**T1.00037 Boson peak, Ioffe-Regel Crossover, and Liquid-Liquid phase transition in Supercooled Water** , PRADEEP KUMAR, Univ of Arkansas-Fayetteville — We have investigated the onset of Boson peak in a model of liquid water which exhibits a clear first-order phase transition between a low-density liquid phase and a high-density liquid phase of water at low temperature and high pressure. We find that the at low pressures, the onset of Boson peak coincides with the Widom-line of the system. At high pressures, the onset occurs at the transition temperature between the two liquids. Furthermore, we show that at both low and high pressure, the frequency of the Boson peak coincides with the Ioffe-Regel crossover of the transverse phonons, suggesting that the breakdown of Debye behavior is a general feature of Ioffe-Regel limit crossover in supercooled water. The frequency of the Boson peak is weakly pressure dependent and decreases with increasing pressure. Our work bridges gap between the experimental results on the Boson peak nanoconfined water and the behavior that one would expect from a bulk system.

**T1.00038 Testing and using the Lewin-Lieb bounds in density functional theory<sup>1</sup>**, DAVID FEINBLUM, Department of Chemistry, University of California, Irvine, JOHN KENISON, Department of Physics and Astronomy, University of California, Irvine, KIERON BURKE, Department of Chemistry, University of California, Irvine — Lewin and Lieb have recently proven several new bounds on the exchange-correlation energy that complement the Lieb-Oxford bound. We test these bounds for atoms, for slowly-varying gases, and for Hooke's atom, finding them usually less strict than the Lieb-Oxford bound. However, we also show that, if a generalized gradient approximation (GGA) is to guarantee satisfaction of the new bounds for all densities, new restrictions on the exchange-correlation enhancement factor are implied.

<sup>1</sup>We thank Mathieu Lewin and Elliott Lieb for bringing their new bounds to our attention, and Eberhard Engel for developing the OPMKS atom code. This work was supported by NSF under grant CHE-1112442.

**T1.00039 Ab-Initio Modeling of Embedded Subsystems that Exchange Energy and Charge with the Environment**, MICHELE PAVANELLO, Rutgers University-Newark — We claim that a subsystem formulation of Density-Functional Theory simplifies both the theoretical framework and the computational effort for calculating the electronic structure of condensed phase systems. In addition, the naturally subsystem-like form of molecular aggregates makes subsystem DFT a better descriptor of the underlying physics than regular DFT of the supersystem. Our claims are substantiated by simulations of embedded ground and excited states (including charge transfer) of liquids, crystals, and layered systems. By suppressing the inter-subsystem self-interaction error inherent in the exchange-correlation functional, subsystem DFT yields substantially improved simulations compared to Kohn-Sham DFT at a fraction of the computational cost - achieving a dual saving: time to the researcher, and energy to our planet.

**T1.00040 Correcting for the Self-Interaction Error in Ab-Initio Molecular Dynamics Simulations**, ALESSANDRO GENOVA, Rutgers University - Newark, DAVIDE CERESOLI, CNR, ISTM, ALISA KRISHTAL, MICHELE PAVANELLO, Rutgers University - Newark — The Self-Interaction Error (SIE) in semilocal Kohn-Sham (KS) DFT is omnipresent and it can strongly affect the quality of the properties predicted by ab-initio molecular dynamics (AIMD). Liquid water offers two good examples of this behavior: (1) semilocal KS-DFT overestimates the hydrogen bond strength resulting in an overly structured liquid, similar to ice; (2) in the case of solvated radical species, such as OH, KS-DFT exhibits unphysical spin density leakage to neighboring water molecules. We identify the cause of such behavior to be the SIE in the interaction between different molecules (rather than within). Unfortunately, it is a challenge to only rid of the SIE in the intermolecular interactions without introducing spurious corrections for the intramolecular interactions. Semilocal formulations of subsystem DFT offer an elegant solution to this problem: they remove the intermolecular self interaction, and result in an optimal description of liquid water and solvated OH radical, as compared against the experiment. In addition, the subsystem DFT simulations involve a much reduced computational effort compared to KS-DFT. [1] A. Genova et al., JCP 2014, 141, 174101 [2] A. Genova et al., JPCM 2015, Accepted

**T1.00041 Time-dependent Liouville density functional theory for laser-induced ultrafast demagnetization in ferromagnets<sup>1</sup>**, GUOPING ZHANG, Department of Physics, Indiana State University, Terre Haute, IN 47809, USA, YIHUA BAI, Office of Information Technology, THOMAS F GEORGE, University of Missouri-St. Louis — Abstract: The traditional time-dependent density functional theory is very powerful to simulate the dynamic process, but is very time consuming. When it was first used to understand laser-induced ultrafast demagnetization in ferromagnets, the results were disappointing, with the laser amplitude at least three orders of magnitude larger than the experimental one to achieve the similar spin reduction. We develop a new theory within the density functional theory (DFT) for laser-induced ultrafast demagnetization in ferromagnets. We first solve the Liouville equation in the time domain and then feed the excited state density into the DFT code, so the dynamics proceeds on the excited and constraint potential surface. We test this for several magnetic systems and find a significantly larger demagnetization than the static approach, but is still smaller than the experimental finding. Both the local density approximation and the generalized gradient approximation fail. Our finding strongly suggests that a new functional must be developed. As a first test, we introduce a spin power scaling method. Some primitive results will be presented.

**T1.00042 Magnetic Exchange Couplings in Heterodinuclear Transition Metal Complexes based on Differential Local Spin Rotations<sup>1</sup>**, RAJENDRA JOSHI, Department of Physics and Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA, JORDAN PHILLIPS, Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA, JUAN PERALTA, Department of Physics and Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA — We assess the performance of a new method based on a generalized perturbative approach, which uses differential local spin rotations for the calculation of magnetic exchange couplings for the case of heterodinuclear transition metal complexes of Cu, Ni, and V. These types of complexes pose a challenge for estimating exchange couplings, mainly due to the asymmetrical spin on the metal centers and the different mapping schemes that can be applied to such systems. The reliability of calculated couplings has been examined by comparing with couplings obtained from the broken symmetry (BS) energy differences method with different exchange correlational functionals, and experimental values. Results show that our method to calculate magnetic exchange couplings can be reliably employed with heterodinuclear complexes, and gives results similar to BS energy differences, when a proper mapping is used.

**T1.00043 Large-Scale Hybrid Density Functional Theory Calculations in the Condensed-Phase: *Ab Initio* Molecular Dynamics in the Isobaric-Isothermal Ensemble<sup>1</sup>**, HSIN-YU KO, BISWAJIT SANTRA, Princeton University, ROBERT A. DISTASIO JR, Cornell University, XIFAN WU, Temple University, ROBERTO CAR, Princeton University — Hybrid functionals are known to alleviate the self-interaction error in density functional theory (DFT) and provide a more accurate description of the electronic structure of molecules and materials. However, hybrid DFT in the condensed-phase has a prohibitively high associated computational cost which limits their applicability to large systems of interest. In this work, we present a general-purpose order(N) implementation of hybrid DFT in the condensed-phase using Maximally localized Wannier function; this implementation is optimized for massively parallel computing architectures. This algorithm is used to perform large-scale *ab initio* molecular dynamics simulations of liquid water, ice, and aqueous ionic solutions. We have performed simulations in the isothermal-isobaric ensemble to quantify the effects of exact exchange on the equilibrium density properties of water at different thermodynamic conditions. We find that the anomalous density difference between ice Ih and liquid water at ambient conditions as well as the enthalpy differences between ice Ih, II, and III phases at the experimental triple point (238 K and 20 Kbar) are significantly improved using hybrid DFT over previous estimates using the lower rungs of DFT. **T1.00044 Calibration of a cavity ring down spectrometer and nephelometer using polystyrene spheres and Mie theory**<sup>1</sup>, KHALIL MCMILLAN, SUJEETA SINGH, MARC FIDDLER, SOLOMON BILILIGN, North Carolina AT State Univ — The extinction and scattering cross section of 700 nm polystyrene spherical particles are measured in the 500-660 nm light wavelength range using CRD (Cavity Ring Down) Spectroscopy and an integrating nephelometer. The measurement using spherical particles can be compared with Mie theory predictions to evaluate sources of errors in the system in order to use the system for studying real aerosols. Measurement of optical properties of aerosols such as absorption and scattering cross sections and single scattering albedo are important to quantify the radiative properties of aerosols for climate models.

<sup>1</sup>We acknowledge the support of NSF through grant number AGS1262876

**T1.00045 Investigation of Growth Patterns due to Environmental Factors on the Surface of Bivalve shells with LIBS and Raman Spectroscopy**<sup>1</sup>, ANDRIA PALMER, JOSEPH MAYS, JAMES AMOS, TOM DYNKA, LASZLO UJJ, University of West Florida — Environmental disturbances (such as temperature or chemical disturbances) can cause bivalve mollusk shells to grow faster or slower and cause changes in color and surface ring pattern. We have selected a few shells from our local habitat in Pensacola Beach, FL to analyze without sample treatment to determine what factors may have come into play during growth and use this as a way to analyze our marine environment. Laser Induced Breakdown Spectroscopy (LIBS) uses high energy laser pulses (355 and 532nm) to ablate the sample and create a micro-plasma from which emission spectra can be recorded. Based upon the analysis of intensities, wavelengths, and band patterns of spectral emission bands, the spatial qualitative elemental composition of the shell samples can be determined. Raman spectra were also recorded and correlated to molecules in the sample. By analyzing these measurements using LIBS-Raman spectroscopic techniques, we will be able to see how the local environment is effecting growth, with the largest chemical disturbance in the area being the BP Oil Spill in the Gulf in 2010. Therefore if samples are selected from this period of time it may be possible to identify the effects on shell growth.

**T1.00046 Encaged molecules in external electric fields: a molecular ‘tug-of-war’**<sup>1</sup>, RAJEEV PATHAK, NALINI GURAV, SHRIDHAR GEJJI, University of Pune, LIBERO BARTOLOTTI, East Carolina University — We investigate applying ab initio theoretical methods, the molecules Hydrogen peroxide, H<sub>2</sub>O<sub>2</sub>, and Methanol, CH<sub>3</sub>OH, encaged in hydrogen-bonded water “buckyballs” (H<sub>2</sub>O)<sub>20</sub>, subjected to an externally applied electric field. While the water-cage (host) tends to confine the guest-molecule, the external electric field tends to stretch it along with its labile hydrogen-bonded host, resulting into a molecular ‘tug-of-war’. We appraise these two competing effects in terms of the extent of ‘screening’ of the host by the cage and compare the response of the composite system in the form of the consequent structural mutations, redistributions in the electron density and the electrostatic potential leading to emergence and suppression of the covalent O-H characteristic frequency shifts in the infra-red vibrational spectrum. This study brings forth the cooperative effect of hydrogen-bonding up to a maximally sustainable threshold electric field, beyond which fragmentation of the water cage occurs.

**T1.00047 Insights into reactivity properties of the ground state structures of (CuS)<sub>x</sub> (x=1-7) using DFT**, JONATHAN LUQUE CEBALLOS, ALVARO POSADA AMARILLAS, Dpto. de Investigacin en Fsica, Univesidad de Sonora, Hermosillo, Sonora — The extraordinary properties of nanoscale materials have generated an enormous interest in the study of nanomaterials, because of the difference of their properties as compared to the corresponding bulk materials. Polyatomic nanomaterials have become important in recent years, due to the possibility of synthesize new materials with similar or better physical and chemical properties, than those of the monoatomic materials, or with a lower cost, to be used in technological applications in medicine, biology, electronics, or catalysis. Among these materials, copper sulfide is one of the transition metal chalcogenides that exhibits different stoichiometric forms with crystal structure varying from orthogonal to hexagonal. In this work we obtained the ground state structures of copper sulfide nanoparticles (CuS)<sub>x</sub>, x=1-7. The corresponding frontier orbitals (HOMO and LUMO) are analyzed, and different reactivity parameters are obtained. We also present the molecular electrostatic potential, which is used to determine the higher and lower electron density regions on the clusters’ structure. All calculations were performed using the TZVP basis set for S and the Christianssen-Ermeler pseudopotential for Cu, employing two different exchange-correlation functionals, PBE and PBE0.

**T1.00048 Theoretical Study of Carborane:Pyridine and Carborane:Pyrimidine Aggregates and Polymers.**, YI GAO, ZHONG-KANG HAN, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, NAN SHAO, WAI-NING MEI, University of Nebraska-Omaha — The carboranes are cross-linked by the pyridines and pyrimidines to form aggregates and polymers. Their geometries and electronic structures are studied by the first-principle calculations. Our results show different connections influence the orientations of the aromatic rings of pyridines and pyrimidines, which would highly affect the electronic structures of carborane:pyridine and carborane:pyrimidine aggregates and polymers. This study might be helpful for the future design of new class of semiconducting boron carbides.

**T1.00049 INTERACTION OF BORON CLUSTERS WITH OXYGEN: A DFT STUDY**<sup>1</sup>, KAMRON SALAVITABAR, West Chester Univeristy of Pennsylvania, KIRAN BOGGAVARAPU, McNeese State University, ANIL KANDALAM, West Chester Univeristy of Pennsylvania — A controlled combustion involving aluminum nanoparticles has often been the focus of studies in the field of solid fuel propellants. However very little focus has been given to the study of boron nanoparticles in controlled combustion. In contrast to aluminum nanoclusters, boron nanoclusters (B<sub>n</sub>) are known to exhibit a planar geometries even at the size of  $n = 19 - 20$ , and thus offer a greater surface area for interaction with oxygen. Earlier experimental studies have shown that boron nanoclusters exhibit different reactivity with oxygen depending on their size and charge. In this poster, we present our recent density functional theory based results, focusing on the reactivity patterns of neutral and negatively charged B<sub>5</sub> cluster with O<sub>n</sub>, where  $n = 1 - 5$ ; and B<sub>6</sub> cluster with O<sub>n</sub> ( $n = 1 - 2$ ). The effect of charge on the reactivity of boron cluster, variation in the stability of product clusters, i.e., neutral and negatively charged B<sub>5</sub>O<sub>n</sub> ( $n = 1 - 5$ ) and B<sub>6</sub>O<sub>n</sub> ( $n = 1 - 2$ ) are also examined.

<sup>1</sup>Financial Support from West Chester University Foundation under FaStR grant is acknowledged.

**T1.00050 High Temperature Raman Spectroscopy Study of the Conversion of Formate into Oxalate: Search for the Elusive  $\text{CO}_2^{2-}$  Intermediate**, CHARLES RYAN, ANNA MEAD, PRASAD LAKKARAJU, Georgian Court University, Dept. of Chemistry, JERRY KACZUR, Liquid Light Chemical Corp., CHRISTOPHER BENNETT<sup>1</sup>, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — Research on conversion of carbon dioxide into chemicals and fuels has the potential to address three problems of global relevance. (a) By removing carbon dioxide from the atmosphere, we are able to reduce the amount of greenhouse gases in the atmosphere, (b) by converting carbon dioxide into fuels, we are providing pathways for renewable energy sources, (c) by converting carbon dioxide into C2 and higher order compounds, and we are able to generate valuable precursors for organic synthesis. Formate salts are formed by the electrochemical reduction of carbon dioxide in aqueous media. However, in order to increase the utilization of carbon dioxide, methods need to be developed for the conversion of formate into compounds containing two carbon atoms such as oxalate or oxalic acid. Recently, we examined the thermal conversion of sodium formate into sodium oxalate utilizing a hydride ion catalyst. The proposed mechanism for this reaction involves the carbon dioxide dianion.

**T1.00052 Energy of the quasi-free electron in hydrogen, deuterium and oxygen: Probing intermolecular potentials within the local Wigner-Seitz model**<sup>1</sup>, KAMIL KRYNSKI, Department of Chemistry and Biochemistry and Department of Physics, Queens College – CUNY, ZACHARY STREETER<sup>2</sup>, School of Sciences, University of Louisiana at Monroe, CHERICE EVANS, Department of Chemistry and Biochemistry, Queens College – CUNY and Department of Chemistry, Graduate Center – CUNY, GARY L. FINDLEY, School of Sciences, University of Louisiana at Monroe — We present for the first time the quasi-free electron energy  $V_0(\rho)$  for  $\text{H}_2$ ,  $\text{D}_2$  and  $\text{O}_2$  from gas to liquid densities, on noncritical isotherms and on a near critical isotherm in each fluid. These data illustrate the ability of field enhanced photoemission (FEP) to determine  $V_0(\rho)$  accurately in strongly optically absorbing fluids (e.g.,  $\text{O}_2$ ) and fluids with extremely low critical temperatures (e.g.,  $\text{H}_2$  and  $\text{D}_2$ ). We also show that the isotropic local Wigner-Seitz model for  $V_0(\rho)$  – when coupled with thermodynamic data for the fluid – can yield optimized parameters for intermolecular potentials, as well as zero kinetic energy electron scattering lengths.

<sup>1</sup>All measurements were performed at the University of Wisconsin Synchrotron Radiation Center. This work was supported by a grant from the National Science Foundation (NSF CHE-0956719).

**T1.00053 Effect of dissolved ions on dipolar correlations in liquid water**, UPAYAN BAUL, The Institute of Mathematical Sciences, C.I.T. Campus, Taramani, Chennai 600113, India, J. MARUTHI PRADEEP KANTH, Vectra LLC, 191, Hamid Building, Mount Road, Chennai 600006, India, RAMESH ANISHETTY, SATYAVANI VEMPARALA, The Institute of Mathematical Sciences, C.I.T. Campus, Taramani, Chennai 600113, India — Structural correlations in liquid water and the effect of dissolved ions on them have generally been characterized through short range density fluctuations. Recent simulation and experimental results have shown that there exists considerably longer ranged ( $> 24$  Angstroms) orientational order in water that can be studied using dipolar correlations. Using extensive molecular dynamics simulations, we show that the spatially long-range nature of such structural correlations are suppressed by the presence of ions, through reduction in co-operativity in orientational fluctuations. At high ( $\geq 2\text{M}$ ) concentrations, strongly solvated ions induce strong perturbations in the hydrogen bond network of water, leading to the formation of bulk like domains with defect sites on boundaries of such domains. Reorientational autocorrelation functions of dipole vectors of water molecules at such defect sites, which are beyond the first hydration shells of ions, also experience significant slowing of reorientation times. Our results show that the effect of ions on the properties of water can propagate well beyond the first solvation shells. Results are discussed in the context of hydrophobic effect and Hofmeister series.

**T1.00054 External dc bias field effects in the nonlinear ac stationary response of permanent dipoles in a uniaxial potential**, NIJUN WEI, WILLIAM T. COFFEY, Department of Electronic and Electrical Engineering, Trinity College, Dublin 2, Ireland, PIRRE-MICHEL DJARDIN, YURI P. KALMYKOV, LAMPS (EA 4217), Universit de Perpignan Via Domitia, France — External dc bias field effects on the nonlinear dielectric relaxation and dynamic Kerr effect of a system of permanent dipoles in a uniaxial mean field potential are studied via the rotational Brownian motion model. Postulated in terms of the infinite hierarchy of differential-recurrence equations for the statistical moments (the expectation value of the Legendre polynomials), the dielectric and Kerr effect ac stationary responses may be evaluated for arbitrary dc bias field strength via perturbation theory in the ac field. We have given two complementary approaches for treating the nonlinear effects. The first is based on perturbation theory allowing one to calculate the nonlinear ac stationary responses using powerful matrix methods. The second approach based on the accurate two-mode approximation [D.A. Garanin, Phys. Rev. E. **54**, 3250 (1996)] effectively generalizes the existing results for dipolar systems in superimposed ac and dc fields to a mean field potential. The results apply both to nonlinear dielectric relaxation and dynamic Kerr effect of nematics and to magnetic birefringence relaxation of ferrofluids. Furthermore, the given methods of the solution of infinite hierarchies of *multi-term* recurrence relations are quite general and can be applied to analogous nonlinear response problems.

**T1.00055 The hydrogen bond network of water supports propagating optical phonon-like modes**<sup>1</sup>, DANIEL ELTON, MARIVI FERNANDEZ-SERRA, Stony Brook University — The local structure of liquid water as a function of temperature is a source of intense research. This structure is intimately linked to the dynamics of water molecules, which can be measured using Raman and infrared spectroscopies. Vibrational modes in liquids are usually considered to be associated to the motions of single molecules or small clusters. Previously, the librational Raman peaks of water were assigned to the librational motions of single molecules. By comparing experimental Raman and IR spectra we show these assignments are problematic. Using molecular dynamics simulations we study the k-dependent dielectric susceptibility of water. We find dispersive optical phonon-like modes in water's librational and OH stretching bands. We argue that on subpicosecond time scales these modes propagate through water's hydrogen bond network over distances of up to two nanometers. In the long wavelength limit these optical modes exhibit longitudinal-transverse splitting, indicating the presence of coherent long range dipole-dipole interactions. Studying how LO-TO splitting evolves with temperature may yield insight into how local structure changes. Our results indicate the dynamics of liquid water have more similarities to ice than previously thought. Reference: arXiv:1507.06363

**T1.00056 Possible Existence of Two Amorphous Phases of D-Mannitol Related by a First-Order Transition**, MEN ZHU, JUN-QIANG WANG, JOHN PEREPEZKO, LIAN YU, University of Wisconsin-Madison — We report that the common polyalcohol D-mannitol may have two amorphous phases related by a first-order transition. Slightly above  $T_g$  (284 K), the supercooled liquid (SCL) of D-mannitol transforms to a low-energy, apparently amorphous phase (Phase X). The enthalpy of Phase X is roughly halfway between those of the known amorphous and crystalline phases. The amorphous nature of Phase X is suggested by its absence of birefringence, transparency, broad X-ray diffraction, and broad Raman and NIR spectra. Phase X has greater molecular spacing, higher molecular order, fewer intra- and more inter-molecular hydrogen bonds than the normal liquid. On fast heating, Phase X transforms back to SCL near 330 K. Upon temperature cycling, it shows a glass-transition-like change of heat capacity. The presence of D-sorbitol enables a first-order liquid-liquid transition (LLT) from SCL to Phase X. This is the first report of polyamorphism at 1 atm for a pharmaceutical relevant substance. As amorphous solids are explored for many applications, polyamorphism could offer a tool to engineer the properties of materials. (Ref: M. Zhu et al, J. Chem. Phys. 2015, 142, 244504)

**T1.00057 Microfaceting of  $\text{Cu}_2\text{O}$  and its implications in photochemistry**, YUNJAE LEE, TAEHUN LEE, YONGHYUK LEE, ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University — The high Miller-index microfacets e.g.  $\{211\}$ ,  $\{311\}$ , and  $\{522\}$  have been proposed to play a key role in shape-controlled crystal engineering of  $\text{Cu}_2\text{O}$  polyhedrons for various clean energy applications. These  $\text{Cu}_2\text{O}$  microcrystals with high Miller-index microfacets are found to have a higher photocatalytic activity than those with octahedra and cube morphologies, and thus suggesting that the catalytically active sites are more abundant on the high Miller-index surfaces. Although much effort has been devoted to the actual synthesis and characterizations of these shaped  $\text{Cu}_2\text{O}$  nanocrystals with various morphologies, a firm theoretical understanding of these system are currently limited to low Miller-index facets of  $\text{Cu}_2\text{O}$ . Here, we perform first-principles density-functional theory (DFT) calculations to study the surface energetics and electronic structure of these high Miller-index  $\text{Cu}_2\text{O}$  surfaces, and evaluate their overpotential for water redox reactions on  $\text{Cu}_2\text{O}$ , in comparison with that for the low Miller-index surfaces.

**T1.00058 Water Adsorption and Dissociation on  $\text{CeO}_2(111)$ .**, YI GAO, ZHONG-KANG HAN, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, NAN SHAO, WAI-NING MEI, University of Nebraska-Omaha — The complexity and flexibility of ceria surface hinders the fully understanding of its reactivity and real applications. Here, we use  $\text{H}_2\text{O}/\text{CeO}_2(111)$  as the model system to investigate the water effect on the electron localization and vacancy diffusion on  $\text{CeO}_2(111)$  surface by the first-principle calculations. Our results indicate the water adsorption would high affect the electronic structures of  $\text{CeO}_2(111)$  surface, which further induce the dissociation of  $\text{H}_2\text{O}$  molecule. This molecular mechanism might provide more guidance to the future applications including the watergas shift reactions.

**T1.00059 Investigating Non-Equilibrium Fluctuations of Nanocolloids in a Magnetic Field Using Direct Imaging Methods<sup>1</sup>**, ASHLEY RICE, ANA OPRISAN, SORINEL OPRISAN, College of Charleston, RICE-OPRISAN COLLEGE OF CHARLESTON TEAM — Nanoparticles of iron oxide have a high surface area and can be controlled by an external magnetic field. Since they have a fast response to the applied magnetic field, these systems have been used for numerous in vivo applications, such as MRI contrast enhancement, tissue repair, immunoassay, detoxification of biological fluids, hyperthermia, drug delivery, and cell separation. We performed three direct imaging experiments in order to investigate the concentration-driven fluctuations using magnetic nanoparticles in the absence and in the presence of magnetic field. Our direct imaging experimental setup involved a glass cell filled with magnetic nanocolloidal suspension and water with the concentration gradient oriented against the gravitational field and a superluminescent diode (SLD) as the light source. Nonequilibrium concentration-driven fluctuations were recorded using a direct imaging technique. We used a dynamic structure factor algorithm for image processing in order to compute the structure factor and to find the power law exponents. We saw evidence of large concentration fluctuations and permanent magnetism. Further research will use the correlation time to approximate the diffusion coefficient for the free diffusion experiment.

**T1.00060 Capillary Condensation in Polymer Blends: an Analysis of Phase Transitions<sup>1</sup>**, CAROLINA C. ILIE, State University of New York at Oswego, Department of Physics, NICHOLAS C. JIRA, IAN R. EVANS, MATTHEW COHEN, JULIA R. D'ROZARIO, MARIE T. ROMANO, ILDAR SABIRIANOV, SUNY Oswego — We explore herein the capillary condensation for various geometries. Capillary condensation is studied in the presence of van der Waals forces. We derive the grand free energy, and we analyze the phase transitions, the absorption isotherms and the triple point. Phase transitions between full, empty and two films are investigated and the shape of the liquid is calculated. We also analyze an important application of wetting phenomena and capillary condensation in binary polymer blends and investigate the type of wetting transitions presented and the phase diagram.

**T1.00062 Frustrated Total Internal Reflection applied to Quantum Tunneling<sup>1</sup>**, NATHANIEL HULL, JIA-AN YAN, Towson Univ — The objective of this project is to demonstrate an optical phenomenon, frustrated total internal reflection (FTIR), by numerically solving the time-dependent Schrodinger equation (TDSE) in quantum mechanics, and to illustrate the correlations between FTIR and the quantum tunneling in one-dimensional quantum structures. We will use a MATLAB program to numerically propagate a Gaussian wave packet to penetrate finite square barriers. The transmission coefficient is then calculated as a function of the distance between two rectangular barriers/wells. The results will be useful to elucidate the correlations between optical FTIR and quantum tunneling.

**T1.00063 Photodissociation Spectroscopy of Ruthenium Polypyridyl Complexes in Vacuo**, SHUANG XU, JAMES SMITH, J. MATHIAS WEBER, JILA/University of Colorado at Boulder — Photoelectrochemical water oxidation is a direct way to produce solar fuels from renewable sources. Since this reaction has a high reaction barrier, a cost-effective catalyst is necessary. Ruthenium polypyridyl complexes are promising catalysts for water oxidation. However, the mechanism of catalytic action is not well understood. One major difficulty of a mechanistic understanding is the complexity of reactive solutions under turnover conditions. To circumvent this problem, we applied electronic photodissociation spectroscopy in the UV and visible spectral range to a series of mass selected ruthenium polypyridyl complex ions in vacuo. The ions in this work are of the form  $[\text{Ru}^{II}\text{-L}]^{2+}$ , where  $\text{Ru}^{II}$  represents ruthenium(II)-bipyridine-terpyridine, a prototype catalyst belonging to the ruthenium-polypyridyl family. By varying the ligand L, we were able to study the ligand influence on the photophysical properties of the complex. The cases where  $\text{L} = (\text{H}_2\text{O})_{1,2,3}$  are of particular interest because they are directly related to an intermediate in the catalytic cycle for water oxidation. Our experiment in vacuo is an essential complement to experiments in solution and provides unique information for understanding the photophysics and photochemistry of these complexes on a molecular level.

**T1.00064 Quantum and Classical Electrostatics Among Atoms<sup>1</sup>**, T. P. DOERR, O.I. BOLENSKY, A. Y. OGURTSOV, YI-KUO YU, National Center for Biotechnology Information — Quantum theory has been unquestionably successful at describing physics at the atomic scale. However, it becomes more difficult to apply as the system size grows. On the other hand, classical physics breaks down at sufficiently short length scales but is clearly correct at larger distances. The purpose of methods such as QM/MM is to gain the advantages of both quantum and classical regimes: quantum theory should provide accuracy at the shortest scales, and classical theory, with its somewhat more tractable computational demands, allows results to be computed for systems that would be inaccessible with a purely quantum approach. This strategy will be most effective when one knows with good accuracy the length scale at which quantum calculations are no longer necessary and classical calculations are sufficient. To this end, we have performed both classical and quantum calculations for systems comprising a small number of atoms for which experimental data is also available. The classical calculations are fully exact; the quantum calculations are at the MP4(SDTQ)/aug-cc-pV5Z and CCSD(T)/aug-cc-pV5Z levels. The precision of both sets of calculations along with the existence of experimental results allows us to draw conclusions about the range of utility of the respective calculations.

<sup>1</sup>This research was supported by the Intramural Research Program of the NIH, NLM and utilized the computational resources of the NIH HPC Biowulf cluster.

**T1.00065 Single micelle force microscopy reveals the coordination interaction between catechol and Fe3+.**, YIRAN LI, YI CAO, WEI WANG, Nanjing Univ — Metal coordination bonds are widely found in natural adhesive, load-bearing, and protective materials, which are thought to be responsible for their high strength and toughness. However, it remains unknown how the metal-ligand complexes could give rise to such superb mechanical properties. Here, combining single molecule force spectroscopy and quantum calculation, we study the mechanical properties of individual catechol-Fe3+ complexes, the key elements accounting for the high toughness and extensibility of byssal threads of marine mussels. We find that catechol-Fe3+ complexes possess a unique combination of mechanical features, including high mechanical stability, fast reformation kinetics, and stoichiometry-dependent mechanics. Therefore, they can serve as sacrificial bonds to efficiently dissipate energy in the material, quickly recover the mechanical properties when load is released, and be responsive to environmental conditions. Our study provides the mechanistic understanding of the coordination bond-mediated mechanical properties of biogenetic materials, and could guide future rational design and regulation of the mechanical properties of synthetic materials.

**T1.00066 Band-gap opening properties of graphene binding with low-concentration fluorine**, YUHUA DUAN, DOE-National Energy Technology Laboratory, Pittsburgh, PA 15236, CHARTER STINESPRING, Chemical Engineering Department, West Virginia University, Morgantown, WV 25506, USA, BENJAMIN CHORPENING, DOE-National Energy Technology Laboratory, Pittsburgh, PA 15236 — To better understand the effects of low-level fluorine (F) in graphene-based sensors, the structure and impact of low-concentration of fluorine defects on the electrical properties of single- and multi-layer graphene films were investigated by density functional theory with van der Waals dispersion interactions. When F bonds to a carbon atom of graphene, the carbon atom is pulled slightly above the graphene plane creating what is referred to as a C<sub>F</sub> defect, and a valence band (B<sub>F</sub>) near the Fermi level is formed mainly from the *p* orbitals of the F atoms with some small contribution from the *p* orbitals of the bonded carbon atoms. Depending on the F binding sites, the B<sub>F</sub> can serve as a valence band or a conduction band and only few configurations of the F-binding graphene can open a band gap. Such results indicate that the band gap opening for graphene with low F-adsorption level strongly depends on the F-binding configurations, which is different from the fully or highly partial fluorinated graphene. At low F-adsorption level, the interaction between neighboring pairs of F adatoms is negligible and the most important interaction is between the F and carbon atoms in the C<sub>F</sub> defect. Such results are useful for sensor and nano-electronics developments.

**T1.00067 A simple model for electronic properties of surface adsorbed molecules.**, RAJESH DHAKAL, WILLIAM SCHWALM, Univ of North Dakota — We adapt a minimal approximation to one electron quantum theory of molecules referred as Fast Accurate Kinetic Energy method. This in principle handles large complex molecular structures with less computational effort to compute electronic properties of adsorbed molecules. Kinetic energy integrals are calculated accurately but multi-electron potential energy integrals are approximated. The neighboring atom interactions are included also. For layers of isophthalic acids formed on pyrolytic graphite the configuration changes as a function of length of hydrocarbon tails. We study properties of this system as a function of tail length.

**T1.00068 Spectroscopic Studies on Graphenes Dispersed Within Polymeric Matrices<sup>1</sup>**, FILIPE FERREIRA, FELIPE BRITO, Instituto Tecnológico de Aeronáutica, So Jos dos Campos-SP, Brazil, DORINA CHIPARA, The University of Texas Rio Grande Valley, PULLICKEL AJAYAN, Rice University, WESLEY FRANCISCO, Instituto Tecnológico de Aeronáutica, So Jos dos Campos-SP, Brazil, CRISTIAN CHIPARA, Rice University, EVELYN SIMONETTI, Instituto Tecnológico de Aeronáutica, So Jos dos Campos-SP, Brazil, CHARLES CARTWRIGHT, The University of Texas Rio Grande Valley, LUCIANA CIVIDANES, Instituto Tecnológico de Aeronáutica, So Jos dos Campos-SP, Brazil, JAMES HINTHORNE, The University of Texas Rio Grande Valley, GILMAR THIM, Instituto Tecnológico de Aeronáutica, So Jos dos Campos-SP, Brazil, ROBERT VAJTAI, Rice University, MIRCEA CHIPARA, The University of Texas Rio Grande Valley, INSTITUTO TECNOLÓGICO DE AERONÁUTICA COLLABORATION, THE UNIVERSITY OF TEXAS PAN AMERICAN COLLABORATION, RICE UNIVERSITY COLLABORATION — Graphenes have been dispersed within various polymeric matrices (polyethylene, polyethylene oxide, polystyrene, and epoxy resins). Some have been used as purchased (pristine and functionalized graphene platelets from Cheap Tubes). Pristine and functionalized graphene oxides have been obtained in laboratory according to W. Hummers, R. Offeman, ("Preparation of Graphitic Oxide". J Am Chem Soc **80**, 6, 1339, 1958) and by original functionalization processes. All these samples were investigated by Raman spectroscopy using a Renishaw InVia spectrometer operating at 532 and 785 nm. Additional information has been obtained by Wide Angle X-Ray Scattering using a Bruker Discover 8 spectrometer. Raman spectra have been fitted by a convolution of modified Breit-Wigner-Fano line shapes and the main parameters (position, intensity, width, asymmetry factor) of each line are discussed. The research aims to a better identification of graphene related nanostructures isolated or dispersed within polymeric matrices by Raman spectroscopy.

**T1.00069 Study of near surface Nitrogen vacancy center (NV<sup>-</sup>) neutralization in diamond<sup>1</sup>**, ABU NAIM RAKIB AHMED, ARTHUR NEWELL, DONTRAY DOWDELL, DEBORAH SANTAMORE, Delaware State Univ — The performance of nitrogen vacancy based sensors strongly depends on the population of NV<sup>-</sup> near the diamond surface. The magnetic sensing capabilities of NV<sup>-</sup> diamonds are diminished as the NV<sup>-</sup> becomes neutralized and turns into NV<sup>0</sup>, where NV<sup>0</sup> represents the neutralized charge state of NV<sup>-</sup>. A theoretical calculation is performed to obtain the electron transfer rate between the NV<sup>-</sup> and surface molecules using the Marcus theory of electron transfer where reorganization energy and electronic wave function coupling are considered. The electronic wave function coupling is determined using the density functional theory method. Band structure simulation is also performed to confirm the NV<sup>-</sup> neutralization at the surface due to surface termination. The electron transfer rate is investigated for various surface terminations (hydrogen, oxygen). Moreover, an investigation of the stability of the NV<sup>-</sup> at different depths relative to the surface is conducted. This work provides the ratio of NV<sup>-</sup> to (NV<sup>0</sup>+NV<sup>-</sup>) at equilibrium, which demonstrates the effect of surface termination and contamination on NV<sup>-</sup> neutralization and also depicts surface properties of NV<sup>-</sup> diamonds.

**T1.00070 Electronic structure of novel charge transfer compounds: application of Fermi orbital self-interaction corrected density functional theory<sup>1</sup>**, TORSTEN HAHN, Institute for Theoretical Physics, TU Freiberg, 09599 Freiberg, Germany, FLORIAN RCKERL, Institute for Solid State Research, IFW-Dresden, P.O. Box 270116, DE-01171 Dresden, Germany, SIMON LIEBING, Institute for Theoretical Physics, TU Freiberg, 09599 Freiberg, Germany, MARK PEDERSON, Department of Chemistry, Johns Hopkins University, Baltimore, Maryland 21218, USA — We present our experimental and theoretical results on novel Picene/F4TCNQ and Manganese-Phthalocyanine/F4TCNQ donor / acceptor systems. We apply the recently developed Fermi-orbital based approach for self-interaction corrected density functional theory (FO-SIC DFT) to these materials and compare the results to standard DFT calculations and to experimental data obtained by photoemission spectroscopy. We focus our analysis on the description of the magnitude of the ground state charge transfer and on the details of the formed hybrid orbitals. Further, we show that for weakly bound donor / acceptor systems the FO-SIC approach delivers a more realistic description of the electronic structure compared to standard DFT calculations. [1] M. R. Pederson, A. Ruzsinszky, and J. P. Perdew, J. Chem. Phys. 140, 121103 (2014). [2] M. R. Pederson, J. Chem. Phys. 142, 064112 (2015).

**T1.00071 Au nanoparticles improve amorphous carbon to be gas sensors**, KENG-WEN LIU, JIAN-HENG LEE, HSIUNG CHOU, TZU-CHING LIN, SI-TING LIN, Dept. of Physics, NSYSU, Kaohsiung 804, Taiwan, SHIH-JYE SUN COLLABORATION<sup>1</sup> — In order to make the amorphous carbon possess the gas sensing capability transferring some sp<sup>3</sup> orbits to sp<sup>2</sup> is necessary. It is proposed that the metallic materials having a large charge exchange with sp<sup>3</sup> carbon orbits are being catalysts to transfer the carbon orbits. We found embedding gold nanoparticles to the amorphous carbon will induce many compact sp<sup>2</sup> orbits around the nanoparticles, which make the amorphous carbon be the candidate material for the gas sensors. The orbits of amorphous carbon near the interface of Au nanoparticles can be changed from sp<sup>3</sup> to compact sp<sup>2</sup> to reduce the surface energy of Au nanoparticles. Meanwhile, our molecular dynamics simulation has confirmed the fact, when an Au nanoparticle is embedded in the amorphous carbon system the ratio of sp<sup>2</sup> orbits increases dramatically. Similar results also have been confirmed from the Raman spectrum measurements. We controlled the carrier transport by changing the hopping barriers formed by amorphous carbon matrix between the Au nanoparticles to modify the resistance. These nanocomposites exhibit a superior sensitivity to NH<sub>3</sub> at room temperature as well as good reproducibility and short response/recovery times, which could have potential applications in gas sensors.

## T1.00072 INSULATORS AND DIELECTRICS —

**T1.00073 Spin-charge separation of edge zero modes in one dimension**, ZHANG DANBO, WANG ZIDAN, Department of Physics, The University of HongKong — We propose a new type of edge zero modes that exhibit spin-charge separation, which can be realized at the boundaries in an exotic one dimensional topological matter that is both fermionic Haldane insulator and topological superconductor. We give a lattice model to illustrate the nature of edge zero modes, both from bosonization and mean-field analysis. Finally, We find that Haldane phase of spin-1 chain also owns spin-charge separation of edge zero modes when mapped into fermionic system by Jordan-Wigner transformation.

**T1.00074 Triggering Incipient Ferroelectricity in Calcium Copper Titanate (CaCu<sub>3</sub>Ti<sub>4</sub>O<sub>12</sub>) ceramics through partial B-site substitution with Te<sup>4+</sup> ion.**, NABADYUTI BARMAN, student, K.B.R VARMA, Retired — Double perovskite structured dielectric ceramic CaCu<sub>3</sub>Ti<sub>4-x</sub>Te<sub>x</sub>O<sub>12</sub> (CCTTO) ( $x = 0, 0.05, 0.1, 0.15, 0.2$ ) was fabricated from the powder obtained by conventional solid state synthetic route. The room temperature XRD patterns for the  $x = 0, 0.05, 0.075$  modified samples were confirmed to possess a single phase with cubic space group  $Im\bar{3}$  by Rietveld refinement. But, the Rietveld refinement performed on XRD patterns recorded for the compositions corresponding to  $x = 0.1, 0.15, 0.2$  shows the coexistence of the cubic phase (space group  $Im\bar{3}$ ;  $a = 7.4065\text{\AA}$ ) and tetragonal phase (space group  $I4/mcm$ ;  $a = 7.369\text{\AA}$  and  $c = 6.967\text{\AA}$ ). The dielectric properties of these ceramics were studied over a wide frequency (40Hz–2MHz) and temperature range (30–400K). The Te<sup>4+</sup> doped samples (CCTTO) exhibited dielectric permittivity ( $\epsilon_r$ ) value of  $\sim 23\text{--}33 \times 10^3$  which is more than twice that of undoped CCTO ( $\sim 11 \times 10^3$ ) at 1kHz. A decreasing trend in dielectric permittivity with increasing temperature, a signature of incipient ferroelectricity, was observed for all the samples. Barrett's formula was invoked to rationalize the dielectric permittivity variation as a function of temperature. The incipient ferroelectric behavior is correlated with soft phonon mode observed in temperature dependent Raman Spectroscopic studies. .

**T1.00075 Electric and Magnetic Characterization of patterned La<sub>0.6</sub>Sr<sub>0.4</sub>MnO<sub>3</sub>/SrTiO<sub>3</sub>/Si junctions using strained SrTiO<sub>3</sub> as a Ferroelectric Barrier.**, PARISA JALILI SHAFIGHI, RYAN COTTIER, DANIEL A CURRIE, BARRY D KOEHNE, Texas State university, San Marcos, ANDREW JOHNSON, JOSHUA P VEAZEY, Hope College, Holland, MI, NIKOLETA THEODOR-POULOU, Texas State university, San Marcos, TEXAS STATE UNIVERSITY, SAN MARCOS, TX TEAM, HOPE COLLEGE, HOLLAND, MI TEAM — Controlling a magnetic device via electrical means is a sought-after goal for technological devices and can be achieved through magnetoelectric coupling between ferroelectric and ferromagnetic materials. We investigate such as possibility through a by epitaxially growing a magnetic oxide, La<sub>0.6</sub>Sr<sub>0.4</sub>MnO<sub>3</sub> (LSMO) as an active magnetic electrode on a ferroelectric oxide, strained SrTiO<sub>3</sub> (STO) on Si. STO thin films grown on Si are compressively strained (1.7 %) and can be ferroelectric at T=300 K when less than 5nm thick. LSMO is ferromagnetic up to 340 K (in bulk), has an in-plane crystal constant of  $a = 0.3870\text{ nm}$ , and is closely lattice matched to STO ( $a = 0.3905\text{ nm}$ ) with a 0.9% in-plane tensile strain. Since STO is compressively strained in Si, an even smaller lattice mismatch is expected between LSMO and STO/Si. We investigate the epitaxial growth of LSMO/STO/Si and electrical characteristics in a capacitor type structure fabricated using photolithography as a function of Temperature and Magnetic Field. Acknowledgements: Support by the NSF-Career grant, DMR-1255629, Hope College Frissel Research Fund, NSF-MRI Grant, CHE-1126462 is gratefully acknowledged.

**T1.00076 Observation of ferroelectricity at room temperature in  $\sim 1\text{ nm}$  thick conducting BaTiO<sub>3- $\delta$</sub>** , SEUNGRAN LEE, KRISS, Daejeon 305-350, Rep. of Korea, L. BAASANFORJ, Uni. of Sci. and Tech., Daejeon 305-350, Rep. of Korea, JUNGWON CHANG, Dept. of Display and Semiconductor Physics, Korea University, Sejong 339-700, Rep. of Korea, INWOONG HWANG, Dept. of Physics, Chungnam Nat'l Uni., Daejeon 305-764, Rep. of Korea, JUNGRAE KIM, CCES-IBS, Seoul 151-742, Rep. of Korea, SEUNGBO SHIM, KRISS, Daejeon 305-350, Rep. of Korea, JONGHYUN SONG, Dept. of Physics, Chungnam Nat'l Uni., Daejeon 305-764, Rep. of Korea, JINHEE KIM, KRISS, Daejeon 305-350, Rep. of Korea — Efforts to search for new and multi-functionalities in thin-film systems have led important findings of unknown phenomena and functionality which do not appear in bulk systems. As film growth technique is advanced, one can decrease the film thickness even thinner down to  $\sim \text{nm}$ , its unique physical properties are still appearing. For example, the superconducting metallic state of an LaAlO<sub>3</sub>/SrTiO<sub>3</sub> (LAO/STO) heterostructure was found where LAO is about 3-4 unit cells (uc). An SrRuO<sub>3</sub> film exhibited its ferromagnetic metallicity down to 4-6 uc; a few years later, its ferromagnetism was found to be disappeared at 2-3 uc. Meanwhile, theoretical methods have predicted existence of ferroelectrical properties mostly in prototype ferroelectric BaTiO<sub>3</sub> (BTO): 3-6 uc. However, experimental verification to find such predicted thickness was hindered by large leakage current. Here we observed that  $\sim 1\text{ nm}$ -thick conducting BTO fillms show ferroelectric switching at room temperature (RT), and BTO films are fully-strained on LAO/STO heterostructures thicker than 5 nm thickness. Our experimental results will enlarge applicable functional oxide devices for future applications.

**T1.00077 Optical Properties and Electronic Transitions of  $\text{YbFe}_2\text{O}_4$  Thin Films**<sup>1</sup>, JOSH HINZ, MICHELLE PASCOLINI, RAM RAI, Physics Department, SUNY Buffalo State, 1300 Elmwood Ave., Buffalo, NY 14222 — We present growth, structural, optical and electronic properties of Ytterbium-Iron-oxide,  $\text{YbFe}_2\text{O}_4$ , thin films.  $\text{YbFe}_2\text{O}_4$  exhibits the unique physical properties due to the presence of  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  valence states within the triangular lattice structure. We prepared the compound by a solid state reaction starting with stoichiometric proportion of  $\text{Yb}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{FeO}$ . The material was then deposited on c-axis sapphire substrates using a reactive electron beam deposition technique to produce ~100 nm thick films. Absorption, reflectance, and transmittance of the  $\text{YbFe}_2\text{O}_4$  films were measured in the temperature range of 10 – 450 K. The optical spectra contain Fe d to d on-site transitions as well as O 2p to Fe 3d, Yb 6s, and Yb 5d charge-transfer transitions. In addition, the optical spectra exhibit strong temperature dependence, indicating evidence of a structural distortion of the crystal structure at ~180 K as well as a magnetic transition at ~250 K. The detail analysis of the optical data in comparison with theoretical studies will be presented.

<sup>1</sup>National Science Foundation (DMR-1406766)

**T1.00078 Structure and Magnetic Properties of Rare Earth Doped Transparent Alumina**, KRISTA LIMMER, MAHESH NEUPANE, TANYA CHANTAWANSRI, US Army Rsch Lab - Aberdeen — Recent experimental studies of rare earth (RE) doped alumina suggest that the RE induced novel phase-dependent structural and magnetic properties [1]. Motivated by these efforts, the effects of RE doping of alpha and theta alumina on the local structure, magnetic properties, and phase stability have been examined in this first principles study. Although a direct correlation between the magnetic field dependent materials properties observed experimentally and calculated from first principles is not feasible because of the applied field and the scale, the internal magnetic properties and other properties of the doped materials are evaluated. The RE dopants are shown to increase the substitutional site volume as well as increasingly distort the site structure as a function of ionic radii. Doping both the alpha (stable) and theta (metastable) phases enhanced the relative stability of the theta phase. The energetic doping cost and internal magnetic moment were shown to be a function of the electronic configuration of the RE-dopant, with magnetic moment directly proportional to the number of unpaired electrons and doping cost being inversely related. [1] Pavlacka, Robert, et al. Ceramic Transactions 252: 3, 2015.

**T1.00079 Magnetic and Ferroelectric Anisotropy in Multiferroic  $\text{FeVO}_4$** <sup>1</sup>, EHAB ABDELHAMID, Wayne State U, AMBESH DIXIT, IIT Jodhpur, KENTA KIMURA, TSUYOSHI KIMURA, Osaka U, ONATTU JAYAKUMAR, Bhabah Atomic Research Ctr, VAMAN NAIK, U of Michigan-Dearborn, RATNA NAIK, GAVIN LAWES, BORIS NADGORN, Wayne State U —  $\text{FeVO}_4$  has been studied as a model system for understanding the magnetoelectric interaction mechanisms in low symmetry multiferroics. Triclinic  $\text{FeVO}_4$  is characterized by two antiferromagnetic phase transitions, occurring at  $T_{N1}$  = 22 K and  $T_{N2}$  = 15 K, with the latter transition signaling a break in the space inversion symmetry, accompanied by the development of a non-collinear magnetic order which induces ferroelectricity. Earlier measurements on polycrystalline  $\text{FeVO}_4$  doped with magnetic (Cr and Mn) as well as non magnetic (Zn) dopants indicate the stability of the two antiferromagnetic transition temperatures. In this work, single crystals of both undoped and doped  $\text{FeVO}_4$  were grown from flux. To track the changes in lattice parameters induced by changing the doping concentration (measured by EDAX), XRD and Raman spectra were obtained. By recording the magnetization along two different crystal orientations, we were able to confirm the easy magnetic axis in this structure. Finally, we obtain the crystal's ferroelectric polarization along two different directions in an attempt to further understand the mechanism responsible for the ferroelectric transition.

**T1.00080 Anomalous enhancement of Neel temperature and magnetic coupling for  $\text{Bi}_{0.9}\text{Ca}_{0.1}\text{FeO}_{3-\delta}$  and  $\text{Bi}_{0.9}\text{Pb}_{0.1}\text{FeO}_{3-\delta}$** , GOPESHWAR-DHAR DWIVEDI, KUNG-SHANG YANG, BO-YU CHEN, HSIUNG CHOU<sup>1</sup>, Dept. of Physics, NSYSU, Kaohsiung 804, Taiwan — Temperature dependent neutron diffraction patterns of the Ca-doped  $\text{BiFeO}_3$  and Pb-doped  $\text{BiFeO}_3$  show that their Neel temperatures ( $T_N$ ) increase to 710 K and 680 K, while pure  $\text{BiFeO}_3$  has a  $T_N$  ~643 K. X-ray absorption spectra clearly shows that there is no evidence of mixed valence states despite divalent cation doping in trivalent Bi-sites. X-ray photoemission spectroscopy study revealed that divalent doping has introduced oxygen vacancies in the system. Oxygen deficiency plays a significant role in contracting Fe-O bond length in  $\text{FeO}_6$  octahedra and hence increasing the Fe-O-Fe bond angle in  $\text{Bi}_{0.9}\text{Ca}_{0.1}\text{FeO}_{3-\delta}$  and  $\text{Bi}_{0.9}\text{Pb}_{0.1}\text{FeO}_{3-\delta}$ . The decreased Fe-O bond length and increased Fe-O-Fe bond angle favors the Goodenough-Kanamori-Anderson (GKA) coupling. The GKA coupling increases the magnetic interaction between the spins and hence increases the  $T_N$ . Additionally, doping of divalent cations ( $\text{Ca}^{2+}$  and  $\text{Pb}^{2+}$ ) results in the destruction of cycloidal spin structure and formation of a simple antiferromagnetic (AFM) structure. This structure can easily be canted near the heterogeneous interface with a ferromagnetic layer to induce the Dzyaloshinskii-Moriya (DM) interaction and enhance the magneto-electric (M-E) coupling.

**T1.00081 Phononic Structure Relationships in the Subgroup Phases of Ferroelectric  $\text{Ca}_3\text{Mn}_2\text{O}_7$** , ELVIS SHOKO, EMAN AL DAWOOD, UDO SCHWINGENSCHLOGL, PSE Division, KAUST, Saudi Arabia — The Ruddlesden-Popper (RP) compound,  $\text{Ca}_3\text{Mn}_2\text{O}_7$ , exhibits hybrid improper ferroelectric (FE) behavior in its  $A2_1am$  phase. However, a new phase (space group  $Acaa$ ), co-existing with the FE phase (200-320 K) and exhibiting negative thermal expansion (NTE) was recently discovered. This discovery highlighted the complexity of the phase relationships in the subgroup structure of  $\text{Ca}_3\text{Mn}_2\text{O}_7$ . Successful exploitation of RP compounds for FE applications depends on a clear understanding of the phononic relationships among the different relevant subgroup phases. Accordingly, we have used density functional theory (DFT) to map out the total energy landscape for the principal subgroup phases relative to the tetragonal phase. In order to elucidate the interrelationships of the soft phonon modes among the different subgroup phases, we performed lattice dynamics and quasi-harmonic approximation calculations. In addition, the latter calculations enabled us to extract mode Gruneisen parameters leading to new insights into the NTE behavior of  $\text{Ca}_3\text{Mn}_2\text{O}_7$ . The implications of our findings are discussed in the context of the potential of RP compounds as FE materials.

**T1.00082 Signatures of Soft Phonons in Impedance Spectroscopy of Barium Titanate Colloidal Solutions**, SCOTT TAN, GRAHAM KRAHN, Pomona College, RICHARD HASKELL, Harvey Mudd College, TODD MONSON, Sandia National Laboratories — Barium titanate (BTO) is a widely used dielectric material in capacitor technologies due to a high bulk dielectric constant between 1500-2000 [1] at room temperature. Although bulk BTO has been extensively studied, it is still not entirely clear how varying BTO nanoparticle size affects the dielectric constant, particularly for non-sintered discrete nanoparticles. The most widely accepted and agreed upon behavior is that smaller BTO particles have lower dielectric constants due to lower tetragonality. However, Wada et al. reported that the BTO dielectric constant reached a high value of ~5000 near a small particle size of ~140 nm. This anomaly was attributed to the soft phonon, which reached a minimum frequency at the particle size of ~140 nm when observed in FIR reflection measurements [2]. The soft phonon explanation for the anomaly observed by Wada et al. implies that the measured value of the dielectric constant will depend on the frequency of the applied electric field when performing impedance measurements. Herein, we present an equivalent circuit model to fit BTO colloidal solution impedance spectra, which accounts for a distribution of capacitance values as a function of applied electric field frequency. This model fits reasonably well to experimental measurements obtained via impedance spectroscopy, which suggests that the soft phonon contribution to the dielectric constant is observed in the impedance spectra for BTO colloidal solutions.

**T1.00083 High-Mobility Sm-Doped Bi<sub>2</sub>Se<sub>3</sub> Ferromagnetic Topological Insulators and Robust Exchange Coupling**, FENGQI SONG, TAISHI CHEN, XUEFENG WANG, Nanjing Univ — Here we prepare a new type of diluted magnetic semiconductor (Sm<sub>x</sub>Bi<sub>1-x</sub>)<sub>2</sub>Se<sub>3</sub>Te<sub>y</sub>. It reaches an anisotropic ferromagnetic phase at x=0.05, which exhibits a Curie temperature of around 50K and a typical coercive field of 0.05T. Its magnetic strength and carrier density can be tuned by controlling the dopant ratio of Sm and Te separately. Robust ferromagnetism is demonstrated by the fact that electronic control makes no significant influence on the Curie temperature. The density functional theory calculation supports the ferromagnetism origin from the Sm atoms. The carrier density is ~10<sup>18</sup>/cm<sup>3</sup> and the mobility is over 18000cm<sup>2</sup>/V s with the pronounced Shubnikov de Haas oscillations. This suggests it is a high-mobility candidate of magnetic topological insulators. (*Advan. Mater.* 201501254(2015))

**T1.00084 Gate-modulated magnetotransport and anomalous quantum oscillations in Dirac semimetal Cd<sub>3</sub>As<sub>2</sub> nanowires**, LIXIAN WANG, CAIZHEN LI, DAPENG YU, ZHIMIN LIAO, State Key Laboratory for Mesoscopic Physics, Department of Physics, Peking University — Magnetotransport studies of three-dimensional (3D) relativistic electrons in Dirac semimetals is critical for identifying exotic topological phenomena and quantum transport. Using gate-modulation method, we conducted systematic transport measurements over our fabricated Cd<sub>3</sub>As<sub>2</sub> nanowire based devices under a variable magnetic field. We observe an obvious ambipolar-field-effect as tuning the gate-voltage bias without applied field and distinctive MR behaviors at different gate-voltage bias with applied field. Remarkably, anomalous quantum oscillations occur at high fields, which may be in close relationship to the sought-after Fermi-arc surface state in Dirac semimetals. The presence of anomalous oscillations may suggest that Cd<sub>3</sub>As<sub>2</sub> nanomaterials with a gate-tunable Fermi-surface may be a promising candidate as an excellent platform to explore the elusive surface state in topological semimetals.

**T1.00085 Identification of topological surface states in (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub> alloy films**, J.C. WALRATH, V.A. STOICA, A.S. CHANG, YEN-HSIANG LIN, WEI LIU, L. ENDICOTT, R. CLARKE, C. UHER, R.S. GOLDMAN, Univ of Michigan - Ann Arbor — Topological insulators (TIs) have emerged as an exciting class of quantum materials, with an insulating bulk and spin-momentum-locked topologically-protected surface states, making them desirable for spintronics and other applications. Recently, tunable surface to bulk conduction has been demonstrated in ternary TI alloys (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub>, providing an ideal candidate for TI spintronic devices. Although room-temperature topological surface transport is desirable for device applications, direct detection of topological surface states at room temperature has yet to be demonstrated in (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub> systems. Here, we use scanning tunneling microscopy and spectroscopy (STM/STS) to characterize the band structure of (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub> alloy films and directly detect the presence of topological surface states at room temperature. We will discuss the thickness and composition dependence of the band structure, including the Fermi level energy, Dirac point, and carrier type, comparing STM/STS and macroscopic transport data.

**T1.00086 Microstructural and magneto-transport characterization of Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> topological insulator thin films grown by pulsed laser deposition method<sup>1</sup>**, ZHENGHE JIN, RAJ KUMAR, FRANK HUNTE, JAY NARAYAN, KI WOOK KIM, North Carolina State Univ, NORTH CAROLINA STATE UNIVERSITY TEAM — Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> topological insulator thin films were grown on Al<sub>2</sub>O<sub>3</sub> (0001) substrate by pulsed laser deposition (PLD). XRD and other structural characterization measurements confirm the growth of the textured Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> thin films on Al<sub>2</sub>O<sub>3</sub> substrate. The magneto-transport properties of thick and thin films were investigated to study the effect of thickness on the topological insulator properties of the Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> films. A pronounced semiconducting behavior with a highly insulating ground state was observed in the resistivity vs. temperature data. The presence of the weak anti-localization (WAL) effect with a sharp cusp in the magnetoresistance measurements confirms the 2-D surface transport originating from the TSS in Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> TI films. A high fraction of surface transport is observed in the Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> TI thin films which decreases in Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> TI thick films. The Cosine ( $\theta$ ) dependence of the WAL effect supports the observation of a high proportion of 2-D surface state contribution to overall transport properties of the Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> TI thin films. Our results show promise that high quality Bi<sub>2</sub>Se<sub>x</sub>Te<sub>3-x</sub> TI thin films with significant surface transport can be grown by PLD method to exploit the exotic properties of the surface transport in future generation spintronic devices.

**T1.00087 Discovery of the first Weyl fermion semimetal and topological Fermi arcs in TaAs<sup>1</sup>**, SUYANG XU, ILYA BELOPOLSKI, NASSER ALIDOUST, MADHAB NEUPANE, GUANG BIAN, Princeton University, CHENGLONG ZHANG, Peking University, RAMAN SANKAR, National Taiwan University, GUOQING CHANG, National University of Singapore, ZHUJUN YUAN, Peking University, CHENGCHENG LEE, SHIN-MING HUANG, National University of Singapore, HAO ZHENG, JIE MA, DANIEL SANCHEZ, Princeton University, BAKKAI WANG, ARUN BANSIL, Northeastern University, FANGCHENG CHOU, National Taiwan University, PAVEL SHIBAYEV, Princeton University, HSIN LIN, National University of Singapore, SHUANG JIA, Peking University, M. ZAHID HASAN, Princeton University — Weyl semimetals have opened a new era in condensed matter physics and materials science. They host Weyl fermions as emergent quasiparticles and admit a topological classification that protects Fermi arc surface states on the boundary. This unusual electronic structure has deep analogies with particle physics and leads to unique topological properties. We report the experimental discovery of the first Weyl semimetal, TaAs. We directly observe the Weyl fermions and the Fermi arcs in a TaAs single crystal and demonstrate its topological character. Our work opens the field for studying of Weyl fermions in table-top experiments.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundations EPIQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.

**T1.00088 Condensation bottleneck as the driver of pseudogap physics in cuprates<sup>1</sup>**, R.S. MARKIEWICZ, I.G. BUDA, P. MISTARK, A. BANSIL, Northeastern Univ — We extend our previous GW calculations on cuprates [T. Das, R.S. Markiewicz, and A. Bansil, *Advances in Physics* 63, 151-266 (2014)] to include vertex corrections via self-consistent renormalization. We find that the antiferromagnetic transition is bottlenecked, as a continuous manifold of competing q-vectors attempts to soften at the same time. The resulting extended range of short-range order strongly resembles pseudogap physics. We discuss the strikingly different phenomena found for different cuprates, and try to determine their origins.

<sup>1</sup>Work supported by the U.S. Department of Energy.

**T1.00089 Magnetism in Olivine-type LiCo<sub>1-x</sub>Fe<sub>x</sub>PO<sub>4</sub> Cathode Materials: Bridging Theory and Experiment**, VIJAY SINGH, YELENA GERSHINSKY, MONICA KOSA, MUDIT DIXIT, DAVID ZITOUN, DAN THOMAS MAJOR, Department of Chemistry, Bar-Ilan University, Ramat-Gan, Israel, DR. DAVID ZITOUN COLLABORATION — We present a non-aqueous sol-gel synthesis of olivine type LiCo<sub>1-x</sub>Fe<sub>x</sub>PO<sub>4</sub> compounds (x = 0.00, 0.25, 0.50, 0.75, 1.00). The magnetic properties of the olivines are measured experimentally and calculated using first-principles theory. Specifically, the electronic and magnetic properties are studied in detail with standard density functional theory (DFT), as well as by including spin-orbit coupling (SOC), which couples the spin to the crystal structure. We find that the Co<sup>2+</sup> ions exhibit strong orbital moment in the pure LiCoPO<sub>4</sub> system, which is partially quenched upon substitution of Co<sup>2+</sup> by Fe<sup>2+</sup>. Interestingly, we also observe a non-negligible orbital moment on the Fe<sup>2+</sup> ion. We underscore that the inclusion of SOC in the calculations is essential to obtain qualitative agreement with the observed effective magnetic moments. Additionally, Wannier functions were used to understand the experimentally observed rising trend in the Néel temperature, which is directly related to the magnetic exchange interaction paths in the materials. We suggest that out of layer M – O – P – O – M magnetic interactions (J<sub>⊥</sub>) are present in the studied materials.

**T1.00090 Electronic and magnetic properties of double-perovskite  $(\text{La}_{1-x}\text{Sr}_x)_2\text{CuIrO}_6$  compounds**, S. X. ZHANG, W. K. ZHU, Indiana University, Bloomington, W. TONG, High Magnetic Field Laboratory, Chinese Academy of Sciences, PO-HAN LEE, National Taiwan Normal University, JEN-CHUAN TUNG, China Medical University, YIN-KOU WANG, National Taiwan Normal University, L. LING, High Magnetic Field Laboratory, Chinese Academy of Sciences, M. STARR, J. M. WANG, Indiana University, Bloomington, H. D. ZHOU, University of Tennessee, CHI-KEN LU, National Taiwan Normal University — Double perovskite oxides that combine 3d and 5d transition metal elements offer a model system to study novel electronic and magnetic states arising from the interplay of strong electron correlations and spin-orbit couplings (SOCs). In this work, we studied the electronic and magnetic properties of a double perovskite iridate  $\text{La}_2\text{CuIrO}_6$  and its hole-doped compounds  $(\text{La}_{1-x}\text{Sr}_x)_2\text{CuIrO}_6$ . Magnetic susceptibility measurements suggest that the Ir sublattice and the Cu sublattice both form antiferromagnetic order but at two different temperatures. Two-dimensional magnetism that was reported in many other Cu-based double-perovskites is not observed in our samples, indicating the existence of Cu-Ir interaction despite a weak orbital mixing. Sr-doping is shown to decrease the magnetic ordering temperatures and enhance the electrical conductivity. Density functional theory (GGA+SOC+U) calculations suggest that an isolated band is generated above the Fermi level as a result of strong SOC and U. The exchange coupling constants between transition metal ions are estimated by calculating the total energies for various magnetic ground states with expanded unit cells.

**T1.00091 Van der Waals Epitaxy of Ultrathin Halide Perovskites**, YIPING WANG, YUNFENG SHI, JIAN SHI, Department of Material Science and Engineering, Rensselaer Polytechnic Institute — We present our understanding, with  $\text{CH}_3\text{NH}_3\text{PbX}_3$  as a model system, on the 2D van der Waals growth and kinetics of 3D parent materials. We show the successful synthesis of ultrathin (sub-10 nm), large scale (a few tens of  $\mu\text{m}$ ) single crystalline 2D perovskite thin films on layered mica substrate by van der Waals (VDW) epitaxy. Classical nucleation and growth model explaining conventional epitaxy has been modified to interpret the unique 2D results under VDW mechanism. The generalization of our model shows that a 3D crystal with low cohesive energy tends to favor the 2D growth while the one with strong cohesive energy has less kinetic window. With Monte Carlo simulations, we show that the fractal 2D morphology in perovskite precisely manifests the kinetic competition between VDW diffusivity and thermodynamic driving force, a unique phenomenon to VDW growth, suggesting a fundamental limit on the morphology stability of the 2D form of a 3D material. On the other hand, our single crystal thin film growth results and subsequent cryogenic study in the iodide perovskite provide a perfect resource for the exploration of its complex optical and electronic properties and unveiling the origins of its popularity in the energy conversion field.

**T1.00092 Exciton spin dynamics in  $\text{MAPbI}_3$  measured by Hanle effect<sup>1</sup>**, WILLIAM TALMADGE, University of Utah Department of Physics and Astronomy, RUIZHI WANG, University of Utah Department of Physics and Astronomy, Nanjing University of Science and Technology, PATRICK ODENTHAL, NATHAN GUNDLACH, CHUANG ZHANG, DALI SUN, ZEEV VALY VARDENY, YAN (SARAH) LI, University of Utah Department of Physics and Astronomy — The organic-inorganic hybrid perovskites have emerged as a highly promising class of semiconductors for photovoltaic applications. The properties responsible for the high photoconversion efficiency are under extensive investigation. There have; however, been fewer investigations of spin-dependent effects in this class of materials. We present energy dependent photoinduced Faraday rotation in polycrystalline thin film  $\text{CH}_3\text{NH}_3\text{PbI}_3$ , which benefit from the band structure and optical selection rules. The Faraday rotation spectrum follows the exciton absorption band at low temperatures, indicating its excitonic origin. Through the Hanle effect, based on Faraday rotation, we found the coexistence of two spin components at 4 K, which was confirmed through time resolved measurements. **T1.00093 Majorana transport in superconducting nanowire with Rashba and Dresselhaus spin-orbit couplings**, JIABIN YOU, The University of Hong Kong, XIAO-QIANG SHAO, Northeast Normal University, QING-JUN TONG, The University of Hong Kong, A H CHAN, C H OH, National University of Singapore, VLATKO VEDRAL, University of Oxford — The tunneling experiment is a key technique for detecting Majorana fermion (MF) in solid state systems. We use Keldysh non-equilibrium Green function method to study two-lead tunneling in superconducting nanowire with Rashba and Dresselhaus spin-orbit couplings. A zero-bias dc conductance peak appears in our setup which signifies the existence of MF and is in accordance with previous experimental results on  $\text{InSb}$  nanowire. Interestingly, due to the exotic property of MF, there exists a hole transmission channel which makes the currents asymmetric at the left and right leads. The ac current response mediated by MF is also studied here. To discuss the impacts of Coulomb interaction and disorder on the transport property of Majorana nanowire, we use the renormalization group method to study the phase diagram of the wire. It is found that there is a topological phase transition under the interplay of superconductivity and disorder. We find that the Majorana transport is preserved in the superconducting-dominated topological phase and destroyed in the disorder-dominated non-topological insulator phase.

**T1.00094 Chiral Topological Superconductor and Half-Integer Conductance Plateau from Quantum Anomalous Hall Plateau Transition**, QUAN ZHOU, JING WANG, BIAO LIAN, SHOUCENG ZHANG, Stanford Univ, ZHANG'S GROUP TEAM — We propose to realize a two-dimensional chiral topological superconducting (tsc) state from the quantum anomalous hall plateau transition in a magnetic topological insulator thin film through the proximity effect to a conventional s-wave superconductor. The optimal condition for realizing such chiral tsc is to have inequivalent superconducting pairing amplitudes on top and bottom surfaces of the doped magnetic topological insulator. We further propose several transport experiments to detect the chiral tsc. The conductance will be quantized into a half-integer plateau at the coercive field in this hybrid system. In particular, with the point contact formed by a superconducting junction, the conductance oscillates between  $e^2/h$  and  $e/h$  with the frequency determined by the voltage across the junction.

**T1.00095 Creation of Dirac cones in two-dimensional  $\text{HgTe}$  honeycomb lattices produced by gate voltage**, HUA-HUA FU, SHU-TING PING, HUI WANG, RUQIAN WU, University of California, Irvine —  $\text{HgTe}$  is the first 2D topological insulator that was confirmed experimentally. In this material, it is well known that  $\text{HgTe}$  quantum well manifests as a topological insulator only when the parameter  $M$ , which is determined by the energy difference between  $E_1$  and  $H_1$  bands, is negative ( $M < 0$ ). In this study, we demonstrate that the topological feature can still be obtained in the  $\text{HgTe}$  quantum well with  $M > 0$ , if we construct a honeycomb mask on 2D  $\text{HgTe}$  and apply gate voltages. The newly developed topological state has very large and controllable band gaps and can be used for the realization of various topological properties such as fraction Chern insulator and a fractional quantum spin Hall effect. It should be stressed that the newly developed Dirac cones is not ascribed to the band inversion but is driven by the honeycomb mask. Obviously, this idea can be extended to other materials and devices.

**T1.00096 SdH oscillations and pressure effect of the Weyl semimetal NbAs**, YONGKANG LUO, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, N. J. GHIMIRE, Argonne National Laboratory, Argonne, Illinois 60439, USA, M. WARTENBE, HONGCHUL CHOI, M. NEUPANE, R. D. MCDONALD, E. D. BAUER, JIANXIN ZHU, J. D. THOMPSON, F. RONNING, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — Via angular Shubnikov-de Hass (SdH) quantum oscillations measurements, we determine the Fermi surface topology of NbAs. The SdH oscillations consist of two frequencies: 20.8 T ( $\alpha$ -pocket) and 15.6 T ( $\beta$ -pocket). The analysis shows that the  $\beta$ -pocket has a Berry phase of  $\pi$  and a small effective mass 0.033  $m_0$ , indicative of a nontrivial topology; whereas the  $\alpha$ -pocket has a trivial Berry phase of 0 and a heavier effective mass 0.066  $m_0$ . Subtle changes can be seen in the  $\rho_{xx}(T)$  profiles with pressure up to 2.31 GPa. The Fermi surfaces undergo an anisotropic evolution under pressure, while the topological features of the two pockets remain unchanged. Specific heat measurements reveal a small Sommerfeld coefficient  $\gamma_0 = 0.09(1)$  mJ/(mol $\cdot$ K<sup>2</sup>) and a large Debye temperature,  $\Theta_D = 450(9)$  K, confirming a “hard” crystalline lattice. The Kadowaki-Woods ratio and a suppressed transport scattering rate are also studied. **References:** [1] N. J. Ghimire *et al.*, JPCM **27**, 152201 (2015) [2] Y. Luo *et al.*, arXiv: 1506.01751 (2015) [3] Y. Luo *et al.*, arXiv: 1510.08538 (2015)

**T1.00097 Weak Antilocalization Effect in Metallic  $\text{Bi}_2\text{Te}_3$  Topological Insulator**, K. SHRESTHA, TcSUH and Department of Physics, University of Houston, 3201 Cullen Blvd., Houston, Texas 77204, USA, M. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Taiwan, D. GRAF, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310, USA, H. D. YANG, Department of Physics, National Sun Yat-Sen University, Taiwan, B. LORENZ, PAUL C. W. CHU<sup>1</sup>, TcSUH and Department of Physics, University of Houston, 3201 Cullen Blvd., Houston, Texas 77204, USA — We have observed weak antilocalization effect in the metallic  $\text{Bi}_2\text{Te}_3$  single crystals having different bulk carrier densities. The angle dependence of weak antilocalization with respect to the direction of the magnetic field showed the surface states dominating in the samples having lower carrier concentration. The surface states dominance in weak antilocalization does not depend on the nature of the bulk charge carriers (p or n-type). Using the Hikami-Larkin-Nagaoka (HLN) formula, we have found the number of conduction channels is smaller in the samples having lower carrier concentration.

