sub> Single Crystals, ZHENYU

DIAO, JIANNENG LI, AHMAD US SALEHEEN, TAPAS SAMANTA, W.ADAM PHELAN, SHANE STADLER, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University — BaMn<sub>2</sub>Sb<sub>2</sub> forms the ThCr<sub>2</sub>Si<sub>2</sub>-type crystal structure and has the magnetic semiconducting ground state. In attempt to alter its ground-state properties, Mn is partially substituted by Fe resulting in Ba(Mn<sub>1-x</sub>Fe<sub>x</sub>)<sub>2</sub>Sb<sub>2</sub>. While the doped system remains the same structure for  $x \leq 0.5$ , its electrical and thermal conductivity decreases with increasing  $x$ , suggesting that doping-induced disorder plays an important role. Magnetically, we find that, with increasing  $x$ , the magnetic transition temperature  $T_M$  decreases (from 700 K for  $x = 0$  to 500 K for  $x = 0.5$ ) but magnetic susceptibility increases above and below  $T_M$ . These and low-temperature magnetization anisotropy suggest the canted-antiferromagnetic configuration with net magnetic moment in BaMn<sub>2</sub>Sb<sub>2</sub>. The antiferromagnetic interaction is gradually suppressed upon Fe doping, leading to the enhanced ferromagnetic component in Ba(Mn<sub>1-x</sub>Fe<sub>x</sub>)<sub>2</sub>Sb<sub>2</sub>.

### 10:00AM K19.00009 Magnetic Coupling in FeBi<sub>2</sub>Se<sub>4</sub> and FeSb<sub>2</sub>Se<sub>4</sub> from first principles, LOGAN

WILLIAMS, EMMANOUIL KIOUPAKIS, JUAN LOPEZ, PIERRE FERDINAND P. POUDEU, University of Michigan — Spintronic devices offer benefits in power efficiency and size reduction over current electronics, but require the development of semiconductor materials with favorable magnetic properties. Specifically, a high ferromagnetic-to-paramagnetic Curie transition temperature is required for spintronics operation at room temperature. FeBi<sub>2</sub>Se<sub>4</sub> and FeSb<sub>2</sub>Se<sub>4</sub> are two n and p-type magnetic semiconductors, respectively, with Curie transition temperatures of 450K. We employ first-principles calculations based on density functional theory to examine the magnetic coupling mechanisms in these materials. Our results indicate that antisite defects of Fe upon the Bi/Sb sites are crucial to the ferromagnetic coupling of the Fe magnetic moments in the crystals. This research was supported by the National Science Foundation CAREER award through Grant No. DMR-1254314. Computational Resources were provided by the DOE NERSC facility.

### 10:12AM K19.00010 Strain fields and electronic structure of CrN<sup>1</sup>, TOMAS ROJAS, SERGIO E. ULLOA,

Ohio University — Chromium nitride (CrN) has a promising future for its resistance to corrosion and hardness, and very interesting magnetic and electronic properties. CrN presents a phase transition in which the crystal structure, magnetic ordering and electronic properties change at a (Nel) temperature  $\sim 280$  K. Thin films from different labs exhibit different conductance behavior at low temperature. We study the unusual electronic and magnetic properties of thin layers. For that purpose we develop a tight binding Hamiltonian based on the Slater-Koster approach, and estimate the interaction between the Cr-3d and N-2p orbitals, by analyzing the band structure and comparing it with ab initio calculations performed using the LSDA+U method [1]. These calculations show the system to behave as a semiconductor below the Nel temperature. Based on our model we calculate the effective masses and analyze the effect of strain fields in the electronic structure in order to understand the electronic behavior near the phase transition. ### 10:24AM K19.00011 Observation of the room-temperature local ferromagnetism and its nanoscale growth in the ferromagnetic semiconductor GeFe<sup>1</sup>, Y. K. WAKABAYASHI, S. SAKAMOTO, The Univ.

of Tokyo, Y. TAKEDA, JAEA, K. ISHIGAMI, Y. TAKAHASHI, Y. SAITOH, The Univ. of Tokyo, H. YAMAGAMI, JAEA, A. FUJIMORI, M. TANAKA, S. OHYA, The Univ. of Tokyo — Group-IV-based ferromagnetic semiconductor GeFe is expected to be efficient spin injectors and detectors in group-IV-based semiconductor devices, because it can be epitaxially grown on Si and Ge substrates [1,2] and the  $T_C$  can be increased up to 210 K by annealing [3]; however, detailed microscopic understanding of the ferromagnetism is lacking. In this study, we have investigated the local magnetic properties of the GeFe films, using soft X-ray magnetic circular dichroism. We found that nanoscale local ferromagnetic regions formed in the high-Fe-content regions exist even at room temperature, well above the Curie temperature of 20 - 100 K. We also observed the intriguing nanoscale growth process of the local ferromagnetic regions in which they expand as temperature decreases, followed by a transition of the entire film into a ferromagnetic state at the Curie temperature [4]. **10:36AM K19.00012 Magnon-drag and thermomagnetic transport properties of Ca doped YIG<sup>1</sup>**, YUANHUA ZHENG, BIN HE, The Ohio State University - Columbus, XI CHEN, JIANSHI ZHOU, University of Texas at Austin, LI SHI, ROBERTO MYERS, JOSEPH HEREMANS, The Ohio State University - Columbus — Yttrium-iron garnet (YIG) is an insulating ferromagnet commonly used to study various spin transport phenomena: in conjunction with a Pt film, it generates the well-known spin-Seebeck effect [1]. Because of the close relationship between the spin-Seebeck effect and the magnon-drag charge Seebeck effect [2], we investigate the thermoelectric transport properties of an electrically conducting bulk YIG crystal doped p-type with Ca. A large and sharp change in the thermopower of Ca:YIG near the Curie temperature has been observed, which is potentially explained by the magnon-drag model. We present the temperature dependence of electrical conductivity, magneto-thermopower, and Hall coefficient of Ca:YIG. Photo-excitation of the carriers from the valence band into the Ca level results in photoconductivity and photo-Seebeck effects as well. [1] Jin et al., *Phys. Rev. B* 92, 054436 (2015) [2] Lucassen et al., *Appl. Phys. Lett.* 99 262506 (2011)

**8:00AM K20.00001 Continuous-time auxiliary field quantum Monte Carlo study of charge ordering in two-dimensional extended Hubbard model.**, HANNA TERLETSKA, University of Michigan, TIANRAN CHEN, West Chester University of Pennsylvania, EMANUEL GULL, University of Michigan — The competition between local and non-local long-range Coulomb repulsions in strongly interacting electron systems leads to emergence of complex charge ordering phases. To perform the quantum many-body simulations of such effects, we extend the existing continuous-time auxiliary field quantum Monte Carlo method to incorporate the non-local density-density interactions. We apply the developed method to the two-dimensional extended Hubbard model (with all range of non-local interactions) at and away from the half-filling. We explore the properties of the model in different parameter regimes of short and long range interactions, temperature and fillings.

**8:12AM K20.00002 Diagrammatic Monte Carlo for Dual Fermions**, SERGEI ISKAKOV, EMANUEL GULL, Univ of Michigan - Ann Arbor — The dual fermion series is a diagrammatic extension of the dynamical mean field theory that includes non-local dynamic correlations. Evaluating this series analytically has proven to be challenging. In this talk we show results for a diagrammatic Monte Carlo method that stochastically samples two-particle vertex diagrams of the dual fermion perturbation series. We present an introduction to the method and show applications to correlated systems.

**8:24AM K20.00003 The numerical renormalization group and multi-orbital impurity models**, ANDREAS WEICHELBAUM, K. M. STADLER, J. VON DELFT, Ludwig Maximilians University, Munich, Germany, Z. P. YIN, G. KOTLIAR, Rutgers University, Piscataway, New Jersey, ANDREW MITCHELL, Utrecht University, The Netherlands — The numerical renormalization group (NRG) is a highly versatile and accurate method for the simulation of (effective) fermionic impurity models. Despite that the cost of NRG is exponential in the number of orbitals, by now, symmetric three-band calculations have become available on a routine level. [1] Here we present a recent detailed study on the spin-orbital separation in a three-band Hund metal with relevance for iron-pnictides via the dynamical mean field theory (DMFT). [2] In cases, finally, where the orbital symmetry is broken, we demonstrate that interleaved NRG [3] still offers an accurate alternative approach within the NRG with dramatically improved numerical efficiency at comparable accuracy relative to conventional NRG.

**8:36AM K20.00004 DFT+DMFT calculation of band gaps for the transition metal monoxides NiO, CoO, FeO and MnO.**<sup>1</sup>, LONG ZHANG, Department of Physics, University of Florida, Gainesville, Florida, USA, PETER STAAR, Institute for Theoretical Physics, ETH Zurich, Switzerland, ANTON KOZHEVNIKOV, Swiss National Supercomputing Centre, ETH Zurich, Switzerland, THOMAS SCHULTHEISS, Institute for Theoretical Physics, ETH Zurich, Switzerland, HAI-PING CHENG, Department of Physics, University of Florida, Gainesville, Florida, USA — We report calculated spectral functions of the four late transition metal monoxides MnO, FeO, CoO and NiO in the paramagnetic phase. We used density functional theory (DFT) in combination with dynamic mean field theory (DMFT), which gives much better description of band gaps. Both projected Wannier orbitals and the on-site screened Coulomb interactions are obtained from DFT ground states to ensure consistency. Because of the p-d hybridization in these materials, we calculated Coulomb interactions for the dp model as well as the d-dp model using the cRPA method. With the standard fully localized limit double counting correction, we found that the d-dp model gives results in better agreement with experiments. This work was supported by the US Department of Energy (DOE), Office of Basic Energy Sciences (BES), under Contract No. DE-FG02-02ER45995.

**8:48AM K20.00005 Probing many body effects using Fourier Transform Scanning Tunneling Spectroscopy: Can spin-orbit splitting in dispersion be observed in q-space?** , GELAREH FARAH, Univ of British Columbia, UBC LABORATORY FOR ATOMIC IMAGING RESEARCH (LAIR)) TEAM — Well studied surface systems such as Ag and Cu provide a safe platform to test novel spectroscopy methods that can have extended applications in near future. Our current focus is given to Fourier Transform Scanning Tunneling Spectroscopy (FT-STs) that allows us to study scattering effects (quasiparticle interactions - namely QPI) of CO and Co on Cu(111) surface. Magnetic Co adatoms are expected to generate a spin-orbit split in dispersion in QPI(q) space, the existence of which is confirmed by the k-space angle-resolved photo-emission spectroscopy (ARPES) of Cu(111) surface in the recent years. Hence the previously observed electron-phonon kink and spin-orbit splitting of the dispersion, as well as the scattering properties of CO molecules and Co adatoms, should also be observable in QPI space via FT-STs of Cu(111), and compatible with previous studies on similar systems. We are using a low temperature (4.2 K) commercial Scanning Tunneling Microscope (CREATEC STM) that operates using Nanonis electronic controllers and software which allows us to perform FT-STs as well as topological imaging.

**9:00AM K20.00006 Deconfined criticality in "easy-plane"  $SU(N)$  anti-ferromagnets<sup>1</sup>** , JONATHAN D'EMIDIO, GANPATHY MURTHY, RIBHU KAUL, University of Kentucky — Motivated by evidence for deconfined criticality in  $SU(N)$  anti-ferromagnets, we investigate the phase diagram of these models in the case where the  $SU(N)$  symmetry is reduced to rotations about the diagonal generators ("easy-plane" symmetry). We carry out extensive numerical simulations using quantum Monte Carlo, revealing a first-order magnetic to valence bond solid phase transition that becomes a continuous deconfined transition at large  $N$ . We support our numerical data by performing epsilon expansions of the easy-plane deformed  $CP^{N-1}$  field theory near both the upper and lower critical dimensions. This renormalization group analysis shows that the symmetric deconfined fixed point is unstable in the presence of easy-plane anisotropy, resulting in a runaway flow for intermediate values of  $N$  and a flow towards a stable easy-plane deconfined fixed point at large  $N$ , which is consistent with the critical behavior of our lattice models.

**9:12AM K20.00007 Magnetic transitions and quantum criticality in the three-dimensional Hubbard model<sup>1</sup>** , THOMAS SCHÄFER, Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria, ANDREY KATANIN, Institute of Metal Physics, Ural Federal University, Ekaterinburg, Russia, KARSTEN HELD, ALESSANDRO TOSCHI, Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria — We analyze the (quantum) critical properties of the simplest model for electronic correlations, the Hubbard model, in three spatial dimensions by means of the dynamical mean field theory (DMFT, including all local correlations) and the dynamical vertex approximation (D $\Gamma$ A, including non-local correlations on all length scales). Both in the half-filled/unfrustrated [1] and in the hole-doped system [2] the transition temperature is significantly lowered by including non-local fluctuations.

In the latter case, however, the magnetic order becomes incommensurate, eventually leading to a complete suppression of the order and giving rise to a magnetic quantum critical point (QCP) at zero temperature [2]. We analyze the (quantum) critical properties of this QCP (e.g. critical exponents) and relate our findings to the standard theory of quantum criticality in metals, the Hertz-Millis-Moriya theory.

**9:24AM K20.00008 A Multiorbital DMFT Analysis of Electron-Hole Asymmetry in the Dynamic Hubbard Model** , CHRISTOPHER POLACHIC, Williams Baptist College, FRANK MARSIGLIO, University of Alberta — The dynamic Hubbard model (DHM) improves on the description of strongly correlated electron systems provided by the conventional single-band Hubbard model through additional electronic degrees of freedom, namely a second, higher energy orbital and associated hybridization parameters for interorbital transitions. The additional orbital in the DHM provides a more realistic modeling of electronic orbital "relaxation" in real lattices. One result of orbital relaxation is a clear electron-hole asymmetry, absent in the single-band case. We have employed the computational technique of dynamical mean field theory, generalized to the two-orbital case, to study this asymmetry with respect to varying system parameters, including both intersite and intrasite orbital hybridization as well as the role played by Mott physics. Our results stand in good agreement with previous exact diagonalization studies of the DHM.

**9:36AM K20.00009 Interlaced coarse-graining for the dynamical cluster approximation<sup>1</sup>** , URS HAEHNER, ETH Zurich, PETER STAAR, IBM Research - Zurich, MI JIANG, ETH Zurich, THOMAS MAIER, Oak Ridge National Laboratory, THOMAS SCHULTHEISS, ETH Zurich — The negative sign problem remains a challenging limiting factor in quantum Monte Carlo simulations of strongly correlated fermionic many-body systems. The dynamical cluster approximation (DCA) makes this problem less severe by coarse-graining the momentum space to map the bulk lattice to a cluster embedded in a dynamical mean-field host. Here, we introduce a new form of an interlaced coarse-graining and compare it with the traditional coarse-graining. We show that it leads to more controlled results with weaker cluster shape and smoother cluster size dependence, which with increasing cluster size converge to the results obtained using the standard coarse-graining. In addition, the new coarse-graining reduces the severity of the fermionic sign problem. Therefore, it enables calculations on much larger clusters and can allow the evaluation of the exact infinite cluster size result via finite size scaling. To demonstrate this, we study the hole-doped two-dimensional Hubbard model and show that the interlaced coarse-graining in combination with the DCA<sup>+</sup> algorithm permits the determination of the superconducting  $T_c$  on cluster sizes, for which the results can be fitted with the Kosterlitz-Thouless scaling law.

<sup>1</sup>This research used resources of the Oak Ridge Leadership Computing Facility (OLCF) awarded by the INCITE program, and of the Swiss National Supercomputing Center. OLCF is a DOE Office of Science User Facility supported under Contract DE-AC05-00OR22725.

**9:48AM K20.00010 Diagrammatic Monte Carlo sampling of the dual-fermion expansion for the Hubbard model** , JAN GUKELBERGER, University of Sherbrooke, EVGENY KOZIK, King's College London, HARTMUT HAFERMANN, Huawei Technologies Co. Ltd. — The dual-fermion approach provides a formally exact prescription for calculating the properties of a correlated electron system in terms of a diagrammatic expansion around dynamical mean-field theory (DMFT). The approach can address the full range of interactions, is exact in both the weak- and strong-coupling limits, and naturally incorporates long-range correlations beyond the reach of current cluster extensions to DMFT. Practical implementations have so far been limited to leading-order or ladder-type approximations to the expansion. In this work we compute the dual-fermion expansion for the Hubbard model to higher orders by means of a diagrammatic Monte Carlo algorithm which stochastically samples all diagram topologies. This approach allows a systematic check for the convergence of the series and hence provides a route towards a fully controlled treatment of correlated electrons.

**10:00AM K20.00011 Hubbard operator density functional theory for Fermionic lattice models**, ZHENGQIAN CHENG, CHRIS MARIANETTI, Columbia Univ — We formulate an effective action as a functional of Hubbard operator densities whose stationary point delivers all local static information of the interacting lattice model. Using the variational principle, we get a self-consistent equation for Hubbard operator densities. The computational cost of our approach is set by diagonalizing the local Fock space. We apply our method to the one and two band Hubbard model (including crystal field and on-site exchange) in infinite dimensions where the exact solution is known. Excellent agreement is obtained for the one-band model. In the two-band model, good agreement is obtained in the metallic region of the phase diagram in addition to the metal-insulator transition. While our approach does not address frequency dependent observables, it has a negligible computational cost as compared to dynamical mean field theory and could be highly applicable in the context total energies of strongly correlated materials and molecules.

**10:12AM K20.00012 Towards an ab-initio treatment of nonlocal electronic correlations with dynamical vertex approximation<sup>1</sup>**, ANNA GALLER, PATRIK GUNACKER, JAN TOMCZAK, PATRIK THUNSTRÖM, KARSTEN HELD, Vienna University of Technology — Recently, approaches such as the dynamical vertex approximation (DΓA) [1] or the dual-fermion method [2] have been developed. These diagrammatic approaches are going beyond dynamical mean field theory (DMFT) by including nonlocal electronic correlations on all length scales as well as the local DMFT correlations. Here we present our efforts to extend the DΓA methodology to ab-initio materials calculations (ab-initio DΓA) [3]. Our approach is a unifying framework which includes both GW and DMFT-type of diagrams, but also important nonlocal correlations beyond, e.g. nonlocal spin fluctuations. In our multi-band implementation we are using a worm sampling technique [4] within continuous-time quantum Monte Carlo in the hybridization expansion to obtain the DMFT vertex, from which we construct the reducible vertex function using the two particle-hole ladders. As a first application we show results for transition metal oxides. [1] A. Toschi, A. A. Katanin, and K. Held, Physical Review B 75, 045118 (2007). [2] A. N. Rubtsov, M. I. Katsnelson, A. I. **10:24AM K20.00013 Extremely Correlated Fermi Liquid theory: Imposing the hole density sum-rule<sup>1</sup>**, B. SRIRAM SHASTRY, Univ of California-Santa Cruz — The analytical theory of extremely strongly correlated Fermi liquids (ECFL) for the large U models, when applied to Cuprate superconductors in the nodal direction, provides ARPES spectral line shapes that are very close to experiments. Approximate lowest order calculations within this formalism also closely reproduce the spectral line shapes for the single impurity Anderson model found using the Numerical Renormalization Group. Similarly excellent comparison is possible with the Dynamical Mean Field Theory self energy for the Hubbard model in high dimensions. However these calculations yields too large an energy scale for frequency dependence, in the proximity of integer (or Mott) filling. We show that the theory permits the imposition of sum rules for hole density, rather than the electron density used earlier, on the Greens functions of the theory. The numerical results of these variants are presented, and compared to the earlier calculations. The new results go a long way towards resolving the energy scale problem, while retaining the excellence of line shapes.

**10:36AM K20.00014 Space-time separation of electronic correlations**, JAN M. TOMCZAK, THOMAS SCHÄFER, BENJAMIN KLEBEL, ALESSANDRO TOSCHI, Vienna University of Technology — While second-order phase transitions always cause strong nonlocal fluctuations, their effect on spectral properties crucially depends on the dimensionality. First, we show that for the important case of three dimensions the electron self-energy is well separable into a local dynamical part and static nonlocal contributions[1]. In particular, using the dynamical vertex approximation for the doped 3D Hubbard model, we demonstrate that the quasiparticle weight remains essentially momentum independent, despite overall large nonlocal corrections to the self-energy when approaching the spin-ordered state. This generalizes earlier empirical findings of this property in the iron pnictides[2] and transition metal oxides[3] based on Hedin's *GW* approximation. With this insight, we here propose a "space-time-separated" scheme for many-body perturbation theory that is up to ten times more efficient than current implementations. Finally, we discuss limits of the space-time separation of correlation effects by studying the crossover from three to two dimensions.

**10:48AM K20.00015 Computation of ab initio energy savings due to magnetic interactions<sup>1</sup>**, ALEXANDER MUNOZ, LUCAS WAGNER, Univ of Illinois - Urbana — The double-exchange mechanism [1] is the traditional explanation for antiferromagnetic coupling between magnetic ions. In this theory, the energy savings within the context of a hopping model is derived from kinetic energy terms. However, the connection to ab initio energy savings to our knowledge has not been studied using an explicitly correlated theory that can obtain quantitative accuracy. Our study focuses on determining, from ab initio calculations, whether the origin of interactions in magnetic systems is explainable through conventional arguments. To this end, we investigate the contributions (kinetic, ionic, electron-electron) to the total energy of the (Mn-O-Mn)<sup>+2</sup> system using quantum Monte Carlo techniques. We will report on progress in elucidating the connection between the ab initio energy savings and the effective model energy savings that result in an antiferromagnetic interaction in this system. Session K21 DCMP GPC: Geophysics and Planetary Science 320 - Arianna Gleason, Los Alamos National Laboratory

**8:00AM K21.00001 Ab initio Raman spectroscopy of water under extreme conditions**, VIKTOR ROZSA, DING PAN, QUAN WAN, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Water exhibits one of the most complex phase diagrams of any binary compound. Despite extensive studies, the melting lines of high-pressure ice phases remain very controversial, with reports differing by hundreds of Kelvin. The boundary between ice VII and liquid phase is particularly disputed, with recent work exploring plasticity and amorphization mediating the transition. Raman measurements are often used to fingerprint melting, yet their interpretation is difficult without atomistic modeling. Here, we report a study of high P/T water where we computed Raman spectra using a method [1] combining ab initio molecular dynamics and density functional perturbation theory, as implemented in the Qbox code [2]. Spectra were computed for the liquid at 10 and 20 GPa, both at 1000 K, and for solid ice VII (20 GPa, 500 K). Decomposing the spectra into inter and intra molecular contributions provided insight into the dynamics of the hydrogen-bonded network at extreme conditions. The relevance of our simulation results for models of water in Earth, Uranus, and Neptune will be discussed, and an interpretation of existing experiments at high pressure will be presented. [1] Wan, Q., Spanu, L., Galli, G., Gygi, F., J. Chem. Theory Comput. 9, 4124. (2013) [2] <http://qboxcode.org>

**8:12AM K21.00002 Conductivity and Correlations in Fe at Earth Core Conditions**, R.E. COHEN, Carnegie Inst for Science and LMU, PENG ZHANG, Department of Physics, Xi'an Jiaotong University, KRISTJAN HAULE, Dept. Physics, Rutgers University — We have computed electrical conductivity in iron at Earth core conditions self-consistently within many-body theory using DFT/DMFT. We find that electron correlations are important even in the generation of Earth's magnetic field. Earth's magnetic field was believed to arise from thermal convection of molten iron alloy in Earth's outer core, but density functional theory (DFT) calculations suggested that the conductivity of iron is too high to support thermal convection, so that new geodynamo models were being developed. The DFT computations for resistivity were based on the scattering of electrons off of atomic vibrations, or electron-phonon (e-p) scattering. We applied self-consistent density functional theory plus dynamical mean-field theory (DFT+DMFT) to iron and found that at high temperatures electron-electron (e-e) scattering is comparable to the e-p scattering, bringing theory into agreement with experiments and solving the transport problem in Earth's core, consistent with the conventional thermal geodynamo [Peng, Cohen, and Haule, Nature 517, 605, 2015]. How electron correlations change with pressure, and how this affects material properties, will be discussed. This work is supported by the US National Science Foundation and the ERC Advanced grant ToMCA<sup>2</sup>.

**8:24AM K21.00003 A Green Function Approach to the Effects of Core-state Overlap on Interatomic Interactions at Extreme Densities**, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, G MALCOLM STOCKS, Materials Science and Technology Division, Oak Ridge National Laboratory — Under extreme conditions of temperature and pressure, interatomic separations in condensed matter can approach a small fraction of those under normal laboratory conditions. For example, during high-energy ( $\sim 100$  keV) radiation damage cascades, interatomic separations can be as small as  $0.5\text{\AA}$ . Under such conditions, core states between neighboring atoms could overlap and must be included as band states. Here we use Greens function method in the framework of multiple scattering theory, also known as Korringa-Kohn-Rostoker (KKR) electronic structure methods, to seamlessly integrate these core overlap effects within an all-electron *ab initio* approach. To accomplish these we use multiple integration contours in the complex plane that incorporate states normally treated as bound atomic levels. We show results for Ni and NiFe alloys in extreme densities ( $a/a_0 \sim 0.3$ ) to illustrate the convergence of the method with respect to which core states are banded as well as the angular momentum cut-off required to establish absolute convergence of the total energies. Results are compared with those of plane-wave methods for different choices of the underlying pseudo potential to establish the range of validity of the various approaches.

**8:36AM K21.00004 Dissolved carbon in extreme conditions characterized by first principles simulations<sup>1</sup>**, DING PAN, GIULIA GALLI, Institute for Molecular Engineering, the University of Chicago — One key component to understanding carbon transport in the Earth interior is the determination of the molecular species formed when carbon bearing materials are dissolved in water at extreme conditions. We used first principles molecular dynamics to investigate oxidized carbon in water at high pressure (P) and high temperature (T), up to the conditions of the Earth's upper mantle. Contrary to popular geochemistry models assuming that  $\text{CO}_2$  is the major carbon species present in water, we found that most of the dissolved carbon at 10 GPa and 1000 K is in the form of solvated  $\text{CO}_3^{2-}$  and  $\text{HCO}_3^-$  anions. We also found that ion pairing between alkali metal cations and  $\text{CO}_3^{2-}$  or  $\text{HCO}_3^-$  anions is greatly affected by P-T conditions, decreasing with pressure along an isotherm. Our study shows that it is crucial to take into account the specific molecular structure of water under extreme conditions and the changes in hydrogen bonding occurring at high P and T, in order to predict chemical reactions in dissolved carbon. Our findings also shed light on possible reduction mechanisms of  $\text{CO}_2$  when it is geologically stored, depending on the availability of water.

**8:48AM K21.00005 ABSTRACT WITHDRAWN —**

**9:00AM K21.00006 Novel stable compounds in the Mg-Si-O system under exoplanet pressures and their implications in planetary science**, HAIYANG NIU, State Univ of NY- Stony Brook, ARTEM OGANOV, Skolkovo Institute of Science and Technology, XINGQIU CHEN, DIANZHONG LI, Institute of Metal Research — The Mg-Si-O system is the major Earth and rocky planet-forming system. Here, through quantum variable-composition evolutionary structure explorations, we have discovered several unexpected stable binary and ternary compounds in the Mg-Si-O system. Besides the well-known  $\text{SiO}_2$  phases, we have found two extraordinary silicon oxides,  $\text{SiO}_3$  and  $\text{SiO}$ , which become stable at pressures above 0.51 TPa and 1.89 TPa, respectively. In the Mg-O system, we have found one new compound,  $\text{MgO}_3$ , which becomes stable at 0.89 TPa. We find that not only the  $(\text{MgO})_x(\text{SiO}_2)_y$  compounds, but also two  $(\text{MgO}_3)_x(\text{SiO}_3)_y$  compounds,  $\text{MgSi}_3\text{O}_{12}$  and  $\text{MgSiO}_6$ , have stability fields above 2.41 TPa and 2.95 TPa, respectively. The highly oxidized  $\text{MgSi}_3\text{O}_{12}$  can form in deep mantles of mega-Earths with masses above  $20 M_\oplus$  ( $M_\oplus$ :Earth's mass). Furthermore, the dissociation pathways of pPv- $\text{MgSiO}_3$  are also clarified, and found to be different at low and high temperatures. The low-temperature pathway is  $\text{MgSiO}_3 \Rightarrow \text{Mg}_2\text{SiO}_4 + \text{MgSi}_2\text{O}_5 \Rightarrow \text{SiO}_2 + \text{Mg}_2\text{SiO}_4 \Rightarrow \text{MgO} + \text{SiO}_2$ , while the high-temperature pathway is  $\text{MgSiO}_3 \Rightarrow \text{Mg}_2\text{SiO}_4 + \text{MgSi}_2\text{O}_5 \Rightarrow \text{MgO} + \text{MgSi}_2\text{O}_5 \Rightarrow \text{MgO} + \text{SiO}_2$ . Present results are relevant for models of the internal structure of giant exoplanets, and for understanding the high-pressure behavior of materials.

**9:12AM K21.00007 Spin crossover in solid and liquid (Mg,Fe)O at extreme conditions<sup>1</sup>**, LARS STIXRUDE, Department of Earth Sciences, University College London, EERO HOLMSTROM, Department of Applied Physics, COMP Centre of Excellence, Aalto University, Finland — Ferroperricite,  $(\text{Mg,Fe})\text{O}$ , is a major constituent of the Earth's lower mantle (24-136 GPa). Understanding the properties of this component is important not only in the solid state, but also in the molten state, as the planet almost certainly hosted an extensive magma ocean initially. With increasing pressure, the Fe ions in the material begin to collapse from a magnetic to a nonmagnetic spin state. This crossover affects thermodynamic, transport, and electrical properties. Using first-principles molecular dynamics simulations, thermodynamic integration, and adiabatic switching, we present a phase diagram of the spin crossover. In both solid and liquid, we find a broad pressure range of coexisting magnetic and non-magnetic ions due to the favorable enthalpy of mixing of the two. In the solid increasing temperature favors the high spin state, while in the liquid the opposite occurs, due to the higher electronic entropy of the low spin state. Because the physics of the crossover differ in solid and liquid, melting produces a large change in spin state that may affect the buoyancy of crystals freezing from the magma ocean in the earliest Earth.

**9:24AM K21.00008 Amorphization and nanocrystallization of silicon under laser shock compression: bridging experiment with atomic simulation.**<sup>1</sup>, SHITENG ZHAO, BIMAL KAD, ERIC HAHN, Univ of California - San Diego, BRUCE REMINGTON, CHRISTOPHER WEHRENBURG, Lawrence Livermore National Laboratory, EDUARDO BRINGA, Universidad Nacional de Cuyo, CHANNING HUNTINGTON, HYE-SOOK PARK, Lawrence Livermore National Laboratory, KARREN MORE, Oak Ridge National Laboratory, MARC MEYERS, Univ of California - San Diego — Terawatt, nanosecond-duration, laser-driven, shock compression and recovery experiments on [001] silicon unveiled remarkable structural changes above a pressure threshold. Two distinct amorphous regions were identified: (a) a bulk amorphous layer close to the surface and (b) amorphous bands initially aligned with {111} slip planes. Further increase of the laser energy leads to the re-crystallization of amorphous silicon into nanocrystals with high concentration of nano-twins. Shock-induced defects play a very important role in the onset of amorphization. Calculations of the free energy changes with pressure and shear, using the Patel-Cohen methodology, are in agreement with the experimental results. Molecular dynamics simulation corroborates the amorphization, showing that it is initiated by the nucleation and propagation of partial dislocations. The nucleation of amorphization is analyzed by classical nucleation theory.

**9:36AM K21.00009 First-principles study of the amorphization of stishovite by isotropic volume expansion**, MASAOKI MISAWA, FUYUKI SHIMOJO, Kumamoto University, RAJIV K. KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Simple synthesis of ceramics with high hardness and high toughness from Earth-abundant materials is one of the most important issues in materials science. Nishiyama et al. synthesized nano-crystalline stishovite with extremely high toughness and high hardness via compression and decompression of silica, and proposed fracture-induced amorphization mechanisms for the toughening [1]. Furthermore, it was shown that the toughening mechanisms are effective even in nanoscale order [2]. Our first-principles molecular dynamics simulations have shown rapid amorphization of stishovite within picoseconds under increasing volume, thus substantiating the proposed amorphization mechanisms. Furthermore, we have calculated the critical stress, energy difference, and energy barrier for the crystalline-to-amorphous structural transition. [1] N. Nishiyama et al., Scientific Reports 4, 6558 (2014). [2] K. Yoshida et al., Scientific Reports 5, 10993 (2015).

**9:48AM K21.00010 Phase diagram of the itinerant helical magnet MnSi at high pressures and strong magnetic fields**, SERGEI STISHOV, Russian Acad of Sci-Troitsk — We performed a series of resistivity, heat capacity and ultrasound speed measurements of a MnSi single crystal at high pressures and strong magnetic fields [1-3]. Two notable features of the phase transition in MnSi that disappear on pressure increase are a sharp peak marking the first order phase transition and a shallow maximum, situated slightly above the critical temperature and pointing to the domain of prominent helical fluctuations. The longitudinal and transverse ultrasound speeds and attenuation were measured in a MnSi single crystal in the temperature range of 2-40 K and magnetic fields to 7 Tesla. The magnetic phase transition in MnSi in zero magnetic field is signified by a quasi-discontinuity in the  $c_{11}$  elastic constant, which almost vanishes at the skyrmion - paramagnetic transition at high magnetic fields. The powerful fluctuations at the minima of  $c_{11}$  make the mentioned crossing point of the minima and the phase transition lines similar to a critical end point, where a second order phase transition meets a first order one.

**10:00AM K21.00011 A DFT+DMFT study of magnetic properties of FeO at high pressure.**, PENG ZHANG<sup>1</sup>, Department of Physics, Xi'an Jiaotong university & Geophysical Laboratory, RONALD COHEN<sup>2</sup>, Extreme Materials Initiative, Geophysical Laboratory, Carnegie Institution for Science, Washington, D.C. USA, K. HAULE, Department of Physics and Astronomy, Rutgers University, NJ, USA — FeO is an insulator with anti-ferromagnetic (AFM) spin ordering at ambient pressure. When external pressure is increased, the Néel temperature first increases at the pressure below 40 GPa. Experiments show the AFM ordering collapses at high pressures. Using the density functional theory plus dynamical mean-field theory (DFT+DMFT), we examined the nature of magnetic collapse of FeO and derived its magnetic phase diagram up to 180 GPa. We found coexistence of high spin-low spin transition and paramagnetic-AFM transition, both driven by increased pressure. The high spin-low spin transition is result of partition and pairing of 3d electrons in iron. The local moment of iron atom after high spin-low spin transition is small but finite up to 180 GPa.

**10:12AM K21.00012 Effects of composition and iron spin state on the structural transition of (Mg,Fe)CO<sub>3</sub> in the Earth's lower mantle**, HAN HSU, SHENG-CHIEH HUANG, National Central University, CHENG-RONG HSING, CHING-MING WEI, Academia Sinica — Iron-bearing magnesium carbonates (Mg,Fe)CO<sub>3</sub> are believed the major carbon carriers in the Earth's deep lower mantle; knowledge of their physical properties is thus essential to understand the Earth's deep carbon cycle. It is known that (Mg,Fe)CO<sub>3</sub> ferromagnesite is stable up to 80-100 GPa. At 45-50 GPa, ferromagnesite undergoes a high-spin to low-spin crossover, accompanied by a volume reduction and elastic anomalies. Above 100 GPa, ferromagnesite goes through a complicated structural transition, which is still a subject under debate. So far, several distinct high-pressure (Mg,Fe)CO<sub>3</sub> structures have been inferred from experiments, including  $P2_1/c$  [1] and  $Pmm2$  phases [2]. In theory,  $C2/m$  [3] and  $P-1$  phases [4] have been suggested, but the  $Pmm2$  phase is not found. One possible reason for this discrepancy is that the above-mentioned calculations are based on pure MgCO<sub>3</sub>, while experiments were performed using (Mg,Fe)CO<sub>3</sub> with high iron concentration (>50%). Here, we use density functional theory + self-consistent Hubbard  $U$  (DFT+ $U_{sc}$ ) calculations to study this structural transition. The effects of composition and iron spin state on these (Mg,Fe)CO<sub>3</sub> phases are also discussed. [1] E. Boulard et al., Proc. Natl. Acad. Sci. USA **108**, 5184 (2011). [2] J. Liu et al., Sci. Rep. **5**, 7640 (2015). [3] A. R. Oganov et al., Earth Planet. Sci. Lett. **273**, 38 (2008). [4] C. J. Pickard and R. J. Needs, Phys. Rev. B **91**, 104101 (2015).