**T1.00098 Ultrafast terahertz spectroscopy study of Kondo insulating thin film  $\text{SmB}_6$ : evidence for an emergent surface state**<sup>1</sup>, JINGDI ZHANG, Univ of California - San Diego, JIE YONG, ICHIRO TAKEUCHI, RICHARD GREENE, University of Maryland, College Park, RICHARD AVERITT, Univ of California - San Diego — We utilize terahertz time domain spectroscopy to investigate thin films of the heavy fermion compound  $\text{SmB}_6$ , a prototype Kondo insulator. Temperature dependent terahertz (THz) conductivity measurements reveal a rapid decrease in the Drude weight and carrier scattering rate at  $T^* = 20$  K, well below the hybridization gap onset temperature (100 K). Moreover, a low-temperature conductivity plateau (below 20K) indicates the emergence of a surface state with an effective electron mass of  $0.1m_e$ . Conductivity dynamics following optical excitation are also measured and interpreted using Rothwarf-Taylor (R-T) phenomenology, yielding a hybridization gap energy of 17 meV. However, R-T modeling of the conductivity dynamics reveals a deviation from the expected thermally excited quasiparticle density at temperatures below 20K, indicative of another channel opening up in the low energy electrodynamics. Taken together, these results suggest the onset of a surface state well below the crossover temperature (100K) after long-range coherence of the f-electron Kondo lattice is established.

<sup>1</sup>JZ and RDA acknowledge support from DOE - Basic Energy Sciences under Grant No. DE-FG02-09ER46643, under which the THz measurements and data analysis were performed. JY, IT and RLG acknowledge support from ONR N00014-13-1-0635 and NSF DMR 1410665.

**T1.00099 Topological insulator with negative spin-orbit coupling**, XIAN-LEI SHENG, Univ of Delaware, ZHIJUN WANG, RUI YU, HONGMING WENG, ZHONG FANG, XI DAI, Institute of Physics, Chinese Academy of Sciences, KEY LABORATORY OF CONDENSED MATTER THEORY AND COMPUTATION TEAM — Based on the first-principles calculations, we reveal that  $\text{TlN}$ , a simple binary compound with Wurtzite structure, is a three-dimensional (3D) topological insulator (TI) with effectively negative spin-orbit coupling  $\lambda_{eff} < 0$ , which makes it distinguished from other TIs by showing opposite spin-momentum locking effect in its surface states. The sign of  $\lambda_{eff}$  depends on the hybridization between N-2p and Tl-5d states, and can be tuned from negative to positive by lattice strain or chemical substitution, which drive the system into a Dirac semimetal with 3D Dirac cones in its bulk states. Such topological phase transition can be realized by electronic mechanism without breaking any crystal symmetry.

## T1.00100 COMPLEX STRUCTURED MATERIALS, INCLUDING GRAPHENE —

**T1.00101 Bosonic Dirac materials in two dimensions**, SAIKAT BANERJEE, Nordic Institute for Theoretical Physics, Sweden, JONAS FRANSSON, ANNICA BLACK-SCHAFER, Uppsala University, Sweden, HANS GREN, Royal Institute of Technology, Sweden, ALEXANDER BALATSKY, Nordic Institute for Theoretical Physics, Sweden — We examine the low energy effective theory of phase oscillations in a two-dimensional granular superconducting sheet where the grains are arranged in honeycomb lattice structure. Two different types of collective phase oscillations are obtained, which are analogous to the massive Leggett and massless Bogoliubov-Anderson-Gorkov modes in a two-band superconductor. It is shown that the spectra of these collective bosonic modes cross each other at the  $K$  and  $K'$  points in the Brillouin zone and form a Dirac node. Dirac node dispersion of bosonic excitations is representative of Bosonic Dirac Materials (BDM). We show that the Dirac node is preserved in presence of an inter-grain interaction, despite induced changes of the qualitative features of the two collective modes. Finally, breaking the sublattice symmetry by choosing different on-site potentials for the two sublattices leads to a gap opening near the Dirac node, in analogy with Fermionic Dirac materials.

**T1.00102 Black Arsenic-Phosphorus: Layered Anisotropic Infrared Semiconductors with Highly Tunable Compositions and Properties**, BILU LIU, CHONGWU ZHOU, University of Southern California — 2D layered materials with diverse properties have attracted significant interest in the past decade. The layered materials discovered so far have covered a wide, yet discontinuous electromagnetic spectral range from semimetallic graphene, insulating boron nitride, to semiconductors with bandgaps from middle infrared to visible light. Here, we introduce new layered semiconductors, black arsenic-phosphorus (b-AsP), with highly tunable chemical compositions and electronic and optical properties. Transport and infrared absorption studies demonstrate the semiconducting nature of b-AsP with tunable bandgaps, ranging from 0.3 to 0.15 eV. These bandgaps fall into long-wavelength infrared (LWIR) regime and cannot be readily reached by other layered materials. Moreover, polarization-resolved infrared absorption and Raman studies reveal in-plane anisotropic properties of b-AsP. This family of layered b-AsP materials extend the electromagnetic spectra covered by 2D layered materials to the LWIR regime, and may find unique applications for future all 2D layered material based devices. Ref. Liu, B., et al., Black Arsenic-Phosphorus: Layered Anisotropic Infrared Semiconductors with Highly Tunable Compositions and Properties. Adv. Mater., 2015, 27, 4423-4429.

**T1.00103 High free carrier density in aluminum adsorbed graphene**, YU-TSUNG LIN, MING-FA LIN, Department of Physics, National Cheng Kung University — Electronic properties of graphene are enriched by aluminum adsorption on surface. The Al adsorbate could be used in n-type transfer doping in graphene. From the first-principle density functional calculations, performed by Vienna ab initio simulation package, there are lots of free conduction electrons in the distorted Dirac-cone structure. Charges transferred from Al to C atoms are about 1.24 e, almost irrespective of the concentration and distribution of the adatoms. A high carrier density is estimated to be  $\sim 6 \times 10^{-14} / \text{cm}^2$  for a ratio of Al/C = 12.5%. Such carriers mainly originate from the hybridization of Al 3s and C 2p<sub>z</sub> orbitals, as clearly indicated from the orbital-projected density states, charge distributions and atom-dominated energy bands. Aluminum adsorbed graphene is predicted to have the highest free carriers density except for Al/C  $\geq 25\%$  compared with the other adatom-adsorbed systems.

**T1.00104 Zigzag phosphorene nanoribbons: one dimensional resonant tunnelling in two dimensional atomic crystals**, CARLOS PAEZ, ANA PEREIRA, University of Campinas, DARIO BAHAMON, Mackenzie Presbyterian University, PETER SCHULZ, University of Campinas — We theoretically investigate phosphorene zigzag nanoribbons as a platform for constriction engineering. In the presence of a constriction at one of the edges, quantum confinement of edge protected states reveals breit-wigner-like resonant tunneling, if the edge is uncoupled to the other. If the constriction is narrow enough to promote coupling between edges, it gives rise to fano-like as well as anti-resonances in the transmission spectrum. These effects are shown to mimic an atomic chain like behavior in a two dimensional atomic crystal.

**T1.00105 Room-Temperature, Low-Barrier Boron Doping of Graphene**, SHIXUAN DU, Institute of Physics, Chinese Academy of Sciences — Doping graphene with boron has been difficult because of high reaction barriers. Here, we describe a low-energy reaction route derived from first-principles calculations and validated by experiments. We find that a boron atom on graphene on a ruthenium(0001) substrate can replace a carbon by pushing it through, with substrate attraction helping to reduce the barrier to only 0.1 eV, implying that the doping can take place at room temperature. High-quality graphene is grown on a Ru(0001) surface and exposed to B<sub>2</sub>H<sub>6</sub>. Scanning tunneling microscopy/spectroscopy and X-ray photoelectron spectroscopy confirmed that boron is indeed incorporated substitutionally without disturbing the graphene lattice. (L.D. Pan et al., Nano Lett. 2015, 15, 6464. In collaboration with Lida Pan, Yande Que, Hui Chen, Dongfei Wang, Jun Li, Chengmin Shen, Wende Xiao, Hongjun Gao in CAS, and S. Pantellides in Vanderbilt University.)

**T1.00106 Peculiarities of sliding friction in graphene, graphene fluoride, graphite: Comparison of experiment with atomistic simulations**, LIUDMYLA BARABANOVA, JEFFREY MCCAUSLAND, ALPER BULDUM, SERGEI LYUKSYUTOV, University of Akron — Friction is the major source of energy dissipation at the nanoscale. We use atomic force microscopy (AFM) to study slide friction based on analysis of trace-minus-retrace (TMR) signals. To obtain the signals a directional dependence of the sliding friction using a rotational technique was used at the edges and interiors of the samples graphene (G), graphene fluoride (GF), and graphite. The friction coefficient experimental results were based on a methodology assuming orthotropic friction and found to be in the range of  $10^{-3}$  to  $10^{-1}$  over all samples. Supplementing experimental measurements, we also performed atomistic modeling and simulations to investigate tribological properties of G including the edges. Molecular dynamics simulations and geometry optimization calculations were carried and compared with experimental measurements. It is suggested that the atoms at the apex of the asperities and at the graphene edges have important effect on friction.

**T1.00107 Recognition of DNA sequencing through binding of nucleobases to graphene**, VALENTINA ZAFFINO, Univ of Central Florida — Graphene is one of the most promising materials in nanotechnology. Its large surface to volume ratio, high conductivity and electron mobility at room temperature are outstanding properties for use in DNA sensors. For this study, we used Density Functional Theory (DFT), with and without the inclusion of van der Waals (vdW) interactions, to investigate the adsorption of nucleobases (cytosine, guanine, adenine, thymine, and uracil) on pristine graphene and graphene with defects (Divacancy and Stone-Wales). We investigated the performance of two types of vdW-DF functional (optB86b-vdW and rPW86-vdW), as well as the PBE functional, and their description of the adsorption geometry and electronic structure of the nucleobase-graphene systems. The inclusion of defects results in an increase in binding energy, closer adsorption of the molecule to graphene and greater buckling in both the graphene structure and nucleobase.

**T1.00108 Orientationally Misaligned Zipping of Lateral Graphene and Boron Nitride Nanoribbons with Minimized Strain Energy and Enhanced Half-Metallicity<sup>1</sup>**, JIANG ZENG, Univ of Sci & Tech of China, WEI CHEN, Harvard University, PING CUI, Univ of Sci & Tech of China, DONG-BO ZHANG, Beijing Computational Science Research Center, ZHENYU ZHANG, Univ of Sci & Tech of China — Lateral heterostructures of two-dimensional materials may exhibit various intriguing emergent properties. Yet when specified to the orientationally aligned heterojunctions of zigzag graphene and hexagonal boron nitride (hBN) nanoribbons, realizations of the high expectations on their properties encounter two standing hurdles. First, the rapid accumulation of strain energy prevents largescale fabrication. Secondly, the pronounced half-metallicity predicted for freestanding graphene nanoribbons is severely suppressed. By properly tailoring orientational misalignment between zigzag graphene and chiral hBN nanoribbons, here we present a facile approach to overcome both obstacles. Our first-principles calculations show that the strain energy accumulation in such heterojunctions is significantly diminished for a range of misalignments. More strikingly, the half-metallicity is substantially enhanced from the orientationally aligned case, back to be comparable in magnitude with the freestanding case. The restored half-metallicity is largely attributed to the recovered superexchange interaction between the opposite heterojunction interfaces. The present findings may have important implications in eventual realization of graphene-based spintronics.

**T1.00109 Oscillatory behavior of the surface reduction process of multilayer graphene oxide at room temperature<sup>1</sup>**, DMITRY VOYLOV, Univ of Tennessee, Knoxville, ILIA IVANOV, Oak Ridge National Laboratory, VALERII BYKOV, Emanuel Institute of Biochemical Physics RAS, SVETLANA TSYBENOVA, Moscow City Teacher Training University, IGOR MERKULOV, Oak Ridge National Laboratory, SERGEI KUROCHKIN, Institute of Problems of Chemical Physics RAS, ADAM HOLT, Univ of Tennessee, Knoxville, ALEXANDR KISLIUK, Oak Ridge National Laboratory — The graphene oxide (GO) is one of 2D materials which continues to be studied intensively since it is thought can be used as a precursor of graphene. Recently, it was found that the chemical composition of multilayer GO is metastable on the time scale of one month even at room temperature. The observed changes in chemical composition were attributed to a reduction process controlled by the in-plane diffusion of functional groups which progresses through radical reactions. Here we report the observation of oscillatory oxidation-reduction (redox) reactions on the surface of multilayer GO films at room temperature. The redox reactions exhibited damped oscillatory behavior with a period of about 5 days and found to be dependent on the time elapsed from GO deposition. The kinetic behavior of the processes and observed metastability of the surface functional groups are adequately described by two models involving reactions between functional groups of GO and reactant diffusion.

**T1.00110 Atomistic Simulation Studies on the Friction of 2D materials**, MINWOONG JOE, CHANGGU LEE, Department of Mechanical Engineering and Center for Human Interface Nano Technology (HINT), Sungkyunkwan University — Frictional properties of two-dimensional (2D) layered materials including graphene, MoS<sub>2</sub>, NbSe<sub>2</sub>, and h-BN, have been revealed using atomic force microscopy (AFM) [1]. All the materials exhibit similar trends on friction: the thicker the sheet the lower the friction is. Puckering effect has been suggested as the primary mechanical reason for this thickness-dependent behaviors. Despite this novel findings, detailed atomic-scale processes during tip sliding against such atomically thin sheets are not fully understood yet. In this work, we provide a detailed study of the role of the buried interface between tip and surface on atomic friction using molecular dynamics (MD) simulation. We investigate the magnitude of puckering under various tip and surface conditions such as tip size and surface orientation, to unravel its effect on friction. Our systematic approach could provide a comprehensive understanding of friction phenomena at atomic level.

**T1.00111 Transferring graphene onto hydrated "soft" substrates using a modified H<sub>2</sub> bubbling method<sup>1</sup>**, W. PIERRE, M. BLADES, P. VENDOLA, S. JEDLICKA, S.V. ROTKIN, Lehigh University — Graphene has many applications, most of which require its deposition onto a specific substrate. Several methods exist for transferring large areas of graphene. However, there is a lack of existing techniques for proper transfer onto soft hydrated substrates. We demonstrate a method for transferring a large wrinkle-free area of graphene onto soft substrates using a modified bubbling technique. Widefield microscopy was used to characterize the results.

<sup>1</sup>NSF ECCS-1509786

**T1.00112 Effect of the sample mounting geometry on the grain size of single-crystalline transition-metal dichalcogenide monolayers grown by chemical vapor deposition**, ZHENG YANG, BO HSU, University of Illinois at Chicago, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING TEAM — In this presentation, it is reported that the local pressure near the surface of the substrate plays a significant role affecting the single crystal grain size of two-dimensional (2D) transition-metal dichalcogenide  $\text{MX}_2$  ( $\text{M}=\text{Mo}, \text{W}$ ;  $\text{X}=\text{S}, \text{Se}$ ) monolayers in addition to other regular growth parameters such as growth chamber pressure, temperature, and gas flow rates etc during the chemical vapor deposition growth. Different sample mounting geometries (such as substrate facing up, facing down, sandwiching) and vapor trapping techniques (such as vapor trapping tube) to introduce qualitatively various local pressure have been employed in the growth to systematically study this effect. The grain size, optical, and electrical properties of 2D  $\text{MX}_2$  monolayer samples grown at different local pressures are compared. It is observed that the enhanced local pressure facilitates larger single crystal grain size and higher quality of the 2D  $\text{MX}_2$  monolayers. The size of the single-crystalline  $\text{MX}_2$  monolayers achieved by this method were comparable to the literature reported largest size.

**T1.00113 Mechanisms of Bowtie- and Star-Shaped  $\text{MX}_2$  Nanoisland Formation**, VASILII I. ARTYUKHOV, ZHILI HU, ZHUHUA ZHANG, BORIS I. YAKOBSON, Rice University — A large number of experimental studies over the last few years observed the formation of unusual highly symmetric polycrystalline twinned nanoislands of transition metal dichalcogenides, resembling bowties or stars. Here we analyze their morphology in terms of equilibrium and growth shapes. We propose a mechanism for their formation via collision of concurrently growing islands and validate the theory with phase-field simulations. Finally, we use first-principles calculations to propose an explanation of the predominance of high-symmetry polycrystals with 60-degree lattice misorientation angles.

**T1.00114 Metal Contact Formation and Substrate Ferroelectric Poling: Effective Means of Determining  $\text{MoS}_2$  Transport Properties**, LUDWIG BARTELS, JOSEPH MARTINEZ, ARIANA NGUYEN, MICHAEL GOMEZ, EDWIN PRECIADO, VELVETH KLEE, MICHAEL VALENTIN, I-HSI LU, DAVID BARROSO, University of California Riverside, THOMAS SCOTT, PETER DOWBEN, University of Nebraska- Lincoln — Monolayer transition metal dichalcogenides (TMDs) are of rising interest due to their direct band gap at the single-layer limit and pronounced spin splitting in the valence band. Metal contact formation to such materials is a persistent issue yet it holds tremendous opportunity for improving TMD transport properties: simply through their composition, metal contacts can increase the very low carrier numbers in single-layer films leading to significant shifts of the Fermi energy. X-ray photoelectron spectroscopy (XPS) measurements of the charge transfer during metal contact formation reveal the TMD valence band edge to approach the Fermi level underneath the contact, so that TMD devices resemble *pnp*-junctions. We employ a combination of scanning photocurrent microscopy (SPCM) and surface acoustic spectroscopy on ferroelectric substrates to ascertain our findings. SPCM measurements allow us to probe the impact of electrical contacts on the photoconductivity of the materials. In contrast, surface acoustic spectroscopy allows access to the transport properties of the material even in the absence of contacts. The combination of these technique sheds new light on the band alignment in TMD materials between contacts and on ways to manipulate it.

**T1.00115 Substrate induced phase transformation of monolayer transition metal dichalcogenides**, SHUDUN LIU, University of Louisville, XIAOJUN FU, ZHENYU ZHANG, WENGUANG ZHU, University of Science and Technology of China — Using density functional theory calculations, we investigate the effects of a metal substrate on the structural and electronic properties of a monolayer of transition metal dichalcogenide (TMD). We find that a suitable choice of substrate can induce a transformation of the phase of the monolayer from 2H to 1T. We will discuss the impact of the results on some earlier studies of TMD/metal contacts as well as potential applications of our system in catalysis.

**T1.00116 HYDROGENATED GRAPHENE- METAL OXIDE NANOHYBRIDS: AN INVENTIVENESS PLINTH FOR SENSING DEVICES**, P BARANEEDHARAN, S. RAMAPRABHU, Indian Institute of Technology Madras — Graphene- a two dimensional sheet of  $\text{sp}^2$  hybridized carbon atoms has been considered as promising materials in sensor design for detection of target molecule. Charge carriers in graphene obey linear dispersion relation and it behaves like mass less relativistic particles which act as base for enhanced electron transport. Thus the electrons move ballistically without scattering giving higher mobility even at room temperature. Further, the presence of oxygen containing functional group and crystal defects assisted via hydrogenation process take vital part in electrochemical adsorption of electro active species and catalyses the same. Though issues with selectivity, stability and sensitivity are limited for several nanostructured metal oxides sensing, the hybrid system started its effective role in design of sensing platform. Thus considering the potential important of hydrogenated graphene -metal oxide systems, a nanohybrid system is developed and its structural, morphological and optical properties were understood using respective characterization tool. Further, the prepared hybrid nanosystem used as a platform for bimolecule detection, where the sensor exhibits higher range of sensitivity and selectivity.

**T1.00117 Bias dependent transport property of defective phosphorene.**<sup>1</sup>, M FAROOQ, ARQUM HASHMI, pukyong National University, CHANYONG HWANG, KRISS, JISANG HONG, pukyong National University — Phosphorene is receiving great research interests because of its peculiar physical properties. Nonetheless, no systematic studies on the transport properties modified due to defects have been performed. Here, we present the electronic band structure, defect formation energy and bias dependent transport property of various defective systems. We found that the defect formation energy is much less than that in graphene. The defect configuration strongly affects the electronic structure. The band gap vanishes in single vacancy layers, but the band gap reappears in divacancy layers. Interestingly, a single vacancy defect behaves like a p-type impurity for transport property. Unlike the common belief, we observe that the vacancy defect can contribute to greatly increasing the current. Along the zigzag direction, the current in the most stable single vacancy structure was significantly increased as compared with that found in the pristine layer. In addition, the current along the armchair direction was always greater than along the zigzag direction and we observed a strong anisotropic current ratio of armchair to zigzag direction.

**T1.00118 Low-temperature optical spectroscopy of single-layer transition metal dichalcogenides**, GERD PLECHINGER, PHILIPP NAGLER, CHRISTIAN SCHÜLLER, TOBIAS KORN, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, D-93040 Regensburg, Germany — In recent years, layered materials beyond graphene have attracted immense interest in the scientific community. Among those, particularly the semiconducting transition metal dichalcogenides (TMDCs) in their monolayer form are in the focus of the current research due to their intriguing optical properties and their potential application in valleytronic-based devices. The optical properties are governed by excitonic features, even at room temperature. The excitons in monolayer TMDCs have unusually large binding energies due to the two-dimensional carrier confinement and weak dielectric screening. Here, we investigate the photoluminescence spectra of monolayer TMDCs at low temperatures. We present clear evidence for the existence of biexcitons in monolayer  $\text{WS}_2$ , exhibiting a superlinear behavior in excitation-power-dependent measurements. Applying a gate-voltage in a FET-configuration, we can identify charge-neutral and negatively charged excitons (trions) in the optical spectrum of different TMDCs. The trion binding energies range in the order of 30 meV. The evolution of the excitonic peaks under the application of external magnetic fields give further insight into the internal structure of these materials.

**T1.00119 Valley polarization and coherence in atomically thin tungsten disulfide via optical spectroscopy**, BAIREN ZHU, The University of Hong Kong, HUALING ZENG, The Chinese University of Hong Kong, JUNFENG DAI, South University of Science and Technology of China, ZHIRUI GONG, XIAODONG CUI, The University of Hong Kong — Atomically thin group-VI transition metal dichalcogenides (TMDC) has been emerging as a family of intrinsic 2-dimensional crystals with a sizeable bandgap, opening a potential avenue for ultimate electronics and optoelectronics. Besides, the characteristic structural inversion symmetry breaking in monolayers leads to non-zero but contrasting Berry curvatures and orbital magnetic moments at K/K' valleys. These features provide an opportunity to manipulate electrons' additional internal degrees of freedom, namely the valley degree of freedom, making monolayer TMDC a promising candidate for the conceptual valleytronics. Here, our experimental approach on valley dependent circular dichroism in monolayer and bilayer WS<sub>2</sub> via optical spectroscopy are elaborated. Consequently, the polarization of photoluminescence inherits that of excitations, circularly and linearly polarized, confirming the valley dependent selectivity rule. However, the valley polarization and valley coherence in bilayer WS<sub>2</sub> owing to the coupling of spin, valley and layer degrees of freedom, are anomalously robust compared with monolayer WS<sub>2</sub>. We propose potential mechanisms of the anomalous behavior in WS<sub>2</sub> bilayers.

**T1.00120 Optical nano-imaging of waveguide exciton polaritons in transition-metal dichalcogenides**, ZHE FEI, Iowa State University, MARIE SCOTT, University of Washington, DAVID GOSZTOLA, Argonne National Laboratory, JONATHAN FOLEY, William Paterson University, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory, HAIDAN WEN, Argonne National Laboratory, PENG ZHOU, DAVID ZHANG, Fudan university, YUGANG SUN, JEFFREY GUEST, STEPHEN GRAY, Argonne National Laboratory, WENZHONG BAO, Fudan university, GARY WIEDERRECHT, Argonne National Laboratory, XIAODONG XU, University of Washington — Exciton polaritons, which are collective oscillations of photons and excitons in semiconductors, trigger tremendous research interests in both fundamental physics and technological applications. Previous studies retain to spectroscopic studies of exciton polaritons confined in microcavities. Here, we report on optical nano-imaging study of waveguide exciton polaritons of thin flakes of transition-metal dichalcogenides (TMDCs) using the near-field scanning optical microscopy. The observed polaritons are formed by strong coupling between waveguide photons and A excitons in TMDCs. The wavelength of these exciton polaritons can reach as low as 300 nm. By tuning the laser frequency, we are able to map the entire polariton dispersion both above and below the A exciton energy. Further analysis indicates that polaritons in the lower-energy branch have a propagation length over many microns while the modes in the upper-energy branch are strongly damped due to the Landau damping.

**T1.00121 ABSTRACT WITHDRAWN** —

**T1.00122 Anisotropic Electron transport and device applications of atomically thin ReS<sub>2</sub>**, ERFU LIU, YAJUN FU, YAOJIA WANG, YANQING FENG, HUIMEI LIU, XIANGANG WAN, WEI ZHOU, BAIGENG WANG, JUNWEN ZENG, Nanjing University, CHING-HWA HO, YING-SHENG HUANG, National Taiwan University of Science and Technology, HONGTAO YUAN, HAROLD Y. HWANG, YI CUI, Stanford University, DINGYU XING, FENG MIAO, Nanjing University — Semiconducting two-dimensional transition metal dichalcogenides are emerging as top candidates for post-silicon electronics. While most of them exhibit isotropic behavior, lowering the lattice symmetry could induce anisotropic properties, which are both scientifically interesting and potentially useful. In this talk, we will present atomically thin rhenium disulfide (ReS<sub>2</sub>) flakes with unique distorted 1T structure, which exhibit in-plane anisotropic properties. We first fabricated mono- and few-layer ReS<sub>2</sub> field effect transistors, which exhibit competitive performance with large current on/off ratios (~10<sup>7</sup>) and low subthreshold swings (100 mV dec<sup>-1</sup>). The observed anisotropic ratio along two principle axes reaches up to 3.1. Furthermore, we successfully demonstrated an integrated digital inverter with good performance by utilizing two ReS<sub>2</sub> anisotropic field effect transistors, suggesting the promising implementation of large-scale two-dimensional logic circuits. Recent results on ultra-high responsivity (as high as 88,600 A W<sup>-1</sup>) phototransistors based on few-layer ReS<sub>2</sub> will also be discussed. Our results underscore the unique properties of two-dimensional semiconducting materials with low crystal symmetry for future electronic and optoelectronic applications.

**T1.00123 Nonlinear dynamics of the normal and superfluid dipolariton gas in transition-metal dichalcogenide-based heterostructures**, GERMAN KOLMAKOV, NYC College of Technology, CUNY, TIM BYRNES, New York University, ANDY HE, ROMAN YA. KEZERASHVILI, NYC College of Technology, CUNY — Propagation of a dipolariton quantum gas in normal and superfluid states in a patterned microcavity in the presence of an external electric field is studied. The double layer transition-metal dichalcogenide structure is embedded into the microcavity. The dipolaritons are formed as a superposition of direct and indirect excitons in the layers and cavity photons. By numerically solving the Boltzmann equation for a gas of interacting dipolaritons in a normal state at room temperatures and the Gross-Pitaevskii equation for a dipolariton Bose-Einstein condensate in superfluid state at low temperatures we show that the dipolariton flow can be controlled by the electric field in the cavity. We also numerically studied the dipolariton propagation in channels of various geometries in the cavity and determine conditions when the dipolariton flow can be guided in the channels.

**T1.00124 Tunable valley polarization of quantum confined excitons in WSe<sub>2</sub>**, SAJAL DHARA, CHITRALEEMA CHAKRABORTY, KENNETH GOODFELLOW, NICK VAMIVAKAS, Univ of Rochester — The discovery of single photon emitters in two dimensional transition metal dichalcogenides opens up a new research direction in the field of two-dimensional layered materials. In order to understand the origin of the quantum confinement that is responsible for these localized excitonic states we perform polarization resolved optical measurements. The quantum dots are embedded in a diode-like device to control the quantum dot energy levels via the quantum confined Stark effect. In addition to applied electric field, an external magnetic field is also used to control the quantum dot exciton properties. In this work we present our findings that sheds light on the symmetry of the confinement potential. The observed extent of valley polarization indicates quantum confined exciton's valley degree of freedom protection from environmental disturbances.

**T1.00125 Phonons in Stabilized B or N doped graphene**, GIRIJA DUBEY, York College-CUNY, NY11451, SARITA MANN, POOJA RANI, VIJAY JINDAL, Department of Physics, Panjab University, Chandigarh 160014, India — Based on *Ab-initio* density functional perturbation theory, we have investigated various doped B and N based graphene sheets by raising their concentrations upto 50% of the host carbon. Although the doped structures seem to stabilize in 2-D configurations, but the resulting Phonon frequencies do not confirm the stability as the transverse modes above critical concentrations of B and N tend to result in negative eigenvalues. This essentially requires strained 2-D sheets when doped above such critical concentrations. We find the results of phonons and thermodynamics very interesting and attempt to report these in strained lattices. The motivation to do such a calculation results from our primary goal to address the issue of heat dissipation rate in the devices based on designable electronic and optical properties of such doped graphene reported already.

**T1.00126 Multi-Level Memory Effect of CVD Graphene Transferred on SiO<sub>2</sub> by Controlled Hydron Adsorption at Interface<sup>1</sup>**, SUNGCHUL JUNG, JUNHYOUNG KIM, HOON HAHN YOON, HAN BYUL JIN, GAHYUN CHOI, JUNG-YONG LEE, Ulsan Natl Inst of Sci & Tech, DAEJIN EOM, Korea Research Institute of Standards and Science, KIBOG PARK, Ulsan Natl Inst of Sci & Tech — Memory effect of graphene based on the Fermi-level shift driven by external electric field has been studied in various ways. There have been several experimental reports exploring the fabrication of two-level memory devices relying on the hysteresis loop of channel current vs. gate voltage of Graphene/SiO<sub>2</sub>/Si field effect transistor (FET). This channel current hysteresis has been explained by the motion of the water molecules trapped between graphene and SiO<sub>2</sub> insulator. In this study, we fabricated a CVD-grown graphene FET on a SiO<sub>2</sub>/Si substrate and found four different channel conductivity states tunable by varying the applied gate voltage pulse. It is noticed that the stabilization of reset state (lowest conductivity state) is one of the challenging issues in fabricating memory devices with graphene FET. We found that the stabilization of reset state can be achieved by positioning the Fermi-level in reset state as close to the charge neutrality point as possible during read-out. We propose one easy way to ensure the proper positioning of the reset state Fermi-level, which is to apply a constant gate voltage during read-out. Our study demonstrates the possibility of fabricating graphene-based multi-bit memory devices.

**T1.00127 Gate-tunable tunneling resistance in graphene/topological insulator vertical junctions<sup>1</sup>**, LIANG ZHANG, 1 State Key Laboratory for Mesoscopic Physics, Department of Physics, Peking University, Beijing 100871, P.R. China, YUAN YAN, State Key Laboratory for Mesoscopic Physics, Department of Physics, Peking University, Beijing 100871, P.R. China, HAN-CHUN WU, School of Physics, Beijing Institute of Technology, Beijing, 100081, P.R. China, ZHI-MIN LIAO, DA-PENG YU, State Key Laboratory for Mesoscopic Physics, Department of Physics, Peking University, Beijing 100871, P.R. China — The emergence of graphene-based vertical heterostructures, especially stacked by various layered materials, opens up new promising possibilities for investigations and applications. The junction based on two famous Dirac materials, graphene and topological insulator, Bi<sub>2</sub>Se<sub>3</sub>, can considerably enlarge the family of van der Waals heterostructures, while the experimental approach to obtain controllable interface of these junctions is still a challenge. Here we show the experimental realization of the vertical heterojunction between Bi<sub>2</sub>Se<sub>3</sub> and monolayer graphene. The tunneling-mediated quantum oscillations are identified to arise from several two-dimensional conducting layers. The electrostatic field induced by back gate voltage, as well as the magnetic field, is applied to tailor the available density of states near the Fermi surface. We observe exotic gate-tunable tunneling resistance in high magnetic field, which is attributed to semimetal-quantum Hall insulator transition in the underlying graphene.

**T1.00128 Theory of hot electron photoemission from graphene**, LAY KEE ANG, SHIJUN LIANG, Singapore University of Technology and Design — Motivated by the development of Schottky-type photodetectors, some theories have been proposed to describe how the hot carriers generated by the incident photon are transported over the Schottky barrier through the internal photoelectric effect. One of them is Fowler's law proposed as early as 1931, which studied the temperature dependence of photoelectric curves of clean metals. This law is very successful in accounting for mechanism of detecting photons of energy lower than the band gap of semiconductor based on conventional metal/semiconductor Schottky diode. With the goal of achieving better performance, graphene/silicon contact-based- graphene/WSe<sub>2</sub> heterostructure-based photodetectors have been fabricated to demonstrate superior photodetection efficiency. However, the theory of how hot electrons is photo-excited from graphene into semiconductor remains unknown. In the current work, we first examine the photoemission process from suspended graphene and it is found that traditional Einstein photoelectric effect may break down for suspended graphene due to the unique linear band structure. Furthermore, we find that the same conclusion applies for 3D graphene analog (e.g. 3D topological Dirac semi-metal). These findings are very useful to further improve the performance of graphene-based photodetector, hot-carrier solar cell and other kinds of sensor.

**T1.00129 Memristive Phenomena in Polycrystalline Single Layer MoS<sub>2</sub>**, VINOD SANGWAN, DEEP JARIWALA, IN-SOO KIM, KAN-SHENG CHEN, TOBIN MARKS, LINCOLN LAUHON, MARK HERSAM, Northwestern University, HERSAM LABORATORY TEAM<sup>1</sup> — Recently, a new class of layered two-dimensional semiconductors has shown promise for various electronic applications. In particular, ultrathin transition metal dichalcogenides (e.g. MoS<sub>2</sub>) present a host of attractive features such as high carrier mobility and tunable band-gap. However, available growth methods produce polycrystalline films with grain-boundaries and point defects that can be detrimental in conventional electronic devices. In contrast, we have developed unconventional device structures that exploit these defects for useful electronic functions.[1] In particular, we observe grain-boundary mediated memristive phenomena in single layer MoS<sub>2</sub> transistors. Memristor current-voltage characteristics depend strongly on the topology of grain-boundaries in MoS<sub>2</sub>. A grain boundary directly connecting metal electrodes produces thermally assisted switching with dynamic negative differential resistance, whereas a grain boundary bisecting the channel shows non-filamentary soft-switching. In addition, devices with intersecting grain boundaries in the channel show bipolar resistive switching with high on/off ratios up to ~10<sup>3</sup>. [1] Furthermore, the gate electrode in the field-effect geometry can be used to control the absolute resistance of the on and off states. Correlated electrostatic force microscopy, photoluminescence, and Raman microscopy reveal the role of sulfur vacancies in the switching mechanism. Refs: 1. Sangwan et al., *Nature Nanotech*, 10 403 (2015)

**T1.00130 Resonance frequency shifts due to quantized electronic states in atomically thin NEMS**, CHANGYAO CHEN, Argonne National Lab, VIKRAM DESHPANDE, Department of Physics and Astronomy, University of Utah, MIK-ITO KOSHINO, Department of Physics, Tohoku University, SUNWOO LEE, Department of Electrical Engineering, Columbia University, ALEXANDER GONDARENKO, Department of Mechanical Engineering, Columbia University, ALLAN MACDONALD, Department of Physics, University of Texas, Austin, PHILIP KIM, Department of Physics, Harvard University, JAMES HONE, Department of Mechanical Engineering, Columbia University — The classic picture of the force exerted on a parallel plate capacitor assumes infinite density of states (DOS), which implies identical electrochemical and electrostatic potential. However, such assumption can breakdown in low-dimensional devices where the DOS is finite or quantized. Here we consider the mechanical resonance shift of a nanoelectromechanical (NEMS) resonator with small DOS, actuated and detected capacitively at fixed electrochemical potential. We found three leading correction terms to the classical picture: the first term leads to the modulation of static force due to the variation in chemical potential, and the second and third terms are related to the static and dynamic changes in spring constants, caused by quantum capacitance. The theory agrees well with recent experimental findings from graphene resonator in quantum Hall regimes, where the chemical potential and quantum capacitance are tuned by magnetic field, while the gate voltage is kept constant.

**T1.00131 A theoretical design of graphene-based spin field-effect transistors**, LIXUE LIU, University of Science and Technology of China, SHUDUN LIU, University of Louisville, ZHENYU ZHANG, WENGUANG ZHU, University of Science and Technology of China — The search for a feasible design of graphene-based materials for spintronics applications has been intensified in recent years. Encouraged by recent experimental achievements, here we propose a new scheme to realize graphene-based spin field-effect transistors. The new design is constituted of a half-hydrogenated graphene nanoroad embedded in a fully-hydrogenated graphene. Using first-principles density function theory calculations, we demonstrate that such a design can convert non-magnetic pristine graphene into a bipolar ferromagnetic semiconductor. More importantly, the magnetism of such a nanoroad is very robust: independent of its width and orientation. We also discuss the stability of such nanoroads, as well as a simple design of an all-electric controlled device for generation and detection of a fully spin-polarized electric current.

**T1.00132 Control of Rewriteable Doping Patterns in Graphene/Boron Nitride Heterostructures**, SALMAN KAHN, JAIRO VELASCO JR., DILLON WONG, JUWON LEE, HSIN ZON TSAI, University of California - Berkeley, LONG JU, Cornell University, LILI JIANG, ZHIWEN SHI, PAUL ASHBY, University of California - Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ALEX ZETTL, FENG WANG, MICHAEL CROMMIE, University of California - Berkeley — Spatial control of charge doping in 2D materials is a prerequisite for designing future electronic devices and understanding novel physics. Electrostatic gating and chemical doping are two of the most common methods to achieve this. However, these approaches suffer from complicated fabrication processes that introduce impurities, change material properties irreversibly, and lack flexibility. Here we introduce a new method for patterning rewriteable doping profiles using an STM tip by way of local tip-voltage-induced ionization of defects in a BN substrate. We characterize these spatial doping patterns through local probe and transport techniques. This technique enables many novel device designs for 2D materials, including atomically thin p-n junctions and rewriteable memory devices.

**T1.00133 Effects of interface oxygen vacancies at the FeSe/SrTiO<sub>3</sub> interface**, MINGXING CHEN, D. F. AGTERBERG, L. LIAN, MICHAEL WEINERT, Univ of Wisconsin, Milwaukee — The effects of oxygen vacancies on the electronic bands at the interface of between monolayer and bilayer FeSe and SrTiO<sub>3</sub> are investigated by first-principles supercell calculations. Unfolded bands derived from the *k*-projection method reveal that the oxygen vacancy not only provides electron doping to the interface FeSe layer, but also significantly renormalizes the width of the Fe-3*d* band near the Fermi level for the checkboard antiferromagnetic (AFM) state. However, the effects of the oxygen vacancies on the electronic properties of the top layer of bilayer FeSe are limited. The *k*-projected bands for the checkboard AFM state are in good agreement with ARPES results.

**T1.00134 ABSTRACT WITHDRAWN —**

**T1.00135 Even-dimensional topological semimetals under disorders**, X. J. HUANG, Y. X. ZHAO, Z. D. WANG, The Univ of Hong Kong — A topological theory of even-dimensional, chiral symmetry-preserving topological semimetal, which is known as the counterpart of Weyl semimetal, is developed in this work. We show that, in presence of disorder, an anisotropic topological  $\theta$ -term emerges in the action of effective non-linear sigma model, meanwhile, an anisotropic Chern character term in terms of  $U(1)$  gauge response theory, which gives the electromagnetic response, whose stability against disorders is ensured by the former topological  $\theta$ -term, has also been derived. Moreover, it is found that this topological semimetal can be included in the family of topological quantum matter preserving chiral symmetry. The relations of this topological semimetal to odd-dimensional topological insulator and even-dimensional Dirac fermion are revealed in both effective non-linear sigma model and gauge theory. And importantly, above results can be applied to graphene if we set dimension  $d = 2$  and thus reveal the topological character of this kind of 2-dimensional topological semimetal with two Dirac cones with opposite chiralities.

**T1.00136 Supercurrent in the quantum Hall regime**, MING-TSO WEI, Duke Univ, FRANCOIS AMET, Appalachian State University, CHUNG-TING KE, Duke Univ, IVAN BORZENETS, University of Tokyo, JIYINGMEI WANG, Duke Univ, KEJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, RUSSELL DEACON, Center for Emergent Matter Science, RIKEN, MICHIOHISA YAMAMOTO, University of Tokyo, YURIY BOMZE, Duke Univ, SEIGO TARUCHA, University of Tokyo, GLEB FINKELSTEIN, Duke Univ — Combining superconductivity and the quantum Hall (QH) effect is a promising route for creating new types of topological excitations. Despite this potential, signatures of superconductivity in the quantum Hall regime remain scarce, and a superconducting current through a QH weak link has so far eluded experimental observation. Here we demonstrate the existence of a novel type of Josephson coupling through a QH region at magnetic fields as high as 2 Tesla. The supercurrent is mediated by states encompassing QH edge channels, which are flowing on opposite sides of the sample. The edges are coupled together by the hybrid electron-hole modes at the interfaces between the QH region and the superconducting contacts. These chiral modes, which share some features with Majorana modes, are formed when electron and hole edge states are mixed by the superconductor.

**T1.00137 Cooper pairing protected by spin-valley locking in two-dimensional superconductivity on MoS<sub>2</sub>**, YU SAITO, The University of Tokyo, YASU HARU NAKAMURA, Kyoto University, MOHAMMAD BAHRAMY, The University of Tokyo, YOSHIMITSU KOHAMA, ISSP, JIANTING YE, The University of Tokyo, YUICHI KASAHARA, Kyoto University, MASASHI TOKUNAGA, ISSP, TSUTOMU NOJIMA, Tohoku University, YUICHI YANASE, Kyoto University, YOSHIHIRO IWASA, The University of Tokyo — MoS<sub>2</sub> is an archetypal layered semiconductor; monolayer shows out-of-plane spin polarization at the K-points due to intrinsic Zeeman-type spin-orbit coupling (SOC) derived from its in-plane broken inversion symmetry. By ionic-liquid gating, almost all carriers are confined only to topmost layer, realizing two-dimensional superconductivity in this system [1]. We reported the first observation of a huge in-plane upper critical field of about 52 T and a clear saturating behaviour in the low temperatures using pulsed magnetic fields up to 55 T [2]. From first-principles-based tight binding supercell calculations followed by realistic numerical calculations of  $H_{c2}$  based on the subband structure, we revealed that this unusual behavior is due to the moderately large Zeeman-type spin splitting of 13 meV at the Fermi level (vicinity of the K points) [3]. This forces Cooper pairs to be completely aligned to out-of-plane direction by spin-valley locking effect, thereby causing the dramatic enhancement of the Pauli limit. Our calculation also indicates that even if the carrier density and then spin splitting (9–15 meV) at the Fermi level changes, the Pauli limit is predominantly controlled by both the Zeeman-type SOI and  $T_c$ , and the contribution of Rashba-type SOI is negligibly small. [3]. [1] Y. Saito et al. <http://meetings.aps.org/link/BAPS.2014.MAR.T52.8> [2] Y. Saito, et al. <http://meetings.aps.org/link/BAPS.2015.MAR.G11.11> [3] Y. Saito et al. Nature Phys. doi: 10.1038/nphys3580. (arXiv:1506.04146).

**T1.00138 Highly anisotropic Dirac fermions in square graphynes**, LIZHI ZHANG, Univ of Electronic Sci & Tech / University of Utah, ZHENGFEI WANG, University of Science and Technology of China, JIANSHEG RAO, ZIHENG LI, WULIN HUANG, ZHIMING WANG, Univ of Electronic Sci & Tech, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, FENG LIU, University of Utah — Recently, there have been intense search of new 2D materials, and one especially appealing class of 2D materials is the all-carbon allotropes of Dirac materials. Here, we predict a new family of 2D carbon allotropes, square graphynes (S-graphynes) that exhibit highly anisotropic Dirac Fermions, using first-principle calculations within density functional theory. The equal-energy contour of their 3D band structure shows a crescent shape, and the Dirac crescent has varying Fermi velocities from  $0.6 \times 10^5$  to  $7.2 \times 10^5$  m/s along different *k* directions. Near the Fermi level, the Dirac crescent can be nicely expressed by an extended 2D Dirac model Hamiltonian. Furthermore, tight-binding band fitting reveals that the Dirac crescent originates from the next-nearest-neighbor interactions between C atoms. Our findings enrich the Dirac physics founded in other 2D Dirac systems, and offer a new design mechanism for creating Dirac band by tuning the interaction range. We envision that the highly anisotropic Dirac crescent may be exploited in all-carbon-based electronic devices for manipulating anisotropic electron propagation.

**T1.00139 Microwave Irradiation on Halloysite-Polypropylene Nanocomposites**, OMAR ESPINO, BRIAN YUST, DORINA CHIPARA, Univ of Texas, Pan American, PULLICKEL AJAYAN, ALIN CHIPARA, Rice University, MIRCEA CHIPARA, Univ of Texas, Pan American, UTRGV COLLABORATION, RICE COLLABORATION — Halloysite is an unique cylindrical nanoclay characterized by poor electrical and thermal conductivity, which may become the filler of choice for the reinforcement of polymeric matrix, where electrical or thermal insulation are required. The main limits in the use of halloysite as replacement for carbon nanotube (CNT) are: 1. Smaller aspect ratio as halloysites are typically shorter than CNTs. 2. Smaller Young modulus of halloysites compared with CNTs. 3. Reduced thermal stability due to the loss of water upon heating. A research on halloysite dispersed within isotactic polypropylene is reported. To improve the interface between the halloysite and the polymeric matrix a microwave irradiation step has been considered. The local heating of the halloysite nanotubes is mediated by the absorbed/structural water content of the nanoclay. Nanocomposites loaded by various amounts of halloysite ranging from 0 % to 20 % wt. have been prepared by melt mixing by using a Haake RheoMixer. The as obtained nanocomposites have been subjected to microwave irradiation at 75 W in an Anton Paar Monowave 300 system and various irradiation times ranging from 5, 10, 15, 30, 45, and 60 minutes. The effect of microwave irradiation has been studied by Raman and FTIR spectroscopy

**T1.00140 On the Radial Breathing Mode in SWCNTs dispersed within PVC**, FERNANDO FLOR, The University of Texas Rio Grande Valley, PULLICKEL AJAYAN, ALIN CHIPARA, Rice University, KAREN LOZANO, DORINA CHIPARA, The University of Texas Rio Grande Valley, ROBERT VAJTAI, Rice University, MIRCEA CHIPARA, The University of Texas Rio Grande Valley, UTRGV-RICE COLLABORATION — The Radial Breathing Mode (RBM) is an unique set of Raman lines, characterized by shifts smaller than  $500\text{ cm}^{-1}$ , assigned to vibrations that affect the diameter of carbon nanotubes. The position of the RBM lines is inversely proportional to the diameter of nanotubes. RBM was reported in Single Walled Carbon Nanotubes (SWCNTs) and Double Walled Carbon Nanotubes. This mode is very sensitive being frequently used to obtain information regarding the stress transfer from the polymeric matrix. Nanocomposites have been prepared by loading the polyvinylchloride (PVC) purchased from Sigma Aldrich with SWCNTs from Cheap Tubes Inc., by melt mixing, using Haake Rheomix equipped with two counter rotating screws. The concentration of SWCNTs dispersed within PVC ranged from 0 % wt. up to 20 % wt. The as recorded spectra have been deconvoluted into several individual lines characterized by an extended Breit-Wigner-Fano line shape. A full analysis of the Raman spectra of the polymeric matrix and of the matrix is reported with emphasize on the RBM features. The spectra have been recorded by using a Renishaw InVia spectrometer equipped with Eclipse filters that allow the recording of Raman lines starting from about  $25\text{ cm}^{-1}$ .

**T1.00141 First Principles Study of Carbyne Structural Stability<sup>1</sup>**, KEVIN KWON<sup>2</sup>, COLIN HOLMES<sup>3</sup>, KI CHUL KIM<sup>4</sup>, SEUNG SOON JANG<sup>5</sup>, Georgia Institute of Technology — Carbyne is composed of linear sp-hybridized carbon bonds and yields promising results to surpass graphene's mechanical and electrical properties. Carbyne has two semi-stable conformations: Polyyne (alternating triple and single bonds) and Polycumulene (repeating double bonds). This study investigated the stability of these forms at infinite chain lengths by using periodic boundary conditions. Geometric optimization was performed via DFT calculations using DMol3 and PBE GGA functional group. Each configuration's chain was stretched or compressed until the most stable form – lowest energy – was obtained. After comparing the energies, the most stable form alternated between Polyyne and Polycumulene as the number of carbon atoms within each boundary increased. Polyyne was the most stable form for odd number of carbons and Polycumulene was the most stable for even number of carbons. Finally, K-point sampling was increased in the direction of the chain axis to obtain a more accurate depiction of structural stability. As the number of k-points increased, the Polycumulene structure became more stable compared to Polyyne.

**T1.00142 Monoclonal Antibodies Attached to Carbon Nanotube Transistors for Paclitaxel Detection**, WONBAE LEE, CALVIN LAU, MARK RICHARDSON, ARITH RAJAPAKSE, GREGORY WEISS, PHILIP COLLINS, Univ of California - Irvine, UCI, MOLECULAR BIOLOGY AND BIOCHEMISTRY COLLABORATION, UCI, DEPARTMENTS OF PHYSICS AND ASTRONOMY COLLABORATION — Paclitaxel is a naturally-occurring pharmaceutical used in numerous cancer treatments, despite its toxic side effects. Partial inhibition of this toxicity has been demonstrated using weakly interacting monoclonal antibodies (3C6 and 8A10), but accurate monitoring of antibody and paclitaxel concentrations remains challenging. Here, single-molecule studies of the kinetics of antibody-paclitaxel interactions have been performed using single-walled carbon nanotube field-effect transistors. The devices were sensitized with single antibody attachments to record the single-molecule binding dynamics of paclitaxel. This label-free technique recorded a range of dynamic interactions between the antibody and paclitaxel, and it provided sensitive paclitaxel detection for pM to nM concentrations. Measurements with two different antibodies suggest ways of extending this working range and uncovering the mechanistic differences among different antibodies.

**T1.00143 Observation of dopant-induced impurity states in bottom-up graphene nanoribbons**, ZAHRA PEDRAMRAZI, CHEN CHEN, TOMAS MARANGONI, RYAN CLOKE, TING CAO, STEVEN LOUIE, FELIX FISCHER, MICHAEL CROMMIE, Univ of California - Berkeley — Graphene nanoribbons (GNRs) provide a means for inducing energy gaps in graphene and are a promising candidate for many nanotechnological applications. New bottom-up fabrication techniques allow the structure of GNRs to be tuned with atomic precision, thus providing new opportunities for modifying their electronic structure. Here we report the synthesis of bottom-up armchair GNRs (AGNRs) with isolated substitutional boron-dopant centers; thus creating localized impurity states in the GNR. These impurities are realized via dilute doping of pristine n=7 AGNRs with sparse boron-containing monomer units, resulting in uniform-width n=7 AGNR segments where only two carbon atoms have been substitutionally replaced by boron atoms. Scanning tunneling microscopy (STM) and spectroscopy (STS) were performed to study the electronic structure of these AGNR impurity systems, enabling us to observe localized mid-gap impurity states.

**T1.00144 *In Situ* Characterization of Nanostructures Using Rayleigh Scattering<sup>1</sup>**, BISWAJIT SANTRA, MIKHAIL N. SHNEIDER, ROBERTO CAR, Princeton University, Princeton, USA — Controlling selective growth of nanotubes has posed a considerable challenge over the last two decades. A crucial step to overcoming such hurdle is to gain detailed knowledge of the early stage of nanomaterial syntheses for which *in situ* measurements are required. Laser-based probes, such as Rayleigh scattering (RS), can potentially characterize the shape and size of nanoparticles *in situ*. The intensity of RS in a gas mixed with nanoparticles is proportional to the polarizabilities of the constituent particles, therefore, theoretical spectroscopy can complement such measurements. Here, we employed time-dependent density functional theory to compute the frequency-dependent polarizabilities of various nanostructures and predicted the corresponding RS intensity and depolarization. We found that with increasing length and asymmetry of the nanostructures the longitudinal polarizability exhibited characteristic resonances leading to measurable signatures in the RS intensity and depolarization. Also by considering gas-particle mixtures at estimated experimental conditions for nanoparticle synthesis on the periphery of an arch, we predict that *in situ* characterization of a few nanometer long particles with concentration as low as one particle per million is feasible using RS.

**T1.00145 Giant Rashba spin-orbit splitting in  $n-p$  codoped graphene<sup>1</sup>**, SHIFEI QI, YINGPING YANG, Shanxi Normal University, ZHENHUA QIAO, University of Science & Technology of China, XIAOHONG XU, Shanxi Normal University, INSTITUTE OF MATERIALS CHEMISTRY TEAM, ICQD TEAM — Enhancement of the spin-orbit coupling (SOC) in graphene may lead to various topological phenomena and also find applications in spintronics. However, increasing the SOC strength in graphene without drastically affecting the basic physical properties is proving extremely difficult. Here, we propose a new approach, based on compensated  $n-p$  codoping, that can simultaneously address all the main shortcomings associated with single-element adsorption in graphene, effectively resulting in giant Rashba spin-orbit splitting. Our proposal is to deposit strong SOC adatoms with outer shell  $p$  electrons, acting as  $n$ -type dopants, onto already  $p$ -doped (e.g., by B) graphene. We found that: (1) the electrostatic attraction between the  $n$ - and  $p$ -type dopants effectively enhances the adsorption of the metal adatoms and suppress their undesirable clustering, (2) considerable ( $\sim 130$  meV) Rashba-type SO splitting can be achieved in the graphene  $\pi$  bands, (3) the charge compensated nature and mutually screening each other of the  $n-p$  codopants helps to preserve the Dirac nature of the charge carriers, and (4) the B doping effect together with intrinsic induced SOC by adatom also lead the codoped system open about 20  $\sim$  90 meV band gap.

**T1.00146 Flexible, Transparent and Conductive Carbon Nanotube Aerogels /PEDOT:PSS Electrodes created by Top-bottom Fabrication**, PATRICIA M. MARTINEZ, Univ of Texas, Dallas, ANDREA CERDAN PASARAN, University of Guanajuato, ANVAR ZAKHIDOV, Univ of Texas, Dallas, UNIVERSITY OF GUANAJUATO, MEXICO COLLABORATION — The sheets of Carbon Nanotubes (CNT) have proven to be a good substitute for ITO. To improve their conductivity and increase optical transparency we have created composites which incorporate silver nanowires or other evaporated metals. Coating CNT/metals with PEDOT:PSS is important for creating hole transport/electron barrier layer functionality, but it is not easy to achieve using PEDOT:PSS solutions due to the hydrophobicity of CNT. We report a new top-to-bottom approach for the fabrication of highly flexible, transparent and conductive carbon nanotube-based electrodes using PDMS as a substrate. A uniform and smooth layer of approximately 50 nm of PEDOT:PSS was spin coated on top of a PDMS stamp followed by the deposition of vapor densified freestanding Multiwall Carbon Nanotube (MWNT) aerogels. An incorporation of silver nanowires, silver or Aluminum thin layer can be sprayed or evaporated on top of the freestanding MWNT aerogels in order to lower the sheet resistance even further. The PDMS substrate is drop cast on top of the configuration then the PDMS stamp is lifted-up. The PEDOT:PSS layer is selectively deposited on top of the MWNT only. The composite electrodes can be laminated on photovoltaic devices and on LEDs.

**T1.00147 Computational design of metal-organic frameworks with paddlewheel-type secondary building units**, UDO SCHWINGENSCHLOGL, MAXIM V. PESKOV, NEJIB MASGHOUNI, PSE Division, KAUST, Thuwal 23955, Saudi Arabia — We employ the TOPOS package to study 697 coordination polymers containing paddlewheel-type secondary building units. The underlying nets are analyzed and 3 novel nets are chosen as potential topologies for paddlewheel-type metal organic frameworks (MOFs). Dicarboxylate linkers are used to build basic structures for novel isorecticular MOF series, aiming at relatively compact structures with a low number of atoms per unit cell. The structures are optimized using density functional theory. Afterwards the Grand Canonical Monte Carlo approach is employed to generate adsorption isotherms for CO<sub>2</sub>, CO, and CH<sub>4</sub> molecules. We utilize the universal forcefield for simulating the interaction between the molecules and hosting MOF. The diffusion behavior of the molecules inside the MOFs is analyzed by molecular dynamics simulations.

**T1.00148 Structural, Electronic and Magnetic Properties of Ti<sub>1+x</sub>FeSb and TiFe<sub>0.75</sub>M<sub>0.25</sub>Sb (M= Ni, Mn) Heusler Alloys**, SAID AL AZAR, Basic Sciences Department, Dar Al Uloom University, Riyadh, Saudi Arabia, AHMAD MOUSA, Department of Basic Sciences, Middle East University, Amman, Jordan — Density functional theory calculations based on full potential linearized augmented plane-wave (FPLAPW) plus local orbital method in the framework of GGA-PBE, as embodied in the WIEN2k code, is used to investigate the structural, electronic and magnetic properties of intermetallic Ti<sub>1+x</sub>FeSb Heusler compounds, where ( $x = i/4$ ,  $i = -3, -2, -1, 0, 1, 2, 3, 4$ ) and the TiFe<sub>0.75</sub>M<sub>0.25</sub>Sb (M = Ni, Mn) quaternary semi-Heusler compounds. Moreover, the modified Becke-Johnson exchange potential, as a semi-local method, was employed to predict the band-gap more precisely. We examined the site preference of the parent compound TiFeSb and varying the electron concentration by doping or removing a Ti atom. It is found that they play a crucial role in physical properties of these material systems. The lattice parameters and spin magnetic moment calculated were consistent with the previous experimental and theoretical data available. Moreover, alloys with  $x < 0$  are found to exhibit a ferrimagnetic phase, and the alloy with  $x = 0.25$  exhibit a non-magnetic properties, whereas the rest have shown ferromagnetic phase. The band-structure analysis of Ti<sub>1.75</sub>FeSb, Ti<sub>2</sub>FeSb and TiFe<sub>0.75</sub>Ni<sub>0.25</sub>Sb alloys suggested that they could be a ferromagnetic half-metallic members with band-gaps 0.67, 0.41 and 0.54 eV, respectively.

**T1.00149 Stability of Carbyne: First Principles Approach**, KEVIN KWON, COLIN HOLMES, SEUNG SOON JANG, School of Materials Science and Engineering, Georgia Institute of Technology 771 Ferst Drive, Atlanta, GA 30332-0245 — Over the last decade, carbon based nanomaterials have gained attention due to the discovery of graphene and its extraordinary properties. This has inspired new research into other carbon allotropes to obtain their unique properties. Carbyne is one such allotrope composed of linear sp-hybridized carbon bonds that has promising results and characteristics to surpass graphene's mechanical strength and possess novel electrical properties. It has two semi-stable conformations: Polyyne (alternating triple and single bonds) and Polycumulene (repeating double bonds). We investigated the stability of these forms with infinite chain lengths by employing periodic boundary conditions. Geometric optimization was performed using DMol3 with GGA PBE. After comparing the energies, the most stable form alternated between Polyyne and Polycumulene as the number of carbon atoms within each boundary increased; furthermore, every odd carbon atoms showed Polyyne as the most stable form, while every even number of carbon atoms showed Polycumulene as the most stable form. Considering k-point sampling resulted in the Polycumulene structure being the most stable as the number of k-points increased.

**T1.00150 Development and Validation of Polarized Models for Peptide-Graphene Interactions**, HENDRIK HEINZ, AMANDA GARLEY, NABANITA SAIKIA, University of Colorado - Boulder, STEPHEN BARR, GARY LEUTY, RAJIV BERRY, Air Force Research Laboratory — Biosensor technologies require the understanding of interactions between organic and inorganic materials to tune electric response functions, such as peptide assembly on graphitic substrates. Laboratory characterization of specific interactions and molecular assembly of such biomolecules in atomic resolution remains challenging. These methods can be complemented by molecular simulations and quantum-mechanical analysis of band gaps and expected conductivity. We improved common dispersive interatomic potentials for graphite and graphene to include pi electron density at virtual sites. The new models reproduce experimental X-ray structure, density, cleavage energy, hydration energy, and contact angles. As a result we have improved existing models which gave the wrong sign of hydration energies and deviations on the order of 30% in other properties. The parameters are embedded in CHARMM, CVFF, TEAM-AMBER, and other common force fields as part of the INTERFACE force field. An analysis of binding residues, binding energies, conformations, and dynamic information of molecular mobility on the surfaces will be presented.

**T1.00151 Accurate prediction of the refractive index of polymers using first principles and data modeling**, MOHAMMAD ATIF FAIZ AFZAL, CHONG CHENG, JOHANNES HACHMANN, State Univ of NY - Buffalo — Organic polymers with a high refractive index (RI) have recently attracted considerable interest due to their potential application in optical and optoelectronic devices. The ability to tailor the molecular structure of polymers is the key to increasing the accessible RI values. Our work concerns the creation of predictive *in silico* models for the optical properties of organic polymers, the screening of large-scale candidate libraries, and the mining of the resulting data to extract the underlying design principles that govern their performance. This work was set up to guide our experimentalist partners and allow them to target the most promising candidates. Our model is based on the Lorentz-Lorenz equation and thus includes the polarizability and number density values for each candidate. For the former, we performed a detailed benchmark study of different density functionals, basis sets, and the extrapolation scheme towards the polymer limit. For the number density we devised an exceedingly efficient machine learning approach to correlate the polymer structure and the packing fraction in the bulk material. We validated the proposed RI model against the experimentally known RI values of 112 polymers. We could show that the proposed combination of physical and data modeling is both successful and highly economical to characterize a wide range of organic polymers, which is a prerequisite for virtual high-throughput screening.

**T1.00152 Nanoscale Characterization of Organometal Trihalide Perovskite using Photothermal Induced Resonance (PTIR) Technique**, JUNGSEOK CHAE, ANDREA CENTRONE, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, YONGBO YUAN, YUCHUAN SHAO, QI WANG, ZHENG GUO XIAO, QINGFENG DONG, JINSONG HUANG, Department of Mechanical and Materials Engineering, University of Nebraska-Lincoln — Further improvement of the performance of organometal trihalide perovskites (OTP) solar cells can be aided by nanoscale characterization. Photothermal induced resonance (PTIR), is a novel scanning probe method that enable measuring vibrational and electronic absorption maps and spectra with a resolution as high as 20 nm. In this presentation, the chemical composition and bandgap of OTP thin films was characterized with PTIR: 1) to identify the origin of the switchable photovoltaic effect and 2) to quantify the local chloride content in mixed-halide perovskites. PTIR vibrational maps recorded in correspondence of methyl ammonium ions (MA<sup>+</sup>) for a as prepared lateral structure solar cell were uniform but displayed stronger intensity in proximity of the cathode after electric poling. Those measurements provide the first direct proof of ion electron migration in OTP devices. Because chloride incorporation modifies the bandgap in MAPbI<sub>3</sub>-xCl<sub>x</sub> perovskites, PTIR electronic maps and spectra were used to extract the local chloride content as a function of annealing. Results show that the as-prepared sample consist of a mixture of Cl-rich and Cl-poor phases that evolves into a homogenous Cl-poorer phase upon annealing. This measurement suggests that Cl<sup>-</sup> is progressively expelled from the film.

**T1.00153 High Pressure Raman Spectroscopic Studies on CuInTe<sub>2</sub> Quantum Dots<sup>1</sup>**, HOWARD YANXON, RAVHI KUMAR, University of Nevada Las Vegas - HiPSEC, HIPSEC - UNIVERSITY OF NEVADA LAS VEGAS TEAM — High pressure Raman spectroscopy studies were performed on CuInTe<sub>2</sub> Quantum Dots (QD) up to 7.7 GPa. At ambient conditions, the Raman modes of the QD loaded into a high-pressure diamond anvil cell (DAC) were observed at 125.1 cm<sup>-1</sup> (A<sub>1</sub> mode) and 142.8 cm<sup>-1</sup> (B<sub>2</sub> or E mode). As the pressure increases, the A<sub>1</sub> mode starts to split above 2 GPa and shifts to the left as indication of a structural change. A pressure-induced phase transition was observed around 2.9 GPa due to the collapse of the modes with the appearance of a new Raman peaks. The phase transition observed in our experiments compare well with the characteristics of bulk and larger nanoparticles. Further, it could be concluded that the phase transition pressure observed mainly depends on the particle size.

<sup>1</sup>H.Y. thanks McNair foundation for fellowship award. He also acknowledges Melanie White, Jason Baker and Phuc Tran for help in the experiments. He thanks Michael Pravica for using the Raman facility.

**T1.00154 Tunneling spectroscopy of multi-shell carbon fullerenes<sup>1</sup>**, KEITH DOORE, MATT COOK, ERIC CLAUSEN, TIM KIDD, ZHIPENG YE, GAIHUA YE, RUI HE, ANDREW STOLLENWERK, University of Northern Iowa — Carbon allotropes such as fullerenes and nanotubes have generated considerable interest due possible exploitation of their mechanical and electrical properties for practical applications. Carbon onions are a type of fullerene consisting of multiple spherically concentric shells of curved graphitic sheets. Compared to single-shell fullerenes, few studies have been directed toward understanding the structural and electrical properties of carbon onions. Because carbon onions have proven difficult to fabricate in a controlled method, most of these studies have focused on synthesis methods. In this study, we investigate the electrical properties of carbon onions using a scanning tunneling microscope. Carbon onions were fabricated using ultrasonic agitation to break down isopropanol facilitated by a MoS<sub>2</sub> catalyst. Particles suspended in the remaining solution were deposited onto atomically flat HOPG substrates. Scanning tunneling spectroscopy indicate that carbon onions can exhibit both metallic and semiconducting properties, similar to carbon nanotubes.

**T1.00155 Electro-optical properties of a bilayer  $\beta$ -graphyne<sup>1</sup>**, MÓNICA PACHECO, UNIVERSIDAD TECNICA FEDERICO SANTA MARIA, ALEJANDRO LEÓN, UNIVERSIDAD DIEGO PORTALES — Graphynes (GYs) are graphene-like structures that can be constructed by replacing some bonds = C = C = in graphene by acetylenic linkages, - C  $\equiv$  C - [1]. According to first-principles calculations [2] the so-called  $\beta$ -graphyne, has a Dirac cone not located at the K and K' points of the Brillouin zone but on lines between the high symmetry  $\Gamma$  and M points. In a previous work we show that a bilayer of  $\beta$ -graphyne can be metal or semiconductor, depending on the staking. An electric field applied perpendicular to the layers has remarkable effects on the electronic properties of this structure. We have found that the field can close the gap in the case of semiconductor bilayers [3]. In this work we perform a theoretical study of the electro-optical properties of a bilayer  $\beta$ -graphyne. Calculations are based on density functional theory (DFT) method. The indirect and direct band gap of the optimized lattice parameters is calculated by ABINIT. Finally, the dielectric function of the bilayer  $\beta$ -graphyne is calculated. Our results show that the optical properties of this type of graphyne are strongly anisotropic and that the optical band gap can be tuned by means of an external electric field. **T1.00156 ABSTRACT WITHDRAWN —**

**T1.00157 Reactivity of Graphene Investigated by Density-Functional Theory<sup>1</sup>**, HIMADRI SONI, JULIAN GEBHARDT, ANDREAS GRUNG, Friedrich-Alexander Universität Erlangen-Nürnberg, CHAIR OF THEORETICAL CHEMISTRY TEAM — Using spin-polarized density-functional theory, we study the adsorption and reaction of hydrogen and fluorine with graphene. Graphene has a bipartite lattice with two different sublattices and hence, due to Lieb's theorem, the inequality between two sublattices should lead to a net magnetic moment upon adsorption of hydrogen or fluorine. Our calculations using density-functional theory with the generalized gradient approximation predict a magnetic moment of 1 B for a single hydrogen adsorbed on graphene but not for a single fluorine atom adsorbed on graphene. Switching to hybrid density-functional theory with the HSE functional [1], we obtain a magnetic moment of 1 B for a single fluorine atom adsorption on graphene. This is in line with work of Kim et al. [2], who also found in density-functional theory calculations with the HSE exchange-correlation functional spin-polarization for a fluorine adatom on graphene. Here, we present a systematic study of the reactivity and relevant adsorption mechanism for single-sided graphene, i.e., a graphene sheet which is accessible by an adsorbate from only one side with hydrogen and fluorine using hybrid density-functional theory. **T1.00158 Electronic structures of hybrid graphene/boron nitride nanoribbons with hydrogen adsorption<sup>1</sup>**, CHI-HSUAN LEE, CHIH-KAI YANG, National Chengchi University — Electronic properties of hybrid graphene/boron nitride nanoribbons are investigated using density functional calculations. It is found that hydrogen adsorption on a graphene nanoribbon alters band structures drastically. Furthermore, H-vacancy chains and lines can effectively shape the conduction properties. Influences of edge atoms with nonzero magnetic moments and the interface between B and N are also prominent in the electronic structures.

**T1.00159 Role of Cooperative Interactions in the Intercalation of Heteroatoms between Graphene and a Metal Substrate**, SHIXUAN DU, Institute of Physics, Chinese Academy of Sciences — Graphene, a two-dimensional crystal of carbon atoms packed in a honeycomb structure, has many promising mechanical, electrical, and optical properties. The intercalation of heteroatoms between graphene and a metal substrate has been studied intensively over the past few years, due to its effect on the graphene properties, and as a method to create vertical heterostructures. Various intercalation processes have been reported with different combinations of heteroatoms and substrates. In this talk, I will present the investigation of the key processes governing the intercalation of heteroatoms between graphene and a substrate by combining atomic-scale characterization with density functional theory (DFT). Si intercalation between graphene and Ru(0001) is chosen as a test bed. We elucidate the role of cooperative interactions between heteroatoms, graphene, and substrate. By combining scanning tunneling microscopy with density functional theory, the intercalation process is confirmed to consist of four key steps, involving creation of defects, migration of heteroatoms, self-repairing of graphene, and growth of an intercalated monolayer. Other combinations of heteroatoms (such as Ni, Pd and Pt) and substrates (such as Ir(111) and SiC(0001)) are also investigated to support the generality of our study. Both theory and experiments indicate that this mechanism applies also to other combinations of heteroatoms and substrates. (G. Li et al., J. Am. Chem. Soc. 137 (2015) 7099. In collaboration with G. Li, H.T. Zhou, L.D. Pan, Y. Zhang, L. Huang, W.Y. Xu, and H.J. Gao in CAS, Min Ouyang in MU, and A.C. Ferrari in U. Cambridge.)

**T1.00160 Optical properties of AAB-stacked trilayer graphene.**, CHIH-WEI CHIU, Department of Physics, National Kaohsiung Normal University, Taiwan, RONG-BIN CHEN, Center of General Studies, National Kaohsiung Marine University, Taiwan, MING-FA LIN, Department of Physics, National Cheng Kung University, Taiwan, YUAN-CHENG HUANG, Center for General Education, Kao Yuan University, Taiwan — The band structures and optical properties of AAB-stacked trilayer graphenes (AAB-TLG) are calculated by the tight-binding model and gradient approximation. There are one pair of parabolic bands and two pairs of wavy bands at low energy, and three pairs of saddle points at the middle energy. At zero electric field, 3<sup>2</sup> excitation channels exist in both the low and middle frequencies, and cause the very rich joint density of states (JDOS). However, the structures in the JDOS do not appear in the absorption spectra completely. In the spectra, due to the velocity metric elements, the transitions between the same pair only make the slight contributions in the low frequency, except for the transition between the pair of the lowest bands. Furthermore, three transitions with the similar energies at the saddle points peaks lead to a strong peak in the middle frequency. The energy dispersions and the energy spacing exhibit obvious variations with the change of the electric field, and thus the absorption spectra..

**T1.00161 A new way of describing the Dirac bands in graphene**, GREGORY KISSINGER, SASHI SATPATHY, University of Missouri-Columbia — We develop a new way of describing the electronic structure of graphene, by treating the honeycomb lattice as a network of one-dimensional quantum wires. The electrons travel as free particles along these quantum wires and interfere at the three-way junctions formed by the carbon atoms. The model generates the linearly dispersive Dirac cone band structure as well as the chiral nature of the pseudo-spin sublattice wave functions. When vacancies are incorporated, we find that it also reproduces the well known zero mode states. This simple approach might have advantages over other methods for some applications, such as in analyzing electronic transport through graphene nanoribbons. In addition, this finding suggests new ways of constructing Dirac band materials in the laboratory by nano-patterning for investigating Dirac fermions.

**T1.00162 Electronic and geometrical properties of monoatomic and diatomic 2D honeycomb lattices. A DFT study<sup>1</sup>**, NGELA ROJAS, RAFAEL REY, KAREN FONSECA, Universidad Nacional de Colombia, GRUPO DE FÍSICA E INFORMÁTICA CUNTA TEAM — Since the discovery of graphene by Geim and Novoselov at 2004, several analogous systems have been theoretically and experimentally studied, due to their technological interest. Both monoatomic lattices, such as silicene and germanene, and diatomic lattices (h-GaAs and h-GaN) have been studied. Using Density Functional Theory we obtain and confirm the chemical stability of these hexagonal 2D systems through the total energy curves as a function of interatomic distance. Unlike graphene, silicene and germanene, gapless materials, h-GaAs and h-GaN exhibit electronic gaps, different from that of the bulk, which could be interesting for the industry. On the other hand, the ab initio band structure calculations for graphene, silicene and germanene show a non-circular cross section around K points, at variance with the prediction of usual Tight-binding models. In fact, we have found that Dirac cones display a dihedral group symmetry. This implies that Fermi speed can change up to 30% due to the orientation of the wave vector, for both electrons and holes. Traditional analytic studies use the Dirac equation for the electron dynamics at low energies. However, this equation assumes an isotropic, homogeneous and uniform space.

**T1.00163 Magneto-optical transitions in bilayer graphene nanoribbons<sup>1</sup>**, HSIEN-CHING CHUNG, MING-FA LIN, Natl Cheng Kung Univ — We utilize the tight-binding theory to study the magneto-optical transitions in bilayer graphene nanoribbons. The magneto-absorption spectra highly depend on the stacking, edge orientation, ribbon width, and strength of magnetic field. The competition between the magnetic quantization and lateral confinement results in the coexistence of edge-dependent selection rules and magneto-absorption selection rule. The magneto-electronic properties, including energy dispersions, density of states, and wave functions, are also discussed in detail.

<sup>1</sup>One of us (Hsien-Ching Chung) thanks Ming-Hui Chung and Su-Ming Chen for financial support. This work was supported in part by the National Science Council of Taiwan under grant number NSC 102-2112-M-006-007-MY3.

**T1.00164 Semiconducting graphene nanoribbon fabricated by gate-controlled, edge-selective photo-oxidation of graphene.**, MORIHIRO MATSUMOTO, RYO NOUCHI, Nanoscience and Nanotechnology Research Center, Osaka Prefecture University, Sakai 599-8570, Japan — Graphene is attracting much attention for its ultrahigh carrier mobility, and is expected as the next generation material which makes high speed communication possible. However, since graphene has no bandgap, its conductivity cannot be turned completely off. Thus, pristine graphene cannot be used as a transistor in logic applications, where high on/off current ratios are required. It is known that narrow graphene nanoribbons with nanometer-scale widths show semiconducting characteristics with sufficiently large bandgap [1]. In this presentation, we propose and demonstrate a new method to fabricate graphene nanoribbons at room temperature in air. We have found that ultraviolet(UV)-induced photochemical reactions can be controlled by a configuration of a field effect transistor, and graphene edges are selectively photo-oxidized by the UV irradiation under a negative gate voltage and a finite drain voltage [2]. By means of this gate-controlled, edge-selective photo-oxidation, we succeeded to improve the on/off ratio from 2.7 to 43 at room temperature. [1] Y. W. Son, M. L. Cohen, and S. G. Louie, Phys. Rev. Lett. **97**, 216803 (2006). [2] N. Mitoma and R. Nouchi, Appl. Phys. Lett. **103**, 201605 (2013).

**T1.00165 Controllably Inducing and Modeling Optical Response from Graphene Oxide**, NICHOLAS LOMBARDO, Central Connecticut State University, ANTON NAUMOV, Texas Christian University — Graphene, a novel 2-dimensional  $sp^2$ -hybridized allotrope of Carbon, has unique electrical and mechanical properties. While it is naturally a highly conductive zero band gap semiconductor, graphene does not exhibit optical emission. It has been shown that functionalization with oxygen-containing groups elicits an opening of band gap in graphene. In this work, we aim to induce an optical response in graphene via controlled oxidation, and then explore potential origins of its photoluminescence through mathematical modeling. We employ timed ozone treatment of initially non-fluorescent reduced graphene oxide (RGO) to produce graphene oxide (GO) with specific optical properties. Oxidized material exhibits substantial changes in the absorption spectra and a broad photoluminescence feature, centered at 532 nm, which suggests the appearance of a band gap. We then explore a number of possible mechanisms for the origin of GO photoluminescence via PM3 and ab initio calculations on a functionalized single sheet of graphene. By adjusting modeling parameters to fit experimentally obtained optical transition energies we estimate the size of the  $sp^2$  graphitic regions in GO and the arrangement of functional groups that could be responsible for the observed emission.

**T1.00166 Plasmon-polaritonic bands in sequential doped graphene superlattices<sup>1</sup>**, FELIPE RAMOS-MENDIETA, Departamento de Investigación en Física, Universidad de Sonora, MARTHA PALOMINO-OVANDO, Facultad de Ciencias Físico-Matemáticas, Benemérita Universidad Autónoma de Puebla, ALEJANDRO HERNÁNDEZ-LÓPEZ, Facultad de Ciencias Físico-Matemáticas, Benemérita Universidad Autónoma de Puebla, IVÁN FUENTECILLA-CÁRCAMO, Facultad de Ciencias Físico-Matemáticas, Benemérita Universidad Autónoma de Puebla — Doped graphene has the extraordinary quality of supporting two types of surface excitations that involve electric charges (the transverse magnetic surface plasmons) or electric currents (the transverse electric modes). We have studied numerically the collective modes that result from the coupling of surface plasmons in doped graphene multilayers. By use of structured supercells with fixed dielectric background and inter layer separation, we found a series of plasmon-polaritonic bands of structure dependent on the doping sequence chosen for the graphene sheets. Periodic and quasiperiodic sequences for the graphene chemical potential have been studied. Our results show that transverse magnetic bands exist only in the low frequency regime but transverse electric bands arise within specific ranges of higher frequencies. Our calculations are valid for THz frequencies and graphene sheets with doping levels between 0.1 eV and 1.2 eV have been considered.

**T1.00167 Localization properties of graphene Landau levels: The role of edge states**, DANIEL SOLIS, Instituto de Física IFGW, Universidade Estadual de Campinas, CARLOS PAEZ, PETER SCHULZ, ANA PEREIRA, Faculdade de Ciências Aplicadas FCA, Universidade Estadual de Campinas, Limeira — The observation of the quantum Hall effect for graphene in 2005 represented an important landmark, proving the genuine two-dimensional nature of graphene. Here we use a tight-binding approach to investigate the localization properties of quantum Hall edge states of graphene flakes with sharp edges. In order to identify which wave function is concentrated in the edges, or distributed in the bulk, we defined a quantity named "Edge Fraction", indicating the fraction of electronic probability densities over the atomic sites at distances from the edges limited to twice the magnetic length  $l_B$ . We also calculate separately the fraction of the wave function amplitude over zigzag or armchair edges, observing an interesting and clear pattern for different energies between consecutive Landau levels. The edge states are manifested in the presence of states among the Landau levels. Here we explored the interplay of different square lattices sizes and disorder in the localization properties of the system. We observed that size variation do not affect the behavior of the Edge Fraction. Also it was found that exist a dependence between the behavior of the Edge Fraction for the armchair and zigzag contribution with respect to disorder.

**T1.00168 STRONGLY CORRELATED SYSTEMS, INCLUDING QUANTUM FLUIDS AND SOLIDS** —

**T1.00169 Optical Signatures of Weyl Points in TaAs**, BING XU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China, YAOMIN DAI, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, LINGXIAO ZHAO, KAI WANG, RUN YANG, WEI ZHANG, JINYUN LIU, HONG XIAO, GENFU CHEN, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China, A. J. TAYLOR, D. A. YAROTSKI, R. P. PRASANKUMAR, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, XIANGGANG QIU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China — We present a systematic study of both the temperature and frequency dependence of the optical response in TaAs, a material that has recently been realized to host the Weyl semimetal state. Our study reveals that the optical conductivity of TaAs features a narrow Drude response alongside a conspicuous linear dependence on frequency. The width of the Drude peak decreases upon cooling, following a  $T^2$  temperature dependence which is expected for Weyl semimetals. Two linear components with distinct slopes dominate the 5-K optical conductivity. A comparison between our experimental results and theoretical calculations suggests that the linear conductivity below  $\sim 230 \text{ cm}^{-1}$  is a clear signature of the Weyl points lying in very close proximity to the Fermi energy.

**T1.00170 Theoretical analysis of high-resolution X-ray absorption spectra and 2p-3d resonant X-ray emission spectra of CeO<sub>2</sub>** , HIRONORI TONAI, Osaka Prefecture University, NAOMI KAWAMURA, MASAICHIRO MIZUMAKI, JASRI/SPRing-8, TAKAYUKI UOZUMI, Osaka Prefecture University — The 3d and 4f systems show various attractive phenomena due to strong electron correlations. The X-ray core-level spectroscopy, such as X-ray absorption spectroscopy (XAS), is an efficient technique to investigate electronic states of the systems. Recent years, the experimental techniques have been rapidly developing, and, especially, the progress in the experimental resolution has enabled us to observe fine spectral features. For example, a pioneering work was made by K. Hmlinen et al.[1] Recently, we performed high-resolution XAS experiments (partial fluorescence yield; PFY) and observed a peak corresponding to 2p-4f quadrupole transition around the pre-edge region of the L<sub>3</sub>-edge of CeO<sub>2</sub>. Conventionally, X-ray spectra have been analyzed using a phenomenological impurity Anderson model (IAM). However, such a simplified model does not seem to be appropriate for analysis of high-resolution spectrum because of possible ambiguities from the choice of adjustable parameters included. Thus we constructed an IAM framework combined with a first principle band calculation. In this meeting, we report experimental results and theoretical analysis for the PFY spectrum and 2p-3d resonant X-ray emission spectroscopy. [1] K. Hmlinen et al., PRL 67 (1991) 2850.

**T1.00171 The 4f multipole ordering effect on core-level spectroscopies of Ce intermetallics** , NORIMASA SASABE, HIRONORI TONAI, TAKAYUKI UOZUMI, Osaka Prefecture University — The 3d transition metal compounds and 4f rare earth compounds show attractive phenomena, such as superconductivity and Kondo effect, due to strong electron correlations among localized 3d and 4f electrons. Especially, multipole ordering of orbital and/or spin in 4f and 5f compounds are attracting much attention these years. For example, CeB<sub>6</sub> is known to show antiferro-quadrupolar (AFQ) ordering below 3.2K. X-ray core-level spectroscopy is an efficient technique to investigate the electronic states of strongly correlated systems. Recent years, experimental techniques have been rapidly developing and, especially, the progress in experimental resolution has enabled us to observe fine spectral features, which were not formerly observed. These advantages will enable us to observe spectral fine features related with the multipole ordering. In this study, we discuss multipole ordering effects on X-ray spectra for CeB<sub>6</sub>, especially paying attention on the polarization dependence. In order to simulate the electronic state of CeB<sub>6</sub> with the multipole ordering, we use an impurity Anderson model including realistic valence structure and a simplified RKKY interaction.

**T1.00172 Twisted Boundary Conditions for Lattice Monte Carlo Simulations** , JOSEPH PAKI, EMANUEL GULL, University of Michigan, SIMMONS MANY BODY PHYSICS COLLABORATION — Numerical simulations for spatially correlated lattice models have made progress via Dynamical Mean Field Theory and Dynamical Cluster Approximation, but are still hindered by a computational cost that scales exponentially with lattice size. We present a method of addressing finite size errors in a computationally efficient manner by running simulations with twisted boundary conditions. Averaging over these boundary conditions allows for thermodynamic extrapolation of physical quantities of interest without the cost associated with large system simulations.

**T1.00173 Structural and Magnetic Phase Coexistence in Oxygen Deficient Perovskites (Sr,Ca)FeO<sub>2.5+δ</sub>** , J. P. CARLO, M. E. EVANS, J. A. ANCZARSKI, J. OCK, K. BOYD, J. R. POLICHEMI, I. A. LEAHY, W. VOGEL, A. J. VIESCAS, G. C. PAPAETHYMIU, Villanova University — A variety of compounds crystallize into perovskite and similar structures, making them versatile laboratories for many phenomena and applications, including multiferroicity, superconductivity, and photovoltaics. Oxygen-deficient perovskites ABO<sub>x</sub> have attracted interest for use in fuel cells and related applications due to high oxygen mobility and the possibility of charge disproportionation. Vast chemical flexibility is obtained through reductions in lattice symmetry and rotation/distortion of the BO<sub>6</sub> octahedra, as well as ordering of oxygen vacancies. We have synthesized and studied the structural and magnetic properties of oxygen-deficient perovskites (Sr,Ca)FeO<sub>2.5+δ</sub> using x-ray diffraction and Mossbauer spectroscopy. While the ideal perovskite has  $\delta = 0.5$ , this requires Fe<sup>4+</sup>, and hence strongly oxidizing environments. When grown in air, Fe<sup>3+</sup> is favored, yielding  $\delta \approx 0$ . SrFeO<sub>2.5+δ</sub> exhibits cubic symmetry and paramagnetism at 300K, but CaFeO<sub>2.5+δ</sub> crystallizes into the orthorhombic brownmillerite structure, and is magnetically ordered at 300K. In the doped intermediaries we find coexistence of cubic/paramagnetic and orthorhombic/magnetic phases over a wide range of Ca content.

**T1.00175 Introducing a New Capability at SSRL: Resonant Soft X-ray Scattering** , JUN-SIK LEE, HOYOUNG JANG, DONGHUI LU, SSRL/SLAC National Accelerator Laboratory, CHI-CHANG KAO, SLAC National Accelerator Laboratory — Stanford Synchrotron Radiation Lightsource (SSRL) at SLAC recently developed a setup for the resonant soft x-ray scattering (RSXS). In general, the RSXS technique uniquely probes not only structural information, but also chemical specific information. This is because this technique can explore the spatial periodicities of charge, orbital, spin, and lattice with spectroscopic aspect. Moreover, the soft x-ray range is particularly relevant for a study of soft materials as it covers the K-edge of C, N, F, and O, as well as the L-edges of transition metals and M-edges of rare-earth elements. Hence, the RSXS capability has been regarded as a very powerful technique for investigating the intrinsic properties of materials such as quantum- and energy-materials. The RSXS capability at the SSRL composes of in-vacuum 4-circle diffractometer. There are also the fully motorized sample-motion manipulations. Also, the sample can be cooled down to 25 K via the liquid helium. This capability has been installed at BL 13-3, where the photon source is from elliptically polarized undulator (EPU). Covering the photon energies is from 230 eV to 1400 eV. Furthermore, this EPU system offers more degree of freedoms for controlling x-ray polarizations (linear and circular). Using the advance of controlling x-ray polarization, we can also investigate a morphology effect of local domain/grain in materials. The detailed introduction of the RSXS end-station and several results will be touched in this poster presentation.

**T1.00176 Electric-field-driven resistive switching in dissipative Hubbard model** , JIAJUN LI, State Univ of NY - Buffalo, CAMILLE ARON, Princeton University, GABRIEL KOTLIAR, Rutgers University, JONG HAN, State Univ of NY - Buffalo — Understanding of solids driven out of equilibrium by external fields has been one of the central goals in condensed matter physics for the past century and is relevant to nanotechnology applications such as resistive transitions. We study how strongly correlated electrons on a dissipative lattice evolve from equilibrium when driven by a constant electric field, focusing on the extent of the linear regime and hysteretic non-linear effects at higher fields. We access the non-equilibrium steady states, non-perturbatively in both the field and the electronic interactions, by means of a non-equilibrium dynamical mean-field theory in the Coulomb gauge. The linear response regime is limited by Joule heating effects and breaks down at fields orders of magnitude smaller than the quasi-particle energy scale. For large electronic interactions, strong but experimentally accessible electric fields can induce a resistive switching by driving the strongly correlated metal into a Mott insulator. Hysteretic I-V curves suggest that the non-equilibrium current is carried through a spatially inhomogeneous metal-insulator mixed state.<sup>1</sup>

**T1.00177 Unconventional but tunable phase transition above the percolation threshold by two-layer conduction in electroless-deposited Au nanostructures on silicon substrate<sup>1</sup>**, SEUNG-HOON LEE, Department of Physics, Pukyong National University, SEONGPIL HWANG, Department of Advanced Materials Chemistry, Korea University, JAW-WON JANG<sup>2</sup>, Department of Physics, Pukyong National University — Previous research has shown that disorder, dislocation, and carrier concentration are the main factors impacting transitions in the traditional metal–insulator transition (MIT) and metal–semiconductor transition (MST). In this study, it is demonstrated that a non-traditional MST governed by two-layer conduction is possible by tuning the conducting channel of one layer of the two-layer conduction system. By means of the electroless deposition method we produced Au nanostructures (AuNFs) on p-type silicon (p-Si) as the two-layer conduction system, controlling AuNF coverage (Au%) below and above the percolation threshold (pc). Even when the AuNF coverage percentage is larger than pc, the resistivities of the AuNFs on p-Si show MST as the temperature increases. We present a conduction model based upon two predominant parallel conduction channels by AuNFs and p-Si in the present paper. In the results, we show how the temperature of the MST is tuned from 145 to 232 K as Au% is changed from 82.7 to 54.3%.

**T1.00178 Fractal nature of metallic and insulating domain configurations in nearly grain-boundary-free VO<sub>2</sub>/TiO<sub>2</sub> thin films**, AHRUM SOHN, Ewha womans university, TERUO KANKI, HIDEKAZU TANAKA, Osaka university, DONG-WOOK KIM, Ewha womans university — We investigated evolution of the surface work function ( $W_S$ ) maps of epitaxial 15-nm-thick VO<sub>2</sub>/TiO<sub>2</sub> thin films using Kelvin probe force microscopy (KPFM) measurements while the film undergoes the metal–insulator transition (MIT). The metallic and insulating domains coexist in the VO<sub>2</sub> thin films during the transition, since the MIT is the first-order phase transition. Nearly grain-boundary-free samples allowed observation of metallic and insulating domains with distinct  $W_S$  values, throughout the transition. Each domain allowed us to obtain real space domain maps with nanoscopic spatial resolution. The two-dimensional percolation model well explained the relationship between the metallic domain fraction and the measured the resistivity. The domain maps also suggested that the percolation clusters formed a fractal surface.

**T1.00179 On metal-insulator transition in cubic fullerides**, NAOYA IWAHARA, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — The interplay between degenerate orbital and electron correlation is a key to characterize the electronic phases in, for example, transition metal compounds [1,2] and alkali-doped fullerides [3]. Besides, the degenerate orbital couples to spin and lattice degrees of freedom, giving rise to exotic phenomena. Here, we develop the self-consistent Gutzwiller approach for the simultaneous treatment of the Jahn-Teller effect and electron correlation, and apply the methodology to reveal the nature of the ground electronic state of fullerides [4]. For small Coulomb repulsion on site  $U$ , the fulleride is quasi degenerate correlated metal. With increase of  $U$ , we found the quantum phase transition from the metallic phase to JT split phase. In the latter, the Mott transition (MT) mainly develops in the half-filled subband, whereas the empty and the completely filled subbands are almost uninvolved. Therefore, we can qualify the metal-insulator transition in fullerides as an orbital selective MT [2] induced by JT effect. [1] Y. Tokura and N. Nagaosa, Science **288**, 462 (2000). [2] A. **T1.00180 Vanadium dioxide thin films prepared on silicon by low temperature MBE growth and ex-situ annealing<sup>1</sup>**, PIA HOMM, BART VAN BILZEN, MARIELA MENGHINI, JEAN-PIERRE LOCQUET, KU Leuven, TODORA IVANOVA, LUIS SANCHEZ, PABLO SANCHIS, Universidad Politécnica de Valencia — Vanadium dioxide (VO<sub>2</sub>) is a material that shows an insulator to metal transition (IMT) near room temperature. This property can be exploited for applications in field effect devices, electro-optical switches and nonlinear circuit components. We have prepared VO<sub>2</sub> thin films on silicon wafers by combining a low temperature MBE growth with an ex-situ annealing at high temperature. We investigated the structural, electrical and optical characteristics of films with thicknesses ranging from 10 to 100 nm. We have also studied the influence of the substrate cleaning. The films grown with our method are polycrystalline with a preferred orientation in the (011) direction of the monoclinic phase. For the films produced on silicon with a native oxide, an IMT at around 75 °C is observed. The magnitude of the resistance change across the IMT decreases with thickness while the refractive index at room temperature corresponds with values reported in the literature for thin films. The successful growth of VO<sub>2</sub> films on silicon with good electrical and optical properties is an important step towards the integration of VO<sub>2</sub> in novel devices.

**T1.00181 Magnetic-order-driven topological transition in the Haldane-Hubbard model.**, HUITAO SHEN, WEI ZHENG, ZHONG WANG, HUI ZHAI, Tsinghua Univ — We study the Haldane model with on-site repulsive interactions at half-filling. We show that the mean-field Hamiltonian with magnetic order effectively modifies parameters in the Haldane Hamiltonian, such as sublattice energy difference and phase in next nearest hopping. As interaction increases, increasing of magnetic order corresponds to varying these parameters and consequently, drives topological transitions. At the mean-field level, one scenario is that the magnetic order continuously increases, and inevitably, the fermion gap closes at the topological transition point. Beyond the mean-field, fluctuation induced interaction can further open up the gap, rendering a first-order transition. Another scenario is a first-order transition at mean-field level across which a canted magnetic order develops discontinuously, avoiding the fermion gap closing. We find that both scenarios exist in the phase diagram of the Haldane-Hubbard model. Our predication is relevant to recent experimental realization of the Haldane model in cold atom system.

**T1.00182 Dilute magnetic topological semiconductors**, KYOUNG-MIN KIM, YONG-SOO JHO, KI-SEOK KIM, POSTECH — Replacing semiconductors with topological insulators, we propose the problem of dilute magnetic topological semiconductors. Performing the renormalization group analysis for an effective field theory, where doped magnetic impurities give rise to a spatially modulated random axion term, we find a novel insulator-metal transition from either a topological or band insulating phase to an inhomogeneously distributed Weyl metallic state with such insulating islands, where extremely broad distributions of ferromagnetic clusters combined with strong spin-orbit interactions are responsible for the emergence of randomly distributed Weyl metallic islands. Since electromagnetic properties in a Weyl metal are described by axion electrodynamics, the role of random axion electrodynamics in transport phenomena casts an interesting problem beyond the physics of percolation in conventional disorder-driven metal-insulator transitions.

**T1.00183 Confinement transition of  $Z_2$  gauge theory coupled to fermions. A sign problem free quantum Monte Carlo study.** , SNIR GAZIT, University of California, Berkeley, MOHIT RANDERIA, The Ohio State University, ASHVIN VISHWANATH, University of California, Berkeley — In two space dimensions, the  $Z_2$  lattice gauge theory is known to undergo a zero temperature confinement to de-confinement quantum phase transition . In this work, we study how this transition is modified in the presence of lattice fermions which are minimally coupled to the  $Z_2$  gauge field. This may be viewed as an extreme version of the BEC-BCS transition where fermions are confined in the strong coupling phase. We investigate both a square lattice model with a large fermi surface and Dirac fermions realized on a  $\pi$  flux and honeycomb lattices. The models are found to be free of the numerical sign problem for all fermion density. In addition, we introduce a numerical method to stochastically incorporate the Gauss law constraint in a quantum Monte Carlo (QMC) simulation. The phase diagram as a function of the model parameters, chemical potential and temperature is determined by means of a large scale determinant QMC.

**T1.00185 Angle dependence of Shubnikov-de Haas effect of filled skutterudite compounds  $\text{CeOs}_4\text{Sb}_{12}$  and  $\text{NdOs}_4\text{Sb}_{12}$** <sup>1</sup>, P.-C. HO, Califor. State U., Fresno, J. SINGLETON, F. F. BALAKIREV, NHMFL/LANL, M. B. MAPLE, UC San Diego, T. YANAGISAWA, Hokkaido U., Jpn. — Intriguingly the three filled skutterudite compounds  $\text{CeOs}_4\text{Sb}_{12}$ ,  $\text{PrOs}_4\text{Sb}_{12}$ , and  $\text{NdOs}_4\text{Sb}_{12}$  span the range from the Kondo insulator to a 1K antiferromagnetic (AFM) order, a 1.85K unconventional superconductor (SC), to a 1K mean-field type ferromagnet (FM), indicating that they reside near quantum critical points of AFM and FM with unconventional SC induced within this regime. Therefore, understanding the Fermi surfaces of  $\text{NdOs}_4\text{Sb}_{12}$  and  $\text{CeOs}_4\text{Sb}_{12}$  becomes crucial in elucidating the superconducting pairing mechanism in  $\text{PrOs}_4\text{Sb}_{12}$ . Penetration depths of single crystals of  $\text{CeOs}_4\text{Sb}_{12}$  and  $\text{NdOs}_4\text{Sb}_{12}$  were measured for temperatures down to 1.3 K and magnetic fields up to 60 tesla by using proximity detection oscillators in the Pulsed Field Facility at NHMFL/LANL. Angle dependence of Shubnikov-de Haas oscillations was detected for rotating the field with respect to the crystalline orientations [010] and [0-10]. The results indicate that  $\text{LaOs}_4\text{Sb}_{12}$ ,  $\text{PrOs}_4\text{Sb}_{12}$  and  $\text{NdOs}_4\text{Sb}_{12}$  have similar Fermi surfaces. The Fermi surface of  $\text{CeOs}_4\text{Sb}_{12}$  is rather isotropic and is much different from the other three compounds.

**T1.00186 Dipolar glass and strong magneto-electric coupling within a purely organic system** , ADAM BERLIE, ISIS Neutron and Muon Source, Science and Technology Facilities Council, UK, IAN TERRY, Department of Physics, Durham University, UK, YUN LIU, Research School of Chemistry, Australian National University, Australia, MAREK SZABLEWSKI, Department of Physics, Durham University, UK — There is much interest in the search for novel materials that show ferroelectric as well as magneto-electric coupling, such as that observed in multiferroics. Within organic based materials the electronic polarisation can come from a charge distribution across a molecule or molecules and so one must search for systems that have a electronic (and magnetic) dipole that is intrinsic. One such material is tetraethylammonium bis-7,7,8,8-tetracyanoquinodimethane ( $\text{TEA}(\text{TCNQ})_2$ ) which is a charge transfer system where there is a single electron delocalised across a TCNQ dimer. We show that dielectric measurements yield anomalies at the Peierls structural distortion and on going through the spin-Peierls transition. In both cases the electric response is glassy and at low temperature the corresponding magnetic measurements evidence the strong magneto-electric coupling within the material showing analogies to spin glass systems.

**T1.00187 Epitaxial  $\text{Ni}/\text{VO}_2$  heterostructures on Si (001)** , SRINIVASA RAO SINGAMANENI, GABRIELLE FOLEY, JOHN PRATER, JAY NARAYAN, North Carolina State University —  $\text{VO}_2$  is a strongly correlated oxide, undergoes a first order metal-insulator (MIT) well above the room temperature 340K. Previous works have shown that the stress associated with structural changes across MIT,  $\text{VO}_2$  can produce significant changes in magnetic properties of over layer ferromagnetic films such as Ni. This control of the magnetic properties could be very important to many technological applications. However, the current use of r-sapphire as substrate can be restrictive in the microelectronics industry. The previous works focused their studies on polycrystalline Ni and  $\text{VO}_2$  films, which do not allow the precise controlling of the associated properties due to poor reproducibility of polycrystalline films. We have investigated the magnetic and electronic properties of  $\text{Ni}/\text{VO}_2$  films when epitaxially integrated on Si (001) by pulsed laser deposition using domain matching epitaxy paradigm. Ni was grown both in nanoscale islands and layered form. The XRD results showed that the Ni,  $\text{VO}_2$  and YSZ layers were grown epitaxially in single out of plane orientations. We found that the hysteresis in resistance vs. temperature curves in  $\text{VO}_2$  thin films was retained even when it is in close proximity with the Ni layer which helped confirm that  $\text{VO}_2$  layer preserves its characteristic features, revealed the fingerprint magnetic features of Ni layer. We will present and discuss our comprehensive experimental findings.

**T1.00188 Exact sign structure and variational wave function of t-J chain and ladder** , QING-RUI WANG, ZHENG ZHU, Tsinghua Univ, YANG QI, Perimeter Institute, D. N. SHENG, California State University, Northridge, ZHENG-YU WENG, Tsinghua Univ — The motion of a doped hole in the anti-ferromagnetic spin background generally induces a many-body phase shift, which is identified by an exact sign structure of the t-J model known as the phase string. We find that the characteristic momentum structure, the one dimensional (1D) Luttinger liquid behavior, the quantum phase interference of the hole under a periodic boundary condition, and the breakdown of Landau's quasiparticle description can all be attributed to it. Based on the exact sign structure, we introduce a variational wave function for the t-J model and calculate physical properties such as the momentum distribution, quasiparticle weight, and hole distribution of the single-hole 1D and ladder system in detail using Monte Carlo (MC) method. An excellent agreement is found between the MC and Density Matrix Renormalization Group results.

**T1.00189 Experimental Apparatus to Observe Dynamical Manifestations of Hamiltonian Monodromy** , M. PERRY NEREM, DANIAL SALMON, JOHN DELOS, SETH AUBIN, William & Mary Coll — An experiment to observe a topological change in a classical system with nontrivial monodromy is presented. Monodromy is the study of the topological behavior of a system as it evolves along a closed path. If the system does not return to the initial topological state at the end of the circuit, that system exhibits nontrivial monodromy. Such a topological change has been predicted in certain mechanical systems, but has not yet been observed experimentally. One such system is a family of paths in a cylindrically symmetric champagne-bottle potential, with a classically forbidden region centered at the origin. We constructed this system with a long spherically symmetric pendulum and a permanent magnet attached at the end. Magnetic fields from coils are used to create the potential barrier and the external forces to drive the pendulum about a monodromy circuit. A loop of initial conditions, that is initially on one side of the forbidden region, is driven smoothly about this circuit such that it continuously evolves into a loop that surrounds the forbidden region. We will display this phenomena through numerical simulations and hopefully experimental measurement.

**T1.00190 Elastoconductivity measurements as a probe of broken mirror symmetries** , PATRIK HLOBIL, Karlsruhe Institute of Technology, AKASH V. MAHARAJ, PAVAN HOSUR, MAXWELL C. SHAPIRO, IAN R. FISHER, SRINIVAS RAGHU, Stanford University — We propose the possible detection of broken mirror symmetries in correlated two-dimensional materials by elastotransport measurements. Using linear response theory we calculate the shearconductivity  $\Gamma_{xx,xy}$ , defined as the linear change of the longitudinal conductivity  $\sigma_{xx}$  due to a shear strain  $\epsilon_{xy}$ . This quantity can only be non-vanishing when in-plane mirror symmetries are broken and we discuss how candidate states in the cuprate pseudogap regime (e.g. various loop current or charge orders) may exhibit a finite shearconductivity. We also provide a realistic experimental protocol for detecting such a response, including the specific form of the elastoresistance for broken tetragonal symmetry.

**T1.00191 Casimir effect mechanism of pairing between fermions in the vicinity of a magnetic quantum critical point**, YAROSLAV KHARKOV, UNSW, Sydney, Australia, OLEG P SUSHKOV TEAM — We consider two spin 1/2 fermions in a two-dimensional magnetic system that is close to the  $O(3)$  magnetic quantum critical point (QCP) which separates magnetically ordered and disordered phases. Focusing on the disordered phase in the vicinity of the QCP, we demonstrate that the criticality results in a strong long range attraction between the fermions, with potential  $V(r) \propto -1/r^\alpha$ ,  $\alpha \approx 0.75$ , where  $r$  is separation between the fermions. The mechanism of the enhanced attraction is similar to Casimir effect and corresponds to multi-magnon exchange processes between the fermions. While we consider a model system, the problem is originally motivated by recent experimental establishment of magnetic QCP in hole doped cuprates under the superconducting dome at doping of about 10%. We suggest the mechanism of magnetic critical enhancement of pairing in cuprates.

**T1.00192 Application of the Debye formula to the computation of x-ray diffraction patterns of nanostructured diffusion couples<sup>1</sup>**, CHARLES CHEUNG, BRIAN KELLY, KARL UNRUH, MATTHEW DECAMP, Department of Physics and Astronomy, University of Delaware — Time resolved optical pump/x-ray probe techniques have made it possible to acquire x-ray diffraction patterns corresponding to very early diffusion times in nanostructured diffusion couples. The analysis of these diffraction patterns, however, is complicated by significant line broadening and other finite size effects that appear in samples containing a relatively small number of scatterers. In order to better quantify these issues, x-ray diffraction patterns have been calculated by the direct application of the Debye formula to core/shell and thin film diffusion couples. In particular a series of diffraction patterns have been calculated as a function of the sample size and composition profile determined from the appropriate solutions to Fick's second law. The results of these calculations have been used to guide the interpretation of the measured diffraction patterns of Pt/Ni core/shell nanoparticles and Pt/Ni thin film multilayers.

## **T1.00193 SUPERCONDUCTIVITY —**

**T1.00194 All-metal superconducting planar microwave resonator<sup>1</sup>**, MATT HORSLEY, SERGEY PEREVERZEV, JONATHAN DUBOIS, STEPHAN FRIEDRICH, DONGXIA QU, STEVE LIBBY, VINCENZO LORDI, GIANPAOLO CAROSI, WOLFGANG STOEFFL, GEORGE CHAPLINE, OWEN DRURY, Lawrence Livermore National Laboratory, QUANTUM NOISE IN SUPERCONDUCTING DEVICES TEAM — There is common agreement that noise and resonance frequency jitter in superconducting microwave planar resonators are caused by presence of two-level systems, or fluctuators, in resonator materials- in dielectric substrate, in superconducting and dielectric layers and on the boundaries and interfaces. Scaling of noise with device dimensions indicate that fluctuators are likely concentrated around boundaries; physical nature of those fluctuators remains unclear. The presence of dielectrics is not necessary for the superconducting device functionality, and one can ask question about properties of all-metal device, where dielectric substrate and oxide films on metal are absent. Resonator made from of thin conducting layer with cuts in it is usually called slot line resonator. We report on the design, fabrication and initial testing of multiple split rings slot line resonator made out of thin molybdenum plate.

<sup>1</sup>This work is being funded as part of a three year strategic initiative (LDRD 16-SI-004) to better understand noise in superconducting devices

**T1.00195 Normal state above the upper critical field in Fe<sub>1+y</sub>Te<sub>1-x</sub>(Se,S)<sub>x</sub>.**, AIFENG WANG, Brookhaven National Laboratory, ERIK KAMPERT, Hochfeld-Magnetlabor Dresden (HLD), H. SAADAOUI, H. LUETKENS, Paul Scherrer Institute, RONGWEI HU, Brookhaven National Laboratory, E. MORENZONI, Paul Scherrer Institute, J. WOSNITZA, Hochfeld-Magnetlabor Dresden (HLD), CEDOMIR PETROVIC, Brookhaven National Laboratory — We have investigated characteristics of the normal state above the upper critical field ( $H_{c2}$ ) in Fe<sub>1.14</sub>Te<sub>0.7</sub>Se<sub>0.3</sub>, Fe<sub>1.02</sub>Te<sub>0.61</sub>Se<sub>0.39</sub>, Fe<sub>1.05</sub>Te<sub>0.89</sub>Se<sub>0.11</sub>, and Fe<sub>1.06</sub>Te<sub>0.86</sub>S<sub>0.14</sub>. Superconductivity is suppressed in high magnetic fields above 60 Tesla, allowing for the insight into normal state below the superconducting transition temperature ( $T_c$ ). We show that Fe<sub>1.14</sub>Te<sub>0.7</sub>Se<sub>0.3</sub> and Fe<sub>1.02</sub>Te<sub>0.61</sub>Se<sub>0.39</sub> resistivity above the  $H_{c2}$  is metallic as  $T \rightarrow 0$ , just like the normal state resistivity above  $T_c$ . On the other hand, Fe<sub>1.05</sub>Te<sub>0.89</sub>Se<sub>0.11</sub> and Fe<sub>1.06</sub>Te<sub>0.86</sub>S<sub>0.14</sub> normal state resistivity is nonmetallic as  $T \rightarrow 0$ , reflecting the normal state resistivity above  $T_c$ . These results suggest that conductivity of normal states above  $H_{c2}$  is connected with the details of crystal structure inhomogeneity.

**T1.00196 Observation of Superconducting Fluctuations above  $T_c$  in underdoped BaFe<sub>2-x</sub>Ni<sub>x</sub>As<sub>2</sub>**, WEI ZHANG, HUIQIAN LUO, RUI ZHANG, XINGYE LU, BING XU, KAI WANG, RUN YANG, JINYUN LIU, Institute of Physics, Chinese Academy of Sciences, HAO YANG, College of Physics, Optoelectronics and Energy Collaborative Innovation Center of Suzhou Nano Science and Technology, Soochow University, XIANGGANG QIU, Institute of Physics, Chinese Academy of Sciences, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, COLLEGE OF PHYSICS, OPTOELECTRONICS AND ENERGY COLLABORATIVE INNOVATION CENTER OF SUZHOU NANO SCIEN TEAM — Angular dependent torque measurements have been performed on the electron doped iron pnictide superconductors BaFe<sub>2-x</sub>Ni<sub>x</sub>As<sub>2</sub> with a series Ni doping ( $0.03 \leq x \leq 0.3$ ). In the superconducting state, an irreversibility, as the evidence for the pinning of vortex, is observed between the torque measured with increasing and decreasing angle. Our results in underdoped sample ( $x = 0.065$ ) show that the irreversible torque signal can survive up to a temperature  $T_{irr}$  well above the superconducting transition temperature  $T_c$ , suggesting the existence of superconducting fluctuations (SCF) above  $T_c$ . The Ni doping dependent phase diagram both for  $T_{irr}$  and  $T_c$  with a strong SCF region in the underdoped samples, is summarized based on our results.

**T1.00197 Persistence of Dirac Node near Antiferromagnetic-to-Superconducting Phase Boundary in Ba(Fe<sub>1-x</sub>Co<sub>x</sub>)<sub>2</sub>As<sub>2</sub>**, HITOSHI TAKITA, NAOYA KISHIMOTO, YOUSUKE NAKASHIMA, Hiroshima University, AKIHIRO INO, MASASHI ARITA, HIROHUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima Synchrotron Radiation Center, YOSHIHIRO AIURA, IZUMI HASE, HIROSHI EISAKI, KUNIHIRO KIHOU, CHUL-HO LEE, AKIRA IYO, National Institute of Advanced Science and Technology, MASAMICHI NAKAJIMA, Osaka University, SHIN-ICHI UCHIDA, University of Tokyo, HIROSHIMA UNIVERSITY TEAM, HIROSHIMA SYNCHROTRON RADIATION CENTER TEAM, NATIONAL INSTITUTE OF ADVANCED SCIENCE AND TECHNOLOGY TEAM, OSAKA UNIVERSITY TEAM, UNIVERSITY OF TOKYO TEAM — Since the ground state of iron-pnictides changes from an antiferromagnetic (AF) phase to a superconducting (SC) phase, the evolution of electronic structure has attracted much attention. However, systematic investigation has been hindered by the intricate multiple bands arising from the orbital degree of freedom of iron 3d states. Here we performed a polarization-dependent ARPES study of Ba(Fe<sub>1-x</sub>Co<sub>x</sub>)<sub>2</sub>As<sub>2</sub> across the AF-SC phase boundary. The doping-dependence of ARPES spectra has shown that the Dirac node reported in the AF phase of BaFe<sub>2</sub>As<sub>2</sub> persists in  $x = 0.04$  near the AF-SC phase boundary, and that it disappears in the SC phase of  $x = 0.05$ . We parametrized the cone-like dispersion in  $x = 0.04$ . The polarization-dependence of our ARPES spectra is consistent with the view that the Dirac node is protected by Berry phase arising from orbital degree of freedom under the inversion symmetry.

**T1.00198 Unconventional superconductivity in  $\text{CaFe}_{0.85}\text{Co}_{0.15}\text{AsF}$  evidenced by torque measurements**, HONG XIAO, Center for High Pressure Science and Technology Advanced Research, X. J. LI, G. MU, T. HU, Shanghai Institute of Microsystem and Information Technology — Out-of-plane angular dependent torque measurements were performed on  $\text{CaFe}_{0.85}\text{Co}_{0.15}\text{AsF}$  single crystals. Abnormal superconducting fluctuation, featured by enhanced diamagnetism with magnetic field, is detected up to about 1.5 times superconducting transition temperature  $T_c$ . Compared to cuprate superconductors, the fluctuation effect in iron-based superconductor is less pronounced. Anisotropy parameter  $\gamma$  is obtained from the mixed state torque data and it is found that  $\gamma$  shows both magnetic field and temperature dependence, pointing to multiband superconductivity. The temperature dependence of penetration depth  $\lambda(T)$  suggests unconventional superconductivity in  $\text{CaFe}_{0.85}\text{Co}_{0.15}\text{AsF}$ .

**T1.00199 High- $T_c$  Superconductivity and Raman Scattering Study of the phonon properties of electron doped (transition metal, rare-earth) - Oxygen-Free  $\text{CaFeAsF}$  and compared with  $\text{RFeAsO}$  system.**, KALYAN SASMAL, VIKTOR HADJIEV, C.W(PAUL) CHU, Texas Center for Superconductivity & Dept of Physics, University of Houston, TX, USA — Quaternary  $\text{CaFeAsF}$  has  $\text{ZrCuSiAs}$ -type structure,  $(\text{RO})^{\delta+}$  layer in  $\text{RFeAsO}$  replaced by  $(\text{CaF})^{\delta+}$  layer, with tetragonal ( $P4/nmm$ )-orthorhombic ( $Cmma$ ) phase transition at 134K, while magnetic order, SDW sets in at 114K. Partial replacement of Fe with Co/Ni is direct electron doping to  $(\text{FeAs})^{\delta+}$  layer.  $T_c \sim 15\text{K}$  in  $\text{CaFe}_{0.9}\text{Ni}_{0.1}\text{AsF}$ . Substitution of rare earth metal for alkaline earth metal suppresses anomaly in resistivity & induces superconductivity.  $T_c \sim 52\text{K}$  in  $\text{Ca}_{0.5}\text{Pr}_{0.5}\text{FeAsF}$ . Characterized by resistivity, susceptibility, XRD & EDX-SEM. Upper critical field estimated from magneto resistance. Bulk superconductivity proved by DC magnetization. Hall coefficient  $R_H$  revealed hole-like charge carriers in parent compound  $\text{CaFeAsF}$ , while electron-type ( $R_H$  in normal state is  $-Ve$ ) for  $\text{Ca}_{0.5}\text{Pr}_{0.5}\text{FeAsF}$ . Evolution of Raman active phonons of  $\text{Ca}_{1-x}\text{Pr}_x\text{FeAsF}$  measured with polarized Raman spectroscopy at room temperature from  $ab$  surfaces of impurity-free microcrystals. Spectra exhibit sharp phonon lines on very weak electronic scattering background. Frequency and symmetry of Raman phonons involving out-of-plane atomic vibrations are found at  $162.5\text{ cm}^{-1}$  ( $A1g$ , Pr),  $201\text{ cm}^{-1}$  ( $A1g$ , As),  $215.5\text{ cm}^{-1}$  ( $B1g$ , Fe),  $265\text{ cm}^{-1}$  ( $Eg$ , Fe) and  $334\text{ cm}^{-1}$  ( $B1g$ , F) for  $\text{Ca}_{0.5}\text{Pr}_{0.5}\text{FeAsF}$ . Observations are compared with  $\text{RFeAsO}$  unconventional superconductors also possibly related to magnetic fluctuations

**T1.00200 Functional renormalization group study of the pairing symmetry and pairing mechanism in iron-selenide superconductors**, YUAN-YUAN XIANG, HoHai University, QIANG-HUA WANG, Nanjing University — In iron-selenide superconductors only electron-like Fermi pockets survive, challenging the  $s_{\pm}$  pairing based on the quasi-nesting between the electron and hole pockets (as in iron arsenides). By functional renormalization group study we show that an in-phase  $s$ -wave pairing on the electron pockets is realized. The pairing mechanism involve two competing driving forces: the strong C-type spin fluctuations cause attractive pair scattering between and within electron pockets via Cooperon excitations on the virtual hole-like pockets, while the G-type spin fluctuations cause repulsive pairing scattering. The latter effect is however weakened by the hybridization splitting of the electron-like pockets. The in phase  $s$ -wave pairing symmetry is consistent with the existing experiments.

**T1.00201 Electronic structure of the titanium-based oxypnictide superconductor  $\text{Ba}_{0.95}\text{Na}_{0.05}\text{Ti}_2\text{Sb}_2\text{O}$  and direct observation of its charge density wave order**, QI SONG, JUAN JIANG, YAJUN YAN, ZIRONG YE, MINGQIANG REN, SHIYONG TAN, XIAOHAI NIU, BINPING XIE, TONG ZHANG, DONGLAI FENG, Fudan Univ — The unconventional superconducting ground state usually emerges in proximity to a spin or charge ordering state, such as that in cuprates, iron-based superconductors and layered chalcogenides. This unique character offers a platform for searching unconventional superconductivity in analogous layered compounds. Recently, superconductivity has been achieved in  $\text{Ba}_{1-x}\text{Na}_x\text{Ti}_2\text{Sb}_2\text{O}$  with maximum  $T_c$  at 5.5 K, which makes this material more interesting. Here we perform high resolution angle-resolved photoemission spectroscopy and scanning tunneling microscopy studies on the titanium-based oxypnictide superconductor  $\text{Ba}_{0.95}\text{Na}_{0.05}\text{Ti}_2\text{Sb}_2\text{O}$ . The electronic structure shows both multi-orbital and three-dimensional nature, consistent with the theoretical calculations. The observed Fermi surface is well nested along the  $(\pi, \pi)$  direction, which might probably be the driving force of the CDW transition. This is further proved by the scanning tunneling microscopy result, which directly observed a CDW wave vector at  $(\pi, \pi)$  direction. However, due to the weak CDW coupling, we didn't observe the CDW gap here. Our results give a comprehensive picture of the electronic structure and direct observation of the CDW order in  $\text{Ba}_{0.95}\text{Na}_{0.05}\text{Ti}_2\text{Sb}_2\text{O}$

**T1.00202 ABSTRACT WITHDRAWN —**

**T1.00203 Dynamic Stimulation of Superconductivity with Resonant Terahertz Phonons**, ALAN M. KADIN, Princeton Junction, NJ, STEVEN B. KAPLAN, Estes Park, CO — Can superconductivity be induced at a temperature far above the equilibrium critical temperature  $T_c$ ? While small enhancements were observed many years ago and associated with nonequilibrium electron distributions, it is proposed here that much larger enhancements (up to a factor of two in temperature) may be possible by generation of coherent phonons at appropriate resonant frequencies comparable to the gap frequency, in the terahertz range. These phonon standing waves may induce real-space electron localization that forms the basis for superconducting coherence within a novel model of superconductivity [1,2]. This concept may be generalized to dynamic stimulation using coherent spin waves for non-phonon mediated superconductors such as the cuprates. Several experiments to test this are proposed. [1] S.B. Kaplan and A.M. Kadin (2012), "Superconductivity via Two-Phase Condensation of Localized Electrons", <http://absimage.aps.org/image/MAR12/MWS.MAR12-2011-002491.pdf> [2] A.M. Kadin (2009), "Superconductivity without Pairing?," <http://arxiv.org/abs/0909.2901>.

**T1.00204 Break the electron- hole balance and pressure induced superconductivity in Tungsten Ditelluride.<sup>1</sup>**, FENGQI SONG, XING-CHEN PAN, Nanjing Univ — Tungsten ditelluride has garnered immense interest due to the recent discovery of titanic unsaturated magnetoresistance up to 60 Tesla and its possible topological metal nature. The titanic unsaturated magnetoresistance is attributed to the perfect compensation between the opposite carriers in this material. Motivated by the small and sensitive Fermi surface of 5d electronic orbitals, we break the electron-hole balance by the application of high pressure. Superconductivity sharply appears at the pressure of 2.5 GPa, quickly reaching a maximum critical temperature of 7 K at around 16.8 GPa, and followed by a monotonic decrease in  $T_c$  with increasing pressure exhibiting the typical dome-shaped superconducting phase. What's more, linear magnetoresistance dominates the transport behavior under high pressure instead of semi-classical parabolic magnetoresistance, like in other topological metals. Reference: Nature Commun. 6, 7805 (2015), arXiv 1505, 07968.

**T1.00205 Photoemission spectra of charge density wave states in cuprates**, WEI-LIN TU, Department of Physics, National Taiwan University, PENG-JEN CHEN, TING-KUO LEE, Institute of Physics, Academia Sinica — Angle-resolved photoemission spectroscopy (ARPES) experiments have reported many exotic properties of cuprates, such as Fermi arc at normal state, two gaps at superconducting state and particle-hole asymmetry at the antinodal direction[1]. On the other hand, a number of inhomogeneous states or so-called charge density waves (CDW) states have also been discovered in cuprates by many experimental groups. The relation between these CDW states and ARPES spectra is unclear. With the help of Gutzwiller projected mean-field theory[2], we can reproduce the quasiparticle spectra in momentum space. The spectra show strong correspondence to the experimental data with afore-mentioned exotic features in it. \pard1. I. Vishik et al, PNAS 109, 18332-18337(2012).. Wei-Lin Tu and Ting-Kuo Lee, arXiv: 1505.07728(2015).

**T1.00206 Quantum creep in a highly crystalline two-dimensional superconductor** , YU SAITO, The University of Tokyo, YUICHI KASAHARA, Kyoto University, JIANTING YE, University of Groningen, YOSHIHIRO IWASA, The University of Tokyo, TSUTOMU NOJIMA, Tohoku University — Conventional studies on quantum phase transitions, especially on superconductor-insulator or superconductor-metal-insulator transitions have been performed in deposited metallic thin films such as Bismuth or MoGe. Although the techniques of thin films deposition have been considerably improved, unintentional disorder such as impurities and deficiencies, generating the pinning centers, seems to still exist in such systems. The mechanical exfoliated highly crystalline two-dimensional material can be a good candidate to realize a less-disordered 2D superconductor with extremely weak pinning, combined with transfer method or ionic-liquid gating. We report on the quantum metal, namely, magnetic-field-induced metallic state observed in an ion-gated two-dimensional superconductor based on an ultra-highly crystalline layered band insulator, ZrNCl [1]. We found that the superconducting state is extremely fragile against external magnetic fields; that is, zero resistance state immediately disappears, once an external magnetic field switches on. This is because the present system is relatively clean and the pinning potential is extremely weak, which cause quantum tunneling and flux flow of vortices, resulting in metallic ground state. [1] Y. Saito et al. Science 350, 409-413 (2015).

**T1.00207 Negative Oxygen Isotope Effect on the Static Spin Stripe Order in  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$  ( $x = 1/8$ )** , ZURAB GUGUCHIA, RUSTEM KHASANOV, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, MARKUS BENDELE, Physik-Institut der Universität Zurich, Zurich, Switzerland, EKATERINA POMJAKUSHINA, KAZIMIERZ CONDER, Laboratory for Developments and Methods, Paul Scherrer Institut, Switzerland, ALEXANDER SHENGELAYA, Department of Physics, Tbilisi State University, Tbilisi, Georgia, HUGO KELLER, Physik-Institut der Universität Zurich, Zurich, Switzerland — Cuprate high temperature superconductors (HTS's) are characterized by a complex interplay between lattice, charge, and spin degrees of freedom. One of the remarkable phases is a self-organized charge/spin structure, which is known as "stripes" and is observed in some cuprates near 1/8 doping. The microscopic origin of the stripe phase is still unclear at present. We report large negative oxygen-isotope ( $^{16}\text{O}/^{18}\text{O}$ ) effects (OIE's) on the static spin-stripe ordering temperature  $T_{\text{so}}$  and the magnetic volume fraction  $V_{\text{m}}$  in  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$  ( $x = 1/8$ ) observed by means of muon spin rotation experiments [1]. The corresponding OIE exponents were found to be  $\alpha_{T_{\text{so}}} = -0.57(6)$  and  $\alpha_{V_{\text{m}}} = -0.71(9)$ , which are sign reversed to  $\alpha_{T_{\text{c}}} = 0.46(6)$  measured for the superconducting transition temperature  $T_{\text{c}}$ . This indicates that the electron-lattice interaction is involved in the stripe formation and plays an important role in the competition between bulk superconductivity and static stripe order in the cuprates. [1] Z. Guguchia et. al., Phys. Rev. Lett. 113, 057002 (2014).

**T1.00208 Calculation of the superconducting transition temperature of a graphene layer doped with titanium and palladium.** , GERARDO VAZQUEZ, FERNANDO MAGANA, OSIRIS SALAS-TORRES, Instituto de Física, UNAM — We explore the structural interactions between graphene and transition metals such as palladium (Pd) and titanium (Ti) and the possibility of inducing superconductivity in a graphene sheet in two cases, one by doping its surface with palladium atoms sit on the center of the hexagons of the graphene layer and other by covering the graphene layer with two layers of titanium metal atoms. The results here were obtained from first-principles density functional theory in the local density approximation. The Quantum-Espresso package was used with norm conserving pseudopotentials. All of the structures considered were relaxed to their minimum energy configuration. Phonon frequencies were calculated using the linear-response technique on several phonon wave-vector mesh. The electron-phonon coupling parameter was calculated with several electron momentum k-mesh. The superconducting critical temperature was estimated using the Allen-Dynes formula with  $\mu^* = 0.1 - 0.15$ . We note that palladium and titanium are good candidate materials to show a metal-to-superconductor transition. We thank Dirección General de Asuntos del Personal Académico de la Universidad Nacional Autónoma de México, partial financial support by Grant IN-106514 and we also thank Miztli Super-Computing center the technical assistance.

**T1.00209 Formation of As-As bond and its effect on absence of superconductivity in the collapsed tetragonal phase of  $\text{Ca}_{0.86}\text{Pr}_{0.14}\text{Fe}_2\text{As}_2$ : An optical spectroscopy study** , RUN YANG, XIANGGANG QIU, Institute of Physics, Chinese Academy of Sciences, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, HIGH MAGNETIC FIELD LABORATORY, CHINESE ACADEMY OF SCIENCES TEAM — The temperature dependence of in-plane optical conductivity has been investigated for  $\text{Ca}_{0.86}\text{Pr}_{0.14}\text{Fe}_2\text{As}_2$ , which shows a structural transition from tetragonal (T) to collapsed tetragonal (cT) phase at  $T_{\text{cT}} \sim 73$  K. Upon entering the cT phase, drastic change characterized by the formation of a midinfrared peak near  $3200 \text{ cm}^{-1}$  (0.4 eV) in the optical conductivity is observed. Analysis of the spectral weight reveals reduced electron correlation after the cT phase transition. Based on the calculated band structure and simulated optical conductivity, we attribute the new feature around 0.4 eV to the formation of an interlayer As-As bond. The As-As bond strongly affects the Fe-As hybridizations and, in turn, drastically changes the  $\text{Ca}_{0.86}\text{Pr}_{0.14}\text{Fe}_2\text{As}_2$  into a nonmagnetic Fermi liquid system without bulk superconductivity in the cT phase.

## T1.00210 METALS AND ALLOYS —

**T1.00211 Structural  $\gamma$ - $\varepsilon$  phase transition in Fe-Mn alloys: a CPA+DMFT study<sup>1</sup>** , ALEXANDER BELOZEROV, SERGEY SKORNYAKOV, ALEXANDER POTERYAEV, VLADIMIR ANISIMOV, Institute of Metal Physics, 620137 Yekaterinburg, Russia — We study the  $\gamma$ - $\varepsilon$  structural transition in paramagnetic Fe-Mn alloys for Mn content from 10 to 20 at.% using CPA+DMFT method. This method employs the coherent potential approximation (CPA) combined with the dynamical mean-field theory (DMFT). The material-specific Hamiltonians in the Wannier function basis are obtained by density functional theory. The electronic correlations are found to play a crucial role in this transition. The calculated transition temperature decreases with increasing Mn content and is in a good agreement with experiment. We demonstrate that in contrast to the  $\alpha$ - $\gamma$  transition in pure iron, the  $\gamma$ - $\varepsilon$  transition in Fe-Mn alloys is driven by a combination of kinetic and Coulomb energies. The latter is found to be responsible for the decrease of the  $\gamma$ - $\varepsilon$  transition temperature with Mn content.

<sup>1</sup>The study was supported by the grant of the Russian Scientific Foundation (project no. 14-22-00004).

**T1.00212 An ab initio study of the structure and dynamics of bulk liquid Ag and its liquid-vapor interface.** , BEATRIZ GONZALEZ DEL RIO, LUIS ENRIQUE GONZALEZ TESEDO, DAVID JOSE GONZALEZ FERNANDEZ, Fisica Teorica, Atomica y Optica, Universidad de Valladolid — Several static and dynamic properties of bulk liquid Ag at a thermodynamic state near its triple point have been calculated by means of *ab initio* molecular dynamics simulations. The calculated static structure shows a very good agreement with the available experimental data. The dynamical structure reveals collective density excitations with an associated dispersion relation which points to a small positive dispersion. Results are also reported at a slightly higher temperature in order to study the structure of the free liquid surface. The ionic density profile shows an oscillatory behaviour with two different wavelengths, as the spacing between the outer and first inner layer is different from that between the other inner layers.

**T1.00213 Optical pump/x-ray probe studies of lattice parameter evolution in Pt nanoparticles due to sintering and grain growth**<sup>1</sup>, BRIAN KELLY, AARON LOETHER, Department of Physics and Astronomy, University of Delaware, ANTHONY DICHARA, ROBERT HENNING, Advanced Photon Source, Argonne National Laboratory, KARL UNRUH, MATTHEW DECAMP, Department of Physics and Astronomy, University of Delaware — An *in-situ* optical pump/x-ray probe technique has been developed to study the evolution in the lattice parameter of nanometer-sized Pt particles as a function of the particle size during sintering and grain growth. In particular, the lattice parameter of the as-prepared nanoparticles was observed to be about 0.4% smaller than the corresponding bulk value in good agreement with the value expected for isolated spherical particles subject only to a simple surface stress. As the as-prepared nanoparticles sinter and grow as a result of the photo-thermal irradiation, however, the evolution in the lattice parameter reflects the effects of both an increasing grain size and the evolving particle-particle interface. As a result, the lattice parameter does not evolve monotonically with increasing grain size.

## T1.00214 MAGNETISM —

**T1.00215 The Magnetism of  $Mn_{2-x}Fe_xB$  Alloys : First-Principles Calculations**, PO-HAN LEE, Affiliated Senior High School of National Taiwan Normal University, Taipei, Taiwan, SHIH-WEI WANG, Stevenson School, Pebble Beach, CA USA, CHAO-YANG LIN, Department of Electrical Engineering, National Tsing Hua University, Hsinchu, Taiwan, KUANG-LING CHEN, Department of Electrical and Computer Engineering, Cornell University, NY USA, HSUAN-AN HSIA, Affiliated Senior High School of National Taiwan Normal University, Taipei, Taiwan, KUANG-YU CHEN, Department of Physics, National Taiwan University, Taipei, Taiwan, PANG-YU LIU, Department of Engineering and System Science, National Tsing Hua University, Hsinchu, Taiwan, KE-BENG CHEN, Department of Law, National Taiwan University, Taipei, Taiwan, EN-HUI LIU, Center for Nanotechnology, Materials Science and Microsystems, National Tsing Hua University, Hsinchu, Taiwan — Magnetic, electronic and structural properties of  $Mn_{2-x}Fe_xB$  ( $0 \leq x \leq 2$ ) are investigated by the First principles calculations with the virtual crystal approximation (VCA) based on the density-functional theory (DFT) with generalized gradient approximation (GGA). Although both of  $Mn_2B$  and  $Fe_2B$  have the same electronic structure of I4/MCM with different lattice constants, the former is anti-ferromagnetic and the latter ferromagnetic. All calculations, based on the four types of magnetic states of NM (non-magnetic), FM (ferromagnetic), AFM1 and AFM2 (anti-ferromagnetic), illustrate that there is a critical point of magnetic phase transition occurred at  $x$  as 0.5 from AFM2 to FM state under the condition of the lowest energy. Results are also in agreement with the Stoner model within the range of FM state.

**T1.00216 Magnetic Nanoparticles in Non-magnetic CNTs and Graphene**<sup>1</sup>, MOSES KAYONDO, DEREJE SEIFU, Morgan State University, PHYSICS — Magnetic nanoparticles were embedded in non-magnetic CNTs and graphene matrix to incorporate all the advantages and the unique properties of CNTs and graphene [1]. Composites of CNTs and graphene with magnetic nanoparticles may offer new opportunities for a wide variety of potential applications such as magnetic data storage, magnetic force microscopy tip, electromagnetic interference shields, thermally conductive films, reinforced polymer composites, transparent electrodes for displays, solar cells, gas sensors, magnetic nanofluids, and magnetically guided drug delivery systems. Magnetic nanoparticles coated CNTs can also be used as an electrode in lithium ion battery to replace graphite because of the higher theoretical capacity. Graphene nanocomposites, coated with magnetic sensitive nanoparticles, have demonstrated enhanced magnetic property. 1. D. Seifu, S. Neupane, L. Giri, S. P. Karna, H. Hong, and M. S. Seehra, "Multilayered graphene acquires ferromagnetism in proximity with magnetite particles", Appl. Phys. Lett., **106**, 212401, (2015).

**T1.00217 Ferromagnetic  $Fe_2CrAl$  Nanowires**<sup>1</sup>, RAJENDRA DULAL, BISHNU DAHAL, IAN L PEGG, JOHN PHILIP, The Catholic University of America — Heusler alloy  $Fe_2CrAl$  (FCA) nanowires were grown on silicon substrates. Nanowires have diameters in the range 50 to 200 nm and lengths up to 100  $\mu$ m. They exhibit cubic  $L_{21}$  and  $A_2$  type structure with a space group,  $Pm\bar{3}m$ . Magnetic characterization reveals that they display ferromagnetic behavior and has a Curie temperature above 400 K. Magnetic behavior of FCA nanowires is different from the reported bulk behavior. Bulk FCA with  $L_{21}$  structure has a Curie temperature around 274 K.

**T1.00218 Magnetic Properties of 3D Printed Toroids**, LINDSEY BOLLIG, AUSTIN OTTO, PETER HILPISCH, GREG MOWRY, BRITTANY NELSON-CHEESEMAN, School of Engineering, University of St. Thomas, RENEWABLE ENERGY AND ALTERNATIVES LAB (REAL) TEAM — Transformers are ubiquitous in electronics today. Although toroidal geometries perform most efficiently, transformers are traditionally made with rectangular cross-sections due to the lower manufacturing costs. Additive manufacturing techniques (3D printing) can easily achieve toroidal geometries by building up a part through a series of 2D layers. To get strong magnetic properties in a 3D printed transformer, a composite filament is used containing Fe dispersed in a polymer matrix. How the resulting 3D printed toroid responds to a magnetic field depends on two structural factors of the printed 2D layers: fill factor (planar density) and fill pattern. In this work, we investigate how the fill factor and fill pattern affect the magnetic properties of 3D printed toroids. The magnetic properties of the printed toroids are measured by a custom circuit that produces a hysteresis loop for each toroid. Toroids with various fill factors and fill patterns are compared to determine how these two factors can affect the magnetic field the toroid can produce. These 3D printed toroids can be used for numerous applications in order to increase the efficiency of transformers by making it possible for manufacturers to make a toroidal geometry.

**T1.00219 Electro-magneto-thermal characterization of ferromagnetic thin films.**, SANDEEP KUMAR, DAVIL GARCIA, Univ of California - Riverside — In this work we report electro-magneto-thermal characterization of ferromagnetic multilayer thin films. These thin films include Co/Pd, Co/Pt and CoFeB/MgO multilayers. We carried out in-situ focused magneto optic Kerr effect based hysteresis measurement while the specimen was under DC bias to ascertain the electro-magnetic behavior. These experiments are then supplemented with in-situ transmission electron microscope studies to verify the microstructural changes. We also report thermal conductivity measurements using 3-omega method. Thermal conductivity measurements suggest thermo-magnetic resistance due to spin scattering at the interfaces in multilayer thin films.

**T1.00220 Brillouin Light Scattering study of the rotatable magnetic anisotropy in exchange biased bilayers of Ni<sub>81</sub>Fe<sub>19</sub>Ir<sub>20</sub>Mn<sub>80</sub>**, ROBERTO RODRIGUEZ, Pontificia Universidad Catlica de Chile, ALEXANDRE OLIVEIRA, Univ. Fed. Rio Grande do Norte, BR-59072970 Natal, RN, Brazil, FRANCISCO ESTRADA, OBED SANTOS, ANTONIO AZEVEDO, SERGIO REZENDE, Universidade Federal de Pernambuco, 50670-901, Recife, PE, Brasil. — It is known that when a ferromagnet (FM) is in atomic contact with an antiferromagnet (AF) the exchange coupling between the FM and AF spins at the interface induces a unidirectional anisotropy in the ferromagnetic film. This effect is known as exchange bias (EB). Despite the large amount of research on this topic there are still several aspects of the EB mechanism that are not well understood. One of this aspects is the origin of the rotatable anisotropy in polycrystalline AFs. By means of Brillouin Light Scattering (BLS) measurements, we investigated the dependence of the rotatable anisotropy field  $H_{RA}$  and exchange field  $H_E$  with the magnitude of the external magnetic field ( $H_0$ ) in FM/AM bilayers of Ni<sub>81</sub>Fe<sub>19</sub>(10nm)/Ir<sub>20</sub>Mn<sub>80</sub>(t<sub>AF</sub>). We developed an algorithm to numerically fit the in-plane angular dependence of the magnon frequency, at a fixed value of  $H_0$  measured by BLS. From the fit parameters we were able to investigate  $H_{RA}$  and  $H_E$  dependency on  $H_0$ . The results reveal that  $H_{RA}$  value depends on  $H_0$ , so we argue that AF grain distribution at the interface is partially modified by the applied field strength. Contrary to this, the relation between  $H_E$  and  $H_0$  is not straightforward, remaining constant at high values of  $H_0$ .

**T1.00221 Atomic structure prediction of Zr-Co and Hf-Co nanoclusters using the evolutionary algorithm**, NABIL AL-AQTASH, The Hashemite University, RENAT SABIRIANOV, University of Nebraska at Omaha — Nanostructures of Hf-Co and Zr-Co rare earth free magnetic material that exhibit a high room-temperature energy product. In our study, the evolutionary algorithm coupled with density functional (DFT) method is used to identify the global energy minimum atomic structure of Zr-Co and Hf-Co clusters. Using evolutionary crystal structure optimization algorithm, as implemented in USPEX, we studied the atomic structure, binding energies, magnetic properties, and anisotropy of Zr<sub>x</sub>Co<sub>y</sub> and Hf<sub>x</sub>Co<sub>y</sub> (x=1,2 and y=5,7,11) clusters. A set of metastable and global minimum atomic structures are identified. Several new lower energy configurations were identified for Zr<sub>2</sub>Co<sub>11</sub>, Zr<sub>1</sub>Co<sub>5</sub>, Zr<sub>1</sub>Co<sub>7</sub>, Hf<sub>2</sub>Co<sub>11</sub>, Hf<sub>1</sub>Co<sub>5</sub> and Hf<sub>1</sub>Co<sub>7</sub> clusters by our calculations. We discussed the magnetic interaction between the atoms of the clusters which is critical in finding the lowest energy structure. Our calculation show that Zr-Co and Hf-Co have ferromagnetic coupling and large magnetization. We will also discuss the magnetocrystalline anisotropy (MAE) variation in these clusters.

**T1.00222 Magneto-electric control of magnetization in a chain of circular nanomagnets as new paradigm for ultra low power binary information propagation.**, MOHAMMAD SALEHI-FASHAMI, University of Delaware, MAMUN AL-RASHID, Virginia Commonwealth University, WEI-YANG SUN, PAUL NORDEEN, University of California, Los Angeles, SUPRIYO BANDYOPADHYAY, Virginia Commonwealth University, GREGORY CARMAN, University of California, Los Angeles, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — Elliptical nanomagnets with bi stable magnetization states are traditionally employed for dipole coupled Bennett clocked nanomagnetic logic. Logic bits are propagated down a chain of nanomagnets by sequentially rotating their magnetizations with an electric field [1]. In this talk, we present for the first time, the notion of replacing elliptical nanomagnets with circular nanomagnets that have no inherent shape anisotropy. The circular nanomagnets would develop bi stable magnetization orientations with the application of an electrical field to induce in-plane strain anisotropy. This new strategy provides two significant advantages for nanomagnetic logic applications: (i) re-orienting the magnetizations does not require overcoming a shape-anisotropy energy barrier and hence the electric field needed to reorient is reduced, leading to lower energy dissipation in the clocking process, and (ii) scalability to dimensions substantially smaller than what presently exists becomes possible. [1] J. Atulasimha and S. Bandyopadhyay, Appl. Phys. Lett., 97, 173105 (2010). This work was supported by NSF CAREER grant CCF-1253370 and by FAME, one of six centers of STARnet, Semiconductor Research Corporation program sponsored by MARCO and DARPA.

**T1.00223 The impact of substrate stimulated functional interface on magnetic and magneto-transport signature of martensitic transformation in NiMnIn shape memory alloy<sup>1</sup>**, R. SABIRIANOV, University of Nebraska Omaha, A. SOKOLOV, University of Nebraska Lincoln, E. KIRIANOV, A. ZLENKO, Lincoln South West High School, A. QUETZ, A. ARYAL, S. PANDEY, I. DUBENKO, N. ALI, Southern Illinois University, S. STADLER, Louisiana State University, N. AL-AQTASH, Hashemite University — We study the impact of the substrate on the martensite transformation of Ni-Mn-In thin films by Hall resistance measurements and discuss it using density functional theory calculations. Similarly to the bulk systems, thin films grown on MgO exhibit the martensitic transformation accompanied by large magnetoresistance and a sign reversal of the ordinary as well as anomalous Hall coefficient. Martensite transition temperature of films grown on (100) surface of MgO is near 170K, while the films grown on (111) surface of MgO show the change of Hall coefficient at 110K. The calculated total energy difference between FM austenite and FiM martensite states in Ni<sub>2</sub>Mn<sub>1.5</sub>In<sub>0.5</sub> film on MgO (001) substrate (with Ni/MgO interface) is 0.20eV per NiMnIn f.u., compared to 0.24eV in the bulk at the same equilibrium lattice parameters, i.e. when film is “unstrained”. When lattice parameters of Ni<sub>2</sub>Mn<sub>1.5</sub>In<sub>0.5</sub>/MgO are of those of MgO substrate, i.e. when the film experiences strong bi-axial tensile strain  $\Delta a/a = 2.4\%$ , the energy difference is 0.08eV per NiMnIn f.u. These results clearly indicate strong interplay between lattice strain/stress and the relative stability martensite and austenite phase

**T1.00224 Ferromagnetic properties of manganese doped iron silicide.**, ANGEL RUIZ-REYES, LUIS F. FONSECA, University of Puerto Rico, RENAT SABIRIANOV, University of Nebraska at Omaha — We report the synthesis of high quality Iron silicide (FeSi) nanowires via Chemical Vapor Deposition (CVD). The materials exhibits excellent magnetic response at room temperature, especially when doped with manganese showing values of  $2.0 \times 10^{-4}$  emu for the Fe<sub>x</sub>Mn<sub>y</sub>Si nanowires. SEM and TEM characterization indicates that the synthesized nanowires have a diameter of approximately 80nm. MFM measurements present a clear description of the magnetic domains when the nanowires are doped with manganese. Electron Diffraction and XRD measurements confirms that the nanowires are single crystal forming a simple cubic structure with space group P213. First-principle calculations were performed on (111) FeSi surface using the Vienna ab initio simulation package (VASP). The exchange correlations were treated under the Ceperley-Alder (CA) local density approximation (LDA). The Brillouin Zone was sampled with 8x8x1 k-point grid. A total magnetic moment of about 10  $\mu_B$  was obtained for three different surface configuration in which the Iron atom nearest to the surface present the higher magnetization. To study the effect of Mn doping, Fe atom was replaced for a Mn. Stronger magnetization is presented when the Mn atom is close to the surface. The exchange coupling constant have been evaluated calculating the energy difference between the ferromagnetic and anti-ferromagnetic configurations.

**T1.00225 Effect of Milling Time on the Blocking Temperature of Nanoparticles of Magnetocaloric Gd<sub>5</sub>Si<sub>4</sub>.**, RAVI HADIMANI, Iowa State University, SHALBH GUPTA, Ames Laboratory, US Department of Energy, SHANE HARSTAD, Iowa State University, VITALIJ PECHARSKY, Ames Laboratory, US Department of Energy, DAVID JILES, Iowa State University, DAVID C JILES TEAM, VITALIJ PECHARSKY COLLABORATION — Extensive research has been done on giant magnetocaloric material Gd<sub>5</sub>(Si<sub>x</sub>Ge<sub>1-x</sub>)<sub>4</sub> to improve adiabatic temperature/isothermal entropy change. However, there have been only a few reports on fabrication of nanostructure/nanoparticles that can be used to tune various properties by changing the length scale. Recently we have reported fabrication of room temperature ferromagnetic nanoparticles of Gd<sub>5</sub>Si<sub>4</sub> using high energy ball milling. These nanoparticles have potential applications in biomedical engineering such as better T<sub>2</sub> MRI contrast agents and in hypothermia. Here we report the effect of milling time on the blocking temperature, micro-structure, crystal structure, and magnetic properties of these nanoparticles. Magnetization vs. temperature at an applied field of 100 Oe is measured for all the ball milled samples. Bulk Gd<sub>5</sub>Si<sub>4</sub> has a transition temperature of  $\approx 340$  K. There are two phase transitions observed in the nanoparticles, one near 300 K corresponding to the Gd<sub>5</sub>Si<sub>4</sub> phase and another between 75-150 K corresponding to Gd<sub>5</sub>Si<sub>3</sub>. Zero Field Cooling (ZFC) and Field Cooling (FC) were measured. The blocking temperatures for the nanoparticles increase with decrease in milling time.

**T1.00226 Magnetic and optical properties of Co-doped and Mn-doped ZnO nanocrystalline particles.** , ABDEL ALSMADI, B. SALAMEH, Kuwait University, M. SHATNAWI, The Hashimite University, G. ALNAWASHI, The Hashemite University, I. BSOU, Al al-Bayt University — We carried out a systematic study on the effect of Co doping and Mn doping on the structural, magnetic and optical properties of ZnO nanocrystalline particles, using x-ray diffraction, x-ray photoelectron spectroscopy (XPS), Quantum Design PPMS-9 magnetometry, and Ultra Violet-Visible spectroscopy. The  $\text{Zn}_{1-x}\text{Co}_x\text{O}$  and  $\text{Zn}_{1-x}\text{Mn}_x\text{O}$  nanoparticles with  $0 \leq x \leq 0.1$  were successfully prepared by the formal solid-state reaction method. The XPS results and the XRD analysis with full structural Rietveld refinement reveal that both structures have hexagonal wurtzite structure. For all Co-doped ZnO nanoparticles under investigation, the field dependence of the magnetization curves exhibits ferromagnetic behavior with relatively small coercive fields at room temperature. In addition, we found a signature for antiferromagnetic ordering between the Co ions. For the Mn-doped ZnO nanoparticles, we observed ferromagnetic behavior only below 50 K. We also observed a strong correlation between the magnetic and optical behavior of the Co-doped ZnO nanoparticles. Optical diffuse reflectance and absorption spectra exhibit a red shift at room temperature in the absorption band edge with increasing Co-doping. The red shift is attributed to the *sp-d* exchange interaction between free charge carriers in ZnO band and the localized magnetic moments.