**10:24AM K21.00013 Gravitational Collapse and Shocks in Two-Phase Celestial Bodies**, MICHAEL GRINFELD, The U.S. Army Research Laboratory, PAVEL GRINFELD, Drexel University, Department of Mathematics — The phenomenon of gravitational collapse (GC) is well-known in theoretical astro- and planetary physics. It occurs when the incompressibility of substances is unable to withstand the pressure due to gravitational forces in celestial bodies of sufficiently large mass. The GC never occurs in incompressible models – homogeneous or layered. This situation changes dramatically when different incompressible layers appear to be different phases of the same chemical substance and the mass exchange between the phases can occur due to phase transformation. The possibility of destabilization in such system becomes realistic, as it was first discovered in the Ramsey static analysis [1,2]. We will present our generalization of the Ramsey's results using dynamic approach. [1] W.H. Ramsey, "On the instability of small planetary cores", Mon. Not. R. Astron. Soc. **110** (4), 325-338 (1950). [2] H. Jeffreys, "The Earth: Its Origin, History, and Physical Constitution". Cambridge University Press (1976).

**8:00AM K22.00001 An Automated Application Framework to Model Disordered Materials Based on a High Throughput First Principles Approach**, COREY OSES, Duke Univ, KESONG YANG, UC San Diego, STEFANO CURTAROLO, Duke Univ, DUKE UNIV COLLABORATION, UC SAN DIEGO COLLABORATION — Predicting material properties of disordered systems remains a long-standing and formidable challenge in rational materials design. To address this issue, we introduce an automated software framework capable of modeling partial occupation within disordered materials using a high-throughput (HT) first principles approach. At the heart of the approach is the construction of supercells containing a virtually equivalent stoichiometry to the disordered material. All unique supercell permutations are enumerated and material properties of each are determined via HT electronic structure calculations. In accordance with a canonical ensemble of supercell states, the framework evaluates ensemble average properties of the system as a function of temperature. As proof of concept, we examine the framework's final calculated properties of a zinc chalcogenide ( $\text{ZnS}_{1-x}\text{Se}_x$ ), a wide-gap oxide semiconductor ( $\text{Mg}_x\text{Zn}_{1-x}\text{O}$ ), and an iron alloy ( $\text{Fe}_{1-x}\text{Cu}_x$ ) at various stoichiometries.

**8:12AM K22.00002 An Extensive Database of Electronic Structure Calculations between Transition Metals<sup>1</sup>**, SHEREEF SAYED, DIMITRIOS PAPACONSTANTOPOULOS, George Mason Univ — Density Functional Theory and its derived application methods, such as the Augmented Plane Wave (APW) method, have shown great success in predicting the fundamental properties of materials. In this work, we apply the APW method to explore the properties of diatomic pairs of transition metals in the CsCl structure, for all possible combinations. A total of 435 compounds have been studied. The predicted Density of States, and Band Structures are presented, along with predicted electron-phonon coupling and Stoner Criterion, in order to identify potential new superconducting or ferromagnetic materials. This work is performed to demonstrate the concept of high-throughput calculations at the crossing-point of Big Data and materials science.

**8:24AM K22.00003 High throughput ab-initio modeling of proton transport in solid electrolytes**, JANAKIRAMAN BALACHANDRAN, LIANSHAN LIN, PANCHAPAKESAN GANESH, Oak Ridge National Laboratory — Solid oxide materials that can selectively transport protons have great potential for fuel cell applications. However several fundamental questions remain unanswered such as (a) How do the dopants organize at various dopant concentrations, (b) How spatial organization of dopants influence proton migration energy, (c) How disorder and strain in a material influence its ionic transport. In this work we have developed an integrated high throughput framework to calculate proton transport properties by integrating open source packages (such as pymatgen, fireworks) The high throughput framework scales well on supercomputing clusters. We have used this framework to analyze over 100 perovskites compounds with over 12 different dopant atoms. These computational models enable us to obtain insights how the proton transport properties depend on host and dopant atoms. Further, we also perform ab-initio modeling to understand how dopants spatially organize at different dopant concentrations, and how this spatial organization affects proton conductivity. This analysis enabled us to obtain fundamental insights on why proton conductivity decreases in Y doped BaZrO<sub>3</sub> at high dopant concentrations.

**8:36AM K22.00004 From organized high throughput data to phenomenological theory: The example of dielectric breakdown**, CHIHO KIM, University of Connecticut, GHANSHYAM PILANIA, Los Alamos National Laboratory, RAMPI RAMPRASAD, University of Connecticut — Understanding the behavior (and failure) of dielectric insulators experiencing extreme electric fields is critical to the operation of present and emerging electrical and electronic devices. Despite its importance, the development of a predictive theory of dielectric breakdown has remained a challenge, owing to the complex multiscale nature of this process. Here, we focus on the *intrinsic* dielectric breakdown field of insulators—the theoretical limit of breakdown determined purely by the chemistry of the material, *i.e.*, the elements the material is composed of, the atomic-level structure, and the bonding. Starting from a benchmark dataset (generated from laborious first principles computations) of the intrinsic dielectric breakdown field of a variety of model insulators, simple predictive phenomenological models of dielectric breakdown are distilled using advanced statistical or machine learning schemes, revealing key correlations and analytical relationships between the breakdown field and easily accessible material properties. The models are shown to be general, and can hence guide the screening and systematic identification of high electric field tolerant materials.

**8:48AM K22.00005 The Robustness of Cluster Expansion: Assessing the Role of Relaxation<sup>1</sup>**, ANDREW H. NGUYEN, CONRAD W. ROSENBROCK, GUS L. W. HART, Brigham Young Univ - Provo — Cluster expansion (CE) has been used widely in combination with first-principles calculations to predict stable structures of metal alloys. CE treats alloys as a purely configuration problem, *i.e.*, a problem in the distribution of the alloying elements on a fixed lattice. CE models are usually built from data taken from “relaxed” first-principles calculations where the individual atoms assume positions that minimize the total energy. A perennial question in the cluster expansion community is how the accuracy of the CE is affected by relaxations—technically, the formalism of CE breaks down when the underlying lattice is not preserved—but practitioners often argue that there is a one-to-one correspondence between relaxed and unrelaxed structures so that the formalism holds. We quantify the effect of relaxation on the robustness of cluster expansions by comparing CE fits for relaxed and unrelaxed data sets. Our results give a heuristic for when CE models can be trusted.

**9:00AM K22.00006 The New NRL Crystallographic Database<sup>1</sup>**, MICHAEL MEHL, Naval Research Laboratory, Washington DC 20375, STEFANO CURTAROLO, DAVID HICKS, CORMAC TOHER, Duke University, Durham, NC, OHAD LEVY, Duke University, Durham, NC and NRCN, Israel, GUS HART, Brigham Young University, Provo, Utah — For many years the Naval Research Laboratory maintained an online graphical database of crystal structures for a wide variety of materials. This database has now been redesigned, updated and integrated with the AFLOW framework for high throughput computational materials discovery (<http://materials.duke.edu/afLOW.html>). For each structure we provide an image showing the atomic positions; the primitive vectors of the lattice and the basis vectors of every atom in the unit cell; the space group and Wyckoff positions; Pearson symbols; common names; and Strukturbericht designations, where available. References for each structure are provided, as well as a Crystallographic Information File (CIF). The database currently includes almost 300 entries and will be continuously updated and expanded. It enables easy search of the various structures based on their underlying symmetries, either by Bravais lattice, Pearson symbol, Strukturbericht designation or commonly used prototypes. The talk will describe the features of the database, and highlight its utility for high throughput computational materials design.

<sup>1</sup>Work at NRL is funded by a contract with the Duke University Department of Mechanical Engineering.

**9:12AM K22.00007 First-principles determination of low-energy structures in epitaxially-strained perovskite SrMnO<sub>3</sub>** , JIALAN ZHANG, KARIN RABE, Rutgers, The State University of New Jersey — Using a physically-motivated form for the energy as a function of magnetic ordering and lattice distortions around the high symmetry reference structure, we present a systematic method for determining the ground state and low-energy structures of transition-metal ABO<sub>3</sub> compounds from first principles. The structural information obtained through this method forms the foundation for the first-principles structural determination of the structure of perovskite oxide superlattices. The method is demonstrated for SrMnO<sub>3</sub>, which has a nontrivial phase sequence with varying epitaxial strain that has been of recent interest both in first-principles and experimental investigations.

**9:24AM K22.00008 Finding new ternary transition metal selenides and sulphides<sup>1</sup>** , AWADHESH NARAYAN, ANKITA BHUTANI, JAMES N. ECKSTEIN, DANIEL P. SHOEMAKER, LUCAS K. WAGNER, Univ of Illinois - Urbana — The transition metal oxides exhibit many interesting physical properties, and have been explored in detail over time. Recently, the transition metal chalcogenides including selenium and sulfur have been of interest because of their correlated electron properties, as seen in the iron based superconductors and the layered transition metal dichalcogenides. However, the chalcogenides are much less explored than the oxides, and there is an open question of whether there may be new materials heretofore undiscovered. We perform a systematic combined theoretical and experimental search over ternary phase diagrams that are empty in the Inorganic Crystal Structure Database containing cations, transition metals, and one of selenium or sulfur. In these 27 ternary systems, we use a probabilistic model to reduce the likelihood of false negative predictions, which results in a list of 24 candidate materials. We then conduct a variety of synthesis experiments to check the candidate materials for stability. While the prediction method did obtain compositions that are stable, none of the candidate materials formed in our experiments. We come to the conclusion that these phase diagrams are either truly empty or have unusual structures or synthesis requirements.

**9:36AM K22.00009 High-Throughput Identification of Unique Structure Prototypes in the Inorganic Crystal Structure Database** , DAVID HICKS, CORMAC TOHER, OHAD LEVY, STEFANO CURTAROLO, Duke Univ — High-throughput computational assessment of materials properties is currently a major component of the effort to develop new useful materials by uncovering trends and correlations between structures, compositions, and functionalities. Efficient implementation of this approach thus requires a systematic identification of distinct material structure prototypes. We have developed a robust algorithm that calculates the level of similarity between crystal structures independent of the unit cell representation, using the comparison method proposed by Burzlaff [1]. This algorithm has been implemented in the high-throughput framework, Automatic Flow (AFLOW) [2], and applied to the Inorganic Crystal Structure Database (ICSD) [3] entries in the AFLOWLIB.org [4] online repository. We have determined the uniqueness statistics for the ICSD and have created a comprehensive set of the unique structural prototypes represented in it. [1] H. Burzlaff and Y. Malinovsky Acta Cryst. A53, 217-224 (1997). [2] S. Curtarolo et al. Comp. Mater. Sci. 58, 218-226 (2012). [3] FIZ Karlsruhe and NIST, Inorganic Crystal Structure Database, <http://icsd.fiz-t.karlsruhe.de/icsd/> [4] S. Curtarolo et al. Comp. Mater. Sci. 58, 227-235 (2012).

**9:48AM K22.00010 Prediction of the first stable compound with flat hexagonal tin layers<sup>1</sup>** , JUNPING SHAO, CLEMENT BEAUFILS, ALEKSEY KOLMOGOROV, Binghamton University, SUNY — An analysis of stability trends in a large family of metal stannides has directed our attention towards a previously unknown compound featuring a backbone of flat hexagonal tin layers. Ab initio calculations show that this compound is at least metastable under ambient conditions and is furthermore stabilized under pressure. Compounds with such layered frameworks may possess exotic electronic properties and also serve as precursors for the synthesis of 2D derivatives.

**10:00AM K22.00011 Can k-point integration for metals be dramatically improved?** , GUS HART, JEREMY JORGENSEN, Brigham Young University, PRIYA GOPAL, Central Michigan University, MARCO BUONGIORNO-NARDELLI, University of North Texas — Our group has spent hundreds of millions of cpu hours calculating the energies of different materials and their competing structures. The energy of the occupied electron states is a small part of the total energy of a given material, but electron energy accounts for almost all of the numerical error in these calculations (at least in metals). Current methods of integrating electron band energies are simple (usually rectangle rule + smearing) but converge very slowly, requiring many, many k-points, even for simple metals. But integration approaches with better convergence rates, such Gauss quadrature, are hard to utilize. Because of the multivalued nature of electron bands (leading to crossings, kissings, etc.) standard interpolation methods are ineffective. We will discuss a number of improvements we have made and discuss a possible solution to the interpolation problem.

**10:12AM K22.00012 The Quantum Monte Carlo Database: towards high-accuracy and high-throughput calculation of material properties** , JOSHUA SCHILLER, University of Illinois at Urbana-Champaign, RAYMOND PLANTE, National Institute of Standards and Technology, LUCAS WAGNER, ELIF ERTEKIN, University of Illinois at Urbana-Champaign — Quantum Monte Carlo (QMC) techniques comprise a class of promising methods that offer a path towards higher accuracy for materials property prediction. However, their application in bulk materials has historically been limited to one-at-a-time evaluation of a given material. While these results often provide benchmark-level accuracy for quantities of interest, they do not allow for high-throughput analysis of the data since each calculation is done slightly differently. We present a combined data format and automatic generation platform based on the QWalk code for QMC data: QMCDB. This platform collects QMC results and provenance information automatically and stores the information in a database. We will report on the construction of this database and what lessons can be learned about using QMC for high-throughput applications.

**10:24AM K22.00013 Predictive modeling of surface morphology of multicomponent catalysts for their optimum performance** , ALTAF KARIM, SYED ISLAMUDDIN SHAH, COMSATS Institute of Information Technology, Islamabad, Pakistan — Multi-component microstructures of artificially engineered catalysts are promising for the best ever performance in alternative fuel production. We have designed and implemented a set of intelligent algorithms capable of predicting the surface morphology of multicomponent catalysts for their optimum performance. For example we come up with three kinds of different catalysts. Based on a database obtained from the density functional theory based kinetic Monte Carlo simulations, the first kind of single component catalytic surface promotes and helps dissociative adsorption of chemical species, but it hinders the diffusion of intermediate species. On the other hand, the second kind of single component catalytic surface promotes the diffusion of intermediate species, but suppresses the reactions and desorption processes. However the third kind of single component catalytic surfaces can significantly enhance reactions among intermediate species. Therefore no single component material surface would be a suitable candidate for becoming a good catalyst. However a combination of all above mentioned kind of materials may exhibit the maximum ever performance. Our algorithm models the surface morphology of these multicomponent catalysts by varying the surface area of each component and also by changing the shape of each component in such a way that the catalyst gives the highest rate of chemical formation. Our results confirm the best ever performance of our artificially engineered catalysts.

**10:36AM K22.00014 Doping Li and K into  $\text{Na}_2\text{ZrO}_3$  Sorbent to Improve Its  $\text{CO}_2$  Capture Capability**, YUHUA DUAN, DOE-National Energy Technology Laboratory — Carbon dioxide is one of the major combustion products which once released into the air can contribute to global climate change. Solid sorbents have been reported in several previous studies to be promising candidates for  $\text{CO}_2$  sorbent applications due to their high  $\text{CO}_2$  absorption capacities at moderate working temperatures. However, at a given  $\text{CO}_2$  pressure, the turnover temperature ( $T_t$ ) of an individual solid capture  $\text{CO}_2$  reaction is fixed and may be outside the operating temperature range ( $\Delta T_o$ ) for a particular capture technology. In order to shift such  $T_t$  for a solid into the range of  $\Delta T_o$ , its corresponding thermodynamic property must be changed by changing its structure by reacting (mixing) with other materials or doping with other elements. As an example, by combining thermodynamic database searching with *ab initio* thermodynamics calculations, in this work, we explored the Li- and K-doping effects on the  $T_t$  shifts of  $\text{Na}_2\text{ZrO}_3$  at different doping levels. The obtained results showed that compared to pure  $\text{Na}_2\text{ZrO}_3$ , the Li- and K-doped mixtures  $\text{Na}_{2-\alpha}\text{M}_\alpha\text{ZrO}_3$  ( $\text{M}=\text{Li, K}$ ) have lower  $T_t$  and higher  $\text{CO}_2$  capture capacities.

**Session K23 DMP DCOMP: Focus Topic: Computational Materials Discovery and Design - Structure Prediction and Phase Diagrams** 322 - Stephan Lany, National Renewable Energy Laboratory

**8:00AM K23.00001 Entropy descriptors and Entropy Stabilized Oxides**, STEFANO CURTAROLO, Duke University — In this presentation we will discuss the development of entropy descriptors for the AFLOWLIB.org *ab-initio* repository and the path leading to the synthesis of the novel entropy stabilized oxides. [Nat. Comm. 6:8485 (2015)]. Research sponsored by DOD-ONR N000141310635 and N000141512863.

**8:36AM K23.00002 Computational Discovery of New Heusler Compounds: Structures, Stabilities, and Applications**, JIANGANG HE, VINAY HEGDE, CHRIS WOLVERTON, Department of Materials Science and Engineering, Northwestern University — Since their discovery by Fritz Heusler in 1903, Heusler compounds,  $\text{X}_2\text{YZ}$ , have been attracting a lot of research attention and have been intensely studied for their potential usage in spintronics, shape-memory devices, superconductors, thermoelectrics, topological insulators, and other applications. However, although more than 1000 Heusler compounds have been reported experimentally or computationally, a lot of potential Heusler compounds have not been explored yet due to complexities involved in dealing with such a huge phase space. As searching for new compounds experimentally is an expensive and a lengthy process, in this talk, we will demonstrate how to use a multi-step high-throughput computational screening method to predict several hundreds new stable and metastable Heusler compounds from 186588 compositions. As an example application, we will illustrate how to find age hardening precipitates using our screening strategy

**8:48AM K23.00003 Discovering complete pressure-temperature phase diagrams with Hamiltonian Monte Carlo nested sampling**, ROBERT BALDOCK, University of Cambridge, NOAM BERNSTEIN, Naval Research Laboratory, LIVIA BARTÓK-PARTÁY, GÁBOR CSÁNYI, University of Cambridge — Nested sampling is a Monte Carlo algorithm that can be used to efficiently calculate the complete configurational density of states in a material that undergoes multiple first-order phase transitions. From the density of states one can calculate the partition function as an explicit function of temperature and perform statistical mechanics from first principles. Indeed, we have shown how nested sampling can be used to automatically discover complete pressure-temperature phase diagrams with no prior knowledge of the locations of phase transitions or the structures of phases. In this talk I will present a new version of the nested sampling algorithm, based on a modified Hamiltonian ("Hybrid") Monte Carlo scheme. This new scheme reduces the scaling of a general nested sampling calculation. In particular the new algorithm expedites the sampling of atomic configuration spaces in condensed phases, and permits one to perform nested sampling calculations at a fraction of the cost required by ordinary nested sampling with standard Monte Carlo.

**9:00AM K23.00004 Equilibrium phase diagrams of alloys using nested sampling**, NOAM BERNSTEIN, Naval Research Laboratory, ROBERT J N BALDOCK, LIVIA BARTÓK-PARTÁY, GÁBOR CSÁNYI, Cambridge University — Temperature-pressure-composition phase diagrams describe the structures of materials in thermal equilibrium, and are an essential tool in understanding material properties. Predicting phase diagrams is challenging, even given a description of the interatomic interactions, because of the need to sample a very large configuration space. Nested sampling (NS) has been shown to be an efficient tool for calculating the partition function, and therefore all thermodynamic properties and ensemble averages, by systematically sampling the configuration space of isolated and periodic systems. Its effectiveness comes from sampling starting from high energy, where barriers are relatively low and equilibration is relatively fast, and iteratively eliminating a fixed *fraction* of the remaining configuration space. We present an application of NS at constant pressure to the phase diagram of a model binary alloy, CuAu, using an embedded atom method potential. We identify phase transitions indicated by peaks in the calculated specific heat, and the dominant phase at each temperature from ensemble-averaged structural ordering, as represented by quantities such as the radial distribution function. These results demonstrate the power of NS as a method for calculating complete phase diagrams.

**9:12AM K23.00005 Taking Materials Design Into The Space Of Polymorphs: Structure Predictions And Realizability<sup>1</sup>**, VLADAN STEVANOVIC, Colorado School of Mines — The phenomenon of polymorphism exemplifies the significance of structural degrees of freedom in determining physical properties of solids. Classic case is elemental carbon with markedly different mechanical, optical and electronic properties between its graphite and diamond forms. To harness the richness of this phenomenon and extend rational materials design into the space of polymorphs, there is a need for developing approaches that are capable of exploring systematically and efficiently the potential energy surface, and (desirably) assist in experimental realization of different structures. While the former presents a common place in the field of structure predictions, less attention is given to the latter. Namely, available experimental data indicate that the energy above the ground state alone is insufficient to quantify the realizability of different structures. For example, MgO crystallizes exclusively as the rocksalt despite the predicted existence of a number of low-energy structures. Similarly, ZnO is realized in the wurtzite, zincblende and a relatively high-energy rocksalt structure, again, apparently disregarding a number of theoretically predicted low-energy structures. In this talk I will present recent attempts to tackle these issues focused on partially ionic systems. The structure prediction part is carried out by performing local DFT relaxations on a large set of random superlattices (RSLs) with atoms distributed randomly over different planes in a way that favors cation-anion coordination. Second, application of the RSL sampling to a range of binary ionic systems such as MgO, ZnO, SnO<sub>2</sub> and other, reveals that the frequency of occurrence of a given structure offers an estimate of the volume of configuration space occupied by the corresponding local minimum, which is shown to be connected to the realizability of different structures.

**9:48AM K23.00006 Prediction of boron carbon nitrogen phase diagram**, SANXI YAO, Carnegie Mellon Univ, HANTAO ZHANG, Univ of Science and Technology of China, MICHAEL WIDOM, Carnegie Mellon Univ — We studied the phase diagram of boron, carbon and nitrogen, including the boron-carbon and boron-nitrogen binaries and the boron-carbon-nitrogen ternary. Based on the idea of electron counting and using a technique of mixing similar primitive cells, we constructed many "electron precise" structures. First principles calculation is performed on these structures, with either zero or high pressures. For the BN binary, our calculation confirms that a rhombohedral phase can be stabilized at high pressure, consistent with some experimental results. For the BCN ternary, a new ground state structure is discovered and an Ising-like phase transition is suggested. Moreover, we modeled BCN ternary phase diagram and show continuous solubility from boron carbide to the boron subnitride phase.

**10:00AM K23.00007 Design and discovery of heterostructural alloys**, AARON HOLDER, SEBASTIAN SIOL, PAUL NDIONE, HAOWEI PENG, ANDRIY ZAKUTAYEV, STEPHAN LANY, NREL, BETHANY MATTHEWS, JANET TATE, Oregon State Univ., BRIAN GORMAN, Colorado School of Mines, ROY GORDON, Harvard, LAURA SCHELHAS, MIKE TONEY, SLAC — The tailoring of materials properties by alloying is routinely utilized to design materials for targeted technological applications. Despite the great successes of alloying in isostructural systems, heterostructural alloying remains a fundamentally unexplored area. In heterostructural alloys, the crossover between different crystal structures enables a new parameter for control over structure and properties by variation of the composition. Here, we present a complementary theoretical and experimental investigation of novel semiconducting metal chalcogenide alloys to develop design principles and approaches for utilizing heterostructural alloying as a materials design strategy. We use *ab initio* methods to predict the structural and electronic properties of novel alloys with commensurate and incommensurate lattice symmetries. Non-equilibrium deposition methods are employed to overcome thermodynamic solubility limits and produce metastable thin-film samples across the entire alloy composition range. The prediction, theory-guided combinatorial synthesis, and characterization of heterostructural alloys demonstrate the design and discovery of functional metastable materials. Our approach establishes a new route for the control of structure-property and composition-structure relationships by accessing non-equilibrium phase space to develop new materials with uniquely tailored properties.

**10:12AM K23.00008 Informatics-aided computational design of functional layered oxides**, PRASANNA V BALACHANDRAN, Los Alamos National Laboratory, Los Alamos, NM, JOSHUA YOUNG, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA, TURAB LOOKMAN, Los Alamos National Laboratory, Los Alamos, NM, JAMES RONDINELLI, Department of Materials Science and Engineering, Northwestern University, Evanston, IL — We discuss a data-driven *ab initio* protocol with predictive capability to design and accelerate the discovery of noncentrosymmetric (NCS) inorganic oxides. Our approach synergistically integrates applied group theory, materials informatics and density functional theory (DFT) to uncover geometry-chemistry-symmetry guidelines for computational design of new NCS materials, specifically oxygen octahedra containing basic building units. Using this approach, we identify new and previously unknown compositions with potential for realizing NCS structures in the bulk  $n=1$  Ruddlesden-Popper (RP) oxides. We then validate our predictions using DFT calculations. Our approach enables rational design and engineering of both crystal structures and functionalities.

**10:24AM K23.00009 Computational Discovery of Materials Using the Firefly Algorithm<sup>1</sup>**, GUILLERMO AVENDAO-FRANCO, ALDO ROMERO, West Virginia University — Our current ability to model physical phenomena accurately, the increase computational power and better algorithms are the driving forces behind the computational discovery and design of novel materials, allowing for virtual characterization before their realization in the laboratory. We present the implementation of a novel firefly algorithm, a population-based algorithm for global optimization for searching the structure/composition space. This novel computation-intensive approach naturally take advantage of concurrency, targeted exploration and still keeping enough diversity. We apply the new method in both periodic and non-periodic structures and we present the implementation challenges and solutions to improve efficiency. The implementation makes use of computational materials databases and network analysis to optimize the search and get insights about the geometric structure of local minima on the energy landscape. The method has been implemented in our software PyChemia, an open-source package for materials discovery.

**10:36AM K23.00010 Superconductivity in metastable phases of phosphorus-hydride compounds under high pressure<sup>1</sup>**, JOSE FLORES LIVAS, University of Basel, MAXIMILIAN AMSLER, Northwestern University, ANTONIO SANNA, Max-Planck Institut für Mikrostrukturphysik, CHRISTOPH HEIL, LILIA BOERI, Graz University of Technology, GIANNI PROFETA, Dipartimento di Fisica Università degli Studi di L'Aquila, CHRIS WOLVERTON, Northwestern University, STEFAN GOEDECKER, University of Basel, E. K. U. GROSS, Max-Planck Institut für Mikrostrukturphysik — Recently, compressed phosphine was reported to metallize at pressures above 45 GPa, reaching a superconducting transition temperature ( $T_c$ ) of 100 K at 200 GPa. However, neither the exact composition nor the crystal structure of the superconducting phase have been conclusively determined. In this work the phase diagram of  $\text{PH}_n$  ( $n = 1, 2, 3, 4, 5, 6$ ) was extensively explored by means of *ab initio* crystal structure prediction methods. The results do not support the existence of thermodynamically stable  $\text{PH}_n$  compounds, which exhibit a tendency for elemental decomposition at high pressure even when vibrational contributions to the free energies are taken into account. Although the lowest energy phases of  $\text{PH}_{1,2,3}$  display  $T_c$ 's comparable to experiments, it remains questionable if the measured values of  $T_c$  can be fully attributed to a phase-pure compound of  $\text{PH}_n$ .

**10:48AM K23.00011 Hybrid MC/MD Method For High Entropy Alloy<sup>1</sup>**, BOJUN FENG, MICHAEL WIDOM, Carnegie Mellon University — High entropy alloys (HEA) are materials that contain multiple components of elements consisting of a single solid solution phase which could make the entropy of mixing very high. From recent investigations, HEAs possess promising properties such as strength at high temperature, tensile strength, thermal stability and corrosion resistance. In this talk, a hybrid Molecular Dynamics (MD)/Monte Carlo (MC) simulation method is introduced to the computational analysis of HEA, treating atomic displacement by MD as well as swapping atomic species by MC. This method efficiently models the phase separation and short range order by swapping between different types of atoms, while structural deviation from the perfect lattice sites of atoms is equilibrated quickly by MD. We apply this method to HfNbTaZr HEA modeled using an embedded-atom potential. The result gives a strong phase separation of Hf-Zr and Nb-Ta pairs shown by the pair correlation function. Diffuse scattering patterns are predicted and compared to experiments.

**8:00AM K24.00001 DFT+ $U(\omega)$ : Frequency-dependent Hubbard  $U$  correction**, DAVID D. O'REGAN, Trinity College Dublin, NICOLA MARZARI, Ecole Polytechnique Fédérale de Lausanne (EPFL) — In contemporary first-principles atomistic simulation based on DFT, the augmentation of approximate exchange-correlation functionals with spatially or energetically localized corrections, such as DFT+ $U$ , is a successful approach for improving its applicability to strongly interacting systems. Electronic screening is a dynamical process, and since the Hubbard  $U$  parameter, in particular, is a measure of the screened Coulomb interaction, its frequency-dependent generalisation for the dynamical regime is possible. We introduce a conceptually pragmatic and computationally straightforward method, named DFT+ $U(\omega)$ , for calculating and incorporating strong dynamical screening effects in spectroscopic calculations based on Kohn-Sham DFT. Our method is designed to be a minimal dynamical extension of DFT+ $U$ , one in which computing approximate dynamical Hubbard  $U$  functions only requires functionality that is widely available. We demonstrate our effective plasmon fitting and self-energy approximation scheme for DFT+ $U(\omega)$ , which enables the resulting low-energy dynamical model to be solved at the  $G_0W_0$  level, and beyond, efficiently and effectively.

**8:12AM K24.00002 RIXS of Ammonium Nitrate using OCEAN**, JOHN VINSON, TERRENCE JACH, NIST, Gaithersburg, MD, MATTHIAS MUELLER, RAINER UNTERUMSBERGER, BURKHARD BECKHOFF, PTB, Berlin, Germany — The OCEAN code allows for calculations of near-edge x-ray spectroscopies using a *GW*/Bethe-Salpeter equation (BSE) approach. Here we present an extension of the code for calculating resonant inelastic x-ray scattering (RIXS). Recent work has shown that peak-specific broadening of nitrogen  $K\alpha$  emission in nitrates is due to a valence-band lifetime that is an order of magnitude shorter than that of the nitrogen 1s hole, an inversion of the usual assumption that valence holes have longer lifetimes than core-level holes. Using the BSE, including *GW* corrections to the DFT energies, as implemented in OCEAN we are able to compare calculations of RIXS with measured spectra of the same. By utilizing an approach free from fitting parameters we are able to identify the origins of various broadening effects observed in experiment.

**8:24AM K24.00003 Signatures of correlation in transition metal oxides**, MATTEO GATTI, LSI, Ecole Polytechnique, France, MATTEO GUZZO, Humboldt-Universität zu Berlin, Germany, LUCIA REINING, LSI, Ecole Polytechnique, France — Photoemission satellites are a genuine fingerprint of electronic correlation that cannot be interpreted within the quasiparticle band-structure picture. Here we show that they can be understood in terms of the coupling between different elementary excitations, as in the case of plasmon sidebands. Using examples from different correlated materials, we discuss how this coupling can be explained by advanced calculations based on first-principles many-body perturbation theory that combine *GW*-like approximations for the self-energy with the cumulant expansion of the Green's function [1-3]. This approach is not limited to low-energy satellites, but allows for a consistent explanation of signatures of correlation over a wide range of binding energies. [1] M. Guzzo *et al.*, Phys. Rev. Lett. **107**, 166401 (2011). [2] M. Gatti and M. Guzzo, Phys Rev B **87**, 155147 (2013). [3] M. Gatti *et al.*, Phys. Rev. Lett. **114**, 116402 (2015).

**8:36AM K24.00004 High-resolution Valence and Core Excitation Spectra via First-Principles Calculations and Experiment**<sup>1</sup>, ERIC SHIRLEY, NIST, F. FOSSARD, ONERA-CNRS, LEM, K. GILMORE, ESRF, G. HUG, ONERA-CNRS, LEM, J.J. KAS, J.J. REHR, F. VILA, U. Wash., Seattle — We calculate the optical and C K-edge near edge spectra of crystalline and molecular  $C_{60}$  measured with high-resolution electron energy-loss spectroscopy. The calculations are carried out using at least three different methods: Bethe-Salpeter calculations using the NIST Bethe-Salpeter Equation solver (NBSE) in the valence and OCEAN (Obtaining Core Excitation with Ab initio methods and NBSE) suite [Gilmore *et al.*, Comp. Phys. Comm., (2015)]; excited-core-hole calculations using XCH [D. Prendergast and G. Galli, Phys. Rev. Lett. **96**, 215502 (2006)]; and constrained occupancy using StoBe (Stockholm-Berlin core-excitation code) [StoBe-deMon version 3.0, K. Hermann *et al.* (2009)]. They include self-energy effects, lifetime-damping, and Debye-Waller effects. A comparison of spectral features to those observed illustrates the sensitivity of certain features to computation details (e.g., self-energy corrections and core-hole screening). This may point to limitations of various approximations, e.g. in conventional BSE paradigm and/or the incomplete treatment of vibrational effects.

**8:48AM K24.00005 Obtaining X-ray absorption near-edge structure for transition metal oxides via the Bethe-Salpeter equation**, YUFENG LIANG, Lawrence Berkeley National Lab, The Molecular Foundry, JOHN VINSON, National Institute of Standards and Technology, SRI PEMMARAJU, Lawrence Berkeley National Lab, The Molecular Foundry, ERIC SHIRLEY, National Institute of Standards and Technology, DAVID PRENDERGAST, Lawrence Berkeley National Lab, The Molecular Foundry — Transition metal oxides are an important class of materials featured with strongly correlated effects. Most interesting and yet to-be-unveiled physics is associated with the metal 3d orbitals, which can be probed by X-ray absorption near-edge spectroscopy. A thorough interpretation of the x-ray spectroscopy is often accompanied with first-principles simulations of structures, electronic properties and the corresponding x-ray spectra. However, the simulation for TMOs is particularly challenging with the localized 3d orbitals. Most previous studies relied on the ground-state calculations without the core-hole as a compromise. Other treated the excited atom as a charged impurity but the calculated spectra turn out to be even more deviated from experiments [1]. Here, we present the first study for the O K-edge for several typical TMOs via solving the Bethe-Salpeter equation (BSE). We have found that electron-core-hole interactions can alter the absorption spectra significantly. Our study helps to disentangle core-hole effects from the intrinsic electron correlations and hence facilitates the development of more advanced many-electron theories. [1] Isao Tanaka, Teruyasu Mizoguchi, and Tomoyuki Yamamoto J. Am. Ceram. Soc., **88** [8] 20130209 (2005)

**9:00AM K24.00006 First-Principles Study of Frequency-Dependent Resonant Raman Scattering**, YANNICK GILLET, Université catholique de Louvain, STEFAN KONTUR, Humboldt-Universität zu Berlin, MATTEO GIANTOMASSI, Université catholique de Louvain, CLAUDIA DRAXL, Humboldt-Universität zu Berlin, XAVIER GONZE, Université catholique de Louvain — A resonance phenomenon appears in the Raman response when the exciting light has frequency close to electronic transitions. Unlike for molecules and for graphene, the theoretical prediction of such frequency-dependent Raman response of crystalline systems has remained a challenge. Indeed, many Raman intensity first-principle calculations are nowadays done at vanishing light frequency, using static Density-Functional Perturbation Theory, thus neglecting the frequency dependence and excitonic effects. Recently, we proposed a finite-difference method for the computation of the first-order frequency-dependent Raman intensity [1], with excitonic effects described by the Bethe-Salpeter equation. We found these to be crucial for the accurate description of the experimental enhancement for laser photon energies around the gap. In this work, we generalize this approach to the more complex second-order Raman intensity, with phonon losses coming from the entire Brillouin zone. Interestingly, even without excitonic effects, one is able to capture the main relative changes in the frequency-dependent Raman spectrum at fixed laser frequencies. The excitonic effects are discussed. [1] Y. Gillet, M. Giantomassi, X. Gonze, Phys. Rev. B **88**, 094305 (2013).