**T1.00227 Investigation of the Magnetic Properties of Ni-implanted ITO Thin Films<sup>1</sup>** , FIGEN AY, BEKIR AKTAS, Gebze Technical University, Department of Physics, RUSTEM KHAIBULLIN, VLADIMIR NUZHIDIN, Kazan Physical-Technical Institute of RAS, BULAT RAMEEV, Gebze Technical University, Department of Physics; Kazan Physical-Technical Institute of RAS — Commercially available ITO thin films on fused silica substrates were implanted with 40 keV  $\text{Ni}^+$  ions to fluences of  $(0.5, 1.0 \& 1.5) \times 10^{17}$  ions/cm<sup>2</sup> at room temperature. XRR measurements show that the thickness of the implanted films ( $\sim 28.5$  nm) does not change noticeably with the fluence, while the surface roughness increases essentially. SEM and EDX studies revealed a highly non-uniform distribution of Ni atoms. Room temperature ferromagnetism was observed in the samples with fluences of  $(1.0 \& 1.5) \times 10^{17}$  ions/cm<sup>2</sup>. VSM hysteresis curves and FMR signal point to the formation of a ferromagnetic near-surface layer in the implanted films due to agglomeration of closely-spaced metal Ni nanoparticles. The filling factor of the Ni ferromagnetic phase in the granular magnetic layer was estimated from the FMR results. Super- and para- magnetic phases were observed in the temperature dependence of magnetization by VSM. Superparamagnetic phase is attributed to the Ni nanoparticles located in deeper regions near the film/substrate interface, while paramagnetic phase is related to the impurity centers. For the samples with fluences of  $(1.0 \& 1.5) \times 10^{17}$  ions/cm<sup>2</sup> average sizes of the superparamagnetic nanoparticles were calculated from the blocking temperatures  $T_B$  observed in thermo-magnetic dependences.

**T1.00228 Magnetization reversal in the orthochromite  $\text{Y}_0.5\text{Gd}_0.5\text{CrO}_3$ .**<sup>1</sup> , ALEJANDRO DURAN, Centro de Nanociencias y nanotecnología-UNAM, ROBERTO ESCUDERO, RAUL ESCAMILLA, FRANCISCO MORALES, Instituto de Investigaciones en Materiales-UNAM, EDUARDO VERDIN, Departamento de Física-UNISON — Complex oxide of transition metal with perovskite structure represent fascinating playground for basic solid state research: new electronics and exotic ground states emerge via the competing interplay like spin, orbital, charge as well as lattice degree of freedom. Accordingly, orthochromites are not exception to the rule. In these compounds have been found ferroelectric polarization, spin reorientation transition along with the characteristic behavior known as; magnetization reversal (MR) consisting that a characteristic temperature,  $T^*$ , the system becomes diamagnetic. In this work, the magnetic behavior of the equimolar  $\text{Y}_0.5\text{Gd}_0.5\text{CrO}_3$  composition was studied. Negative magnetization was observed at  $T^* \sim 70$  K in FC mode, and applied field of 100 Oe. The characteristic hysteresis loop in the M-H graph of the pristine sample disappears for a wide range of temperature below of  $T_N$ , and the characteristic spin reorientation is shifted from 14 K in  $\text{GdCrO}_3$  to 5 K for  $\text{Y}_0.5\text{Gd}_0.5\text{CrO}_3$ . The negative magnetization is explained according the model that take into account the anisotropic and antisymmetric exchange interaction between Gd+3 – Cr+3 sublattice.

<sup>1</sup>A.D. and R.E. thanks to grants by DGAPA-PAPIIT, IN103213 and IN 106014 respectively.

**T1.00229 Investigation of Low Temperature Non-Linear Magnetization Behavior in Al and Ga- Substituted  $\text{La}_{0.4}\text{Bi}_{0.6}\text{MnO}_3$  Manganites.** , VIJAYLAKSHMI DAYAL, PUNITH KUMAR V, Maharaja Institute of Technology-Mysore, RAVI HADIMANI, DAVID JILES, Iowa State University, DAVID C JILES TEAM, VIJAYLAKSHMI DAYAL COLLABORATION — Low temperature magnetization measurements have been carried out for the samples containing Al and Ga at B-site in  $\text{La}_{0.4}\text{Bi}_{0.6}\text{MnO}_3$  manganites. The magnetization (M) vs. T(K) data shows strong ferromagnetic behavior with highest magnetization of 6.45 emu/g for  $\text{La}_{0.4}\text{Bi}_{0.6}\text{Mn}_{0.95}\text{Al}_{0.05}\text{O}_3$  and 5.40 emu/g for  $\text{La}_{0.4}\text{Bi}_{0.6}\text{Mn}_{0.90}\text{Ga}_{0.10}\text{O}_3$  samples respectively for an applied magnetic field of  $H=100$  Oe at  $T=20$  K. Similarly at  $T=20$  K for  $\text{La}_{0.4}\text{Bi}_{0.6}\text{Mn}_{0.95}\text{Ga}_{0.05}\text{O}_3$  the highest magnetization ( $M_S$ ) was found to be 5.44 emu/g and for  $\text{La}_{0.4}\text{Bi}_{0.6}\text{Mn}_{0.90}\text{Ga}_{0.10}\text{O}_3$  the  $M_S$  is 5.05 emu/g. The decrease in magnetization with both Al and Ga substitution produces magnetic dilution with increasing concentrations. Both Al and Ga substituted samples exhibit non-linear behavior in their magnetization ( $M_{NL}$ ) curves around 40–120 K due to the frustrations arising from mismatch in their magnetic spin arrangements. The quantity non linear susceptibility,  $\chi_{NL} = -M_{NL}/H$ , diverges as the temperature approaches the frustrated region  $T_f$  from above (i.e.  $T_C$ ). Further from  $d\chi_{NL}/dT$  vs. T(K) plots and critical analysis with unusual critical exponent's  $\gamma$  and  $\beta$  gives an experimental evidence for the observed non linearity and magnetic frustration.

**T1.00230 Tunnel Magneto Resistance of Fe/Insulator/Fe** <sup>1</sup> , DENNIS ARYEE, DEREJE SEIFU, Morgan State University, PHYSICS — Tri-layer thin films of Fe/Insulator/Fe were synthesized using magnetron DC/ RF sputtering with MgO insulator and  $\text{Bi}_2\text{Te}_3$  topological insulators as middle buffer layer. The multi-layered samples thus produced were studied using in-house built magneto-optic Kerr effect (MOKE) instrument, vibrating sample magnetometer (VSM), torque magnetometer (TMM), AFM, MFM, and magneto-resistance (MR). This system, that is Fe/Insulator/Fe on MgO(100) substrate, is a well-known tunnel magneto resistance (TMR) structure often used in magnetic tunnel junction (MTJ) devices. TMR effect is a method by which MTJs are used in developing magneto-resistive random access memory (MRAM), magnetic sensors, and novel logic devices. The main purpose behind this research is to measure the magnetic anisotropy of Fe/Insulator /Fe structure and correlate it to magneto-resistance [1]. In this presentation, we will present results from MOKE, VSM, TMM, AFM, MFM, and MR studies of Fe/Insulator/Fe on MgO(100). [1] A. Newman, S. Khatriwada,, S. Neupane, D. Seifu, "Nano Wires of Fe/MWCNTs and Nanometric Thin Films of Fe/MgO", J. of Appl. Phys., **117**, 144302 (2015).

**T1.00231 Integration of Multifunctional Epitaxial Oxide Heterostructures with Si(001)** , SRINIVASA RAO SINGAMANENI, JOHN PRATER, JAY NARAYAN, North Carolina State University — Multifunctional heterostructures exhibit a wide range of functional properties, including colossal magneto-resistance, multiferroic behavior, and spin, charge, and orbital ordering. However, putting this functionality to work remains a challenge. To date, most of the previous works reported in the literature have dealt with heterostructures deposited on closely lattice matched (using lattice matching epitaxy-LME) insulating substrates such as  $\text{DyScO}_3$ ,  $\text{NdGaO}_3$ , MgO,  $\text{SrTiO}_3$  and MBE-grown STO buffered Si(100). This presentation discusses the major advances in the integration of multifunctional oxide materials onto ubiquitous silicon semiconductor platform reported<sup>1–6</sup> in the recent past by the presenting authors using a novel thin film growth approach, called 'domain matching epitaxy'(DME), which minimizes the strain and nucleation of unwanted defects. The DME paradigm has been used across the large misfit scale (7–25%). Of particular interest, thin film heterostructures including two-phase multiferroics such as  $\text{BiFeO}_3$ (BFO)/ $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  (LSMO),  $\text{BaTiO}_3$ (BTO)/LSMO, and LSMO/SrRuO<sub>3</sub>(SRO). These significant materials advancements may herald a flurry of exciting new advances in CMOS-compatible multifunctional devices.<sup>1</sup> S. S. Rao, et al., Nano Letters **13**, 5814 (2013); J. Phys., **117**, 17B711 (2015); <sup>6</sup>Current Opinion in Solid State and Materials Science. **19**, 301-304 (2015).

**T1.00232 Untangling the contributions of cerium- and iron- sublattices to the magnetism of Ce-doped yttrium iron garnet.** , GERVASI HERRANZ, BLAI CASALS, MARINA ESPINOLA, RAFAEL CICHELO, JOSEP FONTCUBERTA, Institut de Ciència de Materials de Barcelona ICMA-B-CSIC, Campus UAB, 08193 Bellaterra, Spain, STEPHAN GEPRAGS, MATTHIAS OPEL, RUDOLF GROSS, Walther-Meiner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — The remarkable magnetic properties of yttrium iron garnets (YIGs) underpin the use of these materials in a broad scope of spintronic and photonic applications. In particular, the addition of rare-earth metals in the structure enhances to a great extent the magneto-optical activity, which is beneficial for the development of nonreciprocal devices for communication along optical fibers. Yet, the physical mechanisms that lead to the observed enhanced gyrotropic response of doped YIG are not fully unveiled. Here we present a methodology based on magneto-optical spectroscopy that may be instrumental to better understand the optical response of these materials. In particular, we have exploited the wavelength selectivity of magneto-optics to identify a range of frequencies at which one can unravel the individual contributions to the magnetism and gyrotropic response arising from the individual cerium and iron sublattices. The approach outlined here paves the way to assess quantitatively the effect on the optical properties of rare-earth incorporation into YIG, providing an instrumental methodology towards tailoring the functional properties of YIG.

**T1.00233 Growth of EuO films on Si using Pulsed Laser Deposition<sup>1</sup>** , VIVEK S. JAIN, GAURAB RIMAL, JINKE TANG, Department of Physics & Astronomy, University of Wyoming — Epitaxial monolayers of europium monoxide (EuO) deposited on silicon (Si) wafers are suited for spintronic applications such as adding spin filter tunneling and spin current to Si technology, and for probing phenomena like Anomalous Hall effect and Topological Hall effect. However, the innate chemical reactivity of europium (Eu) and Si prevents a direct synthesis of EuO by pulsed laser deposition technique, without significant contamination of the EuO/Si interface and degradation of the EuO thin film. Silicon oxides ( $\text{SiO}_{2-\delta}$ ) on the surface of Si substrates, partial pressure of oxygen ( $\text{O}_2$ ) gas and water vapors in the vacuum chamber act as contaminants. Techniques like standard wet etching process, thermal annealing, and decomposition of  $\text{SiO}_{2-\delta}$  by the bombardment of metal ions, and their effectiveness is studied using the X-Ray diffraction (XRD) system. Our goal is one-process in situ integration of spin-functional magnetic oxides seamless on Si wafers. Also the mechanism for the ferromagnetic order in oxygen-deficient europium monoxide ( $\text{EuO}_{1-x}$ ) at temperatures higher than 69K (the Curie temperature of stoichiometric EuO) remains controversial. We have investigated the magnetization of  $\text{EuO}_{1-x}$  thin films prepared via PLD as a function of (emu) vs (K)

**T1.00234 Room temperature ferromagnetism of Cr-doped  $\text{In}_2\text{O}_3$  bi-layer consisted of a triangular crystal-amorphous interface** , DAI-JHEN JHONG, BO-YU CHEN, CHUN-YU HSU, YAUN-CHAO LIANG, HSIUNG CHOU<sup>1</sup>, Department of Physics, NSYSU, Kaohsiung 804, Taiwan —  $\text{In}_2\text{O}_3$  film is a very conductive and can be modified to exhibit room temperature ferromagnetism upon doping of Cr. In this study, we developed a method, based on the RF power, to control the Cr-doped  $\text{In}_2\text{O}_3$  (CIO) thin-films to form a crystalline phase, at a high power region, or an amorphous phase, at a low power region. When the RF power is set at a medium power, the CIO film self-assemble into a two layers system consisted of crystalline and amorphous layers with interface manifests zig-zag feature. The two layer system has a saturation magnetization  $M_s$ , of  $\sim 0.27$  to  $\sim 1.78$  emu/c.c. with increase of Cr-doping content. In contrast, the  $M_s$  of the amorphous films are  $\sim 0.45$  emu/c.c independent of Cr content. Electron energy loss spectroscopy (EELS) measurements suggested that Cr existed in mixed oxidation states in all films. The Cr with lower oxidation state prefers crystalline structure, while the higher oxidation state Cr prefers an amorphous structure. Due to this charge imbalance, a transport of charge across the interface originates the ferromagnetic interaction, and hence, we observe enhanced  $M_s$  in crystal-amorphous interface system.

**T1.00235 Two phase multiferroics for voltage-induced entropy change with application in near-room-temperature refrigeration<sup>1</sup>** , PRAKASH GIRI, University of Nebraska - Lincoln, DHANANJAY KUMAR, North Carolina Agricultural and Technical State University, CHRISTIAN BINEK, University of Nebraska-Lincoln — The demand for environmental friendly, cost-effective and energy efficient cooling drives the emerging technology of magnetic refrigeration at room temperature. We fabricate a two phase multiferroic  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3\text{-PbTiO}_3(001)$  via pulsed laser deposition for application in advanced near room-temperature refrigeration and miniature cooling devices. The key innovation rests on utilizing the magnetocaloric effect in zero applied magnetic fields. The magnetocaloric effect of the composite is activated purely by electric field. We utilize strain originating from stress which is voltage-induced via the inverse piezoelectric effect of PMN-PT. The strain is carried over into the adjacent LSMO thin film thus changing its magnetic order. The voltage-induced variation in magnetization leads to change in isothermal entropy when the experiment is carried out in contact with a thermostat and gives correspondingly rise to an adiabatic temperature change when heat exchange is suppressed.

**T1.00236 Enhanced Magnetic Proximity Effect at Ferromagnetic Insulator / Magnetic Topological Insulator Interface** , MINGDA LI, CUI-ZU CHANG, MIT, BRIAN KIRBY, NIST, MICHELLE E. JAMER, Northeastern University, WENPING CUI, Boston College, LIJUN WU, Brookhaven National Lab, PENG WEI, MIT, YIMEI ZHU, Brookhaven National Lab, DON HEIMAN, Northeastern University, JU LI, JAGADEESH MOODERA, MIT, MIT TEAM, NIST TEAM, NORTHEASTERN UNIVERSITY COLLABORATION, BOSTON COLLEGE COLLABORATION, BROOKHAVEN NATIONAL LAB COLLABORATION — Magnetic proximity effect at magnetic insulator / topological insulator interface provides a promising approach to realize low-dissipation quantum devices. However, the commonly used magnetic insulators have in-plane anisotropy hence cannot magnetize topological insulator. Here we report an enhancement of proximity exchange coupling in ferromagnetic insulator / magnetic topological insulator  $\text{EuS} / \text{Sb}_{2-x}\text{V}_x\text{Te}_3$  hybrid heterostructure, where proximity effect is enhanced by a factor of 3 through the Vanadium doping. Moreover, an artificial antiferromagnetic-like structure is created between two strong ferromagnets, which may account for the proximity effect enhancement. The interplay between the proximity effect and doping in hybrid heterostructure provides insights into the engineering of magnetic ordering.

**T1.00237 Structural and magnetic properties of epitaxial  $\text{FeMn}_2\text{O}_4$  film on  $\text{MgO}$  (100).** , THIET DUONG VAN, THI MINH HAI NGUYEN, ANH PHUONG NGUYEN, DUNG DANG DUC, ANH TUAN DUONG, QUANG NGUYEN VAN, SUNGLAE CHO, Univ of Ulsan —  $\text{FeM}_2\text{X}_4$  spinel structures, where  $M$  is a transition metal and  $X$  is oxygen or sulfur, are candidate materials for spin filters, one of the key devices in spintronics. On the other hand, the electronic and magnetic properties of these spinel structures could be modified via the control of cation distribution. Among the spinel oxides, iron manganese oxide is one of promising materials for applications.  $\text{FeMn}_2\text{O}_4$  shows inverse spinel structure above 390 K and ferrimagnetic properties below the temperature. In this work, we report on the structural and magnetic properties of epitaxial  $\text{FeMn}_2\text{O}_4$  thin film on  $\text{MgO}(100)$  substrate. The reflection high energy electron diffraction (RHEED) and X-ray diffraction (XRD) results indicated that films were epitaxially grown on  $\text{MgO}(100)$  without the impurity phases. The valence states of Fe and Mn in the  $\text{FeMn}_2\text{O}_4$  film were carried out using x-ray photoelectron spectrometer (XPS). The magnetic properties were measured by vibrating sample magnetometer (VSM), indicating that the samples are ferromagnetic at room temperature. The structural detail and origin of magnetic ordering in  $\text{FeMn}_2\text{O}_4$  will be discussed.

**T1.00238 Study of Magnetic and Electric Properties in  $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  Thin Film**<sup>1</sup>, ISABEL ARANGO, JOHN ORDOEZ, ALBA AVILA, WILSON LOPERA, MARIA GOMEZ, None, THIN FILM GROUP TEAM<sup>2</sup>, DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING COLLABORATION<sup>3</sup> —  $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  (LSMO) is the most interesting compound of the manganite perovskite family due to its Curie temperature above 300K that makes its remarkable properties desirable for practical applications. However, it is well known that ferromagnetic properties weaken when dimensions are reduced. We have grown LSMO thin films by sputtering DC in pure oxygen atmosphere on  $\text{SrTiO}_3$  (STO) and  $\text{LaAlO}_3$  (LAO) substrates at temperature of 830 C. From x-ray diffraction analysis, we have found the Bragg peaks of LSMO thin films around (002) reflection, indicating a textured growth. We have characterized the morphology of the samples by atomic force microscopy. LSMO thin film was patterned using standard UV photolithography. Dependence of resistivity with temperature shows a behavior typical of ferromagnetic system with metal-insulator transition above 300 K. The electrical properties of the structured will be contrasted with thin film. We carried out isothermal resistance and magnetization versus applied magnetic field loops to characterize the samples. We study the dependence of magnetic transport properties with film thickness of 25nm and path size (5 micron) for potential applications like magnetic sensors.

**T1.00239 A Focker-Planck description of the spin Seebeck effect**, GUILLERMO REYES, JUAN ADRIAN REYES, Universidad Nacional de Mexico, Instituto de Fisica — Thermally driven spin-wave spin current in a ferromagnetic material FM and the resulting electric signal in a metal probe placed on the FM are theoretically investigated by considering a thermally fluctuating spin at the interface of a FM-metal junction. We develop an analytical formulation to establish a Focker Plank equation for the probability distribution as a function of magnetization components of the material, for calculating the spin Seebeck signal detected by the metal probe, which converts spin current to charge current by the inverse spin Hall effect. The spin current is induced in the metal probe via an exchange interaction when the metal senses the temperature gradient.

**T1.00240 Ferromagnetic thickness dependence of current-driven spin-orbit torques in different ferromagnetic and heavy metal bilayers**, JUN WU, University of Delaware, XIN FAN, University of Denver, TAO WANG, YUNPENG CHEN, Q. JOHN XIAO, University of Delaware — The spin-orbit torques in ferromagnetic (FM) and heavy metal (HM) bilayers have attracted extensive research interests recently because of the rich physical phenomena and potential applications. We measured the effective fields of field-like torques in Ni/Pt, NiFe/Pt and CoFeB/Pt bilayer systems by the second-order planar Hall effect. When the FM layers are less than 2nm, the effective fields increase rapidly with decreasing the FM layer thickness for all three different FM layers. Among the three FMs, the effective field in Ni is largest, followed by NiFe, then CoFeB. Above 2nm, the effective fields decrease much slower with increasing the FM layer thickness and level off to the Orested field due to the current in the Pt layer. Through FM layer thickness dependence of the field-like torque study, we found that the spin dephasing length in the FM layer, which is related to the scattering in FM layer, plays an important role in determining the magnitude of field-like spin-orbit torque in FM/HM bilayers.

**T1.00241 Thermal conductivity of magnetic insulators with strong spin-orbit coupling**<sup>1</sup>, GEORGIOS STAMOKOSTAS, PANTELEIMON LAPAS, GREGORY A. FIETE, Physics department, Univ of Texas, Austin — We study the influence of spin-orbit coupling on the thermal conductivity of various types of magnetic insulators. In the absence of spin-orbit coupling and orbital-degeneracy, the strong-coupling limit of Hubbard interactions at half filling can often be adequately described in terms of a pure spin Hamiltonian of the Heisenberg form. However, in the presence of spin-orbit coupling the resulting exchange interaction can become highly anisotropic. The effect of the atomic spin-orbit coupling, taken into account through the effect of magnon-phonon interactions and the magnetic order and excitations, on the lattice thermal conductivity of various insulating magnetic systems is studied. We focus on the regime of low temperatures where the dominant source of scattering is two-magnon scattering to one-phonon processes. The thermal current is calculated within the Boltzmann transport theory.

**T1.00242 spin pumping occurred under nonlinear spin precession**, HENGAN ZHOU, XIAOLONG FAN, Lanzhou University, LI MA, SHIMING ZHOU, Tongji University, DESHENG XUE, Lanzhou University — Spin pumping occurs when a pure-spin current is injected into a normal metal thin layer by an adjacent ferromagnetic metal layer undergoing ferromagnetic resonance, which can be understood as the inverse effect of spin torque, and gives access to the physics of magnetization dynamics and damping. An interesting question is that whether spin pumping occurring under nonlinear spin dynamics would differ from linear case. It is known that nonlinear spin dynamics differ distinctly from linear response, a variety of amplitude dependent nonlinear effect would present. It has been found that for spin precession angle above a few degrees, nonlinear damping term would present and dominated the dynamic energy/spin-moment dissipation. Since spin pumping are closely related to the damping process, it is interesting to ask whether the nonlinear damping term could be involved in spin pumping process. We studied the spin pumping effect occurring under nonlinear spin precession. A device which is a Pt/YIG microstrip coupled with coplanar waveguide was used. High power excitation resulted in spin precession entering in a nonlinear regime. Foldover resonance lineshape and nonlinear damping have been observed. Based on those nonlinear effects, we determined the values of the precession cone angles, and the maximum cone angle can reach a values as high as 21.5 degrees. We found that even in nonlinear regime, spin pumping is still linear, which means the nonlinear damping and foldover would not affect spin pumping process.

**T1.00243 Spin Hall and spin Nernst effects: temperature dependence**, ANNA DYRDAL, JOZEF BARNAS, Faculty of Physics, Adam Mickiewicz University, ul. Umultowska 85, 61-614 Poznan, Poland, VITALII DUGAEV, Department of Physics and Medical Engineering, Rzeszow University of Technology, al. Powstancow Warszawy 6, 35-959 Rzeszow, Poland — We have considered temperature dependence of spin Hall and spin Nernst effect in two-dimensional electron gas with spin-orbit interaction of Rashba type [arXiv:1510.03080]. In our considerations we have employed the approach based on the Matsubara Green functions. The formalism used in the case of electric field as a driving force was subsequently adopted to the situation of a spin current driven by a temperature gradient. To achieve this, we have used the concept of an auxiliary vector field. Such a description gives the possibility to consider all mechanisms leading to the spin Hall and spin Nernst effect on equal footing and also their behavior at finite temperatures. Both spin Hall and spin Nernst conductivities were calculated in the approximation including the vertex correction. The total spin Hall conductivity, including vertex correction, has been shown to vanish exactly in the whole temperature range. Thus, our results extend the earlier ones to an arbitrary temperatures. In turn, the total spin Nernst conductivity remains finite when the vertex corrections are included. Using the Ioffe-Regel localization criterion, we have also estimated the range of parameters where the calculated results for the spin Hall and spin Nernst conductivities are applicable.

**T1.00244 Non-equilibrium spin polarization and spin-orbit torque induced by electric field and temperature gradient in a magnetized two-dimensional electron gas with Rashba spin-orbit interaction** , ANNA DYRDAL, JOZEF BARNAS, Adam Mickiewicz University, ul. Umultowska 85, 61-614 Poznan, Poland, VITALII DUGAEV, Department of Physics and Medical Engineering, Rzeszow University of Technology, al. Powstancow Warszawy 6, 35-959 Rzeszow, Poland — We have considered theoretically temperature dependence of non-equilibrium spin polarization of electrons that appears in a magnetized two-dimensional electron gas with Rashba spin-orbit interaction due to external electric field and/or temperature gradient. To do this we have employed the approach based on the Matsubara Green function formalism. We analyzed in detail variation of the induced spin polarization with position of the Fermi level, temperature, and Rashba coupling constant. Moreover, we analyzed the temperature dependence of the electrically and thermally induced spin polarization in the temperature regime, where the spin relaxation time can be assumed constant (independent of temperature). In contrast to the case of nonmagnetic Rashba gas, all three components of the induced spin polarization are now nonzero. The induced spin-polarization is exchange-coupled to the local equilibrium magnetization and therefore exerts a torque on the magnetization vector. We have considered in detail the temperature behavior of spin-orbit torque induced by electric field and by temperature gradient for specific relative orientation of the magnetization and electric field or temperature gradient, respectively.

**T1.00245 Cross-tunneling and phonon bottleneck effects in the relaxation phenomena of the XY pyrochlore antiferromagnet  $\text{Er}_2\text{Ti}_2\text{O}_7$ .**<sup>1</sup> , MARTIN ORENDÁČ, P. J. Šafárik University, Košice, Slovak republic, KATARINA TIBENSKÁ, Technical University, Košice, Slovak Republic, JOZEF STREČKA, JANA ČISÁROVÁ, VLADIMÍR TKÁČ, ALŽBETA ORENDÁČOVÁ, ERIK ČIŽMÁR, P. J. Šafárik University, Košice, Slovak republic, JAN PROKLEŠKA, VLADIMÍR SECHOVSKÝ, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — Multiple time-scale relaxation dynamics are revealed by alternating-current (ac) susceptibility measurements of a single crystal of  $\text{Er}_2\text{Ti}_2\text{O}_7$  studied at high temperatures ( $k_B T \gg J/k_B$ ) and in a wide-range of static magnetic fields. The analysis of the frequency dependence of the ac susceptibility revealed the existence of two relaxation mechanisms identified as an Orbach process with a pronounced effect of phonon bottleneck and cross-tunneling. The origin of the phonon bottleneck is attributed to a resonant phonon trapping. The relevance of the obtained results for relaxation phenomena found in other rare-earth pyrochlores, studied under similar conditions, is discussed.

**T1.00246 Characterization of defect structures on triangular antiferromagnet  $\text{PdCrO}_2$  using scanning tunneling microscopy and spectroscopy** , JINOH JUNG, KAIST , WON-JUN JANG, IBS CAPP, HYUN WOO CHOI, SEOKHWAN CHOI, KAIST, JONG MOK OK, POSTECH, DONG HYUN SON, KAIST, HWAN SOO SUH, SAIT, JUN SUNG KIM, POSTECH, JHINHWAN LEE, KAIST — Frustrated magnetic systems have received significant attentions due to the possibility as source of ferroelectricity. We studied atomic structures and electronic structures of defects in two dimensional triangular-lattice antiferromagnet  $\text{PdCrO}_2$  using scanning tunneling microscopy and spectroscopy (STM / STS). In  $\text{CrO}_2$  layers and Pd layers, atomic resolution STM images showed distinguishable defects and differential conductance images showed unusual standing wave patterns. We identified the origin of defect structures using STS measurements, atomic ball model analysis and Density Functional Theory (DFT) calculations. Atomic structure analysis of defects gives the opportunity to understand a ground state of frustrated magnetic materials.

**T1.00247 Imaging Magnetic Order and Frustration on Distinct Sublattices in Artificial Quasicrystals**<sup>1</sup> , BARRY FARMER, Department of Physics and Astronomy, University of Kentucky, ANDREW BALK, Center for Nanoscale Science and Technology, National Institute of Standards and Technology. Maryland Nanocenter, University of Maryland, VINAYAKA BHAT, Technical University of Munich, ERIC TEIPEL, NATHAN SMITH, Department of Physics and Astronomy, University of Kentucky, JOHN UNGURIS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, JEFFREY TODD HASTINGS, Department of Electrical and Computer Engineering, University of Kentucky, LANCE DE LONG, Department of Physics and Astronomy, University of Kentucky — Scanning electron microscopy with polarization analysis (SEMPA) was used to acquire direct images of as-grown magnetization textures for Permalloy thin films patterned into Penrose P2 tilings (P2T). Simulations yield a low-energy manifold of textures composed of two distinct, perfectly ordered sublattices and two sublattices that remain frustrated. As-grown P2T samples exhibited large domains of the two ordered sublattices in the room-temperature SEMPA images. Higher resolution Monte Carlo simulations based on long-range dipolar interactions predict the two frustrated sublattices will order. These results indicate 3<sup>rd</sup> generation P2T will offer the first example of magnetic order in a quasicrystalline material.

**T1.00248 Itinerant Ferromagnetism in Rashba Spin-Orbit Coupled Semiconductors** , WEIZHE LIU, School of Physics, University of New South Wales, Sydney, Australia, ROLAND WINKLER, Department of Physics, North Illinois University, De Kalb, USA, ULRICH ZUELICKE, School of Chemical and Physical Sciences, Victoria University of Wellington, New Zealand, ROBERT JOYNT, Department of Physics, University of Wisconsin-Madison, Madison, USA, DIMITRIE CULCER, School of Physics, University of New South Wales, Sydney, Australia — We theoretically studied the itinerant ferromagnetism in the Rashba spin-orbit coupled 2D electron system by oppositely shifting the two spin-split Fermi surfaces, on condition that electric current vanishes. We found that the system is stable for the infinitesimal displacements only if  $r_s$  is smaller than around 10. But when  $r_s$  becomes much larger than 10, the system becomes unstable at the original state, and finally we obtained another stable state with nonzero spin polarisation.

**T1.00249 Magnetic torque measurements in a chiral magnet  $\text{CrNb}_3\text{S}_6$**  , JUNICHIRO YONEMURA, Osaka Prefecture Univ, TAKANORI KIDA, DAICHI YOSHIZAWA, Osaka Univ, YUSUKE KOSAKA, JUN AKIMITSU, SADAFUMI NISHIHARA, KATSUA INOUE, Hiroshima Univ, JUNICHIRO KISHINE, The Open Univ of Japan, MASAYUKI HAGIWARA, Osaka Univ, YOSHIIHIKO TOGAWA, Osaka Prefecture Univ — Chiral magnetic orders emerge in a particular class of magnetic materials with a chiral crystal structure. As a consequence of the competition between Heisenberg exchange and Dzyaloshinskii-Moriya (DM) interactions in the presence of external magnetic field, chiral helimagnetic order (CHM) formed at zero magnetic field transforms into a nonlinear magnetic superlattice called chiral soliton lattice (CSL) under magnetic fields perpendicular to the chiral axis. The CSL consists of forced ferromagnetic (FM) regions periodically partitioned by chiral soliton kinks of spins. The period of the CSL increases gradually with increasing magnetic field. The CSL is the ground state and exhibits a phase transition into forced FM state above the critical field. To understand the nature of the phase transition, it is important to examine thermodynamic quantities such as magnetization. Furthermore, it is interesting to explore the possibility of the discretization of such physical quantities in a finite CSL system. In this talk, we will present the development of magnetic torque measurement method using micro cantilever in order to precisely measure the magnetization of a micro-sized sample and a set of experimental data obtained by magnetic torque measurements performed in chiral magnet  $\text{CrNb}_3\text{S}_6$ . Hysteresis and stepped behavior of magnetization observed are discussed.

### T1.00250 Realization of Ground State Artificial Skyrmion Lattices at Room Temperature ,

DUSTIN A. GILBERT, BRIAN B. MARANVILLE, ANDREW J. BALK, BRIAN J. KIRBY, DANIEL T. PIERCE, JOHN UNGURIS, JULIE A. BORCHERS, National Institute of Standards and Technology, PETER FISCHER, Lawrence Berkeley National Laboratory, KAI LIU, University of California, Davis — Artificial skyrmion lattices stable at ambient conditions offer a convenient and powerful platform to explore skyrmion physics and topological phenomena and motivates their inclusion in next-generation data and logic devices. In this work we present direct experimental evidence of artificial skyrmion lattices with a stable ground state at room temperature [1]. Our approach is to pattern vortex-state Co nanodots (560 nm diameter) in hexagonal arrays on top of a Co/Pd multilayer with perpendicular magnetic anisotropy; the skyrmion state is prepared using a specific magnetic field sequence. Ion irradiation has been employed to suppress PMA in the underlayer and allow imprinting of the vortex structure from the nanodots to form skyrmion lattices, as revealed by polarized neutron reflectometry. Circularity control is realized through Co dot shape asymmetry, and confirmed by microscopy and FORC magnetometry. The vortex polarity is set during the field sequence and confirmed by magnetometry. Spin-transport studies further demonstrate a sensitivity to the skyrmion spin texture. Work supported by NSF (DMR-1008791, ECCS-1232275 and DMR-1543582). [1]. D. A. Gilbert, et al, Nat. Commun. 6, 8462 (2015)].

### T1.00251 Unexpected observation of splitting of skyrmion phase in Zn doped $\text{Cu}_2\text{OSeO}_3$ ,

HUNG-DUEN YANG, HUNG-CHENG WU, KAKALA-DEVI CHANDRASEKHAR, TIEN-YU WEI, TA-YE CHEN, Department of Physics, National Sun Yat-Sen University, Kaohsiung, 804 Taiwan, HELMUTH BERGER, Institute of Physics of Complex Matter, Ecole Polytechnique Federal de Lausanne, CH-1015 Lausanne, Switzerland — Polycrystalline  $(\text{Cu}_{1-x}\text{Zn}_x)_2\text{OSeO}_3$  ( $0 \leq x \leq 0.2$ ) samples were characterized by X-ray diffraction. The effect of Zn doping upon saturation magnetization ( $M_S$ ) indicates that the Zn favors to occupying Cu(II) square pyramid crystallographic site. The Zn doping concentration is found to greatly affect the  $M$ - $T$  and  $\chi'_{ac}$ - $T$ . The skyrmion phase has been inferred from the  $\chi'_{ac}$ - $H$  data, and then indicated within the  $H$ - $T$  phase diagrams for various Zn doping concentrations. The striking and unexpected observation is that the skyrmion phase region becomes split upon Zn doping concentration. Interestingly, second conical boundary accompanied by second skyrmion phase was also observed from  $d\chi'_{ac}/dH$  vs.  $H$  curves. Atomic site disorder created by the chemical doping modulates the delicate magnetic interactions via changes in the Dzyaloshinskii-Moriya (DM) vector of distorted Cu(II) square pyramid, thereby splitting of skyrmion phase might occurred. These findings illustrate the potential of using chemical and atomic modification for tuning the temperature and field dependence of skyrmion phase of  $\text{Cu}_2\text{OSeO}_3$ .

### T1.00252 Vanadyl Phthalocyanine ( $\text{C}_{32}\text{H}_{16}\text{N}_8\text{VO}$ ): a near-perfect molecular paramagnet , z.

WANG, M.S. SEEHRA, Department of Physics and Astronomy, West Virginia University — Transition-metal-doped phthalocyanines (TMPc, TM = Mn, Fe, Co, Ni, and Cu) are semiconductors with interesting photoconductive properties and so have potential applications in optoelectronic devices [1]. TMPc are planar molecules with the TM atom at the center bound to four N atoms and forming a linear chain along the monoclinic b-axis. Recent magnetic studies reported in CuPc, CoPc, and MnPc show that the exchange coupling between the TM ions are either ferromagnetic as in MnPc [2] or antiferromagnetic as in CuPc [3] and CoPc [4]. In contrast to TMPc, VOPc has a five-coordinate square pyramidal structure with a single electron associated with  $\text{VO}^{2+}$  ion [5]. Here we report results from detailed investigations of the magnetic properties of powder sample of VOPc X-ray diffraction of which shows it to be triclinic. Temperature dependence of magnetization  $M$  from 2 K to 300 K in  $H = 1$  kOe fits the Curie-Weiss (CW) law with  $\theta = 0$  K,  $\mu = 1.665\mu_B$  and  $g = 1.922$  for spin  $S = 1/2$  which indicates VOPc is paramagnetic without any exchange coupling between  $\text{VO}^{2+}$  ions, quite different from CuPc, CoPc and MnPc. Also,  $M$  vs.  $H$  data (up to 90 kOe) at 2 K, 5 K, 10 K, 25 K, 50 K, 100 K, and 300 K fit well with the Brillouin function variation for  $S = 1/2$ , again confirming perfect paramagnetism in VOPc. [4]M.Serri et al, Nature Commun. 5, 3079(2014). [5]H.Adler et al, J. Phys. Chem. C. 119, 8755 (2015).

**T1.00253 Quantum mechanical forces in the presence of spin and rotational states of nano-magnets ,** GWANG-HEE KIM, Sejong Univ — We study nanomagnets that are free to rotate about their anisotropy and display quantum mechanical forces originated from quantum tunneling between classically degenerate magnetic states. Employing superpositions of spin and rotational states, we show that such forces can exist in the presence of a microwave field and a static magnetic field with a gradient. The optimal conditions for the observation of the oscillating force with quantum beats are presented.

**T1.00254 How to probe transverse magnetic anisotropy of a single-molecule magnet by electronic transport?**<sup>1</sup> , M. MISIORNY, Chalmers UT, Sweden and Adam Mickiewicz Univ., Poland, E. BURZURI, R. GAUDENZI, Delft UT, The Netherlands, K. PARK, Virginia Tech, USA, M. LEIJNSE, Lund Univ., Sweden, M. WEGEWIJS, FZ Jülich, Germany and RWTH Aachen, Germany, J. PAASKE, Univ. of Copenhagen, Denmark, A. CORNIA, Univ. of Modena and Reggio Emilia, Italy, H. VAN DER ZANT, Delft UT, The Netherlands — We propose an approach for *in-situ* determination of the transverse magnetic anisotropy (TMA) of an individual molecule by electronic transport measurements, see Phys. Rev. B **91**, 035442 (2015). We study a Fe4 single-molecule magnet (SMM) captured in a gateable junction, a unique tool for addressing the spin in different redox states of a molecule. We show that, due to mixing of the spin eigenstates of the SMM, the TMA significantly manifests itself in transport. We predict and experimentally observe the pronounced intensity modulation of the Coulomb peak amplitude with the magnetic field in the linear-response transport regime, from which the TMA parameter  $E$  can be estimated. Importantly, the method proposed here does not rely on the small induced tunnelling effects and, hence, works well at temperatures and electron tunnel broadenings by far exceeding the tunnel splittings and even  $E$  itself. We deduce that the TMA for a single Fe4 molecule captured in a junction is substantially larger than the bulk value.

### T1.00255 Micromagnetic Simulation for Exploring Spin-wave Filtering Effects<sup>1</sup> ,

CHAO MA, XIANGYIN LI, TOBIAS STUECKLER, Fert Beijing Research Institute, School of Electronics and Information Engineering, Beihang University, Beijing, China, SHENGDA WANG, Technical University Munich, PEDRAM KHALILI, KANG L. WANG, Department of Electrical Engineering, University of California, Los Angeles, California, WEISHENG ZHAO, HAIMING YU, Fert Beijing Research Institute, School of Electronics and Information Engineering, Beihang University, Beijing, China, FERT BEIJING RESEARCH INSTITUTE TEAM, DEVICE RESEARCH LABORATORY COLLABORATION, TECHNICAL UNIVERSITY LABORATORY COLLABORATION — Spin wave propagation in periodical magnetic structures has been studied in experiments and simulations over last few years and offers potential applications in spin wave filters. We conduct simulation studies on the band gap structure of three types of structures for potential spin filter applications: first, antidot lattice based on yttrium iron garnet (YIG); second, magnonic crystal with iron dots embedded in YIG film; third, grating coupler formed by iron dots above YIG film. We found that the width and frequency position of band gap vary among these different structures. In addition, we investigate spin filter properties depend on the geometry parameters of the periodic pattern, e.g. lattice period, dot diameter. Such studies can be helpful for the realization of the spin filter device with optimized periodical structure and geometry parameters using nanotechnology.

<sup>1</sup>NSF China under Grant No. 11444005

**T1.00256 Propagating spin waves in YIG micro-channel on Silicon** , JILEI CHEN, PING CHE, SA TU, Fert Beijing Research Institute, School of Electronics and Information Engineering, Beihang University, Beijing, China, YAN ZHANG, JUN QIN, LEI BI, State Key Laboratory of Electronic Thin Films and Integrated Devices, University of Electronic Science and Technology of China, Chengdu, China, CHUANPU LIU, ZHIMIN LIAO, DAPENG YU, State Key Laboratory for Mesoscopic Physics, School of Physics, Peking University, Beijing, China, HAIMING YU, Fert Beijing Research Institute, School of Electronics and Information Engineering, Beihang University, Beijing, China, FERT BEIJING RESEARCH INSTITUTE TEAM, UNIVERSITY OF ELECTRONIC SCIENCE AND TECHNOLOGY OF CHINA TEAM, PEKING UNIVERSITY COLLABORATION — Recently the utilization of spin waves in the field of information processing has been widely developed because it is free of Joule heat dissipation and beneficial to miniaturization of the magnon based devices. Here we study spin waves in yttrium iron garnet (YIG) with a low damping property. The YIG film is fabricated on silicon substrate using pulsed laser deposition and the measured FMR linewidth is only a few Gauss. Using ebeam lithography, we are able to pattern the YIG film into a micro-channel and integrate sub-meter waveguides to generate and detect spin waves of wavelength down to  $1\mu\text{m}$  or below. We show results of propagating spin waves in the YIG micro-channel measured by the  $S_{12}$  parameter of the vector network analyzer.

**T1.00257 User-friendly software for modeling collective spin wave excitations<sup>1</sup>** , STEVEN HAHN, PETER PETERSON, RANDY FISHMAN, GEORG EHLERS, Oak Ridge National Laboratory — There exists a great need for user-friendly, integrated software that assists in the scientific analysis of collective spin wave excitations measured with inelastic neutron scattering. SpinWaveGenie is a C++ software library that simplifies the modeling of collective spin wave excitations, allowing scientists to analyze neutron scattering data with sophisticated models fast and efficiently. Furthermore, one can calculate the four-dimensional scattering function  $S(\mathbf{Q}, E)$  to directly compare and fit calculations to experimental measurements. Its generality has been both enhanced and verified through successful modeling of a wide array of magnetic materials. Recently, we have spent considerable effort transforming SpinWaveGenie from an early prototype to a high quality free open source software package for the scientific community.

**T1.00258 Field-driven domain wall motion in ferromagnetic nanowires with Dzyaloshinskii-Moriya interaction** , ZHUO FENGJUN, SUN ZHOUSHOU, College of Physics, Optoelectronics and Energy & Jiangsu Key Laboratory of Thin Films, Soochow University, China — Field-driven domain-wall (DW) motion in ferromagnetic nanowires with easy- and hard-axis anisotropies was studied theoretically and numerically in the presence of the Dzyaloshinskii-Moriya interaction (DMI) based on the Landau-Lifshitz-Gilbert equation. We proposed a new trial function and found the exact solution for the DW motion along a uniaxial nanowire driven by an external magnetic field. A new strategy was suggested to speed up the DW motion in a uniaxial magnetic nanowire with large DMI parameters. In the presence of the hard-axis anisotropy, we found that the breakdown field and velocity of the DW motion was strongly affected by the strength and sign of the DMI parameter under external fields. The work may be useful for future magnetic information storage devices based on the DW motion.

**T1.00259 Ultralow field magnetization reversal of two-body Stoner particles system<sup>1</sup>** , FEI LI, XIAOFENG LU, RUJUN TANG, Z. Z. SUN, Soochow Univ — Magnetic mechanism of nanoparticles has attracted explosive attention in the development of modern information industry. On the base of Landau-Lifshitz-Gilbert equation, we studied the magnetization reversal in a system of two Stoner particles with uniaxial anisotropies and static magnetic interaction. Using micromagnetic simulation, two typical geometrical configurations of perpendicular (PERP) and parallel (PARA) configuration where the diameter of each particle is 20nm are considered. We found that when the separation between two particles has 23nm in PERP configuration ultralow switching field strength, 17mT can be realized, which satisfies the zero-field condition in our previous works[J. Appl. Phys. 109, 104303(2011)] according to the chosen parameters of cobalt material. For other separation values the switching field are multiple of lowest field. However, in PARA configuration the switching field changes with the separation faintly. This two-body system considered in our work might be implement as a composite information bit and our results offer further possibilities for its applications in information storage and/or fast magnetic response.

<sup>1</sup>Ultralow field magnetization reversal of two-body Stoner particles system

**T1.00260 Static Magnetic Properties of Films Measured by Means of Angular Perturbative Magnetoresistance** , ALEXANDRE OLIVEIRA, ABNER MELO, RICARDO DA COSTA, CARLOS CHESMAN, Universidade Federal do Rio Grande do Norte — In this work we introduced a new technique to measure magnetic anisotropies and magnetoelectrical properties, such as Anisotropic Magnetoresistance (AMR) and Giant Magnetoresistance (GMR) amplitudes. The Perturbative Magnetoresistance (PMR) consist of a regular collinear four probe magnetoresistance set up with an AC magnetic field ( $h_{ac}$ ) applied perpendicular to the DC ( $H_{dc}$ ) one.  $h_{ac}$  amplitude is about 1.0 Oe and oscillate at 270 Hz. We successfully interpreted the signal response from the voltage measured by lock-in amplifier and proposed a model based on energy minimization to extract magnetic anisotropies, AMR and GMR amplitudes. Measuring the in-plane angular dependency of PMR signal we were able to identify the usual magnetic anisotropy, such as uniaxial, unidirectional and cubic. Taking into account the perturbative nature of this technique (small  $h_{ac}$  amplitude and low frequency), we argue that angular PMR can be used to investigate some dynamic magnetic effects where static technique can not provide such information. A distinct feature of angular PMR is the capability to be used in saturated and non-saturated regime, so revealing magnetic properties dependency on applied field strength. We addressed the Rotatable Anisotropy as an example in this work.

**T1.00261 New mechanism of kinetic exchange interaction induced by strong magnetic anisotropy** , NAOYA IWAHARA, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — It is well known that the kinetic exchange interaction between single-occupied magnetic orbitals (s-s) is always antiferromagnetic, while between single- and double-occupied orbitals (s-d) is always ferromagnetic and much weaker. Here we show that the exchange interaction between strongly anisotropic doublets of lanthanides, actinides and transition metal ions with unquenched orbital momentum contains a new s-d kinetic contribution equal in strength with the s-s one [1]. In noncollinear magnetic systems, this s-d kinetic mechanism can cause an overall ferromagnetic exchange interaction which can become very strong for transition metal ions. The importance of the s-d kinetic interaction and the possibility of the ferromagnetic interaction are confirmed in some existing complexes on the basis of the density functional theory calculations. [1] N. Iwahara and L. F. Chibotaru, arXiv:1502.04180.

**T1.00262 Itinerant ferromagnetism in fermionic systems with  $SP(2N)$  symmetry** , WANG YANG, CONGJUN WU, University of California San Diego — The Ginzburg-Landau free energy of systems with  $SP(2N)$  symmetry describes a second order phase transition on the mean field level, since the Casimir invariants of the  $SP(2N)$  group can be only of even order combinations of the generators of the  $SP(2N)$  group. This is in contrast with systems having the  $SU(N)$  symmetry, where the allowance of cubic term generally makes the phase transition into first order. In this work, we consider the Hertz-Millis type itinerant ferromagnetism in an interacting fermionic system with  $SP(2N)$  symmetry, where the ferromagnetic orders are enriched by the multi-component nature of the system. The quantum criticality is discussed near the second order phase transition point.

**T1.00263 Partially Screened Edgemagnetoplasmons**, MEHMET GOKSU, Millersville University — We present a study of edgemagnetoplasmons in a partially-screened system of electrons on a helium surface. We compare experiment results with Fetter's theory fits the mode frequency versus field and screening parameter for small magnetic fields. Fetter's theory fits the mode frequency versus field and screening parameter for small magnetic fields. Deviations at larger fields occur near the point where the penetration length becomes shorter than the width of the density profile at the sample perimeter. At larger fields, the mode frequencies are in reasonable agreement with the theoretical predictions of Volkov and Mikhailov. The linewidths are in fair qualitative agreement with their theory.

**T1.00264 First-principles investigation of transient spin transfer torque in magnetic layers**, ZHIZHOU YU, JIAN WANG, The Univ of Hong Kong — By employing the nonequilibrium Green's function (NEGF) method, the transient current-induced spin transfer torque (STT) of the magnetic layered system is investigated based on the density functional theory (DFT). The computational cost of the transient STT is huge due to the dense mesh of  $k$ -sampling for the layered system. In order to speed up the calculation, the Hamiltonian of leads is replaced by the complex absorbing potential (CAP) so that the Green's function can be cast into the wide-band form. After employing the Padé spectrum decomposition, the energy integrals in the formalism of transient electric current and STT, including that of the Fermi distribution function, can be analytically calculated by the theorem of residue, which dramatically reduces the computational complexity of the transient STT. As an application, the NEGF-DFT-CAP formalism with the Padé approximation is implemented to study the transient electric current and current-induced STT of Co/Cu/Co trilayers under an upward pulse of bias with different rotating angles of magnetization direction between two leads. The oscillation behavior is obtained for the transient STT when it approaches the steady state.

**T1.00265 Generalized non-Local Resistance Expression and its Application in F/N/F Spintronic Structure with Graphene Channel**<sup>1</sup>, HUAZHOU WEI, SHIWEI FU, China University of Petroleum - Beijing — We report our work on the spin transport properties in the F/N/F(ferromagnets/normal metal/ferromagnets) spintronic structure from a new theoretical perspective. A significant problem in the field is to explain the inferior measured order of magnitude for spin lifetime. Based on the known non-local resistance formula and the mechanism analysis of spin-flipping within the interfaces between F and N, we analytically derive a broadly applicable new non-local resistance expression and a generalized Hanle curve formula. After employing them in the F/N/F structure under different limits, especially in the case of graphene channel, we find that the fitting from experimental data would yield a longer spin lifetime, which approaches its theoretical predicted value in graphene.

**T1.00266 Theoretical Study on Twofold and Fourfold Symmetric Anisotropic Magnetoresistance Effect**, SATOSHI KOKADO, Graduate School of Integrated Science and Technology, Shizuoka University, MASAKIYO TSUNODA, Graduate School of Engineering, Tohoku University — We theoretically study the twofold and fourfold symmetric anisotropic magnetoresistance (AMR) effect [1]. We first extend our previous model [2] to a model including the crystal field effect [1]. Using the model, we next obtain an analytical expression of the AMR ratio, i.e.,  $AMR(\phi) = C_0 + C_2 \cos(2\phi) + C_4 \cos(4\phi)$ , with  $C_0 = C_2 - C_4$  [1]. Here,  $\phi$  is the relative angle between the magnetization direction and the electric current direction and  $C_2$  ( $C_4$ ) is a coefficient of the twofold (fourfold) symmetric term. The coefficients  $C_2$  and  $C_4$  are expressed by a spin-orbit coupling constant, an exchange field, a crystal field, and s-s and s-d scattering resistivities. Using this expression, we analyze the experimental results for Fe<sub>4</sub>N [3], in which  $|C_2|$  and  $|C_4|$  increase with decreasing temperature. The experimental results can be reproduced by assuming that the tetragonal distortion increases with decreasing temperature.

**T1.00267 Dynamical correlation functions of the transverse Ising model with next-nearest-neighbor interactions**, P. R. C. GUIMARES, Universidade Federal de Viosa, Minas Gerais, Brazil, J. A. PLASCAK, University of Georgia, Athens - GA, USA, O. F. DE ALCANTARA BONFIM, University of Portland, Portland, Oregon, USA, J. FLORENCIO, Universidade Federal Fluminense, Niteri, RJ, Brazil — We investigate the effects of next-nearest-neighbor (NNN) interactions on the dynamics of the one-dimensional spin-1/2 transverse Ising model in the high temperature limit. Using exact diagonalization of finite chains, we obtain the time-dependent transverse correlation function and the corresponding spectral density for a tagged spin. Our results for chains of 13 spins with periodic boundary conditions produce results which are valid in the infinite-size limit. In general we find that the NNN coupling produces slower dynamics accompanied by an enhancement of the central mode behavior. Even in the case of a strong transverse field, if the NNN coupling is sufficiently large there is a crossover from collective mode to central mode behavior. We also obtain several recurrences for the continued fraction representation of the relaxation function.

**T1.00268 Precise quantum control on solid-state spins**, JIANPEI GENG, University of Science and Technology of China — Precise quantum control is of great importance for quantum information processing, high resolution spectroscopy, and quantum metrology. One of the key obstacles to realizing precise quantum control on solid-state spins is the noises arising from both environment and control field. Here, we design a composite pulse to realize precise quantum control on a single electron spin in diamond by suppressing the effect of both noises simultaneously. The control is experimentally demonstrated to be with a low error rate of 4.8E-5. We improve quantum optimal control method to realize precise two-qubit quantum control on a system comprised by a single electron spin and <sup>14</sup>N nuclear spin. With the improved quantum optimal control method, we design a pulse sequence for CNOT gate to suppress the noises simultaneously. The error rate of CNOT gate is measured to be 8E-3. To the best of our knowledge, the control we have realized stands for the state of art in precise quantum control on solid-state spins.

**T1.00269 Micromagnetic Simulation of Amorphous TbFeCo Thin Films with Self Exchange Bias**<sup>1</sup>, CHUNG MA, XIAOPU LI, JIWEI LU, JOSEPH POON, Univ of Virginia — Amorphous ferrimagnetic TbFeCo thin films are found to exhibit self exchange bias effect near compensation temperature by magnetic hysteresis loop measurement. Atom probe tomography, scanning transmission electron microscopy, and energy dispersive spectroscopy mapping have revealed two nanoscale amorphous phases with different Tb concentrations distributed within the amorphous films. The observed exchange anisotropy originates from the exchange interaction between the two nanoscale amorphous phases. Here, we present a computational model of TbFeCo with two nanoscale amorphous phases using micromagnetic simulation. To obtain a structure similar to the two nanoscale amorphous phases, two kinds of cells with different Tb concentration are distributed within the simulated space. Each cell contains separated Tb and FeCo components, forming two antiferromagnetically coupled sublattices. Using this model, we show exchange bias effect near compensation temperature, in agreement with experimental results. The effect can be tuned by controlling the microstructure and composition.

**T1.00270 Spin-to-charge-current conversion in yttrium iron garnet-graphene hybrid structure<sup>1</sup>**, JOAQUIM MENDES, Universidade Federal de Vicosa, OBED ALVES SANTOS, Universidade Federal de Pernambuco, LEONEL MEIRELES, RODRIGO LACERDA, Universidade Federal de Minas Gerais, LUIS VILELA-LEO, FERNANDO MACHADO, ROBERTO RODRIGUEZ-SUREZ, ANTONIO AZEVEDO, SERGIO REZENDE, Universidade Federal de Pernambuco — The use of graphene in spintronic devices depends, among other things, on its ability to convert a spin excitation into an electric charge signal, a phenomenon that requires a spin-orbit coupling (SOC). In this work we report the observation of two effects that show the existence of SOC in large-area CVD grown single-layer graphene (SLG) deposited on a single crystal film of the ferrimagnetic insulator yttrium iron garnet (YIG). The first is a magnetoresistance of graphene induced by the magnetic proximity effect with YIG. The second is the detection of a DC voltage along the graphene layer resulting from the conversion of the spin current generated by spin pumping from microwave driven FMR into charge current. We interpret the spin-to-charge conversion as arising from the inverse Rashba-Edelstein effect (IREE) made possible by the extrinsic spin-orbit coupling in graphene. These observations show that spin orbit coupling can be extrinsically enhanced in graphene by the proximity effect with a ferromagnetic layer. This result opens new possibilities for the use of graphene in spintronic devices with unique functionalities.

**T1.00271 Magnetic Anisotropy and Crystalline Electric Field in Quaternary Intermetallic Compounds.<sup>1</sup>**, W. C. LEE, Dept. of Physics, Sookmyung Women's Univ. Seoul 140-742 — All isostructural compounds  $RNi_2B_2C$  ( $R=Er, Ho, Dy$ ) show some magnetic transitions in magnetization isotherms at certain applied magnetic fields and temperatures above and below Neel and superconducting temperatures ( $T_N, T_C$ ) where  $T_N/T_C$  varies from 0.57 to 1.66 for  $ErNi_2B_2C$  and  $DyNi_2B_2C$ . By using theoretical group analysis of  $D_{4h}$  ( $I_4/mmm$ ) to the energy level scheme of crystalline electric field of magnetization isotherms anisotropy at various temperatures, we have obtained some possible ground state energy levels such as singlet  $\Gamma_4$  and first excited doublet state  $\Gamma_5$  in addition to another excited singlet  $\Gamma_1$ . Our crystalline electric field energy scheme analysis shows some qualitative agreement between theoretical calculation and experiments at high magnetic fields regime only, which means the interplay between antiferromagnetism and superconductivity should be included.

<sup>1</sup>Magnetic Anisotropy and Crystalline Electric Field in Quaternary Intermetallic Compounds.

**T1.00272 Tailoring of  $SmCo_5$  for optimal structure, magnetic anisotropy, and reduced criticality<sup>1</sup>**, DURGA PAUDYAL, R. CHOUHAN, The Ames Laboratory, Iowa State University, Ames, IA 50011, K. A. GSCHNEIDNER, JR., The Ames Laboratory and Department of Materials Science and Engineering, Iowa State University, Ames, IA 50011 —  $SmCo_5$  forms hexagonal  $CaCu_5$ -type structure with three non-equivalent sites: Sm (1a), Co (2c), and Co (3g). Sm lies in the middle of the Co (2c) hexagonal layers. Advanced density functional theory calculations employing Hubbard model show crystal field split localized Sm 4f states, which are responsible for the large part of the magnetic anisotropy exhibited by this system. In addition, the hexagonal Co (2c) layers help enhancing the anisotropy. Due to the partially quenched Sm 4f orbital moment, there is a net Sm 4f moment, which also helps enhancing magnetic moment. The substitution of some of the Sm sites by Nd adds Nd 4f multiplet thereby enhancing crystal field split 4f states and overall magnetic moment. The substitution of Co (2c) by Fe is preferred over Co (3g) but the compound becomes chemically unstable. The criticality issues could be addressed by substituting abundant Ce.

**T1.00273 Rare-earth element based permanent magnets: a theoretical investigation<sup>1</sup>**, RAJIV K CHOUHAN, DURGA PAUDYAL, Ames Laboratory, U S department of Energy, Iowa State University, Ames, IA 50011 — Permanent magnetic materials with large magnetization and high magnetocrystalline anisotropy are important for technical applications. In this context rare-earth (R) element based materials are good candidates because of their localized 4f electrons. The 4f crystal field splitting provides large part of magnetic anisotropy depending upon the crystal environment. The d spin orbit coupling of alloyed transition metal component provides additional anisotropy.  $RCo_5$  and its derivative  $R_2Co_{17}$  are known compounds for large magnetic anisotropy. Here we have performed electronic structure calculations to predict new materials in this class by employing site substitutions. In these investigations, we have performed density functional theory including on-site electron correlation (DFT+U) and L-S coupling calculations. The results show that the abundant Ce substitution in R sites and Ti/Zr substitutions in some of the Co sites help reduce criticality without substantially affecting the magnetic moment and magnetic anisotropy in these materials.

**T1.00274 Magnetostrictive stress reconfigurable thin film resonators in vacuum**, PETER FINKEL, US Naval Research Laboratory — The magnetic response of microdevices is significantly enhanced at structural resonance allowing for improved sensitivity and signal-to-noise ratio. The magnetic field resolution of these devices can be further improved when operating in vacuum due to an increase in mechanical quality factor. In this work, free-standing thin film CoFe bridge resonators have been fabricated and investigated. A strong magnetic field dependence of the fundamental resonance frequency is a function of magnetic field orientation due to a large unidirectional anisotropy. Under vacuum, a quality factor of up to 25 times greater than at atmosphere was revealed as well as an increased magnetic field sensitivity. Such stress reconfigurable sensors offer the possibility of broadband sensing with high resolution, and may therefore represent a new approach to fully integrated resonant magnetic field sensing technology.

**T1.00275 Heisenberg antiferromagnetic chain with multiple spin 1/2 particles of different flavors per site<sup>1</sup>**, SOLOMON F. DUKI, YI-KUO YU, NCBI/NLM/NIH — Motivated by the discoveries of quasi-1D magnetic systems, we studied a quantum mechanical spin lattice system consisting of a one-dimensional antiferromagnetic Heisenberg chain. In this system we considered M spin 1/2 particles of different flavors per site, and the low-lying states, ground state included, of the Hamiltonian was solved numerically using the exact diagonalization method for finite cluster sizes. We have also obtained the corresponding solutions for systems of the same chain length but with one spin M/2 particle per site. The low energy spectra of both systems are then compared. For  $M=2$  and  $M=3$ , our result shows that the two spin chain systems (one spin M/2 per site vs. M spin 1/2 of different flavors per site) have the same excitation spectra at low energy and the number of overlapped states increases as the size of the cluster increases. The observed overlap also indicates that low energy excitations of the M flavored spin 1/2 chain system selects the high spin states, effectively satisfying the Hund's Rule even though the system does not possess the orbital angular momentum.

**T1.00276 Comparison of Magnetic Behavior in Nanostructured and Bulk-Crystalline  $\text{Mn}_x\text{TaS}_2$** <sup>1</sup>, PAUL SHAND, LUCAS BEVING, MATTHEW FLEMING, PAYTON BURKEN, TIM KIDD, LAURA STRAUSS, University of Northern Iowa, CHIH-WEI CHEN, EMILIA MOROSAN, Rice University — The magnetic behavior of nanostructured  $\text{Mn}_x\text{TaS}_2$  for several different Mn concentrations  $x$  have been studied and a magnetic phase diagram obtained. For  $x$  values between 0.15 (the lowest measured) and 0.19, the nanostructured system shows cluster-glass behavior as evidenced by spin relaxation well described by the Vogel-Fulcher-Tammann law as well as aging effects in the dc magnetization and ac susceptibility. For  $x$  values between 0.19 and 0.24, nanostructured  $\text{Mn}_x\text{TaS}_2$  displays re-entrant cluster-glass characteristics, with transitions from paramagnetism to ferromagnetism at higher temperature and ferromagnetism to cluster glass at lower temperature. The tricritical point where all three phases converge seems to be close to  $x = 0.19$ . Results for single-crystal  $\text{Mn}_x\text{TaS}_2$  from the literature show single transitions: paramagnetism to ferromagnetism for  $x = 0.25$  and paramagnetism to cluster glass for  $x$  values in the range 0.02–0.1. For comparable  $x$  values, Curie temperatures seem to be slightly higher and cluster-glass transition temperatures slightly lower in the nanostructures. Bulk crystalline samples with Mn concentrations in the range 0.1–0.25 are currently being studied to more comprehensively compare the magnetic phase diagrams.

**T1.00277 Effects of disorder in the  $\text{Sr}_2\text{FeMoO}_6$  double perovskite via first principles calculations.**, O. NAVARRO, A.M. REYES, Unidad Morelia, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, Y. ARREDONDO, Escuela Nacional de Estudios Superiores, Unidad Morelia, Universidad Nacional Autónoma de México — First principles calculations were done in the double perovskite  $\text{Sr}_2\text{FeMoO}_6$  regarding the effects of cationic disorder and electronic correlation in the ground-state properties such as spin polarization and magnetic moment. We used the Generalized Gradient Approximation (GGA) method including a U Hubbard term. Disorder is introduced via atomic substitution with a ratio of 25% and 12.5%. It is found a magnetic saturation of 2.22 $\mu_B$  and 2.99 $\mu_B$  for 25% and 12.5% of disorder respectively, in agreement with neutron magnetic scattering experiments. The half-metallic behavior of the above double perovskite remains only for a 12.5% of disorder.

**T1.00278 Magnetic Properties of Single-Crystal and Polycrystalline YIG Films Using a Custom Broad-Band FMR System**, SCOOTER JOHNSON, HARVEY NEWMAN, SANGHOON SHIN, EVAN GLASER, Naval Research Laboratory — We present a comparison of ferromagnetic resonance data acquired from single-crystal and polycrystalline yttrium iron garnet thick films deposited by liquid phase epitaxy and aerosol deposition, respectively. Data were taken using a custom broad-band measurement system consisting of a 1.2 T dc magnet and a 40 GHz vector network analyzer, which is used to track the ferromagnetic resonance signal up to 40 GHz. Ferromagnetic resonance data of the films were also taken using a high-sensitivity cavity system operating at 9.5 GHz. We include details on the experimental configuration and include an empirical conversion scheme relating frequency-swept to field-swept linewidths obtained from analysis of  $S$ -parameter data. Our results show that using these complementary measurement techniques can provide insight into dynamic magnetization characteristics of ferromagnetic materials.

**T1.00279 Alternatives to Rare Earth Permanent Magnets for Energy Harvesting Applications**<sup>1</sup>, HELENA KHAZDOZIAN, RAVI HADIMANI, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — Direct-drive permanent magnet generators (DDPMGs) offer increased reliability and efficiency over the more commonly used geared doubly-fed induction generator, yet are only employed in less than 1 percent of utility scale wind turbines in the U.S. One major barrier to increased deployment of DDPMGs in the U.S. wind industry is NdFeB permanent magnets (PMs), which contain critical rare earth elements Nd and Dy. To allow for the use of rare earth free PMs, the magnetic loading, defined as the average magnetic flux density over the rotor surface, must be maintained. Halbach cylinders are employed in 3.5kW Halbach PMGs (HPMGs) of varying slot-to-pole ratio to concentrate the magnetic flux output by a lower energy density PM over the rotor surface. We found that for high pole and slot number, the increase in magnetic loading is sufficient to allow for the use of strontium iron oxide hard ferrite PMs and achieved rated performance. Joule losses in the stator windings were found to increase for the hard ferrite PMs due to increased inductance in the stator windings. However, for scaling of the HPMG designs to 3MW, rated performance and high efficiency were achieved, demonstrating the potential for elimination for rare earth PMs in commercial scale wind turbines.

**T1.00280 Triple Halo Coil: Development and Comparison with Other TMS Coils**<sup>1</sup>, PRIYAM RASTOGI, RAVI HADIMANI, DAVID JILES, Electrical and Computer Engineering, Iowa State University — Transcranial Magnetic Stimulation (TMS) is a non-invasive stimulation technique that can be used for the treatment of various neurological disorders such as Parkinson's Disease, PTSD, TBI and anxiety by regulating synaptic activity. TMS is FDA approved for the treatment of major depressive disorder. There is a critical need to develop deep TMS coils that can stimulate deeper regions of the brain without excessively stimulating the cortex in order to provide an alternative to surgical methods. We have developed a novel multi-coil configuration called "Triple Halo Coil" (THC) that can stimulate deep brain regions. Investigation of induced electric and magnetic field in these regions have been achieved by computer modelling. Comparison of the results due to THC configuration have been conducted with other TMS coils such as "Halo Coil", circular coil and "Figure of Eight" coil. There was an improvement of more than 15 times in the strength of magnetic field, induced by THC configuration at 10 cm below the vertex of the head when compared with the "Figure of Eight" coil alone.

**T1.00281 Anomalous Hall effect sensors based on magnetic element doped topological insulator thin films**, YAN NI, Iowa State University, ZHEN ZHANG, Purdue University, IKENNA NLEBEDIM, Ames Laboratory, U.S. Department of Energy, DAVID JILES, Iowa State University — Anomalous Hall effect (AHE) is recently discovered in magnetic element doped topological insulators (TIs), which promises low power consumption highly efficient spintronics and electronics. This discovery broadens the family of Hall effect (HE) sensors. In this work, both HE and AHE sensor based on Mn and Cr doped  $\text{Bi}_2\text{Te}_3$  TI thin films will be systematically studied. The influence of Mn concentration on sensitivity of  $\text{Mn}_x\text{Bi}_{2-x}\text{Te}_3$  HE sensors will be discussed. The Hall sensitivity increase 8 times caused by quantum AHE will be reported. AHE sensor based on Cr-doped  $\text{Bi}_2\text{Te}_3$  TI thin films will also be studied and compared with Mn doped  $\text{Bi}_2\text{Te}_3$  AHE sensor. The influence of thickness on sensitivity of  $\text{Cr}_x\text{Bi}_{2-x}\text{Te}_3$  AHE sensors will be discussed. Ultrahigh Hall sensitivity is obtained in Cr doped  $\text{Bi}_2\text{Te}_3$ . The largest Hall sensitivity can reach 2620  $\Omega/\text{T}$  in sensor which is almost twice higher than that of the normal semiconductor HE sensor. Our work indicates that magnetic element doped topological insulator with AHE are good candidates for ultra-sensitive Hall effect sensors.

**T1.00282 Enhanced Response of Magneto-active Elastomers by Anisotropy**, SAMUEL LOFLAND, CHRIS KASSNER, CHRIS ROTELLA, WILLIAM RIEGER, ROBERT WALKO, PAUL HORNUNG, STEVE KUTSKA, Department of Physics, Rowan University — We have investigated the magnetostriction of magneto-active elastomers which have random or aligned packing and magnetic filler particles of varying aspect ratios. We have systematically also varied the volume fraction. In general, we find that the response is a complex function of both particle aspect ratio as well as volume fraction. While for any given aspect ratio, there is a maximum in the magnetostriction as a function of volume fraction, for a given volume fraction, there is a local minimum for spherical particles. That is, stubby rods and thick disks show maximal response. We discuss these results in terms of competition between the magnetic dipole interactions, magnetic torque, and elastic response.

**T1.00283 Surface magnetic properties and magnetoimpedance of Co-rich amorphous and nanocrystalline  $(\text{Co}_{1-x}\text{Fe}_x)_{89}\text{Zr}_7\text{B}_4$  ribbons with oxide layer formed by long-term exposure to air**, TATIANA EGGERS, Dept. of Physics, Univ. of South Florida, ALEX LEARY, MICHAEL MCHENRY, Materials Science and Engineering, Carnegie-Mellon University, IVAN SKORVANEK, Institute of Experimental Physics, Slovak Academy of Sciences, HARIHARAN SRIKANTH, MANH-HUONG PHAN, Department of Physics, University of South Florida, Tampa — The surface magnetic properties and magnetoimpedance (MI) of amorphous and nanocrystalline  $(\text{Co}_{1-x}\text{Fe}_x)_{89}\text{Zr}_7\text{B}_4$  melt-spun ribbons with  $x = 0, 0.025, 0.05$  &  $0.1$  was investigated. A 540C heat treatment for 1 hour under a 2 T transverse field formed a large volume fraction of nanocrystalline phases in the ribbons, in addition to a well-defined transverse anisotropy indicated by x-ray diffraction and magneto-optical Kerr effect microscopy. After the heat treatment, the ribbon samples were exposed to open air for an extended period of time producing a visible oxide layer on the surfaces. High frequency magnetoimpedance measurements in the driving frequency range of 1-1000 MHz were made to characterize the potential impact of the surface oxide layer on the ac magnetization process. Unique field-dependent behavior of the real and imaginary components of the MI was found in nanocrystalline ribbons with higher Co content ( $x \geq 0.05$ ), showing multiple peaks above 50 MHz driving current.

**T1.00284 Interface and surface effects on Magnetic Properties in FeRh**, PERIHAN AKSU, ADEM PARABAS, FIKRET YILDIZ, gebze technical university department of physics —  $\text{Fe}_x\text{Rh}_{1-x}$  alloy systems has different magnetic properties depending of composition and temperature. When  $x$  is around 0.5, it is antiferromagnetic at room temperature and has phase transition around 370K from antiferromagnetic to ferromagnetic ordering. Due to this property, the FeRh alloy has a big potential for technological applications. In this study, effects of growing parameters, using buffer and cap layers on magnetic ordering and on phase transition have been studied. All films were grown on  $\text{MgO}(100)$  surface by sputter technique at different substrate temperatures. Rh and Pt were deposited on substrate as buffer and cap layer. Structural properties of the film were investigated by X-ray diffraction. Magnetization measurements were performed as a function of temperature by PPMS. And FMR spectra were registered and the results were analyzed for the ferromagnetic phases. Magnetization measurements showed that growing temperature has noteworthy effect on magnetic properties and structure of FeRh thin films. Depending of growth temperature, ferromagnetic and antiferromagnetic ordered samples were observed at room temperature. Phase transition also was controlled successfully by using buffer and cap layers.

**T1.00285 Analysis of ringing due to magnetic core materials used in pulsed nuclear magnetic resonance applications**, NEELAM PRABHU GAUNKAR, CAJETAN NLEBEDIM, RAVI HADIMANI, Iowa State Univ, IRFAN BULU, YI-QIAO SONG, Schlumberger-Doll Research Division, MANI MINA, DAVID JILES, Iowa State Univ — Oil-field well logging instruments employ pulsed nuclear magnetic resonance (NMR) techniques and use inductive sensors to detect and evaluate the presence of particular fluids in geological formations. Acting as both signal transmitters and receivers most inductive sensors employ magnetic cores to enhance the quality and amplitude of signals recorded during field measurements. It is observed that the magnetic core also responds to the applied input signal thereby generating a signal ('ringing') that interferes with the measurement of the signals from the target formations. This causes significant noise and receiver dead time and it is beneficial to eliminate/suppress the signals received from the magnetic core. In this work a detailed analysis of the magnetic core response and in particular loading of the sensor due to the presence of the magnetic core is presented. Pulsed NMR measurements over a frequency band of 100 kHz to 1MHz are used to determine the amplitude and linewidth of the signals acquired from different magnetic core materials. A lower signal amplitude and a higher linewidth are vital since these would correspond to minimal contributions from the magnetic core to the inductive sensor response and thus leading to minimized receiver dead time.