**9:12AM K24.00007 Cumulant approach for electronic excitations in x-ray and electron spectra**<sup>1</sup>, J. J. REHR, Univ of Washington — A quantitative treatment of electronic excitations and other many-body effects in x-ray and electron spectra has long been challenging. Physically, electronic correlations and atomic vibrations lead to inelastic losses and damping effects that are ignored in ground state methods or approximations such as TDDFT. Quasi-particle (QP) approaches such as the *GW* approximation yield significant improvements, as demonstrated in real-space Greens function [1] and *GW*/Bethe-Salpeter equation [2] calculations, but still ignore multi-electron excitations. Recently such excitations have been treated with considerable success using cumulant expansion techniques and the quasi-boson approximation [3,4]. In this beyond QP approach, excitations such as plasmons and electron-hole excitations appear as satellites in the spectral function. The method naturally accounts for multiple-satellites and can be extended to include extrinsic losses and interference effects. Extensions for effects of vibrations and strong correlations including charge-transfer satellites may also be possible [5]. These advances are illustrated with a number of applications.

**9:48AM K24.00008 Real-time cumulant approach for inelastic losses in x-ray spectra<sup>1</sup>**, J. J. KAS, J. J. REHR, U of Washington, J. B. CURTIS, U of Rochester — Intrinsic inelastic losses in core level x-ray absorption (XAS), emission (XES), and x-ray photo-emission spectra (XPS), arise from excitations of the system due to the sudden creation or annihilation of a deep core hole. Additional extrinsic losses arise during the propagation of the photoelectron, and interference processes are also important. These excitations are reflected in the satellite peaks observed in XPS. Formally the distribution of these excitations are described in terms of the core-hole spectral function, which can be calculated in terms of the core-hole Green's function represented in exponential form. Here we discuss an approach for calculating the exponent, or cumulant in terms of local density fluctuations via real-space, real-time time-dependent density functional theory.<sup>2</sup> The role of extrinsic and interference terms is also discussed. Our method is illustrated in calculations of XAS and XPS for number of systems, including weakly correlated as well as *d*- and *f*-electron materials.

**10:00AM K24.00009 Approaching the quantum limit for plasmonics: linear atomic chains**, EMILY TOWNSEND, GARNETT BRYANT, National Institute of Standards and Technology — Linear atomic chains, such as atom chains on surfaces, linear arrays of dopants in semiconductors, or linear molecules, provide ideal testbeds for studying quantum plasmonics in nanosystems. We study the many-body excitations of finite (10-25) linear atomic chains. We use both time-dependent density functional theory (TDDFT) and exact diagonalization to analyze the excitations. TDDFT reveals optically driven excitations that can be single-particle-like, plasmon-like or mixed states. Such states can have very different dependencies on the electron-electron interaction strength, which can be used to help identify the states. TDDFT can identify plasmonic resonances, but it does not reveal how to quantize them. Exact diagonalization is used to get the full quantum description. However, exact diagonalization results can be very different from TDDFT results. Highly correlated, multi-excitonic states, also strongly dependent on the electron-electron interaction strength, appear in the exact response but not in TDDFT excitation spectra. These excitonic many-body states make it hard to identify plasmonic excitations. Exact results are also strongly dependent on the strength of the exchange interaction. We present these results to show how quantum plasmons appear in linear atomic chains.

**10:12AM K24.00010 On the Role of Fe<sub>2</sub>O<sub>3</sub> Surface States for Water Splitting**, MAYTAL CASPARY TOROKER, Department of Materials Science and Engineering, Technion - Israel Institute of Technology — Understanding the chemical nature and role of electrode surface states is crucial for improved electrochemical cell operation. For iron (III) oxide ( $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>), which is one of the most widely studied anode electrodes used for water splitting, surface states were related to the appearance of a dominant absorption peak during water splitting. The chemical origin of this signature is still unclear and this open question has provoked tremendous debate. In order to pin down the origin and role of surface states, we perform first principle calculations with density functional theory +U on several possible adsorbates at the  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>(0001) surface. We show that the origin of the surface absorption peak could be a Fe-O•type bond that functions as an essential intermediate of water oxidation

**10:24AM K24.00011 Many body calculations of the optoelectronic properties of *h*-AlN: from 3D to 2D<sup>1</sup>**, DENIZ KECIK, National Nanotechnology Research Center, Bilkent University, Ankara 06800, Turkey, CIHAN BACAKSIZ, Department of Physics, Izmir Institute of Technology, 35430 Izmir, Turkey, ENGIN DURGUN, Institute of Materials Science and Nanotechnology, Bilkent University, Ankara 06800, Turkey, TUGRUL SENER, Department of Physics, Izmir Institute of Technology, 35430 Izmir, Turkey — Outstanding electronic and optical properties of graphene, *h*-BN, MoS<sub>2</sub> etc. motivate the further discovery of novel 2D materials such as AlN, a III-V compound, with remarkable features for potential optoelectronic applications, due to its wide indirect band gap. The layer and strain dependent optoelectronic properties of the recently synthesized monolayer hexagonal AlN (*h*-AlN) were investigated using density functional and many body perturbation theories, where RPA and BSE were employed on top of the QP<sub>GW</sub> method. The optical spectra of 1-4 layered *h*-AlN revealed prominent absorption beyond the visible light regime; absorbance within the UV range increasing with the number of layers. In addition, the applied tensile strain (1 – 7%) was observed to gradually redshift the absorption spectra. While the many body corrections induced significant blueshift to the optical spectra, evidence of bound excitons were also found for the layered structures. Hence, the optoelectronic properties of layered *h*-AlN can be tuned by modifying their structure and applying strain, moreover are greatly altered when electron-hole interactions are considered.

**10:36AM K24.00012 Putting DFT to the Test: A First-Principles Study of Electronic, Magnetic, and Optical Properties of Co<sub>3</sub>O<sub>4</sub>**, VIJAY SINGH, MONICA KOSA, KOUSHIK MAJHI, DAN THOMAS MAJOR, Department of Chemistry, Bar-Ilan University, Ramat-Gan, Israel, PROF. ARIE ZABAN COLLABORATION — First-principles density functional theory (DFT) and a many-body Green's function method have been employed to elucidate the electronic, magnetic, and photonic properties of a spinel compound, Co<sub>3</sub>O<sub>4</sub>. Co<sub>3</sub>O<sub>4</sub> is believed to be a strongly correlated material, where the on-site Coulomb interaction (*U*) on Co *d* orbitals is presumably important, although this view has recently been contested. The suggested optical band gap for this material ranges from 0.8 to 2.0 eV, depending on the type of experiments and theoretical treatment. Thus, the correlated nature of the Co *d* orbitals in Co<sub>3</sub>O<sub>4</sub> and the extent of the band gap are still under debate, raising questions regarding the ability of DFT to correctly treat the electronic structure in this material. To resolve the above controversies, we have employed a range of theoretical methods, including pure DFT, DFT+U, and a range-separated exchange–correlation functional (HSE06) as well as many-body Green's function theory (i.e., the GW method). We compare the electronic structure and band gap of Co<sub>3</sub>O<sub>4</sub> with available photoemission spectroscopy and optical band gap data and confirm a direct band gap of ca. 0.8 eV. Furthermore, we have also studied the optical properties of Co<sub>3</sub>O<sub>4</sub> by calculating the imaginary part of the dielectric function (Im( $\epsilon$ )), facilitating direct comparison with the measured optical absorption spectra.

**10:48AM K24.00013 Objective performance of the GW approximation and the Bethe-Salpeter Equation for molecules**, FABIEN BRUNEVAL, CEA, SRMP (France) & Dept. of Physics, UC Berkeley & Lawrence Berkeley National Lab (USA), SAMIA M. HAMED, TONATIUH RANGEL-GORDILLO, JEFFREY B. NEATON, Dept. of Physics, UC Berkeley & Lawrence Berkeley National Lab (USA) — We have evaluated the quality of the quasiparticle energies obtained within the *GW* approximation and of the optical excitations with the solution of the Bethe-Salpeter equation (BSE) for molecules. The calculations have been performed with a recently developed code based on Gaussian [1,2] that allowed us to use the exact same techniques as the one employed in traditional quantum chemistry. We demonstrate [3] the extreme sensitivity of the *GW* and BSE results upon the Kohn-Sham starting point. Most of the starting point dependence in BSE is to be ascribed to the underlying *GW* band structure. We highlight the problem of the triplet excitations that are equally underestimated in time-dependent density-functional theory and in BSE. [1] F. Bruneval, J. Chem. Phys. **136**, 194107 (2012). [2] F. Bruneval and M.A.L. Marques, J. Chem. Theory Comput. **9**, 324 (2013). [3] F. Bruneval, S. M. Hamed and J. B. Neaton, J. Chem. Phys. **142**, 244101 (2015).

**Wednesday, March 16, 2016 8:00AM - 11:00AM –**

**Session K25 DCMP: Superconductivity: Theory I** 324 - Harald Jeschke, Goethe-Universitt Frankfurt

**8:00AM K25.00001 Revised phase diagram and anomalous thermal evolution of the antinodal gap and Raman response in high-temperature superconductors**, YUAN ZHOU, Nanjing University and Brookhaven Natl Lab, ZUODONG YU, Nanjing University, WEIGUO YIN, Brookhaven Natl Lab, HAIQING LIN, Beijing Computational Science Research Center, CHANGDE GONG, Nanjing University — The interplay of competing orders is essential to high-temperature superconductivity, which emerges upon suppression of an antiferromagnetic order typically via charge doping. However, where the zero-temperature quantum critical point (QCP) takes place — in terms of the doping level — is still elusive for it is hidden by the superconducting dome. The QCP has long been believed to follow the continuous extrapolation of the characteristic temperature ( $T^*$ ) for a normal-state order, but recently  $T^*$  within the superconducting dome was found to exhibit unexpected back-bending in the cuprate  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$  and the iron-pnictide  $\text{BaFe}_{1-x}\text{Co}_x\text{As}$ . Here we show that the original and the revised phase diagrams can be understood in terms of weak and moderate competitions, respectively, between superconductivity and a pseudogap state such as d-density-wave, based on Ginzburg-Landau theory and the microscopic extended t-J model. We further illustrate that the anomalous thermal dependences of the measured antinodal gap and Raman response in cuprates can be well understood by a two-step evolution, dominated by superconductivity and pseudogap, respectively.

**8:12AM K25.00002 The Andreev reflection in a superconductor-normal metal junction of a doped correlated quantum spin Hall insulator<sup>1</sup>**, YUNG-YEH CHANG, Department of Electrophysics, National Chiao-Tung University, HsinChu, Taiwan, 300, CHUNG-YU MOU, Department of Physics, National Tsing-Hua University, HsinChu, Taiwan 300, CHUNG-HOU CHUNG, Dept. of Electrophysics, Natl. Chiao-Tung Univ., HsinChu, Taiwan, 300; Physics Division, Natl. Center for Theoretical Sciences, HsinChu, Taiwan, 300 — Andreev conductance across a normal metal-superconductor (N-S) junction of doped correlated quantum spin Hall insulator on honeycomb lattice is theoretically studied via Blonder-Tinkham-Klapwijk (BTK) formalism. The normal side is modeled by the doped Kane-Mele (KM) model. The superconducting side is a doped correlated KM t-J model, which has been shown to feature d+id'-wave spin singlet pairing. With increasing intrinsic spin-orbit coupling, the doped KM t-J system undergoes a topological phase transition from the chiral d-wave superconductivity to the  $Z_2$  spin-Chern superconducting phase with helical Majorana fermions at edges. We apply a local strain on the N-S interface to generate an effective Dirac-delta barrier and study the transport near the chiral-helical phase transition in the weak tunneling limit. We explore the Andreev conductance at the K and K Dirac points, respectively and find the distinctive behaviors across the transition. Relevance of our results for the adatom-doped graphene is discussed. Reference: S.J. Sun, C.H. Chung, Y.Y. Chang, W.F. Tsai, and F.C. Zhang, arxiv:1506.02584."

**8:24AM K25.00003 Macroscopic character of composite high temperature superconducting wires**, STEVEN KIVELSON, Stanford Univ, BORIS SPIVAK, University of Washington — The "d-wave" symmetry of the superconducting order in the cuprate high temperature superconductors is a well established fact, and one which identifies them as "unconventional." However, in macroscopic contexts — including many potential applications (*i.e.* superconducting "wires") — the material is a composite of randomly oriented superconducting grains in a metallic matrix, in which Josephson coupling between grains mediates the onset of long-range phase coherence. Here, we analyze the physics at length scales large compared to the size of such grains, and in particular the macroscopic character of the long-range order that emerges. While XY-superconducting glass order and macroscopic d-wave superconductivity may be possible, we show that under many circumstances — especially when the d-wave superconducting grains are embedded in a metallic matrix — the most likely order has global s-wave symmetry.

**8:36AM K25.00004 Random field disorder and charge order driven quantum oscillations in cuprates**, ANTONIO RUSSO, SUDIP CHAKRAVARTY, UCLA — In the pseudogap regime of the cuprates, charge order breaks a  $Z_2$  symmetry. Therefore, the interaction of charge order and quenched disorder due to potential scattering, can, in principle, be treated as a random field Ising model. A numerical analysis of the ground state of such a random field Ising model reveals local, glassy dynamics in both  $2D$  and  $3D$ . The glassy dynamics are treated as a heat bath which couple to the itinerant electrons, leading to an unusual electronic non-Fermi liquid. If the dynamics are strong enough, the electron spectral function has no quasiparticle peak and the effective mass diverges at the Fermi surface, precluding quantum oscillations. In contrast to charge density,  $d$ -density wave order (reflecting staggered circulating currents) does not directly couple to potential disorder, allowing it to support quantum oscillations. At fourth order in Landau theory, there is a term consisting of the square of the  $d$ -density wave order parameter, and the square of the charge order. This coupling could induce parasitic charge order, which may be weak enough for the Fermi liquid behavior to remain uncorrupted. Here, we argue that this distinction must be made clear, as one interprets quantum oscillations in cuprates.

**8:48AM K25.00005 Onsager rule, quantum oscillation frequencies, and the density of states in the mixed-vortex state of cuprates**, ZHIQIANG WANG, SUDIP CHAKRAVARTY, UCLA — Onsager rule that determines the frequencies of quantum oscillations in high magnetic fields serves as an anchor point. In its absence it would be very difficult to interpret the experimental results, because for each instance the problem would have to be considered anew. In the mixed-vortex state of the underdoped cuprates where, major consequential discoveries have recently taken place, its validity has been recently questioned. Here we show that this rule remains intact to an excellent approximation. The models we consider are fairly general, consisting of a variety of density wave states combined with  $d$ -wave superconductivity. Another exceptionally interesting result from our model calculations is that the oscillations ride on top of a field independent density of states,  $\rho(B)$ , for higher fields. This feature appears to be consistent with the recent specific heat measurements.

**9:00AM K25.00006 Collective modes in non-uniform superconductors**, ANTON VORONTSOV, ANDREW HAMMER, Montana State University — We study dynamics of a superconducting condensate in the presence of a domain wall defect in the order parameter. We find that broken translation and reflection symmetries result in new collective excitations, bound to the domain wall region. Two additional amplitude/Higgs modes lie below the bulk pairbreaking edge  $2\Delta$ ; one of them is a Goldstone mode with vanishing excitation energy. Spectrum of bound collective modes is related to the topological structure and stability of the domain wall. The 'unbound' bulk collective modes and transverse gauge field mostly propagate across the domain wall, but the longitudinal component of the gauge field is completely reflected. Softening of the amplitude mode suggests reduced damping and possible route to its detection in geometrically confined superfluids or in superconductor-ferromagnetic heterostructures.

**9:12AM K25.00007 Quasiclassical approach to magnetic susceptibility<sup>1</sup>**, CAROLINE RICHARD, ANTON VORONTSOV, Montana State University — Quasiclassical theory is a powerful technique that allows calculation of physical observables using just the low-energy states of the system. It is especially useful in studying properties of the non-uniform superfluid phases. We extend this approach to calculate response functions that involve high-energy correlations. Using example of Pauli magnetic susceptibility we employ Andreev approximation to express the spin-spin correlation function near a pairbreaking surface, in terms of low-energy, high-energy and mixed state contributions. This provides a convenient way to calculate response of a non-uniform superconductor at finite  $q$ -vectors.

**9:24AM K25.00008 Boosted one dimensional superconductors on a lattice**, SAYONEE RAY, SUBROTO MUKERJEE, VIJAY B. SHENOY, Indian Institute of Science — We study the effect of a boost (that engenders a current-carrying state) on one dimensional systems of lattice fermions with short-ranged attractive interactions. In the absence of a boost such systems possess algebraic superconducting order. Naively, one might expect a boost to weaken and ultimately destroy superconductivity, as in higher dimensions. However, we show that for one dimensional systems its effect is to *strengthen* the algebraic superconducting order by making correlation functions fall off more slowly with distance. We explain the physical underpinnings of these findings.

**9:36AM K25.00009 Negative isotope effect in Hubbard-Holstein model.**, DA WANG, Nanjing University — In phonon mediated conventional s-wave superconductors, higher-frequency phonon (or smaller atomic mass) leads to a higher superconducting transition temperature, known as the isotope effect. However, in correlated systems, various competing electronic order (such as spin-density-wave, charge-density-wave, and unconventional superconductivity) arises and the effect of electron-phonon coupling on these orders is a long-standing problem. Using the functional renormalization group, here we investigated the interplay between the electron correlation and electron-phonon coupling in the Hubbard-Holstein model on a square lattice. At half-filling, we found spin-density-wave and charge-density-wave phases and the transition between them, while no superconducting phase arises. Upon finite doping, d-wave/s-wave superconductivity emerges in proximity to the spin-density-wave/charge-density-wave phase. Surprisingly, lower-frequency Holstein phonons are either less destructive or even beneficial to the various phases, resulting in a negative isotope effect. For the superconducting phases, such an effect is apparently beyond the Bardeen-Cooper-Schrieffer theory.

**9:48AM K25.00010 The superconducting state of Holstein model using dynamical mean field theory**, CHUNGWEI LIN, BINGNAN WANG, KOON TEO, Mitsubishi Elec Res Lab — To enhance the superconducting temperature within the conventional superconductors, we solve the Holstein model, where conduction electrons are coupled to some boson field, using dynamical mean field theory (DMFT) with the configuration interaction impurity solver. Thanks to the non-perturbative nature of DMFT, we determine the zero-temperature order parameter for a wide range of boson energies to find the optimal range for superconductivity. This is beyond the Migdal-Eliashberg theory where the boson energy is assumed to be small compared to the Fermi energy. The effect of Hubbard on-site repulsion will be also discussed.

**10:00AM K25.00011 Unconventional superconductivity and interaction induced Fermi surface reconstruction in the two-dimensional Edwards model**, DAI-NING CHO, STEFFEN SYKORA, IFW Dresden — We study the possibility of unconventional superconducting pairing in the framework of a novel two-dimensional quantum transport model, where the charge carriers are strongly affected by the correlations and fluctuations of a background medium, described by bosonic degrees of freedom. Using the projective renormalization method (PRM) we find in the half-filled band case an interplay between stable superconducting solutions and a charge-density wave order parameter which determines the ground state in the limit of large bosonic energies. The superconducting pairing mainly appears on a new hole-like Fermi surface, which is formed nearby the center of the Brillouin zone due to strong renormalization of the original fermionic band. In the superconducting state, the Fermi surface splits into two disconnected parts, which are characterized by different sign of the superconducting order parameter.

**10:12AM K25.00012 A comprehensive model for high- $T_c$  based on pair-pair interactions.**, WILLIAM SACKS, ALAIN MAUGER, IMPMC, Sorbonne Universities, France, YVES NOAT, INSP, Sorbonne Universities, France — The superconducting (SC) state of cuprates is characterized by a dome-shaped  $T_c$  versus carrier density and an unconventional *pseudogap* (PG) state above  $T_c$  - basic properties remain highly debated. We have recently proposed a mechanism [1] based on the mutual interaction between incoherent Cooper pairs existing above  $T_c$ . At the critical temperature, this interaction induces a Bose-like condensation leading to the coherent SC state.

Absent in the conventional BCS case, the mutual pair-pair interaction is proportional to the condensate density  $n_{oc}(T)$  but is also related to the quasiparticle excitations. It gives an excellent fit to the DOS as measured by electron tunneling for a wide range of samples and carrier concentration. We conclude that long-range order is achieved by a direct quasiparticle - Cooper-pair coupling.

We then focus on the *temperature dependence* of the thermodynamic functions (condensation energy, entropy, etc.) and of the quasiparticle DOS. We show that these quantities depend on the unique combination of pair (boson) and quasiparticle (fermion) excitations, allowing a qualitative understanding of the phase diagram.

**10:24AM K25.00013 Two types of superconducting domes in unconventional superconductors**, TANMOY DAS, Indian Institute of Science, Bangalore, CHRISTOS PANAGOPOULOS, Nanyang Technological University, Singapore — In this talk, we present a comprehensive analysis of the SC properties and phase diagrams across several families of unconventional superconductors within the copper-oxides, heavy-fermions, organics, and the recently discovered iron-pnictides, iron-chalcogenides, and oxybismuthides. We find that there are two types of SC domes present in all families of SC materials, arising sometimes as completely isolated, or merged into one, or in some materials only any one of them appears. One of the SC dome appearing at or near a possible QCP usually possesses a lower transition temperature ( $T_c$ ). The other SC dome appearing at a different value of the tuning parameter around a non-Fermi liquid (NFL) state often has higher  $T_c$ . Both SC domes are not necessarily linked to each other, and so does the QCP and NFL state. In materials, where both domes are present, they can be isolated by multiple tuning (such as such as disorder, or pressure, or magnetic field in addition to doping, and vice versa), giving a unique opportunity to decouple the relationship between QCP, NFL, and their role on superconductivity. The systematic study the NFL state might be a generic route to higher- $T_c$  superconductivity.

**10:36AM K25.00014 Theory of pump-probe photoemission from a d-wave superconductor**, BENJAMIN NOSARZEWSKI, BRIAN MORITZ, SLAC National Accelerator Laboratory and Stanford University, ALEXANDER F. KEMPER, North Carolina State University, JAMES K. FREERICKS, Georgetown University, THOMAS P. DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University — Motivated by recent tr-ARPES experiments on high-temperature superconductors, we use the nonequilibrium Keldysh formalism to study the time-resolved photoemission spectra of a model electron-boson coupled system out of equilibrium. We introduce a momentum dependence to the electron-boson coupling to produce a superconducting state with d-wave symmetry. We investigate the nature of quasiparticle relaxation and recombination as well as the signatures of amplitude mode oscillations of the superconducting order parameter. We interpret our results in terms of existing experiments in the cuprates.

**10:48AM K25.00015 First principles calculations of  $\text{La}_2\text{CuO}_4$** , ANDREI PLAMADA, Institute for Theoretical Physics, ETH Zurich, ANTON KOZHEVNIKOV, Swiss National Supercomputer Centre, ETH Zurich, URS HAEHNER, MI JIANG, Institute for Theoretical Physics, ETH Zurich, PETER STAAR, IBM Research - Zurich, THOMAS MAIER, Computer Science and Mathematics Division and Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, THOMAS SCHULTHEISS, Institute for Theoretical Physics, ETH Zurich — We use the DFT+DCA method for a high-end study of the electronic structure properties of  $\text{La}_2\text{CuO}_4$ . The parameters of a tight-binding model are created using the first-principles electronic structure calculations. The all-electron full-potential linearised augmented plane-wave method is used to solve the non-interacting band problem. Then the set of physically relevant Wannier functions is chosen as a basis for the underlying Hubbard model. The Wannier functions and the corresponding non-interacting Hamiltonian  $H_{nm}^0(\mathbf{k})$  are created using the well-established downfolding approach. The screened Coulomb interaction parameters  $U_{nm}$  of the model are computed using the constrained random-phase approximation technique. The double counting term is assumed to be a constant multiplied by the identity operator in the correlated subspace and it is determined based on first-principles considerations. The resulting *ab-initio* parameterisation of the Hubbard model is solved within dynamical cluster approximation (DCA).

**8:00AM K26.00001 Nanocrystal Ghosting: Extensive radiation damage in MgO induced by low-energy electrons**, WILLIAM SAWYER, ZACHERY FRANKENFIELD, Deptment of Physics, West Chester University, KENNETH KANE, Deptment of Physics, Virginia Commonwealth University — Radiation damage in magnesium oxide has been an ongoing source of investigation. Early work was motivated by its simple cubic structure and its excellent electrical insulating properties over a wide range of temperatures and mechanical conditions. The goal was to determine its suitability as an electrical insulator in radiation intense environments including nuclear reactors and proposed nuclear fusion devices. During this period experimental results for irradiation of MgO using electrons with energies less than 500 keV produced very limited damage. These results, supported by theoretical arguments, lead to the conclusion that MgO was relatively impervious to damage from electrons with energies below this threshold. More recently its excellent insulating properties and relative mechanical stability combined with an increased interest in nanomaterials applications have created renewed interest in MgO. In this paper direct evidence is presented for extensive radiation damage in MgO nanocrystals from intense irradiation by electrons ( $2 \times 10^4$  electrons/nm<sup>2</sup> sec) with beam energies between 120 keV and 60 keV.

**8:12AM K26.00002 Point defects in yttria-stabilized zirconia**, C. STEPHEN HELLBERG, NOAM BERNSTEIN, STEVEN C. ERWIN, Naval Research Lab — The densification that occurs during sintering of certain ceramics has been observed to occur more rapidly and at lower temperatures when a weak external electric field is applied.<sup>1</sup> We compute the formation energies of point defects in yttria-stabilized zirconia using first principles density functional theory. We examine interstitials, vacancies, and vacancy complexes including Schottky defects in a Y<sub>2</sub>Zr<sub>14</sub>O<sub>31</sub> computational cell, which corresponds to approximately 7 mol% yttria stabilized zirconia. We relate our results to recent experimental work on electric-field-assisted sintering in yttria-stabilized zirconia, showing how the expansion of lattice constants observed in diffraction measurements results from increasing defect densities. 1. Raj, R., Cologna, M., and Francis, J. S. C. Influence of Externally Imposed and Internally Generated Electric Fields on Grain Growth, Diffusional Creep, Sintering and Related Phenomena in Ceramics. *Journal of the American Ceramic Society* 94, 1941 (2011).

**8:24AM K26.00003 Investigation of Defect Structure to Determine the Primary Photorefractive Centers Responsible for Enhanced Beam Coupling in KNbO<sub>3</sub>:Fe**, DEAN EVANS, Air Force Rsch Lab - WPAFB, SERGEY BASUN<sup>1</sup>, Azimuth Corp., AIR FORCE RSCH LAB - WPAFB TEAM, AIR FORCE RSCH LAB - WPAFB TEAM — A series of experiments are used to determine the location of the energy levels of various Fe centers and associated defect centers in KNbO<sub>3</sub>:Fe, as well as conclude which centers are the primary photorefractive centers. In particular, the methods include electron paramagnetic resonance, optical absorption spectroscopy, electric conductivity, and beam coupling. A correlated study using data acquired with these techniques has been performed on as-grown (unreduced) and reduced KNbO<sub>3</sub>:Fe crystals, which identified which Fe centers were reduced and which ones were not. Conditions for an increased electron source population (improved beam coupling performance) was determined and compared to beam coupling results for pure electron, pure hole, and electron-hole competition processes.

**8:36AM K26.00004 Raman and Fluorescence Study of Erbium-Doped Laser-Induced Crystals-in-Glass**, BRIAN KNORR, Fairleigh Dickinson Univ, KEITH VEENHUIZEN, ADAM STONE, Lehigh University, HIMANSHU JAIN, Fairleigh Dickinson Univ, VOLKMAR DIEROLF, Lehigh University — Laser induced crystallization of glasses is a spatially selective process which has the potential to produce photonic integrated circuits in a glass matrix. Low temperature Combined Excitation Emission Spectroscopy in Er:LaBGeO<sub>5</sub> show that erbium incorporates at predominantly one majority site in both glass-ceramics and laser-induced crystals-in-glass, but that other minority sites also exist. The energy levels of the majority site were quantified. The fluorescence characteristics of the erbium ions in any site in the laser-induced crystals were found to be only weakly influenced by the irradiation conditions during growth. On the other hand, a hidden parameter, potentially boron deficiency-related defects, resulted in a significant change in the incorporation behavior of the erbium ions. Simultaneous scanning confocal Raman and fluorescence spectroscopy showed that the energies of the Raman modes are shifted, and the erbium fluorescence intensity varies, in a non-uniform manner, despite the host glass being homogeneously doped, across the cross-sections of laser-induced crystals in glass. These fluctuations within the Raman and fluorescence are spatially correlated, implying that different erbium sites form preferentially at different locations in the crystal cross-section.

**8:48AM K26.00005 Excitons and band edge alignment in CdSe/CdS core-shell nanocrystals: ab initio**, DANYLO ZHEREBETSKYY, LIN-WANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, COMPUTATIONAL MATERIALS SCIENCE AND NANOSCIENCE TEAM — Quantum confinement is a foundational nanoscience concept that allows tuning electronic properties of quantum dots. Core-shell quantum dots are promising nanoparticles and found applications as light-emitting optoelectronic devices and biomarkers [1] due to their robustness and tunability of both core and shell. The fluorescent quantum yield of these quantum dots can achieve 100% [2] even at room temperature [3]. However, to understand many phenomena of carrier dynamics, photoluminescence efficient and Auger effects, fine electronic structures of the exciton are needed. Here, using large scale electronic structure calculations based on charge patching method, we have investigated the exciton binding energy, band alignment between core and shell, charge separation between electron and hole. We will discuss how these can be tuned by changing the core/shell dimensions. 1. Shirasaki Y., Supran G., Bawendi M., Bulović V. *Nature Photonics* 7, 13 (2013). 2. Javaux C. et al, *Nature Nanotech.* 8, 206 (2013) 3. Achieved in Alivisatos lab (2014).

**9:00AM K26.00006 Photocreation and hyperbolic decay of Sb<sup>2+</sup> in Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub>:Sb.**, SERGEY BASUN, Air Force Res. Lab. WrightPatterson Air Force Base, LARRY HALLIBURTON, Dept of Physics, West Virginia University, SERGEY ODOULOV, ALEXANDR SHUMELYUK, Institute of Physics, 03 650 Kyiv, Ukraine, ALEXANDER GRABAR, Institute of Solid State Physics and Chemistry, DEAN EVANS, Air Force Res. Lab. WrightPatterson Air Force Base — In Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub>:Sb, photorecharging of Sb<sup>3+</sup> ions to Sb<sup>2+</sup> causes a new interesting phenomenon – photo-sensitizing of photorefraction.[1,2] The decay of the optically produced Sb<sup>2+</sup> ions was directly measured through EPR and was found to have a hyperbolic character:  $\sim 1/(t/\tau+1)$  with an activation energy of 0.42 eV. This decay character and a very similar activation energy were also found in photorefraction and optically induced absorption experiments. The observed hyperbolic decay was explained through the set of rate equations that takes into account the EPR result: only Sb<sup>3+</sup> ions are present in Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub>:Sb in thermal equilibrium. The long-wavelength onset of the EPR-measured Sb<sup>2+</sup> “photocreation” spectrum together with the activation energy of the Sb<sup>2+</sup> decay allowed to firmly locate the position of the Sb<sup>2+/3+</sup> electron level in the bandgap of Sn<sub>2</sub>P<sub>2</sub>S<sub>6</sub>: 0.42 eV below the conduction band bottom. [1] D. R. Evans, A. Shumelyuk, G. Cook, S. Odoulov. *Opt. Lett.* 36, 454 (2011). [2] Y. Skrypka, A. Shumelyuk, S. Odoulov, S. Basun, D. Evans, *Opt. Comm.* 356, 208 (2015).

**9:12AM K26.00007 Surface Analysis of  $sp^2$  Carbon in Ag and Al Covetic Alloys\***, H M IFTEKHAR JAİM, Materials Science and Engineering Department, University of Maryland, College Park, MD 20742, USA, DANIEL P. COLE, U.S. Army Research Laboratory, Aberdeen Proving Ground, MD 21005, LOURDES G. SALAMANCA-RIBA, Materials Science and Engineering Department, University of Maryland, College Park, MD 20742, USA — Ag, Al-6061 and Al-7075 were doped with carbon by an electrocharging assisted process where high electric current is applied to the molten metal containing particles of activated carbon. This process gives rise to epitaxial growth of graphene nanoribbons (GNR) and carbon nanostructures within the metal matrix. Alloys produced with such technique are named Covetics. Al-6061 and Al-7075 covetics have shown superior mechanical, electrical and anti-corrosion properties. The nanostructured carbon incorporation has been confirmed by XPS, Raman, and TEM studies. Here, we present detailed surface characterization of the carbon nanostructures in these new alloys. Raman and EELS mapping of carbon nanostructure were carried out to identify the nature of bonding, strain and defect characteristics. Mostly, crystalline GNR or graphene sheets were found to create networks with  $sp^2$  character, under compressive strain with high concentration of defects. AFM and KPFM showed contrast in phases and potentials for ribbon like features. Incorporation of  $sp^2$  carbon in metals is an initial step for the integration of carbon nanostructures for future applications requiring high strength and conductivity.

**9:24AM K26.00008 Direct visualization of atomically precise nitrogen-doped graphene nanoribbons.**, HONG-LIANG LU, University of Chinese Academy of Sciences and Institute of Physics, Chinese Academy of Sciences, Beijing 100049, China, YI ZHANG, YANFANG ZHANG, GENG LI, JIANCHEN LU, Institute of Physics and University of Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing 100190, China, XIAO LIN, University of Chinese Academy of Sciences and Institute of Physics, Chinese Academy of Sciences, Beijing 100049, China, SHIXUAN DU, Institute of Physics and University of Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing 100190, China, REINHARD BERGER, XINLIANG FENG, KLAUS MULLEN, Max Planck Institute for Polymer Research, Ackermannweg 10, D-55128 Mainz, Germany, HONG-JUN GAO, Institute of Physics and University of Chinese Academy of Sciences, Chinese Academy of Sciences, Beijing 100190, China — We have fabricated atomically precise nitrogen-doped chevron-type graphene nanoribbons by using the on-surface synthesis technique combined with the nitrogen substitution of the precursors. Scanning tunneling microscopy and spectroscopy indicate that the well-defined nanoribbons tend to align with the neighbors side-by-side with a band gap of 1.02 eV, which is in good agreement with the density functional theory calculation result. The influence of the high precursor coverage on the quality of the nanoribbons is also studied. We find that graphene nanoribbons with sufficient aspect ratios can only be fabricated at sub-monolayer precursor coverage. This work provides a way to construct atomically precise nitrogen-doped graphene nanoribbons.

**9:36AM K26.00009 First-principle study on substrate-induced structures of bismuth adsorption on graphene.**, SHIH-YANG LIN, Department of Physics, National Cheng Kung University, SHEN-LIN CHANG, Department of Electrophysics, National Chiao Tung University, HSIN-HSIEN CHEN, SHU-HSUAN SU, JUNG-CHUN HUANG, MING-FA LIN, Department of Physics, National Cheng Kung University — The geometric and electronic properties of Bi-adsorbed monolayer graphene, enriched by the strong effect of substrate, are investigated by the first-principles calculations. The six-layered substrate, corrugated buffer layer, and slightly deformed monolayer graphene are all simulated. Adatom arrangements are optimized through detailed analyses on adsorption energies and ground-state energies of various adsorption sites, revealing a hexagonal array of Bi atoms dominated by the interactions between buffer layer and monolayer graphene. The increasing temperature can overcome a ~50 meV energy barrier and induce triangular and rectangular nanoclusters. The most stable and the metastable structures agree with the scanning tunneling microscopy measurements. The density of states exhibits a finite value at the Fermi level, a dip at low energy, and a shoulder at ~-0.8 eV, as observed in the experimental measurements of tunneling conductance.

**9:48AM K26.00010 Atomic-scale investigation of grain boundary motion in graphene**, DONGWOOK KIM, Seoul National University, YOUNGKUK KIM, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, JISOON IHM, EUIJOON YOON, GUN-DO LEE, Seoul National University — Grain boundaries (GBs) in graphene can migrate when irradiated by electron beams from a transmission electron microscope (TEM). Here, we present an ab initio study on the atomic scale mechanism for the GB motion with misorientation angle of 30 in graphene. From total energy calculations and energy barrier calculations, we find that a Stone–Wales(SW)-type transformation can occur more easily near GBs than in pristine graphene due to a reduced energy barrier. There are other cases of migration which can be understood by other type of transformation, named evaporation of a carbon dimer. We also find that a mismatch in the crystalline orientation at GBs can drive the evaporation of a carbon dimer easily by greatly reducing the corresponding overall energy barrier. After evaporation of the carbon dimer, the GBs can be stabilized through a series of SW-type transformations that result in GB motion. The GB motion induced by evaporation of the dimer is in excellent agreement with recent TEM experiments.

**10:00AM K26.00011 Rippllocations: A Novel Defect in Layered Materials**, JACOB GRUBER, ANDREW LANG, JUSTIN GRIGGS, GARRITT TUCKER, MICHEL BARSOUM, Drexel Univ — Recently, a new defect, the rippllocation, the mechanical buckling of a single atomic layer, was proposed to explain the behavior of two dimensional materials. Leveraging atomistic simulations, this concept is extended to bulk layered materials. Unlike dislocations, rippllocations do not possess a Burgers vector and do not have polarity. In graphite, rippllocations are attracted both to vacancies, where they can annihilate, and other rippllocations, forming larger complexes and eventually kink boundaries. While some rippllocation behavior can be described by dislocation complexes, the failure of these models to explain core interactions suggests that rippllocations are a fundamentally new class of defect. Furthermore, TEM examination of nanoindented  $Ti_3SiC_2$ , where dislocation theory does not provide a complete description of behavior, reveals the presence of defects with no Burgers vector and with rotation and strain fields similar to those predicted in simulation, suggesting the presences of buckled basal planes. Rippllocations have profound implications for the deformation of plastically anisotropic solids, including graphite, layered silicates and the MAX phases.

**10:12AM K26.00012 Spin chains and electron transfer at stepped silicon surfaces**, STEVEN ERWIN, Naval Research Laboratory, JULIAN AULBACH, RALPH CLAESSEN, JOERG SCHAEFER, Universitaet Wuerzburg — Stepped silicon surfaces oriented between Si(111) and Si(001) show unusual behavior when submonolayer amounts of gold are adsorbed: they self-assemble to form arrays of steps with virtually perfect structural order. Known examples include Si(553), Si(557), and Si(775). For the first two of these there is, in addition, strong theoretical and experimental evidence that the silicon step edges are spin polarized, raising the possibility of a magnetically ordered ground state at a silicon surface. The situation is different, however, for Si(775): theory and experiment both show that spin polarization does not occur. Here we use density-functional theory and scanning tunneling microscopy to develop a physically transparent picture explaining the formation of these 'spin chains' on the family of Si(hhk)-Au surfaces. Specifically, we explain why spin chains form on particular silicon (hhk) orientations but not on others. Finally, we use this understanding to propose strategies for using surface chemistry to control the formation or suppression of spin chains on Si(hhk)-Au surfaces.

**10:24AM K26.00013 Film Growth on Nanoporous Substrate<sup>1</sup>**, XUE ZHANG, JAMES JOY, CHENWEI ZHAO<sup>2</sup>, Brown University, Department of Physics, J.M. XU, Brown University, School of Engineering, JAMES VALLES, Brown University, Department of Physics — Self-ordered nanoporous anodic aluminum oxide (AAO) provides an easy way to fabricate nano structured material, such as nano wires and nano particles. We employ AAO as substrates and focus on the thermally evaporated film growth on the surface of the substrate. With various materials deposited onto the substrate, we find the films show different structures, e.g. ordered array of nano particles for Lead and nanohoneycomb structure for Silver. We relate the differing behaviors to the difference of surface energy and diffusion constant. To verify this, the effect of substrate temperature on the film growth has been explored and the structure of the film has been successfully changed through the process.

**10:36AM K26.00014 Thermal Expansion of  $\text{ScF}_3$ .** , R. BHANDIA, Occidental College, A. GROCKOWIAK, T. SIEGRIST, T. BESARA, S.W. TOZER, National High Magnetic Field Laboratory, G.M. SCHMIEDESHOFF, Occidental College —  $\text{ScF}_3$  is an insulator, has a cubic crystal structure, and exhibits negative thermal expansion over a very wide temperature range. We will present and discuss thermal expansion measurements made with capacitive and fiber-Bragg-grating dilatometers. Work at Occidental College is supported by the National Science Foundation under DMR-1408598. A portion of this work was funded by the US Department of Energy NNSA SSAA DE-NA0001979, and performed at the National High Magnetic Field Laboratory, which is supported by National Science Foundation Cooperative Agreement No. DMR-1157490 and the State of Florida.

**10:48AM K26.00015 Electronic and optical properties of co-doped  $\text{BaTiO}_3$  with fluorine and nitrogen: A first-principles study.** , JAWAD ALSAEI<sup>1</sup>, Universit of Bahrain, PUAL TANGNEY, ARASH MOSTOFI, Imperial College London — Ferroelectric oxides such as  $\text{BaTiO}_3$  (BTO) are very good candidates for tunable dielectric devices. Tailoring the electronic and optical properties of these materials is usually achieved through means of strain engineering and compositional variations. In this work, we use first-principles calculations to study the effect of the co-substitution of F and N in BTO on its electronic and optical properties. Our simulations suggest that the optical properties are very sensitive to the atomic configuration of the dopant atoms. Our simulations show that the most energetically favorable configuration is that in which the F and N atoms form linear parallel chains of F-Ti-N motif that tend to cluster with each other. This configuration induces a large birefringence that can be further enhanced by means of biaxial strain. Our results shed more light on this particular type of anionic doping that has been rarely studied in the literature [?].

**8:00AM K27.00001 Carbon nanotube based field-effect transistors: merits and fundamental limits** , LIAN-MAO PENG, Peking University — The development of even more powerful computer systems are made possible by scaling of CMOS transistors, and this simple process has afforded continuous improvement in both the device switch time and integration density. However, CMOS scaling has become very difficult at the 22-nm node and unlikely to be rewarding beyond the 14-nm node. Among other new approaches, carbon nanotube devices are emerging as the most promising technique with unique properties that are ideal for nanoelectronics. In particular, perfect n-type and p-type contacts are now available for controlled injection of electrons into the conduction band and holes into the valence band of the CNT, paving the way for a doping free fabrication of CNT based ballistic CMOS, high performance optoelectronic devices, and integrated circuits [1-3]. These results will be compared with data projected for Si CMOS toward the end of the roadmap at 2026, as well as with those thermodynamic and quantum limits. References: [1] L.-M. Peng, Z.Y. **8:36AM K27.00002 Integration of High-Purity Carbon Nanotube Solution into Electronic Devices** , GEORGE TULEVSKI, IBM TJ Watson Research Center, IBM TJ WATSON RESEARCH CENTER TEAM — Due to their exceptional electronic properties, carbon nanotubes (CNT) are leading candidates to be employed as channel materials in future nanoelectronic devices. A key bottleneck to realizing device integration is the sorting of carbon nanotubes, namely the isolation of high-purity, semiconducting CNT solutions. This talk will describe our efforts in using polymer-based sorting methods to isolate high-density and high-purity semiconducting CNT solutions. We explore the dependence of starting material and polymer to CNT ratio on the effectiveness of the separation. We confirm optically and electrically that the semiconducting purity is >99.99% through several thousand individual device measurements. In addition to single-CNT devices, thin-film transistors were also fabricated and tested. Due to the high purity of the solutions, device switching ( $\sim 10^5 I_{\text{ON}}/I_{\text{OFF}}$ ) was observed at channel lengths below the percolation threshold (<500 nm). Operating below the percolation threshold allows for devices with much higher current densities and effective mobilities as transport is now the result of direct transport as opposed to hopping between CNTs.

**8:48AM K27.00003 One-dimensional quantum transport in hybrid metal-semiconductor nanotube systems.**<sup>1</sup> , MAXIM GELIN, Munich Technical University, IGOR BONDAREV, North Carolina Central University — We study the inter-play between the intrinsic 1D conductance of metallic atomic wires (AWs) and plasmon mediated near-field effects for semiconducting single wall carbon nanotubes (CNTs) that encapsulate AWs of finite length. We use the matrix Green's functions formalism to develop an electron transfer theory for such a hybrid quasi-1D metal-semiconductor nanotube system. The theory predicts Fano resonances in electron transmission through the system. That is the AW-CNT near-field interaction blocks some of the pristine AW transmission band channels to open up new coherent channels in the CNT forbidden gap outside the pristine AW transmission band. This makes the entire hybrid system transparent in the energy domain where neither of the individual pristine constituents, neither AW nor CNT, are transparent. The effect can be used to control electron charge transfer in semiconducting CNT based devices for nanoscale energy conversion, separation and storage [1-3]. — [1]S.Nanot, et al., Sci. Rep. 3, 1335 (2013); [2]M.Barkelid and V.Zwiller, Nature Photo 8, 47 (2014); [3]A.Sharma, et al., Nature Nano DOI:10.1038/nnano.2015.220.

**9:00AM K27.00004 Making End-Bonded Contacts to Carbon Nanotubes** , JIANSHI TANG, QING CAO, GEORGE TULEVSKI, SHU-JEN HAN, IBM Thomas J. Watson Research Center, Yorktown Heights, NY 10598, USA — As a promising candidate for post-Si era, the implementation of carbon nanotube (CNT)-based CMOS technology requires both high-quality channel and electrical contacts that can be scaled down to sub-10 nm. In the efforts of making scalable contacts to CNT, we have recently demonstrated low-resistance end-bonded carbide contacts, formed by the reaction of Mo with CNT through high-temperature annealing (>800 °C) [1]. Such end-bonded contact scheme leads to a size-independent contact resistance of about 30 kilo-ohms, which overcomes the scaling limit of conventional side contacts. In this talk, we will present another strategy to make end-bonded contacts to CNTs through thermal annealing at much lower temperatures (400-600 °C). The contact metals are carefully chosen to have a high carbon solubility, so that the carbon atoms could dissolve into the contacts to inherently form end-bonded contacts. Experimental results, including Raman, SEM, and electrical measurements, with different annealing temperatures will be presented. The length-dependent contact resistance for this new end-bonded contact will be evaluated and compared with that of conventional side contact and also end-bonded carbide contact. [1] Q. Cao, et al., Science, 350, 68-72 (2015).

**9:12AM K27.00005 Carbon nanotube transistor based high-frequency electronics<sup>1</sup>** , MICHAEL SCHROTER, Technical University Dresden — At the nanoscale carbon nanotubes (CNTs) have higher carrier mobility and carrier velocity than most incumbent semiconductors. Thus CNT based field-effect transistors (FETs) are being considered as strong candidates for replacing existing MOSFETs in digital applications. In addition, the predicted high intrinsic transit frequency and the more recent finding of ways to achieve highly linear transfer characteristics have inspired investigations on analog high-frequency (HF) applications. High linearity is extremely valuable for an energy efficient usage of the frequency spectrum, particularly in mobile communications. Compared to digital applications, the much more relaxed constraints for CNT placement and lithography combined with already achieved operating frequencies of at least 10 GHz for fabricated devices make an early entry in the low GHz HF market more feasible than in large-scale digital circuits. Such a market entry would be extremely beneficial for funding the development of production CNTFET based process technology. This talk will provide an overview on the present status and feasibility of HF CNTFET technology will be given from an engineering point of view, including device modeling, experimental results, and existing roadblocks.

**9:48AM K27.00006 Transport properties of C60/nanotube heterostructures** , WU SHI, Lawrence Berkeley National Laboratory; Univ of California, Berkeley, THANG PHAM, HAMID BARZEGAR, Univ of California, Berkeley, ALEX ZETTTL, Lawrence Berkeley National Laboratory; Univ of California, Berkeley — Crystal structures determine the electronic properties. The fullerene C60 is insulating but can become superconducting with Tc above 30 K by inserting atoms or apply a pressure. In addition, Tc changes with the distance between fullerene molecules. Because of relatively weak intermolecular interactions, C60 molecules can even pack into nanowire structures with low dimensional constraints imposed by carbon nanotubes (CNTs) or boron nitride nanotubes (BNNTs). In this study, we will report the characterization of C60/nanotube heterostructures and their transport properties. By filling into nanotubes, C60 molecules form one-dimensional quasi-crystal structures, which are absent in bulk or film forms. The C60-C60 intermolecular distance changes with the tube diameters, which could potentially yield rich transport properties.

**10:00AM K27.00007 Environmental effects on the electrical properties of narrow-gap carbon nanotubes** , LEE ASPITARTE, DAN MCCULLEY, ETHAN MINOT, Oregon State University — Observations of single-walled carbon nanotubes (CNTs) with band gaps of 50 - 100 meV and diameters of approximately 2 nm pose an intriguing puzzle. The orthodox theory of CNTs predicts that such CNTs should have band gaps between 0 and 25 meV, yet these “narrow-gap” CNTs are routinely observed (band gaps in the range 50 – 100 meV). A possible explanation is that strong Coulomb interactions cause a Mott gap in nominally metallic CNTs (Deshpande et al., Science, 2009). To test this hypothesis, we have fabricated field-effect transistor devices from suspended narrow-gap CNTs. We have tested these devices in a variety of dielectric environments, including air, vacuum, TiO<sub>2</sub> coatings, and molecular liquids such as oil, anisole, toluene, isopropanol, and water. In many cases we can relate changes in electrical properties to changes in electrostatic disorder, gate capacitance, mobility and band alignment. We will discuss the possibility of an interaction-driven effect that is changed by the dielectric environment.

**10:12AM K27.00008 Absorption of CO<sub>2</sub> on Carbon-based Sensors: First-Principle Analysis.** , NACIR TIT, Physics Department, UAE University, P.O.Box 15551, Al-Ain, UAE, MOHAMMED ELEZZI, HASAN ABDULLAH, HOCINE BAHLOULI, Physics Department, KFUPM, P.O.Box 1690, Dhahran 31261, Saudi Arabia, ZAIN YAMANI, Center for Research Excellence in Nanotechnology, KFUPM, P.O.Box 5040, Dhahran 31261, Saudi Arabia — We present first-principle investigation of the adsorption properties of CO and CO<sub>2</sub> molecules on both graphene and carbon nano-tubes (CNTs) in presence of metal catalysis, mainly iron (Fe). The relaxations were carried out using the self-consistent-charge density-functional tight-binding (SCC-DFTB) code in neglect of heat effects. The results show the following: (1) Defected graphene is found to have high sensitivity and high selectivity towards chemisorption of CO molecules and weak physisorption with CO<sub>2</sub> molecules. (2) In case of CNTs, the iron “Fe” catalyst plays an essential role in capturing CO<sub>2</sub> molecules. The Fe ad-atoms on the surface of CNT introduce huge density of states at Fermi level, but the capture of CO<sub>2</sub> molecules would reduce that density and consequently reduce conductivity and increase sensitivity. Concerning the selectivity, we have studied the sensitivity versus various gas molecules (such as: O<sub>2</sub>, N<sub>2</sub>, H<sub>2</sub>, H<sub>2</sub>O, and CO). Furthermore, to assess the effect of catalysis on sensitivity, we have studied the sensitivity of other metal catalysts (such as: Ni, Co, Ti, and Sc). We found that CNT-Fe is highly sensitive and selective towards detection of CO and CO<sub>2</sub> molecules. CNT being conductive or semiconducting does not matter much on the adsorption properties.

**10:24AM K27.00009 Detection of the Odor Signature of Ovarian Cancer using DNA-Decorated Carbon Nanotube Field Effect Transistor Arrays** , CHRISTOPHER KEHAYIAS, NICHOLAS KYBERT, JEREMY YODH, A. T. CHARLIE JOHNSON, Univ of Pennsylvania — Carbon nanotubes are low-dimensional materials that exhibit remarkable chemical and bio-sensing properties and have excellent compatibility with electronic systems. Here, we present a study that uses an electronic olfaction system based on a large array of DNA-carbon nanotube field effect transistors vapor sensors to analyze the VOCs of blood plasma samples collected from patients with malignant ovarian cancer, patients with benign ovarian lesions, and age-matched healthy subjects. Initial investigations involved coating each CNT sensor with single-stranded DNA of a particular base sequence. 10 distinct DNA oligomers were used to functionalize the carbon nanotube field effect transistors, providing a 10-dimensional sensor array output response. Upon performing a statistical analysis of the 10-dimensional sensor array responses, we showed that blood samples from patients with malignant cancer can be reliably differentiated from those of healthy control subjects with a p-value of  $3 \times 10^{-5}$ . The results provide preliminary evidence that the blood of ovarian cancer patients contains a discernable volatile chemical signature that can be detected using DNA-CNT nanoelectronic vapor sensors, a first step towards a minimally invasive electronic diagnostic technology for ovarian cancer.

**10:36AM K27.00010 Monitoring DNA polymerase with nanotube-based nanocircuits** , YAN LI, MIROSLAV HODAK, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, PHILIP COLLINS, University of California Irvine — DNA polymerases play an important role in the process of life by accurately and efficiently replicating our genetic information. They use a single-stranded DNA as a template and incorporate nucleotides to create the full, double-stranded DNA. Recent experiments have successfully monitored this process by attaching a Klenow fragment of polymerase I to a carbon nanotube and measuring the current along the tube [1]. Follow-up experiments have shown promise for distinguishing between DNA base pairs when nucleotide analogs are used [2], thus opening a new avenue for DNA sequencing. In this talk, we present results from computational studies on DNA polymerase I nanocircuits. The enzyme was first equilibrated in molecular dynamics and then density functional theory and Keldysh non-equilibrium Green's function methods were used to calculate the ballistic transmission coefficients and currents for different enzymatic states. Our results show significant change in current when the enzyme alternates between open (idle) and closed (synthesizing) states. We can also differentiate between some template bases when modified nucleotides and gate scanning are used. [1] T. J. Olsen et. al., JACS 135, 7855 (2013) [2] K. M. Pugliese et. al., JACS 137, 9587 (2015)

**10:48AM K27.00011 A photonic microscope for observing real-time vibrations of carbon nanotubes**, ARTHUR W. BARNARD, MIAN ZHANG, School of Applied and Engineering Physics, Cornell University, GUSTAVO WIEDERHECKER, Instituto de Física Gleb Wataghin, Universidade Estadual de Campinas, MICHAL LIPSON, School of Electrical and Computer Engineering, Cornell University, PAUL L. MCEUEN, Department of Physics, Cornell University; Kavli Institute at Cornell for Nanoscale Science — Vibrational modes in suspended carbon nanotubes (CNTs) are incredibly responsive to small forces, which makes them a prime candidate as nano-mechanical sensors. However, transducing this mechanical motion into detectable signals is a considerable challenge. Electrical detection, which has been the prevailing method thus far, suffers a significant impedance mismatch to macroscopic electronics and is thus susceptible to noise. We demonstrate an alternative: optical readout of CNT vibrations in real-time. By combining a unique CNT microtweezer platform with a high-finesse optical microdisk resonator, we dramatically enhance the naturally small optical cross-section of CNTs and thereby achieve unprecedented detection sensitivity. With this novel photonic microscope, we directly measure the thermal Brownian motion of CNTs and observe marked spectral diffusion at room temperature, shedding light on CNTs unique thermal physics. By further enhancing the optical coupling, we demonstrate optical amplification of CNT vibrations and directly observe period-doubling in the amplified state.

**Session K28 DMP: Quantum Anomalous Hall Effect II** 327 - Anthony Richardella, Pennsylvania State University

**8:00AM K28.00001 Searching for better magnetic topological insulator materials for the quantum anomalous Hall effect<sup>1</sup>**, KE HE, Department of Physics, Tsinghua University — The recent experimental observation of the quantum anomalous Hall (QAH) effect in thin films of magnetic topological insulators (TIs) paves the ways for practical applications of dissipationless quantum Hall edge states and for realizations of the novel quantum phenomena such as chiral topological superconductivity and axion magnetoelectric effect. Further studies in these directions require magnetic TI materials that are able to show the QAH effect at higher temperature and with conduction channels of lower dissipation. We have performed systematic study on the QAH effect in magnetically doped TI films with different thicknesses, magnetic dopants and compositions. The results clarify the relations between the QAH effect and energy band structure, electronic localization and ferromagnetism, which not only give a comprehensive understanding on the nature of the QAH effect but also provide insights into designing and fabrication of superior QAH materials.

**8:36AM K28.00002 Precise Quantization of Anomalous Hall Effect**, ANDREW BESTWICK<sup>1</sup>, Stanford University — In the quantum anomalous Hall effect, electron transport in a magnetically-doped topological insulator takes place through chiral, dissipationless edge channels. In this talk, we discuss the behavior of a nearly ideal implementations of the effect in which the Hall resistance is within a part per 10,000 of its quantized value and the longitudinal resistivity can reach below  $1 \Omega$  per square. Nearly all Cr-doped topological insulator samples demonstrate extreme temperature dependence that is well-modeled by a small effective gap, allowing control over quantization with an unexpected magnetocaloric effect. We also discuss measurements of new device geometries and non-local resistances that identify the sources of dissipation that limit the effect.

<sup>1</sup>(Now at Rigetti Computing)

**9:12AM K28.00003 Distinct Effect of Cr Bulk and Surface Doping on the Local Environment and Electronic Structure of Bi<sub>2</sub>Se<sub>3</sub><sup>1</sup>**, TURGUT YILMAZ, Univ of Connecticut - Storrs, IVO PLETIKOSIC, Princeton University, TONICA VALLA, Brookhaven National Laboratory, BORIS SINKOVIC, Univ of Connecticut - Storrs — We report on studies of Cr doping of Bi<sub>2</sub>Se<sub>3</sub> by comparing surface doped with bulk doped Bi<sub>2</sub>Se<sub>3</sub> films and their electronic and local structures studied by in-situ ARPES and core-level photoemission spectroscopies, respectively. In the case of surface doping we see the evidence for Cr substituting the Bi by observation of the extra feature in the Bi 5d photoemission spectra that increases with doping. On the other hand the Cr 3p spectra show two distinct chemical states indicating that there are two different Cr locations with different local electronic configuration. However, unlike theoretical expectations, the electronic structure measured at 15 K shows that surface states preserve gapless feature with well defined Dirac cone and presence of quantum well states, induced by doping. In contrast, the bulk Cr doped Bi<sub>2</sub>Se<sub>3</sub> films show gapped surface states with gap energy as large as 100 meV even at room temperature, which is far above the reported ferromagnetic transition temperature.

**9:24AM K28.00004 Tuning the electronic structure in nearly gapless HgCdTe with temperature: infrared magneto-spectroscopy study**, SEONGPHILL MOON, Natl High Magnetic Field Lab, Florida State University, M. MARCINKIEWICZ, C. CONSEJO, S. RUFFENACH, W. KNAP, F. TEPPE, Laboratoire Charles Coulomb, University of Montpellier, France, J. LUDWIG, Natl High Magnetic Field Lab, Florida State University, K. THIRUNAVUKKARASU, D. SMIRNOV, National High Magnetic Field Laboratory, S. KRISH-TOPIENKO, V. I. GAVRILENKO, Institute for Physics of Macrostructures, Nizhni Novgorod, Russia, S. A. DVORETSKII, N. N. MIKHAILOV, Rzhanelov Institute of Semiconductor Physics, Novosibirsk, Russia — Replace this text with your abstract body. Recently, a temperature-induced transition from a conventional two-dimensional semiconductor to a topological insulator has been demonstrated through magneto transport studies on HgTe/CdHgTe quantum wells [Wiedmann, S. et al. Phys. Rev. B 91, 205311 (2015)]. Here we report on a temperature-driven semiconductor-to-semimetal transition in 3-dimensional CdxHg1-xTe (x=0.15) revealed by infrared magneto-spectroscopy. We show that changing the temperature from 4K to 120K enables continuous tuning of the band structure from inverted to normal alignment through a critical gapless state realized at ~80K, where the inter-Landau level transitions exhibit a characteristic  $\sqrt{B}$  dependence intersecting at zero energy. Using an effective Dirac model, we determine the effective mass and the Fermi velocity for the studied temperature range.

**9:36AM K28.00005 Distorted weak anti-localization effects in Bi<sub>2</sub>Se<sub>3</sub>/La<sub>0.70</sub>Sr<sub>0.30</sub>MnO<sub>3</sub> (TI/FM) heterostructures grown by pulsed laser deposition**, FRANK HUNTE, RAJ KUMAR, YI-FANG LEE, SANDHYARANI PUNUGUPATI, JUSTIN SCHWARTZ, JAY NARAYAN, Materials Science and Engineering, North Carolina State University, Raleigh, NC - 27695 — Topological insulator/ferromagnet (TI/FM) heterostructures with broken time reversal symmetry by interface-induced magnetism are the potential platforms for the observation of novel quantum transport phenomena, magnetic monopoles and exotic quantum magneto-electric effects. TI/FM heterostructures with low Curie temperature ferromagnets i. e. GdN, EuS have been fabricated and studied. One of the challenges encountered with these heterostructures is their low Curie temperatures which limits their potential for applications in spintronic devices at room temperature. To address this issue, we have grown Bi<sub>2</sub>Se<sub>3</sub>/La<sub>0.70</sub>Sr<sub>0.30</sub>MnO<sub>3</sub> (TI/FM) heterostructures by the method of pulsed laser deposition. La<sub>0.70</sub>Sr<sub>0.30</sub>MnO<sub>3</sub> (LSMO) is a strong ferromagnetic material with T<sub>c</sub> ~350 K and Bi<sub>2</sub>Se<sub>3</sub> is the most studied topological insulator. XRD and phi scan results show that epitaxial thin films of Bi<sub>2</sub>Se<sub>3</sub> are grown on the LSMO template. Strong in-plane magnetization is confirmed by magnetometry measurements of the Bi<sub>2</sub>Se<sub>3</sub>/LSMO heterostructure. Magneto-transport measurements show a distorted weak anti-localization effect with hysteretic behavior due to interface induced ferromagnetism in the Bi<sub>2</sub>Se<sub>3</sub> TI films. This work was supported, in part, by National Science Foundation ECCS-1306400.

**9:48AM K28.00006 Growth and Characterization of Mn Doped InAs/GaSb Quantum Wells: Toward a 2D Quantum Anomalous Hall Insulator**, DI XIAO, SUSAN KEMPINGER, NITIN SAMARTH, Department of Physics, The Pennsylvania State University — The new discovery of a class of quantum spin Hall insulators (QSHIs), namely the type-II broken gap InAs/GaSb quantum wells (QWs), has drawn much attention in the condensed matter community. Counter-propagating helical states protected by time reversal symmetry exist at the edge, giving a quantized Hall conductance of  $2e^2/h$ , while the bulk remains insulating in this 2D topological insulator (TI). Compared to other TI systems, InAs/GaSb QW has a great advantage that the band structure, with a small hybridization gap, can be continuously tuned through electric fields, allowing the topological phase transition between trivial and topological phases. A recent theoretical proposal [PRL, 113.14(2014)] indicates that it is possible to keep only one chiral edge state without external magnetic field, i.e. the quantum anomalous Hall (QAH) state, by introducing long-range ferromagnetic order into this QW system. (In,Mn)As and (Ga,Mn)Sb have been well studied as diluted magnetic semiconductors, making Mn-doping a reasonable choice. Here, we present preliminary results on the MBE growth and characterization of electrically-gated Mn doped InAs /GaSb QWs. We will present a discussion of magnetization and magneto-transport measurements. Funded by ONR.

**10:00AM K28.00007 Interface driven states in ferromagnetic topological insulator heterostructures.**<sup>1</sup>, VALERIA LAUTER, Oak Ridge National Lab, FERHAT KATMIS, JAGADEESH MOODERA, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA-02139, USA — The broken time reversal symmetry (TRS) states can be introduced into a topological insulator (TI) material by ferromagnetic ordering at the interface. Recently [1] we demonstrated a fundamental step towards realization of high temperature magnetization in Bi<sub>2</sub>Se<sub>3</sub>-EuS TI-FMI heterostructures through observation of magnetic proximity-induced symmetry breaking on the Bi<sub>2</sub>Se<sub>3</sub> surface via the exchange interaction by depositing EuS film on the top of the Bi<sub>2</sub>Se<sub>3</sub> surface. Here we show that we can independently break the TRS on both surfaces of a TI, which brings the long-range induced magnetism on either or both surfaces of a TI in a controlled way. We provide a depth-sensitive data on details of magnetic proximity effect in hidden interfaces by Polarized Neutron Reflectometry. The proximity coupling strength and penetration depth of magnetism into TI are extracted as functions of temperature, magnetic field and magnetic history. The large neutron absorption of Eu atoms serves as the element sensitivity and enables us to identify such magnetism in TI as proximity magnetism. This provides a next step to realization of complex heterostructures of TI and FMI leading to wide applications in TI-based next generation spintronic devices. [1] F. Katmis, V. Lauter et al, submitted.

**10:12AM K28.00008 Step-wise switching of anomalous Hall effect in a topological insulator**<sup>1</sup>, LUKAS ZHAO, ZHIYI CHEN, INNA KORZHOVSKA, SHIHUA ZHAO, LIA KRUSIN-ELBAUM, CCNY - CUNY, MARCIN KONCZYKOWSKI, Ecole Polytechnique — Surfaces of three-dimensional (3D) topological insulators (TIs) have emerged as one of the most remarkable states of condensed quantum matter where exotic charge and spin phases of Dirac particles could arise. The main challenge to finding these phases comes from a non-vanishing conductivity of the bulk. Recently we have demonstrated that we can access 2D surface transport and reach the charge neutrality point (CNP) by compensating intrinsically *p*-type TIs using high energy electron beams, and increase bulk resistivity by orders of magnitude. Here we report a discovery of anomalous Hall signal (AHE) at the CNP in Bi<sub>2</sub>Te<sub>3</sub> of unprecedented appearance; it shows regions of plateaus on sweeping the temperature, where Hall resistivity is flat in temperature, and has sharp (nearly discontinuous) 'steps' in-between the plateaus. The height of the steps increases on cooling, consistently following the ratio of 1:3 with each step. We will show by electrostatically tuning gated structures how this macroscopic switching of spins evolves in the vicinity of CNP and discuss the phenomenon of step-wise AHE in the context of charge inhomogeneities (puddles) and correlations between the localized bulk spins and Dirac spins.

**10:24AM K28.00009 Prediction of Quantum Anomalous Hall Insulator in Functionalized GaBi Honeycomb**, CHRISTIAN CRISOSTOMO, SUNG-PING CHEN, ZHI-QUAN HUANG, CHIA-HSIU HSU, FENG-CHUAN CHUANG, Natl. Sun Yat-sen U., HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — Using first-principles electronic calculations, we predict functionalized GaBi honeycomb under tensile strain to harbor quantum anomalous hall (QAH) insulating phase. A single band inversion at  $\Gamma$  point was found in spin-polarized band structure of half-fluorinated planar strained GaBi. In order to confirm the topological properties, we evaluated the Chern number (C) and found that  $C = 1$ , indicating the presence of QAH phase. Additionally, the same value was also obtained by using hydrogen atoms, instead of fluorine atoms, as the adsorbate in both planar and buckled GaBi. Moreover, the electronic spectrum of a half-fluorinated GaBi nanoribbon with armchair or zigzag edges possess only one edge band crossing the Fermi level within the band gap. Finally, a suitable substrate which could induce the similar effect of half-hydrogenation or half-fluorination on the GaBi honeycomb could be used for spintronic devices.

**10:36AM K28.00010 Metal-to-insulator switching in quantum anomalous Hall states**, LEI PAN, XUFENG KOU, Univ of California - Los Angeles, JING WANG, Stanford university, YABIN FAN, Univ of California - Los Angeles, EUN SANG CHOI, National High Magnetic Field Laboratory, Florida State University, QIMING SHAO, Univ of California - Los Angeles, SHOU CHENG ZHANG, Stanford university, KANG LUNG WANG, Univ of California - Los Angeles — Quantum anomalous Hall effect (QAHE) was recently achieved in magnetic topological insulator films as a form of dissipationless transport without external magnetic field. However, the universal phase diagram of QAHE and its relation with quantum Hall effect (QHE) remain to be investigated. Here, we report the experimental observation of the giant longitudinal resistance peak and zero Hall conductance plateau at the coercive field in the six quintuple-layer (Cr<sub>0.12</sub>Bi<sub>0.26</sub>Sb<sub>0.62</sub>)<sub>2</sub>Te<sub>3</sub> film, and demonstrate the metal-to-insulator switching between two opposite QAHE plateau states up to 0.3 K. The universal QAHE phase diagram is further confirmed through the angle-dependent measurements. Our results address that the quantum phase transitions in both QAHE and QHE regimes are in the same universality class, yet the microscopic details are different.

**10:48AM K28.00011 Investigating dissipation in the quantum anomalous Hall effect**<sup>1</sup>, ELI FOX, ANDREW BESTWICK, DAVID GOLDBABER-GORDON, Stanford University, YANG FENG, YUNBO OU, KE HE, YAYU WANG, QI-KUN XUE, Tsinghua University, XUFENG KOU, LEI PAN, KANG WANG, University of California, Los Angeles — In the quantum anomalous Hall effect, a magnetic exchange gap in a 3D topological insulator gives rise to dissipationless chiral edge states. Though the effect has recently been realized in a family of ferromagnetically-doped (Bi,Sb)<sub>2</sub>Te<sub>3</sub> topological insulator thin films, experiments to date have found non-vanishing longitudinal resistance, contrary to initial theoretical expectations. Proposed sources of this dissipation include extra gapless or activated quasi-helical edge states, thermally activated 2D conduction, and variable-range hopping. Here, we discuss transport measurements of Corbino disk and non-local geometries to identify the mechanism of non-ideal behavior.

**8:00AM K29.00001 Tunneling Seebeck and Anomalous Nernst effects in three-dimensional topological insulators<sup>1</sup>**, CHENGHAO SHEN, BENEDIKT SCHARF, ALEX MATOS-ABIAGUE, IGOR ZUTIC, State University of New York at Buffalo — We theoretically investigate the longitudinal (Seebeck) and transverse (Nernst) thermopowers generated by thermally-induced tunneling across a magnetic barrier on the surface of a three-dimensional insulator. As a manifestation of Klein tunneling, the tunneling Seebeck coefficient exhibits oscillatory behavior with respect to the barrier thickness. Moreover, in spite of the absence of a source of spin polarization (only the barrier is magnetic), the tunneling anomalous Nernst coefficient is not only finite but can even be much larger than its Seebeck counterpart.

**8:12AM K29.00002 Amperean pairing mediated by magnetic fluctuations at the surface of a topological insulator**, MEHDI KARGARIAN, DMITRY K. EFIMKIN, VICTOR GALITSKI, Department of Physics, University of Maryland, College Park, Maryland 20742 — We study the interface between a three-dimensional topological insulator and a ferromagnetic thin film. Due to the Dirac nature of surface states, in-plane magnetization couples to them as a gauge field, leading to emergent electric and magnetic fields. We argue that magnetic fluctuations mediate strongly anisotropic interaction and can be the origin of an unconventional superconductivity with Amperean pairings.

**8:24AM K29.00003 Edge state contributions to the Loschmidt echo in topological insulators and superconductors**, NICHOLAS SEDLMAYR, Institute of Mathematical and Theoretical Physics, Michigan State University, ELIO KÖNIG, ALEX LEVCHENKO, Department of Physics, University of Wisconsin-Madison — Non-analytic behavior in the time evolution of a quantum system at critical times can be seen in the Loschmidt echo, the overlap between a time evolved state and an initial state. This is referred to as a dynamical phase transition, an analogue of the non-analytic behavior in the free energy across temperature driven phase transitions. In particular it has been demonstrated that in topological systems a quench across the topological phase transition and dynamical phase transitions are intimately related. Here we look at the contribution to the Loschmidt echo of the topologically protected edge states of 1D topological insulators and superconductors. These edge state have already been shown to have interesting contributions to the fidelity and entanglement entropy, which can also be useful for characterizing the topological phases and phase transitions.