**T1.00286 Ground State of the One Dimensional Heisenberg Model with  $NNN$  Interactions**, J.D. MANCINI, Kingsborough Community College, V. FESSATIDIS, Fordham University, S.P. BOWEN, J. MALY, Chicago State University, R.K. MURAWSKI, Drew University — A great number of insights into a variety of complex physical many-body systems have been gleaned from the study of the one-dimensional Heisenberg model. There exists a number of quasi one-dimensional inorganic compounds such as  $\text{TTF}-\text{C}_6\text{H}_4(\text{CF}_3)_4$ ,  $\text{SRCu}_2\text{O}_3$ ,  $\text{VO}_2\text{P}_2\text{O}_7$  and  $\text{CuGeO}_3$  for which this Hamiltonian system is relevant. For this work we shall study the one-dimensional Heisenberg Model with nearest, next nearest and next -next nearest interactions. The Hamiltonian is given by:

$$H = J_1 \sum_k \mathbf{S}_k \cdot \mathbf{S}_{k+1} + J_2 \sum_k \mathbf{S}_k \cdot \mathbf{S}_{k+2} + J_3 \sum_k \mathbf{S}_k \cdot \mathbf{S}_{k+3}$$

where  $\mathbf{S}_k$  represents the spin 1/2 operator along a chain of  $N$  sites and periodic boundary conditions is assumed for the closed chain. We note that it is further possible to describe the Coulomb interaction subject to the Pauli exclusion principle for two quantum dots an  $XY$  model. Here we shall study the ground-state energy as well as the energy gap of this system using both a Lanczos (tridiagonal) scheme as well as a generalized Moments approach.

**T1.00287 Ground-State of the Bose-Hubbard Model**, J.D. MANCINI, Kingsborough Community College, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University, R.K. MURAWSKI, Drew University, J. MALY, Kingsborough Community College — The Bose-Hubbard Model represents a simple theoretical model to describe the physics of interacting Boson systems. In particular it has proved to be an effective description of a number of physical systems such as arrays of Josephson arrays as well as dilute alkali gases in optical lattices. Here we wish to study the ground-state of this system using two disparate but related moments calculational schemes: the Lanczos (tridiagonal) method as well as a Generalized moments approach. The Hamiltonian to be studied is given by (in second-quantized notation):

$$H = -t \sum_{\langle i,j \rangle} b_i^\dagger b_j + \frac{U}{2} \sum_i n_i (n_i - 1) - \mu \sum_i n_i.$$

Here  $i$  is summed over all lattice sites, and  $\langle i,j \rangle$  denotes summation over all neighboring sites  $i$  and  $j$ , while  $b_i^\dagger$  and  $b_i$  are bosonic creation and annihilation operators.  $n_i = b_i^\dagger b_i$  gives the number of particles on site  $i$ . Parameter  $t$  is the hopping amplitude, describing mobility of bosons in the lattice. Parameter  $U$  describes the on-site interaction, repulsive, if  $U > 0$ , and attractive for  $U < 0$ .  $\mu$  is the chemical potential. Both the ground-state energy and energy gap are evaluated as a function of  $t$ ,  $U$  and  $\mu$ .

**T1.00288 Atomic structure prediction of Zr-Co and Hf-Co nanoclusters using the evolutionary algorithm.**, AHMAD ALSAAD, Department of Physics, Jordan university of sci. & Technology, Irbid 22110, Jordan, NABIL AL-AQTASH, Department of Physics, The Hashemite University, Zarqa 13133, Jordan, RENAT SABIRIANOV, Department of Physics, University of Nebraska at Omaha, 6001 Dodge St., Omaha, NE, USA — Nanostructures of Hf-Co and Zr-Co rare earth free magnetic materials exhibit a high room-temperature energy product. In our study, the evolutionary algorithm coupled with density functional theory (DFT) is used to identify the global energy minimum atomic structures of Zr-Co and Hf-Co clusters. Using evolutionary crystal structure optimization algorithm, as implemented in USPEX, we studied the atomic structure, binding energies, magnetic properties, and anisotropy of  $\text{Zr}_x\text{Co}_y$  and  $\text{Hf}_x\text{Co}_y$  ( $x=1,2$  and  $y=5,7,11$ ) clusters. A set of metastable and global minimum atomic structures are identified. Several new lower energy configurations were identified for  $\text{Zr}_2\text{Co}_{11}$ ,  $\text{Zr}_1\text{Co}_5$ ,  $\text{Zr}_1\text{Co}_7$ ,  $\text{Hf}_2\text{Co}_{11}$ ,  $\text{Hf}_1\text{Co}_5$  and  $\text{Hf}_1\text{Co}_7$  clusters by our calculations. We discussed the magnetic interaction between the atoms of the clusters which is critical in finding the lowest energy structure. Our calculations show that Zr-Co and Hf-Co clusters have ferromagnetic coupling and large magnetization. Magnetocrystalline anisotropy energies (MAE) of these clusters were also found to be large.

## T1.00289 POSTDEADLINE —

**T1.00290 Analytical Phase Equilibrium Function for Mixtures Obeying Raoult's and Henry's Laws<sup>1</sup>**, ROBERT HAYES, North Carolina State University — When a mixture of two substances exists in both the liquid and gas phase at equilibrium, Raoult's and Henry's laws (ideal solution and ideal dilute solution approximations) can be used to estimate the gas and liquid mole fractions at the extremes of either very little solute or solvent. By assuming that a cubic polynomial can reasonably approximate the intermediate values to these extremes as a function of mole fraction, the cubic polynomial is solved and presented. A closed form equation approximating the pressure dependence on mole fraction of the constituents is thereby obtained. As a first approximation, this is a very simple and potentially useful means to estimate gas and liquid mole fractions of equilibrium mixtures. Mixtures with an azeotrope require additional attention if this type of approach is to be utilized.

**T1.00291 Oxide double quantum dot - an answer to the qubit problem?**, SUDHAKAR YARLAGADDA<sup>1</sup>, AMIT DEY, Saha Institute of Nuclear Physics, Kolkata — We propose that oxide-based double quantum dots with only one electron (tunnelling between the dots) can be regarded as a qubit with little decoherence; these dots can possibly meet future challenges of miniaturization. The tunnelling of the  $e_g$  electron between the dots and the attraction between the electron and the hole on adjacent dots can be modelled as an anisotropic Heisenberg interaction between two spins with the total z-component of the spins being zero. We study two anisotropically interacting spins coupled to optical phonons; we restrict our analysis to the regime of strong coupling to the environment, to the antiadiabatic region, and to the subspace with zero value for  $S_{zT}$  (the z-component of the total spin). In the case where each spin is coupled to a different phonon bath, we assume that the system and the environment are initially uncorrelated (and form a simply separable state) in the polaronic frame of reference. By analyzing the polaron dynamics through a non-Markovian quantum master equation, we find that the system manifests a small amount of decoherence that decreases both with increasing nonadiabaticity and with enhancing strength of coupling  $g$ .

<sup>1</sup>Recently I got an invitation to visit Argonne National Lab from Jan./2106 to end of March/2016. I thought I would give a talk at APS March meeting. Please accept the submission.

**T1.00292 Chiral projected entangled-pair state with topological order<sup>1</sup>**, SHUO YANG, Perimeter Institute for Theoretical Physics, Waterloo, ON, N2L 2Y5, Canada, THORSTEN WAHL, HONG-HAO TU, Max-Planck Institute for Quantum Optics, Hans-Kopfermann-Str. 1, D-85748 Garching, Germany, NORBERT SCHUCH, JARA Institute for Quantum Information, RWTH Aachen University, D-52056 Aachen, Germany, J. IGNACIO CIRAC, Max-Planck Institute for Quantum Optics, Hans-Kopfermann-Str. 1, D-85748 Garching, Germany — We show that projected entangled-pair states (PEPS) can describe chiral topologically ordered phases. For that, we construct a simple PEPS for spin-1/2 particles in a two-dimensional lattice. We reveal a symmetry in the local projector of the PEPS that gives rise to the global topological character. We also extract characteristic quantities of the edge conformal field theory using the bulk-boundary correspondence.

**T1.00293 OIST - A New Model of Graduate Education.**, NEIL CALDER, Okinawa Institute of Science and Technology — I would present the Okinawan Institute of Science and Technology Graduate University. The Graduate University offers outstanding opportunities for students looking to study for a Ph.D. I would outline what makes OIST different from other Graduate Schools and explain the opportunities for students but also the posts open for Faculty. The Okinawa Institute of Science and Technology is an interdisciplinary graduate school offering a 5-year PhD program in Science. Over half of the faculty and students are recruited from outside Japan, and all education and research is conducted entirely in English.

**T1.00294 Controlling Surface Chemistry of Gallium Liquid Metal Alloys to Enhance their Fluidic Properties**, NAHID ILYAS, BRAD CUMBY, ALEXANDER COOK, MICHAEL DURSTOCK, CHRISTOPHER TABOR, Air Force Research Laboratory, MATERIALS AND MANUFACTURING DIRECTORATE TEAM — Gallium liquid metal alloys (GaLMAs) are one of the key components of emerging technologies in reconfigurable electronics, such as tunable radio frequency antennas and electronic switches. Reversible flow of GaLMA in microchannels of these types of devices is hindered by the instantaneous formation of its oxide skin in ambient environment. The oxide film sticks to most surfaces leaving unwanted metallic residues that can cause undesired electronic properties. In this report, residue-free reversible flow of a binary alloy of gallium (eutectic gallium indium) is demonstrated via two types of surface modifications where the oxide film is either protected by an organic thin film or chemically removed. An interface modification layer (alkyl phosphonic acids) was introduced into the microfluidic system to modify the liquid metal surface and protect its oxide layer. Alternatively, an ion exchange membrane was utilized as a sponge-like channel material to store and slowly release small amounts of HCl to react with the surface oxide of the liquid metal. Characterization of these interfaces at molecular level by surface spectroscopy and microscopy provided with mechanistic details for the interfacial interactions between the liquid metal surface and the channel materials.

**T1.00295 Hellmann-Feynman Forces within the DFT+U in Wannier functions basis**, DMITRY NOVOSELOV, DMITRY KOROTIN, VLADIMIR ANISIMOV, Institute of Metal Physics — The most general way to describe localized atomic-like electronic states in strongly correlated materials is to use Wannier functions. In the present paper we continue development of widely-used DFT+U method with the Wannier function basis set and propose a technique to calculate Hubbard contribution to atomic forces. The technique was implemented as a part of plane-waves pseudopotential code Quantum-ESPRESSO and tested on two compounds: charge transfer insulator NiO with cubic crystal structure and correlated metal SrVO<sub>3</sub> with perovskite structure.

**T1.00296 Generation of nondegenerate narrow-band photon pairs for hybrid quantum network**, JIAN WANG, PENGYINJIE LV, JINMING CUI, BIHENG LIU, JIANSUN TANG, YUNFENG HUANG, CHUANFENG LI, GUANGCAN GUO, Univ of Sci & Tech of China — In a hybrid quantum network, the linking two types of quantum nodes through photonic channels requires excellent matching of the central frequency and bandwidth between both nodes and their interfacing photons. However, pre-existing photon sources cannot fulfill this requirement. Using a novel conjoined double-cavity strategy, we report the generation of nondegenerate narrow-band photon pairs by cavity-enhanced spontaneous parametric down-conversion. The central frequencies and bandwidths of the signal and idler photons are independently set to match with trapped ions and solid-state quantum memories. With this source we achieve the bandwidths and central frequencies of 4 MHz at 935 nm and 5 MHz at 880 nm for the signal and idler photons, respectively, with a normalized spectral brightness of 4.9/s/MHz/mW. Due to its ability to be independently locked to two different wavelengths, the conjoined double-cavity is universally suitable for a hybrid quantum network consisting of various quantum nodes.

**T1.00297 Optimization of the profile of a pulsed slow positron beam extracted from a buffer-gas positron trap for the production of a variable energy positronium beam<sup>1</sup>**, R. GLADEN, Univ of Texas at Arlington, K. MICHISHIO, L. CHIARI<sup>2</sup>, Tokyo University of Science, N. OSHIMA, AIST, Tsukuba, Japan, Y. NAGASHIMA, Tokyo University of Science — In this poster we will present some details of steps taken to optimize the beam profile of a pulsed slow positron beam extracted from a buffer-gas positron trap. The beam will be employed for the production of a novel positronium beam by the acceleration and photodetachment of positronium negative ions [1, 2]. The TUS group is planning on using this beam to study positronium diffraction from solid surfaces, providing a unique neutral-particle spectroscopic method with several advantages over conventional neutral-particle spectroscopy, such as a reduced particle mass and, hence, the reduction of damage to the sample surface. **T1.00298 Synthesis, Characterization and Electrochemical Analysis of Composite Cathode Material  $0.5\text{Li}_2\text{MnO}_3\text{-}0.25\text{LiMn}_2\text{O}_4\text{-}0.25\text{LiNi}_{0.5}\text{Mn}_{0.5}\text{O}_2$  for LIB applications.<sup>1</sup>**, MONICA LOPEZ DE VICTORIA, JIFI SHOJAN, LORAIN TORRES, RAJESH KATIYAR, VALERIO DORVILIEN, RAM KATIYAR, University of Puerto Rico — Structural stability, environment friendliness, low cost as well as good electrochemical performances are the major requirements for cathode materials.  $\text{Li}_2\text{MnO}_3$  based composite cathode materials are one of the widely investigated positive cathode materials due to their ability to provide high discharge capacity and good rate capability. We have synthesized layered- spinel composite cathode material  $0.5\text{Li}_2\text{MnO}_3\text{-}0.25\text{LiMn}_2\text{O}_4\text{-}0.25\text{LiNi}_{0.5}\text{Mn}_{0.5}\text{O}_2$  by sol-gel synthesis technique and surface characterized using XRD, Raman, SEM and EDX. Peaks corresponding to layered and spinel structures are identified by XRD and Raman studies. SEM images depict the nano-sized particles and EDX data confirms the presence of constituent transition metals and oxygen. Electrochemical studies were performed on coin cells, which were assembled in the Ar- filled glove box using Li as anode and spread material as cathode.  $\text{LiPF}_6$  with EC:DMC::1:2 ratio was used as the electrolyte. CV, EIS and charge discharge studies shows that the developed cathode material is a promising electrode for next generation Li ion batteries.

**T1.00299 Propulsion and Levitation with a Large Electrodynamic Wheel**, NATHAN GAUL, HANNAH LANE, Northern Virginia Community College, Annandale, VA — We constructed an electrodynamic wheel using a motorized bicycle wheel with a radius of 12 inches and 36 one-inch cube magnets attached to the rim of the wheel. The radial magnetic field on the outside of the wheel was maximized by arranging the magnets into a series of Halbach arrays which amplify the field on one side of the array and reduce it on the other side. Rotating the wheel produces a rapidly oscillating magnetic field. When a conductive metal “track” is placed in this area of strong magnetic flux, eddy currents are produced in the track. These eddy currents create magnetic fields that interact with the magnetic fields from the electrodynamic wheel. The interaction of the magnetic fields produces lift and drag forces on the track which were measured with force gauges. Measurements were taken at a variety of wheel speeds, and the results were compared to the theoretical prediction that there should be a linear relationship between the lift and drag forces with increasing wheel speed. Partial levitation was achieved with the current electrodynamic wheel. In the future, the wheel will be upgraded to include 72 magnets rather than 36 magnets. This will double the frequency at which the magnetic field oscillates, increasing the magnetic flux. Electrodynamic wheels have applications to the transportation industry, since multiple electrodynamic wheels could be used on a vehicle to produce a lift and propulsion force over a conductive track.

**T1.00300 The Microwave Hall Effect Measured Using a Waveguide Tee**, WILLIAM JOHNSON, JOYCE COPPOCK, J. ROBERT ANDERSON, Univ of Maryland-College Park — We describe a simple microwave apparatus to measure the Hall effect in semiconductor wafers. This technique does not require contacts on the sample or the use of a resonant cavity. Our method consists of placing a semiconductor wafer into a slot in an X-band (8 - 12 GHz) waveguide series tee, injecting microwave power into the two opposite arms of the tee, and measuring the microwave output at the third arm. A magnetic field is applied perpendicular to the wafer and produces a microwave Hall signal that is linear in the magnetic field and which reverses phase when the magnetic field is reversed. The microwave Hall signal is proportional to the semiconductor mobility, which we compare for calibration purposes with d. c. mobility measurements obtained using the van der Pauw method. We obtain the resistivity by measuring the microwave reflection coefficient of the sample. We determine a calibration constant as a function of the ratio of thickness to skin depth for two and three inch silicon and germanium samples doped with boron or phosphorus. The measured mobilities ranged from 270 to 3000  $\text{cm}^2 / (\text{Vsec})$

**T1.00301 Adsorption of Water Molecule on Silicene-FE System**, GREGORIO RUIZ CHAVARRIA, UNIVERSIDAD AUTONOMA CHAPINGO — After graphene synthesis[1], there have been numerous studies on similar systems in two dimensions so, we have the borophene [2], germanene [3], silicene [4,5], phosphorene [6], etc. Following this line, I do a study that takes the silicene system at its starting point, system to which it add Fe atom. At first, the stability of SILICENE-Fe system is studied, which is stable. Then a water molecule is added to the SILICENE-Fe system, which is captured, as is bounded to the Fe atom. To make this study I used Functional Density Theory, Born-Openheimer Approximation, Atomic Pseudopotentials and Molecular Dynamics.

**T1.00302 Effect of immersion in simulated body environment on mechanical properties of twist-oriented poly(lactic acid) screws.**, MASATO SAKAGUCHI, SATOSHI KOBAYASHI, Tokyo metropolitan university, COMPOSITE ENGINEERING LAB COLLABORATION — Poly(lactic acid) (PLA) has been applied to bone fixation devices, since it has high biocompatibility. In order to apply PLA device to a higher loaded part, mechanical properties of PLA have been improved by uniaxial drawing. However, mechanical properties along the other loading direction than the drawing direction such as torsion were not improved. Therefore, surgeon should be carefully conducted not to brake the reinforced PLA screw when tightening. In this study, screw is focused on as a bone fixation device. In order to improve torsional strength of a PLA screw, twist-orientation method was developed. PLA screw is prepared through a series of routes including casting, extrusion drawing, twist-orientation and forging. This screw was immersed in the phosphate buffered solution for 0, 8, 16 and 24 weeks, then shear strength, orientation function, crystallinity and molecular weight were measured. As a result, twist-orientation improves the initial torsional strength of PLA screw without the decrease in initial shear strength. In addition, the shear strength on twist-oriented screw is equivalent that of non-twist oriented screw during immersion until 24 weeks. This result shown that the twist-orientation does not decrease shear strength after immersion.

### **T1.00303 Lift to Drag Ratio Analysis in Magnetic Levitation with an Electrodynamic Wheel<sup>1</sup>**

, ANGEL GUTARRA-LEON, VINCENT CORDREY, WALERIAN MAJEWSKI, Northern Virginia Comm Coll — Our experiments explored inductive magnetic levitation (MagLev) using simple permanent magnets and conductive tracks. Our investigations used a circular Halbach array with a 1 Tesla variable magnetic field on the outer rim of the ring. Such a system is usually called an Electrodynamic Wheel (EDW). Rotating this wheel around a horizontal axis above or below a flat conducting surface should induce eddy currents in said surface through the variable magnetic flux. The eddy currents produce, in turn, their own magnetic fields, which interact with the magnets of the EDW. We constructed a four-inch diameter Electrodynamic Wheel using twelve Neodymium permanent magnets and demonstrated that the magnetic interactions produce both lift and drag forces on the EDW. These forces can be used for levitation and propulsion of the EDW to produce magnetic levitation without coils and complex control circuitry. We achieved full levitation of the non-magnetic aluminum and copper plates. Our results confirm the expected behavior of lift to drag ratio as proportional to  $(L/R)\omega$ , with L and R being the inductance and resistance of the track plate, and  $\omega$  being the angular velocity of the magnetic flux.

### **T1.00304 Electromigration in focused ion beam deposited tungsten single nanowires<sup>1</sup>**

, PABITRA MANDAL, BIPUL DAS<sup>2</sup>, A. K. RAYCHAUDHURI, S. N. Bose National Center for Basic Sciences, Salt lake, Kolkata-98, India — As the focused ion beam induced deposited (FIBID) nanowires (NWs) of W, Pt are being used in nanoelectronic technology to connect individual nanodevices, repairing damaged interconnects in integrated circuit (IC), electromigration study in FIBID-NWs has become essential. Briefly, when a thin conductor, like metallic Al, Cu interconnects in an IC chip carry quite high current density  $\sim 10^{12}$  A/m<sup>2</sup>, ions or atoms start migrating. Such migration causes void and hillock formation leading to interconnect discontinuity, short circuit and ultimately IC failure. Our electromigration study in single FIBID-NWs of W reveals that failure in NWs of width and thickness  $\approx 100$  nm occurs typically at  $10^{11}$  A/m<sup>2</sup>. Most notably, void and hillock always form in opposite polarity compared to typical metallic NWs. Such distinctly new outcome is explained via electromigration driven by direct force (ionic charge\*electric field) opposed to wind force driven migration observed in metallic NWs. As FIBID-NWs are composite in nature, different species (e.g., Ga, W and C) migrate with different degree and direction depending on their oxidation state, leading to redistribution of species across NW length and formation of a Ga rich hillock.

### **T1.00305 Robust surface states in epitaxial Bi(111) thin films**

, KAI ZHU, XIAOFENG JIN, Physics department of Fudan University — Bulk Bi a prototype semimetal with trivial electronic band topology. Unanticipatedly, we show the Altshuler-Aronov-Spivak and Aharonov-Bohm effects in epitaxial Bi(111) thin films. Meanwhile, we clearly identify the interaction of the top and bottom surface states via quantum tunneling by the electrical conductance and weak anti-localization measurements. These results have significantly enriched our understanding about the electronic structure of Bi, which might be helpful for clearing up some of its longstanding subtle issues.

### **T1.00306 Ternary Synaptic Plasticity Arising from Memdiode Behavior of TiOx Single Nanowire<sup>1</sup>**

, DESHUN HONG, YUANSHA CHEN, JIRONG SUN, BAOGEN SHEN, Chinese Academy of Sciences, Beijing, GROUP 3 OF MAGNETISM LABORATORY, BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS TEAM — Electric field-induced resistive switching (RS) effect has been widely explored as a novel nonvolatile memory over the past few years. Recently, the RS behavior with continuous transition has received considerable attention for its promising prospect in neuromorphic simulation. Here, the switching characteristics of a planar-structured TiOx single nanowire device were systematically investigated. It exhibited a strong electrical history-dependent rectifying behavior that was defined as a "memdiode". We further demonstrated that a ternary synaptic plasticity could be realized in such a TiOx nanowire device, characterized by the resistance and photocurrent responses. For a given state of the memdiode, a conjugated memristive characteristic and a distinct photocurrent can be simultaneously obtained, resulting in a synchronous implementation of various Hebbian plasticities with the same temporal order of spikes. These intriguing properties of TiOx memdiode provide a feasible way toward the designing of multifunctional electronic synapses as well as programmable artificial neural network

### **T1.00307 Formation of silicene-germanene heterostructures by Ge deposition on epitaxial silicene**

, YUTO AWATANI, ANTOINE FLEURENCE, YUKIKO YAMADA-TAKAMURA, Japan Advanced Institute of Science and Technology — Silicene and germanene are two dimensional honeycomb sheets composed of Si and Ge atoms. Epitaxial silicene and germanene form spontaneously on ZrB2(0001) thin films grown on Si(111) [1] and Ge(111) [2] substrates and can be identified by (2X2)- and ( $\sqrt{3}X\sqrt{3}$ )-reconstruction of ZrB2(0001) respectively. In the present work, we demonstrate that silicene-germanene heterostructures can be formed by deposition of Ge on epitaxial silicene and by subsequent annealing. LEED and STM analysis revealed the growth of the following Si-Ge structures depending on preparation conditions. (1): After annealing at 830 K, (2X2)- and ( $\sqrt{3}X\sqrt{3}$ )-reconstructed areas existed side by side, which suggests that a two-dimensional silicene-germanene heterostructures is formed. (2): After annealing at 1070 K, the surface is (2X2)-reconstructed, with a heterogeneous atomic contrast different from silicene which suggests the incorporation of Ge atoms in the silicene lattice. (3): After annealing this mixed Si-Ge layer at 830 K, a ( $2\sqrt{3}X2\sqrt{3}$ )-reconstruction is observed, in agreement with the overlapping of ( $\sqrt{3}X\sqrt{3}$ )- and (2X2)-reconstructed layers. The structure is presumably a silicene-germanene heterostack structure. [1] A.Fleurence, et al., Phys. Rev. Lett. 108 245501(2012). [2] A.Fleurence, et al., APS March Meeting 2016.

### **T1.00308 Analysis of magnetic anisotropy on BaTiO3/La2/3Sr1/3MnO3 bilayers**

, JOHN EDWARD ORDONEZ, MARIA E GOMEZ, PEDRO PRIETO, Univ del Valle Cali, GRUPO DE PELICULAS DELGADAS TEAM — We have deposited BTO/LSMO bilayers as a possible route to design systems with artificial magnetoelectric coupling. We maintain a fixed ferroelectric layer thickness (tBTO= 100 nm) and ferromagnetic layer (tLSMO = 25 nm). We analyze the influence of direction substrate on electrical and magnetic properties of manganite. From XRD we found that the BTO layer for STO(001) growth textured with almost two different distribution of domains (c domains in plane and out-plane) with cBTO=4.108 Å and LSMO layer growth textured with cLSMO=3.855 Å. Interestingly, for STO(110) and STO(111) the BTO layer and LSMO layer the growth is textured with cBTO=4.037 Å and cBTO=4.018 Å while LSMO growth is also textured with cLSMO=3.867 Å and cLSMO=3.858 Å, respectively. Magnetization with temperature curves shows a ferromagnetic transition for all bilayers at room temperature with a magnetization between 280-320 emu/cm3. Measures of anisotropy at 300 K show a change in magnetic anisotropy for bilayer growth on STO(001) from biaxial magnetic ordering (LSMO/STO) to uniaxial magnetic ordering (bilayer), probably due to BTO layer influence on magnetic properties on LSMO layer. This work has been supported by "Colciencias-CENM Research Project CI7917-CC 10510 contract 0002-2013 and CI 7978.

**T1.00309 The anomalous Hall effect of Fe(001) in ultrathin film regime**, LIN WU, XIAOFENG JIN, Physics Department, Fudan University — The anomalous Hall effect (AHE) in ultrathin film regime is investigated in Fe(001)(1 nm-3 nm) epitaxial on MgO(001). We find the intrinsic anomalous Hall conductivity (AHC) is reducing when the thickness decreasing. The reduction of the intrinsic AHC is interpreted as modification of electronic band structure of iron through boundary confinement. We also observe localization correction to longitudinal resistivity, while the anomalous Hall resistivity of different temperature can be figured out by a set of variable skew scattering coefficients and a constant side-jump contribution. The analysis indicates that localization correction has a significant impact on skew scattering but little on side-jump.

**T1.00310 Unusual magnetic properties of superconducting Bi/Ni bilayers**, HEXIN ZHOU, XIAOFENG JIN, Fudan University, JIN GROUP TEAM — Superconductivity and ferromagnetism are two incompatible phenomena. However, the interaction between them attracts numerous physicists' interests for both theoretical and experimental purposes. Recently, increasing experimental discoveries reveal unconventional effects in superconductor and ferromagnet hybrids, which stimulates a new field called superconducting spintronics. In present work, we report various intriguing magnetic properties of an unexpected superconducting bilayer consisting of non-superconducting Bi and ferromagnetic Ni. A large spontaneous magnetization is induced when the temperature is decreased below the superconductivity transition temperature, which indicates a complex interaction between superconductivity and ferromagnetism in this bilayer. The zero field cooling results show normal Meissner effect while the field cooling results show paramagnetic Meissner effect. Besides, magnetic hysteresis loops in low temperatures show flux pinning and flux jumping effects. Our findings pave the way for exploring unconventional superconductivity coupled to ferromagnetism and potential applications in superconducting spintronics.

**T1.00311 Long-lived non-equilibrium states in a quantum-Hall Tomonaga-Luttinger liquid<sup>1</sup>**, TOSHIMASA FUJISAWA, KAZUHISA WASHIO, RYO NAKAZAWA, MASAYUKI HASHISAKA, Tokyo Inst of Tech - Tokyo, KOJI MURAKI, NTT Basic Research Laboratories, YASUHIRO TOKURA, Univ. Tsukuba — The existence of long-lived non-equilibrium states without showing thermalization, which has previously been demonstrated in time evolution of ultracold atoms (quantum quench), suggests the possibility of their spatial analogue in transport behavior of interacting electrons in solid-state systems. Here we report long-lived non-equilibrium states in one-dimensional edge channels in the integer quantum Hall regime. For this purpose, non-trivial binary spectrum composed of hot and cold carriers is prepared by an indirect heating scheme using weakly coupled counterpropagating edge channels in an AlGaAs/GaAs heterostructure. Quantum dot spectroscopy clearly reveals that the carriers with the non-trivial binary spectrum propagate over a long distance (5 - 10  $\mu\text{m}$ ), much longer than the length required for electronic relaxation (about 0.1  $\mu\text{m}$ ), without thermalization into a trivial Fermi distribution. This observation is consistent with the integrable model of Tomonaga-Luttinger liquid. The long-lived spectrum implies that the system is well described by non-interacting plasmons, which are attractive for carrying information for a long distance.

**T1.00312 A unified understanding of the thickness-dependent bandgap transition in hexagonal layered semiconductors**, JOONGOO KANG, DGIST, Daegu 711-873, Korea, LIJUN ZHANG, Jilin University, Changchun 130012, China, SU-HUAI WEI, Beijing Computational Science Research Center, Beijing 100094, China — Over the past few years, it has been recognized that a single layer of hexagonal two-dimensional semiconductors—such as hexagonal boron nitride (hBN) and transition metal dichalcogenides (TMDs)—has a direct bandgap, while it becomes an indirect semiconductor as the number of layers increases to two or more. Understanding and control of the direct-to-indirect bandgap transition (DIBT) of hexagonal layered semiconductors is of great scientific and technological importance, because the DIBT converts multilayer hBN or TMD into optically less active materials. Here, taking hBN and MoS<sub>2</sub> as examples, we provide a microscopic understanding of the DIBT of hexagonal layered semiconductors based on our symmetry analysis and direct first-principles calculations. Starting from a simple phenomenological explanation of the DIBT within the first-order perturbation theory of multilayer phases, we show how the bandgap transition arises from the selective orbital couplings in hexagonal layered semiconductors.

**T1.00313 Making Distinct Dynamical Systems Look Identical Spectrally**, ANDRE GONTIJO CAMPOS, DENYS BONDAR, RENAN CABRERA, HERSCHEL RABITZ, Princeton University — We use tracking control techniques to match the optical responses of distinct dynamical systems interacting with laser pulses in both quantum and classical regimes. As a result we provide illustrations where a variety of open and closed systems display the same optical response, demonstrating that the optical spectrum alone is not enough to uniquely characterize general dynamical systems. These findings have important implications in quantum inversion techniques encompassing both linear and nonlinear optics. Moreover, the presented results can be applied to designing materials with desired optical responses.

**T1.00314 Searching for Correlations with the HCO<sup>+</sup> 4-3 Molecular Spectra of Protostars<sup>1</sup>**, OGULCAN ACIKGOZ, SEDA BASTURK, Middle East Tech Univ — The assignment is based on HCO<sup>+</sup> J=4-3 spectral line molecular observations of protostars from the James Clerk Maxwell Telescope, which has the 15 m diameter dish and located in Mauna Kea, Hawaii, USA. Data of 20 protostars are taken from the public LOMASS database and analyzed. We looked for correlations between a few observational quantities.

<sup>1</sup> We thank Dr Umut Yildiz (NASA/JPL-Caltech) for providing data and his comments and support to our research project.

**T1.00315 Dependence of the Crossing Time on the Sequence Length in a Diploid Discrete-Time Mutation-Selection Model for a Finite Population<sup>1</sup>**, WONPYONG GILL<sup>2</sup>, Pusan Natl Univ — This study examined the crossing time in the diploid discrete-time mutation-selection model in a finite population for a range of dominance parameters and selective advantages by switching on a diploid, asymmetric, bridged landscape, from an initial state, a steady state in a diploid, bridged landscape. The dependence of the crossing time on the sequence length was examined for a fixed extension parameter, which was defined as the mean Hamming distance from the optimal allele of the initial steady state divided by the sequence length. The boundary between the deterministic and stochastic regions in the diploid discrete-time mutation-selection model was characterized using the same formula as that in the haploid discrete-time mutation-selection model. The crossing time in a finite population with various population sizes, dominance parameters and selective advantages began to deviate from the crossing time for an infinite population at the critical sequence length. The crossing time for a finite population in the stochastic region was found to be an exponentially increasing function of the sequence length, whose rate was unchanged, regardless of changes in the population size, dominance parameter and selective advantage with a fixed extension parameter.

**T1.00316 Molecular Origins of Higher Harmonics in Large-Amplitude Oscillatory Shear Flow: Shear Stress Response**, PETER GILBERT, A. JEFFREY GIACOMIN, Chemical Engineering Department, Queen's University, ANDREW SCHMALZER, Chemical Diagnostics and Engineering, Los Alamos National Laboratory, R. B. BIRD, Chemical Engineering Department, University of Wisconsin - Madison — Recent work has focused on understanding the molecular origins of higher harmonics that arise in the shear stress response of polymeric liquids in large-amplitude oscillatory shear flow. These higher harmonics have been explained using only the orientation distribution of a dilute suspension of rigid dumbbells in a Newtonian fluid, which neglects molecular interactions and is the simplest relevant molecular model of polymer viscoelasticity [R.B. Bird et al., *J Chem Phys*, **140**, 074904 (2014)]. We explore these molecular interactions by examining the Curtiss-Bird model, a kinetic molecular theory that accounts for restricted polymer motions arising when chains are concentrated [Fan and Bird, *JNNFM*, **15**, 341 (1984)]. For concentrated systems, the chain motion transverse to the chain axis is more restricted than along the axis. This anisotropy is described by the link tension coefficient,  $\epsilon$ , for which several special cases arise:  $\epsilon = 0$  corresponds to reptation,  $\epsilon > 1/8$  to rod-climbing,  $1/2 \geq \epsilon \geq 3/4$  to reasonable shear-thinning predictions in steady simple shear flow, and  $\epsilon = 1$  to a dilute solution of chains. We examine the shapes of the shear stress versus shear rate loops for the special cases,  $\epsilon = (0, 1/8, 3/8, 1)$ , of the Curtiss-Bird model, and we compare these with those of rigid dumbbell and reptation model predictions.

**T1.00317 Micro-architected Composite Lattices with Tunable Negative Thermal Expansions**, QIMING WANG, University of Southern California — Solid materials with minimum or negative thermal expansion (NTE) have broad applications, from dental fillings to thermal-sensitive precision instruments. Previous studies on NTE structures were mostly focused on theoretically design and 2D experimental demonstrations. Here, aided with multimaterial projection micro-stereolithography, we experimentally fabricate multi-material composite lattices that exhibit significant negative thermal expansion in three directions and over a large range of temperature variations. The negative thermal expansion is induced by the structural interaction of material components with distinct thermal expansion coefficients. The NTE performance can be tuned over a large range by varying the thermal expansion coefficient difference between constituent beams and geometrical arrangement. Our experimental results match qualitatively with a simple scaling law and quantitatively consistently with computational models.

**T1.00318 Surface Tension of Methanol as a Function of cut-off Radius and Temperature Controllers.**<sup>1</sup>, ABDALLA OBEIDAT, ADNAN JARADAT, BUSHRA HAMDAN, JUST — Molecular dynamics is used to calculate the surface tension of van Leeuwen methanol. The van Leeuwen model of methanol is chosen over other models of methanol, since this model is widely used to study nucleation at low temperature. Usually, scientists use the cut-off radius to be three order of magnitude of segment diameter. In this study, we varied the cut-off radius to estimate the best cut-off at which the surface tension reaches its plateau. After deciding the best cut-off radius for van der Waals and Coulomb interactions (CUT-OFF and PME were used for Coulomb interaction), we varied the temperature controller (van-Housen, Berendsen, and v-rescale) to decide the best temperature controller to be used to study methanol. In all simulations, Gromacs is used at T=200-300K with periodic boundary conditions in all dimensions.

**T1.00319 Geometrical design of self-phoretic colloids**<sup>1</sup>, AMIR NOURHANI, Penn State University, PAUL E. LAMMERT, Phys. Dept., Penn State University — Within a unified formalism we study the generic properties of self-phoretic particles for source-or-sink (such as self-diffusiophoresis and self-thermophoresis) and sink-and-source (such as self-electrophoresis) flux distribution across a continuous range of geometries from disk-like to sphere to rod-like shapes. We obtain new insights into the performance of self-phoretic particles as a function of the distribution of surface flux and their shape. Surprisingly, upon varying the geometry between the sphere and rod-like shape, the velocity is not simply an interpolation, but has a nonmonotonic dependent on particle geometry.

**T1.00320 Effect of Graphene, Carbon Black, and Multi-wall Carbon Nano Tube as fillers on Dielectric Response Function of Polystyrene Matrix.**, ADNAN JARADAD, None, HIND ABU GHAZLEH COLLABORATION, HASSAN GHANEM COLLABORATION — A set of thin samples of three different fillers (graphene, carbon black, and multi-wall carbon nano-tubes) has been prepared in the laboratory. The thin composite films have different concentration of the filler (weight concentration). The dielectric response function of the prepared samples shows strong relaxation at high frequency (>500 KHz), the position of this peak is found to be a function of weight percent of the composite.

**T1.00321 ABSTRACT MOVED TO V40.003 —**

**T1.00322 SANG-a kernel density estimator incorporating information about the measurement error.**<sup>1</sup>, ROBERT HAYES<sup>2</sup>, North Carolina State University — Analyzing nominally large data sets having a measurement error unique to each entry is evaluated with a novel technique. This work begins with a review of modern analytical methodologies such as histogramming data, ANOVA, regression (weighted and unweighted) along with various error propagation and estimation techniques. It is shown that by assuming the errors obey a functional distribution (such as normal or Poisson), a superposition of the assumed forms then provides the most comprehensive and informative graphical depiction of the data set's statistical information. The resultant approach is evaluated only for normally distributed errors so that the method is effectively a Superposition Analysis of Normalized Gaussians (SANG). SANG is shown to be easily calculated and highly informative in a single graph from what would otherwise require multiple analysis and figures to accomplish the same result. The work is demonstrated using historical radiochemistry measurements from a transuranic waste geological repository's environmental monitoring program.

**T1.00323 Interface enhanced superconductivity in single unit-cell FeSe films on SrTiO<sub>3</sub>(110)**, LILI WANG, Tsinghua University — The advent of enhanced superconductivity in FeSe/STO(001) has instigated great interests in other interfacial systems both experimentally and theoretically. To figure out the key role of substrate, STO(110) substrate is of great interest because it resembles STO(001) in high density subsurface oxygen vacancies but distinguishes itself by anisotropic in-plane lattice constants and dielectric constant. Here, we investigated molecular beam epitaxy growth of 1-UC FeSe films on STO(110) substrates and studied the superconducting properties by combined *in-situ* scanning tunneling spectroscopy (STS) and *ex-situ* transport measurement. By STS we observed a superconducting gap as large as 17 meV. Transport measurements on 1-UC FeSe/STO(110) capped with FeTe layers reveal superconductivity with an onset transition temperature ( $T_C$ ) of 31.6 K and an upper critical magnetic field of 30.2 T. We also find that  $T_C$  can be further increased by an external electric field, but the effect is weaker than that on STO(001) substrate. Our study highlights the important roles of interface related charge transfer and electron-phonon coupling in the high temperature superconductivity of FeSe/STO. References: [1] Q. Y. Wang, et al., Chin. Phys. Lett., **29**, 037402 (2012). [2] J. J. Lee et al., Nature **515**, 245 (2014).

**T1.00324 Micro-Structure of Iron in *Petroselinum crispum* and its dependence with the chemical nature of the soil.**<sup>1</sup>, SUNIL DEHIPAWALA, Queensborough Community College, PUBUDU SAMARASEKARA, RASIKA DAHANAYAKE, University of Peradeniya, LEUNG EDMUND, Queensborough Community College — The micro structure of the iron in *Petroselinum crispum* is investigated using synchrotron X-ray Absorption and Mossbauer spectroscopy. Plants were grown under controlled soil conditions with different pH, and iron concentrations. The correlation between the micro structure of the iron in *Petroselinum crispum* plants and the soil conditions were studied. Most of the iron present in the plants has the form  $\text{Fe}^{3+}$  or electron density at the site of the iron nucleus similar to that of  $\text{Fe}^{3+}$ . But the amount of iron absorbed by the plants depends on the soil conditions. These findings will help establish soil conditions necessary to increase  $\text{Fe}^{2+}$  intake by plants similar to the form of iron present in most supplements.

**T1.00325 Numerical study of the butterfly effect on the solutions of the logistic difference equation using arbitrary significant digits**, JESUS RODRIGUEZ-NUNEZ, JESUS CASTILLO, Departamento de Investigacion en Fisica, Universidad de Sonora, MARTIN MOLINAR-TABARES, Organismo de Cuenca Noroeste, Comision Nacional del Agua — The solutions of the logistic difference equation when they are under the influence of the chaotic regime are very sensitive to initial conditions due to the butterfly effect. In this study we used arbitrary significant digits to generate solutions of the logistic difference equation under the influence of chaos, and a follow of its effects along each digit of the solutions was made. A large amount of significant digits to generate the solutions is necessary since it is the only way of naturally appreciating the implications of chaos on these solutions. We compared digit by digit the numerical solutions that were generated by several different initial conditions that contain modifications in a very far significant digit, with respect to the solution of another initial condition that was selected for a control solution. The results shown that it is possible to track the butterfly effect and easily predict the moment on which its effects will be noticeable.

**T1.00326 Experimental determination of fluxoid quantum's contribution to magnetic moment for force metrology**, JAE-HYUK CHOI, HEONHWA CHOI, YUN WON KIM, MIN-SEOK KIM, Korea Research Institute of Standards and Science, SOON-GUL LEE, Korea University Sejong Campus — Utilizing a cantilever torque-magnetometry equipped with fiber-scanning capability, we have executed precision measurements of the magnetic moment of a micron-sized Nb ring in superconducting state at  $T = 4$  K, which is a key element for sub-piconewton force standard previously suggested by some of the authors. The magnetic moments due to diamagnetic response and individual magnetic fluxoid have been independently determined with a resolution of sub-femto-Am<sup>2</sup>. Within the accuracy of the spring constant determined from a thermal noise method, the results are very consistent with the estimation by Brandt and Clems model that considers finite-penetration-depth effect.

**T1.00327 Analytical Phase Equilibrium Function for Mixtures Obeying Raoult's and Henry's Laws.**<sup>1</sup>, ROBERT HAYES, North Carolina State Univ — When a mixture of two substances exists in both the liquid and gas phase at equilibrium, Raoult's and Henry's laws (ideal solution and ideal dilute solution approximations) can be used to estimate the gas and liquid mole fractions at the extremes of either very little solute or solvent. By assuming that a cubic polynomial can reasonably approximate the intermediate values to these extremes as a function of mole fraction, the cubic polynomial is solved and presented. A closed form equation approximating the pressure dependence on mole fraction of the constituents is thereby obtained. As a first approximation, this is a very simple and potentially useful means to estimate gas and liquid mole fractions of equilibrium mixtures. Mixtures with an azeotrope require additional attention if this type of approach is to be utilized.

**T1.00328 Possible Unconventional superconductivity in  $\text{YCo}_{0.7}\text{C}_2$** , ORLANDO CIGARROA, Univ de Sao Paulo, PRISCILA FERRARI ROSA, University of California Irvine, LUIZ TADEU ELENIO, Univ de Sao Paulo, ZACHARY FISK, University of California Irvine, ANTONIO JEFFERSON DA SILVA MACHADO, Univ de Sao Paulo — Non-centrosymmetric superconductors as  $\text{CePt}_3\text{Si}$  [1,2] and sequicarbides  $(\text{La,Y})_2\text{C}_3$  [3] are remarkable examples of unusual properties displayed associated to unconventional pairing due to an antisymmetric spin-orbit coupling. Another interesting case is the family of compounds belonging to the  $\text{CeNiC}_2$  type structure, in which more than thirty stable compounds have found to crystallize in this structure. Here we report magnetization, resistivity, and heat capacity measurements on poly-crystalline samples of non-centrosymmetric  $\text{YCo}_{0.7}\text{C}_2$ , showing clear evidence of bulk superconductivity with a critical temperature of  $T_c = 4$  K. Interestingly the specific heat of the superconducting state deviates from conventional exponential temperature dependence, which is suggestive of possible unconventional superconducting behavior in  $\text{YCo}_{0.7}\text{C}_2$ , similar to that seen in the isostructural and isoelectronic superconductor  $\text{LaNiC}_2$  [4]. Besides, these results strongly suggest that this material is a strong candidate of multiband superconductivity.

**T1.00329 Structural and electronic properties of atomically thin germanium selenide polymorphs**, ZIYU HU, Beijing Computational Science Research Center — Using comprehensive density functional theory calculations, we systematically investigate the structure, stability, and electronic properties of five polymorphs of GeSe monolayer, and highlight the differences in their structural and electronic properties. Our calculations show that the five free-standing polymorphs of GeSe are stable semiconductors.  $\beta$ -GeSe,  $\gamma$ -GeSe,  $\delta$ -GeSe, and  $\varepsilon$ -GeSe are indirect gap semiconductors, whereas  $\alpha$ -GeSe is a direct gap semiconductor. We calculated Raman spectra and scanning tunneling microscopy images for the five polymorphs. Our results show that the  $\beta$ -GeSe monolayer is a candidate for water splitting.

**T1.00330 Structure and Self-Assembly of Oligocarbonate-Fluorene End Functionalized Poly (ethylene glycol) ABA Triblock Polymer**, GUANGMIN WEI, VIVEK PRABHU, National Institute of Standards and Technology, SHRINIVAS VENKATARAMAN, YI YAN YANG, Institute of Bioengineering and Nanotechnology, The Nanos, Singapore, JAMES HEDRICK, IBM Almaden Research Center, California USA, VIVEK PRABHU TEAM, SHRINIVAS VENKATARAMAN, YI YAN YANG COLLABORATION, JAMES HEDRICK COLLABORATION — Hierarchical structures of oligocarbonate-fluorene end-functionalized poly(ethylene glycol) triblock copolymer  $(\text{P}(\text{F-TMC})_m\text{-PEG444-P}(\text{F-TMC})_m)$  were characterized by light scattering, atomic force microscopy, and Ultraviolet-visible spectroscopy in dilute regime in water, a poor solvent of F-TMC block. The evidence for pai-pai stacked of F-TMC block in self-assembled structure was provided. The self-assembly behavior is highly dependent on concentration and F-TMC block length, m. The presence of clusters dominates the population of scatterers once m is larger than 2, where there is no clear evidence of a separation of micelles and clusters. The molecular aggregation driven by F-TMC groups appears too strong to permit labile micelle-cluster dynamics as observed with  $m = 2$  and 1.2. The non-mean field scaling of the aggregation number, when compared to models for triblock copolymers, highlights the need for a molecular-based model to predict the self-assembly at low end-group numbers. In our case, the end-groups are oligomers, so the comparison to Flory scaling may not be justified.

**T1.00331 Negative magnetization and exchange bias effect in  $\text{Ni}_{1.4}\text{Mn}_2\text{Ga}_{0.6}$** , ABDULLAH ALBAGAMI, MAHMUD KHAN, Miami University — Ni-Mn-X based Heusler alloys have attracted significant interest in recent years due to their multifunctional properties. Exchange bias (EB) is one such property that results from competing magnetic interactions in these alloys. The EB effect is typically observed in materials where ferromagnetic (FM) and antiferromagnetic (AFM) interactions co-exist. Since the discovery of EB effect in CoO (AFM) coated Co (FM) nanoparticles by Meikle John and Bean in 1956, a significant amount of research efforts have been made on this subject. Here, we have performed an experimental study on the magnetic and exchange bias properties of polycrystalline  $\text{Ni}_{1.4}\text{Mn}_2\text{Ga}_{0.6}$  alloy by X-ray diffraction, dc magnetization, and ac susceptibility measurements. The material exhibits a ferromagnetic Curie temperature of  $\sim 300$  K. The magnetization versus field data obtained at 5 K under zero field condition exhibits a double shifted hysteresis loop that disappears at higher temperatures. When the sample is cooled from room temperature to 5 K in applied magnetic fields, exchange bias is observed, whose magnitude is strongly dependent on the cooling field. A maximum exchange bias field of 730 Oe is observed under field cooling condition at 5 K. A negative magnetization is observed in the magnetization versus temperature data obtained at magnetic fields smaller than 75 Oe. The experimental results are explained in terms of the competing ferromagnetic and antiferromagnetic exchange interaction that exist in the materials due to the Mn atoms occupying multiple crystalline sites resulting in a spin glass-type frustrated ground state.

**T1.00332 Anomalous transport properties of  $\text{Ni}_2\text{Mn}_{1-x}\text{Cr}_x\text{Ga}$  Heusler alloys at the martensite-austenite phase transition**, JEFFREY BROCK, MAHMUD KHAN, Miami Univ — The Heusler alloy  $\text{Ni}_2\text{MnGa}$  exhibits a first order martensitic phase transition at  $T_M \approx 202$  K. During this transition, the high temperature cubic  $L2_1$  phase (austenite) of the alloy transforms to a low temperature phase (martensite) with a lower symmetry. In both stoichiometric and off-stoichiometric  $\text{Ni}_2\text{MnGa}$  based materials, jump-like anomalies are observed in the resistivity versus temperature data in the vicinity of  $T_M$ . The magnitude of the jump has been reported to vary from less than 1% to a few percent. This variation in the magnitude of resistivity change has been attributed to the difference in scattering on the vibrational motion of the lattice between the austenitic and martensitic phases and the reconstruction of the electronic structure. Although, several reports can be found in existing literature that discuss the change of resistivity of Heusler alloys at MPT, detailed study of a complete system that shows a systematic change of resistivity at MPT is missing. Here we report an experimental study on a series of  $\text{Ni}_2\text{Mn}_{1-x}\text{Cr}_x\text{Ga}$  Heusler alloys. A detailed study has been performed on this previously unexplored system by magnetization and transport measurements. Sharp step-like anomalies are observed in the resistivity data of the alloys, in the vicinity of the  $T_M$ , that changes dramatically with increasing Cr concentration. The magnitude of the jump in resistivity changes dramatically from less than 1 % to nearly 18 %. The results provide a further understanding of the mechanisms that may cause the change in resistivity in the vicinity of MPT.

**T1.00333 Information jet: Handling noisy big data from weakly disconnected network**, DEEDER AURONGZEB, Texas AM university, Department of Statistics. — Sudden aggregation (information jet) of large amount of data is ubiquitous around connected social networks, driven by sudden interacting and non-interacting events, network security threat attacks, online sales channel etc. Clustering of information jet based on time series analysis and graph theory is not new but little work is done to connect them with particle jet statistics. We show pre-clustering based on context can element soft network or network of information which is critical to minimize time to calculate results from noisy big data. We show difference between, stochastic gradient boosting and time series-graph clustering. For disconnected higher dimensional information jet, we use Kallenberg representation theorem (Kallenberg, 2005, arXiv: 1401.1137) to identify and eliminate jet similarities from dense or sparse graph.

**T1.00334 Scale Invariant Fluctuations of Proteins Native States<sup>1</sup>**, QIAN-YUAN TANG, YANG-YANG ZHANG, JUN WANG, WEI WANG, Collaborative Innovation Center of Advanced Microstructures, National Laboratory of Solid State Microstructure, Nanjing University, China, DANTE R CHIALVO, Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICET), Argentina — Long-range correlations in biological systems often hints for the presence of universal mechanism at work. Here we study protein native dynamics by analyzing a large set of structure ensembles determined by solution NMR. For proteins of diverse sizes, the average distance-dependent cross-correlation functions  $\phi(r)$  and its correlation length  $\xi_\phi$  are analyzed. The analysis uncovered the presence of nontrivial scaling in the proteins' equilibrium dynamics around native states. We show that the correlation length is proportional to the gyration radius of the molecule, implying that the motion of any residue could influence all the others, up to the entire molecule. In addition, it is found that certain shapes are favored, such that for any given protein size the folding process "chooses" the shape with the maximum susceptibility. These results suggest that the proteins native state is critical in the same sense with other slowly built self-organized critical systems, which once posed near the minimum of the energy landscape, preserve their dynamic flexibility.

<sup>1</sup>Supported by Natural Science Foundation of China (Grants 11334004, 11174133, 81421091) and National Basic Research Program of China (Grant 2013CB834100).

**T1.00335 Verwey transition of nano-sized magnetite crystals investigated by  $^{57}\text{Fe}$  NMR**, SUMIN LIM, BAEK SOON CHOI, SOON CHIL LEE, department of physics, KAIST, JAEYOUNG HONG, JISOO LEE, TAEHUN HYEON, Center for Nanoparticle Research, Institute for Basic Science (IBS), Seoul 151-742, Korea, TAEHUN KIM, JAEHONG JEONG, JE-GEUN PARK, Center for Correlated Electron Systems, Institute for Basic Science — It is well known that magnetite crystals undergo a metal-insulator transition at the Verwey transition temperature,  $T_V = 123$  K. In this work, we studied the Verwey transition of nano-sized crystals with  $^{57}\text{Fe}$  NMR. In the metallic state above  $T_V$ , the NMR spectrum shows a single sharp peak, which broadens below  $T_V$  indicating the Verwey transition. We measured the spectra of the nano-crystals with radii of 16 nm, 25 nm, and 40 nm and compared with that of a bulk. The transition temperature obtained from the NMR spectra depends on both the crystal size and crystallinity. When the crystal size decreases from bulk to 16 nm, the transition temperature drops from 123 K to 100 K. The transition temperature of the samples kept dry air decrease due to aging.

**T1.00336  $\text{Cr}^{3+}$  NMR for Multiferroic Chromium spinel  $\text{ZnCr}_2\text{Se}_4$** , SEJUN PARK, Department of Physics, KAIST, SANGIL KWON, Institute for Quantum Computing, University of Waterloo, SOONCHIL LEE, Department of Physics, KAIST, SEUNGHYUN KHIM, DILIP KUMAR BHOI, KEE HOON KIM, CENSCMR, Department of Physics and Astronomy, Seoul National University — Multiferroic systems including  $\text{ZnCr}_2\text{Se}_4$ , the chromium spinel with helical spin structure, have been in huge interest for decades due to its physical variety and applicability. In the temperature range between 21K and 80K, this material shows negative thermal expansion. Due to the bond frustration, the spins of the chromium ions order helically below the transition temperature, 21K, though the exchange constant tends to make a ferro-order. The anomalous  $1^{st}$  order-like magnetic transition is yet clarified and still an interesting topic. To probe microscopic origin of these features, we measured zero-field NMR of  $\text{Cr}^{3+}$  ions having nuclear spin 3/2. Six peaks were observed revealing Nuclear Quadrupole Resonance(NQR) and anisotropic hyperfine field at chromium sites. The NQR spectrum reveals that the structure is highly distorted below the magnetic transition temperature where the normal Jahn-Teller distortion is absent. Temperature dependence of the spectrum is also measured to obtain the magnetization as a function of temperature.

**T1.00337 Topological Analysis, Modeling, and Imaging of Gelatin-Based Hydrogels**, MAHO KOGA, Ward Melville High School, CLEMENT MARMORAT, MIRIAM RAFILOVICH, Stony Brook University, YISHAI TALMON, EYAL ZUSSMAN, ARKADII ARINSTEIN, Technion Institute of Technology — Gelatin is a component of natural biocompatible scaffolds used in tissue engineering constructs. However, due its supra-molecular structure, the mesh size is drastically larger compared to synthetic polymers having the same moduli, and therefore the Rubber Elastic Theory cannot be used to describe properties of gelatin. Gelatin forms distinct fibrils, bundles of triple helix chains, which form rigid areas. We experimented with two different gel moduli, made possible by varying the concentration of microbial transglutaminase (mTG). mTG forms permanent cross links and affects the morphology of the gelatin by changing the number of fibrils formed. Thus, the mesh size calculated from the Rubber Elastic Theory was much smaller than the actual size of the mesh, as measured from cryoscanning electron microscopy images and fluorescent bead particle migration. We also observed the en-mass migration behavior of dermal fibroblast cells as a function of the substrate rheological response. Our results will present the ability of the cells to sense the structure of the underlying substrate, as well as the absolute value of the modulus. Furthermore, the data will be interpreted in terms of a modified theoretical model, which takes into account the structure and mesh size of the gel.

**T1.00338 Charge transport in the organic doped spin-liquid candidate,  $\kappa$ -(ET)<sub>4</sub>Hg<sub>2.89</sub>Br<sub>8</sub>, under Pressure**, YUJI SUZUKI, JUN IBUKA, University of Tokyo, HIROSHI OIKE, RIKEN, KAZUYA MIYAGAWA, University of Tokyo, HIROMI TANIGUCHI, Saitama University, KAZUSHI KANODA, University of Tokyo — The family of layered organic conductors  $\kappa$ -(ET)<sub>2</sub>X plays an important role in the study of Mott physics, which is a major subject in the condensed matter physics. While most  $\kappa$ -(ET)<sub>2</sub>X compounds have half-filled bands and antiferromagnetic nature, the title compound  $\kappa$ -(ET)<sub>4</sub>Hg<sub>2.89</sub>Br<sub>8</sub> ( $\kappa$ -HgBr) is an exceptional doped system which is supposed to be the only doped spin-liquid candidate up to the present. The transport study under controlled pressure, which enables us to investigate this intriguing system with tuning the correlation strengths, revealed that  $\kappa$ -HgBr shows a transition or crossover from a non-Fermi liquid to a Fermi-liquid as pressure increases.<sup>1,2</sup> In the present work, we have carried out the detailed transport measurement under pressure for  $\kappa$ -HgBr with static magnetic fields applied normal to the conducting layers. I will discuss the in-plane and out-of-plane charge transport in normal and superconducting states in this doped spin-liquid candidate with variable electron correlation.

<sup>1</sup>H. Taniguchi *et al.*, J. Phys. Soc. Jpn. **76**, 113709 (2007).

<sup>2</sup>H. Oike *et al.*, Phys. Rev. Lett. **114**, 067002 (2015).

**T1.00339 Analytical Lower and Upper Bounds for the Threshold Surfaces of Quantum Error Correcting Codes**, RYUJI TAKAGI, THEODORE YODER, ISAAC CHUANG, Massachusetts Institute of Technology — If all the physical gates in a fault tolerant code construction have a failure probability below a certain value, the failure probability of the construction approaches zero after many concatenations. This value is called the threshold value of the code and lower bounds for it for various codes have been reported in the literature. However, these approaches do not take into account that the failure probability of each species of logical gate depends on that of many different species of physical gates, and that the distribution of logical failure probability depends on that of many different physical gates. How can we reconcile the interdependency of the failure probabilities of all the various species of gates? Direct simulation would be one of the possible ways to attack this question, but it would be difficult to be done at high concatenation levels because of the exponential growth of simulation time. Here, we deal with this question by instead considering a multidimensional space of the failure probabilities of the physical gates and study the set of points that approach zero error after a large number of concatenations. We present a way to obtain lower and upper bounds for the boundary of this set, what we call the threshold surface, given a particular code and constructions of logical gates. Our method uses only the logical failure probabilities after one concatenation, and moreover the running time of the algorithm scales linearly with respect to concatenation levels. We hope this will establish a reasonable goal for experiments to work towards a scalable quantum computer.

**T1.00340 Measurement of Diffraction Properties of Colloidal Crystals<sup>1</sup>**, NICHOLAS SELAN, MICHAEL BLADES, MIDHUN JOY, JAMES GILCHRIST, SLAVA ROTKIN, Lehigh University — Close-packed, self-assembled arrays of micrometer polystyrene or silica spheres are high quality artificial crystals that generate well-defined diffraction patterns in the visible range. Such crystals are explored as possible substrates for deposition of nanomaterials such as graphene. Quasi-monochromatic visible light diffraction microscopy is used to characterize effective refractive index and crystal structure, specifically grain size, orientation, and lattice parameters. These parameters can be used to monitor deformations of the colloidal crystal lattice during transfer of nanomaterials.

<sup>1</sup>NSF ECCS-1509786, N.S. acknowledges RET supplement to NSF ECCS-1202398

**T1.00341 Nonparametric estimation of quantum states, processes and measurements**, PAVEL LOUGOVSKI, RYAN BENNINK, Oak Ridge National Lab — Quantum state, process, and measurement estimation methods traditionally use parametric models, in which the number and role of relevant parameters is assumed to be known. When such an assumption cannot be justified, a common approach in many disciplines is to fit the experimental data to multiple models with different sets of parameters and utilize an information criterion to select the best fitting model. However, it is not always possible to assume a model with a finite (countable) number of parameters. This typically happens when there are unobserved variables that stem from hidden correlations that can only be unveiled after collecting experimental data. How does one perform quantum characterization in this situation? We present a novel nonparametric method of experimental quantum system characterization based on the Dirichlet Process (DP) that addresses this problem. Using DP as a prior in conjunction with Bayesian estimation methods allows us to increase model complexity (number of parameters) adaptively as the number of experimental observations grows. We illustrate our approach for the one-qubit case and show how a probability density function for an unknown quantum process can be estimated.

**T1.00342 Adsorption and Transport of Methane Molecules through One-Dimensional Channels in Dipeptide-Based Materials**, DANIELE PARADISO, Department of Chemistry, University of Tennessee, Knoxville, TN, United States, ENRICO PERELLI CIPPO, CNR - IFP, Milano, Italy, GIUSEPPE GORINI, Department of Physics, Milano-Bicocca University, Milano, Italy, GIORGIO ROSSI, Department of Physics, Universita' degli Studi di Milano, Milano, Italy, JOHN Z. LARESE, Department of Chemistry, University of Tennessee, Knoxville, TN, United States — The development of new materials for use in energy and environmental applications is of great interest, in particular in the areas of gas separation and carbon capture, where molecular transport plays a significant role. The dipeptides are organic molecules that offer an attractive possibility in such areas, because they form open hexagonal crystalline structures (space group P6<sub>1</sub>) with quasi one-dimensional channels of tunable pore diameters in the range 3-6 Å. These molecular crystals exhibit selective adsorption, as well as, water and gas transport properties: these are believed to result from collective vibrations of the crystal structure that are coupled to the motions of the guest molecules within the channels. Current studies focus on characterizing the system methane and L-Isoleucyl-L-Valine (IV): this was initially done with high-resolution adsorption isotherms; then, high-resolution Inelastic Neutron Scattering measurements at the Spallation Neutron Source (BASIS spectrometer) revealed clear rotational tunneling peaks, offering details to unravel the potential energy surface of the system, as well as, evidences that channels flexibility and dynamical motion of the molecules have influence on the dipeptides adsorption properties.

**T1.00343 Development of Cellulose/PVDF-HFP Composite Membranes for Advanced Battery Separators** , ALEJANDRO CASTILLO, VICTOR AGUBRA, MATAZ ALCOUTLABI, YUANBING MAO, University of Texas Rio Grande Valley — Improvements in battery technology are necessary as Li-ion batteries transition from consumer electronic to vehicular and industrial uses. An important bottleneck in battery efficiency and safety is the quality of the separators, which prevent electric short-circuits between cathode and anode, while allowing an easy flow of ions between them. In this study, cellulose acetate was dissolved in a mixed solvent with poly(vinylpyrrolidone) (PVP), and the mixture was forcespun in a pseudo paper making process to yield nanofibrillated nonwoven mats. The mats were soaked in NaOH/Ethanol to strip PVP and regenerate cellulose from its acetate precursor. The cellulose mats were then dipped in poly(vinylidene fluoride-co-hexafluoropropylene) (PVDF-HFP) to yield the cellulose/PVDF-HFP composite membranes. These membranes were characterized chemically through FTIR spectroscopy and solvent-stability tests, thermally through DSC, physically by stress/strain measurements along with weight-based electrolyte uptake, and electrically by AC-impedance spectroscopy combined with capacitive cycling.

**T1.00344 An Automated, High-Throughput System for GISAXS and GIWAXS measurements of thin films<sup>1</sup>** , ERIC SCHAIBLE, Lawrence Berkeley National Laboratory, JESSICA JIMENEZ, Lawrence Livermore Natl Lab, MATTHEW CHURCH, Matthew Church Engineering and Design, EUNHEE LIM, University of California Santa Barbara, POLITE STEWART, Lawrence Berkeley National Laboratory, ALEXANDER HEXEMER, Lawrence Berkeley National Laboratory — Grazing incidence small-angle X-ray scattering (GISAXS) and grazing incidence wide-angle X-ray scattering (GIWAXS) are important techniques for characterizing thin films. In order to meet rapidly increasing demand, the SAXSWAXS beamline at the Advanced Light Source (beamline 7.3.3) has implemented a fully automated, high-throughput system to conduct SAXS, GISAXS and GIWAXS measurements. An automated robot arm transfers samples from a holding tray to a measurement stage. Intelligent software aligns each sample in turn, and measures each according to user-defined specifications. Users mail in trays of samples on individually barcoded pucks, and can download and view their data remotely. Data will be pipelined to the NERSC supercomputing facility, and will be available to users via a web portal that facilitates highly parallelized analysis.

**T1.00345 Energy storage by droplet/bubble capillary force** , ZHIFENG ZHANG, The Pennsylvania State University, XIAOLONG ZHANG, Washington State University, TONY JUN HUANG, The Pennsylvania State University, XIAOLIN CHEN, Washington State University — In present research, a capillary energy storage device is designed by a channel-expansion chamber structure. In the proposed model, the energy is stored in the form of compressed droplet/ bubble in a smaller channel with the release of energy in the form of capillary driven flow. The power output curve for this device is provided by numerical studies. Trials are also engaged to design a continuous output supply by considering the power output and the viscous loss. This device can potentially be used in both micro- and nano- scale energy storage.

**T1.00346 Imaging ballistic carrier trajectories in graphene using scanning gate microscopy<sup>1</sup>** , ZIWEI DOU, University of Cambridge, SEI MORIKAWA, University of Tokyo, SHU-WEI WANG, CHARLES SMITH, University of Cambridge, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, SATORU MASUBUCHI, TOMOKI MACHIDA, University of Tokyo, MALCOLM CONNOLLY, University of Cambridge — Graphene layers encapsulated by hexagon boron-nitride enable charge carriers to travel ballistically over several microns and provide an opportunity to realise electron optics with Dirac fermions. Scanning gate microscopy is a valuable tool for directly imaging such effects and has recently been applied to investigate coherent scattering in graphene *pnp* junctions [1]. In this work we use SGM to image magnetic focusing of ballistic carriers in a graphene device [2]. By locally varying the carrier concentration and electrostatic potential with the tip we are able to image electrons bouncing from the graphene edges. Moreover, by refocusing misaligned electrons back to collector, our results show how scanning probe tips can be used as mobile lenses for manipulating Dirac fermions in novel device concepts. **T1.00347 NEXT GENERATION GAMMA RAY DIAGNOSTICS FOR THE NATIONAL IGNITION FACILITY** , HANS HERRMANN, Y.H. KIM, A.M. MCEVOY, A.B. ZYLSTRA, C. S. YOUNG, F. E. LOPEZ, J.R. GRIEGO, V. E. FATHERLEY, J. A. OERTEL, H. J. JORGENSON, D. B. BARLOW, Los Alamos National Laboratory, W. STOEFFL, J. A. CHURCH, J.E. HERNANDEZ, A. CARPENTER, Lawrence Livermore National Laboratory, M. S. RUBERY, C. J. HORSFIELD, S. GALES, A. LEATHERLAND, Atomic Weapons Establishment, T. HILSABECK, J.D. KILKENNY, General Atomics, R. M. MALONE, K. MOY, National Security Technologies, J.D. HARES, Kentech Instruments Ltd., J. MILNES, Photek Ltd. — Fusion reaction history and ablator areal density measurements based on gamma ray detection are an essential part of Inertial Confinement Fusion (ICF) experiments on the National Ignition Facility (NIF). Capability improvements are being implemented in sensitivity, temporal and spectral response relative to the existing Gamma Reaction History diagnostic (GRH-6m). The “Super” Gas Cherenkov Detector (GCD) [1] will provide 200x more sensitivity, reduce the effective temporal resolution from 100 to 10 ps, and lower the energy threshold from 2.9 to 1.8 MeV, relative to GRH-6m. The Gamma-to-Electron Magnetic Spectrometer (GEMS) [2] - a Compton spectrometer intended to provide true gamma energy resolution ( $\leq 5\%$ ) for isolation of specific lines such as  $t(d,\gamma)$ ,  $D(n,\gamma)$ ,  $^{12}C(n,\gamma)$  and energetic charged particle nuclear reactions indicative of ablator/fuel mix. [1] H.W. Herrmann, et al., Rev. Sci. Instrum. 85, 11E124 (2014) [2] Y. Kim, et al., Rev. Sci. Instrum. 85, 11E122 (2014)

**T1.00348 Thermodynamic, Modeling and Neutron Investigations of Cycloalkanes Adsorbed on MgO (100) and Graphite Basal Plane** , FATEMA WAHIDA, NICHOLAS STRANGE, JOHN Z. LARESE, Department of Chemistry, University of Tennessee, Knoxville, TN — Understanding the adsorption of molecules on solid surfaces is central to many scientific and technological challenges. Solid surfaces such as metal oxides, carbonaceous archetypes, porous silica, and metal organic frameworks currently represent significant components of nanomaterial research because of their widespread use in optoelectronics, separation chemistry, and catalysis. Understanding the interaction between adsorbed molecules and surfaces is a necessity for developing synthetic methods to produce materials with specific functional properties. An investigation of the effects of molecular and adsorbate symmetry is proposed in this study. The principal aim of this work is to identify the role of surface and molecular symmetry on the physicochemical properties of 2D layers of cyclic molecules adsorbed on metal oxide and semiconductor substrates. Initially our characterization will focus on the thermodynamic and microscopic structure and dynamics of cyclopentane and cyclohexane on the MgO (100) surface and graphite basal plane. In order to realize this goal adsorption isotherms, inelastic neutron scattering (INS) and molecular dynamics (MD) simulation studies will be performed to investigate the structure, dynamics and wetting properties.

**T1.00349 Resistance-Strain Relation On Vanadium Dioxide Thin Films** , ALI AMIRI, PATRICK LECLAIR, University of Alabama, Department of Physics, ARUN GUPTA, University of Alabama, MINT Center — Vanadium dioxide is a strongly correlated material with a sharp metal to insulator transition at  $\sim 341$  K. It is well known that the strain along c-axis can change the transition temperature, but the other effects of the strain have not been drawing much attention. In this work we have studied the effects of the strain on resistance changes in the polycrystalline and epitaxial films. Polycrystalline films of  $VO_2$  are deposited on the  $Pb(Mg_{1/3}Nb_{2/3})_2O_7$  (PMN-PT) using a  $SiO_2$  buffer layer. The strain on film is tuned by applying a bias electric field through the piezoelectric substrate, and the resistance is measured using four-probe method. The epitaxial films of  $VO_2$  are grown on  $TiO_2$  (001) and have been glued to PMN-PT substrate to transfer strain. The change in the resistance of the epitaxial films is measured to be only about 30% more than polycrystalline films for the same amount of strain. We have studied the strain-induced resistance changes as a function of temperature. we have shown that the resistance is more sensitive to strain in the metallic phase.

**T1.00350 Nonlinear Dynamic Model Explains The Solar Dynamic**, MARIA KUMAN, Holistic Research Institute, 1414 Barcelona Dr., Knoxville, TN 37923 — Nonlinear mathematical model in torus representation describes the solar dynamic. Its graphic presentation shows that without perturbing force the orbits of the planets would be circles; only perturbing force could elongate the circular orbits into ellipses. Since the Hubble telescope found that the planetary orbits of other stars in the Milky Way are also ellipses, powerful perturbing force must be present in our galaxy. Such perturbing force is the Sagittarius Dwarf Galaxy with its heavy Black Hole and leftover stars, which we see orbiting around the center of our galaxy. Since observations of NASAs SDO found that magnetic fields rule the solar activity, we can expect when the planets align and their magnetic moments sum up, the already perturbed stars to reverse their magnetic parity (represented graphically as periodic looping through the hole of the torus). We predict that planets aligned on both sides of the Sun, when their magnetic moments sum-up, would induce more flares in the turbulent equatorial zone, which would bulge. When planets align only on one side of the Sun, the strong magnetic gradient of their asymmetric pull would flip the magnetic poles of the Sun. The Sun would elongate pole-to-pole, emit some energy through the poles, and the solar activity would cease. Similar reshaping and emission was observed in stars called magnetars and experimentally observed in super-liquid fast-spinning Helium nanodroplets. We are certain that NASAs SDO will confirm our predictions.

**T1.00351 Reconstructing quantum states from local data**, MILAN HOLZAEPEL, Institut fuer Theoretische Physik, Universitaet Ulm, Germany, MARCUS CRAMER, Institut fuer Theoretische Physik, Leibniz Universitaet Hannover, Germany, NILANJANA DATTA, Statistical Laboratory, Centre for Mathematical Sciences, University of Cambridge, UK, MARTIN PLENIO, Institut fuer Theoretische Physik, Universitaet Ulm, Germany — Quantum spin chains are systems of extreme complexity, in the sense that the number of parameters that fully characterize the state of a quantum spin chain grows exponentially with the number of spins. Yet, physically relevant subsets of all quantum states can be well-approximated by a small number of parameters using well-known methods such as Matrix Product States (MPS). The structure of such states can guarantee reconstruction of the state from the measurement of a small number of simple observables, merely growing linearly with the number of spins. We compare two classes of quantum states which admit efficient reconstruction from incomplete, local information: States which have vanishing conditional mutual information, and the recently introduced class of states with non-decreasing operator Schmidt rank under partial traces which includes generic Matrix Product Operators (MPO). It is well-known that Rényi entropies can be used to characterize the bond dimension of a pure MPS, i.e. the number of parameters required to describe the state. For mixed MPOs, no similar relation is known. Our comparison provides a first relation between the mutual information and the bond dimension of an MPO representation of a mixed state.

**T1.00352 Validation of Capillarity Theory at the Nanometer Scale by Atomistic Computer Simulations of Water Droplets and Bridges in Contact with Hydrophobic and Hydrophilic Surfaces**, NICOLAS GIOVAMBATTISTA, CUNY-Brooklyn Coll, ALEXANDRE ALMEIDA, ADRIANO ALENKAR, Instituto de Física, Universidade de São Paulo, 05508-090, São Paulo, SP, Brazil, SERGEY BULDYREV, Department of Physics, Yeshiva University, 500 West 185th Street, New York, New York 10033, United States — Capillarity is the study of interfaces between two immiscible liquids or between a liquid and a vapor. Capillarity theory (CT) was created in the early 1800s and it is applicable to macroscopic ( $>1\ \mu\text{m}$ ) systems. In general, macroscopic theories are expected to fail at  $<10\ \text{nm}$  scales where molecular details may become relevant. We show that, surprisingly, CT provides satisfactory predictions at  $210\ \text{nm}$  scales. Specifically, we perform atomistic molecular dynamics (MD) simulations of water droplets and capillary bridges of different symmetry in contact with various surfaces. The surfaces correspond to hydroxylated silica, modified to cover a wide range of hydrophobicity/hydrophilicity. In agreement with CT, it is found that (i) water contact angle is independent of the droplet/bridge geometry and depends only on the surface employed; (ii) CT provides the correct droplet/bridge profile for all hydrophobic/hydrophilic surfaces considered; and, remarkably, (iii) CT works even for the very small droplets/bridges studied, for which the smallest dimension is  $\approx 2\ \text{nm}$ . We confirm the self-consistency of CT at  $210\ \text{nm}$  scales by calculating the *capillary forces* between different surfaces induced by capillary bridges; the agreement between MD simulations and CT theory is remarkable.

**T1.00353 A novel cell penetrating peptide carrier for the delivery of nematocidal proteins drug**, JEA HYUN KIM, Korea Minjok Leadership Academy (KMLA) — Nematodes have recently become a primary source of harmful diseases to the environment that inflict harsh damages to pine trees and marine species. However, nematodes cannot be killed by normal pesticides or chemicals due to their thick outer protective layer mainly composed of collagen and cuticles. Thus, a novel approach to trigger intracellular delivery of chemicals through the layers of nematodes is required. In this study, the selection of the novel CPP was carefully progressed through protein database and serial digested fragmentation, internalization of each amino sequence was analyzed through flow cytometry and confocal microscope. As one of the most effective CPP material, JH 1.6 was compared with other major CPPs and its cellular toxicity was investigated. Furthermore, JH 1.6 was attached to various RNA, DNA, and proteins and internalization efficiency was evaluated for mammalian cells. To examine its effects on nematodes in vivo, JH 1.6 was conjugated with nematocidal protein - botulinum neurotoxin (BnT) and treated in *C.elegans* as a model animal. The results showed that JH 1.6 had high relative internalization rate and low cellular toxicity compared to other major CPP such as TAT and GV1001 peptides.

**T1.00354 The Role of Ligand in the Mechanical Properties of Self-Assembled Nanoparticle Films**, SEAN GRIESEMER, James Franck Institute, The University of Chicago, SEAN YOU, Department of Chemistry & Chemical Biology, Harvard University, PONGSAKORN KANJANABOOS, Materials Science and Engineering, Mahidol University, EDWARD BARRY, Center for Nanoscale Materials, Argonne National Laboratory, WEI BU, Center for Advanced Radiation Sources, The University of Chicago, STUART RICE, James Franck Institute, The University of Chicago and Department of Chemistry, The University of Chicago, BINHUA LIN, James Franck Institute, The University of Chicago and Center for Advanced Radiation Sources, The University of Chicago — Self-assembled films of nanoparticles (NP) capped with ligands at the air/water interface exhibit rich mechanical responses to compression including hashing, wrinkling, and folding, which are the combined result of particle- and ligand-based interactions. Previous studies have shown that a high concentration of ligands inhibits wrinkling and folding, but the mechanism remains elusive. By using inductively coupled plasma optical emission spectrometry (ICP-OES) to measure the ligand concentration of our NP solutions and then back-adding excess ligands at controlled amounts, we precisely control ligand-based interactions, enabling an investigation of how these interactions guide self-assembly and correspondingly on mechanical properties. Our experiments reveal that increasing the ligand concentration of the films causes the formation of free-ligand islands in addition to an increase in the interparticle separation. These effects are correlated with the previously observed inhibition of wrinkling and folding, as well as a decrease in the dilatational and shear moduli. This work was supported by the University of Chicago Materials Research Science and Engineering Center, NSF-DMR-1420709.

**T1.00355 Interleukin 18 secretion and its effect in improving Chimeric Antigen Receptors efficiency<sup>1</sup>**, JAE-KUN KIM, Fort Lee HS, New Jersey — Clinical trials have shown that chimeric antigen receptor T cells modified to target cancer cells expressing a surface antigen found on immature B-cells. The purpose of this experiment is to take a pro-inflammatory cytokine, and analyze its effect in improving the efficiency of the T cells. IL-18 has been previously shown to recruit T cells to the tumor site and improve their secretion of cytotoxic cytokines. A human model of the proposed armored T cell has been created and has shown success in combating cancer cells in vitro. The next step is to design and produce a murine model to test in vivo in immunocompetent mice. This research project aimed to create two models: one utilizing 2A peptides and another utilizing IRES elements as a multicistronic vector. Both models would require the insertion of the desired genes into SFG backbones. IRES, a DNA element which acts as a binding site for the transcriptional machinery to recognize which part of the DNA to transcribe, commonly found in bicistronic vectors, is large with 500-600 base pairs, and has a lower transgene expression rate. P2A is smaller, only consisting of about 20 amino acids, and typically has a higher transgene expression rate, which may or may not result in higher effectiveness of the model.

<sup>1</sup>I would like to thank Dr. Renier Brentjens for being a mentor who cared about giving his interns as much educational value as possible.

**T1.00356 Towards Producing Black Nobel Laureates Affiliated with "African Universities"** , JUDE KENNETH, African Univ — While Africa has produced a handful Nobel laureate in literature and peace, it has continued to shy away from producing any in the other categories. The reason is not farfetched; our university system is not up to standard. It is saddening that in this century, African countries place emphasis on certificates and not on knowledge. This has made the continent produce students that lack the intellectual capability, experimental ability, fundamental training, creativity, and motivation to excel except they get a foreign training. It is this backdrop that precipitated the research into the methods of teaching and research in universities across Africa. The study is designed to identify the problems and proffer solution to them. Two important questions immediately come to mind. (1) What factors account for the difficulty in producing Nobel laureates affiliated with African universities? (2) What strategies could be adopted to improve teaching and research in African universities? Several factors were investigated which revolve around funding, the competence of the lecturers, quality of students admitted, attitude of the students, parents and government. Nigerian universities were investigated and important deductions were made. During the study an inquiry was made on the method of instruction at various universities, from result obtained, the study therefore concluded that adequate funding, the presence of erudite scholars and brilliant minds will produce future Nobel laureate affiliated with the continent. The study therefore recommended admission and employment of only students and lecturers who have got a thing for academics into the universities and adequate funding of universities and research centres.

**T1.00357 Applied research for quantitative analysis of fluorescent whitening agent in emulsion paint** , LIN ZHANG, Hohai University — Fluorescent whitening agents (FWAS) are widely used in the emulsion paint for brightening effect. In spite of extensive use of FWAS, there are no reports about the measurement method of FWAS in emulsion paint. In this work, a very simple quantitative approach is proposed. Based on the digital grayscale images of three-dimensional fluorescence spectra and two-dimensional fluorescence images, several wavelet moment invariants are calculated and used to establish the standard models for the quantitative analysis. The influence factors of storage time and exposure time are also studied here. Measurement results indicated the feasibility and precision of using this method for quantitative analysis of FWAS. The research results also provides a reliable basis for the application of FWAS in emulsion paint. Keywords: fluorescent whitening agents, three-dimensional fluorescence spectra, fluorescence image, wavelet moment invariants

**T1.00358 Weyl semimetal generated from Dirac semimetal using off-resonance light** , JIE CAO, Hohai University — We propose a simple realization of a three-dimensional (3D) Weyl semimetal phase using off-resonance circularly polarized light in a 3D Dirac semimetal with mirror symmetry. We show that a fourfold degeneracy Dirac node can be further evolved into two Weyl nodes in the context of our simplified model using both analytical and numerical methods. Observable properties of Weyl semimetal such as surface Fermi arc can be realized since the distance of the two Weyl points in momentum space is proportional to the Fermi velocity. We also use the axionic field theory to discuss the realistic case and find similar conclusion.

**T1.00359 Investigation of Local Structure and Cation Ordering in Dielectric Oxide Microwave Ceramics with stoichiometry  $A(Li_x(Nb,Ta)_y)O_3$  Using  $^7Li$  and  $^{93}Nb$  solid-state NMR spectroscopy.** , RONY KALFARISI, NMR Spectroscopy Group, Physics Department, College of William and Mary — The local structure and cation ordering in dielectric oxide microwave ceramics with stoichiometry  $A(Li_x(Nb,Ta)_y)O_3$  are investigated using  $^7Li$  and  $^{93}Nb$  solid-state NMR spectroscopy. For all samples,  $^7Li$  MAS NMR spectra show one strong and sharp resonance peak indicating one unique environment which corresponds to local lithium environment of nearest B-site neighbor (nBn) surrounded by 4  $LiO_6$  octahedra and 2  $NbO_6$  octahedra ( $TaO_6$  in some samples). In addition to this,  $^7Li$  MAS NMR spectrum of  $(Ca_{2/3}La_{1/3})(Li_{1/3}Nb_{2/3})O_3$  show one additional weak and broad resonance peak which can be assigned to nBn of 3  $LiO_6$  octahedra and 3  $NbO_6$  octahedra.  $^{93}Nb$  MAS NMR spectra of samples with niobium content, show a resonance peak with tail toward the low frequency limit, an evidence to the existence of chemical shifts and quadrupole couplings distributions. Both  $(Sr_{2/3}La_{1/3})(Li_{1/3}Nb_{2/3})O_3$  and  $Ca(Li_{1/4}Nb_{3/4})O_3$  spectra show one broad resonance peak, which can be interpreted as one  $NbO_6$  octahedron nBn with many slight variations through out the sample. While  $(Ca_{2/3}La_{1/3})(Li_{1/3}Nb_{2/3})O_3$  spectra show four peaks correspond to four distinct  $NbO_6$  octahedra local nBn environments with the nBn configuration as: (i) 3  $LiO_6$  and 3  $NbO_6$ ; (ii) 2  $LiO_6$  and 4  $NbO_6$ ; (iii) 1  $LiO_6$  and 5  $NbO_6$ ; (iv) all 6  $NbO_6$

**T1.00360 3D cancer cell migration in a confined matrix** , AMANI ALOBAIDI<sup>1</sup>, BO SUN<sup>2</sup>, Oregon State Univ — Cancer cell migration is widely studied in 2D motion, which does not mimic the invasion processes in vivo. More recently, 3D cell migration studies have been performed. The ability of cancer cells to migrate within the extracellular matrix depends on the physical and biochemical features of the extracellular matrix. We present a model of cell motility in confined matrix geometry. The aim of the study is to study cancer migration in collagen matrix, as a soft tissue, to investigate their motility within the confined and surrounding collagen environment. Different collagen concentrations have been used to show the ability of these cancer cells to move through such a complex structure by measuring Cancer cell migration velocity as well as the displacement.

**T1.00361 Blackhole formula and example relativity** , PHILIP SHIN<sup>1</sup>, None — Black hole formula 1) Second dimension (x,y)  $f(x)=y$  Energy  $E=m*c^2$  2) Thirddimension(x,y,z) really  $x = y = z$  Blackhole formula  $Root(c^2) = c = Root(E/m)$  As mass go the velocity of light, mass become black holes so there are energy as multiply by mass. Example relativity When  $E = m * c^2$  1)  $Root(c^2) = c = Root(E/m)$  2)  $3*c*Root(c^2) = 3*c*Root(E/m) = 3*c^2$  From 1) to 2) as an example, As velocity is faster, mass increased. It means when velocity is increased, sec(t)

<sup>1</sup>The number is good to study physics.

**T1.00362 ABSTRACT WITHDRAWN —**

**T1.00363 Epitaxial growth of Cu films on Ag(111) characterized on monitoring the evolution of their surface states** , DAH-AN LUH, CHIH-HAO HUANG, Department of Physics, National Central University, CHENG-MAW CHENG, KU-DING TSUEI, National Synchrotron Radiation Research Center — The growth of Cu on Ag(111) attracts interest because of its unusual growth behavior. Previous STM work indicated that, when Cu was deposited on Ag(111) at room temperature, Cu islands formed with a Cu coverage as small as 0.02 ML. However, a (99) reconstruction was observed on the surface of these Cu islands, suggesting that the surface of the Cu islands on Ag(111) might be covered with one atomic layer of Ag. The suggestion was not verified because the STM lacked the capability to discern various chemical species. To address the issue, we characterized the growth of Cu films on Ag(111) with a novel approach based on ARPES. On monitoring the evolution of the surface states, we showed that the surface of the Cu islands on Ag(111) with the (99) reconstruction was indeed covered with Ag. Our results also showed that the mobility of Ag on Cu(111) greatly depends on temperature. Ag does not migrate on the surface of the Cu islands at a low temperature, but does at 300 K and significantly at 380 K. In addition, the migration of Ag on Cu is associated with the existence of the Ag(111) surface; Ag atoms migrate to the Cu(111) surface not through the Cu film but along the walls of the holes in the Cu films that penetrate deeply into the Ag substrate.

**T1.00364 Studying the Enhanced Ductility of Bimodal Nanocrystalline Copper Using a Coarse-Grained Model** , GUO-JIE JASON GAO, Natl Taiwan Univ, YUN-JIANG WANG, Chinese Academy of Sciences, SHIGENOBU OGATA, Osaka University — Viewing a bimodal configuration of nanocrystalline copper as composed of soft grains containing stiff cores, we proposed a coarse-grained model with systematically tunable stiffness of grains to study the enhanced ductility of bimodal nanocrystalline copper [Y. Wang, M. Chen, F. Zhou, and E. Ma, Nature 419 (2002) 912]. Using molecular dynamics simulations, we shear our model quasistatically. Our results not only qualitatively confirms that a bimodal configuration could behave more ductile than a monomodal one but also predicts there exists a range of ratio of soft/stiff domains that best minimizes shear localization. Moreover, our model indicates that a bimodal configuration could sometimes exacerbate shear localization and therefore jeopardize ductility if the ratio of soft/stiff domains is not properly chosen. This may explain why some experimental results are hard to be reproduced.

**T1.00365 Biocompatible Ferromagnetic Cr-Trihalide Monolayers** , QIANG SUN, Peking University — Cr with an electronic configuration of  $3d^5 4s^1$  possesses the largest atomic magnetic moment ( $6\mu_B$ ) of all elements in the 3d transition metal series. Furthermore, the trivalent chromium ( $Cr^{3+}$ ) is biocompatible and is widely found in food and supplements. Here using first principles calculations combined with Monte Carlo simulations based on Ising model, we systematically study a class of 2D ferromagnetic monolayers  $CrX_3$  ( $X = Cl, Br, I$ ). The feasibility of exfoliation from their layered bulk phase is confirmed by the small cleavage energy and high in-plane stiffness. Spin-polarized calculations, combined with self-consistently determined Hubbard  $U$  that accounts for strong correlation energy, demonstrate that  $CrX_3$  ( $X=Cl, Br, I$ ) monolayers are ferromagnetic and Cr is trivalent and carries a magnetic moment of  $3\mu_B$ , the resulting  $Cr^{3+}$  ions are biocompatible. The corresponding Curie temperatures for  $CrCl_3$ ,  $CrBr_3$ ,  $CrI_3$  are found to be 66, 86, and 107 K, respectively, which can be increased to 323, 314, 293 K by hole doping. The biocompatibility and ferromagnetism render these Cr-containing trichalcogenide monolayers unique for applications.

**T1.00366 Spectral Gauss quadrature method with subspace interpolation for Kohn-Sham Density functional theory** , XIN WANG, US Army Rsch Lab - Aberdeen — Algorithms with linear-scaling ( $\mathcal{O}(N)$ ) computational complexity for Kohn-Sham density functional theory (K-S DFT) is crucial for studying molecular systems beyond thousands of atoms. Of the  $\mathcal{O}(N)$  methods that use a polynomial-based approximation of the density matrix, the linear-scaling spectral Gauss quadrature (LSSGQ) method (Suryanarayana *et al.*, JPMPS, 2013) has been shown to exhibit the fastest convergence. The LSSGQ method requires a Lanczos procedure at every node in a real-space mesh, leading to a large computational pre-factor. We propose a new interpolation scheme specific to the LSSGQ method that lift the need to perform a Lanczos procedure at every node in the real-mesh. This interpolation will be referred to as subspace interpolation. The key idea behind subspace interpolation is that there is a large overlap in the Krylov-subspaces produced by the Lanczos procedures of nodes that are close in real-space. The subspace interpolation scheme takes advantage of the block-Lanczos procedure to group the Krylov-subspaces from a few representative nodes to approximate the density matrix over a large collection of nodes. Subspace interpolation outperforms cubic-spline interpolation by several orders of magnitude.

**T1.00367 Quantum Monte Carlo with known sign structures** , JOHAN NILSSON, Uppsala University — We investigate the merits of different Hubbard-Stratonovich transformations (including fermionic ones) for the description of interacting fermion systems, focusing on the single band Hubbard model as a model system. In particular we revisit an old proposal of Batrouni and Forcrand (PRB 48, 589 1993) for determinant quantum Monte Carlo simulations, in which the signs of all configurations is known beforehand. We will discuss different ways that this knowledge can be used to make more accurate predictions and simulations.

I have another submission in the same category:

MAR16-2015-004583

**T1.00368 High-temperature transport properties of a two-dimensional material** Santa Cruz, EDWARD PEREPELITSKY, University, JERNEJ MRAVLJE, Jozsef Attila University, Hungary — We study the frequency and momentum dependence of the single-particle scattering rate and its consequence of this is a resistivity with a non-monotonic temperature dependence. We are able to calculate the first few moments of the scattering rate in arbitrary dimensions. Further in the case of two dimensions we find a relation between these moments and those of the optical conductivity  $\sigma(\omega) = \lim_{k \rightarrow 0} \text{Im} \chi(k, \omega)$ .

<sup>1</sup>The work at UCSC was supported by the National Science Foundation Grant DMR-06ER46319.

I request that these be sequentially placed in the same session.

**T1.00369 Anharmonicity alters the stability of  $Fe_7C_3$  at the conditions of the Earth's core** , ZAMAAN RAZA, NINA SHULUMBA, OLLE HELLMAN, Linköping Univ - Linköping, LEONID DUBROVINSKY, Universitat Bayreuth - Bayreuth, IGOR ABRIKOSOV, Linköping Univ - Linköping — Recently, a new orthorhombic phase of iron carbide ( $Fe_7C_3$ ) with an unusually high Poisson's ratio was discovered experimentally, raising the possibility that it may be important at the Earth's core. However, calculations of the Gibbs free energy in the quasiharmonic approximation suggested that it would be metastable with respect to the well known hexagonal phase at the pressure and temperature of the Earth's core. We present new anharmonic calculations of the Gibbs free energy using the temperature-dependent effective potential (TDEP) method, which suggest that the orthorhombic phase is more stable at the conditions of the Earth's core. Anharmonicity is shown to be important at relatively low temperatures, and has a decisive effect on the phase diagram. Moreover, we show that  $Fe_7C_3$  decomposes to form  $Fe_2C$  and  $Fe_3C$  over a narrow region of the phase diagram between the orthorhombic and hexagonal phases.

**T1.00370 Role of Nanostructure Coating Quality in Delay of Surface Flooding during Jumping Droplet Condensation**, DANIEL J PRESTON, DION ANTAO, MIT, NENAD MILJKOVIC, UIUC, BANAFSHEH BARABADI, JOHN QUEENEY, EVELYN WANG, MIT — Vapor condensation is commonly observed in everyday life and routinely used in industry as an effective means of transferring heat. In industrial systems, condensed vapor typically forms a thin liquid film which is not desired due to the large thermal resistance to heat transfer; however, if the condensing surface is functionalized with a hydrophobic coating, the condensate forms discrete liquid droplets which shed at sizes approaching the capillary length and refresh the surface for re-nucleation, resulting in a 5–7x heat transfer improvement. Furthermore, when a micro- or nanostructured surface is functionalized, a superhydrophobic surface can be created on which small ( $\approx 10$ – $100$   $\mu\text{m}$ ) droplets coalesce and can spontaneously jump away from the surface due to release of excess surface energy; this jumping droplet mode of condensation has been shown to increase heat transfer by an additional 30 – 40%. However, at elevated supersaturations, nanostructured superhydrophobic surfaces can become flooded with condensate and form pinned droplets which cannot jump, thereby eliminating the desired heat transfer improvement. In this work, we experimentally demonstrated a delay in the supersaturation at which surface flooding occurs by reducing the hydrophobic coating defect density. This resulted in a lower proportion of structure unit cells occupied by condensate, which allowed higher droplet mobility and jumping at elevated supersaturation.

**T1.00371 Analysis of Adsorbed Natural Gas Tank Technology**, ERNEST KNIGHT, CONRAD SCHULTZ, TYLER RASH, ELMAR DOHNKE, DAVID STALLA, ANDREW GILLESPIE, MARK SWEANY, FLORIAN SEYDEL, PETER PFEIFER, Univ of Missouri - Columbia — With gasoline being an ever decreasing finite resource and with the desire to reduce humanity's carbon footprint, there has been an increasing focus on innovation of alternative fuel sources. Natural gas burns cleaner, is more abundant, and conforms to modern engines. However, storing compressed natural gas (CNG) requires large, heavy gas cylinders, which limits space and fuel efficiency. Adsorbed natural gas (ANG) technology allows for much greater fuel storage capacity and the ability to store the gas at a much lower pressure. Thus, ANG tanks are much more flexible in terms of their size, shape, and weight. Our ANG tank employs monolithic nanoporous activated carbon as its adsorbent material. Several different configurations of this Flat Panel Tank Assembly (FPTA) along with a Fuel Extraction System (FES) were examined to compare with the mass flow rate demands of an engine.

**T1.00372 Development of facile property calculation model for adsorption chillers based on equilibrium adsorption cycle.**, MASATO YANO, KENJI HIROSE, MINORU YOSHIKAWA, NEC smart energy lablatory, THERMAL MANAGEMENT TECHNOLOGY TEAM — Facile property calculation model for adsorption chillers was developed based on equilibrium adsorption cycles. Adsorption chillers are one of promising systems that can use heat energy efficiently because adsorption chillers can generate cooling energy using relatively low temperature heat energy. Properties of adsorption chillers are determined by heat source temperatures, adsorption/desorption properties of adsorbent, and kinetics such as heat transfer rate and adsorption/desorption rate etc. In our model, dependence of adsorption chiller properties on heat source temperatures was represented using approximated equilibrium adsorption cycles instead of solving conventional time-dependent differential equations for temperature changes. In addition to equilibrium cycle calculations, we calculated time constants for temperature changes as functions of heat source temperatures, which represent differences between equilibrium cycles and real cycles that stemmed from kinetic adsorption processes. We found that the present approximated equilibrium model could calculate properties of adsorption chillers (driving energies, cooling energies, and COP etc.) under various driving conditions quickly and accurately within average errors of 6% compared to experimental data.

**T1.00373 A learner's multiple views of the connection between mathematics and quantum mechanics**, VESAL DINI, DAVID HAMMER, Tufts Univ — Students' physical intuitions and prior knowledge are critical to making sense of and solving problems in classical mechanics. In quantum mechanics (qm), coordinating concepts connected to such everyday thinking becomes more difficult. How then can students develop coherence in their knowledge of qm? Consider how experts do it: they build meaning in, around, and through the mathematics of the theory. This view on the role of mathematics, which is one of among many possible to take, seems most productive for qm. In our work to characterize student views of knowledge that emerge in the context of qm coursework, we came to analyze one student who mostly adopted such a view until a shift in context moved him to express an alternative. We present his case and discuss important implications for instruction.

**Thursday, March 17, 2016 2:30PM - 5:30PM –**  
**Session V1 DCMP DMP: Non-Equilibrium Aspects of Electron-Boson Coupling in High Temperature Superconductors** Ballroom I - Zhi-Xun Shen, Stanford University

**2:30PM V1.00001 Understanding electron-boson coupling in high temperature superconductors using time-resolved photoemission.**, SHUOLONG YANG, Stanford University — Time- and angle-resolved photoelectron spectroscopy (trARPES) is a powerful technique for studying non-equilibrium properties of high temperature superconductors. The access to electronic band structure upon optical excitation enables a detailed investigation of the temporal evolution of photo-excited carriers. With strong optical excitations changing electronic properties non-adiabatically, coherent phonon modes can also be launched and detected. We employed trARPES to study both the copper- and iron-based high temperature superconductors. In optimally doped Bi<sub>2</sub>212, we find that the trARPES-derived population lifetimes deviate from the ARPES-derived single-particle lifetimes by one to two orders of magnitude [1]. This disparity can only be understood if processes beyond electron-phonon interactions play a significant role in the electron dynamics. In FeSe/SrTiO<sub>3</sub> systems, we observe an abrupt phonon frequency renormalization in the monolayer FeSe as compared to thicker films [2]. This result sets the basis to quantitatively understand the interfacial lattice strain. Combining the collective response of the electronic bands with information about the underlying coherent lattice motion measured by time-resolved X-ray diffraction, we develop a fundamental understanding of the electron-phonon coupling in FeSe [3]. These examples demonstrate some remarkable microscopic insights on electronic and phononic properties which can only be accessed by trARPES. [1] S.-L. Yang et al. Phys. Rev. Lett. 114, 247001 (2015) [2] S.-L. Yang et al. Nano Lett. 15, 4150 (2015) [3] S. Gerber et al. in preparation (2015)

**3:06PM V1.00002 Femtosecond snapshots of the electron-boson coupling in copper oxides and other correlated materials**, CLAUDIO GIANNETTI, Università Cattolica del Sacro Cuore — One of the pivotal questions in the physics of unconventional superconductors is whether the low-energy dynamics of the charge carriers is mediated by bosons with a characteristic timescale. This issue has remained elusive as electronic correlations are expected to greatly accelerate the electron–boson scattering processes, confining them to the very femtosecond timescale. Recent advances in ultrafast spectroscopy allowed us to simultaneously push the time resolution and frequency range of transient reflectivity measurements, up to the point of direct observing the effective electron–boson interaction in doped copper oxides. The extremely fast timescale ( $\sim 15$  fs) is in agreement with numerical calculations based on the  $t - J$  model and the repulsive Hubbard model, in which the relaxation of the photo-excited charges is achieved via inelastic scattering with short-range antiferromagnetic excitations with an energy spectrum extending up to  $\sim 300$  meV. Our results support a scenario in which the strong local magnetic correlations provide a dissipative channel that is effective on the 10 fs timescale. Secondly, we will present very recent results on the model system Na<sub>2</sub>IrO<sub>3</sub>, in which the interplay of the spin-orbit coupling, the onsite Coulomb repulsion and the hopping within the Ir hexagons gives rise to a complex magnetic ground state, characterized by strong antiferromagnetic correlations below 100 K and the emergence of a zig-zag magnetic phase at T=12 K. The energy exchange between the photoexcited charge carriers and the antiferromagnetic background is observed by monitoring a specific high-energy quasi-molecular orbital, which turns out to be sensitive to the magnetization of the system.

### 3:42PM V1.00003 Signatures of electron-boson coupling in the time domain: beyond the equilibrium interpretation

ALEXANDER KEMPER, North Carolina State University — A powerful method to study the interactions between electrons and bosons in high- $T_c$  superconductors is the measurement of the single-particle spectral function. The recent development of time-resolved ARPES (tr-ARPES) has allowed this measurement to be performed out of equilibrium, where the material is driven by an ultrafast laser pump pulse. We have developed a theoretical framework to complement to these experiments, and here we report on several aspects of electron-boson coupling out of equilibrium. First, we will illustrate how time-resolved spectroscopy can be used to study the coupling between electrons and phonons observing the decay rate of the transient signals as a function of energy, momentum, and time. A sufficiently strongly coupled phonon will exhibit a signature in the tr-ARPES spectra as both a kink in the dispersion as well as a sharp change of the decay rates, and we will discuss how these effects appear out of equilibrium. [1][2] Second, we will focus on the return to equilibrium in systems with multiple interaction types, and show that there are two distinct types of scattering processes: those types of interactions that conserve the energy within a subsystem, and those that do not. While in equilibrium these two contribute equally to the linewidth, we will show that out of equilibrium they behave differently – the first type are mainly responsible for thermalization within the electronic subsystem, whereas the second type drain the energy out. As a result, the scattering rates out of equilibrium can be vastly different from the linewidth, and the features of the second type of interactions can be clearly observed.[3][4]

### 4:18PM V1.00004 Time-resolved study of Higgs mode in superconductors<sup>1</sup>

RYO SHIMANO, Cryogenic Research Center and Department of Physics, The University of Tokyo — The behavior of superconductors far from equilibrium has been intensively studied over decades. Goals of these studies are the elucidation of bosonic fluctuations essential for the pairing mechanisms, the manifestation of competing orders or hidden phases, and the optical manipulation of superconductivity. The study of collective modes is crucially important for these perspectives as it provides the information on the dynamics of order parameters in non-equilibrium states. Generally, collective modes in ordered phases associated with spontaneous symmetry breaking are classified into 1) gapless phase modes and 2) gapped amplitude modes. In superconductors, the phase mode is eaten by gauge field, according to the Anderson-Higgs mechanism. The remaining amplitude mode is recently termed as Higgs mode from its analogy to the Higgs boson in particle physics. Despite its long history of investigation, unambiguous observation of Higgs mode has remained elusive. This is because the Higgs mode does not have a charge nor electric dipole and therefore it does not couple directly to the electromagnetic field. Here we report on our recent observation of Higgs mode in s-wave superconductors by using THz-pump and THz-probe spectroscopy technique. After nonadiabatic excitation near the superconducting gap energy with monocycle THz pulses, Higgs mode was observed as oscillations in the transmission of THz probe pulse. The resonant nonlinear coupling between the Higgs mode and coherent radiation field was also discovered, resulting in an efficient third order harmonic generation of the incident THz radiation. The extension of experiments to multiband superconductors and unconventional superconductors will be discussed.

<sup>1</sup>Time-resolved study of Higgs mode in superconductors

### 4:54PM V1.00005 Optical probes of symmetry breaking in magnetic and superconducting

$\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ <sup>1</sup>, JOSEPH ORENSTEIN, UC Berkeley/LBNL — The discovery of iron pnictide superconductors has opened promising new directions in the effort to fully understand the phenomenon of high- $T_c$ , with a focus on the connections between superconductivity, magnetism, and electronic nematicity. The  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$  (P:Ba122) system in particular has received attention because isovalent substitution of As for P generates less disorder than doping on the Fe site. The phase diagram of P:Ba122 is characterized by a line of simultaneous antiferromagnetic (AF) and tetragonal-to-orthorhombic transitions,  $T_s(x)$ , that penetrates the superconducting dome at  $x=0.28$ , just below optimal doping ( $x_{opt}=0.30$ ). In this work, we use spatially-resolved optical polarimetry and photomodulated reflectance to detect linear birefringence and therefore breaking of 4-fold rotational ( $C_4$ ) symmetry. In underdoped ( $x<0.28$ ) samples, birefringence appears at  $T>T_s$  and grows continuously with decreasing  $T$ . The birefringence is unidirectional in a large ( $300\text{ }\mu\text{m} \times 300\text{ }\mu\text{m}$ ) field of view, suggesting that  $C_4$  breaking in this range of  $T$  is caused by residual strain that couples to a diverging nematic susceptibility. Birefringence maps just below  $T_s(x)$  show the appearance of domains, indicating the onset of spontaneous symmetry breaking to an AF ground state. Surprisingly, in samples with  $x>0.28$ , in which the low  $T$  phase is superconducting/ tetragonal rather than AF/orthorhombic,  $C_4$  breaking is observed as well, with an abrupt onset and domain formation at 55 K. We tentatively associate these features with a transition to an AF phase induced by residual strain, as previously proposed [H.-H. Kuo et al. Phys. Rev. B86, 134507 (2012)] to account for structure in resistivity vs.  $T$ . Time-resolved photomodulation allow us to follow the amplitude of the AF order with time following pulsed photoexcitation. Below  $T_c$  the AF order at first weakens, but then strengthens in response to the photoinduced weakening of superconductivity. This complex time evolution is accounted for quantitatively by a model based on the coexistence and competition of AF and superconducting order.

Session V2 DCMP GSOFT: Liquid Droplets: From Surface Topology to Active Motion Ballroom II - Paul Chakin, New York University

### 2:30PM V2.00001 Vapour-mediated sensing and active motion in two-component droplets

MANU PRAKASH, Department of Bioengineering, Stanford University, USA — No abstract available.

### 3:06PM V2.00002 Toroidal Nematics

ALBERTO FERNANDEZ-NIEVES, Physics. Georgia Tech — We will discuss how nematic liquid crystals organize inside toroidal droplets. When the director is parallel to the bounding surface, we find spontaneous reflection symmetry breaking, which we attribute to the role played by saddle-splay contributions to the Frank free energy. When the director is perpendicular to the bounding surface, we find that the structure is reminiscent of the escape radial configuration seen in cylinders, but with a central doubly-twisted organization, which we attribute to the geometry of the torus. We will end by presenting recent experiments with active nematics on the toroidal surface. In this case, topology and activity both affect the structure and dynamics of the material.

**3:42PM V2.00003 Active Mesogenic Droplets: Impact of Liquid Crystallinity and Collective Behavior<sup>1</sup>**, CHRISTIAN BAHR<sup>2</sup>, Max Planck Institute for Dynamics and Self-Organization (MPIDS), Göttingen, Germany — Droplets of common mesogenic compounds show a self-propelled motion when immersed in aqueous solutions containing ionic surfactants at concentrations well above the critical micelle concentration. After introducing some general properties of this type of artificial microswimmer, we focus on two topics: the influence of liquid crystallinity on the swimming behavior and the collective behavior of ensembles of a larger number of droplets. The mesogenic properties are not essential for the basic mechanism of self-propulsion, nevertheless they considerably influence the swimming behavior of the droplets. For instance, the shape of the trajectories strongly depends on whether the droplets are in the nematic or isotropic state. The droplet swimmers are also ideally suited for the study of collective behavior: Microfluidics enables the generation of large numbers of identical swimmers and we can tune their buoyancy. We report on the collective behavior in three-dimensional environments.

**4:18PM V2.00004 Dynamically Reconfigurable Complex Emulsions via Tunable Interfacial Tensions**, TIMOTHY SWAGER, Department of Chemistry, Massachusetts Institute of Technology — This lecture will focus on the design of systems wherein a reconfiguration of the materials can be triggered chemically or mechanically. The utility of these methods is to generate transduction mechanisms by which chemical and biological sensors can be developed. Three different types of systems will be discussed. (1) Particles wherein a protease enzyme releases strain in the particle by breaking crosslinks. (2) Assemblies of polymers at air water interfaces and the demonstration of a luminescence strain response upon compression. (3) Dynamic colloids produced from immiscible fluorocarbon/hydrocarbon mixtures and ability to convert the core and shell layers of the particles as well as the conversion to Janus particles. The latter systems morphology changes can be triggered chemically or optically.

**4:54PM V2.00005 How faceted liquid droplets grow tails: from surface topology to active motion<sup>1</sup>**, ELI SLOUTSKIN, Physics Department and Institute of Nanotechnology & Advanced Materials, Bar-Ilan University — Among all possible shapes of a volume  $V$ , a sphere has the smallest surface area  $A$ . Therefore, liquid droplets are spherical, minimizing their interfacial energy  $\gamma A$  for a given interfacial tension  $\gamma > 0$ . This talk will demonstrate that liquid oil (alkane) droplets in water, stabilized by a common surfactant can be temperature-tuned to adopt icosahedral and other faceted shapes, above the bulk melting temperature of the oil. Although emulsions have been studied for centuries no faceted liquid droplets have ever been reported. The formation of an icosahedral shape is attributed to the interplay between  $\gamma$  and the elastic properties of the interfacial monomolecular layer, which crystallizes here 10-15K above bulk melting, leaving the droplet's bulk liquid. The icosahedral symmetry is dictated by twelve five-fold topological defects, forming within the hexagonally-packed interfacial crystalline monolayer. Moreover, we demonstrate that upon further cooling this 'interfacial freezing effect makes  $\gamma$  transiently switch its sign, leading to a spontaneous splitting of droplets and an active growth of their surface area, reminiscent of the classical spontaneous emulsification, yet driven by completely different physics. The observed phenomena allow deeper insights to be gained into the fundamentals of molecular elasticity and open new vistas for a wide range of novel nanotechnological applications, from self-assembly of complex shapes to new delivery strategies in bio-medicine.

Session V3 GSNP: Complex Network Dynamics Ballroom III - Adilson Motter, Northwestern University

**2:30PM V3.00001 Cascading Failures and Recovery in Networks of Networks<sup>1</sup>**, SHLOMO HAVLIN, Bar Ilan University — Network science have been focused on the properties of a single isolated network that does not interact or depends on other networks. In reality, many real-networks, such as power grids, transportation and communication infrastructures interact and depend on other networks. I will present a framework for studying the vulnerability and the recovery of networks of interdependent networks. In interdependent networks, when nodes in one network fail, they cause dependent nodes in other networks to also fail. This is also the case when some nodes like certain locations play a role in two networks—multiplex. This may happen recursively and can lead to a cascade of failures and to a sudden fragmentation of the system. I will present analytical solutions for the critical threshold and the giant component of a network of  $n$  interdependent networks. I will show, that the general theory has many novel features that are not present in the classical network theory. When recovery of components is possible global spontaneous recovery of the networks and hysteresis phenomena occur and the theory suggests an optimal repairing strategy of system of systems. I will also show that interdependent networks embedded in space are significantly more vulnerable compared to non embedded networks. In particular, small localized attacks may lead to cascading failures and catastrophic consequences. Thus, analyzing data of real network of networks is highly required to understand the system vulnerability. References: [1] S. Buldyrev, R. Parshani, G. Paul, H.E. Stanley, S. **3:06PM V3.00002 The Life-Changing Magic of Nonlinearity in Network Control**, SEAN CORNELIUS, Northeastern University, Center for Complex Network Research — The proper functioning and reliability of many man-made and natural systems is fundamentally tied to our ability to control them. Indeed, applications as diverse as ecosystem management, emergency response and cell reprogramming all, at their heart, require us to drive a system to—or keep it in—a desired state. This process is complicated by the nonlinear dynamics inherent to most real systems, which has traditionally been viewed as the principle obstacle to their control. In this talk, I will discuss two ways in which nonlinearity turns this view on its head, in fact representing an asset to the control of complex systems. First, I will show how nonlinearity in the form of multistability allows one to systematically design control interventions that can deliberately induce “reverse cascading failures”, in which a network spontaneously evolves to a desirable (rather than a failed) state. Second, I will show that nonlinearity in the form of time-varying dynamics unexpectedly makes temporal networks easier to control than their static counterparts, with the former enjoying dramatic and simultaneous reductions in all costs of control. This is true despite the fact that temporality tends to fragment a network's structure, disrupting the paths that allow the directly-controlled or “driver” nodes to communicate with the rest of the network. Taken together, these studies shed new light on the crucial role of nonlinearity in network control, and provide support to the idea we can control nonlinearity, rather than letting nonlinearity control us.

**3:42PM V3.00003 Novel percolation transitions and coupled catastrophes**, RAISSA D'SOUZA, University of California, Davis — Collections of interdependent networks are at the core of modern society, spanning physical, biological and social systems. Simple mathematical models of the structure and function of networks can provide important insights into real-world systems, enhancing our ability to steer and control them. Here our focus is on abrupt changes in networks, due both to phase transitions and to jumping between bi-stable equilibria. We begin with an overview of novel classes of percolation phase transitions that result from repeated, small interventions intended to delay the transition. These new phenomena allow us to extend percolation approaches to modular networks, Brownian motion, and cluster growth dynamics. We then focus on abrupt transitions due to a system jumping between bi-stable equilibria, modeled as a cusp catastrophe in nonlinear dynamics. We show that when systems that each undergo a cusp catastrophe interact, we can observe a new phenomena of catastrophe-hopping leading to non-local cascading failures. Here an intermediate system facilitates the propagation of a sudden change or collapse, and we show that catastrophe hopping is consistent with the outbreak of protests observed during the Arab Spring of 2011.

**4:18PM V3.00004 Interdisciplinary applications of network dynamics: From microscopic to Macroscopic**<sup>1</sup>, HAWOONG JEONG, KAIST, Korea — Everything touches everything. We are living in a connected world, which has been modeled successfully by complex networks. Ever since, network science becomes new paradigm for understanding our connected yet complex world. After investigating network structure itself, our focus naturally moved to dynamics of/on the network because our connected world is not static but dynamic. In this presentation, we will briefly review the historical development of network science and show some applications of network dynamics ranging from microscopic (metabolic engineering, PNAS, 104 13638) to macroscopic scale (price of anarchy in transportation network, Phys.Rev.Lett. 101 128701).

<sup>1</sup>Supported by National Research Foundation of Korea through Grant No. 2011-0028908

**4:54PM V3.00005 Rank Dynamics**, CARLOS GERSHENSON, Universidad Nacional Autonoma de Mexico — Studies of rank distributions have been popular for decades, especially since the work of Zipf. For example, if we rank words of a given language by use frequency (most used word in English is the, rank 1; second most common word is of, rank 2), the distribution can be approximated roughly with a power law. The same applies for cities (most populated city in a country ranks first), earthquakes, metabolism, the Internet, and dozens of other phenomena. We recently proposed rank diversity to measure how ranks change in time [1], using the Google Books Ngram dataset. Studying six languages between 1800 and 2009, we found that the rank diversity curves of languages are universal, adjusted with a sigmoid on log-normal scale. We are studying several other datasets (sports, economies, social systems, urban systems, earthquakes, artificial life). Rank diversity seems to be universal, independently of the shape of the rank distribution. I will present our work in progress towards a general description of the features of rank change in time, along with simple models which reproduce it. [1]Cocho G, Flores J, Gershenson C, Pineda C, Sanchez S (2015) Rank Diversity of Languages: Generic Behavior in Computational Linguistics. PLoS ONE 10(4): e0121898. <http://dx.doi.org/10.1371/journal.pone.0121898>

**Thursday, March 17, 2016 2:30PM - 5:30PM –**  
**Session V4 DPOLY: Where Morphology Meets Functionality: Light and Electron Transporting Polymeric Complexes** Ballroom IV - Enrique Gomez, Pennsylvania State University

**2:30PM V4.00001 From Morphology to Interfaces to Tandem Geometries: Enhancing the Performance of Perovskite/Polymer Solar Cells**<sup>1</sup>, THOMAS RUSSELL, University of Massachusetts — We have taken a new approach to develop mesoporous lead iodide scaffolds, using the nucleation and growth of lead iodide crystallites in a wet film. A simple time-dependent growth control enabled the manipulation of the mesoporous lead iodide layer quality in a continuous manner. The morphology of lead iodide is shown to influence the subsequent crystallization of methyammoniumleadiodide film by using angle-dependent grazing incidence x-ray scattering. The morphology of lead iodide film can be fine-tuned, and thus the methyammoniumleadiodide film quality can be effectively controlled, leading to an optimization of the perovskite active layer. Using this strategy, perovskite solar cells with inverted PHJ structure showed a *PCE* of 15.7 per cent with little hysteresis. Interface engineering is critical for achieving efficient solar cells, yet a comprehensive understanding of the interface between metal electrode and electron transport layer (ETL) is lacking. A significant power conversion efficiency (PCE) improvement of fullerene/perovskite planar heterojunction solar cells was achieved by inserting a fulleropyrrolidine interlayer between the silver electrode and electron transport layer. The interlayer was found to enhance recombination resistance, increases electron extraction rate and prolongs free carrier lifetime. We also uncovered a facile solution-based fabrication of high performance tandem perovskite/polymer solar cells where the front sub-cell consists of perovskite and the back sub-cell is a polymer-based layer. A record maximum PCE of 15.96 per cent was achieved, demonstrating the synergy between the perovskite and semiconducting polymers. This design balances the absorption of the perovskite and the polymer, eliminates the adverse impact of thermal annealing during perovskite fabrication, and affords devices with no hysteresis.

<sup>1</sup>This work was performed in collaboration with Y. Liu, Z. Page, D. Venkataraman and T. Emrick (UMASS), F. Liu (LBNL) and Q. Hu and R. Zhu (Peking University) and was supported by the Office of Naval Research under contract N00014-15-1-2244xx.

**3:06PM V4.00002 Microwave absorption of free carriers in doped conjugated polymer films**, GARRY RUMBLES, National Renewable Energy Laboratory — Flash photolysis time-resolved microwave conductivity (*fp*-TRMC) is a powerful spectroscopic tool for the detection of mobile charges in organic systems, such as conjugated polymers. We will report on a study of charge carrier generation in a number of polymer systems where the solid-state microstructure (SSM) of the thin films can be controlled using both molecular structure and processing conditions. By incorporating a low concentration of molecular acceptors, such as metallo-phthalocyanines, as well as substituted fullerenes and perylenes, the driving force for photoinduced electron transfer can be controlled through the excited state energy and the reduction potential. Our results indicate the importance of the crystalline phase of the polymer to stabilise and reduce the rate of recombination of the holes with the electrons that remain trapped on the acceptor. In addition, the role that the SSM plays on the stabilization of bound electron-hole pairs, or charge-transfer (CT) states will be examined.

**3:42PM V4.00003 Making Glasses Conduct: Electrochemical Doping of Redox-Active Polymer Thin Films**, BRYAN BOUDOURIS, Purdue University — Optoelectronically-active macromolecules have been established as promising materials in myriad organic electronic applications (e.g., organic field-effect transistors (OFETs) and organic photovoltaic (OPV) devices). To date, however, the majority of the work surrounding these materials has focused on materials with a great deal of conjugation along their macromolecular backbones and with varying degrees of crystalline structure. Here, we describe an emerging class of macromolecular charge conductors, radical polymers, that: (1) do not contain conjugation and (2) are completely amorphous glasses. Radical polymers contain non-conjugated macromolecular backbones and stable radical sites along the side chains of the electronically-active materials. In contrast to conjugated polymer systems, these materials conduct charge in the solid state through oxidation-reduction (redox) reactions along these pendant groups. Specifically, we demonstrate that controlling the chemical functionality of the pendant groups and the molecular mobility of the macromolecular backbones significantly impacts the charge transport ability of the pristine (i.e., not doped) radical polymers species. Through proper control of these crucial parameters, we show that radical polymers can have electrical conductivity and charge mobility values on par with commonly-used conjugated polymers. Importantly, we also highlight the ability to dope radical polymers with redox-active small molecule species. This doping, in turn, increases the electrical conductivity of the glassy radical polymer thin films in a manner akin to what is observed in traditional conjugated polymer systems. In this way, we establish a means by which to fabricate optically-transparent and colorless thin film glasses capable of conducting charge in a rather rapid manner. We anticipate that these fundamental insights will prove crucial in developing new transparent conducting layers for future electronic applications.

**4:18PM V4.00004 Reversible Optical Control of polymer doping: Mechanism and applications**, ADAM MOULE, University of California, Davis — No abstract available.

**4:54PM V4.00005 Nanoparticle Polymer Hybrids for Solar Cells<sup>1</sup>**, MICHAEL MACKAY, Univ of Delaware — Polymer-based solar cells are unique since their processing is extremely cost effective compared to silicon-based solar cells. They are also much less energy intensive to manufacture. However, their power conversion efficiency is low. Discussion of what affects this property in the context of the morphology characterized through thermal analysis as well as x-ray and neutron scattering will be given.

**Session V5 GMAG DMP: Frustrated Magnetism: Low Dimensional Magnets II** 301 - Alexander Chernyshev, University of California, Irvine

**2:30PM V5.00001 Chiral spin liquids in arrays of spin chains**, RODRIGO PEREIRA, University of Sao Paulo — The chiral spin liquid proposed by Kalmeyer and Laughlin is a spin analogue of the fractional quantum Hall effect: it has gapped bulk quasiparticles, charge-neutral chiral edge modes and topological order in the ground state. Recently there has been unambiguous numerical evidence that the chiral spin liquid can be stabilized as the ground state of extended Heisenberg models on the kagome lattice. I will talk about an analytical approach to investigate the emergence and the properties of the chiral spin liquid phase in spatially anisotropic 2D lattices. The approach is inspired by coupled-wire constructions of quantum Hall states: starting from a quasi-1D system, we build towards the 2D limit by coupling Heisenberg chains with three-spin interactions that drive the chiral spin order. Using a renormalization group analysis, we show that the chiral spin liquid is more easily stabilized in the kagome lattice than in the triangular lattice. Moreover, using the conformal field theory that describes single chains, we explicitly construct the operators that create bulk quasiparticles and those that account for the topological degeneracy on the torus. I will also discuss possible extensions of this approach to construct more exotic quantum spin liquids.

**3:06PM V5.00002 Entanglement Entropy and Topological Order in Resonating Valence-Bond Quantum Spin Liquids**, JULIA WILDEBOER, National High Magnetic Field Laboratory, ALEXANDER SEIDEL, Washington University in St. Louis, ROGER MELKO, University of Waterloo, PI — On the triangular and kagome lattices, short-ranged resonating valence bond (RVB) wave functions can be sampled without the sign problem using a recently-developed Pfaffian Monte Carlo scheme [1]. In this talk [2], we present a study of the Renyi entanglement entropy in these wave functions using a replica-trick method [3]. Using various spatial bipartitions, including the Levin-Wen construction, our finite-size scaled Renyi entropy gives a topological contribution consistent with  $\gamma = \ln(2)$ , as expected for a gapped  $Z_2$  quantum spin liquid. We prove that the mutual statistics are consistent with the toric code anyon model and rule out any other quasiparticle statistics such as the double semion model.

**3:18PM V5.00003 A numerical study of the energy gap of the quantum dimer-pentamer model**, OWEN MYERS, University of Vermont, CHRIS HERDMAN, University of Waterloo — We present a study of the energy gap in the quantum dimer-pentamer model (QDPM) on the square lattice. This model is a generalization of the square lattice quantum dimer model (QDM), with a configuration space comprising fully-packed hard-core dimer coverings of the lattice, as well as configurations containing pentamers, where four dimers touch a vertex. Thus in the QDPM, the fully-packed, hard-core constraint of the QDM is relaxed such that the local dimer number at each vertex is fixed modulo 3; correspondingly, the local  $U(1)$  gauge symmetry of the QDM Hilbert space is reduced to a local  $Z_3$  gauge symmetry in the QDPM. Previous work has demonstrated the disordered quantum liquid nature of the ground state of the QDPM at the Rokhsar-Kivelson point. Here we present a study of the energy gap above the ground state at the RK point, as computed via Monte Carlo from imaginary time correlations. To investigate the possibility of  $Z_3$  topological order in this system, we study both the dimer density correlations as well as a  $Z_3$  generalization of  $Z_2$  vison correlations. Such vison correlations have previously been shown to display the nature of the low lying excitations in  $Z_2$  topologically ordered QDMs.

**3:30PM V5.00004 A quantum spin liquid with a large topological degeneracy<sup>1</sup>**, OLEG TCHERNYSHYOV, HAOYU WANG, Johns Hopkins University, YUAN WAN, Perimeter Institute — We present a model of a quantum spin liquid in two dimensions with a large topological degeneracy. The model has spins of length  $S = 1/2$  on sites of a triangular lattice interacting via a 6-spin term. As in models of Kitaev and Wen [1-3], elementary building blocks in our model are strings of several distinct types. Ends of these strings are elementary particles: 4 bosons and 3 fermions. Particles of different types are mutual semions. The degeneracy of the ground state on a torus is  $2^{7-1} = 64$ . Elementary excitations of the model are boson-fermion pairs, which come in  $3 \times 4 = 12$  distinct types. [1] A. Kitaev, Ann. Phys. **303**, 2 (2003). [2] X.-G. Wen, Phys.Rev.Lett. **90**, 016803 (2003). [3] A. Kitaev, Ann. Phys. **321**, 2 (2006).

**3:42PM V5.00005 Magnetic Frustration from Nonuniform  $g$ -factors<sup>1</sup>**, WEIGUO YIN, Brookhaven National Laboratory — Frustrated magnets are commonly known as materials in which localized magnetic moments, or spins, interact through competing exchange interactions that cannot be simultaneously satisfied. Here we show that even when the exchange interactions are fully cooperative, magnetic frustration can be induced by nonuniform Landé  $g$  factors, leading to a mutual interplay of typical ferromagnetic (FM) and antiferromagnetic (AF) features. This novel physics—exactly demonstrated in the one-dimensional Ising model with alternating  $g$  factors [1]—provides new insight into the puzzling phenomenon that the magnetic susceptibility of many AF or FM materials is FM-like at low temperature but AF-like at high temperature. Furthermore, we found a unique magnetic-field-driven quantum critical point at which one half of the spins are frozen into a complete order and the other half are fully disordered. The present theory joins the recent intensive search for frustrated magnets beyond the “standard model” of condensed matter physics. It could broaden our understanding and design of exotic magnetic behaviors such as spin ice, spin glass, and spin liquid that are essential to quantum computing, spintronics, and high-temperature superconductivity. [1] W.-G. Yin and C. R. Roth, arXiv:1510.00030.

**3:54PM V5.00006 Quantum Spin Fluctuations and magnons in antiferromagnetically coupled bilayers with tuneable intra-bilayer exchange - the case of  $\text{Cr}_2\text{W}(\text{Te})\text{O}_6$ <sup>1</sup>**, KINGSHUK MAJUMDAR, Grand Valley State Univ, S. D. MAHANTI, Michigan State University, East Lansing — Recent neutron diffraction studies have shown that in  $\text{Cr}_2(\text{W},\text{Te})\text{O}_6$  systems, which consist of bilayers with strong antiferromagnetic inter-bilayer coupling between Cr moments, the intra-bilayer coupling between the Cr moments can be tuned from ferro (for W) to antiferro (for Te). Ab initio density functional calculations provide a microscopic understanding of the magnetic structure but cannot explain the magnitude of the ordered  $\text{Cr}^{3+}$  moments. In order to understand the reduction of the ordered moment (ROM) caused by quantum spin fluctuations we have studied the magnon dispersion and ROM using a two parameter quantum Heisenberg spin Hamiltonian with tuneable intra- ( $j$ ) and antiferromagnetic inter- ( $J$ ) bilayer couplings. The magnon dispersion and sublattice magnetization have been calculated using non-linear spin wave theory up to second-order corrections in spin  $S$ .

**4:06PM V5.00007 Complex field-induced states in Linarite  $\text{PbCuSO}_4(\text{OH})_2$  with a variety of high-order exotic  $\text{SDW}_p$  states<sup>1</sup>**, STEFAN SÜLLOW, TU Braunschweig, Braunschweig, Germany — Low-temperature neutron diffraction and NMR studies of field-induced phases in linarite are presented for magnetic fields  $H\parallel b$  axis. This way, we establish the magnetic phase diagram up to saturation. A two-step spin-flop transition is observed as well as a transition transforming a helical magnetic ground state into an unusual magnetic phase with sine-wave modulated moments  $\parallel H$  enclosing all other magnetic phases in the  $T-H$  phase diagram. An effective  $\tilde{J}_1 - \tilde{J}_2$  single-chain model with a magnetization-dependent frustration ratio  $\alpha_{eff} = -\tilde{J}_1/\tilde{J}_2$  is proposed. The latter is governed by skew interchain couplings and shifted to the vicinity of the ferromagnetic critical point. It explains qualitatively the observation of a rich variety of exotic (for strongly correlated cuprate spin-1/2 Heisenberg systems) longitudinal collinear spin-density wave  $\text{SDW}_p$  states ( $9 \geq p \geq 2$ ).

**4:42PM V5.00008 Large-scale simulations of spin-density-wave order in frustrated lattices**, KIPTON BARROS, CRISTIAN BATISTA, Los Alamos National Laboratory, GIA-WEI CHERN, University of Virginia — We investigate spin-density-wave (SDW) phases within a generalized mean-field approximation. This approach incorporates the thermal fluctuations of SDW order and the development of short-range order above magnetic ordering temperatures  $T_c$ . Using a new Langevin dynamics method, we study mesoscale structures associated with triple-Q SDW states that are induced by Fermi surface nesting in triangular and kagome lattice Hubbard models. The core of our linear-scaling Langevin dynamics simulations is an efficient stochastic kernel polynomial method for computing the electron density matrix. We also investigate exotic phases above  $T_c$  arising from preformed magnetic moments.

**4:54PM V5.00009 Electronic route to stabilize nanoscale spin textures in itinerant frustrated magnets**, SANJEEV KUMAR, IISER Mohali, SAHINUR REJA, JEROEN VAN DEN BRINK, IFW Dresden, Germany — We unveil novel spin textures in an itinerant fermion model on a frustrated triangular lattice in the limit of low electronic density. Using hybrid Monte Carlo simulations on finite clusters we identify two type of nanoscale spin textures in the background of  $120^\circ$  order: (i) a planar ferromagnetic cluster, and (ii) a non-coplanar cluster with spins oriented perpendicular to the  $120^\circ$  plane. Both these textures lead to localization of the electronic wavefunctions and are in-turn stabilized by the concomitant charge modulations. The non-coplanar spin texture is accompanied by an unusual scalar chirality pattern. A well defined electric charge and magnetic moment associated with these textures allow for their easy manipulation by external electric and magnetic fields – a desirable feature for data storage. We identify a localization-delocalization behavior for electronic wavefunctions which is unique to frustrated magnets, and propose a general framework for stabilizing similar spin textures in spin-charge coupled systems.

**5:06PM V5.00010 Stability and magnetization curve of spin-nematic phase slightly below saturation field**, HIROAKI UEDA, Toyama Prefectural University, KEISUKE TOTSUKA, Yukawa Institute for Theoretical Physics — We discuss the magnetization process slightly below the saturation field in frustrated magnets. A condensation of bound magnons on the spin-polarized state induces either a spin nematic phase or a state with phase separation. The (effective) interaction between the bound magnon pairs not only is crucial to the stability of the nematic phase, but also determines the slope of the magnetization curve near saturation. We generally derive the expression of this interaction by using the perturbative scattering theory. By applying the method to coupled zigzag chains  $\text{LiCuVO}_4$ , we find the positive pair-pair interaction implying the stability of the spin nematic phase. We also point out that the magnetization curve of  $\text{LiCuVO}_4$  is almost vertical (i.e. very large  $dM/dH$ ) near the saturation exhibiting one-dimensional feature despite non-negligible interchain couplings.

**5:18PM V5.00011 Density-matrix renormalization group study of triangular and square Hubbard models**, SHIGETOSHI SOTA, RIKEN AICS, TAKAMI TOHYAMA, Tokyo University of Science, TOMONORI SHIRAKAWA, SEIJI YUNOKI, RIKEN — We perform large-scale density-matrix renormalization group calculations for two-dimensional Hubbard models with a triangular lattice and a square lattice [T. Tohyama, K. Tsutsui, M. Mori, S. Sota, and S. Yunoki, Phys. Rev. B **92**, 014515 (2015)]. In the triangular Hubbard model, we determined a boundary between metal and insulator and a boundary between spin-liquid and antiferromagnetic phases. The presence of spin-liquid phase is confirmed by spin-spin correlation function. In the square Hubbard model, we introduce a second-neighbor hopping interaction and calculate the dynamical spin correlation function to clarify the doping dependence of magnon excitations. We find a shift of a peak position toward higher energy in the electron-doped side, being consistent with recent resonant-inelastic x-ray scattering.

**Session V6 GMAG DMP: Bulk Multiferroics** 302 - Srinivasa Singamaneni, North Carolina State University

**2:30PM V6.00001 Electric field control of magnetization dynamics in multiferroics**, VETLE RIS-INGGARD, IRYNA KULAGINA, JACOB LINDER, Department of Physics, Norwegian University of Science and Technology — Multiferroics with a strong magnetoelectric coupling hold great promise in spintronics because they enable magnetic control of the electric polarization as well as electric control of the magnetization. We take an analytical approach, using the Landau-Lifshitz-Gilbert equation to describe the dynamic state of the magnetization. In particular, we show that in insulating multiferroics which exhibit the inhomogeneous magnetoelectric effect there exists an electrically controlled magnon-induced torque that acts even on a homogeneous magnetization. Unlike the magnon-induced torques that arise from Dzyaloshinskii-Moriya interactions or in the proximity of a topological insulator, the strength and direction of this torque is tunable by the externally applied electric field.

**2:42PM V6.00002 Understanding the spin-driven polarizations in  $\text{BiMO}_3$  ( $M = 3d$  transition metals) multiferroics.**<sup>1</sup>, SANTOSH KC, JUN HEE LEE, VALENTINO R. COOPER, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — Bismuth ferrite ( $\text{BiFeO}_3$ ), a promising multiferroic, stabilizes in a perovskite type rhombohedral crystal structure (space group  $R3c$ ) at room temperature. Recently, it has been reported that in its ground state it possess a huge spin-driven polarization [1]. To probe the underlying mechanism of this large spin-phonon response, we examine these couplings within other Bi based  $3d$  transition metal oxides  $\text{BiMO}_3$  ( $M = \text{Ti, V, Cr, Mn, Fe, Co, Ni}$ ) using density functional theory. Our results demonstrate that this large spin-driven polarization is a consequence of symmetry breaking due to competition between ferroelectric distortions and anti-ferrodistortive octahedral rotations. Furthermore, we find a strong dependence of these enhanced spin-driven polarizations on the crystal structure; with the rhombohedral phase having the largest spin-induced atomic distortions along [111]. These results give us significant insights into the magneto-electric coupling in these materials which is essential to the magnetic and electric field control of electric polarization and magnetization in multiferroic based devices. **2:54PM V6.00003 Spin Excitations and Phonon Anomaly in Quasi-1D Spiral Magnet  $\text{CuBr}_2$** , YUAN LI, CHONG WANG, DAIWEI YU, LICHEN WANG, FA WANG, Peking University, China, KAZUKI IIDA, KAZUYA KAMAZAWA, CROSS, Japan, SHUICHI WAKIMOTO, Japan Atomic Energy Agency —  $\text{CuBr}_2$  can be considered as a model quasi-one-dimensional (quasi-1D) spin-1/2 magnet, in which the frustrating ferromagnetic nearest-neighbor and antiferromagnetic next-nearest-neighbor exchange interactions give rise to a cycloidal magnetic order below  $T_N = 73$  K. The removal of inversion symmetry by the magnetic order also makes the material a type-II multiferroic system with a remarkably simple crystal structure. Using time-of-flight inelastic neutron scattering spectroscopy, we have determined the spin-wave as well as phonon spectra throughout the entire Brillouin zone. The spin-wave spectrum exhibits pronounced anisotropy and magnon damping, consistent with the materials quasi-1D nature and the non-collinear spin structure. The phonon spectrum exhibits dramatic discontinuities in the dispersion across the quasi-1D magnetic wave vector, indicative of strong magnetoelastic coupling and possibly of a spin-orbital texture that comes along with the spin correlations.

**3:06PM V6.00004 Magnetic and Magnetoelastic Excitations in the Multiferroic  $\text{CuBr}_2$  determined by Raman, Infrared and Neutron Spectroscopy**, CHONG WANG, DAIWEI YU, RONGYAN CHEN, XINYU DU, LICHEN WANG, XIAOQIANG LIU, ICQM, Peking University, KAZUKI IIDA, KAZUYA KAMAZAWA, Comprehensive Research Organization for Science and Society, Japan, SHUICHI WAKIMOTO, Japan Atomic Energy Agency, JI FENG, NANLIN WANG, YUAN LI, ICQM, Peking University, YUAN LI GROUP AT ICQM PEKING UNIVERSITY TEAM, NANLIN WANG GROUP AT ICQM PEKING UNIVERSITY TEAM, JI FENG GROUP AT ICQM PEKING UNIVERSITY TEAM, COMPREHENSIVE RESEARCH ORGANIZATION FOR SCIENCE AND SOCIETY (CROSS) TEAM, SHUICHI WAKIMOTO COLLABORATION — Multiferroicity was recently discovered in anhydrous copper (II) bromide  $\text{CuBr}_2$  with a rather high transition temperature ( $T_N = 73.5$  K). By the combination of the Raman, Infrared (IR) and inelastic neutron scattering (INS) experiments, evidences for strong magneto-elastic coupling and magneto-elastic excitations are found in  $\text{CuBr}_2$ . In the Raman spectra, a range of broad peaks were observed with the indications of magnetic and phonon origin at the same time. The inelastic neutron scattering experiment reveals that those nontrivial broad peaks originate from the sites of the phonons at incommensurate Q vectors that correspond to the spiral magnetic order. These results strongly suggest the existence of hybrid excitations that involve both the spin and lattice degrees of freedom, and render  $\text{CuBr}_2$  a promising platform for studying dynamic magneto-elastic coupling.

**3:18PM V6.00005 Pressure effect on ferroelectric properties of multiferroics  $\text{RMn}_2\text{O}_5$ , ( $R = \text{Gd, Tm}$ )**, NARAYAN POUDEL, MELISSA GOOCH, BERND LORENZ, TcSUH and Department of Physics, University of Houston, CHING-WU CHU, TcSUH and Department of Physics, University of Houston and Lawrence Berkeley National Laboratory, JAEWOOK KIM, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University — The pressure effect on the ferroelectric properties of the multiferroics  $\text{GdMn}_2\text{O}_5$  and  $\text{TmMn}_2\text{O}_5$  is studied up to 18.2 kbar. Unlike in  $\text{RMn}_2\text{O}_5$  ( $R = \text{Tb, Ho, Y}$ ), no significant change in polarization is observed in  $\text{TmMn}_2\text{O}_5$  up to 16.6 kbar. However, a new ferroelectric phase is observed in  $\text{GdMn}_2\text{O}_5$  above a critical pressure,  $P_c = 10$  kbar at higher temperature. Our result indicates that pressure decouples the Gd moment from the Mn spin system and splits the ferroelectric phase. Thermal expansion data shows a large increase of the  $c$  axis at the ambient-pressure ferroelectric transition. The pressure-induced contraction of the  $c$  lattice parameter is found to be the cause for splitting of ferroelectric phase by decoupling of two spin systems above  $P_c$ . The pressure-temperature phase diagram is derived based on dielectric and ferroelectric properties.

**3:30PM V6.00006 Doping-Tunable Ferrimagnetic Phase with Large Linear Magnetoelectric Effect in a Polar Magnet  $\text{Fe}_2\text{Mo}_3\text{O}_8$** <sup>1</sup>, TAKASHI KURUMAJI, RIKEN, CEMS, SHINTARO ISHIWATA, Univ. Tokyo, YOSHINORI TOKURA, RIKEN, CEMS, STRONG CORRELATION PHYSICS RESEARCH GROUP TEAM, ISHIWATA LABORATORY TEAM — The magnetoelectric (ME) effect, i.e., cross control of magnetization (electric polarization) by an external electric (magnetic) field, may introduce a new design principle for novel spin devices. To enhance the ME signal, control of a phase competition has recently been revealed as a promising approach. Here, we report the successful chemical-doping control of the distinct ME phases in a polar magnet  $\text{Fe}_2\text{Mo}_3\text{O}_8$ , in which an antiferromagnetic state is competing with a ferrimagnetic state. We demonstrate that Zn doping stabilizes the metamagnetic state to realize the spontaneous ferrimagnetic state and varies the ME coefficients from large negative to large positive values; for instance, the diagonal component of the ME coefficients under the magnetic field perpendicular to the polar axis varies from  $-142 \mu\text{Vs/m}$  to  $107 \mu\text{Vs/m}$  by doping Zn from 12.5% to 50%. This remarkable doping control of the ME property originates from coexisting distinct ME mechanisms, which are selectively tunable by substituting one of the two distinct magnetic sites in the unit cell with nonmagnetic Zn.

**3:42PM V6.00007 Field evolution of magnetism in multiferroic  $(\text{ND}_4)_2[\text{FeCl}_5(\text{D}_2\text{O})]$** <sup>1</sup>, WEI TIAN, HUIBO CAO, JIAQIANG YAN, BRIAN SALES, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory —  $(\text{NH}_4)_2[\text{FeCl}_5(\text{H}_2\text{O})]$  is a new organic multiferroic material that exhibits a very rich magnetic field versus temperature ( $B$  vs.  $T$ ) phase diagram. The material undergoes two successive magnetic transitions at 7.3K and 6.8K, with the onset of ferroelectricity at 6.8K at  $B=0\text{T}$ . Applying magnetic field with  $B//a$ -axis or  $B//c$ -axis induces transitions to different ferroelectric phases, and the electric polarization direction rotates from  $P//a$ -axis at  $B=0\text{T}$  to  $P//c$ -axis at  $B=5\text{T}$ . Here we report single crystal neutron diffraction results studied with  $B//a$ -axis that elucidate the field evolution of magnetism associated with different ferroelectric phases in  $(\text{NH}_4)_2[\text{FeCl}_5(\text{H}_2\text{O})]$ .

<sup>1</sup>Research conducted at ORNL's High Flux Isotope Reactor was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U. S. Department of Energy.

**3:54PM V6.00008 Mueller matrix ellipsometry studies of the optical phonons and crystal field excitations in multiferroic orthoferrites  $\text{RFeO}_3$  ( $\text{R}=\text{Tb}, \text{Dy}$ )**<sup>1</sup>, V.A. MARTINEZ, T.N. STANISLAVCHUK, A.A. SIRENKO, Department of Physics, New Jersey Institute of Technology, Newark, New Jersey 07102, USA, A.P. LITVINCHUK, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA, YAZHONG WANG, S.W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Optical properties of multiferroic orthoferrites  $\text{RFeO}_3$  ( $\text{R}=\text{Tb}, \text{Dy}$ ) bulk crystals have been studied in the far-infrared range from 50 to 1000  $\text{cm}^{-1}$  and temperatures from 7 K to 300 K. Mueller matrix and rotating analyzer ellipsometry measurements were carried out at the U4IR beamline of the National Synchrotron Light Source at Brookhaven National Lab. Optical phonon spectra and crystal field excitations were measured for all three orthorhombic axes of  $\text{RFeO}_3$ . In the experimental temperature dependencies of the phonon frequencies we found non-Grüneisen behavior caused by the electron-phonon and spin-phonon interactions. We determined the symmetries and selection rules for the crystal field transitions in  $\text{Tb}^{3+}$  and  $\text{Dy}^{3+}$  ions. Magnetic field dependencies of the optical spectra allowed us to determine anisotropy of the crystal field g-factors for  $\text{Tb}^{3+}$  and  $\text{Dy}^{3+}$  ions.

<sup>1</sup>This Project is supported by collaborative DOE Grant DE-FG02-07ER46382 between Rutgers U. and NJIT. Use of NSLS-BNL was supported by DOE DE-AC02-98CH10886. V.A. Martinez was supported by NEU NSF-1343716.

**4:06PM V6.00009 Unusual ferroelectricity induced by the Jahn-Teller effect: A case study on lacunar spinel compounds**, KE XU, HONGJUN XIANG, Fudan Univ — The Jahn-Teller effect refers to the symmetry-lowering geometrical distortion in a crystal (or nonlinear molecule) due to the presence of a degenerate electronic state. Usually, the Jahn-Teller distortion is not polar. Recently,  $\text{GaV}_4\text{S}_8$  with a lacunar spinel structure was found to undergo a Jahn-Teller distortion from a cubic to ferroelectric rhombohedral structure at  $T_{\text{JT}} = 38\text{ K}$ . Here, we carry out a general group theory analysis to show how and when the Jahn-Teller effect gives rise to ferroelectricity. On the basis of this theory, we find that the ferroelectric Jahn-Teller distortion in  $\text{GaV}_4\text{S}_8$  is due to the noncentrosymmetric nature of the parent phase and a strong electron-phonon interaction related to two low-energy  $T_2$  phonon modes. Interestingly,  $\text{GaV}_4\text{S}_8$  is not only ferroelectric, but also ferromagnetic with a magnetic easy axis along the ferroelectric direction. This suggests that  $\text{GaV}_4\text{S}_8$  is a multiferroic material in which an external electric field may control its magnetization direction. Our study not only explains the Jahn-Teller physics in  $\text{GaV}_4\text{S}_8$ , but also paves a way for searching and designing different ferroelectrics and multiferroics.

**4:18PM V6.00010 Interplay between magnetism and octahedra distortion in the hybrid improper multiferroic  $\text{Ca}_3\text{Mn}_{1.9}\text{Ti}_{0.1}\text{O}_7$** <sup>1</sup>, FENG YE, Oak Ridge National Lab, JINCHEN WANG, Renmin University of China, JAIME FERNANDEZ-BACA, ANTONIO DOS SANTOS, Oak Ridge National Lab, BIN GAO, SANG-WOOK CHEONG, Rutgers University — A novel microscopic mechanism has been proposed to search for ferroelectric material for realistic application. The instability of the polar phonon mode is driven by the simultaneous condensation of two nonpolar lattice modes associated with oxygen octahedron rotation and tilt modes, and is responsible for the polar symmetry observed in the Ruddlesden-Popper compounds. We have used single crystal neutron diffraction to investigate the temperature and pressure dependence of these oxygen octahedron distortions in  $\text{Ca}_3\text{Mn}_{1.9}\text{Ti}_{0.1}\text{O}_7$  which has a structural transition at 365 K and antiferromagnetic order at 120 K. We observed a strong interplay between magnetism and the local oxygen distortion near the magnetic transition. The control of the magnetism through octahedron rotation is also discussed.