**8:36AM K29.00004 Magnetic ordering and quantum anomalous Hall phase of Cr-doped topological insulators: First principles studies<sup>1</sup>**, JEONGWOO KIM, Department of Physics and Astronomy, University of California, Irvine, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine — Realization of transverse electric currents without external magnetic fields, so called the quantum anomalous Hall effect (QAHE), is achieved in Cr-doped topological insulating (Bi,Sb)2Te3 compounds. However, detailed mechanism of QAHE and magnetic ordering in topological insulators (TIs) is still unclear with several models in controversy. We study the origin of QAHE in magnetic impurity-doped TIs using first-principles calculations. We investigate a possibility of the quantum anomalous Hall phase in conventional three-dimensional topological insulators, such as Bi2Se3, Bi2Te3, and Sb2Te3. We find that Sb2Te3 is the most suitable compound for realizing QAHE, because it maintains insulating phase and relatively strong ferromagnetic ordering in a wide range of Cr doping while Bi2Se3 and Bi2Te3 become metallic even by a small amount of Cr doping. Contrary to previous predictions, the kinetic exchange is responsible for the magnetic phase of Cr-doped TIs and it induces spin-polarized valence and conduction bands in Sb2Te3. We also discuss the role of Bi doping in topological surfaces states of Cr-doped Sb2Te3, which leads to QAHE in (Bi,Sb)2Te3.

**8:48AM K29.00005 Filling-Enforced Quantum Band Insulators in Spin-Orbit Coupled Crystals**, HOI CHUN PO, University of California, Berkeley, HARUKI WATANABE, Massachusetts Institute of Technology, MICHAEL P. ZALETEL, Station Q, Microsoft Research, Santa Barbara, ASHVIN VISHWANATH, University of California, Berkeley; Materials Science Division, Lawrence Berkeley National Laboratories, Berkeley — While band insulators are usually described in wavevector space in terms of fully filled bands, they are sometimes also described in terms of a complementary Wannier picture in which electrons occupy localized, atom-like orbitals. Under what conditions does the latter picture break down? The presence of irremovable quantum entanglement between different sites can obstruct a localized orbital description, which occurs in systems like Chern and topological insulators. We collectively refer to such states as Quantum Band Insulators (QBIs). Here we report the theoretical discovery of a filling-enforced QBI - that is, a free electron insulator in which the band filling is smaller than the minimum number dictated by the atomic picture. Consequently such insulators have no representation in terms of filling localized orbitals and must be QBIs. This is shown to occur in models of certain cubic crystals with non-symorphic space groups. Like topological insulators, filling-enforced QBIs require spin-orbit coupling. However, in contrast, they do not typically exhibit protected surface states. Instead their nontrivial nature is revealed by studying the quantum entanglement of their ground state wavefunction.

**9:00AM K29.00006 Casimir Torque between Topological Insulators: a Physical Implication of the Surface State Hexagonal Warping Effect**, LIANG CHEN, North China Electric Power University, KAI CHANG, Institute of Semiconductors, Chinese Academy of Sciences — We use a variation of the Lifshitz formula to calculate the anisotropic Casimir energy density between two topological insulators in the vacuum. We find that the hexagonal warping effect can induce a Casimir torque between the two topological insulators,  $T_c \propto \sin(6\theta)$  with twisted angle  $\theta$ . The maximal Casimir torque at  $\theta = \pi/12$  is estimated to be  $\sim 10^{-19} N \cdot m/rad$  for Bi<sub>2</sub>Te<sub>3</sub> on the [111] surface when the distance between the two topological insulators is about 20 nm and the surface areas are taken to be  $\sim 1 cm^2$ .

**9:12AM K29.00007 Emergent Topological States at Domain Walls in Bismuth<sup>1</sup>**, JINWOONG KIM, NICHOLAS KIOUSSIS, Department of Physics and Astronomy, California State University, Northridge — The discovery of topological insulators has brought new perceptions in materials science which allows the understanding of material properties as an inevitable result of symmetry and its breaking. Polyacetylene is one example of topological insulators classified by structural symmetry that exhibits zero modes at a domain wall separating two opposite dimerized phases. The sign reversal of the topological mass across a domain wall is not restricted to 1D systems and is ubiquitous in a wide range of 3D materials. Employing both ab initio and model Hamiltonian calculations we have studied the topological properties of structural domain walls in bismuth, which is the 3D analogue of the domain walls in 1D polyacetylene. The model Hamiltonian can be represented to lowest order by two Pauli matrices yielding a mass gap that closes upon dimerization sign reversal. The calculations demonstrate that zero mode states emerge at the domain wall which exhibit quasi-one dimensional linear dispersions. Our results imply that conducting channels may emerge at structural domain walls such as grain boundaries as a consequence of topological protection, whose properties are determined by global rather than local symmetry.

**9:24AM K29.00008 Single-ion magnetic anisotropy of transition metal impurities in  $\text{Bi}_2\text{Se}_3$  bulk and thin film topological insulators**, FHOKRUL ISLAM, ANNA PERTSOVA, Dept. of physics, Linnaeus University, REZA MAHANI, KTH Royal Institute of Technology, CARLO CANALI, Dept. of physics, Linnaeus University — The breaking of time reversal symmetry in a topological insulator (TI) by magnetic doping is one of the most studied phenomena among the properties of Dirac materials. The robustness of the topological surface states (TSS) against magnetic impurities is of critical importance for spin-dependent transport in these systems. The interaction between TSS and magnetic impurities can open a gap, provided that the magnetic order is oriented normal to the surface of the TI. Such gap opening is crucial for realizing TI-based spintronic devices and for the observation of different fundamental phenomena, such as the anomalous quantum Hall effect. Using density functional theory as implemented in the WIEN2k ab-initio package, we have investigated the effect of the magnetization orientation on the gap opening at the Dirac point, for substitutional Mn and Fe impurities on the  $\text{Bi}_2\text{Se}_3$  surface, and have calculated the associated single-ion anisotropy (SIA). We also have studied bulk SIA in order to compare the role played by TSS on the surface SIA.

**9:36AM K29.00009 Strong Correlation effects to Topological Quantum Phase Transitions in Three-Dimensions**, ADRIANO AMARICCI, CNR-IOM, MASSIMO CAPONE, International School for Advanced Studies, JAN BUDICH, University of Innsbruck, Austria, GIORGIO SANGIOVANNI, BJOERN TRAUZETTEL, University of Wuerzburg, Germany — Topological Insulating phases of three dimensions are classified in terms of four  $Z_2$  global invariants. In the non-interacting case the Topological Quantum Phase Transition (TQPT), *i.e.* the sudden change of such invariants, occurs through the continuous closure of the energy gap as long as the symmetries protecting the Topological phase are preserved. However, the recent progress in engineering or predict Topological Insulating states in heavy-elements compounds, pushed the attention to the effects of large electronic interaction. Here we show that strongly correlated 3-dimensional Topological Insulators are characterized by a substantially different physics with respect to their non-interacting counterpart. Our study shows that the TQPT to the Strong Topological Insulator is dominated by the presence of a Quantum Critical Point, the end of a first-order topological transition. In addition we show that the conventional paradigm of a continuous TQPT breaks down for strong enough correlation, through to a discontinuous transition without closure of the spectral gap.

**9:48AM K29.00010 Field theory representation of mixed gauge-gravity symmetry-protected topological invariants, group cohomology and beyond**, JUVEN WANG, Institute for Advanced Study, Princeton, ZHENG-CHENG GU, Perimeter Institute for Theoretical Physics, XIAO-GANG WEN, MIT — The challenge of identifying symmetry-protected topological states (SPTs) is due to their lack of symmetry-breaking order parameters and intrinsic topological orders. For this reason, it is impossible to formulate SPTs under Ginzburg-Landau theory or probe SPTs via fractionalized bulk excitations and topology-dependent ground state degeneracy. However, the partition functions from path integrals with various symmetry twists are universal SPT invariants, fully characterizing SPTs. In this work, we use gauge fields to represent those symmetry twists in closed spacetimes of any dimensionality and arbitrary topology. This allows us to express the SPT invariants in terms of continuum field theory. We show that SPT invariants of pure gauge actions describe the SPTs predicted by group cohomology, while the mixed gauge-gravity actions describe the beyond-group-cohomology SPTs, recently observed by Kapustin. We find new examples of mixed gauge-gravity actions for  $U(1)$  SPTs in 3+1D and 4+1D via the Stiefel-Whitney class and the gravitational Chern-Simons term. [Work based on Phys. Rev. Lett. 114, 031601 (2015) arXiv:1405.7689]

**10:00AM K29.00011 Spin texture of topological surface states of side-surfaces in  $\text{Bi}_2\text{Se}_3$  from first principles<sup>1</sup>**, JOHN VILLANOVA, KYUNGWHA PARK, Virginia Tech - Blacksburg — Topological insulators have recently drawn a lot of attention because of topologically protected surface states with Dirac dispersion and spin-momentum locking induced by time-reversal symmetry and strong spin-orbit coupling, respectively. Recent experiments report interesting transport properties of  $\text{Bi}_2\text{Se}_3$  nanowires and nanoribbons with growth directions normal to the (111) surface. However, most of the studies of  $\text{Bi}_2\text{Se}_3$  are focused on the (111) surface. Additionally, surfaces other than the (111) surface would facilitate hole doping with adatoms since both Bi and Se atoms are present at these other surfaces. We investigate the spin texture and electronic structure of topologically protected surface states of two representative side-surfaces of  $\text{Bi}_2\text{Se}_3$  by using density-functional theory (DFT). In particular, we consider two surfaces normal to the (111) surface, such as  $(1\bar{1}0)$  and  $(11\bar{2})$ , where the former has twofold symmetry and the latter has mirror symmetry. We present our calculated spin textures of the surface states of these side surfaces that qualitatively differ from typical Rashba-like features and from the prediction based on the bulk model Hamiltonian by keeping up to quadratic terms in momentum.

**10:12AM K29.00012 Domain wall of a ferromagnet on a three-dimensional topological insulator**, RYOHEI WAKATSUKI, MOTOHIKO EZAWA, University of Tokyo, NAOTO NAGAOSA, University of Tokyo, RIKEN Center for Emergent Matter Science (CEMS) — Topological insulators (TIs) show rich phenomena and functions which can never be realized in ordinary insulators. Most of them come from peculiar surface or edge states. Especially, the quantized anomalous Hall effect without an external magnetic field is realized in a two-dimensional ferromagnet on a three-dimensional TI, which supports the dissipationless edge current. Here we demonstrate theoretically that the domain wall of this ferromagnet, which carries edge currents, is charged and can be controlled by an external electric field. The chirality and relative stability of the Neel wall and the Bloch wall depend on the position of the Fermi energy as well as the form of the coupling between the magnetic moment and the orbital of the host TI. These findings will pave a path to utilize the magnets on TI for spintronics applications. R. Wakatsuki, M. Ezawa, and N. Nagaosa, Scientific Reports **5**, 13638 (2015).

**10:24AM K29.00013 Topological phases protected by point group symmetry<sup>1</sup>**, SHENG-JIE HUANG, HAO SONG, MICHAEL HERMELE, University of Colorado Boulder — There has been remarkable progress in the theoretical understanding of symmetry protected topological (SPT) phases. However, most theories focus on internal, or on-site, symmetries, even though spatial symmetries are important in solids. In this talk, we classify bosonic SPT phases protected by crystalline point group symmetry, which we dub point group SPT (pgSPT) phases. Our approach is based on a procedure to reduce a d-dimensional pgSPT phase to lower-dimensional SPT phases protected by internal symmetry. For three-dimensional pgSPT phases, this approach allows us to gain insight into non-trivial properties at symmetry preserving surfaces. In particular, we obtain toy models for the surfaces of certain pgSPT phases at which there is a symmetry preserving  $Z_2$  topological order with anomalous symmetry fractionalization. We also discuss connections between bosonic pgSPT phases and electronic topological crystalline insulators.

**10:36AM K29.00014 Visualizing competing trends at topological surfaces<sup>1</sup>**, PAOLO SESSI, Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany, RUDRO BISWAS, Department of Physics and Astronomy, Purdue University, 525 Northwestern Avenue West Lafayette, Indiana, USA, THOMAS BATHON, Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany, ALEXANDER BALATSKY, Institute for Materials Science, Los Alamos New Mexico 87545, USA, MATTHIAS BODE, Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — Topological insulators interacting with magnetic impurities are usually described within the framework of gapping the Dirac quasiparticles energy spectrum by time reversal symmetry breaking. However, the overwhelming majority of studies demonstrate the presence of finite density of states near the Dirac node even once the system becomes magnetic. The contradictory observations call for a better understanding of the nature of the mobility and transport in magnetically doped topological insulators. Here, by combining different experimental techniques with theoretical calculations, we map the response of topological states to magnetic impurities at the atomic scale and reveal that, contrary to what generally believed, gapless density of states and magnetic order can coexist.

**10:48AM K29.00015 Landau Theory of Helical Fermi Liquids**, REX LUNDGREN, University of Texas at Austin, JOSEPH MACIEJKO, University of Alberta — We construct a phenomenological Landau theory for the two-dimensional helical Fermi liquid found on the surface of a three-dimensional time-reversal invariant topological insulator. In the presence of rotation symmetry, interactions between quasiparticles are described by ten independent Landau parameters per angular momentum channel, by contrast with the two (symmetric and antisymmetric) Landau parameters for a conventional spin-degenerate Fermi liquid. We project quasiparticle states onto the Fermi surface and obtain an effectively spinless, projected Landau theory with a single projected Landau parameter per angular momentum channel that captures the spin-momentum locking or nontrivial Berry phase of the Fermi surface. As a result of this nontrivial Berry phase, projection to the Fermi surface can increase or lower the angular momentum of the quasiparticle interactions. We derive equilibrium properties, criteria for Fermi surface instabilities, and collective mode dispersions in terms of the projected Landau parameters. We briefly discuss experimental means of measuring projected Landau parameters.

**8:00AM K30.00001 Artificial chemical and magnetic structure at the domain walls of an epitaxial oxide.**, BEATRIZ NOHEDA, Zernike Institute for Advanced Materials, Univ of Groningen — Progress in nanotechnology requires new paradigms for materials synthesis that allow controlling their functionality down to the smallest scales. Here we report a novel two-dimensional ferromagnetic phase that is synthesized at the domain walls (DWs) of the antiferromagnetic insulator TbMnO<sub>3</sub> when grown in thin layers under epitaxial strain. This Mn oxide phase presents an atomic arrangement that does not exist in bulk and cannot be synthesized by standard chemical routes. The number of 2D ferromagnetic sheets can be controlled by tuning the thickness of the thin films, giving rise to volume fractions that go up to 25% of the total film volume. Such novel phases are driven by a unique environment induced by the symmetry breaking and large stresses present at domain walls, which function as nanoreactors. This new class of nanoscale materials may find innovative applications in nanoelectronics and spintronics. The work is published as S. Farokhipoor, C. Magén, S. Venkatesan, J. Íñiguez, C. J. M. Daumont, D. Rubi, E. Snoeck, M. Mostovoy, C. de Graaf, A. Müller, M. Döblinger, C. Scheu, B. Noheda, Nature 515, 379 (2014)

**8:36AM K30.00002 Microscopic order parameters coupling at domain walls and its effect on macroscopic properties.**, SAEEDH FAROKHIPOOR, Department of Materials Science, University of Cambridge, UK, UMUT ADEM, Department of Materials Science, Izmir Institute of Technology, Turkey, ULI ZEITLER, Radboud University, Nijmegen, NL, AGUNG NUGROHO, Faculty of Mathematics and Natural Sciences, Bandung, Indonesia, JOHAN BUURMA, GRAEME BLAKE, BEATRIZ NOHEDA, THOMAS PALSTRA, Zernike Institute for Advanced Materials, University of Groningen, NL — Domain and domain wall (DW) engineering provides an alternative model to tune the physical properties of materials, typically done via conventional materials chemistry. The interplay of coexisting non-ferroelectric structural order parameters, ferroelectric and magnetic order parameters at the DWs in hexagonal manganites provides a new pathway to determine macroscopic properties by tuning the DW characteristics [1]. Here, we report different types of domain structures and DW types associated with the crystal growth conditions in hexagonal manganites. We show that differences in the DW polar state manifest themselves as variations in the conductivity measured macroscopically. Piezo force microscopy and X-ray diffraction enables us to determine the plane of the DWs and hence, their strain state. The latter findings corroborate with the topographical study. Finally, these results show that DWs under strain lower the critical field of the magnetic phase transition compared to samples with strain-free DWs. This work represents the first example of non-local physical properties being determined by the presence of topographically protected DWs. [1] S. Artyukhin et al., Nat Mater 13 (2014)

**8:48AM K30.00003 Visualization of weak ferromagnetic domains in multiferroic hexagonal ferrite thin film<sup>1</sup>**, WEIDA WU, WENBO WANG, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA, JARRETT A. MOYER, PETER SCHIFFER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801, USA, JULIA A. MUNDY, DAVID A. MULLER, School of Applied and Engineering Physics, Cornell University, Ithaca, New York 14853, USA, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Cornell University, Ithaca, New York 14853, USA — Hexagonal *h*-LuFeO<sub>3</sub> thin film has been reported to be a room-temperature multiferroic [1]. Extensive studies on high quality MBE thin films revealed a magnetoelectric phase with weak ferromagnetism emerges below  $T_N \sim 147$  K [2]. However, the direct observation of weak ferromagnetic domain structures is still lacking. Here we report cryogenic magnetic force microscopy (MFM) results on 200 nm thick *h*-LuFeO<sub>3</sub> film grown by molecular-beam epitaxy (MBE) on (111)-oriented yttria-stabilized cubic zirconia (YSZ) substrates. Labyrinth-like weak ferromagnetic domain structures were observed with a domain size  $\sim 1 \mu\text{m}$  and domain wall width  $\sim 0.4 \mu\text{m}$ . Field-dependent MFM data indicates the coercive field is  $\sim 2.66$  T at 50 K and  $\sim 3.15$  T at 6 K. [1] W. Wang et al., Phys. Rev. Lett. 110, 237601(2013). [2] J. A. Moyer et al., APL MATER. 2, 012106 (2014).

## 9:00AM K30.00004 ABSTRACT WITHDRAWN —

**9:12AM K30.00005 Frequency Dependent Microwave Impedance Microscopy of Ferroelectric Domain Walls**, SCOTT JOHNSTON, ZHI-XUN SHEN, Stanford University — ABO<sub>3</sub> ferroelectrics are known to exhibit domain wall conductivity which is of great fundamental and technological interest. Microwave Impedance Microscopy is a near field measurement technique which allows local, non-contact measurement of AC conductivity and permittivity. In this work, Microwave Impedance Microscopy over a wide frequency range is used to probe the electrical properties of domain walls in ABO<sub>3</sub> ferroelectrics. An unexpected, strong frequency dependence in the microwave dissipation near domain walls is observed.

**9:24AM K30.00006 Spin-phonon interaction of mixed-phase BiFeO<sub>3</sub> films studied by Raman spectroscopy**, YI-CHUN CHEN, YEN-CHIN HUANG, Department of Physics, National Cheng Kung University, WEN-I LIANG, YING-HAO CHU, Department of Material Science and Engineering, National Chiao Tung University — Multiferroic BiFeO<sub>3</sub> (BFO) has ferroelectricity and antiferromagnetism at room temperature, and so was motivated for novel magnetoelectric applications. When a BFO film is epitaxially grown on the LaAlO<sub>3</sub> (LAO) substrate, the strong compressive strain will transform BFO to a mixed-phase state, including rhombohedrally (R-) and tetragonally (T-) distorted monoclinics. The stripe-shape R-BFO is embedded in T-BFO matrix, forming periodic domains which possess enhanced piezoelectric response and spontaneous magnetization. Moreover, the magnetic R-BFO phases can be switched by external electric fields. Here, in order to study the mechanism of strain induced magnetic properties, we report a detailed Raman study of the mixed-phase BFO. The phonons of each phase are distinguished by an in-situ testing system combining an atomic force microscope (AFM) and a Raman spectroscopy. When external magnetic fields are applied, a low-frequency phonon mode of T-BFO phase changes due to the magnetostrictive effect. Variations of mixed-phase phonons versus temperature are also studied, which show that phonon shifts of high-frequency modes are contributed from phonon-phonon anharmonic interaction; by contrast, the shifts of low-frequency modes are due to spin-phonon interactions.

**9:36AM K30.00007 Inducing phase transitions of T-like BiFeO<sub>3</sub> films by low-energy He implantation**, ANDREAS HERKLOTZ, Oak Ridge National Lab, CHRISTIANNE BEEKMAN, Florida State University, STEFANIA FLORINA RUS, National Institute for Research and Development in Electrochemistry and Condensed Matter Romania, ILIA IVANOV, NINA BALKE, THOMAS ZAC WARD, Oak Ridge National Lab — Ferroelectric phase transitions of BiFeO<sub>3</sub> are found to be controllable through the application of single axis, out-of-plane strain. Low-energy He implantation has been deployed to induce out-of-plane strain in T-like BFO films, while the compressive in-plane strain due to the coherent growth on LaAlO<sub>3</sub> substrates remains fixed. Our data shows that He implantation triggers a  $M_C - M_A - T$  phase sequence of the T polymorph that is identical to structural changes that are induced with increasing temperature. Mixed phases nanodomains phases are gradually suppressed and disappear above a certain He doping level. Our data shows that the ferroelectric and optical properties of BiFeO<sub>3</sub> films critically depend on the He doping level. Thus, the results demonstrates that He implantation can be used as an intriguing approach to study lines in the rich phase space of BFO films that cant be accessed by simple heteroepitaxy. This effort was wholly supported by the US Department of Energy (DOE), Office of Basic Energy Sciences (BES), Materials Sciences and Engineering Division, with user projects supported at ORNLs Center for Nanophase Materials Research (CNMS) which is also sponsored by DOE-BES.

**9:48AM K30.00008 ABSTRACT WITHDRAWN —**

**10:00AM K30.00009 Effect of manganese substitution in barium titanate ( $Mn - BaTiO_3$ )<sup>1</sup>**, RAJASEKARAKUMAR VADAPPOO, MUHTAR AHART, Extreme Materials Initiative, Geophysical Laboratory, Carnegie Institution for Science, Washington, DC 20015 USA, R. E. COHEN, Carnegie Institution for Science, Washington, DC USA, Department für Geo- und Umweltwissenschaften, Ludwig-Maximilians-Universitaet, Munich, Germany — Barium titanate single crystals exhibit a very large recoverable nonlinear strain with aging, which is an order higher than the highly strained PZN-PT single crystals.[1] Transition metal dopants improve the electromechanical properties of these classic ferroelectrics and third generation relaxor ferroelectrics.[2] To understand the source of these effects, we systematically investigate the effect of Mn substitution in  $BaTiO_3$  using theory [3] and experiments. Mn substituted  $BaTiO_3$  ceramics were synthesized by solid state reaction. Mn substitution of up to 4 atomic % showed tetragonal phase and further substitution leads to evolution of hexagonal phase. Raman spectra show increasing Mn substitution reduce the intensity of A<sub>1</sub>(TO) and B<sub>1</sub>, E(TO+LO) modes, broaden the E(TO), A<sub>1</sub>(TO) modes and a new peak evolution at  $629\text{ cm}^{-1}$ . Enhanced strain double hysteresis was observed with increase in Mn substitution on electric field. Influence of Mn substitution on dielectric properties will be presented. The enhanced strain properties with aging observed on Mn substituted PIN-PMN-PT crystals is also discussed. References: [1] X. Ren, Nature Mater. 3, 91 (2004). [2] Zhang et al., IEEE Trans. Ultrason.,60, 1572 (2013). [3] J. F. Nossa et al., Phys. Rev. B 91, 214105 (2015).

**10:12AM K30.00010 Enhanced ferroelectric polarization and potential morphotropic phase boundary in PZT-based alloys**, DAVID PARKER, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID SINGH, Dept. of Physics and Astronomy, University of Missouri, Columbia MO — We present a combined theoretical and experimental study of alloys of the high performance piezoelectric PZT (PbZr<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>3</sub>) with BZnT (BiZn<sub>0.5</sub>Ti<sub>0.5</sub>O<sub>3</sub>) and BZnZr (BiZn<sub>0.5</sub>Zr<sub>0.5</sub>O<sub>3</sub>), focussing on lattice instabilities, atomic displacements and ferroelectric polarization. From theory we find that the 75 - 25 PZT - BZnT alloy has substantially larger cation displacements, and hence ferroelectric polarization than the PZT base material, on the tetragonal side of the phase diagram. We also find a possible morphotropic phase boundary in this system by comparing displacement patterns and optimized c/a ratios. Experiments indicate the feasibility of sample synthesis within this alloy system.

**10:24AM K30.00011 Diffuse Scattering from Relaxor PMN-xPT**, MATTHEW KROGSTAD, Northern Illinois Univ, STEPHAN ROSENKRANZ, RAYMOND OSBORN, JUSTIN WOZNIAC, Argonne Nat'l Lab, FENG YE, Oak Ridge Nat'l Lab., JACOB RUFF, Cornell Univ, PETER GEHRING, NIST, ZUO-GUANG YE, Simon Fraser Univ, DANIEL PHELAN, Argonne Nat'l Lab — Relaxor ferroelectrics possess intriguing electromechanical and dielectric properties, the microscopic physics of which is widely regarded to be related to local, correlated atomic displacements from long-range symmetry. However, despite numerous studies over the last few decades, the details of how short range correlations and disorder drive the relaxor behavior remain unresolved. Single crystal diffuse scattering provides a powerful probe of such deviations from an average structure correlated over varying length scales, and over the last few years, techniques and instruments for measuring diffuse scattering with both x-rays and neutrons have seen a dramatic improvement, allowing for large volumes of reciprocal space to be measured in little time. We present our recent complementary neutron and x-ray measurements on solid solutions of PMN-xPT which revealed new structure to the diffuse scattering of relaxors close to the morphotropic phase boundary.

**10:36AM K30.00012 Structural and Dynamical Properties of Barium Stannate**, D. PHELAN, Argonne National Laboratory, M. J. KROGSTAD, Northern Illinois University / Argonne National Laboratory, A. LOPEZ-BEZANILLA, Argonne National Laboratory, D. PARSHALL, NIST Center for Neutron Research, Y. GIM, S. L. COOPER, University of Illinois, H. ZHENG, Argonne National Laboratory — Barium stannate based perovskites have recently drawn attention due to their potential as transparent conducting oxides and reports of high carrier mobility in La-doped single crystals. Published DFT calculations and experimental results have suggested phonon instabilities at high symmetry zone boundary positions and local octahedral rotations, respectively, for BaSnO<sub>3</sub>. Here, we discuss recent structural measurements of BaSnO<sub>3</sub>, in which we have searched for such distortions by employing a combination of single crystal neutron diffraction and total scattering analysis of powder neutron diffraction. Moreover, we discuss lattice dynamical measurements, comparing phonon dispersion measurements to DFT calculations.

**10:48AM K30.00013 Real-space observation of metal-insulator transition at complex oxide heterointerface with cross-sectional STM**, YA-PING CHIU<sup>1</sup>, National Taiwan Normal University, Taiwan, JHENG-CYUAN LIN, Academia Sinica, Taiwan, TRA-VU THANH, National Chiao Tung University, Taiwan, TAI-TE LIN, PO-CHENG HUANG, National Sun Yat-sen University, Taiwan, BO-CHAO HUANG, Academia Sinica, Taiwan, JIUNN-YUAN LIN, YING-HAO CHU<sup>2</sup>, National Chiao Tung University, Taiwan — We report the direct observation of tunable electronic property through visible light at  $LaAlO_3/SrTiO_3$  (LAO/STO) complex oxide heterointerface using cross-sectional scanning tunneling microscopy and spectroscopy (XSTM/S). Many researches have shown that for the interface to be conducting, the thickness of LAO should be equal to or greater than the critical value 4 unit cells (u.c.). With LAO surface modification by Au clusters, interfacial two-dimensional electron gas presents a giant optical switching effect under visible light illumination. In this study, through the interaction between photons and electrons system, a direct observation of the evolution of electronic structures from insulating to conducting has been revealed in the LAO (3u.c.)/STO model using the technique of cross-sectional scanning tunneling microscopy and spectroscopy. Results clearly reveal the changes in the built-in electric field in LAO and the band bending in the STO adjacent to the interface after light illumination.

**8:00AM K31.00001 Ultrafast Laser-Induced Demagnetization: Identifying the Mechanism with Real-Time TDDFT**, E.K.U. GROSS, Max Planck Institute of Microstructure Physics, Halle, Germany — In the past 2 decades several experiments have demonstrated the laser-induced demagnetization of ferromagnetic solids in less than 100 femto-seconds. This is orders of magnitude faster than the present-day magnetic-field-based technology. To shed light on the underlying microscopic mechanism, we have performed an ab-initio study of Fe, Co, Ni and Cr in short laser pulses, using real-time non-collinear time-dependent spin density functional theory (TDDFT). We show [1] that the demagnetization proceeds in two distinct steps: First, a fraction of the electrons is excited without much change in the total spin polarization. In a second step, the spin magnetic moment of the remaining localized d-electrons decreases through spin-flip transitions induced by spin-orbit coupling. For pulse lengths of a few femto-seconds, the whole process of demagnetization happens in less than 50 femto-seconds. For antiferromagnetic Heusler compounds, such as  $Mn_3Ga$  and  $Ni_2MnGa$ , an even faster process is found where magnetic moment is transferred from one sublattice to the other. Employing a combination [2] of TDDFT with Optimal Control Theory, we furthermore demonstrate how the demagnetization process can be controlled with suitably shaped laser pulses. Finally, we assess the influence of the approximation used for the exchange-correlation (xc) functional by comparing non-collinear LSDA results with a novel xc functional [3] that exerts a local exchange-correlation torque.

**8:36AM K31.00002 Real-time dynamics of Hubbard-type model systems via a combination of the Kadanoff-Baym formalism with adiabatic TDDFT**, HOPJAN MIROSLAV, Lund University, DANIEL KARLSSON, University of Jyväskylä, SIMON YDMAN, CLAUDIO VERDOZZI, CARL-OLOF ALMBLADH, Lund University — We propose a description of nonequilibrium systems via a simple protocol that combines DFT-exchange-correlation potentials with self-energies of many-body perturbation theory. The approach, aimed to avoid double counting of interactions, is tested against exact results in Hubbard-type systems, with respect to interaction strength, perturbation speed/inhomogeneity, and system dimensionality/size. In many regimes, we observe good agreement with the exact results, and an improvement over the pure adiabatic local TDDFT or the pure Second-Born NEGF approximations. We also address the reasons behind the residual discrepancies, and briefly discuss possible directions for future work.

**8:48AM K31.00003 Electronic stopping in liquid water from first principles: An application of large-scale real-time TDDFT simulations**, KYLE REEVES, YI YAO, YOSUKE KANAI, University of North Carolina at Chapel Hill — Electronic stopping describes the transfer of energy from a highly-energetic charged particle to electrons in a material. This process induces massive electronic excitations via interaction between the material and the highly localized electric field from the charged particle. Understanding this phenomenon in condensed matter systems under proton irradiation has implications in various modern technologies. First-principles simulations, based on our recently-developed large-scale real-time time-dependent density functional theory approach, provide a detailed description of how electrons are excited via a non-equilibrium energy transfer from protons on the attosecond time scale. We apply this computational approach to the important case of liquid water under proton irradiation. Our work reveals several key features of the excitation dynamics at the mesoscopic and molecular levels which support a clearer understanding of the water radiolysis mechanism under proton irradiation. Importantly, we will demonstrate a first-principles determination of the energy transfer rate, (i.e. electronic stopping power) in liquid water, and a comparison to existing empirical models will be presented. We will conclude by discussing how the exchange-correlation approximation influences the calculation of the electronic stopping power.

**9:00AM K31.00004 Electrical conductivity of metals from real-time time-dependent density functional theory**, XAVIER ANDRADE, ALFREDO CORREA, Lawrence Livermore National Laboratory — In this presentation, I will discuss how to apply real-time electron dynamics to study electronic currents in crystalline systems and, in particular, how to use this method to predict electrical conductivities in different regimes. This approach presents many interesting theoretical challenges associated to the representation of bulk systems as infinitely periodic. For example, in order to induce electronic currents in the system, we use a gauge transformation that allows us to include finite electric fields in the simulation. We have implemented this approach using time-dependent density functional theory (TDDFT). This implementation allows us to induce, measure and visualize the current density as a function of time, in simulations with thousands of electrons (hundreds and even thousands of atoms). We have found that real-time TDDFT can describe how currents naturally decay in metals. From this dissipation process we can directly calculate the frequency-dependent conductivity, including the direct current (DC) conductivity that is not accessible from linear-response approaches like Kubo-Greenwood.

**9:12AM K31.00005 Development of an ab-initio calculation method for 2D layered materials-based optoelectronic devices**, HAN SEUL KIM, YONG-HOON KIM, Korea Advanced Institute of Science and Technology — We report on the development of a novel first-principles method for the calculation of non-equilibrium nanoscale device operation process. Based on region-dependent  $\Delta$  self-consistent field method beyond the standard density functional theory (DFT), we will introduce a novel method to describe non-equilibrium situations such as external bias and simultaneous optical excitations. In particular, we will discuss the limitation of conventional method and advantage of our scheme in describing 2D layered materials-based devices operations. Then, we investigate atomistic mechanism of optoelectronic effects from 2D layered materials-based devices and suggest the optimal material and architecture for such devices.

**9:24AM K31.00006 The Time-Dependent Particle-Hole Map<sup>1</sup>**, CARSTEN ULLRICH, University of Missouri, YONGHUI LI, Vanderbilt University — The particle-hole map (PHM) is proposed as a new visualization tool to analyze electronic excitations in molecules in the time- or frequency domain, to be used in conjunction with TDDFT or other ab initio methods. The purpose of the PHM is to give detailed insight into electronic excitation processes which is not obtainable from local visualization methods such as transition densities, density differences, or natural transition orbitals. The PHM provides information on the origins, destinations, and coherences of charge fluctuations during an excitation process. In contrast with the transition density matrix, the PHM has a statistical interpretation involving joint probabilities of individual states and their transitions, and it is easier to read and interpret. We discuss and illustrate the properties of the PHM and give several examples and applications to excitations in one-dimensional model systems and in organic donor-acceptor systems.

**9:36AM K31.00007 Exploiting initial-state dependence to improve the performance of adiabatic TDDFT**, JOHANNA I. FUKS, Hunter college City University of New York, SOEREN E.B. NIELSEN, MICHAEL RUGGENTHALER, Max-Planck-Institut für Struktur und Dynamik der Materie, Hamburg, NEEPA T. MAITRA, Hunter college City University of New York, HUNTER COLLEGE CITY UNIVERSITY OF NEW YORK COLLABORATION, MAX-PLANCK-INSTITUT FÜR STRUKTUR UND DYNAMIK DER MATERIE, HAMBURG COLLABORATION — Although time-dependent density functional theory (TDDFT) descriptions of dynamics in non-equilibrium situations have seen exciting successes recently, there have also been studies that throw into doubt the reliability of the approximate exchange-correlation functionals to accurately describe the dynamics. Here we study exact exchange-correlation potentials for few electron systems, found using the global fixed-point iteration method [NRL]. We find that the size of dynamical correlation features that are missing in the currently-used adiabatic approximations depend strongly on the choice of the initial Kohn-Sham wavefunction. With a judicious choice, the dynamical effects can be small over a finite time duration, but sometimes they can get large at longer times. We also examine different starting points, in particular an orbital-dependent potential directly obtained from the Kohn-Sham hole [LFSEM14], for approximate xc functionals: instead of building on an adiabatic approximation.

**9:48AM K31.00008 Studies of spuriously time-dependent resonances in TDDFT**, NEEPA MAITRA, Hunter College and the Graduate Center of the City University of New York, JOHANNA FUKS, Hunter College of the City University of New York — Recently the failure of some exchange-correlation functionals to accurately capture non-perturbative dynamics in time-dependent density functional theory (TDDFT) was shown to be correlated with their violation of an exact condition [1]: that the resonance positions of the system remain fixed during the evolution. Closely related is the inconsistent prediction of excitation frequencies in linear response when the reference state is an excited state of the system. We discuss this and the effect on dynamics in a range of molecular systems, exploring system-size dependence of the violation. [1] Time-resolved spectroscopy in time-dependent density functional theory: An exact condition, J. I. Fuchs, K. Luo, E. D. Sandoval, N. T. Maitra, Phys. Rev. Lett. **114**, 183002 (2015).

**10:00AM K31.00009 Open Quantum Transport and Non-Hermitian Real-Time Time-Dependent Density Functional Theory**, JUSTIN ELENEWSKI, Department of Chemistry, The George Washington University, YANXI-ANG ZHAO, Department of Mathematics, The George Washington University, HANNING CHEN, Department of Chemistry, The George Washington University — Sub-nanometer electronic devices are notoriously difficult to simulate, with the most widely adopted transport schemes predicting currents that diverge from experiment by several orders of magnitude. This deviation arises from numerous factors, including the inability of these methods to accommodate dynamic processes such as charge reorganization. A promising alternative entails the direct propagation of an electronic structure calculation, as exemplified by real-time time-dependent density functional theory (RT-TDDFT). Unfortunately this framework is inherently that of a closed system, and modifications must be made to handle incoming and outgoing particle fluxes. To this end, we establish a formal correspondence between the quantum master equation for an open, many-particle system and its description in terms of RT-TDDFT and non-Hermitian boundary potentials. By dynamically constraining the particle density within the boundary regions corresponding to the device leads, a simulation may be selectively converged to the non-equilibrium steady state associated with a given electrostatic bias. Our numerical tests demonstrate that this algorithm is both highly stable and readily integrated into existing electronic structure frameworks

**10:12AM K31.00010 TDDFT-based local control theory for chemical reactions**, IVANO TAVERNELLI, IBM Res Lab, BASILE F. E. CURCHOD, Department of Chemistry and the PULSE Institute, Stanford University, THOMAS J. PENFOLD, School of Chemistry, Newcastle University, Newcastle (UK) — In this talk I will describe the implementation of local control theory for laser pulse shaping within the framework of TDDFT-based nonadiabatic dynamics <sup>1</sup>. The method is based on a set of modified Tully's surface hopping equations and provides an efficient way to control the population of a selected reactive state of interest through the coupling with an external time-dependent electric field generated on-the-fly during the dynamics. This approach is applied to the investigation of the photoinduced intramolecular proton transfer reaction in 4-hydroxyacridine in gas phase and in solution <sup>2</sup>. The generated pulses reveal important information about the underlying excited-state nuclear dynamics highlighting the involvement of collective vibrational modes that would be neglected in studies performed on model systems. Finally, this approach can help to shed new light on the photophysics and photochemistry of complex molecular systems and guide the design of novel reaction paths.

**10:24AM K31.00011 Mixed Quantum-Classical Dynamics Methods for Strong-Field Processes: Multiple-trajectory Ehrenfest dynamics + decoherence terms**, YASUMITSU SUZUKI, KAZUYUKI WATANABE, Tokyo University of Science, ALI ABEDI, Universidad del País Vasco, FEDERICA AGOSTINI, Max Planck Institute of Microstructure Physics, SEUNG KYU MIN, Ulsan National Institute of Science and Technology, NEEPA MAITRA, Hunter College of the City University of New York, E. K. U. GROSS, Max Planck Institute of Microstructure Physics — The exact factorization of the electron-nuclear wave function [1, 2, 3] allows to define the time-dependent potential energy surfaces (TDPEs) responsible for the nuclear dynamics and electron dynamics. Recently a novel coupled-trajectory mixed quantum-classical (CT-MQC) approach based on this TDPEs has been developed [4], which accurately reproduces both nuclear and electron dynamics. Here we study the TDPEs for laser-induced electron localization with a view to developing a MQC method for strong-field processes [5]. We show our recent progress in applying the CT-MQC approach to the systems with many degrees of freedom. [1] A. Abedi, N. T. Maitra, E. K. U. Gross, Phys. Rev. Lett. **105**, 123002 (2010). [2] Y. Suzuki, A. Abedi, N. T. Maitra, K. Yamashita, E. K. U. Gross, Phys. Rev. A, **89**, 040501(R) (2014). [3] A. Abedi, F. Agostini, Y. Suzuki, E. K. U. Gross, Phys. Rev. Lett. **110**, 263001 (2013); F. Agostini, A. Abedi, Y. Suzuki, S. K. Min, N. T. Maitra, E. K. U. Gross, J. Chem. Phys., **142**, 084303 (2015). [4] S. K. Min, F. Agostini, E. K. U. Gross, Phys. Rev. Lett., **115**, 073001, (2015). **10:36AM K31.00012 Nuclear Quantum Effects in the Dynamics of Biologically Relevant Systems from First Principles**, MARIANA ROSSI, University of Oxford, UK, WEI FANG, ANGELOS MICHAELIDES, University College London, UK — Understanding the structure and dynamics of biomolecules is crucial for unveiling the physics behind biology-related processes. These molecules are very flexible and stabilized by a delicate balance of weak (quantum) interactions, thus requiring the inclusion of anharmonic entropic contributions and an accurate description of the electronic and nuclear structure from quantum mechanics. We here join state of the art density-functional theory (DFT) and path integral molecular dynamics (PIMD) to gain quantitative insight into biologically relevant systems. Our design of a better and more efficient approximation to quantum time correlation functions based on PIMD (TRPMD [1,2]) enables the calculation of ab initio TCFs with which we calculate IR/vibrational spectra and diffusion coefficients. In stacked polyglutamine strands (structures often related to amyloid diseases) a combination of NQE and H-bond cooperativity provides a small free energy stabilization that we connect to a softening of high frequency modes, enhanced by nuclear quantum anharmonicity [3]. [1] Rossi, Ceriotti, Manolopoulos, JCP **140**, 234116 (2014); [2] Rossi et al., JCP **141**, 181101 (2014); Rossi, Fang, Michaelides, JPCL **6**, 4233 (2015)

**10:48AM K31.00013 Properties of the Schrödinger Theory for Electrons in External Fields**, VIRAH SAHNI, CUNY-Brooklyn Coll, XIAO-YIN PAN, Ningbo University, China — We consider electrons in external electrostatic  $\mathcal{E}(\mathbf{r}) = -\nabla v(\mathbf{r})$  and magnetostatic  $\mathbf{B}(\mathbf{r}) = \nabla \times \mathbf{A}(\mathbf{r})$  fields. (The case of solely an electrostatic field constitutes a special case.) Via the ‘Quantal Newtonian’ first law for the individual electron we prove the following: (i) In addition to the external electric and Lorentz fields, each electron experiences an internal field representative of electron correlations due to the Pauli exclusion principle and Coulomb repulsion, the kinetic energy, the density, and the magnetic field; (ii) the scalar potential  $v(\mathbf{r})$  arises from a curl-free field and is thus path-independent; (iii) the magnetic field  $\mathbf{B}(\mathbf{r})$  appears explicitly in the Schrödinger equation in addition to the vector potential  $\mathbf{A}(\mathbf{r})$ ; (iv) The Schrödinger equation can be written to exhibit its intrinsic self-consistent form. (The generalization of the conclusions to time-dependent external fields via the ‘Quantal Newtonian’ second law follows.)

**8:00AM K32.00001 Coupling of Acoustic Vibrations to Plasmon Resonances in Metal Nanoparticles**, AFTAB AHMED, Argonne National Laboratory, MATTHEW PELTON, University of Maryland, Baltimore, JEFFREY GUEST, Argonne National Laboratory — Measurements of acoustic vibrations in nanoparticles provide a unique opportunity to study mechanical phenomena at nanometer length scales and picosecond time scales. Phonon vibrations of plasmonic nanoparticles are of particular interest, due to their large extinction efficiencies, and high sensitivity to surrounding medium. There are two mechanisms that transduce the mechanical oscillations into plasmon resonance shift: (1) changes in polarizability; and (2) changes in electron density. These mechanisms have been used to explain qualitatively the origin of the transient-absorption signals, however, a quantitative connection has not yet been made except for simple geometries. Here, we present a method to quantitatively determine the coupling between vibrational modes and plasmon modes in noble-metal nanoparticles including spheres, shells, rods and cubes. We separately determine the parts of the optical response that are due to shape changes and to changes in electron density, and we relate the optical signals to the symmetries of the vibrational and plasmon modes. These results clarify reported experimental results, and should help guide the optimization of future experiments.

**8:12AM K32.00002 Quantum effects in active linear and non-linear plasmonics.**, GARIKOITZ AGUIRRE-GABIRIA, JAVIER AIZPURUA, ANDREY K. KAZANSKY, PEDRO MIGUEL ECHENIQUE, Material Physics Center CSIC-UPV/EHU and Donostia International Physics Center DIPC, Paseo Manuel de Lardizabal 5 20018, Donostia-San Sebastian, Spain, MARIO ZAPATA, Departamento de Fisica, Universidad de los Andes, Bogot D.C., Colombia, PETER NORDLANDER, Department of Physics, MS61, Laboratory for Nanophotonics, Rice University, Houston, Texas 77005, USA, DANA CODRUTA MARINICA, ANDREI G. BORISSOV, Institut des Sciences Moléculaires d'Orsay - UMR 8214, CNRS-Université Paris Sud, Batiment 351, 91405 Orsay Cedex, France — The unique properties of localized surface plasmons have turned plasmonic nanoparticles into a suitable platform for novel and more efficient optoelectronic processes. Therefore, the development of practical approaches to actively control the plasmon excitations is a major fundamental and practical challenge. Using Time Dependent Density Functional Theory we explore the possibility of all electrical control of the optical properties of different plasmonic systems such as isolated nanoparticles as well as nanoparticle dimers, and core-shell nanoparticles with sub nm gaps. We demonstrate that for plasmonic systems with narrow gaps, the quantum regime owing to the electron tunneling offers the possibility of fast and reversible control of the plasmon resonances, by application of an external dc bias. Along with all-electrical control of the linear response, we also show that the external polarizing DC field can be used to actively control high-harmonic generation from plasmonic nanoparticles.

**8:24AM K32.00003 Plasmon-Induced Resonant Energy Transfer: a coherent dipole-dipole coupling mechanism**, ALAN D. BRISTOW, SCOTT K. CUSHING, JIANGTIAN LI, NIANQIANG WU, West Virginia University — Metal-insulator-semiconductor core-shell nanoparticles have been used to demonstrate a dipole-dipole coupling mechanism that is entirely dependent on the dephasing time of the localized plasmonic resonance [1]. Consequently, the short-time scale of the plasmons leads to broad energy uncertainty that allows for excitation of charge carriers in the semiconductor via stimulation of photons with energies below the energy band gap. In addition, this coherent energy transfer process overcomes interfacial losses often associated with direct charge transfer. This work explores the efficiency of the energy transfer process, the dipole-dipole coupling strength with dipole separation, shell thickness and plasmonic resonance overlap. We demonstrate limits where the coherent nature of the coupling is switched off and charge transfer processes can dominate. Experiments are performed using transient absorption spectroscopy. Results are compared to calculations using a quantum master equation. These nanostructures show strong potential for improving solar light-harvesting for power and fuel generation. [1] J. Li et al, Nature Photonics **9**, 601 (2015).

**8:36AM K32.00004 Nanoparticle Lasing Spasers.**, TERI ODOM, Northwestern University — Plasmon nanolasers, or spasers (surface plasmon amplification by stimulated emission of radiation) are devices based on plasmonic cavities and gain media that can compensate loss and achieve amplification of nano-localized electromagnetic fields. Several nanocavity architectures have been reported for spasers, such as a metal film-dielectric spacer-semiconductor nanowire configuration or arrays of plasmonic cavities, where the unit cells are nanoparticles or nanoholes. We will discuss two platforms based on nanoparticle arrays that support lattice plasmons for far-field directional emission that can achieve tunable lasing at room temperature. Also, we will describe competing and unique loss mechanisms in nanoparticle cavity arrays as well as the design principles for an optimized unidirectional lasing device by examining different plasmonic materials, unit cell shapes, and gain materials.

**9:12AM K32.00005 A Self-Consistent Scheme for Optical Response of large Hybrid Networks of Semiconductor Quantum Dots and Plasmonic Metal Nanoparticles**, BERNARDO BARBIELLINI, L. HAYATI, C. LANE, A. BANSIL, H. MOSALLAEI, Northeastern Univ. — We discuss a self-consistent scheme for treating the optical response of large, hybrid networks of semiconducting quantum dots (SQDs) and plasmonic metallic nanoparticles (MNPs). Our method is efficient and scalable and becomes exact in the limiting case of weakly interacting SQDs. The self-consistent equations obtained for the steady state are analogous to the Heisenberg equations of motion for the density matrix of a SQD placed in an effective electric field computed within the discrete dipole approximation (DDA). Illustrative applications of the theory to square and honeycomb SQD, MNP and hybrid SDQ/MNP lattices as well as SQD-MNP dimers are presented. Our results demonstrate that hybrid SQD-MNP lattices can provide flexible platforms for light manipulation with tunable resonant characteristics.

**9:24AM K32.00006 Colloidal aluminum nanoparticles with tunable localized surface plasmon resonances for energy applications**, YAN CHENG, KENNETH SMITH, EBUKA ARINZE, GABRIELLE NYIRJESY, ARTHUR BRAGG, SUSANNA THON, Johns Hopkins University — Localized surface plasmon resonances (LSPRs) of noble metal nanoparticles are of interest for energy applications due to their visible and near infrared wavelength sensitivity. However, application of these materials in optoelectronic devices is limited by their rarity and high cost. Earth-abundant, inexpensive and non-toxic aluminum is a promising alternative material with a plasmon resonance that can also be tuned via size-, shape- and surface-oxide-control. Here, we employ solution-processed methods to synthesize stable colloidal aluminum nanoparticles. We systematically investigate parameters in the synthesis that control size, shape and oxidation of the aluminum nanoparticles and tune their LSPRs over the ultraviolet and visible spectral regions. We optically characterize the nanoparticle solutions and evaluate their potential for future integration into photovoltaic, photocatalytic and photosensing systems.

**9:36AM K32.00007 Exciton-plasmon interactions in carbon nanotube arrays.**<sup>1</sup>, DAVID DROSDOFF, IGOR BONDAREV, North Carolina Central University — The response properties of semiconducting carbon nanotubes (CNs) allow for the excitation of both plasmons and excitons at optical frequencies, which can interact with each other to give rise to a variety of phenomena and applications [1-3]. If carbon nanotubes are aligned in a periodic array, then energy bands can be formed due to the array periodicity. Using a quantum electrodynamics approach, the energy dispersion relation for the coupled exciton and plasmon excitations in the CN array is theoretically analyzed. The predicted result is the formation of photonic bands, which may give rise to tunable optoelectronic devices and other applications. [1] I.V.Bondarev, L.M.Woods, and K.Tatur, PRB 80, 085407 (2009); [2] I.V.Bondarev, PRB 85, 035448 (2012); [3] I.V.Bondarev and A.V.Meliksetyan, PRB 89, 045414 (2014).

**9:48AM K32.00008 Quantum Beats from Entangled Localized Surface Plasmons**<sup>1</sup>, DAVID MASIELLO, University of Washington — Recent experiments report observations of quantum interference between plasmon resonances, inviting descriptions of plasmon-photon interaction using methods from quantum optics. Here we demonstrate, using a Heisenberg-Langevin approach, that the radiation emitted from the localized surface plasmon resonances of a mixed-metal heterodimer may exhibit observable, beat frequency interferences at a far-field detector, known as quantum beats. This prediction represents a correspondence between V-type atoms of quantum optics and the familiar heterodimer system of plasmonics. We explore this analogy in depth and find that although both systems support quantum beats, the heterodimer emits photons in bunches due to the bosonic nature of the plasmon. This highlights a significant difference between the properties of atomic and plasmonic systems.

**10:24AM K32.00009 Toward Quantum Plasmonics with Plasmon Drag Effect. Theory and Experiment**, MAXIM DURACH, MATTHEW LEPAIN, ZOE MAPES, Georgia Southern University, VINCENT RONO, NATALIA NOGINOVA, Norfolk State University — Giant plasmon drag effect observed in plasmonic metal films and nanostructures brings new fundamental insights into ways in which light-matter interaction occurs. We demonstrate analytically, numerically and experimentally that rectified drag forces acting upon electrons in plasmonic metals are intimately related to the absorption of plasmonic excitations. The plasmon energy quanta absorbed by the metal plasma are associated with momentum quanta, which are also transferred to electrons upon energy absorption. We show that this picture directly applies to plasmon drag effect in a variety of systems, and, to our knowledge for the first time, is capable to explain and predict the magnitude of the effect not only qualitatively, but with close quantitative agreement. The plasmon drag effect opens new avenues for plasmonic-based electronics providing opportunities for incorporation of plasmonic circuits into electronic devices, and for optical sensing offering a new operational principle and an opportunity to substitute the bulky optical set-ups with diffraction limited sensing by electronics. Our work not only adds more clarity into the mechanism behind the plasmon drag effect but also contributes to the emerging field of quantum plasmonics.

**10:36AM K32.00010 Cavity-coupled molecular vibrational spectra and dynamics**<sup>1</sup>, JEFFREY OWRUTSKY, ADAM DUNKELBERGER, JAMES LONG, KENAN FEARS, Chemistry Division, Naval Research Lab, WALTER DRESSICK, Center for Biomolecular Sciences and Engineering, Naval Research Lab, RYAN COMPTON, BRYAN SPANN, BLAKE SIMPKINS, Chemistry Division, Naval Research Lab — Coherent coupling between an optical transition and confined optical mode, when sufficiently strong, gives rise to new modes separated by the vacuum Rabi splitting. Such systems have been investigated for electronic-state transitions, for quantum wells and dots, however, only very recently have vibrational transitions been explored. Both static and dynamic results are described for vibrational bands strongly coupled to optical cavities. First, we experimentally and numerically describe coupling between a Fabry-Perot cavity and carbonyl stretch ( $\sim 1730\text{ cm}^{-1}$ ) in poly-methylmethacrylate as a function of several parameters of the system including absorber strength and concentration as well as cavity length. Similar studies are carried out for anions both in solution and exchanged into cationic polymers. Ultrafast pump-probe studies are performed on  $\text{W}(\text{CO})_6$  in solution which reveals changes to the transient spectra and modified relaxation rates. We believe these modified relaxation rates are a consequence of the energy separation between the vibration-cavity polariton modes and excited state transitions. Cavity-modified vibrational states and energy transfer may provide a new avenue for systematic control of molecular processes and chemistry.

**10:48AM K32.00011 Non-adiabatic Dynamics of Molecules in Optical Cavities**<sup>1</sup>, MARKUS KOWALEWSKI, KOCHISE BENNETT, SHAUL MUKAMEL, Department of Chemistry, UC Irvine — Molecular systems coupled to optical cavities are promising candidates for a novel kind of photo chemistry. Strong coupling to the vacuum field of the cavity can modify the potential energy surfaces opening up new reaction pathways. We present a derivation of the non-adiabatic couplings for single molecules in the strong coupling regime. The possibilities for photo chemistry are demonstrated for a set of model systems representing typical situations found in molecules.

**Session K33 DPOLY FIAP: Polymers for Solar Energy Conversion** 336 - Miriam Rafailovich, State University of New York, Stony Brook

**8:00AM K33.00001 Dynamic Covalent Functionalization as a route to Controlling Self Assembly of Organic Molecules**, EMILY PENTZER, Case Western Reserve University — Efforts to optimize the optoelectronic properties of conjugated organic materials are ongoing across many fields of science and engineering. For example, in bulk heterojunction polymer solar cells, researchers seek to optimize absorption of the solar spectrum by the active materials, form interpenetrating domains of p-type and n-type materials to facilitate exciton dissociation, and improve interactions between electrode, charge blocking layers, and active layers to ensure rapid charge transport. One advantage of organic polymers compared to inorganic materials (e.g., silicon), is the low cost and ability process the materials in solution. Moreover, assembly of conjugated organic materials in solution or in the solid state (i.e., films) can be used to optimize both a material's optoelectronic properties and its interface with surfaces and other materials, addressing many of the concerns listed above. Unfortunately, such solution processability requires appendage of insulating alkyl chains to the conjugated frameworks, which don solubility, but are also insulating and thus can hurt device performance. This presentation will report recent results from the Pentzer Lab from Case Western Reserve University on using functional alkyl chains that serve to control self-assembly, control interfaces with other materials, or can be removed by an external stimulus as a route to optimizing the materials for solar cell applications.

**8:36AM K33.00002 Control of Crystallization to Promote Microphase Separation in Fully Conjugated Block Copolymers**, YOUNGMIN LEE, THINH P. LE, Department of Chemical Engineering, The Pennsylvania State University, University Park, PA 16802, ZACH SEIBERS, S. MICHAEL KILBEY, II<sup>1</sup>, Department of Chemistry, University of Tennessee, Knoxville, TN 37996, QING WANG, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802, ENRIQUE D. GOMEZ<sup>2</sup>, Department of Chemical Engineering, The Pennsylvania State University, University Park, PA 16802 — Donor–acceptor fully conjugated block copolymers, where donor and acceptor conjugated polymers are covalently bonded together, are interesting as single-component active-layer materials for photovoltaics because it can adopt mesoscale microphase separated structures with length scales comparable to the exciton diffusion length. Nevertheless, due to the strong crystallization of poly(3-hexylthiophene-2,5-diyl) (P3HT), morphologies of fully conjugated block copolymers containing P3HT are predominantly driven by crystallization as opposed to microphase separation. We control the crystallization in block copolymers to promote microphase separation in fully conjugated block copolymers through the addition of small amounts of 3-octylthiophene to the polymerization of P3HT. Poly(3-hexylthiophene-2,5-diyl-*r*-3-octylthiophene-2,5-diyl)-*block*-poly((9,9-dioctylfluorene-2,7-diyl)-*alt*-(4,7-di(thiophene-2-yl)-2,1,3-benzothiadiazole)-5',5''-diyl) (P3HT-*b*-PFTBT) copolymers were prepared by Grignard metathesis for the alkylthiophene block followed by chain extension through a Suzuki-Miyaura polycondensation. We compare the crystallization, self-assembly and performance in devices of P3HT-*b*-PFTBT with a few mole percent of 3-octylthiophene in the P3HT block.

**8:48AM K33.00003 Spectral analysis of resonant scattering to quantify phase behavior in organic blends**, THOMAS FERRON, Washington State University, JON DOWNING, DEAN DELONGCHAMP, National Institute of Standards and Technology, BRIAN COLLINS, Washington State University — It is important in organic solar cells to understand how phase behavior and possible non-equilibrium states of device morphology relate to functionality. However, characterization of carbon based electronics can be a challenging endeavor due to low levels of crystallinity, anisotropic molecular structure leading to complex three dimensional morphologies, and low contrast that hamper traditional techniques such as electron microscopy or hard X-ray scattering. Recently, studies utilizing resonant x-rays have shown sensitivity to phase behavior but a quantitative characterization is vital to correlate device performance. Here we demonstrate a multi-domain analysis of spectrally resolved scattering using molecular optical constants to accurately calculate absolute domain volume fraction and composition of a model block co-polymer. Our methods address complex absorption and fluorescence that occur at the carbon edge in order to move current models beyond the Born approximation. Techniques developed have been applied to P3HT – PCBM solar cells to draw conclusions of device morphology.

**9:00AM K33.00004 Ternary blend polymer solar cells with self-assembled structure for enhancing power conversion efficiency**, ZHENHUA YANG, HONGFEI LI, State Univ of NY- Stony Brook, CHANG-YONG NAM, KIM KISSLINGER, Brookhaven National Lab, SUSHIL SATIJA, National Institute of Standards and Technology, MIRIAM RAFAILOVICH, State Univ of NY- Stony Brook — Bulk heterojunction (BHJ) polymer solar cells are an area of intense interest due to their advantages such as mechanical flexibility. The active layer is typically spin coated from the solution of polythiophene derivatives (donor) and fullerenes (acceptor) and interconnected domains are formed because of phase separation. However, the power conversion efficiency (PCE) of BHJ solar cell is restricted by the disordered inner structures in the active layer, donor or acceptor domains isolated from electrodes. Here we report a self-assembled columnar structure formed by phase separation between (PCDTBT) and polystyrene (PS) for the active layer morphology optimization. The BHJ solar cell device based on this structure is promising for exhibiting higher performance due to the shorter carrier transportation pathway and larger interfacial area between donor and acceptor. The surface morphology is investigated with atomic force microscopy (AFM) and the columnar structure is studied by investigation of cross-section of the blend thin film of PCDTBT and PS under the transmission electron microscopy (TEM). The different morphological structures formed via phase segregation are correlated with the performance of the BHJ solar cells.

**9:12AM K33.00005 Enhancing efficiency in polymer-blend solar cells: Structural insights through scattering**, VIKRAM KUPPA, University of Dayton — All-polymer solar cells that employ blends of semiconducting polymers are capable of harnessing a greater portion of the incident solar spectrum than singly sensitized devices. However, they invariably show poor performance when compared with small-molecule bulk heterojunction cells. Following our successful approach in adding very small quantities of pristine graphene to the active layer to boost performance in P3HT/PCBM cells, we have recently reported a three-fold enhancement in efficiency of all-polymer (a blend of P3HT and F8BT) photovoltaic devices. These new cells exhibit more balanced transport of electrons and holes, strong dependence of recombination behavior on graphene content, and up to two orders of magnitude increase in mobility, resulting in a peak improvement of over 200

**9:48AM K33.00006 Magnetic field effects in a polymer/fullerene blend photovoltaic cell**, HYUK-JAE JANG, JAMES I. BASHAM, DAVID J. GUNDLACH, CURT A. RICHTER, Engineering Physics Division, National Institute of Standards and Technology — Organic photovoltaic (OPV) systems based on blends of conjugated polymers and fullerene derivatives have shown great promise for low-cost and efficient photovoltaic applications. Recent findings suggest that a weak external magnetic field can disturb the spin configuration of excited states and subsequently change properties of OPV cells such as photocurrent. These changes are referred to as magnetic field effects (MFEs). In order to have a better understanding of the underlying mechanisms responsible for the MFEs in polymer/fullerene blend photovoltaic systems, we fabricated poly-3-hexylthiophene (P3HT):phenyl-C<sub>61</sub>-butyric acid methyl ester (PC<sub>61</sub>BM) cells and carried out photovoltaic device performance and impedance spectroscopy measurements with and without an externally applied magnetic field. A significant reduction in short circuit current ( $J_{SC}$ ) as well as open circuit voltage ( $V_{OC}$ ) was observed with an applied magnetic field of 0.1 tesla compared to those measured without a magnetic field under the same intensity of illumination. Impedance spectroscopy data gives insights into the influence of an external magnetic field on charge generation and recombination near normal photovoltaic operating conditions.

**10:00AM K33.00007 Conductivity Scaling Relationships of Nanostructured Membranes based on Hydrated Protic Polymerized Ionic Liquids: Effect of Domain Spacing**, GABRIEL SANOJA, University of California, Berkeley, BHOOSHAN PÖPERE, University of California, Santa Barbara, BRYAN BECKINGHAM, Joint Center for Artificial Photosynthesis, CHRISTOPHER EVANS, University of California, Santa Barbara, NATHANIEL LYND, University of Texas, Austin, RACHEL SEGALMAN, University of California, Santa Barbara — Elucidating the relationship between chemical structure, morphology, and ionic conductivity is essential for designing novel materials for electrochemical applications. In this work, the effect of lamellar domain spacing ( $d$ ) on ionic conductivity ( $\sigma$ ) is investigated for a model system of hydrated block copolymer based on a protic polymerized ionic liquid. We present a strategy that allows for the synthesis of a well-defined series of narrowly dispersed PS-*b*-PIL with constant volume fraction of ionic liquid moieties ( $f_{IL} \approx 0.39$ ). These materials self-assemble into ordered lamellar morphologies with variable domain spacing (23-59 nm) as demonstrated by SAXS. PS-*b*-PIL membranes exhibit ionic conductivities above  $10^{-4}$  S/cm at room temperature, which are independent of domain spacing. The conductivity scaling relationship demonstrated in this work suggests that a mechanically robust membrane can be designed without compromising its ability to transport ions. In addition, PIL-based membranes exhibit lower water uptake ( $\lambda = 10$ ) in comparison with many proton-conducting systems reported elsewhere. The low water content of these materials makes them promising candidates for solar-fuels electrochemical devices.

**10:12AM K33.00008 Electronic structure properties as signatures of morphological motifs in organic photovoltaics**, MATTHEW GOLDEY, GIULIA GALLI, University of Chicago — The effect of polymer morphologies upon the efficiency of organic solar cells is difficult to determine experimentally; however, theoretical models may directly probe how structural changes affect electronic properties, such as band locations and band gaps and hence provide key insight into solar energy conversion processes. Using density functional and many body perturbation theory (G0W0) calculations, we investigated the dependence of the electronic states on order parameters such as backbone dihedrals of organic donor polymers. We focused on the donor polymers PTB7 and PID2 and the acceptor PC71BM for which recent experiments[1] reported promising photoconversion efficiencies of 8.22% for ternary blend cells. Our results suggest that accurate predictions of the device performance must include a description of local disorder in the active layer. In particular, we found multiple possible configurations of the donor polymer with relative energies 0.06-0.3 eV/monomer above the lowest energy conformer whose electronic structure differ significantly. Using the lowest energy conformations found at zero T, calculated electronic energy levels are in good agreement with experimental values, with errors within 0.2 eV. [1] Lu, L., et. al. Nature Photon, 8(9), 716722 (2014).

**10:24AM K33.00009 Enhancing the performance of BHJ solar cell via self-assembly templates in active layer**, YING LIU, Stony Brook University, HONGFEI LI, ZHENHUA YANG, Stony Brook University, CHANG-YONG NAM, Brookhaven National Lab, SUSHIL SATIJA, National Institute of Standards and Technology, MIRIAM RAFAILOVICH, Stony Brook University — The bulk heterojunction (BHJ) solar cell is an important example of a polymer solar cell technology that has been proposed in recent years. However, due to the disordered inner structures in the active layer, control of the inner structure within the active layer is required to enhance the efficiency. In our approach, a self-assembly of tertiary polymer blend film is confined between the air and solid interfaces. The principal has been proved using a blend of PMMA: P3HT: PCBM where we showed that the PMMA phase formed a column structure in the P3HT, which template the PCBM phase between the electrodes. Neutron reflectometry was used to demonstrate the confinement of PCBM at the interface between P3HT and PMMA in the active layer. The columnar structured template is investigated under atomic force microscopy (AFM) and transmission electron microscopy (TEM). SCLC mobility measurement indicated an obvious improvement on both hole and electron mobility. The different morphological structures formed via phase segregation are correlated with the performance of the PEV cells fabricated at the BNL-CFN and significant enhancement for the efficiency is observed.

**10:36AM K33.00010 Electroabsorption spectroscopy of bulk heterojunction solar cells**, MARIAN TZOLOV, ZANE COHICK, CHRISTOPHER GREEN, Lock Haven University of PA — Bulk heterojunction solar cells were fabricated using PCPDTBT polymer and PCBM in inert atmosphere. Electroabsorption (EA) spectroscopy was performed in the spectral range 350-1000 nm. The first derivative of the optical absorbance spectra explains satisfactory most of the bands in the EA spectra. The only deviation is in the spectral range around 760 nm. Control experiments with devices containing only a PCPDTBT film confirm that the band at 760 nm is associated with the presence of PCBM, despite that pristine PCBM is not expected to have such band. Electrical DC bias strongly affects this band. Negative DC bias almost completely eliminates this band, while positive bias enhances it. We interpret the band at 760 nm as due to photogenerated charge carriers trapped at defect states or at interfaces within the composite PCPDTBT/PCBM film. The effective transfer of photogenerated charge carriers between PCPDTBT and PCBM is confirmed by the quenching of the photoluminescence in the composite film, while the emission of electroluminescence from the devices confirms that PCPDTBT is an effective medium for recombination of charges injected in it.

## Wednesday, March 16, 2016 8:00AM - 11:00AM – Session K34 GSOF: Rheology and Flow 337 - Paolo Arratia, University of Pennsylvania

**8:00AM K34.00001 A rheological signature of frictional interactions in shear thickening suspensions**, JOHN ROYER, NIST, DANIEL BLAIR, Georgetown University, STEVEN HUDSON, NIST — We elucidate the relative contributions from hydrodynamic lubrication and frictional contact forces to colloidal shear thickening by measuring both the viscosity  $\eta$  and first normal stress difference  $N_1$  in suspensions of silica spheres over a wide range of volume fractions. The first normal stress difference reveals a transition not apparent in the viscosity alone, from  $N_1 < 0$  at moderate volume fractions  $\phi \leq 0.52$  to  $N_1 > 0$  at larger values of  $\phi$ . While the  $N_1 < 0$  behavior is consistent with hydrodynamic models, the  $N_1 > 0$  behavior (dilation) is instead a characteristic of frictional 'granular' suspensions. Fitting our viscosity profiles  $\eta(\sigma, \phi)$  to a model for friction-driven shear thickening, we capture the shear thickening for  $\phi \geq 0.52$  but must adjust the maximum fraction of frictional contacts to fit at lower volume fractions. Our results bring together two contrasting theories for shear thickening; they show that friction drives shear thickening in concentrated colloidal suspensions, but also highlight the need to include hydrodynamic effects to fully describe the rheology at moderate concentrations.

**8:12AM K34.00002 Microstructure of Brownian Particles under Cyclic Shear<sup>1</sup>**, SOMAYEH FARHADI, University of Pennsylvania, NATHAN KEIM, California Polytechnic State University - San Luis Obispo, PAULO ARRATIA, University of Pennsylvania — We study the microstructure of a 2D colloidal system subject to cyclic shear. The system consists of  $1\mu\text{m}$  particles which are purely repulsive and are adsorbed at an oil-water interface. The particles, which exhibit Brownian motion, provide a model system for thermal glasses under external shear. Cyclic shear is induced by a magnetized needle which is also placed at the interface. The particles are tracked through consecutive images taken within each cycle. By measuring the non-affine stroboscopic displacement of the particles, we identify the spatial distribution of rearrangements. Similar to nonthermal colloids ( $4 - 6\mu\text{m}$ ), we observe localized regions of non-affine rearrangements. The number and size of these regions shrink as the Péclet number is increased. We also observe that similar to non-Brownian systems, a fraction of reversible cycles undergo plastic deformation. However, the spatial distribution of such Brownian particles is more homogeneous compared to non-Brownian system.

<sup>1</sup>Penn NSF MRSEC (DMR-1120901)

**8:24AM K34.00003 Forces acting in quasi 2d emulsions**, CARLOS ORELLANA, JANNA LOWENSOHN, ERIC WEEKS, Emory University — We study the forces in a quasi two dimensional emulsion system. Our samples are oil-in-water emulsions confined between two close-spaced parallel plates, so that the oil droplets are deformed into pancake shapes. By means of microscopy, we measure the droplet positions and their deformation, which we can relate to the contact forces due to surface tension. We improve over prior work in our lab, achieving a better force resolution. We use this result to measure and calibrate the viscous forces acting in our system, which fully determine all the forces on the droplets. Our results can be applied to study static configurations of emulsion, as well as faster flows.

**8:36AM K34.00004 Flow in Smectic Liquid Crystal Films: Examining the Flow Field of a Smectic Liquid Crystal Film due to Fluid Ejected From a Small Nozzle<sup>1</sup>**, KYLE FERGUSON, ZHIYUAN QI, CHEOL PARK, JOSPEH MACLENNAN, MATTHEW GLASER, NOEL CLARK, University of Colorado, Boulder — The rheological properties of 2D fluids are well-understood theoretically, but few experiments testing theoretical predictions have been carried out. We have used MX 12805, a smectic C liquid crystal at room temperature, to create quasi-2D films with which to study high-Reynolds number flow. We map the flow field as the fluid is ejected from a thin nozzle into a large reservoir, probing both laminar and turbulent flow. We also attempt to carry out the experiment in a vacuum to study the true 2D-regime; despite encountering experimental difficulties, some useful information can still be gleaned.

<sup>1</sup>This work was supported by NASA Grant NNX-13AQ81G, by the Soft Materials Research Center under NSF MRSEC Grants DMR-0820579 and DMR-1420736, by Department of Energy Grant DE-FG02-08ER54995, and by NSF Grant CBET-0854108.