<sup>1</sup>Research at ORNL was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

**4:30PM V6.00011 Dynamics of the  $\text{Ho}^{+3}$  magnetism in the multiferroic compound  $\text{HoMnO}_3$  investigated via time domain terahertz spectroscopy**, N.P. ARMITAGE, N.J. LAURITA, Johns Hopkins University, RONGWEI HU, S-W CHEONG, Rutgers University — The multiferroic insulator  $\text{HoMnO}_3$  possesses a diverse array of magnetism due to both magnetically active  $\text{Mn}^{+3}$  and  $\text{Ho}^{+3}$  moments, the latter of which sit at two distinct sites within its non-inversion symmetric hexagonal crystal structure. While previous studies have focused on the ordering of the  $\text{Mn}^{+3}$  moments, little is known about the magnetic structure below 5K where it is believed that there is at least partial ordering of the  $\text{Ho}^{+3}$  ions. In principle, magnetic exchange interactions exist between both distinct  $\text{Ho}^{+3}$  and  $\text{Mn}^{+3}$  ions, resulting in a complex phase diagram with as many as five distinct phases found below  $T = 5\text{ K}$  and  $H = 3\text{ T}$ . While previous infrared studies have focused on the  $\text{Ho}^{+3}$  crystal field levels, the spin excitations in the low frequency end of the far infrared remain unknown. We report the finding of new infrared absorptions via time domain terahertz spectroscopy which we attribute to the  $\text{Ho}^{+3}$  moments. The corresponding field dependence is studied.

**4:42PM V6.00012 Electric Field Effect on the Magnetic Order in Multiferroic  $\text{LuMnO}_3$** , CHUNRUO DUAN, JUNJIE YANG, Univ of Virginia, LELAND HARRIGER, NIST Center for Neutron Research, DESPINA LOUCA, Univ of Virginia —  $\text{LuMnO}_3$  belongs to the family of hexagonal multiferroics in which ferroelectric and magnetic orders coexist and compete. The  $\text{Mn}^{3+}$  ions reside on a triangular lattice that is geometrically frustrated but undergoes a Neel transition at  $T_N \sim 90\text{ K}$ . Neutron experiments under electric field were carried out on a single crystal of  $\text{LuMnO}_3$  at SPINS to investigate the coupling of the electric field to the magnetic order. The elastic and inelastic scattering around the commensurate (101) magnetic peak and the Mn trimerization induced (100) peak with and without electric field were investigated. When applying an E-field of 13.3 kV/cm along the (001) direction on an unpoled sample, an increase in (101) peak as well as a shift of the inelastic excitation near (100) to higher  $\Delta E$  have been observed. Once the sample is polarized, these effects exist without the field. On the other hand, an E-field along (110) direction shows almost no effect. The spin arrangement of the magnetic order is within the ab-plane, thus the Dzyaloshinskii-Moriya interaction explains why a polarization perpendicular to the magnetic moment gives a larger effect. The implication will be discussed.

**4:54PM V6.00013 First-principles studies of magnetoelectric coupling in hexagonal LuFeO<sub>3</sub> under applied electric fields**, YUBO ZHANG, HONGWEI WANG, PRATIKKUMAR DHUVAD, Temple Univ, XIAOSHAN XU, University of Nebraska, MASSIMILIANO STENGEL, Institut de Ciència de Materials de Barcelona, XIFAN WU, Temple Univ — The recently stabilized hexagonal LuFeO<sub>3</sub> thin-film provides an opportunity in realizing the magnetoelectric coupling in multiferroic materials, in which the weak ferromagnetism due to Dzyaloshinskii-Moriya interaction was found to be closely associated with the trimerization (K<sub>3</sub>) mode. Here, we performed first-principles calculations in hexagonal LuFeO<sub>3</sub> and studied the variations of weak ferromagnetic moment under applied electric fields. It is found that the weak ferromagnetism is a property that can be directly tuned by the external electric fields. As an improper ferroelectric material, such a magnetoelectric coupling is realized by the strong interaction between the trimerization mode and ferroelectric mode. Under the electric field poling, ferroelectric mode will respond. A change in ferroelectric distortion will in turn affect the amplitude of trimerization mode, and therefore, the weak ferromagnetism. Interestingly, the magnetoelectric coupling in LuFeO<sub>3</sub> shows a strong nonlinear behavior originating again from the coupling between the trimerization and ferroelectric modes due to its improper nature.

**5:06PM V6.00014 Energetics of Intrinsic Defects in hexagonal LuFeO<sub>3</sub>**, TULA R. PAUDEL, EVGENY Y. TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska — The hexagonal Lutetium Ferrite (*h*-LuFeO<sub>3</sub>) is one of the few multiferroic materials where the spontaneous ferroelectric and magnetic ordering are simultaneously present at room temperature. Here, we investigate energetics of the intrinsic defects *h*-LuFeO<sub>3</sub> using the first-principles supercell approach in the dilute limit. We find the possibility of intermixing, i.e., Lu replacing Fe when *h*-LuFeO<sub>3</sub> is grown at the Lu rich conditions, and Fe replacing Lu when this compound is grown at the Fe rich conditions. In addition, our calculations predict the formation of a large number of oxygen vacancies when *h*-LuFeO<sub>3</sub> is grown in the reducing conditions. We find that even when the concentration of oxygen vacancies is large, they do not create as much free charge as they form relatively deep localized defect states. Cation vacancies are predicted to have shallow transition levels and the large formation energy, which makes them unlikely in this compound. The electronic structure of all these defects and their effect on the magnetic and polarization properties of *h*-LuFeO<sub>3</sub> are discussed.

**5:18PM V6.00015 Magneto-electric control of toroidic moments in multiferroic LiCoPO<sub>4</sub>**, JUDIT ROMHNYI, Max Planck Institute for Solid State Research, Heisenbergstrasse 1, D-70569 Stuttgart, Germany, VILMOS KOCSIS, ISTVN KZSMRKI, Department of Physics, Budapest University of Technology and Economics, 1111 Budapest, Hungary, KARLO PENC, Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, Hungarian Academy of Sciences, P.O.B. 49, H-1525 Budapest, Hungary — In addition to the three widely known forms of ordering, elastic, electric and magnetic orders, a new so called ferrotoroidic phase has been recently observed.[1] The toroidic moment is asymmetric under both time reversal and space inversion symmetries allowing ferrotoroidic materials to exhibit intrinsic magneto-electric effect. Possibility to control magnetic properties using electric field makes such materials desirable for applications. We discuss the magneto-electric control of toroidic moments in the multiferroic material, LiCoPO<sub>4</sub>. Based on symmetry arguments we derive microscopic model for induced polarization and 'toroidization'. Using multiboson approach we investigate the experimentally observed magnon absorption spectrum following different magneto-electric poling processes. We reproduce the mono-domain ferrotoroidic state established by magneto-electric poling, as well as unconventional optical properties, such as the unidirectional light transmission, emerging in magnon spectrum of LiCoPO<sub>4</sub>. **2:30PM V7.00001 Scanning Tunneling Spectroscopy Study of Single Layer Step Edges on Si (100) Surfaces.**, XIQIAO WANG, University of Maryland-College Park, PRADEEP NAMBOODIRI, KAI LI, XIAO DENG, RICHARD SILVER, National Institute of Standard and Technology — Advanced Hydrogen lithography enables the fabrication of atomically precise donor-based quantum devices on Si(100) surfaces. Understanding the defect and step edge interaction with local electronic and geometric structures is needed to properly interpret device measurement results. Low temperature Si epitaxy, used to encapsulate devices, introduces island growth and step edges near/above buried donor nanostructures, presenting a real challenge in relocating and characterizing buried donor devices using Scanning Tunneling Microscopy/Spectroscopy (STM/STS). We present spatially resolved STS results across single layer steps on Si(100) surfaces. While the electronic properties across SA steps were found to be very similar to that on flat terraces, we observed an edge induced gap state on rebonded SB step edges, which was assigned to the unpaired dangling bond state at the lower edge atom of the rebonded SB steps. In addition, we used computational simulation within Bardeen's formalism to probe the influence of subsurface doping density profiles on the observed STS features over step edges and other defects. This study will help to elucidate the role played by surface step edges and subsurface doping densities in characterizing surface and subsurface nanostructures using STS/STM.

**2:42PM V7.00002 Structural and electrical properties of silicon hyperdoped with gold**, JAY MATH-EWS, Department of Physics, University of Dayton, YINING LIU, Electro-Optics Program, University of Dayton, GIRISH MALLADI, HARRY EFSTATHIADIS, SUNY Polytechnic Institute, JEFFREY WARRENDER, US Army ARDEC-Bent Labs — Recent advances in the field of laser hyperdoping have produced a new class of materials that could lead the way to silicon-based, CMOS-compatible infrared detectors. Using the method of ion implantation followed by pulsed laser melting (II-PLM), silicon films with impurities at concentrations well above the solid solubility limit can be fabricated. Recent work has centered around Si:Au, from which prototype IR detectors have been successfully fabricated, but there are still many questions about the structural, electrical, and optical properties of this material. In order to enhance the infrared absorption and achieve high-efficiency devices, a thorough understanding of these properties is necessary, and the processes for device fabrication must be optimized. In this work, we explore the structural and electrical properties of Si:Au hyperdoped films. Si:Au films were annealed at various temperatures, and RBS channeling was used to measure the fraction of Au atoms sitting at substitutional sites. Additionally, transmission line method (TLM) and van der Pauw (VDP) test structures were fabricated in order to investigate formation of Ohmic contacts on the hyperdoped films and to study the electrical properties of Si:Au.

**2:54PM V7.00003 Intersubband scattering in modulation-doped Si two-dimensional electron gases**, YI-HSIN SU, JIUN-YUN LI, Graduate Institute of Electronic Engineering, National Taiwan University, Taipei, Taiwan, LEONID ROKHINSON, Department of Physics, Purdue University, West Lafayette, IN, USA, JAMES STURM, Department of Electrical Engineering, Princeton University, Princeton, NJ, USA — A bilayer of modulation doped two-dimensional electron gas (2DEG) is of great interest to probe Coulomb drag. For bottom-doped Si 2DEGs, impurity scattering due to poor phosphorus (P) turn-off results in low carrier mobility. Here we demonstrate a record-high electron mobility of 470,000 cm<sup>2</sup>/V-s at 0.3 K in a bottom-doped 2DEG, comparable to that in top-doped structures. The power-law exponent of mobility vs. density was also evaluated for different P turn-off slopes. With fast turn-off, the power is 1.5, indicative of dominant remote doping scattering. The power decreases with slower P turn-off due to the enhanced scattering from the segregated P atoms. Further, for the first time, we report the second subband occupancy and intersubband scattering in a single Si quantum well, supported by the Shubnikov-de Haas oscillation data.

**3:06PM V7.00004 Extending silicon's infrared response through laser hyperdoping with gold**, JEFFREY WARRENDER, QUENTIN HUDSPETH, US Army ARDEC-Benet Laboratories, HARRY EFSTATHIADIS, SUNY-Polytechnic Institute, ELIF ERTEKIN, University of Illinois at Urbana-Champaign, JAY MATHEWS, University of Dayton — Pulsed laser melting of silicon ion-implanted with gold has recently been shown to form a highly crystalline layer with a significantly greater-than-equilibrium gold concentration.[1] Rudimentary devices made with such a laser-doped layer exhibit device response at room temperature under illumination by infrared photons with wavelengths out to 2200 nm.[2] The external quantum efficiency in the infrared is approximately  $10^{-4}$ . In this presentation, we will describe efforts to increase the quantum efficiency and avert the high cost and time of ion implantation. We study the effect of varying the gold implantation dose on the resultant gold concentration in the layer and the optoelectronic properties of the layer. Additionally, we show that an alternative approach to incorporating the gold, through deposition of a thin gold layer onto the silicon surface prior to laser melting, achieves gold concentrations comparable to those achievable by ion implantation, approximately  $2 \times 10^{19}$  atoms per cubic centimeter. We perform optoelectronic measurements on layers fabricated in this way and compare to the results obtained when using the preparation method detailed in [1] and [2]. [1] Recht *et al.*, *J. Appl. Phys.* **114**, 124903 (2013) [2]Mailoa *et al.*, *Nature Communications* **5**, 3011 (2014)

**3:18PM V7.00005 Theoretical interpretation of donor wavefunctions STM images in silicon<sup>1</sup>**, BELITA KOILLER, A. L. SARAIVA, RODRIGO B. CAPAZ, Instituto de Física, Universidade Federal do Rio de Janeiro, Brazil, M.J. CALDERÓN, ICMM-CSIC, Madrid, Spain, J. SALFI, B. VOISIN, J. BOCQUEL, S. ROGGE, Centre for Quantum Computation and Communication Technology, Sydney, Australia — Single dopant wavefunctions in Si have recently been probed by scanning tunneling spectroscopy, revealing localized patterns of resonantly enhanced tunneling currents. We show that the shapes of the conducting splotches resemble cuts through Kohn-Luttinger (KL) hydrogenic envelopes, which modulate the interfering Bloch states of conduction electrons. All the non-monotonic features of the current profile are consistent with the charge density fluctuations observed between successive {001} atomic planes, including a counter-intuitive reduction of the symmetry – a heritage of the lowered point group symmetry at these planes. A model-independent analysis of the diffraction figure constrains the value of the electron wavevector to  $k_0 = (0.82 \pm 0.03)(2\pi/a_{\text{Si}})$ . Unlike prior measurements, averaged over a sizeable density of electrons, this estimate is obtained directly from isolated electrons. We further investigate the model-specific anisotropy of the wave function envelope, related to the effective mass anisotropy. This anisotropy appears in the KL variational wave function envelope as the ratio between Bohr radii  $b/a$ .

**3:30PM V7.00006 Interstitial Functionalization in elemental Si**, BORIS KIEFER, EDWIN FOHTUNG, New Mexico State University — Societies in the 21<sup>st</sup> century will face many challenges. Materials science and materials design will be essential to address and master some if not all of these challenges. Semiconductors are among the most important technological material classes. Properties such as electrical transport are strongly affected by defects and a central goal continues to be the reduction of defect densities as much as possible in these compounds. Here we present results of interstitial Fe doping in elemental Si using first-principles DFT calculations. The preliminary results show that Fe will only occupy octahedral interstitial sites. The analysis of the electronic structure shows that the compounds are ferromagnetic and that a bandgap opens as interstitial Fe concentrations decrease, with a possible intermittent semi-metallic phase. The formation energy for interstitial Fe is unfavorable, as expected, by ~1.5 eV but becomes favorable as the chemical potential of Fe increases. Therefore, we expect that biasing the system with an external electrical field will lead to the formation of these materials. Thus, our results show that interstitial defects can be beneficial for the design of functionalities that differ significantly from those of the host material.

**3:42PM V7.00007 Isolation of dangling bond states on Si(100) surfaces for quantum information applications**, PETER SCHERPELZ, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Hydrogen resist lithography allows dangling bonds to be created and manipulated on Si(100) surfaces, both for use as a controlled quantum system, and as a step in the deterministic placement of dopants at the single-atom level. However, previous experiments and computations [1] have shown conflicting results on the location of dangling bond energy levels, which can impact their utility as qubits. Here we use large-scale density functional theory and many-body perturbation theory (GW) calculations to show that in clean, H-passivated Si(100)-(2x1) surfaces a singly-occupied dangling bond does not give rise to an electronic state isolated from the valence bands. However, very thin (1-3 nm) samples terminated by a (100) surface should provide isolated singly-occupied and doubly-occupied dangling bond states. We also explore the effect of strain, and consider novel uses of boron dopants. [1] See e.g. Bellec *et al.* *Phys. Rev. B* (2013), Ye *et al.* *Surf. Sci.* (2013), Schofield *et al.* *Nat. Commun.* (2013), Wieferink *et al.* *Phys. Rev. B* (2010).

**3:54PM V7.00008 Hybrid functional calculations of Copper impurities and related complexes in Silicon**, ABHISHEK SHARAN, Department of Physics and Astronomy, University of Delaware, Newark DE 19716, ZHIGANG GUI, ANDERSON JANOTTI, Materials Science and Engineering, University of Delaware, Newark DE 19716 — Copper impurities affect electronic and optical properties of semiconductors. Cu is an ubiquitous impurity and can be introduced unintentionally during various processing step. In silicon, the fast-diffusing interstitial Cu donor often passivates shallow-acceptor dopants, affecting the electronic characteristics of devices, while deep levels associated with other forms of the Cu impurity degrade device performance. Here we revisit the problem of the Cu impurity in Si using first principles calculation based on a hybrid functional. We discuss the relative stability of the substitutional and interstitial forms, as well as the formation of complexes with hydrogen and oxygen impurities. The results of our calculations will be compared with recent experiments on the electrical activity of Cu impurities in Si.

**4:06PM V7.00009 Impurity distribution in high purity germanium crystal and its impact on the detector performance.**, GUOJIAN WANG, Department of Physics, University of South Dakota, MARK AMMAN, Ernest Orlando Lawrence Berkeley National Laboratory, University of California, HAO MEI, DONGMING MEI, Department of Physics, University of South Dakota, KLAUS IRMSCHER, Leibniz Institute for Crystal Growth, YUTONG GUAN, GANG YANG, Department of Physics, University of South Dakota — High-purity germanium crystals were grown in a hydrogen atmosphere using the Czochralski method. The axial and radial distributions of impurities in the crystals were measured by Hall effect and Photo-thermal ionization spectroscopy (PTIS). Amorphous semiconductor contacts were deposited on the germanium crystals to make detectors. Three planar detectors were fabricated from three crystals with different net carrier concentrations (1.7, 7.9 and  $10 \times 10^{10} \text{ cm}^{-3}$ ). We evaluated the electrical and spectral performance of three detectors. Measurements of gamma-ray spectra from <sup>137</sup>Cs, <sup>241</sup>Am and <sup>60</sup>Co sources demonstrate that the detectors have excellent energy resolution. The relationship between the impurities and detector's energy resolution was analyzed. Keywords: High-purity germanium crystal, High-purity germanium detector This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota..

**4:18PM V7.00010 Interface effects on acceptor silicon qubits<sup>1</sup>**, JOSE CARLOS ABADILLO-URIEL, MARIA JOSE CALDERON, CSIC - Madrid — Recently, proposals of acceptor-based qubits have drawn considerable attention due to the long range strong dipolar inter-qubit coupling and the possibility of exploiting the spin-orbit interaction to couple spins to phonons or oscillating electric fields. Dopant-based quantum computing implementations often require the dopants to be situated close to an interface to facilitate qubit manipulation with local gates. Interfaces not only modify the energies of the bound states but also affect their symmetry. Making use of the successful effective mass theory we study the energy spectra of acceptors in Si or Ge taking into account the quantum confinement, the dielectric mismatch and the central cell effects. The presence of an interface puts constraints to the allowed symmetries and leads to the splitting of the bulk four-fold degenerate ground state in two Kramers doublets. We show that, as the acceptor gets closer to the interface, the entire spectrum is compressed. Inversion symmetry breaking also implies parity mixing which affects the allowed optical transitions. Consequences for acceptor qubits are discussed.

**4:30PM V7.00011 Quantum states of interacting point defects in silicon**, STEVEN SCHOFIELD, HOLLY HEDGELAND, MANUEL SIEGL, DAVID BOWLER, University College London — We investigate point defect induced quantum states on silicon surfaces using low temperature scanning tunneling microscopy and spectroscopy (STM/STS). We compare defect states produced at missing H atom sites on the Si(001):H monohydride surface and those formed at boron deficient sites of the B-saturated Si(111):B- $\sqrt{3} \times \sqrt{3}R30^\circ$  surface. We find good agreement between measured differential conductance and first principles calculations of the states. Furthermore we explore the interaction of pairs of defects in a range of varying close proximity arrangements and find non-linear interference between the laterally extended excited states of the point defects. The results support the interpretation of interacting excited states as we have presented previously [Nature Communications 4 (2013) 1649].

**4:42PM V7.00012 Quantum Point Contacts and Valley Filters on a 6-fold Degenerate Hydrogen-terminated Si(111) Surface**, LUKE D. ROBERTSON, U. of Maryland, BINHUI HU, NIST Gaithersburg, B. E. KANE, U. of Maryland — Hydrogen-terminated Si(111) surfaces preserve the 6-fold valley degeneracy and anisotropic electron mass predicted in bulk Si, providing a unique environment for 2-D electron systems (2DESs). Our group has demonstrated high mobility as well as the fractional quantum Hall effect for electrons confined on the Si(111) surfaces, establishing evidence that they are ideal platforms for 2DESs and lower dimensional systems. Recently, we have succeeded in fabricating high mobility ambipolar devices and have found that heavily p-doped regions can be used as lateral depletion gates for confinement of 2DESs induced by a top gate [1]. Here, we describe our efforts to extend this technology to the nanoscale and in particular towards the fabrication of quantum point contacts (QPCs). QPCs realized in materials with anisotropic electron mass may exhibit valley filter phenomena [2] leading to extreme sensitivity to single donor occupancy, and thus are of interest to measurement schemes for donor-based quantum information processing. Preliminary measurements and fabrication techniques will be discussed. [1] B. Hu, et al, arXiv, 1509.03849 (2015) [2] Gunawan et al, Phys. Rev. B, 74, 155436 (2006)

**4:54PM V7.00013 Electron spin resonance and relaxation of defects and donors in Silicon Nanowires**, MARCO FANCIULLI, University of Milano Bicocca, Department of Materials Science, MATTEO BELLI, Laboratorio MDM, IMM-CNR, STEFANO PALEARI, ANTONIO PIZIO, University of Milano Bicocca, Department of Materials Science — The current status of the investigation of defects in silicon nanowires and at the interface between the group IV semiconductor and its oxide in 1D nanostructures is reviewed and discussed. The paper concentrates on nanowires produced by metal assisted chemical etching. Donors (such as P and As) and defects at the interface between the semiconductor and its oxide (namely, the Pb centers) are investigated by continuous wave (CW) and pulsed Electron Paramagnetic Resonance (pEPR). The role in the de-activation mechanism of donors played by hydrogen and Pb centers is discussed. The characteristic times, the spin-lattice T1 and spin-spin T2, of the Pb centers are also reported in this study. Their behavior as a function of the temperature is addressed in the framework of Two-Level-Systems. TLS are usually invoked wherever there is a disordered system, which in the case of Pb centers is represented by the amorphous oxide side. The model includes a low- and a high-temperature regime. It is worth noticing that bulk techniques such as CW and pEPR are applied to surface defects thanks to the enhanced surface-to-volume ratio. The results of the present investigation highlight a possible issue for the exploitation of nanostructures in fields like spin-based quantum computing, i.e. the spin-lattice relaxation and the decoherence induced by the TLS in the Pb centers.

**2:30PM V8.00001 Evidence for a  $\pi$ -junction in Nb/F/Nb' trilayers from superfluid density measurements<sup>1</sup>**, THOMAS LEMBERGER, MICHAEL HINTON, STANLEY STEERS, BRYAN PETERS, FENGYUAN YANG, The Ohio State University — Two-coil measurements of the sheet superfluid density of Nb/NiV/Nb' trilayers reveal the transition temperatures and volume superfluid densities of both Nb layers, as functions of the thickness,  $d_F$ , of the intervening ferromagnetic (F) Ni<sub>0.96</sub>V<sub>0.04</sub> layer. The upper transition occurs when the thicker Nb layer goes superconducting and superfluid first appears. Fitting the high-temperature superfluid density to an appropriate functional form reveals the presence of a lower "transition" where additional superfluid appears. This event is really a crossover, but the difference is irrelevant here. There is a surprising minimum in superfluid densities of both Nb layers at  $d_F \approx 30$  Å, followed by a slow rise. This behavior suggests that a  $\pi$  phase difference between the Nb layers develops at  $d_F \approx 30$  Å and continues to larger F thickness.

**2:42PM V8.00002 Checking for odd-triplet pairing using novel superconducting spin valves<sup>1</sup>**, PAVEL N. LAPA, Argonne National Laboratory, Texas A&M University, TRUPTI KHAIRE, JUNJIA DING, JOHN E. PEARSON, VALENTYN NOVOSAD, AXEL HOFFMANN, J.S. JIANG, Argonne National Laboratory — An excitation of odd-triplet pairing in a superconducting spin valve can be revealed by measuring the dependence of the superconducting critical temperature  $T_c$  with increasing non-collinearity of the magnetizations in adjacent ferromagnetic layers. A standard approach to create such a non-collinear magnetization configuration is to pin one ferromagnetic layer and control the magnetization in another layer by rotating the multilayer in a small magnetic field. Unfortunately, the rotation can modify the vortex current which also strongly affects the critical temperature. To exclude such spurious effects, we designed and fabricated a novel superconducting spin valve which allows us to create non-collinear magnetization configurations without using a sample rotator. The valve's operational principle is based on pinning of a synthetic antiferromagnet (SAF) by exchange coupling it to FeMn layer. The ability to imprint non-collinear magnetization configurations in the spin valve was confirmed using giant magnetoresistance (GMR) measurements. The response of the magnetizations on an external magnetic field was simulated based on a coherent rotation model. The dependence of the Nb layer  $T_c$  on imprinted magnetization configuration will be presented.

**2:54PM V8.00003 Colossal Triplet Spin-Valve Effect in Heterostructures containing 100% Spin Polarised  $\text{Fe}_{0.8}\text{Co}_{0.2}\text{Si}^1$** , GAVIN BURNELL, NATHAN SATCHELL, BENJAMIN STEELE, PRIYASMITA SINHA, CHRISTOPHER MARROWS, School of Physics and Astronomy, University of Leeds, SEAN LANGRIDGE, ISIS Neutron and Muon Source, STFC Rutherford Appleton Laboratory, UK EPSRC SUPERCONDUCTING FERROMAGNETIC METAMATERIAL CONSORTIUM COLLABORATION — At the interface between a superconductor (S) and ferromagnet (F), an inhomogeneity can convert singlet Cooper pairs into the (spin aligned) long ranged triplet component (LRTC). Manipulation of the LRTC forms the basis of the emerging field of super-spintronics. The prototypical device in this field is the superconducting spin valve (SSV), where LRTC generation can be controlled by the relative orientation of two F layers in a heterostructure. This generation is accompanied by an observed suppression in the superconductors critical temperature ( $T_c$ ). Motivated by a recent report of colossal proximity effects in a  $F_1/F_2/S$  SSV containing 100% spin polarized  $\text{CrO}_2$  as the bottom drainage layer<sup>2</sup>, we explore the possibility of using highly spin polarized,  $\text{Fe}_{0.8}\text{Co}_{0.2}\text{Si}$  as  $F_1$ . The observed  $T_c$  suppression of 830 mK is nearly an order of magnitude larger than previous studies using standard F layers with Nb, and is consistent with that seen in  $\text{CrO}_2$ . Our results confirm the special importance of high spin polarization in the formation of the LRTC, and we offer the field a new material as a fundamental building block for incorporation into future super-spintronic devices.

**3:06PM V8.00004 Remote Induced Magnetism in a Normal Metal coupled to a Superconductor/Ferromagnet Heterostructure**, NATHAN SATCHELL, University of Leeds, MACHIEL G. FLOKSTRA, University of St Andrews, JANGYONG KIM, GAVIN BURNELL, University of Leeds, PETER J. CURRAN, SIMON J. BENDING, University of Bath, JOSHANIEL F. K. COOPER, CHRISTY J. KINANE, SEAN LANGRIDGE, ISIS Neutron and Muon Source, ALDO ISIDORI, MATTHIAS ESCHRIG, NATALIA PUGACH, Royal Holloway, HUBERTUS LUETKENS, ANDREAS SUTER, THOMAS PROKSCHA, Paul Scherrer Institut, STEPHEN L. LEE, University of St Andrews, SFM CONSORTIUM COLLABORATION — Integrating superconductors (S) into ferromagnetic (F) heterostructures has revealed a rich area of novel physics and led to the development of superconducting spintronics. Of particular interest is the prototypical device, the S spin valve. In this work we use neutron and muon techniques to study the local magnetic profile in such a device, looking for an induced magnetism expected at the S/F interface. Instead we observe an additional unexpected moment arising neither in the S nor F layers, but in the normal metal cap<sup>1</sup>. The magnetisation is always antiparallel to the direction of an applied field (to align the F layers) and appears at the onset of superconductivity, increasing in strength with decreasing temperature. The profile of this induced moment is inconsistent with any known or predicted phenomena. What is particularly remarkable is that there is no applied current or temperature gradients meaning the effect manifests in equilibrium.

**3:18PM V8.00005 Controlling superconducting spin flow with a single homogeneous ferromagnet: interference, torque and spin-flip immunity<sup>1</sup>**, SOL JACOBSEN, IRYNA KULAGINA, JACOB LINDER, Norwegian University of Science and Technology (NTNU) — Superconducting spintronics has the potential to overcome the Joule heating and short decay lengths of electron transport by harnessing the dissipationless spin currents of superconductors in thin-film devices. Using conventional singlet superconductive sources, such dissipationless currents have only been demonstrated experimentally using intricate magnetically inhomogeneous multilayers, which can be difficult to construct, control and measure. Here we present analytic and numerical results proving the possibility of both generating and controlling a long-ranged spin supercurrent using only one single homogeneous magnetic element (arXiv:1510.02488). The spin supercurrent generated in this way does not decay spatially, in stark contrast to normal spin currents that remain polarized only up to the spin relaxation length. Through a novel interference term between long-ranged and short-ranged Cooper pairs, we expose the existence of a superconductivity-mediated torque even without magnetic inhomogeneities, showing that the different components of the spin supercurrent polarization respond fundamentally differently to a change in the superconducting phase difference. This establishes a mechanism for tuning dissipationless spin and charge flow separately via superconductors.

**3:30PM V8.00006 Field-History Dependence of the Superconducting Transition Temperature in Erbium/Niobium Bilayers**, JAMES WITT, NATHAN SATCHELL, University of Leeds, SEAN LANGRIDGE, STFC, GAVIN BURNELL, University of Leeds — Recently, there has been much interest in a new class of superconducting (S) spintronic devices based upon hybrid S/F (ferromagnet) heterostructures. The prototypical super-spintronic device is the superconducting spin valve (SSV), within which the critical temperature ( $T_c$ ) of an S layer can be controlled by the relative orientation of two or more F layers. Such manipulation of the F layers requires careful engineering of the heterostructure and the rotation of the structure with respect to an applied magnetic field. Here, we show that such control over  $T_c$  is also possible in a simple S/F bilayer. By manipulating the remanent magnetic state of a thin Er layer — which is proximity coupled to a Nb S layer — we are able to demonstrate a high level of control over the  $T_c$  of the Nb (which is measured in zero field). The shifts in  $T_c$  are comparable in size to the largest seen in the SSV and are manipulated using solely the field history. The system can be reset by warming the sample through the Er Curie temperature (approximately 20 K). Our results are of particular interest due to the simplicity of both the bilayer and the measurement geometry in comparison to the SSV.

**3:42PM V8.00007 Conductance spectroscopy of topological superconductor wire junctions<sup>1</sup>**, F. SETIAWAN, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park, PHILIP BRYDON, University of Maryland College Park and University of Otago, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We study the zero-temperature transport properties of one-dimensional normal metal-superconductor (NS) junctions with topological superconductors across their topological transitions. Working within the Blonder-Tinkham-Klapwijk (BTK) formalism generalized for topological NS junctions, we analytically calculate the differential conductance for tunneling into two models of a topological superconductor: a spinless intrinsic  $p$ -wave superconductor and a spin-orbit-coupled  $s$ -wave superconductor in a Zeeman field. The zero-bias conductance takes nonuniversal values in the nontopological phase while it is robustly quantized at  $2e^2/h$  in the topological regime. Despite this quantization at zero voltage, the zero-bias conductance only develops a peak (or a local maximum) as a function of voltage for sufficiently large interfacial barrier strength, or certain parameter regimes of spin-orbit coupling strength. Our calculated BTK conductance also shows that the conductance is finite inside the superconducting gap region because of the finite barrier transparency, providing a possible mechanism for the observed soft gap feature in the experimental studies.

**3:54PM V8.00008 Detecting a quantum critical point in topological SN junctions<sup>1</sup>**, YASHAR KOMIJANI, Rutgers University, IAN AFFLECK, University of British Columbia — A spin-orbit coupled quantum wire, with one end proximate to an s-wave superconductor, can become a topological superconductor, with a Majorana mode localized at each end of the superconducting region. It was recently shown that coupling one end of such a topological superconductor to two normal channels of interacting electrons leads to a novel type of frustration and a quantum critical point when both channels couple with equal strength. We propose an experimental method to access this critical point in a single quantum wire and show its resilience to disorder.

<sup>1</sup>This research was supported in part by NSERC, CIFAR and the Swiss National Science Foundation.

**4:06PM V8.00009 On correlation between zero bias conductance peaks and topological invariants in semiconductor Rashba nanowires<sup>1</sup>**, AMIT NAG, Condensed Matter Theory Center, Department of Physics, Univ of Maryland-College Park, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, Univ of Maryland-College Park — The observed zero bias peak in tunneling conductance experiments on semiconductor Rashba nanowire is a signature of presence of Majorana zero modes. Characteristics of zero bias conductance peak (ZBCP) namely, height, width and peak splitting, are a function of microscopic parameters. Zero modes have finite splitting as a result of finiteness of the nanowire rendering the ground state only approximately topological i.e. zero modes are only approximately Majoranas. We calculate the scattering matrix topological invariant to quantify the quality of approximate Majorana modes and study its relation to observed characteristics of ZBCP. Furthermore we study the effect of dephasing on the topological invariant. Finally, we draw connection between the characteristics of the ZBCP and probability of observing non-Abelian statistics in proposed future experiments involving braiding of Majorana modes.

**4:18PM V8.00010 ABSTRACT WITHDRAWN —**

**4:30PM V8.00011 SPT 2-Channel Kondo Model in the Structure of Normal Metal/Quantum Dot/**DIII**-class Topological Superconductor**, WEI-JIANG GONG, university of texas at dallas, ZHEN GAO, north-eastern university, China — We investigate the Kondo effect in a structure which is constructed by embedding one quantum dot between a normal metal and a **DIII**-class topological superconductor supporting Majorana doublets at its ends. It is observed that Kondo correlation occurs between the localized state in the dot and two continuum states simultaneously, i.e., the continuum state in the metal and the continuum Andreev reflection state between the metal and topological superconductor. As a result, the Kondo model Hamiltonian is topologically protected by the  $SU(2) \times Z_2 T$  symmetry. More interestingly, two new Kondo temperatures appear in this system, in comparison with the normal Kondo model. This phenomenon exactly reflects the special role of Majorana doublet in tuning the Kondo effect.

**4:42PM V8.00012 Controlling the critical temperature of superconducting hybrid structures with spin-orbit coupling**, JABIR ALI OUASSOU, SOL JACOBSEN, JACOB LINDER, NTNU — Based on our recent publication Phys. Rev. B **92** 024510 (2015), we present theoretical predictions for the effect of spin-orbit coupling on the critical temperature of superconductor/ferromagnet bilayers. More specifically, we consider mesoscopic diffusive bilayers where the ferromagnet has (i) pure Rashba coupling and (ii) Rashba–Dresselhaus coupling, and show that one can achieve a superconducting spin-valve effect in both of these structures. Furthermore, it is shown that if the Rashba and Dresselhaus coupling have similar magnitudes, the critical temperature of the bilayer can change with over 35 percent as the in-plane magnetization is rotated by 90 degrees. In contrast to existing designs for superconducting spin-valves which require inhomogeneous magnetization, such as having multiple layers with noncollinear magnetizations, the critical temperature in our proposed setup is tunable with one single homogeneous ferromagnet. Thus, these results highlight a new way to exert control over superconductivity in proximity structures, which may prove easier to manufacture and control than the existing designs.

**Session V11 DMP GERA FIAP: Thermoelectrics: McGroddy Prize and Novel Materials** 307 - Eric Toberer, Colorado School of Mines

**2:30PM V11.00001 James C. McGroddy Prize for New Materials Talk: From discovery to design of new materials**, MERCOURI G. KANATZIDIS, Northwestern Univ — The design and discovery of new materials and their crystal growth is critical for continued scientific and technological progress far into the future. It is also a fundamental goal of condensed matter science. We have been developing the chemistry of novel chalcogenide and intermetallic materials which define a remarkably broad set of structurally diverse compounds, associated with a wide range of physical properties and impacting a variety of physics and materials science issues. In contrast to solid-state methods, materials syntheses in liquid fluxes permit crystallization at lower temperatures due to facile diffusion and possible chemical reactions with the flux itself. These reactions can produce a wide range of materials, often metastable such as oxides, chalcogenides and intermetallics, but typically the formation paths are obscure or poorly understood. In this talk I will describe how we observe, understand, and engineer the formation of compounds from inorganic melts and an approach we call panoramic synthesis. I will also highlight some of our recent results on the discovery of remarkable materials and crystal structures and how they can be leveraged for achieving unusual or enhanced properties of interest in a variety of fields such as thermoelectrics,  $\gamma$  ray detection, superconductivity, topological properties, nonlinear optics, etc.

**3:06PM V11.00002 Thermoelectric Properties of Cd Based Zintl Phase Compounds**, ABHISHEK SINGH, TRIBHUWAN PANDEY, Indian Institute of Science — Zintl phase compounds can be described as covalently-bonded anion substructures surrounded by highly electro-positive cations exhibiting essential features for thermoelectric applications. By combining first principles electronic structure and Boltzmann transport theory, here we report excellent thermoelectric properties of CdSb and  $ACd_2Sb_2$  (where, A = Ca, Ba, Sr). The electronic structure shows heavy and light bands near the band edges, which lead to large power factor resulting in good thermoelectric performance. We also calculate lattice thermal conductivity by solving Boltzmann Transport equation using an iterative method. The large Grüneisen parameters and low phonon group velocity indicate strong anharmonicity in these compounds, which results in low lattice thermal conductivity. The low thermal conductivity and the excellent transport properties lead to a high ZT value of 1.9 in  $CaCd_2Sb_2$  and  $BaCd_2Sb_2$  at moderate p and n-type doping. These results indicate that well optimized Cd based Zintl phase compounds have a potential to match the performance of conventional thermoelectric materials.

**3:18PM V11.00003 Impact of electron doping on structure and dynamics of synthetic tetrahedrite<sup>1</sup>**, JENNIFER L. NIEDZIELA, ANDREW F. MAY, MICHAEL A. MCGUIRE, Oak Ridge National Laboratory, Materials Science Division, DOUGLAS L. ABERNATHY, Oak Ridge National Laboratory, Quantum Condensed Matter Division, MELANIE J. KIRKHAM, Oak Ridge National Laboratory, Instrument and Source Division, EDGAR LARA-CURZIO, OLIVIER DELAIRE, Oak Ridge National Laboratory, Materials Science Division — Microscopic control of lattice thermal conductivity is critical to the development of thermoelectric materials. One route to this control is manipulation of anharmonic lattice dynamics with chemical doping. Tetrahedrite compounds, which display an intrinsic lattice anharmonicity, are promising candidates for thermoelectric application, and here we present results of neutron scattering studies on synthetic  $\text{Cu}_{12-x}\text{Zn}_x\text{Sb}_4\text{S}_{13}$ , ( $x = 0, 2$ ). The undoped compound exhibits a structural phase transition associated with a metal-insulator transition near 88 K. Doping with Zn results in the stabilization of the structure, and enhancement of a low energy vibrational mode associated with incoherent oscillations of Cu. The low energy mode is localized, and exhibits pronounced softening with temperature. The ability to tune the location of this low-energy mode with doping may provide a means to enhance the phonon-phonon scattering that leads to low thermal conductivity in these materials, and a corresponding enhancement of the thermoelectric properties.

**3:30PM V11.00004 Spectroscopic evidence for temperature dependent relative movement of light and heavy hole valence bands of PbQ (Q=Te,Se,S)**, UTPAL CHATTERJEE, JUNJING ZHAO, University of Virginia, MERCOURI KANATZIDIS, CHRISTOS MALLIAKAS, Northwestern University — We have conducted temperature dependent Angle Resolved Photoemission Spectroscopy (ARPES) studies of the electronic structures of PbTe, PbSe and PbS. Our ARPES measurements provide direct evidences for the light hole upper valence bands (UVBs) and the so-called heavy hole lower valence bands (LVBs), and an unusual temperature dependent relative movement between their band maxima leading to a monotonic decrease in the energy separation between LVBs and UVBs with increase in temperature. This enables convergence of these valence bands and consequently an effective increase in the valley degeneracy in PbQ at higher temperatures, which has long been believed to be the driving factor behind their extraordinary thermoelectric performance.

**3:42PM V11.00005  $p \times n$ -Transverse Thermoelectrics: Single leg thermoelectrics with scalable integration and cryogenic promise<sup>1</sup>**, M. GRAYSON, Northwestern University — Under the  $p \times n$  type transverse thermoelectric paradigm electrons dominate conduction in one direction and holes dominate perpendicularly, allowing electrical current to drive transverse heat flow [1]. Bulk anisotropic crystals, superlattices, and nanowire arrays have all been previously proposed as viable  $p \times n$  materials. This talk will describe the general philosophy behind  $p \times n$ -type transverse thermoelectrics as well as the tensor equations that define their anisotropic Seebeck effect. The advantages of single-leg thermoelectric devices – available only to transverse thermoelectrics – are detailed. Various device geometries are discussed which take advantage of the single-leg nature, in particular to provide advantages for cryogenic thermoelectric cooling and integrated thermal management. **4:18PM V11.00006 Copper Selenide Nanocrystals as a High Performance, Solution Processed Thermoelectric Material**, JASON FORSTER, Lawrence Berkeley National Lab, JARED LYNCH, Nanosys, NELSON COATES, California Maritime Academy, AYASKANTA SAHU, Lawrence Berkeley National Lab, JUN LIU, North Carolina State University, DAVID CAHILL, University of Illinois at Urbana Champaign, JEFF URBAN, Lawrence Berkeley National Lab — Nano-structuring a thermoelectric material often results in enhanced performance due to a decrease in the materials thermal conductivity. Traditional nano-structuring techniques involve ball milling a bulk material followed by spark plasma sintering, a very energy intensive process. In this talk, we will describe the development of a self-assembled, high-performing, nano-structured thin film based on copper selenide nanocrystals. Mild thermal annealing of these films results in concurrent increases in the Seebeck coefficient and electrical conductivity. We are able to achieve power factors at room temperature that are as high as the best spark plasma sintered materials. These solution-processed films have potential applications as conformal, flexible materials for thermoelectric power generation.

**4:30PM V11.00007 NMR and specific heat study of atomic dynamics and spin-orbit behavior in  $\text{Cu}_{2-x}\text{Ag}_x\text{Te}$** , ALI A. SIRUSI, Texas AM University, SEDAT BALLIKAYA, University of Istanbul, JING-HAN CHEN, Texas AM University, CTIRAD UHER, University of Michigan, JOSEPH H. ROSS, JR., Texas AM University — We report studies of  $\text{Cu}_2\text{Te}$  and  $\text{Cu}_{2-x}\text{Ag}_x\text{Te}$ , promising candidates for thermoelectric and photovoltaic applications. Cu and Te NMR show that above a well-defined 200 K onset,  $\text{Cu}_2\text{Te}$  exhibits Cu-ion hopping, leading to the higher-temperature superionic motion. In  $\text{Cu}_{1.98}\text{Ag}_{0.2}\text{Te}$  the onset increases to 250 K. In the low-temperature static phase the properties are nearly identical. Aside from Korringa terms there are large diamagnetic contributions for all nuclei, comparable to those for other systems with very large spin-orbit and/or inverted band configurations. Thus the system may be a topologically interesting system like the similar phase  $\text{Ag}_2\text{Te}$ . Results will be compared to DFT calculations of NMR shifts. The low-temperature spectra also indicate two distinct local environments for Cu sites, one corresponding to high symmetry such as characterizes the high-temperature cubic phase, and one with much more asymmetry. In addition, specific heat results are consistent with about 50% of the Cu ions being weakly bound on Einstein-oscillator sites. We tentatively connect these results to reported local inhomogeneity due to vacancy condensation in similar systems.

**4:42PM V11.00008 Thermoelectric Properties of CuAgSe doped with Co, Cr.<sup>1</sup>**, PETER CZAJKA, MENGJIANG YAO, CYRIL OPEIL, Department of Physics, Boston College — Thermoelectric materials represent one way that reliable cooling below the boiling point of nitrogen can be realized. Current materials do not exhibit sufficiently high efficiencies at cryogenic temperatures, but significant progress is being made. One material that has generated significant interest recently is CuAgSe. It has been demonstrated (Ishiwata et al., Nature Mater. 2013) that doping CuAgSe with 10% Ni at the Cu sites increases the material's thermoelectric figure of merit (ZT) at 100 K from 0.02 to 0.10. This is intriguing not just because of the dramatic effect that the Ni doping produces, but also because CuAgSe is a semimetal and semimetals are not usually able to exhibit the kind of asymmetric carrier activation necessary for strong thermoelectric performance. In order to further investigate the unusual nature of thermoelectricity in CuAgSe and its strong dependence on chemical composition, we have synthesized and measured the thermoelectric properties of a series of CuAgSe samples doped with Co and Cr. Temperature-dependent magnetic and thermoelectric transport properties of CuAgSe as a function of Co and Cr doping will be discussed.

**4:54PM V11.00009 Low Temperature Thermoelectric Characterization of Ag<sub>2</sub>Se.<sup>1</sup>** , FIVOS DRYMIOTIS, DAVID NEFF, MICHAEL CONEY, SABAH BUX, JEAN-PIERRE FLEURIAL, NASA/Jet Prop Lab — Previous work on Ag<sub>2</sub>Se showed that this n-type material could have a dimensionless thermoelectric figure of merit (zT) ~1 at room temperature, due to its high mobility and low thermal conductivity. However, the results from the initial reports have not yet been reproduced. In this talk, I will summarize our efforts to replicate the aforementioned thermoelectric performance, and also discuss the experimental setup that we utilized in order to perform the low-temperature thermoelectric characterization of this material.

**5:06PM V11.00010 Molecular-Dynamics (MD) Simulations of Copper Diffusion in Copper Chalcogenides** , JING WANG, None — It was recently discovered that copper chalcogenides Cu<sub>2</sub>S and Cu<sub>2</sub>Se are viable candidates for thermoelectric materials with high figure of merit (ZT) values at temperatures around 1,000 K [1,2]. And the possible reason for the high ZT is the low thermal conductivity arising from liquid-like Cu atoms in those phases. In this work, we perform first-principles molecular dynamics simulations to study the motion of Cu atoms in the high-temperature phases of Cu<sub>2</sub>S and Cu<sub>2</sub>Se and confirm the liquid nature of Cu atoms. To get a better understanding of the diffusion patterns of the systems, we have examined all the three phases of Cu<sub>2</sub>S (monoclinic, hexagonal and cubic phases with increasing temperature). Starting from the hexagonal phase the Cu atoms show a disordered/liquid-like feature with a jump diffusion pattern. We find that the diffusion is faster in x-y directions than in the z direction. A more isotropic diffusion pattern is found for high-temperature cubic phase with a much larger diffusion coefficient.1] Y. He et al. Adv. Mater. 26, 3974 (2014) 2] H. L. Liu et al. Nat. Mater. 11, 422 (2012)

**5:18PM V11.00011 Impact of Lone-Pair Electrons on Thermal Conductivity in CuSbS<sub>2</sub> Compound<sup>1</sup>** , BAOLI DU, RUIZHI ZHANG, KAN CHEN, MICHAEL REECE, Queen Mary University of London, MATERIAL RESEARCH INSTITUTE TEAM — Compounds with intrinsically low lattice thermal conductivity are of practical importance for thermoelectric energy conversion. Recent studies suggest that s<sub>2</sub> lone pair orbital electrons are a key contributing factor to the anomalously low lattice thermal conductivity of chalcogenide compounds that contain a nominally trivalent group VA element. CuSbS<sub>2</sub> has an orthorhombic structure with space group Pnma. The pyramidal SbS<sub>5</sub> units are separated by CuS<sub>4</sub> tetrahedron so that the base of the square pyramidal units are aligned to face one another, thus directing the Sb lone pair electron density into the void separating the SbS<sub>5</sub> units. Different from tetrahedrite, all the Cu atoms are bonded in the CuS<sub>4</sub> tetrahedron. So, it has a perfect structure to study the influence of electron lone pair on thermal conductivity without the impact from trigonal coordinated Cu. In this work, the trivalent transition metal atom Fe and IIIA atom Ga without lone-pair electrons were chosen to substitute Sb in CuSbS<sub>2</sub>. The changes in the bonding environment by foreign atoms and their influences on the thermal properties have been studied and correlated.

**Session V12 FIAP: FIAP Prize Session** 308 - Barbara Jones, IBM

**2:30PM V12.00001 George E. Pake Prize: A Few Challenges in the Evolution of Semiconductor Device/Manufacturing Technology** , ROBERT DOERING, Texas Instruments, Inc. — In the early 1980s, the semiconductor industry faced the related challenges of “scaling through the one-micron barrier” and converting single-level-metal NMOS integrated circuits to multi-level-metal CMOS. Multiple advances in lithography technology and device materials/process integration led the way toward the deep-sub-micron transistors and interconnects that characterize today’s electronic chips. In the 1990s, CMOS scaling advanced at an accelerated pace enabled by rapid advances in many aspects of optical lithography. However, the industry also needed to continue the progress in manufacturing on ever-larger silicon wafers to maintain economy-of-scale trends. Simultaneously, the increasing complexity and absolute-precision requirements of manufacturing compounded the necessity for new processes, tools, and control methodologies. This talk presents a personal perspective on some of the approaches that addressed the aforementioned challenges. In particular, early work on integrating silicides, lightly-doped-drain FETs, shallow recessed isolation, and double-level metal will be discussed. In addition, some pioneering efforts in deep-UV lithography and single-wafer processing will be covered. The latter will be mainly based on results from the MMST Program – a \$100M+, 5-year R&D effort, funded by DARPA, the U.S. Air Force, and Texas Instruments, that developed a wide range of new technologies for advanced semiconductor manufacturing. The major highlight of the program was the demonstration of sub-3-day cycle time for manufacturing 350-nm CMOS integrated circuits in 1993. This was principally enabled by the development of: (1) 100% single-wafer processing, including rapid-thermal processing (RTP), and (2) computer-integrated-manufacturing (CIM), including real-time, in-situ process control.

**3:06PM V12.00002 The ”Music” of Light: Optical Resonances for Fun and Profit** , RAYMOND BEAUSOLEIL, Hewlett Packard Labs, 1501 Page Mill Rd., Palo Alto, CA 94304 — Moore’s Law has set great expectations that the performance/price ratio of commercially available semiconductor devices will continue to improve exponentially at least until the end of this decade. But the physics of the metal wires that connect the transistors on a silicon chip already places stringent limits on the performance of integrated circuits, making their continued dramatic improvement highly unlikely. In this talk, I will introduce the basic concept of an optical resonance in a microscopic dielectric cavity in the context of the same type of spatial boundary conditions that give each musical instrument its unique sound. Then I will illustrate applications of these resonances to information technology in a variety of forms and functions using examples from my own laboratory at HP, such as chip-scale optical networks, quantum bits based on spins in diamond, and ultrafast optical switches that could become the foundation for a new generation of optical computers. Our goal is to conduct advanced research that could precipitate an “optical Moore’s Law” and allow exponential performance gains to continue through the end of the next decade.

**2:30PM V13.00001 Giant thermal spin torque assisted magnetic tunnel junction switching** , AAKASH PUSHP, IBM Almaden Res Ctr — Spin-polarized charge-currents induce magnetic tunnel junction (MTJ) switching by virtue of spin-transfer-torque (STT). Recently, by taking advantage of the spin-dependent thermoelectric properties of magnetic materials, novel means of generating spin-currents from temperature gradients, and their associated thermal-spin-torques (TSTs) have been proposed, but so far these TSTs have not been large enough to influence MTJ switching. Here we demonstrate significant TSTs in MTJs by generating large temperature gradients across ultrathin MgO tunnel barriers that considerably affect the switching fields of the MTJ. We attribute the origin of the TST to an asymmetry of the tunneling conductance across the zero-bias voltage of the MTJ. Remarkably, we estimate through magneto-Seebeck voltage measurements that the charge-currents that would be generated due to the temperature gradient would give rise to STT that is a thousand times too small to account for the changes in switching fields that we observe. Reference: A. Pushp\*, T. Phung\*, C. Rettner, B. P. Hughes, S.-H. Yang, S. S. P. Parkin, 112, 6585-6590 (2015).

**3:06PM V13.00002 Picosecond Spin Caloritronics**, DAVID G. CAHILL, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — The coupling of spin and heat, i.e., spin caloritronics, gives rise to new physical phenomena in nanoscale spin devices and new ways to manipulate local magnetization. Our work in this field takes advantage of recent advances in the measurement and understanding of heat transport at the nanoscale using ultrafast lasers. We use a picosecond duration pump laser pulses as a source of heat and picosecond duration probe laser pulses to detect changes in temperature, spin accumulation, and spin transfer torque using a combination of time-domain thermoreflectance and time-resolved magneto-optic Kerr effect. Our pump-probe optical methods enable us to change the temperature of ferromagnetic layers on a picosecond time-scale and generate enormous heat fluxes on the order of  $100 \text{ GW m}^{-2}$  that persist for  $\sim 30 \text{ ps}$ . Thermally-driven ultrafast demagnetization of a perpendicular ferromagnet leads to spin accumulation in a normal metal and spin transfer torque in an in-plane ferromagnet. The data are well described by models of spin generation and transport based on differences and gradients of thermodynamic parameters. The spin-dependent Seebeck effect of a perpendicular ferromagnetic layer converts a heat current into spin current, which in turn can be used to exert a spin transfer torque (STT) on a second ferromagnetic layer with in-plane magnetization. Using a [Co,Ni] multilayer as the source of spin, an energy fluence of  $\approx 4 \text{ J m}^{-2}$  creates thermal STT sufficient to induce  $\approx 1 \%$  tilting of the magnetization of a 2 nm-thick CoFeB layer.

**3:42PM V13.00003 Ultrafast spin-transfer torque driven by femtosecond pulsed-laser excitation.**, BERT KOOPMANS, Eindhoven Univ of Tech — A hot topic in the field of ultrafast laser-induced manipulation of the magnetic state is that of the role and exploitation of laser-induced spin currents. Intense debate has been triggered by claims that such a spin-transfer, e.g. in the form of super-diffusive spin currents over tens of nanometers, might be a main contributor to the demagnetization process in ferromagnetic thin films after femtosecond laser excitation. In this presentation the underlying concepts will be introduced and recent developments reviewed. Particularly we demonstrate the possibility to apply a laser-induced *spin transfer torque* on a free magnetic layer, using a non-collinear multilayer configuration consisting of a free in-plane layer on top of a perpendicularly magnetized injection layer, as separated by a nonmagnetic spacer. Interestingly, this approach allows for a quantitative measurement of the amount of spin transfer. Moreover, it might provide access to novel device architectures in which the magnetic state is controlled by fs laser pulses. Careful analysis of the resulting precession of the free layer allows us to quantify the applied torque, and distinguish between driving mechanisms based on laser-induced transfer of hot electrons versus a spin Seebeck effect due to the large thermal gradients. Further engineering of the layered structures in order to gain fundamental understanding and optimize efficiencies will be reported. A simple model that treats local non-equilibrium magnetization dynamics to spin transport effects via a spin-dependent chemical potential will be introduced.

**4:18PM V13.00004 Magnetization dynamics under heat current in metallic spin valves and in insulators**, HAIMING YU, Beihang University — Spin caloritronics, an emerging branch of spintronics, studying the addition of thermal effects to the electrical and magnetic properties of nanostructures, has recently seen a rapid development. It has been predicted by Hatami et al. that a heat current can exert a spin torque on the magnetization in a nanostructure, analogous to the well-known spin-transfer torque induced by an electrical current. We provided the experimental evidence for the thermal spin-transfer torque effect in spin valves, showing the switching field change with heat current. I will present measurements of the second harmonic voltage response of Co-Cu-Co pseudo-spinvalves deposited in the middle of Cu nanowires. Both the magnitude of the second harmonic response of the spin valve and the field value of the maximum response are found to be dependent on the heat current. Both effects show that the magnetization dynamics of the pseudo-spinvalves is influenced by the heat current. Thus, the data provide a quantitative estimate of the thermal spin torque exerted on the magnetization of the Co layers. In addition, I will present recent study on the magnetization dynamics in a magnetic insulator YIG film under in-plane heat current. The ferromagnetic resonance linewidth is found to be tuned by the applied temperature gradient, i.e. narrowing and broadening. This suggests that the Gilbert damping parameter is compensated or reinforced by the applied temperature gradient in respective direction. These observations can be understood as a heat-driven spin torque in magnetic insulators.

**4:54PM V13.00005 Magnetic equivalent of the Seebeck effect.**, SYLVAIN BRECHET, EPFL — Spin caloritronics seeks to investigate the effect of a thermal gradient on the electronic charge and spin degrees of freedom. In a conductor, a thermal gradient leads a transport of the conduction electrons that in turn generate an electric field along the temperature gradient, which is the well-known Seebeck effect. In an insulator, there are no conduction electrons. Thus no electronic charge transport takes place. However, the electronic spins can reorient themselves in the presence of a temperature gradient as they precess around an external field oriented along the temperature gradient. In fact, the temperature gradient generates a magnetic induction field in the plane orthogonal to the temperature gradient. The effect is the magnetic analog of the Seebeck effect and is thus referred to as the magnetic Seebeck effect. It has been observed for the propagation of spin waves along and against a temperature gradient in a YIG slab. The propagation of spin waves against the temperature gradient lead to a positive thermal damping and the propagation along the temperature gradient leads to the opposite effect, namely a negative thermal damping. Thus, the magnetic Seebeck effect generate of heat driven spin torque that can generate a positive or a negative thermal damping. The magnetic Seebeck effect has been recently established using a fundamental variational approach. In many experimental situations, the system can be treated as a classical continuum with magnetisation on the scale of interest where the quantum fluctuations average out and the underlying microscopic structure is smoothed out. For the propagation of magnetisation waves in a stationary state, the system is slightly out of equilibrium but the magnetic kinetic energy is constant. In such a case, the action of the system is a functional of the magnetisation and the magnetisation current. Since the magnetisation is a function of the temperature, the action variation yields an explicit expression for the magnetic induction field generated by the temperature gradient. This field lead to a heat driven spin torque that has the same geometry in an insulator than the spin transfer torque proposed by Berger and Slonczewski in a conductor.

**Thursday, March 17, 2016 2:30PM - 4:54PM —**

**Session V14 FEd: TA Professional Development: Excellent TA's Making Excellent Researchers**

310 -

**2:30PM V14.00001 Using the TA to Prepare Graduate Students for Research and Employment**, KENNETH HELLER, School of Physics & Astronomy, University of Minnesota — One of the most underused components of the physics graduate program is the time spent being a teaching assistant (TA). Often the TA duties consist of grading and trying to help undergraduates survive a physics course. How those duties are accomplished is left to each TA. The most common TA preparation, if it exists, has a narrow focus on the class being taught. Preparation consists of describing, or perhaps practicing, specific teaching skills and gaining familiarity with the equipment used in the laboratory portion of the class. Instead TAs can be integrated into the entire course in which they function so that they learn the course as a system. This means treating a course in the same way one approaches a research project with the TAs as members of the research team headed by a faculty advisor. TA preparation is broadened and support includes the management, teamwork, and communication skills necessary. This makes the TAs more efficient and effective teachers while explicitly connecting the TA experience to the "soft" skills they need in their own research careers whether in industry, national laboratories, or academia. This talk describes such a program, functioning for over 20 years at the University of Minnesota, that takes no more time than the usual TA but results in graduate students that are more satisfied with their TA experience, are better prepared to function in research groups, and provide a better classroom experience for their undergraduate students.

**3:06PM V14.00002 Mobilizing the Forgotten Army: Improving Undergraduate Math and Science Education through Professional Development of Graduate Teaching Assistants<sup>1</sup>** , JORDAN GERTON, University of Utah — Evidence-based best practices for improving undergraduate STEM education abound. Unfortunately, these practices have not been widely adopted, in part because typical dissemination efforts are mediated in a top-down fashion and fail to obtain critical buy-in from key local stakeholders. Here, we present a novel framework to increase nationwide uptake of STEM-education best practices through grassroots propagation of Professional Development programs for Graduate Teaching Assistants (GTA-PD). Our model pays special attention to overcoming resistance to change by soliciting, from the very start, critical buy-in from departmental chairs, faculty, and GTAs who have direct control over and responsibility for instruction. A key component of our approach involves an annual National GTA Workshop where faculty-GTA leadership teams from many different Physics and Chemistry departments come together to develop best-practices-based GTA-PD improvement plans for their own departments while guided by a core group of nationally recognized expert practitioners in GTA-PD and STEM education. As a pre-condition for participation, each department chair must pledge to facilitate implementation of their leadership teams plan; additional and ongoing support is provided by the core group of experts, together with other teams from the workshop cohort. Our initial pilot efforts point to success via enthusiastic buy-in within each STEM department due to the potential for immediate positive impacts on both undergraduate instruction and the long term research productivity of GTAs. In the future, longitudinal data on the progress of the GTA-PD programs will be gathered and analyzed to provide guidance for improving the success of future GTA-PD programs.

**3:42PM V14.00003 TA Professional Development: A Graduate Student's Perspective** , EMILY ALICEA-MUNOZ, Georgia Inst of Tech — Graduate Teaching Assistants (GTAs) are essential for teaching large introductory physics classes. In such courses, undergraduates spend approximately half of their in-class contact time in instructional environments (e.g., labs and recitations) supervised by GTAs, which means GTAs can have a large impact on student learning. Therefore it is crucial to adequately prepare GTAs before they first enter the classroom, and to offer them continued support throughout. Since many of the skills required to become effective teachers will also be relevant to their future research careers, it is useful for a GTA preparation program to also include professional development strategies. But what exactly do GTAs get out of these programs? The School of Physics at Georgia Tech runs a preparation and mentoring program for GTAs that focuses on pedagogical knowledge, physics content, and professional development, as well as their intersections. Nearly seventy graduate students have gone through this program in the three years since it was established. Here we discuss the impact this program has had on our GTAs, from their own point of view: the program's effect on their teaching abilities, how it has influenced their attitudes towards teaching, what elements they have found useful, and what changes they have suggested to its curriculum. We find that, in general, GTAs are more receptive when the curriculum is more hands-on and they are presented with frequent opportunities for practice and feedback.

**Session V15 DMP: 2D Materials: Charge Density Waves** 314 - Ken Burch, Boston College

**2:30PM V15.00001 Weakly Bound and Strongly Interacting: NbSe<sub>2</sub> and 1T-TaS<sub>2</sub> in the 2D Limit** , ADAM TSEN, University of Waterloo and Columbia University — The layered metallic dichalcogenides are known to exhibit rich collective electron phases such as charge density waves, spin density waves, and superconductivity. In the past, studies on graphene and various semiconducting dichalcogenides have shown that taking layered materials to their physical two-dimensional (2D) limit leads to fundamental changes in band structure, allowing for a powerful experimental knob to tune for electronic functionality. In contrast, due to their instability in the ambient environment, the effect of thickness control over such collective electron phases has been largely unexplored in metallic systems. We have recently demonstrated a new experimental platform for the isolation and assembly of environmentally sensitive 2D materials in inert atmosphere. I will discuss our recent studies of the charge density wave material 1T-TaS<sub>2</sub> and superconducting NbSe<sub>2</sub> in the atomically thin limit, made possible using this technique. For 1T-TaS<sub>2</sub>, we find that the lock-in transition to commensurate charge ordering becomes increasingly metastable for reduced thickness, allowing for all-electrical control over this phase transition in the 2D state. In NbSe<sub>2</sub>, a small magnetic field induces a transition to a quantum metallic phase, the resistivity of which obeys a unique field-scaling property. These methods and experiments open new doors for the study of other correlated 2D materials in the immediate future.

**3:06PM V15.00002 Nanostructure of the charge density wave domains in 1T-TaS<sub>2</sub>** , SOHAM BANERJEE, Columbia University, YUE CAO, Brookhaven National Lab, DENNIS WANG, Columbia University , STEPHAN HRUSZKEWYCZ, MARTIN HOLT, Argonne National Lab, SIMON BILLINGE , Columbia University — The connection between structural and electronic phase separation is thought to play an important role in strongly correlated systems, where ordering at the nanoscale modifies exotic macroscopic properties. 1T-TaS<sub>2</sub> offers us a rare example of a layered material exhibiting both the Mott state and a diversity of charge density wave (CDW) phases, in close analogy to a number of high temperature superconductors with pseudogap behavior. While local scanning probes have identified electronic nanoscale phase separation in low dimensional CDW systems, an explanation of the lattice response to electronic instabilities remains unsettled. Of the 1T-TaS<sub>2</sub> CDW phases, a nearly commensurate (NC) phase is segregated, with nanoscale commensurate CDW domains, separated by metallic incommensurate regions (domain walls). Here, we demonstrate the use of scanning probe X-ray nanodiffraction to analyze structural perturbations in NC 1T-TaS<sub>2</sub> that arise due to an incommensurability of the CDW wavevector and the underlying lattice.

**3:18PM V15.00003 Magnetic Field Studies Near Superconducting Transition in MBE Grown Monolayer NbSe<sub>2</sub> on Bilayer Graphene** , SEITA ONISHI, UC Berkeley/Lawrence Berkeley National Lab. (LBNL), MIGUEL M. UGEDA, UC Berkeley/CIC nanoGUNE, YI ZHANG, LBNL/SLAC National Accelerator Lab., YI CHEN, CLAUDIA OJEDA-ARISTIZABAL, UC Berkeley, HYEJIN RYU, SUNG-KWAN MO, ZAHID HUSSAIN, Lawrence Berkeley National Lab., ZHI-XUN SHEN, SLAC National Accelerator Lab./Stanford University, MICHAEL F. CROMMIE, ALEX ZETTL, UC Berkeley/Kavli ENSI/LBNL — Following the work by Frindt [1] on the superconductivity of NbSe<sub>2</sub> at reduced thicknesses, recent breakthroughs have enabled the study of bilayers and monolayers. Staley et. al. [2], Tsen et. al. [3], Cao et. al. [4] and Xi et. al. [5] have studied superconductivity in bilayers and monolayers of NbSe<sub>2</sub> after mechanical exfoliation and encapsulation with another layered material to protect from air. In this work, we have investigated the superconductivity in monolayer NbSe<sub>2</sub> prepared by molecular beam epitaxy growth (MBE) on bilayer graphene (BLG) [6]. The superconducting transition has an onset temperature of 1.9K, midpoint temperature of 0.65K and reaches zero resistance at 0.46K. The upper critical field perpendicular to the NbSe<sub>2</sub> monolayer is 0.5T at 100mK. We will show the effect of magnetic fields near the superconducting transition and compare with existing theories. [1] R. Frindt, Phys. Rev. Lett. 28, 299 (1972). [2] N. E. Staley, et. al., Phys. Rev. B 80, 184505 (2009). [3] A. W. Tsen, et. al., arXiv:1507.08639 [cond-Mat.supr-Con] 1 (2015). [4] Y. Cao, et. al., Nano Lett. 15, 4914 (2015). [5] X. Xi, et. al., arXiv:1507.08731 [cond-Mat.supr-Con] 1 (2015). [6] M. M. Ugeda, et al., Nat. Phys. 10.1038/nphys3527 (2015).

**3:30PM V15.00004 The Upper Critical Field of Bilayer NbSe<sub>2</sub>**, BENJAMIN HUNT, Carnegie Mellon University, ADAM W. TSEN, Y. D. KIM, Columbia University, Z. J. YUAN, S. JIA, Peking University, R. J. CAVA, Princeton University, J. HONE, Columbia University, P. KIM, Harvard University, ABHAY PASUPATHY, CORY DEAN, Columbia University — We report on the fate of the superconducting state of bilayer NbSe<sub>2</sub> in a large parallel magnetic field. Due to strong spin-orbit coupling, the system exhibits an out-of-plane polarization of electron spins in each valley, which leads to an enhanced upper critical field  $H_{c2}^{\parallel}$  as compared to that expected from the Pauli limit  $H_p$  [1]. We explore the behavior of  $H_{c2}^{\parallel}(T)$  in the low temperature limit, down to  $T = 0.3\text{K}$  (approximately  $0.06T_c$ ), and we find a maximum upper critical field of 28 T which is  $\sim 3$  times the Pauli limit. We find that the measured  $H_{c2}^{\parallel}(T)$  deviates significantly from the standard pair-breaking theory as  $T \rightarrow 0$ , and we compare our results to recent observations of Ising superconductivity in NbSe<sub>2</sub> [1] and in ionic-liquid-gated MoS<sub>2</sub> [2], as well as to calculations of  $H_{c2}$  based on realistic band structure of NbSe<sub>2</sub>. References: [1] Xi et al. arXiv:1507.08731 (2015) [2] Saito et al. arXiv:1506.04146 (2015)

**3:42PM V15.00005 Superconductivity and charge density waves in atomically thin NbSe<sub>2</sub>**, XIAOXIANG XI, Pennsylvania State University — Atomically thin van der Waals materials have emerged as a frontier for both fundamental physics and device applications. Although novel single-particle and excitonic properties have been extensively studied, the collective electron phenomena in these materials remain less well understood. In this talk, we will discuss superconductivity and charge-density-wave (CDW) order in atomically thin group-V transition metal dichalcogenide NbSe<sub>2</sub> down to the monolayer limit. Electrical transport measurements show that the superconducting transition temperature decreases monotonically with reducing the layer thickness. The temperature dependent Raman scattering, on the other hand, shows enhanced CDW order as the sample thickness reduces. While the former can be understood mainly as the result of reduced interlayer Cooper pairing, the latter arises from the enhanced electron-phonon coupling in atomically thin samples. Magnetotransport measurements further reveal the effect of spin-momentum locking, a consequence of broken inversion symmetry and strong spin-orbit coupling in monolayer NbSe<sub>2</sub>, on Cooper pairing and the in-plane upper critical fields. These results set the stage for the exploration and control of collective electronic phases in 2D NbSe<sub>2</sub> and related systems.

**4:18PM V15.00006 Charge Density Waves in the bulk and mono-layer VSe<sub>2</sub>**, YANG-HAO CHAN, CHING-MING WEI, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, USA — Charge density waves (CDWs) are widely observed in the layered transition-metal dichalcogenides (TMDs). With the capability of preparing atomically thin samples in the experiment, the underlying mechanism of the formation of CDWs and the role played by dimensionality in TMDs can now be studied in great detail. We present the first-principles calculations on bulk and mono-layer VSe<sub>2</sub>. Our results agree with the experimental findings that the dominant CDW phase has a  $4\times 4\times 3$  supercell structure in the bulk system. Electronic structure calculations suggest Fermi-surface nesting is a relevant mechanism. On the other hand, we find a new  $3\sqrt{3}\times 3\sqrt{3}$  CDW phase as the lowest energy structure in the mono-layer case induced by strong electron-phonon interaction. We also find that substantial hole doping leads to a CDW-superconducting (SC) phase transition. The SC transition temperature is predicted to be higher than that of the bulk from our first-principles calculations.

**4:30PM V15.00007 Scanning Tunneling Microscopy and Spectroscopy of Graphene on NbSe<sub>2</sub>**, SHENGQIANG HUANG, ZHIMING ZHANG, MATTHEW YANKOWITZ, BRIAN J. LÉROY, Univ of Arizona — A wide range of phenomena can be induced in graphene by creating vertical heterostructures with other two-dimensional materials. NbSe<sub>2</sub> is a layered transition metal dichalcogenide that exhibits a charge density wave transition below  $T_{cdw} = 33\text{ K}$  and then becomes superconducting below  $T_c = 7.2\text{ K}$ . By placing monolayer graphene on NbSe<sub>2</sub> the interplay between charge density waves, superconductivity and Dirac fermions can be explored. We use low temperature scanning tunneling microscopy and spectroscopy to study the electronic properties of this van der Waals heterostructure. We observe the coexistence of a moiré pattern and charge density wave in the graphene on NbSe<sub>2</sub> heterostructure.

**4:42PM V15.00008 Scanning Tunneling Microscopy Study of Atomic and Electronic Structures of PbTaSe<sub>2</sub>**, TIEN-MING CHUANG, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, SYU-YOU GUAN, Institute of Physics, National Taiwan University, Taipei 10617, Taiwan, PENG-JEN CHEN, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, TAY-RONG CHANG, Department of Physics, Princeton University, Princeton, NJ 08544, USA, RAMAN SANKAR, FANG-CHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, CHIA-SENG CHANG, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan — The non-centrosymmetric PbTaSe<sub>2</sub> becomes superconducting at  $T_c = 3.7\text{K}$  and is proposed to have a 3D massive Dirac fermions by large spin orbital coupling. The observation of topological nodal line states has been reported by recent ARPES measurements, making this material a great candidate to investigate the coupling between topological states and superconductivity. Here we conduct detail studies on cleaved PbTaSe<sub>2</sub> surfaces by spectroscopic imaging-scanning tunneling microscope. Our results reveal several types of cleaved surfaces, within which each exhibits distinct different LDOS from scanning tunneling spectroscopy measurements. We identify different surface terminations from their atomic structures and their corresponding electronic properties both above and below  $T_c$ . We will report the impact on superconducting properties of different surfaces, and also discuss the relation between the surface state and superconductivity.

**4:54PM V15.00009 Zone-center phonons of bulk, few-layer, and monolayer 1T-TaS<sub>2</sub>: Application to Raman scattering<sup>1</sup>**, OLIVER R ALBERTINI, Georgetown University, RUI ZHAO, Pennsylvania State University, REBECCA L MCCANN, Georgetown University, SIMIN FENG, MAURICIO TERRONES, Pennsylvania State University, JAMES K FREERICKS, Georgetown University, JOSHUA A ROBINSON, Pennsylvania State University, AMY Y LIU, Georgetown University — The transition metal dichalcogenide 1T-TaS<sub>2</sub> has attracted attention for decades due to its multiple charge density wave phases. More recently it is being considered as a 2D device material, due to the wide range of electrical conductivities in these phases. The metal-insulator transition that occurs when the commensurate charge density wave forms is particularly attractive. We present first-principles calculations of the vibrational properties of 1T-TaS<sub>2</sub> for various thicknesses in the high-temperature (undistorted) phase and the low-temperature commensurate charge density wave phase. We also present measurements of the Raman frequencies for bulk and few-layer samples in the low-T phase. We find strong evidence for the low-T commensurate charge density wave state remaining stable as the crystal is thinned, even down to one layer. We explore the effects of substrate-induced strain on the vibrational spectrum and propose polarized Raman spectroscopy as a method for quickly identifying the c-axis orbital texture in the low-T phase. This orbital texture has recently been identified as playing a role in the metal-insulator transition.