**8:48AM K34.00005 Effect of Confinement on Suspension Rheology**, MEERA RAMASWAMY, BRIAN LEAHY, YEN-CHIH LIN, ITAI COHEN, Department of Physics, Cornell University — Confined systems are ubiquitous in nature and occur at widely separated length scales from the atomic to granular. While the flow properties of both atomic and granular systems has been well studied, examining the rheology of the intermediate length scale in colloidal suspensions is challenging. We use a confocal rheoscope to image the particle configuration in a suspension of silica microspheres while simultaneously measuring its stress responses. The confocal rheoscope has two precisely-aligned parallel plates that can confine the suspension with a variable gap size ranging from 3 to 30 particle diameters, allowing us to measure the response of the system as a function of the gap size. We find that the viscosity of the system decreases with confinement in sharp contrast to the increase reported in atomic and granular systems. The microscopy images indicate that this decrease in viscosity is due to the formation of particle layers in this shear regime where hydrodynamic forces dominate particle interactions. We discuss these results and their implications.

**9:00AM K34.00006 Orientation of dilute multi-walled carbon nanotube suspensions in shear and planar extensional flow**, BINBIN LUO, WESLEY BURGHARDT, Northwestern University — Small-angle x-ray scattering is used to study flow-induced orientation in suspensions of multi-walled carbon nanotubes in viscous, uncured epoxies. Shear flow studies are performed in an annular cone and plate shear cell in which fluid structure is probed in the flow-gradient (1-2) plane, allowing measures of both the degree and direction of nanotube orientation. General orientation behavior is consistent with expectations of Brownian dispersions of elongated particles. At high Peclet number, the degree of orientation saturates, and the orientation angle approaches the flow direction. Interestingly, otherwise identical suspensions in two different epoxies of different viscosity yield dramatically different degrees of orientation, even when compared at comparable Peclet number. The same suspensions are studied in planar extensional flow, using a cross-slot flow cell, in order to probe the relative effectiveness of shear and extensional flow at promoting nanotube orientation.

**9:12AM K34.00007 Alignment and rotation of anisotropic particles in complex flows**, GREG VOTH, Wesleyan University — Anisotropic particles in fluid flows develop orientational order that strongly affects both particle rotation statistics and rheology of multi-phase flows. We have measured the motion and rotation of non-brownian particles in chaotic and turbulent flows using video particle tracking to reconstruct 3D particle trajectories. The preferential alignment of particles of many different shapes can be understood using a simple picture that considers the stretching a particle has recently experienced. The stretching can be quantified using the Cauchy-Green strain tensors. Particle rotation statistics can be understood as a result of the preferential alignment of fluid vorticity and the particles by stretching. The Cauchy-Green eigenvalue fields have been widely used to identify Lagrangian coherent structures that affect fluid mixing. We show how their eigenvector fields can help understand the complex orientational order that occurs in these flows.

**9:24AM K34.00008 A unified description of the rheology of hard particles.**, MICHEL HERMES, BEN GUY, WILSON POON, The University of Edinburgh — The rheology of suspensions of Brownian, or colloidal, particles (diameter  $d \approx 1 \mu\text{m}$ ) differs markedly from that of larger grains ( $d \approx 50 \mu\text{m}$ ). Each of these two regimes has been separately studied, but the flow of suspensions with intermediate particle sizes ( $1 \mu\text{m} < d < 50 \mu\text{m}$ ), which occur ubiquitously in applications, remains poorly understood. By measuring the rheology of suspensions of hard spheres with a wide range of sizes, we show experimentally that shear thickening drives the transition from colloidal to granular flow across the intermediate size regime. This insight makes possible a unified description of the (non-inertial) rheology of hard spheres over the full size spectrum. Moreover, we are able to test a new theory of friction-induced shear thickening, showing that our data can be well fitted using expressions derived from it.

**9:36AM K34.00009 Flow Induced by an Oscillating Sphere in Probing Complex Viscosity of Nonadsorbing Polymer Solutions**, YANZHEN HE, TAI-HSI FAN, Mechanical Engineering, University of Connecticut, USA, REMCO TUINIER, Chemical Engineering and Chemistry, Eindhoven University of Technology, the Netherlands, TAKASHI TANIGUCHI, Chemical Engineering, Kyoto University, Japan — Theoretical investigation is presented for a linear viscoelastic flow induced by an oscillatory colloidal particle in nonadsorbing polymer solutions. The dilute to semi-dilute polymer solutions are treated as linear viscoelastic fluids. At small-amplitude oscillation, the polymer distribution is assumed at equilibrium and forms a depletion zone around the particle based on the mean field approximation. The analytical result based on the two-layer approximation is compared with numerical results using a continuous depletion profile to describe the nonuniform complex viscosity in the flow field. Depending on the polymer concentration, solution conditions and depletion thickness, the obtaining apparent complex viscosity or friction coefficient sensed by the particle could deviate significantly from the actual viscosity of the bulk polymer solution. The models developed can be applied, along with active and passive colloidal probing methods, for microrheological measurements of complex fluids that take depletion into account.

**9:48AM K34.00010 How does inertia affect the steady-shear rheology of disordered solids?**, JOERG ROTTLE, University of British Columbia, JEAN-LOUIS BARRAT, ALEXANDRE NICOLAS, LiPhy, Universit Grenoble-Alpes & CNRS — We study the finite-shear-rate rheology of disordered solids with molecular dynamics simulations in two dimensions. By systematically varying the damping strength  $\zeta$ , we identify two well defined flow regimes, separated by a thin crossover region. In the overdamped regime, the athermal rheology is governed by the competition between elastic forces and viscous forces, whose ratio gives the Weissenberg number  $Wi \propto \zeta\dot{\gamma}$ ; the macroscopic stress  $\Sigma$  follows the frequently encountered Herschel-Bulkley law  $\Sigma = \Sigma_0 + k\sqrt{Wi}$ , with yield stress  $\Sigma_0 > 0$ . In the underdamped (inertial) regime, dramatic changes in the rheology are observed for low damping: the flow curve becomes nonmonotonic. This change is not caused by longer-lived correlations in the particle dynamics at lower damping; instead, for weak dissipation, the sample heats up considerably and proportional to the driving. By thermostating more or less underdamped systems, we are able to link quantitatively the rheology to the kinetic temperature  $T_k$ , while the damping strength enters only indirectly by setting  $T_k$ .

**10:00AM K34.00011 The flow and fracture of concentrated colloidal suspensions**, MIKE SMITH, University of Nottingham — Concentrated colloidal suspensions display dramatic rises in viscosity, leading to jamming and granulation, with increasing shear rate. It has been proposed that these effects result from inter particle friction, as lubrication forces are overcome. This suggests the jamming of concentrated colloidal suspensions should exhibit some shared phenomenology with macroscopic granular systems where friction leads to two different types of jammed state. Here we show that transient rheological measurements can be used to probe the processes of granulation in concentrated colloidal suspensions [1]. Our results support the idea that frictional contacts are created between jammed particles. The jamming behaviour displays two qualitatively different regimes separated by a critical strain rate with qualitatively different types of fracture/break up behaviour. In the lower strain rate regime, it is found that vibrations can be used to control jamming and granulation, resulting in a flowable fluid. [1] Nature Sci. Rep. 5:14175 (2015)

**10:12AM K34.00012 Fragility in dense suspensions**, ROMAIN MARI, MIKE CATES, DAMTP - University of Cambridge — Dense suspensions can jam under shear when the volume fraction of solid material is large enough. In this work we investigate the mechanical properties of shear jammed suspensions with numerical simulations. In particular, we address the issue of the fragility of these systems, i.e., the type of mechanical response (elastic or plastic) they show when subject to a mechanical load differing from the one applied during their preparation history.

**10:24AM K34.00013 Role of inertia in the rheology of amorphous systems: a finite element based elasto plastic model**, KAMRAN KARIMI, JEAN-LOUIS BARRAT, Joseph Fourier University — A simple Finite Element analysis with varying damping strength is used to model the athermal shear rheology of densely packed glassy systems at a continuum level. We focus on the influence of dissipation mechanism on bulk rheological properties. Our numerical studies, done over a wide range of damping coefficients, identify two well-separated rheological regimes along with a cross-over region controlled by a critical damping. In the overdamped limit, inertial effects are negligible and the rheological response is well described by the commonly observed Herschel-Bulkley equation. In stark contrast, inertial vibrations in the underdamped regime prompt a significant drop in the mean-stress level, leading to a non-monotonic constitutive relation. The observed negative slope in the flow curve, which is a signature of mechanical instability and thus permanent shear-banding, arises from the sole influence of inertia, in qualitative agreement with the recent molecular dynamics study of Nicolas *et al.* (*arXiv preprint arXiv:1508.06067*, 2015).

**10:36AM K34.00014 Experimental Timescales of Fracture-Healing Rheological Behavior of Thermoreversible Gels**, TRAVIS L. THORNELL, KRITHIKA SUBRAMANIAM, KENDRA A. ERK, School of Materials Engineering, Purdue University — Acrylic thermoreversible physical gels were used as a model soft material system to investigate fracture-healing behavior by shear rheometry. By using shear start-up experiments, gels at various concentrations and temperatures were measured to determine shear stress responses, and fracture was indicated by a decrease in shear stress (confirmed with rheophysical flow visualization experiments). Fractured gels were allowed to recover in the rheometer for set periods of time and were tested again using the same shear start-up procedure to evaluate the recovery kinetics of network strength. Relationships between the network recovery and the normalized ratio of the resting times and characteristic relaxation times of the gels were determined. It was found that resting times for fully healed networks needed to be 2 or 3 orders of magnitude greater than the relaxation times. The extent of fracture was also investigated. Gels that were deformed to smaller total strain magnitudes were suspected to have incomplete (or partial) fracture as results showed various responses for given resting times.

**10:48AM K34.00015 Rich Janus Colloid Phase Behavior Under Steady Shear**, RONALD A. DELACRUZ-ARAUJO, Department of Chemical Engineering, University of Puerto Rico-Mayagüez, Mayagüez, PR 00681, USA, DANIEL J. BELTRAN-VILLEGAS, RONALD G. LARSON, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI 48109, USA, UBALDO M. CORDOVA-FIGUEROA, Department of Chemical Engineering, University of Puerto Rico-Mayagüez, Mayagüez, PR 00681, USA — We study the assembly of single-patch Janus colloids under steady shear via Brownian dynamic simulations. Under quiescent conditions, varying the patch size, the range, and strength of the interaction potential we observe different aggregates such as micelles, wormlike clusters, vesicles and lamellae. Under shear conditions we observe rearrangement, deformation, and break-up of aggregates. At large Péclet (Pe) numbers the shear forces dominate over Brownian forces and aggregates dissociate in a gas for all structures studied. At small and intermediate Pe, the competition between rearrangement, deformation, and break-up favors the growth of micelles and vesicles with Pe, resulting in mean cluster size increases, consistent with a previous study of Janus particles under shear. After the initial shear-induced growth, micelles and vesicles dissociate into a gas. Wormlike aggregates initially break-up into micelles, and proceed to finally reach a gas phase. Lamellar structures initially break into smaller lamellae that align with the flow direction and finally dissociate into a gas. This work opens new actuation routes for re-configurable materials and applications where different types of aggregates will be present under quiescent conditions while others will form under shear.

Session K35 DBIO: Physics of Sensorimotor Neural Circuits | 338 - Tatyana Sharpee, Salk Institute

**8:00AM K35.00001 Neural relativity principle**, ALEXEI KOULAKOV, Cold Spring Harbor Laboratory — Olfaction is the final frontier of our senses - the one that is still almost completely mysterious to us. Despite extensive genetic and perceptual data, and a strong push to solve the neural coding problem, fundamental questions about the sense of smell remain unresolved. Unlike vision and hearing, where relatively straightforward relationships between stimulus features and neural responses have been foundational to our understanding sensory processing, it has been difficult to quantify the properties of odorant molecules that lead to olfactory percepts. In a sense, we do not have olfactory analogs of "red", "green" and "blue". The seminal work of Linda Buck and Richard Axel identified a diverse family of about 1000 receptor molecules that serve as odorant sensors in the nose. However, the properties of smells that these receptors detect remain a mystery. I will review our current understanding of the molecular properties important to the olfactory system. I will also describe a theory that explains how odorant identity can be preserved despite substantial changes in the odorant concentration.

**8:36AM K35.00002 Molecular Cooperativity Governs Diverse and Monoallelic Olfactory Receptor Expression<sup>1</sup>**, JIANHUA XING, XIAOJUN TIAN, University of Pittsburgh, HANG ZHANG, Virginia Polytechnic Institute and State University, JENS SANNERUD, Brown University — Multiple-objective optimization is common in biological systems. In the mammalian olfactory system, each sensory neuron stochastically expresses only one out of up to thousands of olfactory receptor (OR) gene alleles; at organism level the types of expressed ORs need to be maximized. The molecular mechanism of this Nobel-Prize winning puzzle remains unresolved after decades of extensive studies. Existing models focus only on monoallele activation, and cannot explain recent observations in mutants, especially the reduced global diversity of expressed ORs in G9a/GLP knockouts. In this work we integrated existing information on OR expression, and proposed an evolutionarily optimized three-layer regulation mechanism, which includes zonal segregation, epigenetic and enhancer competition coupled to a negative feedback loop. This model not only recapitulates monoallelic OR expression, but also elucidates how the olfactory system maximizes and maintains the diversity of OR expression. The model is validated by several experimental results, and particularly underscores cooperativity and synergy as a general design principle of multi-objective optimization in biology.

**8:48AM K35.00003 Derivation of Neural Circuits from the Similarity Matching Principle**, CENGIZ PEHLEVAN, DMITRI CHKLOVSKII, Simons Foundation — Our brains analyze high-dimensional datasets streamed by our sensory organs in multiple stages. Sensory cortices, for example, perform tasks like dimensionality reduction, sparse feature discovery and clustering. To model these tasks we pursue an approach analogous to use of action principles in physics and propose a new family of objective functions based on the principle of similarity matching. From these objective functions we derive online distributed algorithms that can be implemented by biological neural networks resembling cortical circuits. Our networks can adapt to changes in the number of latent dimensions or the number of clusters in the input dataset. Furthermore, we formulate minimax optimization problems from which we derive online algorithms with two classes of neurons identified with principal neurons and interneurons in biological circuits. In addition to bearing resemblance to biological circuits, our algorithms are competitive for Big Data applications.

**9:00AM K35.00004 The dynamics of neuronal redundancy in decision making**, BRYAN DANIELS, Arizona State University, JESSICA FLACK, DAVID KRAKAUER, Santa Fe Institute — We propose two temporal phases of collective computation in a visual motion direction discrimination task by analyzing recordings from 169 neural channels in the prefrontal cortex of macaque monkeys. Phase I is a distributed phase in which uncertainty is substantially reduced by pooling information from many cells. Phase II is a redundant phase in which numerous single cells contain all the information present at the population level in Phase I. A dynamic distributed model connects low redundancy to a slow timescale of information aggregation, and provides a common explanation for both behaviors that differs only in the degree of recurrent excitation. We attribute the slow timescale of information accumulation to critical slowing down near the transition to a memory-carrying collective state. We suggest that this dynamic of slow distributed accumulation followed by fast collective propagation is a generic feature of robust collective computing systems related to consensus formation.

**9:12AM K35.00005 Mathematical Relationships between Neuron Morphology and Neurite Growth Dynamics in *Drosophila melanogaster* Larva Class IV Sensory Neurons**, SUJOY GANGULY, Yale Univ, XIN LIANG, Tsinghua University, MICHAEL GRACE, DANIEL LEE, JONATHAN HOWARD, Yale Univ — The morphology of neurons is diverse and reflects the diversity of neuronal functions, yet the principles that govern neuronal morphogenesis are unclear. In an effort to better understand neuronal morphogenesis we will be focusing on the development of the dendrites of class IV sensory neuron in *Drosophila melanogaster*. In particular we attempt to determine how the total length, and the number of branches of dendrites are mathematically related to the dynamics of neurite growth and branching. By imaging class IV neurons during early embryogenesis we are able to measure the change in neurite length  $l(t)$  as a function of time  $v(t) = dl/dt$ . We found that the distribution of  $v(t)$  is well characterized by a hyperbolic secant distribution, and that the addition of new branches per unit time is well described by a Poisson process. Combining these measurements with the assumption that branching occurs with equal probability anywhere along the dendrite we were able to construct a mathematical model that provides reasonable agreement with the observed number of branches, and total length of the dendrites of the class IV sensory neuron.

**9:24AM K35.00006 An investigation into the induced electric fields from transcranial magnetic stimulation.**, RAVI HADIMANI, ERIK LEE, Iowa State University, WALTER DUFFY, MOHAMMED WARIS, WAQUAR SIDDIQUI, FAISAL ISLAM, MAHESH RAJAMANI, RYAN NATHAN, Premier Psychiatric Group, DAVID JILES, Iowa State University, DAVID C JILES TEAM, WALTER DUFFY COLLABORATION — Transcranial magnetic stimulation (TMS) is a promising tool for noninvasive brain stimulation that has been approved by the FDA for the treatment of major depressive disorder. To stimulate the brain, TMS uses large, transient pulses of magnetic field to induce an electric field in the head. This transient magnetic field is large enough to cause the depolarization of cortical neurons and initiate a synaptic signal transmission. For this study, 50 unique head models were created from MRI images. Previous simulation studies have primarily used a single head model, and thus give a limited image of the induced electric field from TMS. This study uses finite element analysis simulations on 50 unique, heterogeneous head models to better investigate the relationship between TMS and the electric field induced in brain tissues. Results showed a significant variation in the strength of the induced electric field in the brain, which can be reasonably predicted by the distance from the TMS coil to the stimulated brain. Further, it was seen that some models had high electric field intensities in over five times as much brain volume as other models.

**9:36AM K35.00007 A Robust Feedforward Model of the Olfactory System<sup>1</sup>**, YILUN ZHANG, TATYANA SHARPEE, Salk Institute for Biological Studies and University of California San Diego — Most natural odors have sparse molecular composition. This makes the principles of compressing sensing potentially relevant to the structure of the olfactory code. Yet, the largely feedforward organization of the olfactory system precludes reconstruction using standard compressed sensing algorithms. To resolve this problem, recent theoretical work has proposed that signal reconstruction could take place as a result of a low dimensional dynamical system converging to one of its attractor states. The dynamical aspects of optimization, however, would slow down odor recognition and were also found to be susceptible to noise. Here we describe a feedforward model of the olfactory system that achieves both strong compression and fast reconstruction that is also robust to noise. A key feature of the proposed model is a specific relationship between how odors are represented at the glomeruli stage, which corresponds to a compression, and the connections from glomeruli to Kenyon cells, which in the model corresponds to reconstruction. We show that provided this specific relationship holds true, the reconstruction will be both fast and robust to noise, and in particular to failure of glomeruli. The predicted connectivity rate from glomeruli to the Kenyon cells can be tested experimentally.

**9:48AM K35.00008 Animal-to-Animal Variation in Odor Preference and Neural Representation of Odors**, KYLE HONEGGER, MATTHEW SMITH, Harvard University, GLENN TURNER, HHMI, Janelia Farm Research Campus, BENJAMIN DE BIVORT, Harvard University — Across any population of animals, individuals exhibit diverse behaviors and reactions to sensory stimuli like tastes and odors. While idiosyncratic behavior is ubiquitous, its biological basis is poorly understood. In this talk, I will present evidence that individual fruit flies (*Drosophila melanogaster*) display idiosyncratic olfactory behaviors and discuss our ongoing efforts to map these behavioral differences to variation in neural circuits. Using a high-throughput, single-fly assay for odor preference, we have demonstrated that highly inbred flies display substantial animal-to-animal variability, beyond that expected from experimental error, and that these preferences persist over days. Using in vivo two-photon calcium imaging, we are beginning to examine the idiosyncrasy of neural coding in the fly olfactory pathway and find that the odor responses of individual processing channels in the antennal lobe can vary substantially from fly to fly. These results imply that individual differences in neural coding may be used to predict the idiosyncratic behavior of an individual - a hypothesis we are currently testing by imaging neural activity from flies after measuring their odor preferences.

**10:00AM K35.00009 Robust spatial memory maps in flickering neuronal networks: a topological model.**, YURI DABAGHIAN, ANDREY BABICHEV, Rice University, FACUNDO MEMOLI, SAMIR CHOWDHURY, Ohio State University, RICE UNIVERSITY COLLABORATION, OHIO STATE UNIVERSITY COLLABORATION — It is widely accepted that the hippocampal place cells provide a substrate of the neuronal representation of the environment—the “cognitive map”. However, hippocampal network, as any other network in the brain is transient: thousands of hippocampal neurons die every day and the connections formed by these cells constantly change due to various forms of synaptic plasticity. What then explains the remarkable reliability of our spatial memories? We propose a computational approach to answering this question based on a couple of insights. First, we propose that the hippocampal cognitive map is fundamentally topological, and hence it is amenable to analysis by topological methods. We then apply several novel methods from homology theory, to understand how dynamic connections between cells influences the speed and reliability of spatial learning. We simulate the rat’s exploratory movements through different environments and study how topological invariants of these environments arise in a network of simulated neurons with “flickering” connectivity. We find that despite transient connectivity the network of place cells produces a stable representation of the topology of the environment.

**10:12AM K35.00010 Efficient Signal Processing in Random Networks that Generate Variability: A Comparison of Internally Generated and Externally Induced Variability**, SAKYASINGHA DASGUPTA, RIKEN Brain Science Institute, ISAO NISHIKAWA, Institute of Industrial Science, The University of Tokyo, KAZUYUKI AIHARA, Department of Mathematical Informatics, The University of Tokyo, TARO TOYOIZUMI, RIKEN Brain Science Institute — Source of cortical variability and its influence on signal processing remain an open question. We address the latter, by studying two types of balanced randomly connected networks of quadratic I-F neurons, with irregular spontaneous activity: (a) a deterministic network with strong connections generating noise by chaotic dynamics (b) a stochastic network with weak connections receiving noisy input. They are analytically tractable in the limit of large network-size and channel time-constant. Despite different sources of noise, spontaneous activity of these networks are identical unless majority of neurons are simultaneously recorded. However, the two networks show remarkably different sensitivity to external stimuli. In the former, input reverberates internally and can be read out over long time, but in the latter, inputs rapidly decay. This is further enhanced with activity-dependent plasticity at input synapses producing marked difference in decoding inputs from neural activity. We show, this leads to distinct performance of the two networks to integrate temporally separate signals from multiple sources, with the deterministic chaotic network activity serving as reservoir for Monte Carlo sampling to perform near optimal Bayesian integration, unlike its stochastic counterpart.

**10:24AM K35.00011 Inference of pain stimulus level from stereotypical behavioral response of *C.elegans* allows quantification of effects of anesthesia and mutation**<sup>1</sup>, KAWAI LEUNG, Emory University, AYLIA MOHAMMADI, WILLIAM RYU, University of Toronto, ILYA NEMENMAN, Emory University — In animals, we must infer the pain level from experimental characterization of behavior. This is not trivial since behaviors are very complex and multidimensional. To establish *C.elegans* as a model for pain research, we propose for the first time a quantitative model that allows inference of a thermal nociceptive stimulus level from the behavior of an individual worm. We apply controlled levels of pain by locally heating worms with an infrared laser and capturing the subsequent behavior. We discover that the behavioral response is a product of stereotypical behavior and a nonlinear function of the strength of stimulus. The same stereotypical behavior is observed in normal, anesthetized and mutated worms. From this result we build a Bayesian model to infer the strength of laser stimulus from the behavior. This model allows us to measure the efficacy of anaesthetization and mutation by comparing the inferred strength of stimulus. Based on the measured nociceptive escape of over 200 worms, our model is able to significantly differentiate normal, anaesthetized and mutated worms with 40 worm samples.

**10:36AM K35.00012 *Drosophila* photo-taxis and odor-taxis are mediated by a shared computational pathway**, MIRNA MIHOVILOVIC SKANATA, RUBEN GEPNER, NATALIE BERNAT, MARGARITA KAPLOW, MARC GERSHOW, New York University — In natural environments, the *Drosophila* larva makes navigational decisions based on variable and conflicting sensory inputs. How larvae respond to multi-modal stimuli and how their neural circuits integrate and prioritize multi-sensory information remains unknown. To identify larval navigational computations we developed a high-throughput reverse-correlation assay. We provided larvae with visual and optogenetically induced fictive olfactory stimuli and measured the correlation between the presented stimulus and evoked turn decisions. We used this technique to fit parameters of a Linear-Nonlinear-Poisson model describing computations underlying turn decisions. For uni-modal inputs, the parameterized model allowed us to predict the behavior of populations of larvae responding to novel stimulus presentations. For multi-modal inputs, our assay showed that larvae linearly combine olfactory and visual signals upstream of the decision to turn. We verified this prediction using controlled combinations of stimuli. We studied other navigational decisions that determine the size and directions of turns and found that larvae integrated odor and light according to the same rule in all cases. These results suggest that photo-taxis and odor-taxis are mediated by a shared computational pathway.

**8:00AM K36.00001 Long-time atomistic simulations with the Parallel Replica Dynamics method**<sup>1</sup>, DANNY PEREZ, Los Alamos National Laboratory — Molecular Dynamics (MD) — the numerical integration of atomistic equations of motion — is a workhorse of computational materials science. Indeed, MD can in principle be used to obtain any thermodynamic or kinetic quantity, without introducing any approximation or assumptions beyond the adequacy of the interaction potential. It is therefore an extremely powerful and flexible tool to study materials with atomistic spatio-temporal resolution. These enviable qualities however come at a steep computational price, hence limiting the system sizes and simulation times that can be achieved in practice. While the size limitation can be efficiently addressed with massively parallel implementations of MD based on spatial decomposition strategies, allowing for the simulation of trillions of atoms, the same approach usually cannot extend the timescales much beyond microseconds. In this article, we discuss an alternative parallel-in-time approach, the Parallel Replica Dynamics (ParRep) method, that aims at addressing the timescale limitation of MD for systems that evolve through rare state-to-state transitions. We review the formal underpinnings of the method and demonstrate that it can provide arbitrarily accurate results for any definition of the states. When an adequate definition of the states is available, ParRep can simulate trajectories with a parallel speedup approaching the number of replicas used. We demonstrate the usefulness of ParRep by presenting different examples of materials simulations where access to long timescales was essential to access the physical regime of interest and discuss practical considerations that must be addressed to carry out these simulations.

**8:36AM K36.00002 Investigating the impact of representation upon coarse-grained models**<sup>1</sup>, THOMAS FOLEY<sup>2</sup>, Pennsylvania State University, M SCOTT SHELL<sup>3</sup>, University of California, Santa Barbara, WILLIAM NOID<sup>4</sup>, Pennsylvania State University — The first step in building a coarse-grained (CG) model is choosing a representation or 'mapping' of the original system at a reduced resolution. In practice, the mapping is often chosen on the basis of 'physical intuition.' Consequently this crucial step would greatly benefit from the development of systematic and principled methodologies. Accordingly, we have studied the relationship between the mapping and the resulting CG model. As a starting point, we have analytically derived, as a function of the CG mapping, the exact many-body potential of mean force (PMF) for the simple Gaussian Network Model (GNM) of protein fluctuations. We use this as a simple model for investigating the effect of the CG mapping upon the information loss and quality of the CG model. Moreover, by considering the GNM's for different proteins, we investigate the significance of high resolution structural features for the quality of the CG model.

**8:48AM K36.00003 Non-Markovian coarse-grained modeling of polymeric fluids based on the Mori-Zwanzig formalism<sup>1</sup>**, ZHEN LI, XIN BIAN, Brown University, XIANTAO LI, Pennsylvania State University, GEORGE KARNIADAKIS, Brown University — The Mori-Zwanzig formalism for coarse-graining a complex dynamical system typically introduces memory effects. The Markovian assumption of delta-correlated fluctuating forces is often employed to simplify the formulation of coarse-grained (CG) models and numerical implementations. However, when the time scales of a system are not clearly separated, the memory effects become strong and the Markovian assumption becomes inaccurate. To this end, we incorporate memory effects into CG modeling by preserving non-Markovian interactions between CG variables based on the Mori-Zwanzig formalism. For a specific example, molecular dynamics (MD) simulations of star polymer melts are performed while the corresponding CG system is defined by grouping many bonded atoms into single clusters. Then, the effective interactions between CG clusters as well as the memory kernel are obtained from the MD simulations. The constructed CG force field with a memory kernel leads to a non-Markovian dissipative particle dynamics (NM-DPD). Quantitative comparisons on both static and dynamic properties between the CG models with Markovian and non-Markovian approximations will be presented.

**9:00AM K36.00004 A new graph-matching-based algorithm to study dynamical processes<sup>1</sup>**, FAUSTO MARTELLI, HSIN-YU KO, ROBERTO CAR, Princeton University — We present a new algorithm to identify and quantify the degree of local order in dynamical systems. To each particle site we associate a given number of neighboring sites the positions of which define the nodes of a pattern graph. We match this graph with a graph describing the geometry of an ordered reference system. The degree of overlap is obtained by recursively maximizing a score function having a value ranging from 0 (in the case of a completely disordered system) to 1 (in the case of a perfect crystal). While typically order parameters are tailored to specific cases, our approach is general and could be applied to different areas of condensed matter physics. Here we illustrate the approach with applications to atomic and molecular fluids, namely melting of Lennard Jones particles, direct crystallization of supercooled water and melting of Yukawa crystals.

**9:12AM K36.00005 HOMOGENOUS NUCLEATION AND CRYSTAL GROWTH IN A MODEL LIQUID FROM DIRECT ENERGY LANDSCAPE SAMPLING SIMULATION**, NATHAN WALTER, YANG ZHANG, University of Illinois at Champaign-Urbana — Nucleation and crystal growth are understood to be activated processes involving the crossing of free-energy barriers. Attempts to capture the entire crystallization process over long timescales with molecular dynamic simulations have met major obstacles because of molecular dynamics' temporal constraints. Herein, we circumvent this temporal limitation by using a brutal-force, metadynamics-like, adaptive basin-climbing algorithm and directly sample the free-energy landscape of a model liquid Argon. The algorithm biases the system to evolve from an amorphous liquid like structure towards an FCC crystal through inherent structure, and then traces back the energy barriers. Consequently, the sampled timescale is macroscopically long. We observe that the formation of a crystal involves two processes, each with a unique temperature-dependent energy barrier. One barrier corresponds to the crystal nucleus formation; the other barrier corresponds to the crystal growth. We find the two processes dominate in different temperature regimes. Compared to other computation techniques, our method requires no assumptions about the shape or chemical potential of the critical crystal nucleus. The success of this method is encouraging for studying the crystallization of more complex

**9:24AM K36.00006 Dynamical Density Functional Theory and Hydrodynamic Interactions in Confined Systems<sup>1</sup>**, BENJAMIN GODDARD, University of Edinburgh, SERAFIM KALLIADAKIS, ANDREAS NOLD, Imperial College London — Colloidal systems consist of nano-micrometer sized particles suspended in a bath of many more, much smaller and much lighter particles. When the colloidal particles move through the bath, e.g. when driven by external forces such as gravity, flows are induced in the bath. These flows in turn impart forces on the colloid particles. These bath-mediated forces, known as Hydrodynamic Interactions (HI) strongly influence the dynamics of the colloid particles. This is particularly true in confined systems, in which the presence of walls substantially modifies the HI compared to unbounded geometries. For many-particle systems, the number of degrees of freedom prohibit a direct solution of the underlying stochastic equations and a reduced model is necessary. We model such systems through Dynamical Density Functional Theory (DDFT), the computational complexity of which is independent of the number of particles. We include both inter-particle and particle-wall HI, demonstrating both their combined and relative effects.

<sup>1</sup>Funded by EPSRC grant no EP/L025159/1

**9:36AM K36.00007 Nondecaying hydrodynamic interactions along narrow channels**, KAROLIS MISIUNAS, STEFANO PAGLIARA, ERIC LAUGA, JOHN R LISTER, ULRICH KEYSER, University of Cambridge — Particle-particle interactions are of paramount importance in every multi-body system as they determine the collective behaviour and coupling strength. Many well-known interactions like electrostatic, van der Waals or screened Coulomb, decay exponentially or with negative powers of the particle spacing  $r$ . Similarly, hydrodynamic interactions between particles undergoing Brownian motion decay as  $1/r$  in bulk, and are assumed to decay in small channels. Such interactions are ubiquitous in biological and technological systems. Here we confine two particles undergoing Brownian motion in narrow, microfluidic channels and study their coupling through hydrodynamic interactions. Our experiments show that the hydrodynamic particle-particle interactions are distance-independent in these channels. This finding is of fundamental importance for the interpretation of experiments where dense mixtures of particles or molecules diffuse through finite length, water-filled channels or pore networks.

**9:48AM K36.00008 Topological properties and edge mode effects in classical thermal transport**, CHIHCHUN CHIEN, University of California, Merced, KIRILL VELIZHANIN, Los Alamos National Laboratory, YONATAN DUBI, Ben Gurion University, Israel, MICHAEL ZWOLAK, National Institute of Science and Technologies — Classical harmonic chains, with suitable parametrizations, can resemble quantum systems exhibiting interesting topological phases. By analytically solving the equations of motion of harmonic chains with alternating masses and coupling constants, the energy bands bear striking resemblance to topological electronic bands of the Su-Schrieffer-Heeger model. As a consequence, localized topological edge modes associated with topological invariants of the system arise in classical harmonic chains. Effects from topological properties on thermal transport through patterned harmonic chains are analyzed and the results are supported by molecular-dynamics simulations. We also found edge modes as a hindrance to achieving the maximal intrinsic thermal conductance. Possible applications in polymers will be discussed.

**10:00AM K36.00009 Durability of Long Equipartition Times In Anharmonic Oscillator Chains**, CHRISTOPHER WATENPOOL, DONALD PRIOUR, Youngstown State University — Vibrational modes, completely decoupled in the case of a purely harmonic chain do not interact, thereby preventing an even spread of energy over both low and high frequency states. The distribution of energy beyond a small set of initially excited modes, known as equipartition, proceeds over finite time scales with the admixture of an anharmonic term. However, in many cases (e.g.  $V(x) = \alpha x^2 + \beta x^4$ ), the transfer of energy from low to high frequency modes is hampered for an isolated chain, with equipartition times diverging with increasing system size. Using Molecular Dynamics simulations we relax the isolation condition, gradually coupling the ends of the chain to a thermal bath. Calculating equipartition times for various coupling strengths, we seek to determine if: (i) The bulk limit divergence persists for any coupling strength, (ii) Bulk equipartition times are finite beyond a coupling threshold, or (iii) Coupling to a thermal bath has a singular effect and yields finite equipartition times for any nonzero coupling strength.

**10:12AM K36.00010 Coarse-grained description of polymer blends as chains of interacting soft particles**, KEVIN WALTON, Department of Physics, University of Oregon, Eugene, Oregon 97403, MARINA GUENZA, Department of Chemistry, University of Oregon, Eugene, Oregon 97403 — We present an analytic pair potential in a coarse grain description of a polymer blend where each chain is represented as a chain of soft-colloidal particles. This coarse grain model is based on integral theory that can represent the chains at variable levels. The particles have soft repulsion at separation less than the size of each coarse grain unit and a long repulsive tail with small attractive portion. While the short range pieces of the potential dominates the liquid structure, the long range tail dominates the thermodynamics of the system. So an accurate potential in both the short and long range distances is needed to keep give correct structure and thermodynamical properties in the coarse grain description.

**10:24AM K36.00011 Langevin Equation for DNA Dynamics**, DAVID GRZYCH, JEREMY COPPERMAN, Univ of Oregon Dept. of Physics, MARINA GUENZA, Univ of Oregon Dept. of Chemistry — Under physiological conditions, DNA oligomers can contain well-ordered helical regions and also flexible single-stranded regions. We describe the site-specific motion of DNA with a modified Rouse-Zimm Langevin equation formalism that describes DNA as a coarse-grained polymeric chain with global structure and local flexibility. The approach has successfully described the protein dynamics in solution and has been extended to nucleic acids. Our approach provides diffusive mode analytical solutions for the dynamics of global rotational diffusion and internal motion. The internal DNA dynamics present a rich energy landscape that accounts for an interior where hydrogen bonds and base-stacking determine structure and experience limited solvent exposure. We have implemented several models incorporating different coarse-grained sites with anisotropic rotation, energy barrier crossing, and local friction coefficients that include a unique internal viscosity and our models reproduce dynamics predicted by atomistic simulations. The models reproduce bond autocorrelation along the sequence as compared to that directly calculated from atomistic molecular dynamics simulations. The Langevin equation approach captures the essence of DNA dynamics without a cumbersome atomistic representation.

**10:36AM K36.00012 Improving the kinetics from molecular simulations using biased Markov state models**, JOSEPH F RUDZINSKI, KURT KREMER, TRISTAN BERAUD, Max Planck Institute for Polymer Research — Molecular simulations can provide microscopic insight into the physical and chemical driving forces of complex molecular processes. Despite continued advancement of simulation methodology, model errors may lead to inconsistencies between simulated and experimentally-measured observables. This work presents a robust and systematic framework for reweighting the ensemble of dynamical paths sampled in a molecular simulation in order to ensure consistency with a set of given kinetic observables. The method employs the well-developed Markov state modeling framework in order to efficiently treat simulated dynamical paths. We demonstrate that, for two distinct coarse-grained peptide models, biasing the Markov state model to reproduce a small number of reference kinetic constraints significantly improves the dynamical properties of the model, while simultaneously refining the static equilibrium properties.

**10:48AM K36.00013 Multiscale Modeling of the Electrocaloric Effect in PVDF-based Polymers**, ALAN MCGAUGHEY, YING-JU YU, Carnegie Mellon University — We apply multi-scale modeling to explore the electrocaloric (EC) effect in PVDF-related ferroelectric polymers, which have application in active cooling of microsystems. The EC effect is the temperature rise and drop in some ferroelectric materials due to changes in the configurational entropy when an external electric field is applied and removed. The polymer is modeled as a series of bi-directional permanent dipoles and induced point dipoles distributed on its monomer sites. The flipping of these dipoles due to an applied electric field leads to polarization changes. Flipping the dipole moment of the polymer chain requires rotation of the individual monomers, each of which has its own energy barrier. This energy pathway is predicted from atomic-level nudged elastic band method calculations for a variety of chain environments. We then use first-passage time analysis to convert each energy pathway into an average transition rate for a full polymer chain rotation. The transition rates for all chains are integrated into a kinetic Monte Carlo algorithm in which the polarization change due to the application of an electric field is determined.

Session K37 GSOF: Soft Matter at Interfaces (Particles) 340 - Michael Rubenstein, Univ. North Carolina

**8:00AM K37.00001 Soft particles at fluid interfaces: wetting, structure, and rheology.**<sup>1</sup>, LUCIO ISA, ETH Zurich — Most of our current knowledge concerning the behavior of colloidal particles at fluid interfaces is limited to model spherical, hard and uniform objects. Introducing additional complexity, in terms of shape, composition or surface chemistry or by introducing particle softness, opens up a vast range of possibilities to address new fundamental and applied questions in soft matter systems at fluid interfaces. In this talk I will focus on the role of particle softness, taking the case of core-shell microgels as a paradigmatic example. Microgels are highly swollen and cross-linked hydrogel particles that, in parallel with their practical applications, e.g. for emulsion stabilization and surface patterning, are increasingly used as model systems to capture fundamental properties of bulk materials. Most microgel particles develop a core-shell morphology during synthesis, with a more cross-linked core surrounded by a corona of loosely linked and dangling polymer chains. I will first discuss the difference between the wetting of a hard spherical colloid and a core-shell microgel at an oil-water interface, pinpointing the interplay between adsorption at the interface and particle deformation. I will then move on to discuss the interplay between particle morphology and the microstructure and rheological properties of the interface. In particular, I will demonstrate that synchronizing the compression of a core-shell microgel-laden fluid interface with the deposition of the interfacial monolayer makes it possible to transfer the 2D phase diagram of the particles onto a solid substrate, where different positions correspond to different values of the surface pressure and the specific area. Using atomic force microscopy, we analyzed the microstructure of the monolayer and discovered a phase transition between two crystalline phases with the same hexagonal symmetry, but with two different lattice constants. The two phases correspond to shell-shell or core-core inter-particle contacts, respectively, where with increasing surface pressure the former mechanically fail enabling the particle cores to come into contact. In the phase-transition region, clusters of particles in core-core contacts nucleate, melting the surrounding shell-shell crystal, until the whole monolayer moves into the second phase. We furthermore extended our analysis to measure the interfacial rheology of the monolayers as a function of the surface pressure using an interfacial microdisk rheometer; the interfaces always show a strong elastic response, with a dip in the elastic modulus in correspondence of the melting of the shell-shell phase, followed by a steep increase upon formation of a percolating network of the core-core contacts. The presented results highlight the complex interplay between the wetting and deformation of individual soft particles at fluid interfaces and the overall interface microstructure and mechanics. They show strong connections to fundamental studies on phase transitions in two-dimensional systems and pave the way for novel nanoscale surface patterning routes.

**8:36AM K37.00002 Sculpting Pickering Emulsion Droplets by Arrest and Jamming**<sup>1</sup>, CHRISTOPHER BURKE, Tufts Univ, ZENGYI WEI, University of New South Wales, MARCO CAGGIONI, Proctor & Gamble, PATRICK SPICER, University of New South Wales, TIM ATHERTON, Tufts Univ — Pickering emulsion droplets can be arrested into non-spherical shapes—useful for applications such as active delivery—through a general mechanism of deformation followed by absorption of additional colloidal particles onto the interface, relaxation of the droplet caused by surface tension and arrest at some point due to crowding of the particles. We perform simulations of the arrest process to clarify the relative importance of diffusive rearrangement of particles and collective forcing due to surface evolution. Experiment and theory are compared, giving insight into the stability of the resulting capsules and the robustness of the production process for higher-throughput production in, for example, microfluidic systems. We adapt theoretical tools from the jamming literature to better understand the arrested configurations and long timescale evolution of the system: using linear programming and a penalty function approach, we identify unjamming motions in kinetically arrested states. We propose a paradigm of metric jamming to describe the limiting behavior of this class of system: a structure is metric-jammed if it is stable with respect to collective motion of the particles as well as evolution of the hypersurface on which the packing is embedded.

### 8:48AM K37.00003 Droplets on a deformable membrane with uniform and anisotropic tension

, RAFAEL SCHULMAN, McMaster University, RENÉ LEDESMA-ALONSO, THOMAS SALEZ, ELIE RAPHAËL, ESPCI, KARI DALNOKI-VERESS, McMaster University — We examine the deformation produced by micro-droplets atop thin elastomeric free-standing films. Under the action of surface tension, the droplets deform the membrane thereby forming a bulge. For films with isotropic tension, we measure the contact angles of the droplet and bulge relative to the planar film surrounding the droplet as a function of membrane tension. We find the measured contact angles to be in excellent agreement with a model which features a force balance at the contact line. Experiments are also performed on membranes with anisotropic tension and compared to theory. In this case, droplets are non-spherical and generate significant deformation of the surrounding film which becomes non-planar.

### 9:00AM K37.00004 Capillary Forces between Floating Objects: Superhydrophobic Surfaces Provide Mechanistic Insight

, MINCHAO ZHANG, THOMAS J. MCCARTHY, ALFRED J. CROSBY, Univ of Mass - Amherst — When two floating objects are close, they will either move towards or away from one another to minimize the energy caused by the overlap of the liquid/air interfacial deformations. Capillary forces cause these behaviors, but directly relating the interfacial deformations and the capillary interactions hasn't been explored experimentally. We choose a liquid marble, which has a superhydrophobic surface, as a free floating object and a fixed "wall" with carefully controlled contact angle as another object to generate two deformations at the interface. When the liquid marble is close to the wall, the two deformations interact, causing changes in the Laplace pressure at the interface and a reconfiguration of the interface. In response, the liquid marble moves either towards or away from the wall. Using image analysis of videos recording the liquid marble position as a function of time, we measured the liquid marble to wall distance and determine the spatio-temporal relationships. Furthermore, capillary forces were calculated from the velocities and accelerations. Based on this data, we present a new explanation for the capillary interactions from the perspective of Laplace pressure changing induced the reconfiguration of the interfacial deformations.

### 9:12AM K37.00005 Adsorption-desorption kinetics of soft particles onto surfaces

, BRENDAN OSBERG, ULRICH GERLAND, Technische Universität München — A broad range of physical, chemical, and biological systems feature processes in which particles randomly adsorb on a substrate. Theoretical models usually assume hard (mutually impenetrable) particles, but in soft matter physics the adsorbing particles can be effectively compressible, implying soft interaction potentials. We recently studied the kinetics of such soft particles adsorbing onto one-dimensional substrates, identifying three novel phenomena: (i) a gradual density increase, or "cramming", replaces the usual jamming behavior of hard particles, (ii) a density overshoot, can occur (only for soft particles) on a time scale set by the desorption rate, and (iii) relaxation rates of soft particles increase with particle size (on a lattice), while hard particles show the opposite trend. The latter occurs since unjamming requires desorption and many-bodied reorganization to equilibrate - a process that is generally very slow. Here we extend this analysis to a two-dimensional substrate, focusing on the question of whether the adsorption-desorption kinetics of particles in two dimensions is similarly enriched by the introduction of soft interactions. Application to experiments, for example the adsorption of fibrinogen on two-dimensional surfaces, will be discussed.

### 9:24AM K37.00006 Adsorption dynamics of colloidal ellipsoids at oil-water interfaces

, ANNA WANG, W. BENJAMIN ROGERS, VINOTHAN N. MANOHARAN, Harvard University — Nonspherical particles at immiscible fluid interfaces have strong interactions with each other and with the curvature of the host interface. However, the dynamics of nonspherical colloidal particles attaching to an interface have not yet been studied. We use digital holographic microscopy to image micron-sized polystyrene ellipsoids breaching an oil-water interface at hundreds of frames per second. We show that the particle height and polar angle have large fluctuations, but both change approximately logarithmically with time, likely due to contact line pinning on the surface of the particle. Equilibrium is reached on a timescale at least three orders of magnitude slower than that expected from Langevin dynamics simulations [1]. We also find that all the trajectories collapse into straight lines when we plot particle polar angle as a function of particle height, unlike the trajectories seen in simulation [1,2]. The differences between experiment and simulation suggest that contact line pinning and the shape of the three phase contact line may strongly influence the dynamics of particle adsorption. [1] The Journal of Chemical Physics 132 (16), 164902, (2010) [2] Soft Matter 10, 4977-4989 (2014)

### 9:36AM K37.00007 Phase Behavior of 2D Charged Hydrophobic Colloids in Flat and Curved

Space, COLM KELLEHER, RODRIGO GUERRA, PAUL CHAIKIN, Dept. of Physics, New York University — Charged hydrophobic colloids, when dispersed in oil with a relatively high dielectric constant, can become highly charged. In the presence of an interface with a conducting aqueous phase, particles bind strongly to the interface via image-charge attraction. At sufficiently high density, these charged interfacial particles self-organize into a 2D repulsive (Wigner) crystalline solid phase, while at lower densities, the particles form a 2D fluid. By observing samples prepared at different densities, we can probe various points in the phase diagram of this soft 2D material, and compare our results with applicable theory and simulations. In this talk, we present two sets of experiments we have performed on this system: first, we show how we can use gravity as an external force to create a controlled density gradient, and thereby directly measure the equation of state and other quantities of interest. Second, we discuss how, by observing particles which are bound to the surface of spherical droplets, we can explore how the presence of finite background curvature affects the phase behavior of the system.

### 9:48AM K37.00008 Bidispersed Sphere Packing on Spherical Surfaces<sup>1</sup>

, TIMOTHY ATHERTON, ANDREW MASCIOLI, CHRISTOPHER BURKE, Tufts University — Packing problems on spherical surfaces have a long history, originating in the classic Thompson problem of finding the ground state configuration of charges on a sphere. Such packings contain a minimal number of defects needed to accommodate the curvature; this is predictable using the Gauss-Bonnet theorem from knowledge of the topology of the surface and the local symmetry of the ordering. Famously, the packing of spherical particles on a sphere contains a 'scar' transition, where additional defects over those required by topology appear above a certain critical number of particles and self-organize into chains or scars. In this work, we study the packing of bidispersed packings on a sphere, and hence determine the interaction of bidispersity and curvature. The resultant configurations are nearly crystalline for low values of bidispersity and retain scar-like structures; these rapidly become disordered for intermediate values and approach a so-called Apollonian limit at the point where smaller particles can be entirely accommodated within the voids left by the larger particles. We connect our results with studies of bidispersed packings in the bulk and on flat surfaces from the literature on glassy systems and jamming.

### 10:00AM K37.00009 Dynamics of particles and defects on spherical crystals

, RODRIGO GUERRA, COLM KELLEHER, PAUL CHAIKIN, New York Univ NYU — Repulsive particles confined to two dimensions can form nearly perfect crystals that melt via the well-known Kosterlitz-Thouless two-step process. By contrast, when identical particles are confined to the surface of a sphere, the curvature and topology of the surface distort the crystal lattice and forces it to accommodate point-like disclinations and chains of dislocations. Extensive numerical and theoretical investigation has shown that these extended scars are intrinsic to the ground-state-energy configuration of these packings, as they relieve some of the stress induced by the curvature of the surface. Nevertheless, the effect of these defects on the kinetics and phase behavior of spherical crystals is not at all well understood. Here we present results of computer simulations and experiments that suggest that these scars facilitate the motion of particles close to them and fundamentally alter the nature of the mobility and liquid-to-solid transition of packings of particles confined to spherical surfaces.

**10:12AM K37.00010 Phase nucleation in curved space**, LEOPOLDO GÓMEZ, NICOLÁS GARCÍA, Department of Physics, Universidad Nacional del Sur-CONICET. Argentina., VINCENZO VITELLI, Instituut-Lorentz, Universiteit Leiden, The Netherlands., JOS LORENZANA, Institute for Complex Systems, Consiglio Nazionale delle Ricerche, Italy, VEGA DANIEL, Department of Physics, Universidad Nacional del Sur-CONICET. Argentina. — Nucleation and growth is the dominant relaxation mechanism driving first-order phase transitions. In two-dimensional flat systems, nucleation has been applied to a wide range of problems in physics, chemistry and biology. Here we study nucleation and growth of two-dimensional phases lying on curved surfaces and show that curvature modifies both critical sizes of nuclei and paths towards the equilibrium phase. In curved space, nucleation and growth becomes inherently inhomogeneous and critical nuclei form faster on regions of positive Gaussian curvature. Substrates of varying shape display complex energy landscapes with several geometry-induced local minima, where initially propagating nuclei become stabilized and trapped by the underlying curvature (Gómez, L. R. et al. Phase nucleation in curved space. Nat. Commun. 6:6856 doi: 10.1038/ncomms7856 (2015).).

**10:24AM K37.00011 Clusters of polyhedra in spherical confinement**<sup>1</sup>, ERIN TEICH, GREG VAN ANDERS, DAPHNE KLOTSAS<sup>2</sup>, JULIA DSHEMUCHADSE, SHARON GLOTZER, University of Michigan — Dense particle packing in a confining volume is a rich, largely unexplored problem, with applications in blood clotting, plasmonics, industrial packaging and transport, colloidal molecule design, and information storage. We report simulation results for dense clusters of the Platonic solids in spherical confinement, for up to  $N = 60$  constituent particles. We discuss similarities between clusters in terms of symmetry, a connection to spherical codes, and generally the interplay between isotropic geometrical confinement and anisotropic particle shape. Our results showcase the structural diversity and experimental utility of families of solutions to the problem of packing in confinement.

**10:36AM K37.00012 Computer Simulation study of polyhedral nanoparticle self-assembly at interfaces.**, VIKRAM THAPAR, UNMUKT GUPTA, FERNANDO ESCOBEDO, Cornell University — The self-assembly of polyhedral particles confined to a fluid-fluid interface is studied using Monte Carlo simulations. Several polyhedral shapes are studied, which are selected from a family of truncated cubes which include cubes, cuboctahedra, and octahedra. First we studied the case of hard particles pinned to the interface by restricting their movement in the direction perpendicular to it while allowing their free rotations. Our results suggest that the known solid phases and mesophases of these shapes in the 3D bulk are "translated" into variants in 2D space. These insights on 2D entropic self-assembly of polyhedral particles is a first step toward understanding the self-assembly of particles at fluid-fluid interfaces, which is driven by a complex interplay of entropic and enthalpic forces. As a second step we hence studied the particle-surface and particle-particle interactions associated with a fluid-fluid interface using both continuum and polybead models to assess the role of enthalpic interactions in determining the particle orientation behavior with respect to interface. We find that the thickness of the interface can introduce non-trivial effects on the preferential particle orientations.

**10:48AM K37.00013 The Relationship between Self-Assembly and Conformal Mappings**, CARLOS DUQUE, CHRISTIAN SANTANGELO, University of Massachusetts Amherst — The isotropic growth of a thin sheet has been used as a way to generate programmed shapes through controlled buckling. We discuss how conformal mappings, which are transformations that locally preserve angles, provide a way to quantify the area growth needed to produce a particular shape. A discrete version of the conformal map can be constructed from circle packings, which are maps between packings of circles whose contact network is preserved. This provides a link to the self-assembly of particles on curved surfaces. We performed simulations of attractive particles on a curved surface using molecular dynamics. The resulting particle configurations were used to generate the corresponding discrete conformal map, allowing us to quantify the degree of area distortion required to produce a particular shape by finding particle configurations that minimize the area distortion.

Session K38 DPOLY GSOF: Glasses Altered by Interfaces I 341 - Andrew Croll, North Dakota State University

**8:00AM K38.00001 Nanorheology of confined polymer films**, PAUL FOWLER, MARK ILTON, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, JOSHUA D. MCGRAW, Dpartement de Physique, Ecole Normale Suprieure / PSL Research University, CNRS, 24 rue Lhomond, 75005 Paris, France, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada — Liquid films with a non-uniform thickness flatten in order minimize surface energy, a process driven by surface tension and mediated by viscosity. For a viscous thin film, the time evolution of the film height profile is accurately described by lubrication theory by the capillary-driven thin film equation. Previous experiments have successfully applied the thin film equation to measure the rheological properties of polymeric liquids. Here we probe confinement effects in thin polymer films. We measure the viscosity by tracking the levelling of surface perturbations with AFM. For films with thicknesses thinner than the end-to-end distance of the molecule we observe deviations from a thin film model with bulk viscosity.

**8:12AM K38.00002 Understanding the relationship between different measures of nanoconfinement effects on segmental dynamics and the glass transition.**<sup>1</sup>, DAVID SIMMONS, JAYACHANDRA HARI MANGALARA, WESTON MERLING, The University of Akron — Several decades of research have indicated that confinement of a polymer or other glass-forming material to a nanoscale domain can significantly alter its glass transition temperature and segmental dynamics. Such effects have been reported in thin films, nanolayered and block copolymers, ionomers, and semicrystalline polymers. These alterations in glass formation behavior have implications for applications ranging from microelectronics to water purification. Many of the major open questions in this field center on apparent differences in nanoconfinement effects as probed by different methods. Recent studies have reported substantial differences in the apparent magnitude, direction, and onset temperature of these effects as probed via ellipsometry, calorimetry, fluorescence, dielectric spectroscopy, neutron scattering, various measures of viscous relaxation, and simulation. Here we employ molecular dynamics simulations to elucidate relationships between different measures of nanoconfinement effects. Particular emphasis is placed on differences in the manner in which different metrologies average over interfacial gradients in dynamics and pseudothermodynamic properties.

**8:24AM K38.00003 Length Scales of Local Glass Transition Temperature Gradients Near Soft and Hard Polymer-Polymer Interfaces**, ROMAN BAGLAY, CONNIE ROTH, Dept. of Physics, Emory University — Polymer-polymer interfaces are ubiquitous in polymer blends and block copolymers, while opening up another avenue for the study of interfacial perturbations to the local glass transition temperature  $T_g(z)$ . We have previously reported the full local  $T_g(z)$  profile across a glassy-rubbery polymer interface between polystyrene (PS) and poly(*n*-butyl methacrylate) (PnBMA), an 80 K difference in bulk  $T_g$  [Baglay & Roth, J Chem Phys 2015, 143, 111101]. By using local fluorescence measurements, we revealed how the  $T_g(z)$  profile extends hundreds of nanometers away from the interface showing an asymmetric behavior penetrating deeper into the glassy PS side relative to the composition profile. Here, we extend these measurements to investigate how the local  $T_g$  profile in PS varies when in contact with a variety of immiscible polymers whose  $T_g$ s vary between +90 K and -80 K relative to the bulk  $T_g$  of PS, so-called hard vs. soft confinement. The data reveal that the onset of local  $T_g$  deviation from bulk in PS occurs at two distinct length scales, which depend on whether PS is the low  $T_g$  component (hard confinement) or the high  $T_g$  component (soft confinement). In addition, we explore the influence of finite system size on the range of dynamics by the introduction of periodic boundary conditions, as is commonly encountered in computer simulations or block copolymer systems.

**8:36AM K38.00004 Glassy Dynamics Altered by a Free Surface**<sup>1</sup>, OPHELIA TSUI, Department of Physics and Division of Materials Science and Engineering, Boston University — Studies of polymer dynamics in thin films showed that a highly mobile region exists at the free surface of most if not all polymers. In this talk, I shall review some of these observations, with highlights given to the recent findings that chain flexibility and connectivity may on occasions be necessary for the free surface to exercise its influence. Afterward, I shall ponder on how the influence of the free surface may penetrate as far as several polymer radii of gyration into the inner region, as found both in experiments and simulations. Near the glass transition temperature, our MD simulations showed that the dynamics consist mainly of string-like particle hopping motions, as found by others. Importantly, as the temperature decreases, the hopping motions become increasingly repetitive and back-and-forth, contributing no structural relaxations. We propose that structural relaxations are then brought about by pair-interactions between strings. Near the free surface, however, similar repetitive hopping motions are only observed sufficiently far removed from the free surface. We propose that the free surface induces a penetrating surface mobile region by breaking the memory in the particle dynamics. A possible mechanism based on string interactions will be discussed.

**9:12AM K38.00005 Understanding and characterizing the effect of nanoscale confinement on glass transition temperature and film dewetting of macrocyclic polystyrene**, LANHE ZHANG, Materials Science and Engineering, Northwestern University, RAVINDER ELUPULA, SCOTT GRAYSON, Department of Chemistry, Tulane University, JOHN TORKELOSON, Materials Science and Engineering, Department of Chemical and Biological Engineering, Northwestern University — There is a growing interest in the dynamics of different polymer topologies when confined to nanoscopic length scales. Macrocyclic polymers have attracted research interest because their lack of chain ends and cyclic topology has led to a range of unique physical properties. Cyclic polystyrene (*c*-PS) of well-defined molecular weight (MW) ranging from 2,300 to 8,700 g/mol was synthesized via click cyclization of dilute solutions of linear PS (*l*-PS) with azide and alkyne end functionalities. The click reaction enables nearly quantitative cyclization of *l*-PS. Differential scanning calorimetry was used to measure bulk glass transition temperature ( $T_g$ ) and fragility of *c*-PS, both of which exhibit less MW dependence compared to *l*-PS. Compared to thin *l*-PS films, thin *c*-PS films exhibited extraordinary stability against dewetting. 22-nm-thick *c*-PS films were nearly stable for up to 4 hr at bulk  $T_g + 45$  C; in contrast, 22-nm-thick *l*-PS films underwent severe dewetting. Nanoconfinement effects on  $T_g$  and fragility of *c*-PS are investigated using ellipsometry and/or fluorescence spectroscopy and compared to effects for *l*-PS precursors as well as commercial anionic *l*-PS standards.

**9:24AM K38.00006 The local segmental dynamics of polymer thin films.**<sup>1</sup>, C.M. ROLAND, RICCARDO CASALINI, Naval Research Laboratory, DANIELE PREVOSTO, MASSIMILIANO LABARDI, University of Pisa, LEI ZHU, ERIC BAER, Case Western University — The local segmental dynamics of poly(methyl methacrylate) (PMMA) in multi-layered films with polycarbonate was investigated using dielectric spectroscopy. The segmental relaxation time decreased with layer thickness down to 4 nm. However, two measures of the cooperativity of the dynamics, the breadth of the relaxation dispersion and the dynamic correlation volume, were unaffected by the film thickness. This absence of an effect of geometric confinement on the cooperativity, even when the confinement length scale approaches the correlation length scale, requires an asymmetric correlation volume; i.e., correlating regions having a string-like nature. To further probe the effect of layering on the segmental dynamics, we measured the segmental dynamics of poly(vinylacetate) thin films in contact with variously an aluminum interface, an incompatible polymer, and air (free surface). From local dielectric relaxation measurements using an AFM tip, the dynamics were observed to be faster in all thin film configurations compared to the bulk. However, no differences were observed for the various interfaces; capping the thin films with a rigid material accelerated the segmental motions equivalently to that for an air interface. This insensitivity of the dynamics to the nature of the interface affords a means to engineer thin films while maintaining desired mechanical properties.

**9:36AM K38.00007 Synthesis and Characterization of Fluorescently Labeled Diblock Copolymers for Location-Specific Measurements of The Glass Transition Temperature**<sup>1</sup>, DANE CHRISTIE, RICHARD REGISTER, RODNEY PRIESTLEY, Princeton University — Interfaces play a determinant role in the size dependence of the glass transition temperature ( $T_g$ ) of polymers confined to nanometric length scales. Interfaces are intrinsic in diblock copolymers, which, depending on their molecular weight and composition, are periodically nanostructured in the bulk. As a result diblock copolymers are model systems for characterizing the effect of interfaces on  $T_g$  in bulk nanostructured materials. Investigating the effect of intrinsic interfaces on  $T_g$  in diblock copolymers has remained unexplored due to their small periodic length scale. By selectively incorporating trace amounts of a fluorescent probe into a diblock copolymer,  $T_g$  can be characterized relative to the diblock copolymer's intrinsic interface using fluorescence spectroscopy. Here, pyrene is selectively incorporated into the poly(methyl methacrylate) (PMMA) block of lamellar forming diblock copolymers of poly(butyl-*b*-methyl methacrylate) (PBMA-PMMA). Preliminary results show a correlation of  $T_g$  as measured by fluorescence with the onset of  $T_g$  as measured by calorimetry in labeled homopolymers of PMMA. This result is consistent with previous characterizations of  $T_g$  using fluorescence spectroscopy. In selectively labeled diblock copolymers  $T_g$  is found to vary systematically depending on the distance of the probe from the PBMA-PMMA interface.

**9:48AM K38.00008 Glass Transition of Polystyrene Thin Films on Silicon Wafer Measured by Dynamic Mechanical Analysis and Ellipsometry**, CATHERYN JACKSON, Dow Chemical, Core RD, Collegeville, PA 19426, TIAN LAN, Departments of Chem. and Bio. Eng. and Mat. Sci. and Eng., Northwestern University, Evanston, Illinois 60208, STEFAN CAPORALE, Dow Chemical, Electronic Materials, Marlborough, MA 01752, JOHN TORKEKELSON, Departments of Chem. and Bio. Eng. and Mat. Sci. and Eng., Northwestern University, Evanston, Illinois 60208 — Measuring the glass transition temperature,  $T_g$ , of polymer films in the thickness range of 20-500 nm is non-routine but commercially important for polymer films used in applications such as membranes and electronic circuit boards. Various specialized methods have been used or developed to determine  $T_g$  in thin films, including thermal ellipsometry and many others. Differential scanning calorimetry (DSC) is a more conventional method that has been used to measure  $T_g$ , but since the thin films must be scraped from the wafer, consolidation and annealing can occur in the pan and may negate effects due to film thickness. Here we report results for polystyrene (PS) spin coated on silicon wafers in the range of 20-500 nm using a benchtop dynamic mechanical analyzer (DMA) in the 3-point bending mode. For the DMA, the peak  $\tan \delta$  temperature is related to the polymer  $T_g$  and effects due to confinement as a function of film thickness are compared to literature values. We use thermal ellipsometry as a control method to measure film thickness and  $T_g$  in parallel. Low level additives present in commercial PS were observed to strongly affect the results for thin films and are described.

**10:00AM K38.00009 Effects of Interfaces and Interactions on Stiffness-Confinement Behavior in Polymer Films: Characterization via Fluorescence and Nanoindentation**, SHADID ASKAR, MIN ZHANG, L BRINSON, JOHN TORKEKELSON, Northwestern Univ — Although stiffness-confinement effects in polymers have been well studied, disagreement exists regarding even the qualitative nature of such effects. With the exception of one experimental and several simulation studies that characterize stiffness gradients, all others report average stiffness-confinement behavior in polymers. These issues demonstrate the need for comparative studies that characterize stiffness gradients in polymers from interfaces. Here, we use a fluorescence technique that utilizes the sensitivity of pyrene dye fluorescence to local caging and nanoindentation to characterize stiffness gradients in the polymer model nanocomposites. Both techniques are in qualitative agreement that stiffness gradients extend a distance exceeding 100 nm from a substrate, and that stiffness-confinement effects are tunable via surface modification of the substrate. It is observed that PMMA supported on methylated cover glass exhibits less stiffening near the substrate compared to PMMA supported on cover glass with enhanced hydroxyl groups that can hydrogen bond with PMMA. PMMA supported on PDMS shows decreasing stiffness near the interface. These findings help address some of the inconsistencies observed in literature regarding stiffness-confinement effects.

**10:12AM K38.00010 Sidechain Dynamics Explain Dissimilar Strength of Nanoconfinement Effect in Polystyrene and Poly(methyl methacrylate) Free Standing Thin Films<sup>1</sup>**, DAVID HSU, WENJIE XIA, JAKE SONG, SINAN KETEN, Northwestern University — Despite substantially similar bulk glass transition temperature ( $T_g$ ) and other bulk properties, polystyrene (PS) and poly(methyl-methacrylate) (PMMA) exhibit characteristically different  $T_g$  depression in the free-standing ultrathin film configuration. The mechanism for this disparate  $T_g$ -nanoconfinement effect due to the free surfaces has not been fully explained. Here we utilize recently established chemically specific coarse grain (CG) models to qualitatively reproduce contrasting thickness dependent  $T_g$  and length scale of enhanced chain relaxation gradient in the interfacial layer. Vibrational mode analysis is utilized to uncover a relationship between the amplitude and frequency of sidechain fluctuations of reduced order models and the degree of  $T_g$ -nanoconfinement. By systematic variation of the distribution of mass in the sidechain versus the backbone, we demonstrate inertia-driven differences in sidechain fluctuations and  $T_g$ -nanoconfinement in the CG model. We hypothesize that mass distribution and sidechain flexibility are governing factors causing PS and PMMA free surface effect differences and also provide insight into broader nanoconfinement phenomena from past experiments.

**10:24AM K38.00011  $T_g$ -Confinement Effects in Polymer Thin Films, Nanotubes, and Nanospheres as Measured by DSC, Ellipsometry and Fluorescence**, JOHN TORKEKELSON, ANTHONY TAN, LAWRENCE CHEN, Northwestern Univ — The effect of nanoscale confinement on the glass transition temperature ( $T_g$ ) of supported and free-standing polymer films has been studied for two decades by various techniques. However, conventional DSC, which is the most common method for measuring  $T_g$  of bulk polymers, is not well suited for such measurements. Here, we demonstrate that  $T_g$ -confinement effects measured by conventional DSC in nanotubes of polymer supported in anodic aluminum oxide (AAO) templates compare well with  $T_g$ -confinement effects measured in supported polymer films by ellipsometry and fluorescence. We further show that  $T_g$ -confinement effect data for nanotubes obtained by fluorescence agree well with data obtained by DSC. Finally, we draw comparisons between the  $T_g$ -confinement behavior of nanoprecipitated polymer nanospheres as measured by fluorescence to  $T_g$ -confinement effects for both supported and free-standing polymer films. The roles, if any, of confinement dimensionality (1-D vs 2-D vs 3-D) and measurement technique on the observed  $T_g$ -confinement effect will be discussed.

**10:36AM K38.00012 Mechanophore activation in a crosslinked polymer matrix via instrumented indentation**, CHELSEA DAVIS, AARON FORSTER, JEREMIAH WOODCOCK, MUZHOU WANG, JEFFREY GILMAN, NIST - Natl Inst of Stds & Tech, MATERIAL MEASUREMENT LABORATORY TEAM — Recent advances in mechanically-activated fluorophores will enable a host of unique scientific challenges and opportunities to be addressed. Several mechanophores (MPs) in polymers have been reported, yet the specific deformation required to activate these molecules in a bulk polymer network has not been sufficiently specified. In an effort to develop the mechano-activation/deformation relationship of a spirolactam-based MP, scratches were applied to a MP-functionalized glassy crosslinked material at varying normal loads and lateral displacement rates. This experimental design allowed strain and strain rate effects to be decoupled. The fluorescence activation was then observed with a laser scanning confocal microscope. Areas of elastic and plastic deformation as well as brittle fracture were observed within each scratch as the normal loading of the indenter increased. The fluorescence intensity increased with increasing strain. Contact mechanics models are employed to demonstrate that relatively high degrees of strain are required to initiate the ring-opening activation transition within the spirolactam-based MP. These self-reporting damage sensors can be incorporated within polymeric coatings to allow real time structural health monitoring for a myriad of applications.

**10:48AM K38.00013 Why the Mechanical Properties of Cross-linked Polydimethylsiloxane Surface Enhance? — A First Principles Study**, ZHIFAN WANG, MENGTING JIN, YANNING ZHANG, Chengdu Green Energy and Green Manufacturing Technology RD Center, BEIJING COMPUTATIONAL SCIENCE RESEARCH CENTER COLLABORATION — Polydimethylsiloxane (PDMS) has been widely used in various areas due to its high flexibility, controllable mechanical properties, brilliant biocompatibility and low cost. Now more work on PDMS focus on tuning its surface physical and chemical properties. Our experimental group has shown that the top surface stiffness of PDMS is significantly enhanced after a surface treatment of hyperthermal hydrogen induced cross-linking (HHIC), without losing its inherent hydrophobicity. To understand why this, we investigated how the HHIC treatment changes the structure of PDMS molecules and chains, by using density functional theory (DFT) calculations with the nonlocal van der Waals interaction. The elastic and hydrophobic properties of PDMS, before and after the surface treatment, will be discussed then, providing deep understandings on the experimental observations. Our theoretical studies could give insights in the new development of HHIC tuning technology.

### **8:00AM K39.00001 Metabolic interactions and dynamics in microbial communities**, DANIEL SEGRE<sup>1</sup>,

Boston Univ — Metabolism, in addition to being the engine of every living cell, plays a major role in the cell-cell and cell-environment relations that shape the dynamics and evolution of microbial communities, e.g. by mediating competition and cross-feeding interactions between different species. Despite the increasing availability of metagenomic sequencing data for numerous microbial ecosystems, fundamental aspects of these communities, such as the unculturability of many isolates, and the conditions necessary for taxonomic or functional stability, are still poorly understood. We are developing mechanistic computational approaches for studying the interactions between different organisms based on the knowledge of their entire metabolic networks. In particular, we have recently built an open source platform for the Computation of Microbial Ecosystems in Time and Space (COMETS), which combines metabolic models with convection-diffusion equations to simulate the spatio-temporal dynamics of metabolism in microbial communities. COMETS has been experimentally tested on small artificial communities, and is scalable to hundreds of species in complex environments. I will discuss recent developments and challenges towards the implementation of models for microbiomes and synthetic microbial communities.

### **8:36AM K39.00002 Gene Expression Noise, Fitness Landscapes, and Evolution<sup>1</sup>**, DANIEL

CHARLEBOIS, Laufer Center for Physical and Quantitative Biology, Stony Brook University — The stochastic (or noisy) process of gene expression can have fitness consequences for living organisms. For example, gene expression noise facilitates the development of drug resistance by increasing the time scale at which beneficial phenotypic states can be maintained [1]. The present work investigates the relationship between gene expression noise and the fitness landscape [2]. By incorporating the costs and benefits of gene expression, we track how the fluctuation magnitude and timescale of expression noise evolve in simulations of cell populations under stress. We find that properties of expression noise evolve to maximize fitness on the fitness landscape, and that low levels of expression noise emerge when the fitness benefits of gene expression exceed the fitness costs (and that high levels of noise emerge when the costs of expression exceed the benefits). The findings from our theoretical/computational work offer new hypotheses on the development of drug resistance, some of which are now being investigated in evolution experiments in our laboratory using well-characterized synthetic gene regulatory networks in budding yeast.