**5:06PM V15.00010 Structural, electronic and vibrational properties of few-layer 2H- and 1T-TaSe<sub>2</sub><sup>1</sup>**, JIA-AN YAN, MACK DELA CRUZ, Department of Physics, Astronomy and Geosciences, Towson University, BRANDON COOK, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, P.O. Box 2008, Oak Ridge, TN, 37831 USA, KALMAN VARGA, Department of Physics and Astronomy, Vanderbilt University, Nashville, Tennessee 37235, USA — Two-dimensional metallic transition metal dichalcogenides (TMDs) are of interest for studying phenomena such as charge-density wave (CDW) and superconductivity. Few-layer tantalum diselenides (TaSe<sub>2</sub>) are typical metallic TMDs exhibiting rich CDW phase transitions. However, a description of the structural, electronic and vibrational properties for different crystal phases and stacking configurations, essential for interpretation of experiments, is lacking. We present first-principles calculations of structural phase energetics, band dispersion near the Fermi level, phonon properties and vibrational modes at the Brillouin zone center for different layer numbers, crystal phases and stacking geometries. Evolution of the Fermi surfaces as well as the phonon dispersions as a function of layer number reveals dramatic dimensionality effects in this CDW material. Our results indicate strong electronic interlayer coupling, detail energetically possible stacking geometries, and provide a basis for interpretation of Raman spectra.

**5:18PM V15.00011 Memristive phase switching in two-dimensional 1T-TaS<sub>2</sub> crystals**, MASARO YOSHIDA, TAKASHI GOKUDEN, RYUJI SUZUKI, YIJIN ZHANG, MASAKI NAKANO, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — Among 2D materials with correlated electrons, 1T-TaS<sub>2</sub> is one of the most attracting systems with charge density wave (CDW) phases [1]. In this presentation, we report an electrical switching between various non-volatile metastable electronic phases in 1T-TaS<sub>2</sub> thin flakes. By applying a high lateral electric field, we realized multiple metastable states, where the system shows truly metallic behavior. The emergence of novel ground states, possibly stabilized by the slow kinetics due to the reduced dimensionality [2], reflects the electronic complexity in 2D materials with nanometer thickness. [1] M. Yoshida et al. Sci. Rep. 4, 7302 (2014); [2] M. Yoshida et al. Sci. Adv. 1, e1500606 (2015).

## **Thursday, March 17, 2016 2:30PM - 5:30PM – Session V16 DCMP DMP: Optical Studies of Transition Metal Dichalcogenides 315 -**

**2:30PM V16.00001 All-Optical Materials Design of Dissipationless Chiral Edge Modes in Transition-Metal Dichalcogenides**, MARTIN CLAASSEN, Department of Applied Physics, Stanford University, CHUNJING JIA, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Sciences, SLAC & Stanford University — Spurred by the recent progress in transient melting, enhancement and induction of electronic order, a particularly tantalizing prospect concerns the possibility to instead access dynamical steady states with distinct non-equilibrium phase transitions, to affect electronic transport. Here, we show that the interplay of crystal symmetry and optical pumping of monolayer transition-metal dichalcogenides (TMDCs) provides a novel avenue to engineer topologically-protected chiral edge modes, facilitating optically-switchable conduction channels that are insensitive to disorder. Intriguingly, while TMDCs are canonically described as condensed-matter realizations of massive relativistic fermions, here we predict from first principles that circularly-polarized pumping instead accesses the intrinsic three-band nature near the band edges to selectively photo-induce topological band inversions at low pump intensities, while simultaneously limiting absorption for sub-gap pump frequencies. The results presented provide a new strategy to predict and design topological materials out of equilibrium, and should be readily applicable to other classes of semiconductors.

**2:42PM V16.00002 Magnetic brightening of dark excitons in transitional metal dichalcogenides**, XIAO-XIAO ZHANG, Columbia University, ZHENG GUANG LU, National High Magnetic Field Laboratory, TING CAO, University of California, Berkeley, FAN ZHANG, JAMES HONE, Columbia University, STEVEN G. LOUIE, University of California, Berkeley, ZHIQIANG LI, DMITRY SMIRNOV, National High Magnetic Field Laboratory, TONY HEINZ, Stanford University — Transitional metal dichalcogenides (TMDC) in the MX<sub>2</sub> (M = Mo, W, X = S, Se) family represent an excellent platform to study of excitonic effects. At monolayer thickness, these materials exhibit both direct band-gap character and enhanced excitonic interactions. Theoretical studies suggest that both the valence and conduction bands are split and exhibit spin polarized character at the K/K' valleys. The lowest energy band-edge excitons are predicted to have different spin configurations for different materials in this family. When the lowest lying exciton has parallel electron and hole spin, radiative decay is forbidden and the state is dark. Here we demonstrate that by applying an in-plane magnetic field we can perturb the exciton spin configuration and brighten this state, allowing it to undergo radiative decay. We identify such a brightened dark state by the emergence of a new emission peak lying below the absorption peak, with a strength growing with applied in-plane magnetic field. On the other hand, for monolayer MoSe<sub>2</sub>, where no low-lying dark state is expected, we do not see the growth of a new emission feature under application of an in-plane magnetic field. Our experimental findings are in agreement with the calculated properties of dark excitons based on GW plus Bethe-Salpeter equation approach

**2:54PM V16.00003 Studies of low temperature photoluminescence spectra and excitonic valley polarization in monolayer MoTe<sub>2</sub>**, SANDHAYA KOIRALA, SHINICHIRO MOURI, YUHEI MIYAUCHI, KAZUNARI MATSUDA, Kyoto Univ - Uji Campus, KYOTO UNIVERSITY TEAM — Recently, atomically thin layered transition-metal dichalcogenide (TMDs) in the form MX<sub>2</sub> (M = Mo, W, X = S, Se, Te) have attracted much interest from the viewpoints of their fundamental physics and potential applications [1, 2]. The characteristic optical features of semiconducting TMDs arise from excitons confined in their atomically thin layers. Molybdenum ditelluride MoTe<sub>2</sub> has attracted emerging research interest because of optical gap energy (lowest exciton transition) of 1.09 eV, and large spin-orbit coupling of 250 meV. Temperature-dependent photoluminescence (PL) and polarization-resolved PL measurement were performed for mechanically exfoliated monolayer MoTe<sub>2</sub> from 4.4 to 300 K. At a low temperature, the PL spectra from MoTe<sub>2</sub> show two sharp peaks for excitons and charged excitons (trions). The systematic temperature-dependent PL measurements reveal that the homogeneous linewidth of the exciton peak broadens linearly as the temperature increased due to exciton-acoustic-phonon interactions [3]. From polarization-resolved PL measurements, the valley polarization of above 40 % in the exciton state has been observed at low temperatures. In this meeting, we will discuss about exciton dephasing and valley polarization in monolayer MoTe<sub>2</sub>. [1] D. Kozawa, K. Matsuda, G. Eda et al., Nat. Commun. 5, 4543 (2014). [2] S. Mouri, Y. Miyauchi and K. Matsuda, Nano Lett. 15, 2336 (2015). [3] S. Koirala, K. Matsuda et al., submitted for publication.

**3:06PM V16.00004 Observation and Characterization of Biexciton States in high-quality Monolayer WS<sub>2</sub>**<sup>1</sup>, MITSUHIRO OKADA, Nagoya Univ, YUHEI MIYAUCHI, Kyoto Univ, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, KAZUNARI MATSUDA, Kyoto Univ, HISANORI SHINOHARA, RYO KITaura, Nagoya Univ — Group-VI transition metal dichalcogenides (TMDCs) have attracted a great deal of attention due to the optical properties dominated by excitonic effects, where emissions in PL arise from excitons and trions are seen even in room temperature (RT). In recent studies on PL emissions from WS<sub>2</sub>, one of TMDCs has shown that even biexcitons can be observed at 4 K with high-power excitation of 50,000 W/cm<sup>2</sup>. In this work, we report the observation of biexciton states at temperature higher than 80 K with excitation power lower than 25 W/cm<sup>2</sup>, by using a high-quality monolayer WS<sub>2</sub> grown directly onto the hBN. PL spectra of the WS<sub>2</sub>/hBN measured at RT show a very sharp excitonic PL emission with a FWHM of 21.5 meV, and at 82.7 K the PL spectra show three additional peaks at the lower energy site. The excitation power dependence and the lifetime measurement of PL peak at 2.00 eV clearly show that this PL peak can be attributed to biexcitons, which has been observed with a low excitation power down to 24 W/cm<sup>2</sup>. We think that the minimal amount of trapping sites in high-quality WS<sub>2</sub>/hBN used is a key factor in the observation of biexcitons at over 80 K and a low excitation power.

<sup>1</sup>This work was supported by Scientific Research on Innovative Areas (No. 25107002) from MEXT, Japan and Leading Graduate School Program, Nagoya University.

**3:18PM V16.00005 High field magneto-spectroscopy of excitons in monolayer WSe<sub>2</sub>**, ZHENG GUANG LU, National High Magnetic Field Laboratory and Florida State University, XIAOXIAO ZHANG, Columbia University, JONATHAN LUDWIG, National High Magnetic Field Laboratory and Florida State University, FAN ZHANG, Columbia University, KOMALAVALLI THIRUNAVUKKUARASU, National High Magnetic Field Laboratory, SEONGPHILL MOON, National High Magnetic Field Laboratory and Florida State University, JAMES HONE, Columbia University, TONY HEINZ, Stanford University, DMITRY SMIRNOV, National High Magnetic Field Laboratory — We have performed circularly polarized photoluminescence (PL) experiments on monolayer WSe<sub>2</sub> in magnetic fields up to 31T and at temperatures between 2K and 45K, focusing on the emission from the neutral (X<sup>0</sup>) and negatively charged (X<sup>-</sup>) excitons. A parallel magnetic field does not affect the exciton energy. At 45K, a perpendicular magnetic field (Faraday geometry) induces linear shift of about 0.12 meV/T ≈ 2μB for both X<sup>0</sup> and X<sup>-</sup> peaks indicating lifting of the valley degeneracy. The magnitude of this valley Zeeman shift agrees with the valence band edge lifting due to atomic orbital contribution. The change of the X<sup>-</sup> PL intensity with the magnetic field suggests that the intravalley configuration is the lower energy state of the trion in WSe<sub>2</sub>. At lower temperatures, the X<sup>0</sup> exhibits the same shift with the magnetic field as at 45K, while the X<sup>-</sup> shows a more pronounced and non-linear shift with respect to magnetic field.

**3:30PM V16.00006 Strong Circularly Polarized Photoluminescence From Multilayer MoS<sub>2</sub> Through Plasma Driven Direct-Gap Transition**, ROHAN DHALL, University of Southern California, KYLE SEYLER, University of Washington, ZHEN LI, University of Southern California, DARSHANA WICKRAMARATNE, MAHESH NEUPANE, UC Riverside, IOANNIS CHATZAKIS, University of Southern California, EWA KOSMOWSKA, XEI Scientific, ROGER LAKE, UC Riverside, XIAODONG XU, University of Washington, STEPHEN CRONIN, University of Southern California — We report circularly polarized photoluminescence spectra taken from few layer MoS<sub>2</sub> after treatment with a remotely generated oxygen plasma. Here, the oxygen plasma decouples the individual layers in MoS<sub>2</sub> by perturbing the weak interlayer van der Waals forces without damaging the lattice structure. This decoupling causes a transition from an indirect to a direct band gap material, which causes a strong enhancement of the photoluminescence intensity. Furthermore, up to 80% circularly polarized photoluminescence is observed after plasma treatment of few layer MoS<sub>2</sub> flakes, consistent with high spin polarization of the optically excited carriers. A strong degree of polarization continues up to room temperature, further indicating that the quality of the crystal does not suffer degradation due to the oxygen plasma exposure. Our results show that the oxygen plasma treatment not only engineers the van der Waals separation in these TMDCs multilayer for enhanced PL quantum yields, but also produces high quality multilayer samples for strong circularly polarized emission, which offers the benefit of layer index as an additional degree of freedom, absent in monolayer MoS<sub>2</sub>.

**3:42PM V16.00007 Nanosecond Valley Polarization in Suspended Monolayer Tungsten Sulfide**, ANDY BARRETTE, CHAO XU, YIFEI YU, YILING YU, LINYOU CAO, KENAN GUNDOGDU, North Carolina State Univ, GUNDOGDU GROUP TEAM, NANOSCALE PHOTOPHYSICS AND PHOTOCHEMISTRY GROUP TEAM — Monolayer transition metal dichalcogenides (TMD) have a vast range of interesting electronic and optical characteristics due to symmetry properties and selection rules. For carriers, these properties result in coupled spin and valley degrees of freedom and coupling between valley polarization circular polarization of excitation source. Because of these unique properties, TMDs are thought to have potential valleytronic applications, however to the detriment of these potential applications, recent optical studies have shown that carriers undergo valley relaxation very quickly, within tens of picoseconds. Using circularly polarized ultrafast transient absorption spectroscopy, we find that valley relaxation in suspended tungsten sulfide (WS<sub>2</sub>) decays on the order of a nanosecond - two orders of magnitude slower than in supported samples. We discuss our results in the context of recent theoretical work which suggests that the predominant valley relaxation mechanism in monolayer TMDs is the electron-hole exchange interaction. Finally, we use valley relaxation measurements at several temperatures to conclude that the remaining nanosecond valley relaxation results from the flexural phonon mechanism.

**3:54PM V16.00008 Imaging Spin Dynamics in Monolayer WS<sub>2</sub> by Time-Resolved Kerr Rotation Microscopy**, ELIZABETH BUSHONG, KELLY (YUNQIU) LUO, The Ohio State University, KATHLEEN MCCREARY, Naval Research Laboratories, MICHAEL NEWBURGER, SIMRANJEET SINGH, The Ohio State University, BEREND JONKER, Naval Research Laboratories, ROLAND KAWAKAMI, The Ohio State University — Monolayer transition metal dichalcogenides (TMDs) such as WS<sub>2</sub> offer a unique platform to probe spin and valley degrees of freedom in two-dimensional condensed matter systems. TMDs are of great interest because they have a direct band gap and optical selection rules that permit the excitation of both valley and spin-polarized electrons. Strong spin-orbit coupling leads to valley-dependent spin-splitting in both the conduction and valence bands, which may suppress spin relaxation and inhibit intervalley scattering, thereby increasing both the spin and valley lifetimes. To measure spin and valley dynamics of CVD grown WS<sub>2</sub>, we developed time-resolved Kerr rotation microscopy with spatial resolution of ~1 micron and temporal resolution of 150 fs. We observe a long spin lifetime of 5.1 ns in WS<sub>2</sub> at T = 6.5 K. We spatially map the spin populations at a given time delay, and observe a complex spatial dependence of the spin lifetimes with regions of spin lifetime less than 100 ps and regions of spin lifetime greater than 5 ns separated by only a few microns. To understand the origin of the long-lived spin states, we investigate the relationship between spin lifetime and the photoluminescence intensity. Application of in-plane magnetic fields shows an oscillatory and non-oscillatory component, indicating two spin populations that experience different effective fields.

**4:06PM V16.00009 Infrared and visible magneto-optical studies of centimeter-scale monolayer MoS<sub>2</sub>**, MUMTAZ MURAT ARIK, ALOK MUKHERJEE, JUNGRYEOL SEO, CHUAN ZHAO, PAYAM TAHERI, BRETT BLIZZARD, HAO ZENG, JOHN CERNE, State Univ of NY - Buffalo — We report extensive magneto-optical measurements on monolayer MoS<sub>2</sub> at temperatures down to 10K and magnetic fields up to 7T. The centimeter-scale monolayer MoS<sub>2</sub> films are grown by the vapor transport method, where a 5 Å-thick pre-deposited MoO<sub>3</sub> film is sulfurized. We measure polarization-sensitive transmission, reflection, photoluminescence, and Kerr response in the infrared and visible range (0.100 – 2.75 eV). We explore the dependence of the optical and electronic properties on the substrate. This work is supported by NSF-DMR1410599 and NSF CBET-1510121.

**4:18PM V16.00010 Exciton and Trion Valley dynamics in WSe<sub>2</sub> measured by two-color pump-probe<sup>1</sup>**, AKSHAY SINGH, KHA TRAN, JOE SEIFERT, YIPING WANG, Univ of Texas, Austin, MARIE SCOTT, university of washington, seattle, DENNIS PLESKOT, NATHANIEL GABOR, University of California, Riverside, JIAQIANG YAN, DAVID MANDRUS, University of Tennessee, Knoxville, XIAODONG XU, university of washington, seattle, XIAOQIN LI, Univ of Texas, Austin — Monolayer transition metal dichalcogenides are semiconducting materials demonstrating spin-valley coupling as well as quasiparticles with large binding energies. These quasiparticles, excitons and trions (charged excitons), have quite different spin polarization properties, with the trion having larger spin lifetimes than excitons. Photoluminescence and time resolved Kerr rotation techniques have been used earlier to measure spin lifetimes. However, most of these early optical measurements have relied on non-resonant excitation conditions which tend to mask the intrinsic valley (spin) scattering properties. Here, we use circularly polarized two-color pump probe spectroscopy to measure valley (spin) polarization in monolayer WSe<sub>2</sub> at low temperatures. We utilize quasi-resonant excitation with pump 1 meV (0.5 nm) spectrally separated from the probe, thus resulting in very efficient valley initialization. We present polarization resolved measurements on resonantly excited excitons and trions, which suggest that trions have larger spin lifetimes. Further, we probe spin polarization of trions when pumping at exciton energies, and vice-versa. We discuss the relative importance of different scattering mechanism at play.

**4:30PM V16.00011 Band edge identification and carrier dynamics of CVD MoS<sub>2</sub> monolayer measured by broadband Femtosecond Transient Absorption Spectroscopy**, SHROUQ ALEITHAN, MAKSYM LIVSHITS, Ohio Univ, JEFFREY RACK, University of New Mexico, MARTIN KORDESCH, ERIC STINAFF, Ohio Univ — Two-dimensional atomic crystals of transition metal dichalcogenides are considered promising candidates for optoelectronics, valleytronics, and energy harvesting devices. These materials exhibit excitonic features with high binding energy as a result of confinement effect and reduced screening when the material is thinned to monolayer. However, previous theoretical and experimental studies report different binding energy results. This work further examines the electronic structure and binding energy in this material using broadband Femtosecond Transient Absorption Spectroscopy. Samples of MoS<sub>2</sub> were grown by chemical vapor deposition, pumped with femtosecond laser, and probed by femtosecond white light resulting in broadband differential absorption spectra with three distinct features related to the three dominant absorption peaks in the material: A, B, and C. The dependence of the transient absorption spectra on excitation wavelength and layer number provides evidence of a band gap located at C (2.9 eV) and therefore an excitonic binding energy of 1 eV. Additional features in the spectra identified as a broadening of the absorption features caused by carrier scattering, surface defects and trap states.

**4:42PM V16.00012 Ultrafast spectroscopy of exciton and exciton dynamics in mono and few layers of WS<sub>2</sub>**, SUDIKSHA KHADKA, SHROUQ ALEITHAN, MAX LIVSHITS, JEFFREY J. RACK, MARTIN KORDESCH, ERIC STINAFF, Ohio University — Single layer of Transitional metal dichalcogenides (MX<sub>2</sub>) are 2D semiconductors that have a direct band gap in visible spectrum and fill the gap in between 2D metallic and insulating materials. They have possible application in optoelectronic devices, photovoltaics and photodetection, molecular sensing, 'valleytronics', and flexible transparent electronics. Tungsten Disulphide (WS<sub>2</sub>), one of the member of MX<sub>2</sub> family, has a direct band gap of 2.2 eV and a large valley splitting of about 0.4 eV. Here, we present a detailed study of exciton states and their decay mechanisms in mono and few layer WS<sub>2</sub> using femto-second transient absorption spectroscopy. We report a new peak at 3.010.1 eV whose origin in k space is believed to be at or around K point and further investigation is underway. The exponential fitting of decay curve of the exciton A reveals three time components as 1.70.3 ps, 33.510 ps and 67015 ps, most likely corresponding to carrier-carrier scattering, carrier-phonon scattering, and radiative relaxation respectively.

**4:54PM V16.00013 Tunable second harmonic generation of monolayer MoS<sub>2</sub> by Se doping<sup>1</sup>**, C. T. LE, Univ of Ulsan, D. J. CLARK, Binghamton University, V. SENTHILKUMAR, Univ of Ulsan, J. I. JANG, Binghamton University, H.-Y. CHO, Y. S. KIM, Univ of Ulsan, BINGHAMTON UNIVERSITY COLLABORATION — As a transition metal dichalcogenides whose bandgap becomes direct with inversion symmetry breaking in the monolayer limit, MoS<sub>2</sub> has been getting ample attention as next-generation nonlinear optic material for its strong optical nonlinear properties. In this study, we demonstrate the wavelength second harmonic generation tunability of monolayer Mo(S, Se)<sub>2</sub>. Employing the two-zone furnaces system, we selenized as-grown monolayer MoS<sub>2</sub> at different temperature. X-ray photoluminescence spectroscopy was used to confirm the chemical composition of selenized film. Photoluminescence spectra shows the red shift in optical bandgap from 1.83 to 1.53 eV as a function of concentration Se replacing S. Second harmonic generation characteristics were measured in reflection geometry using ps pulse from Nd:YAG laser. Applying the previous bulk model, we calculated that the maximum value of  $\chi^{(2)}$  varied from ~40 pm/V for pure MoS<sub>2</sub> to ~100 pm/V for pure MoSe<sub>2</sub>. We believe that our findings along with the ability to stack different 2D materials will create stacked 2D heterostructure with high  $\chi^{(2)}$  over a wide range of wavelength from visible to NIR.

**5:06PM V16.00014 Optical coherence in atomic monolayer transition metal dichalcogenides limited by electron-phonon interactions<sup>1</sup>**, PRASENJIT DEY, JAGANNATH PAUL, University of South Florida, ZEFANG WANG, Pennsylvania State University, CHRISTOPHER STEVENS, CUNMING LIU, University of South Florida, ALDO ROMERO, West Virginia University, JIE SHAN, Pennsylvania State University, DAVID HILTON, University of Alabama Birmingham, DENIS KARAIKAJ, University of South Florida, ALDO ROMERO COLLABORATION, ZEFANG WANG, JIE SHAN COLLABORATION, DAVID HILTON COLLABORATION — We systematically investigate the excitonic dephasing of three representative transition metal dichalcogenides, namely MoS<sub>2</sub>, MoSe<sub>2</sub> and WSe<sub>2</sub> atomic monolayer thick and bulk crystals, in order to gain proper understanding of the factors that determine the optical coherence in these materials. Coherent nonlinear optical spectroscopy, temperature dependent absorption combined with 'ab initio' theoretical calculations of the phonon spectra, indicate electron-phonon interactions to be the limiting factor.

**5:18PM V16.00015 The Eigenstate Thermalization Hypothesis in 1D Anyon Chains**, FIONA BURNELL, University of Minnesota, ANUSHYA CHANDRAN, Perimeter Institute, MARC SCHULZ, University of Minnesota — For ergodic systems with Hilbert spaces satisfying a local product structure, the eigenstate thermalization hypothesis (ETH) is relatively well-established. Using exact diagonalization studies, we investigate whether quantum spin chains based on SU(2)<sub>k</sub> anyon theories, which do not admit a Hilbert space with an exactly local product structure, also satisfy ETH, and which observables exhibit this behaviour.

**2:30PM V17.00001 Optimizing Spin Generation in 2D Materials: Topological Insulators and Graphene**, CHING-TZU CHEN, IBM Thomas J Watson Research Center — Novel two-dimensional electronic systems with Dirac-like dispersion present unique opportunities for spintronic applications. In this seminar I will discuss two specific examples. First we examine the potential of topological insulators as spin-source materials. Using a new spin-polarized tunneling method [1], giant charge-spin conversion efficiency in topological insulators is revealed, well exceeding that in conventional magnetic tunnel junctions.[2] Through a comparative study between Bi<sub>2</sub>Se<sub>3</sub> and (Bi,Sb)<sub>2</sub>Te<sub>3</sub>, we verify the topological-surface-state origin of the observed giant spin signals and further extract the energy dependence of the effective spin polarization in Bi<sub>2</sub>Se<sub>3</sub>. [2] Next we explore the potential of interfacial exchange interaction in 2D materials for spin control and spin generation. Using graphene as a prototype, we demonstrate that its coupling to a model magnetic insulator (EuS) produces a substantial magnetic exchange field ( $>14$  T), which yields orders-of-magnitude enhancement in the spin signal originated from the Zeeman spin-Hall effect.[3] Furthermore, the strong exchange field lifts the spin degeneracy of graphene in the quantum Hall regime, which may lead to interesting spin-polarized edge transport and thus open up new application space for classical and quantum information processing. **3:06PM V17.00002 A theoretical design of graphene-based spin field-effect transistors**, LIXUE LIU, University of Science and Technology of China, SHUDUN LIU, University of Louisville, WENGUANG ZHU, University of Science and Technology of China — The search for a feasible design of graphene-based materials for spintronics applications has been intensified in recent years. Encouraged by recent experimental achievements, here we propose a new scheme to realize graphene-based spin field-effect transistors. The new design is constituted of a half-hydrogenated graphene nanoroad embedded in a fully-hydrogenated graphene. Using first-principles density function theory calculations, we demonstrate that such a design can convert non-magnetic pristine graphene into a bipolar ferromagnetic semiconductor. More importantly, the magnetism of such a nanoroad is very robust: independent of its width and orientation. We also discuss the stability of such nanoroads, as well as a simple design of an all-electric controlled device for generation and detection of a fully spin-polarized electric current.

**3:18PM V17.00003 Giant Rashba spin splitting in Bi bilayer induced by a 2D ferroelectric substrate**, JIANBAO ZHU, University of Science and Technology of China, DI XIAO, Carnegie Mellon University, WENGUANG ZHU, University of Science and Technology of China — Based on density functional theory calculations, we discover that a Bi layer when placed on the top of a recently predicted 2D ferroelectric material with spontaneous out-of-plane electric polarization can exhibit giant Rashba-type spin splitting of over 200 meV, while the whole system still remains semiconducting. In addition, the magnitude of the Rashba spin splitting can be tuned by switching the dipole orientation of the 2D ferroelectric substrate. This finding provides a promising 2D material system for spintronics.

**3:30PM V17.00004 Spin-orbit interactions in two-dimensional holes in quasi-triangular wells: variational calculations**, ELIZABETH MARCELLINA, ALEX HAMILTON, The University of New South Wales, ROLAND WINKLER, Northern Illinois University, DIMITRIE CULCER, The University of New South Wales, UNSW COLLABORATION, NIU COLLABORATION — Spin-orbit (SO) interactions in semiconductors are key to the realization of semiconductor spintronic devices and quantum information processing. Low-dimensional holes are strongly SO-coupled systems, as such, they offer the promise of all-electrical spin control which can lead to more efficient electronic devices. However the spin properties of holes are highly complex, and heavily influenced by the nature of the confining potential. So far, calculations on two-dimensional holes in semiconductor heterojunctions have mostly been numerical and material-specific. In this work, we develop variational-based methods, which are easy to use and applicable to various materials, to quantify SO interactions in two-dimensional holes confined in self-consistent quasi-triangular wells. In particular, we calculate the SO hole spin-splittings and effective masses in common semiconductor materials such as GaAs, Ge, InSb, InAs, and Si. Our results show that the strength of SO interactions is very sensitive to the material type and that in zincblende materials with a bulk inversion asymmetry (BIA), the dominant contribution to the SO interaction is still the structure inversion asymmetry (SIA) term corresponding to the confinement potential.

**3:42PM V17.00005 Kondo physics in the presence of Rashba spin-orbit interactions**, ARTURO WONG, CNYN, UNAM, Mexico, SERGIO ULLOA, NANCY SANDLER, Ohio University, KEVIN INGERSANT, University of Florida — Recent theoretical studies have shown that Rashba spin-orbit interactions in a two-dimensional electron gas (2DEG) affect the thermodynamics of the impurity Kondo effect only through changes in the host density of states [1]. These changes are generally modest [1], but yield exponential enhancement of the Kondo temperature  $T_K$  [2] if the 2DEG can be tuned to a helical regime in which all electrons at the Fermi surface have the same relation between the directions of their spin and momentum. It has been proposed to access the helical regime using irradiation with circularly polarized light, giving rise to an effective Zeeman splitting of the conduction band without any direct splitting of the impurity level. We show that under this scenario, the impurity contribution to the system's net angular momentum is a universal function of the Zeeman energy divided by a temperature scale that (surprisingly at first sight) is not  $T_K$ , but rather is proportional to  $T_K$  divided by the impurity hybridization width. This universal scaling can be understood via a perturbative treatment of irradiation-induced changes in the electron densities of states. [1] R. Zitko and J. Bonca, Phys. Rev. B 84, 193411 (2011). [2] A. Wong, S. E. Ulloa, N. Sandler, and K. Ingersent, arXiv:1509.08433.

**3:54PM V17.00006 Measurement of Spin Torques in WTe<sub>2</sub>/Ferromagnet Bilayers**, DAVID MACNEILL, GREGORY M. STIEHL, MARCOS H. D. GUIMARÃES, JIWOONG PARK, DANIEL C. RALPH, Cornell University — WTe<sub>2</sub> is a semimetallic transition metal dichalcogenide (TMD) stable in the  $T_d$  crystal structure. The strong spin-orbit coupling, metallic conduction, and crystalline layered structure of the material make it interesting for both fundamental and applied spintronics research, but measurements of the spin transport properties (e.g., the spin Hall conductivity) are lacking. Here we report measurements of current induced spin torques in WTe<sub>2</sub>/Ferromagnet bilayers, detected using spin torque ferromagnetic resonance. We will attempt to distinguish whether these torques arise from interfacial spin-orbit coupling or the spin Hall effect in the TMD. We study these torques as a function of TMD layer number, from bulk to few-layer, and correlate our results with layer-number dependent charge transport measurements.

**4:06PM V17.00007 Spin relaxation in hole-doped transition metal dichalcogenides with the crystal defects**, TETSURO HABE, MIKITO KOSHINO, Tohoku University — We theoretically investigate the electronic spin relaxation effect in the hole-doped monolayer and bilayer transition-metal dichalcogenides in the presence of the crystal defects. We simulate lattice vacancies in the multi-orbital tight-binding model obtained by the first-principle method and actually estimate the spin relaxation rate by using the tight-binding model. In the monolayer, the spin-relaxation time is found to be much longer than the momentum relaxation time, and this is attributed to the fact that the spin hybridization in the band structure is suppressed by the mirror reflection symmetry. The bilayer TMD has a much shorter spin relaxation time in contrast because of the stronger spin hybridization due to the absence of the mirror symmetry.

**4:18PM V17.00008 Induced spin orbit coupling in graphene by proximity to transition metal dichalcogenides monolayer<sup>1</sup>**, ABDULRHMAN ALSHARARI, SERGIO ULLOA, Ohio Univ, MAHMOUD ASMAR, Louisiana State University — Proximity effects resulting from depositing a graphene layer on a substrate may induce spin depend interactions that change the topological properties of graphene. A suitable candidate to study this effect is a transition metal dichalcogenides substrate. A 2D layer of these materials has a large SOC that in turn induces a sizable effect near the graphene Dirac points. Graphene and 2D TMDs are nearly commensurate lattices, producing an interesting moiré pattern when adhered to one another. We study theoretically the electronic structure of graphene-TMD systems using a tight binding formalism. We find that graphene exhibits a strong proximity SOC, in addition to other perturbations that strongly affect the states; the linear dispersion near the neutrality point becomes gapped. Based on symmetries allowed by the heterostructure, we find the effective Hamiltonian to describe the low energy states. We find that diagonal SOC and staggered potential terms characterize the wave functions, akin to the structure in TMDs. A relative voltage between the layers enhances the proximity SOC in graphene, providing a tunable effect that may impact the optoelectronic properties of the system.

**4:30PM V17.00009 Electronic transport in the quantum spin Hall state due to the presence of adatoms in graphene<sup>1</sup>**, LEANDRO LIMA, CAIO LEWENKOPF, Federal Fluminense University — Heavy adatoms, even at low concentrations, are predicted to turn a graphene sheet into a topological insulator with substantial gap. The adatoms mediate the spin-orbit coupling that is fundamental to the quantum spin Hall effect. The adatoms act as local spin-orbit scatterer inducing hopping processes between distant carbon atoms giving origin to transverse spin currents. Although there are effective models that describe spectral properties of such systems with great detail, quantitative theoretical work for the transport counterpart is still lacking. We developed a multiprobe recursive Green's function technique with spin resolution to analyze the transport properties for large geometries. We use an effective tight-binding Hamiltonian to describe the problem of adatoms randomly placed at the center of the honeycomb hexagons, which is the case for most transition metals. Our choice of current and voltage probes is favorable to experiments since it filters the contribution of only one spin orientation, leading to a quantized spin Hall conductance of  $e^2/h$ . We also discuss the electronic propagation in the system by imaging the local density of states and the electronic current densities.

**4:42PM V17.00010 Current-Controlled Spin Flip in Magnetically-Substituted Graphene Nanoribbons: Toward the Realization of Graphene-Based Spintronic Devices<sup>1</sup>**, J.T. HARALDSEN, Department of Physics, University of North Florida, G. HOUCINS, C.B. CROOK, Department of Physics and Astronomy, James Madison University, JIAN-XIN ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, A.V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory — We examine the possibility of using graphene nanoribbons with directly substituted chromium atoms as spintronic device. Using density functional theory, we simulate a voltage bias across a constructed graphene nanoribbon in a device setup, where a magnetic dimer has been substituted into the lattice. Using a first principles approach, we calculate the electronic and magnetic properties as a function of Hubbard U, voltage, and magnetic configuration. Through a calculation of the energy of each magnetic configuration, we can determine that initial antiferromagnetic ground state flips to a ferromagnetic state with applied bias. Mapping this transition point to the calculated conductance for the system reveals that there is a distinct change in conductance through the graphene nanoribbon, which indicates the possibility of a spin valve. We also show that this corresponds to a distinct change in the induced magnetization within the graphene. Our goal is to show that graphene, while already being used in electronic, may also have spintronic capabilities as well.

**4:54PM V17.00011 The spin orbit coupling and magnetization in graphene/YIG and WTe<sub>2</sub>/graphene/YIG<sup>1</sup>**, MASATOSHI ONOUE, RUQIAN WU, Univ of California - Irvine, BOWEN YANG, JING SHI, Univ of California - Riverside — Quantum anomalous Hall effect (QAHE) may occur in graphene if there are both exchange field and Rashba spin-orbit coupling (SOC). Since pristine graphene is not magnetic and has extremely weak SOC, these two ingredients need to be induced externally through the proximity effect or electric field. Recently experiment found the anomalous Hall effect in graphene when it is supported on yttrium-iron-garnet (YIG), indicating the proximity-induced spin polarization in graphene. However QAHE has not been observed due to small Rashba SOC. In this work, we explore the means that may lead to strong enhancement of Rashba SOC, through first-principles calculations for graphene/YIG and WTe<sub>2</sub>/graphene/YIG. We find that the Rashba SOC strength is only 1.1 meV for graphene on YIG, whereas the exchange splitting is sizeable, 15 meV. The coverage of a WTe<sub>2</sub> layer on graphene/YIG enhances the Rashba SOC but lowers the magnetization. The presence of electric field may offer a balance between these two quantities and the physical origins will be discussed.

**5:18PM V17.00013 Measurement of current-generated torques in transition metal dichalcogenide / ferromagnet bilayers**, GREGORY M. STIEHL, DAVID MACNEILL, MARCOS H. D. GUIMARÃES, HUI GAO, JIWOONG PARK, DANIEL C. RALPH, Cornell University — We present measurements of current-generated torques in ferromagnet / transition metal dichalcogenide (TMD) bilayers for a wide range of semi-conducting TMDs, including MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub> and WSe<sub>2</sub>. TMDs present a unique opportunity to study interfacial spin-orbit torques at the two dimensional limit due to a wide range in material properties and large spin-orbit coupling. Thin TMD films are either grown by chemical vapor deposition or exfoliated from readily available TMD crystals and are incorporated into ferromagnet / TMD bilayers by either evaporation or off-axis sputtering of the ferromagnet to avoid damage to the TMD surface. Measurements of the current-generated torque are made by spin transfer ferromagnetic resonance and the magneto-optical Kerr effect. Dependence on layer number, spin-orbit coupling strength, mobility and gate dependence will be explored.

**2:30PM V18.00001 Room-temperature creation and spin-orbit torque-induced manipulation of skyrmions in thin film**, GUOQIANG YU, PRAMEY UPADHYAYA, XIANG LI, WENYUAN LI, Electrical Engineering, UCLA, SE KWON K IM, Physics and Astronomy, UCLA, YABIN FAN, KIN L. WONG, Electrical Engineering, UCLA, YAROSLAV TSEKOVNYAK, Physics and Astronomy, UCLA, PEDRAM KHALILI AMIRI, KANG L. WANG, Electrical Engineering, UCLA — Magnetic skyrmions, which are topologically protected spin texture, are promising candidates for ultra-low energy and ultra-high density magnetic data storage and computing applications<sup>1, 2</sup>. To date, most experiments on skyrmions have been carried out at low temperatures. The choice of materials available is limited and there is a lack of electrical means to control of skyrmions. Here, we experimentally demonstrate a method for creating skyrmion bubbles phase in the ferromagnetic thin film at room temperature. We further demonstrate that the created skyrmion bubbles can be manipulated by electric current. This room-temperature creation and manipulation of skyrmion in thin film is of particular interest for applications, being suitable for room-temperature operation and compatible with existing semiconductor manufacturing tools. 1. Nagaosa, N., Tokura, Y. *Nature Nanotechnology* 8, 899-911 (2013). 2. Fert, A., *et al.*, *Nature Nanotechnology* 8, 152-156 (2013).

**2:42PM V18.00002 Spin Torque induced anti-vortex excitations**, KANAN OZBOZDUMAN, VEDAT KARAKAS, SEVDENUR ARPACI, ALI TAHA HABIBIOGLU, AISHA GOKCE, Bogazici Univ, ANNA GIORDANO, University of Messina, FEDERICA CELEGATO, Institute of Materials for Electronics and Magnetism, PAULA TIBERTO, Istituto Nazionale di Ricerca Metrologica, GIOVANNI FINOCCHIO, University of Messina, GULEN AKTAS, OZHAN OZATAY, Bogazici Univ — Nanodevices that are designed to stimulate the formation of unique magnetic configurations (vortex, anti-vortex, skyrmion etc.) are applicable to spin based technologies, namely, microwave oscillators and magnetic sensors. In this talk, we report the observed dynamic behavior of an anti-vortex, which had not been thoroughly studied due to the complexity in stabilization of the structure, by analyzing its interaction with magnetic field and DC current. Permalloy (Ni<sub>81</sub>Fe<sub>19</sub>) based 2x2μm<sup>2</sup> asteroid geometry devices, consisting of four tangent circles of equal radii, facilitate the nucleation of an anti-vortex pair at the center with the application of an in-plane AC demagnetizing field and an out of plane magnetic saturation field. Magnetic force microscopy (MFM) data shows that an external magnetic field can rearrange the positions of diagonally located anti-vortex pair. Spin torque effect induces an anti-vortex pair circular motion, known as gyration. The resulting RF signal is measured using the anisotropic magneto-resistance effect (AMR) which indicates a ~250-300 mΩ change in the resistance of our samples. This study will help develop our understanding of the anti-vortex, current and magnetic field interactions for practical on-chip microwave oscillator applications.

**2:54PM V18.00003 Observation of spin transfer torques in the transverse magnetic susceptibility of the Skyrmion lattice phase of MnSi**, FELIX RUCKER, CHRISTOPH SCHNARR, ANDREAS BAUER, CHRISTIAN PFLEIDERER, Lehrstuhl für Topologie Korrelierter Systeme, Technische Universität München, Garching, Germany — In the Skyrmion lattice phase of MnSi the observation of sizeable spin transfer torques [1-3] promises easy experimental access to the precise qualitative and quantitative form of the Landau Lifshitz Gilbert equation. We report measurements of the transverse magnetic susceptibility,  $\chi_{\perp}$ , in the skyrmion lattice phase of MnSi. Our measurements show a distinct increase of  $\chi_{\perp}$  with increasing current density around the critical current density  $j_c$ . We further find a sizable dissipative part of  $\chi_{\perp}$  evolving above  $j_c$ . We discuss the broader implications of our experimental findings, which provide, for the first time, a direct link between a thermodynamic property and the effects of spin transfer torques in skyrmion lattices.

**3:06PM V18.00004 Chiral Skyrmion Hall effect in Antiferromagnets**, MATTHEW DANIELS, RAN CHENG, Carnegie Mellon University, JIANG XIAO, Fudan University, DI XIAO, Carnegie Mellon University — We study the interaction between magnetic skyrmions and spin wave currents in antiferromagnetic (AFM) insulators. Micromagnetic simulations reveal that magnon-skyrmion scattering in AFMs is dependent on the chirality of the spin wave, a degree of freedom unique to easy-axis AFMs. We also find nontrivial dynamical differences between circularly and linearly polarized waves incident upon AFM skyrmions in simulation. We characterize the resulting chiral magnon Hall effect using the O(3) nonlinear sigma model, and we elucidate the corresponding chiral skyrmion Hall effect as arising from certain magnon spin currents.

**3:18PM V18.00005 Ratchet Effects, Negative Mobility, and Phase Locking for Skyrmions on Periodic Substrates**, CHARLES REICHHARDT, DIPANJAN RAY, CYNTHIA OLSON REICHHARDT, Los Alamos National Laboratory — We examine the dynamics of skyrmions interacting with 1D and 2D periodic substrates in the presence of dc and ac drives. We find that the Magnus term strongly affects the skyrmion dynamics and that new kinds of phenomena can occur which are absent for overdamped ac and dc driven particles interacting with similar substrates. We show that it is possible to realize a Magnus induced ratchet for skyrmions interacting with an asymmetric potential, where the application of an ac drive can produce quantized dc motion of the skyrmions even when the ac force is perpendicular to the substrate asymmetry direction. For symmetric substrates it is also possible to achieve a negative mobility effect where the net skyrmion motion runs counter to an applied dc drive. Here, as a function of increasing dc drive, the velocity-force curves show a series of locking phases that have different features from the classic Shapiro steps found in overdamped systems. In the phase locking and ratcheting states, the skyrmions undergo intricate 2D orbits induced by the Magnus term.

**3:30PM V18.00006 FMR study of thin film FeGe skyrmionic material<sup>1</sup>**, VIDYA P. BHALLAMUDI, MICHAEL R. PAGE, JAMES GALLAGHER, CAROLA PURSER, JOSEPH SCHULZE, FENGYUAN YANG, P. CHRIS HAMMEL, Ohio State Univ - Columbus — Magnetic Skyrmions have attracted intense interest due to their novel topological properties and the potential for energy efficient computing. Magnetic dynamics play an important part in enabling some of these functionalities. Understanding these dynamics can shed light on the interplay of the various magnetic interactions that exist in these materials and lead to a rich magnetic phase diagram, including the Skyrmion phase. We have grown phase-pure FeGe epitaxial films on Si (111) and studied them using ferromagnetic resonance (FMR). FeGe has one of the highest recorded skyrmion transition temperatures, close to room temperature, and thin films are known to further stabilize the Skyrmion phase in the magnetic field-temperature space. We have performed cavity-based single frequency FMR from liquid nitrogen to room temperature on 120 nm thick films in both in-plane and out-of-plane geometries. The resulting complex spectra are consistent with those reported in literature for the bulk material and can be understood in terms of a conical model for the magnetism. Variable temperature broadband spectroscopy and measurements on thinner films, to better identify the various magnetic phases and their dynamic behavior, are ongoing and their progress will be discussed.

**3:42PM V18.00007 Magnetic excitations of the skyrmion host  $\text{Cu}_2\text{OSeO}_3$** , G S TUCKER, Laboratory for Quantum Magnetism, École polytechnique fédérale de Lausanne & Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, J S WHITE, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, J ROMHÁNYI, Institute for Theoretical Solid State Physics, IFW Dresden, D SZALLER, I KÉZSMÁRKI, Department of Physics, Budapest University of Technology and Economics, B ROESSLI, U STUHR, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, A MAGREZ, Laboratory for Crystal Growth, École polytechnique fédérale de Lausanne, F GROITL, Laboratory for Quantum Magnetism, École polytechnique fédérale de Lausanne & Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, P BABKEVICH, P HUANG, I ŽIVKOVIĆ, H M RØNNOW, Laboratory for Quantum Magnetism, École polytechnique fédérale de Lausanne — Inelastic neutron scattering (INS) has been used to measure the magnetic excitation spectrum along high-symmetry directions of the first Brillouin zone of the magnetic skyrmion hosting compound  $\text{Cu}_2\text{OSeO}_3$ . The INS data are mostly consistent with the predictions of a recently proposed model for the magnetic excitations in  $\text{Cu}_2\text{OSeO}_3$ , for which best-fit parameters will be reported. As will be shown, differences exist between the model predictions and the experimental findings in the form of two energy scales that likely arise due to neglected anisotropic interactions. Thus highlighting the need for the inclusion of anisotropy in future theoretical works aimed at a full microscopic understanding of the emergence of the skyrmion state in this material.

**3:54PM V18.00008 Staggered magnetization and low-energy magnon dispersion in the multi-ferroic skyrmion host  $\text{Cu}_2\text{OSeO}_3$** <sup>1</sup>, GUY G. MARCUS, BENJAMIN A. TRUMP, JONAS KINDERVATER, Institute for Quantum Matter and Johns Hopkins University, LACY L. JONES, MATTHEW B. STONE, Quantum Condensed Matter Division, Oak Ridge National Laboratories, TYREL M. MCQUEEN, Institute for Quantum Matter and Johns Hopkins University, COLLIN L. BROHOLM, Institute for Quantum Matter, Johns Hopkins University, and Quantum Condensed Matter Division, Oak Ridge National Laboratories — We present neutron diffraction and inelastic scattering of the insulating helimagnet,  $\text{Cu}_2\text{OSeO}_3$  which provide evidence for staggered magnetization and elucidate the associated low-energy magnon spectrum. The modulation wavelength of approximately  $\lambda \approx 50$  nm detected at antiferromagnetic Bragg points is of the same length scale as previously reported for the skyrmion lattice. This superstructure evidences the composite nature of the spin-1 tetrahedra that form the topological magnetic structure of the material. To understand the interplay of ferrimagnetism and long wavelength modulated magnetism, we have performed inelastic neutron scattering on a co-aligned sample of chemical vapor transport grown single crystals. We shall present the low-energy magnon dispersion and infer an effective spin Hamiltonian to account for the long-wavelength, low-energy magnetism of  $\text{Cu}_2\text{OSeO}_3$ .

<sup>1</sup>The work at IQM was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under Grant No. DEFG02-08ER46544. GGM also acknowledges support from the NSF-GRFP Grant No. DGE-1232825.

**4:06PM V18.00009 Neutron scattering study of the field-induced tricritical point in  $\text{MnSi}$** <sup>1</sup>, J. KINDERVATER<sup>2</sup>, A. BAUER, Physik-Department, Technische Universität München, Garching, Germany, M. GARST, Institute for Theoretical Physics, Universität zu Köln, Köln, Germany, M. JANOSCHEK, Los Alamos National Laboratory, Los Alamos, USA, N. MARTIN, S. MÜHLBAUER, W. HÄUSSLER, Heinz Maier-Leibnitz Zentrum, Technische Universität München, Garching Germany, P. BÖNI, C. PFLEIDERER, Physik-Department, Technische Universität München, Garching, Germany — The intermetallic compound  $\text{MnSi}$  attracts great scientific interest due to two unusual phase transitions, namely the transition from the conical phase to a skyrmion lattice in small fields and the transition from the helical to the paramagnetic phase without external magnetic field that was recently identified to be a fluctuation induced first-order transition, i.e. a so called Brazovskii-transition. Recent measurements of the specific heat provide striking evidence for a tricritical point (TCP), were the first order transition alters to second order. We report neutron spin echo measurements using the MIEZE technique. The recorded quasi elastic linewidth shows a change of the characteristic spin fluctuations at the TCP. The combination with additional SANS measurements and a generalized Brazovskii theory establishes a consistent picture of the statics and dynamics of the transition.

**4:18PM V18.00010 Controlling and imaging chiral spin textures**, GONG CHEN, Lawrence Berkeley National Laboratory — Chirality in magnetic materials is fundamentally interesting and holds potential for logic and memory applications [1,2,3]. Using spin-polarized low-energy electron microscopy at National Center for Electron Microscopy, we recently observed chiral domain walls in thin films [4,5]. We developed ways to tailor the Dzyaloshinskii-Moriya interaction, which drives the chirality, by interface engineering [6] and by forming ternary superlattices [7]. We find that spin-textures can be switched between left-handed, right-handed, cycloidal, helical and mixed domain wall structures by controlling uniaxial strain in magnetic films [8]. We also demonstrate an experimental approach to stabilize skyrmions in magnetic multilayers without external magnetic field [9]. These results exemplify the rich physics of chirality associated with interfaces of magnetic materials. [1] A. Fert et al. *Nat. Nanotechnol.* **8**, 152 (2013). [2] N. Nagaosa et al. *Nat. **4:54PM V18.00011 Observation of room-temperature skyrmion Hall effect.**, W. JIANG, Argonne National Laboratory, X. ZHANG, University of Hong Kong, P. UPADHYAYA, UCLA, W. ZHANG, Argonne National Laboratory, G. YU, UCLA, M. JUNGFLAISCH, F. FRADIN, J. PEARSON, Argonne National Laboratory, Y. TSERKOVNYYAK, K. WANG, UCLA, O. HEINONEN, Argonne National Laboratory, Y. ZHOU, University of Hong Kong, SUZANNE TE VELTHUIS, A. HOFFMANN, Argonne National Laboratory — The realization of room-temperature magnetic skyrmions is key to enabling the implementation of skyrmion-based spintronics. In this work, we present the efficient conversion of chiral stripe domains into Néel skyrmions through a geometrical constriction patterned in a  $\text{Ta}/\text{CoFeB}/\text{TaO}_x$  trilayer film at room temperature. This is enabled by an interfacial Dzyaloshinskii-Moriya interaction, and laterally divergent current-induced spin-orbit torques [1]. We further show the generation of magnetic skyrmions solely by the divergent spin-orbit torques through a nonmagnetic point contact. By increasing the current density, we observe the skyrmion Hall effect – that is the accumulation of skyrmions at one side of the device. The related Hall angle for skyrmion motion is also revealed under an *ac* driving current. Financial support for the work at Argonne came from Department of Energy, Office of Science, Basic Energy Science, Materials Sciences and Engineering Division, work at UCLA was supported by TANMS. **5:06PM V18.00012 Controlling skyrmion helicity via engineered Dzyaloshinskii-Moriya interactions**, SEBASTIAN DIAZ, Department of Physics, University of California, San Diego, ROBERTO TRONCOSO, Departamento de Física, Universidad Técnica Federico Santa María, Chile — Single magnetic skyrmion dynamics in chiral magnets with a spatially inhomogeneous Dzyaloshinskii-Moriya interaction (DMI) is considered. Based on the relation between DMI coupling and skyrmion helicity, it is argued that the latter must be included as an extra degree of freedom in the dynamics of skyrmions. An effective description of the skyrmion dynamics for an arbitrary inhomogeneous DMI coupling is obtained through the collective coordinates method. The resulting generalized Thiele's equation<sup>1</sup> is a dynamical system for the center of mass position and helicity of the skyrmion. It is found that the dissipative tensor and hence the Hall angle become helicity dependent. The skyrmion position and helicity dynamics are fully characterized by our model in two particular examples of engineered DMI coupling: half-planes with opposite-sign DMI and linearly varying DMI. In light of a recent experiment<sup>2</sup> on the magnitude and sign of the DMI, our results constitute the first step toward a more complete understanding of the skyrmion helicity as a new degree of freedom that could be harnessed in future high-density magnetic storage and logic devices.

**5:18PM V18.00013 Quantum Anomalous Hall effect in a Topological Insulator coupled to a Skyrmion Lattice.**<sup>1</sup>, TONMOY BHOWMICK, YAFIS BARLAS, GEN YIN, ROGER LAKE, Univ of California - Riverside — A Skyrmion is a topologically protected spin texture characterized by a topological charge that has been experimentally observed in both bulk B20 compounds and thin films. In a quantum anomalous Hall phase, a material develops a topologically nontrivial electronic structure giving rise to quantized hall conductivity without any external magnetic field. We predict that a conventional bulk topological insulating material (e.g. Bi<sub>2</sub>Se<sub>3</sub>, Bi<sub>2</sub>Te<sub>3</sub>, Sb<sub>2</sub>Te<sub>3</sub>) in proximity with a Skyrmion crystal, with a weak exchange coupling, will be driven into an anomalous Hall insulating phase characterized by a nonzero integer chern number in the gap. We have calculated band structure, identified the gaps, and calculated the chern number at those gaps. The calculations show that the non trivial topological properties of the Skyrmion spin texture can be imprinted on the Dirac electrons of the topological insulator.

**Session V19 GMAG DMP: Magnetic Oxide Thin Films and Heterostructures: Spin Seebeck Effects** 318 - Jobu Matsuno, RIKEN

**2:30PM V19.00001 Paramagnetic and Antiferromagnetic Spin Seebeck Effect**, STEPHEN WU, Argonne National Laboratory — We report on the observation of the longitudinal spin Seebeck effect in both antiferromagnetic and paramagnetic insulators. By using a microscale on-chip local heater, it is possible to generate a large thermal gradient confined to the chip surface without a large increase in the total sample temperature. This technique allows us to easily access low temperatures (200 mK) and high magnetic fields (14 T) through conventional dilution refrigeration and superconducting magnet setups. By exploring this regime, we detect the spin Seebeck effect through the spin-flop transition in antiferromagnetic MnF<sub>2</sub> when a large magnetic field (>9 T) is applied along the easy axis direction. Using the same technique, we are also able to resolve a spin Seebeck effect from the paramagnetic phase of geometrically frustrated antiferromagnet Gd<sub>3</sub>Ga<sub>5</sub>O<sub>12</sub> (gadolinium gallium garnet) and antiferromagnetic DyScO<sub>3</sub> (DSO). Since these measurements occur above the ordering temperatures of these two materials, short-range magnetic order is implicated as the cause of the spin Seebeck effect in these systems. The discovery of the spin Seebeck effect in these two materials classes suggest that both antiferromagnetic spin waves and spin excitations from short range magnetic order may be used to generate spin current from insulators and that the spin wave spectra of individual materials are highly important to the specifics of the longitudinal spin Seebeck effect. Since insulating antiferromagnets and paramagnets are far more common than the typical insulating ferromagnetic materials used in spin Seebeck experiments, this discovery opens up a large new class of materials for use in spin caloritronic devices. **3:06PM V19.00002 Spin Seebeck measurements of current-induced switching in YIG**<sup>1</sup>, JASON BARTELL, COLIN JERMAIN, SRIHARSHA ARADHYA, Cornell University, HAILONG WANG, The Ohio State University, ROBERT BUHRMAN, Cornell University, FENGYUAN YANG, The Ohio State University, DANIEL RALPH, GREGORY FUCHS, Cornell University — Quantifying spin torques generated at the interface between a normal metal (NM) and a ferromagnetic insulator (FI) is an important step in understanding the spin hall effect without charge transport. Measuring magnetization in NM/FI devices is challenging, however, because both magnetoresistive and magneto-optical signals are tiny in thin-film bilayers. We show that a promising alternative measurement approach is the use of picosecond thermal gradients to study spin torques in Pt/Yttrium Iron Garnet (YIG) bilayers. Recently, we demonstrated the application of heat to stroboscopically transduce a local magnetic moment into an electrical signal via the time resolved anomalous Nernst effect (TRANE) in ferromagnetic metals [1]. Using a similar geometry the spin Seebeck effect of YIG combined with the inverse spin Hall effect of Pt enables measurement of local magnetization [2]. Here we describe our study using this technique to study current-induced switching in Pt/YIG with sub-10 nm thick YIG films. [1] Bartell et al., Nat. Commun. **6**, 8460 (2015). [2] Weiler et al., Phys. Rev. Lett. **108**, 106602 (2012).

**3:18PM V19.00003 Irreversible Thermodynamics of Uniform Ferromagnets with Spin Accumulation: Bulk and Interface Phenomena**, WAYNE SASLOW, Texas A&M Univ, FUXIANG LI, Los Alamos National Laboratory, TOMOHIRO TANIGUCHI, National Institute of Advanced Industrial Science and Technology (AIST), Spintronics Research Center — We extend the irreversible thermodynamics of uniform ferromagnets to include the non-equilibrium phenomenon of spin accumulation, both for conductors and for insulators. The dynamics of the quantization axis  $\hat{M}$  is governed by the Landau-Lifshitz equation. The spin accumulation, whose longitudinal and transverse parts we label  $\delta M$  and  $\vec{m}$ , is due to a non-equilibrium distribution of magnetic excitations. Its dynamics is governed by a Bloch equation that includes spin diffusion. We also consider transport across surfaces, including boundary conditions for  $\hat{M}$ ,  $\delta M$ , and  $\vec{m}$ , and apply the results to the nature of the reciprocity between spin transfer torque and spin pumping.

**3:30PM V19.00004 Temperature dependences of magnetic anisotropy and longitudinal spin Seebeck effect in  $\text{Y}_3\text{Fe}_5\text{O}_{12}$** <sup>1</sup>, VIJAYSANKAR KALAPPATTIL, RAJA DAS, MANH-HUONG PHAN, HARIHARAN SRIKANTH, Department of Physics, University of South Florida, Tampa FL 33620 — Spin caloritronics is an emerging, exciting research area in condensed matter owing to its potential use in advanced spintronics devices. Pure spin current without having charge current has been achieved through spin Seebeck effect (SSE). Over the last 7 years SSE has been observed in ferromagnetic metals, insulators, and semiconductors using longitudinal and transverse SSE measurement configurations. In this work, we have carried out an experimental study to understand the effect of magnetic anisotropy on the temperature evolution of longitudinal spin Seebeck effect (LSSE) in a single crystalline yttrium iron garnet (YIG). The effective anisotropy field ( $H_K$ ) and inverse spin Hall (ISH) voltage ( $V_{ISH}$ ) were measured using the radio-frequency transverse susceptibility (TS) and LSSE configuration, respectively. The  $V_{ISH}$  of a 15 nm Pt strip on (6\*2\*1 mm) YIG slab with a temperature gradient of 3 K was measured in the temperature range of 120 to 300 K. The observed values of  $V_{ISH}$  vary from 1 microV for 120 K to 0.5 microV for 300 K. These values fall into the previously reported theoretical and experimental results. The temperature evolution of  $H_K$  has been compared with that of  $V_{ISH}$  to gain better fundamental understanding.

**3:42PM V19.00005 Investigation of the timescale of the spin-Seebeck effect in yttrium iron garnet from pico to nanoseconds**<sup>1</sup>, JOHN JAMISON, ZIHAO YANG, ROBERTO MYERS, Ohio State Univ - Columbus — We investigate the timescale of the spin-Seebeck effect (SSE) in yttrium iron garnet (YIG) by exciting transient thermal gradients with 150-fs laser heating pulses. The transient thermal gradient generates a spin current which is measured by a Pt top contact via the inverse spin Hall-effect (ISHE). A pulse selection system is used to lower the repetition rate of the laser to low frequencies (e.g. 10 kHz) such that the transient thermal gradient decays completely before the arrival of the next pulse. Lock-in detection, referenced at the laser repetition rate, is used to measure ISHE as a function of magnetic field, verifying that SSE is generated from the individual ultrafast laser pulses. Next, utilizing an optical delay line we vary the time delay between two equal fluence pulses. The correlated ISHE signal is measured with lock-in detection as a function of delay time with 0.1 ps resolution out to 1 ns to examine the characteristic decay times of the ultrafast laser pulse induced spin-Seebeck effect.

**3:54PM V19.00006 Heat Transport between Antiferromagnetic Insulators and Normal Metals**, EIRIK LOHAUGEN FJAERBU, HANS SKARVAAG, ERLAND G. TVETEN, ARNE BRATAAS, Norwegian University of Science and Technology (NTNU) — Antiferromagnetic insulators can become active spintronics components by controlling and detecting their dynamics via spin currents in adjacent metals. This cross-talk occurs via spin-transfer and spin-pumping, phenomena that have been predicted to be as strong in antiferromagnets as in ferromagnets. In a recent article,<sup>1</sup> we demonstrate that a temperature gradient drives a significant heat flow from magnons in antiferromagnetic insulators to electrons in adjacent normal metals. The same coefficients as in the spin-transfer and spin-pumping processes also determine the thermal conductance. However, in contrast to ferromagnets, the heat is not transferred via a spin Seebeck effect which is absent in antiferromagnetic insulator-normal metal systems. Instead, the heat is proportional to a large staggered spin Seebeck effect.

**4:06PM V19.00007 Spin Nernst and torque effects in Dzyaloshinskii-Moriya ferromagnets.**<sup>1</sup>, ALEXEY A. KOVALEV, VLADIMIR ZYUZIN, University of Nebraska-Lincoln — We predict that a temperature gradient can induce a magnon-mediated intrinsic torque and a transverse spin current in ferromagnets with non-trivial magnon Berry curvature. With the help of a microscopic linear response theory of nonequilibrium magnon-mediated torques and spin currents we identify the interband and intraband components that manifest in ferromagnets with Dzyaloshinskii-Moriya interactions and magnetic textures. In addition to the torque and spin current, we also identify the mechanical torque effect in accordance with the conservation of angular momentum. To illustrate and assess the importance of such effects, we apply our theory to the magnon-mediated spin Nernst and torque responses in a kagome lattice ferromagnet.

**4:18PM V19.00008 Spin-Hall magnetoresistance and spin Seebeck effect in Pt/CoCr<sub>2</sub>O<sub>4</sub> bilayer system**, AISHA AQEEL, NYNKE VLIETSTRA, JEROEN A. HEUVER, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, GERRIT E. W. BAUER, Institute for Materials Research and WPI-AIMR, Tohoku University, Sendai, Miyagi 980-8577, Japan, BEATRIZ NOHEDA, BART J. VAN WEES, THOMAS T. M. PALSTRA, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — Recently, the spin-Hall Magnetoresistance (SMR) and the spin Seebeck effect (SSE) have attracted much interest in the field of spintronics. However, these effects have been studied only for collinear magnetic systems. The nature and sensitivity of these effects in non-collinear magnets is still unknown. Here, we investigate the SMR and the SSE in the Pt/CoCr<sub>2</sub>O<sub>4</sub> heterostructure, by using a lock-in detection technique[1]. CoCr<sub>2</sub>O<sub>4</sub> (CCO) is a spinel with a collinear ferrimagnetic state below  $T_c = 94$  K and non collinear magnetic phases at lower temperatures. We investigated the SMR and the SSE at different temperatures (5K-300K). We observe a large enhancement in SMR and SSE in the non-collinear phase of the CCO. Moreover, finite SMR and SSE signals are also observed above  $T_c$ , where CCO is in the paramagnetic state. Our results show that SMR and SSE are very sensitive to the different magnetic phases of the CCO. [1] N. Vlietstra et al., Phys. Rev. B **90**, 174436 (2014)

**4:30PM V19.00009 Spin Seebeck Effect Signals from Antiferromagnets**<sup>1</sup>, ARATI PRAKASH, JACK BRANGHAM, FENGYUAN YANG, JOSEPH HEREMANS, The Ohio State University — The Longitudinal Spin Seebeck Effect (LSSE), in which a heat current stimulates spin propagation across an interface between a magnetic material and a normal metal, is well established and observed in ferromagnetic systems [1]. Data have been presented indicating that antiferromagnetic systems could also give rise to LSSE signals [2]. We report here on LSSE signal measured on the Pt/NiO/YIG structure, where NiO is an antiferromagnet. This system is reported to exhibit antiferromagnonic transport [3]. We explore the dependence of the signal on the thickness of the NiO and YIG layers. We also report its temperature dependence, which was not explored before [3]. The results are interpreted in terms of the temperature dependence of the magnon density of states. It appears that magnon modes with energies below about 40 K are most involved in the process, as was the case to the LSSE on YIG itself [4]. Preliminary results using other antiferromagnets and other inverse spin-Hall layers look promising and will also be reported. [1] S. R. Boona et al., Energy Environ. Sci. **7** 885-910 (2014) [2] Y. **4:42PM V19.00010 Effects of thermal magnetic fluctuations on spin transport in Pt.**<sup>1</sup>, RYAN FREEMAN, ANDREI ZHOLUD, RONGXING CAO, SERGEI URAZHIDIN, Emory University — Despite extensive studies and applications of Pt as a spin Hall material in spintronic devices, its spin-dependent transport properties are still debated. We present a comprehensive experimental study of spin transport in Pt, utilizing measurements of giant magnetoresistance (GMR) in nanoscale Permalloy (Py)-based spin valves with Pt inserted in the nonmagnetic spacer. The spin diffusion length and the interfacial spin flipping coefficients are extracted from the dependence of MR on the Pt thickness. For samples with Pt separated from Py by Cu spacers, the spin diffusion length is 6 nm at 7K, and decreases to 3 nm at room temperature. The interfacial spin flipping decreases with increasing temperature, resulting in nonmonotonic temperature dependence of MR in samples with thin Pt. In contrast, in samples with Pt in direct contact with Py, we do not observe such a nonmonotonic dependence, and the spin diffusion length is significantly larger than in samples with Pt surrounded by Cu spacers. Our results indicate a large effect of the giant paramagnetic fluctuations in the nearly ferromagnetic Pt. These fluctuations are suppressed due to the proximity magnetism when Pt is in contact with Py, resulting in enhanced spin diffusion length and reduced spin flipping at the Pt interfaces. These observations indicate the need for a critical revision of spin transport and spin Hall-related properties of Pt-based structures.

**4:54PM V19.00011 Magnon-drag contribution to the Nernst effect of single-crystal iron**, SARAH WATZMAN, The Ohio State University, HYUNGYU JIN, Stanford University, JOSEPH HEREMANS, The Ohio State University — The thermopower of single-crystal iron has recently been proven to be dominated by magnon-drag [1]. Experimental results align with hydrodynamic and microscopic theories [2] that underline the similarity between the magnon-drag charge Seebeck effect and the spin-Seebeck effect. Here, the results are expanded to the Nernst effect. The Nernst coefficient of iron is shown to be quite large and is expected to contain a contribution similar to the spin-Seebeck effect. In this case, it is present in the absence of a ferromagnet-normal metal interface or spin-orbit interactions. This talk will present a new model based on ambipolar transport. Spin-up and spin-down electrons are considered as charge carriers with separate magnon-drag Seebeck coefficients. The difference between these partial Seebeck coefficients leads to a large magnon-drag Nernst coefficient in the absence of a skew force. Furthermore, methods to increase the thermopower of iron while maintaining its magnon-drag effects will be presented with preliminary results. 1. S. J. Watzman et al., San Antonio APS March Meeting talk (2015) 2. M. E. Lucassen et al., Appl. Phys. Lett. **99** 262506 (2011)

**5:06PM V19.00012 Time-domain measurement of spin-Seebeck effect as a function of temperature: interface magnon effect**, ZIHAO YANG, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, Ohio, USA, JOHN JAMISON, Department of Material Science and Engineering, The Ohio State University, Columbus, Ohio, USA, ROBERTO MYERS, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, Ohio, USA — Time-resolved longitudinal spin Seebeck effect (LSSE) measurements allow a means to separate the influence of thermally excited electrons, phonons and magnons on the detected spin current. In this study, we measured the time dependence of the LSSE signal in Pt/YIG structures using a high bandwidth oscilloscope and a modulated CW laser from 20 K to 300 K. The rise of the LSSE signal is sharp and not truncated indicating that the measurement is not limited by the bandwidth of the setup. The temporal profile of the LSSE signal consists of two distinct components, a fast rise (200 ns) and a slow rise. The fast component is temperature independent and roughly on par with the rise time of the modulated laser intensity, while the slow component does not saturate upto 50  $\mu$ s. We model the temporal evolution of the LSSE signal by carrying out three-temperature 3D time domain heat diffusion finite element modeling of the magnon temperature gradient profile in YIG to determine the electron, magnon, and phonon temperature profile versus time. It is found that the magnon temperature gradient near the YIG interface exhibits the same fast rise time that is measured in the LSSE signal. We discuss implications for this measurement on the existing models of LSSE.

**5:18PM V19.00013 Non-local thermal spin injection to study spin diffusion in yttrium iron garnet**<sup>1</sup>, BRANDON GILES, Dept. of Materials Science and Engineering, The Ohio State University, ZIHAO YANG, JOHN JAMISON, Dept. of Electrical and Computer Engineering, The Ohio State University, ROBERTO MYERS, Dept. of Materials Science and Engineering, The Ohio State University — Understanding the generation, detection, and manipulation of spin current is critical for the development of devices that depend on spin transport for information processing and storage. Recent studies have shown that spin transport over long distances is possible in the magnetic insulator yttrium iron garnet (YIG) through the diffusion of non-equilibrium magnons. Electrically excited magnons have been shown to diffuse up to 40 $\mu$ m at room temperature [1], while thermally injected magnons were detected at ranges greater than 125 $\mu$ m at 23K [2]. However, much work is still required to fully understand the processes responsible for magnon diffusion. Here, we present an in-depth study of the diffusion of magnons in YIG. By using the non-local thermal spin detection method [2], we analyze spin transport as a function of temperature. Spin diffusion maps, which can be used to experimentally determine the spin diffusion length in YIG as a function of temperature, are presented. [1] L. J. Cornelissen, *et al.* Nat Phys (2015). [2] B. L. Giles, *et al.* arXiv:1504.02808 [cond-Mat] (2015).

**2:30PM V20.00001 Possibilities of the free-complement methodology for solving the Schrödinger equation of atoms and molecules**, HIROSHI NAKATSUJI, Quantum Chemistry Research Institute — Chemistry is a science of complex subjects that occupy this universe and biological world and that are composed of atoms and molecules. Its essence is diversity. However, surprisingly, whole of this science is governed by simple quantum principles like the Schrödinger and the Dirac equations. Therefore, if we can find a useful general method of solving these quantum principles under the fermionic and/or bosonic constraints accurately in a reasonable speed, we can replace somewhat empirical methodologies of this science with purely quantum theoretical and computational logics. This is the purpose of our series of studies – called exact theory in our laboratory. Some of our documents are cited below [1-8]. The key idea was expressed as the free complement (FC) theory (originally called ICI theory [3]) that was introduced to solve the Schrödinger and Dirac equations analytically. For extending this methodology to larger systems, order N methodologies are essential, but actually the antisymmetry constraints for electronic wave functions become big constraints. Recently [8], we have shown that the antisymmetry rule or 'dogma' can be very much relaxed when our subjects are large molecular systems. In this talk, I want to present our recent progress in our FC methodology. The purpose is to construct predictive quantum chemistry that is useful in chemical and physical researches and developments in institutes and industries. [1] H. Nakatsuji, Acc. Chem. ### 3:06PM V20.00002 Natural generalization of Slater determinants to more than one dimension

, DENIS SUNKO, Department of Physics, Faculty of Science, University of Zagreb — The calculation of realistic  $N$ -body wave functions for identical fermions is still an open problem in physics, chemistry, and materials science, even for  $N$  as small as two. Here a fundamental algebraic structure of many-body Hilbert space is described, enabling theoretically well-founded systematic investigation of wave-function space. The structure allows an arbitrary many-fermion wave function to be written in terms of a finite number of antisymmetric functions called shapes, which cannot be constructed by combining one-dimensional wave functions. Shapes naturally generalize the single-Slater-determinant form for the ground state to more than one dimension. Their number is exactly  $N!^{d-1}$  in  $d$  dimensions. A general algorithm is given to list them all in terms of standard Slater determinants. Conversely, excitations which can be induced from the one-dimensional case are bosonised into a system of distinguishable bosons, called Euler bosons, much like the electromagnetic field is quantized in terms of photons distinguishable by their wave numbers. Their wave functions are given explicitly in terms of elementary symmetric functions, reflecting the fact that the fermion sign problem is trivial in one dimension. The shapes are all possible vacua for the Euler bosons.

### 3:18PM V20.00003 Configuration space method for calculating binding energies of exciton complexes in quasi-1D/2D semiconductors.<sup>1</sup>

, IGOR BONDAREV, North Carolina Central University — A configuration space method, pioneered by Landau and Herring in studies of molecular binding and magnetism[1], is developed to obtain universal asymptotic relations for lowest energy exciton complexes (trion, biexciton) in confined semiconductor nanostructures such as nanowires and nanotubes[2], as well as coupled quantum wells. Trions are shown to be more stable (have greater binding energy) than biexcitons in strongly confined quasi-1D structures with small reduced electron-hole masses. Biexcitons are more stable in less confined quasi-1D structures with large reduced electron-hole masses. The theory predicts a crossover behavior, whereby trions become less stable than biexcitons as the transverse size of the quasi-1D nanostructure increases, which might be observed on semiconducting carbon nanotubes of increasing diameters. This method is also efficient in calculating binding energies for trion-type electron-hole complexes formed by indirect excitons in double coupled quantum wells, quasi-2D nanostructures that show new interesting electroabsorption/refraction phenomena. — [1]Landau & Lifshitz, Quantum Mechanics; C.Herring, RMP 34, 631 (1962). ### 3:30PM V20.00004 Tests for Wavelets as a Basis Set<sup>1</sup>

, THOMAS BAKER, Department of Physics & Astronomy, University of California, Irvine, CA 92697, GLEN EVENBLY, Institute for Quantum Information and Matter, California Institute of Technology, Pasadena CA 91125, USA, STEVEN WHITE, Department of Physics & Astronomy, University of California, Irvine, CA 92697 — A wavelet transformation is a special type of filter usually reserved for image processing and other applications. We develop metrics to evaluate wavelets for general problems on test one-dimensional systems. The goal is to eventually use a wavelet basis in electronic structure calculations. We compare a variety of orthogonal wavelets such as coiflets, symlets, and daubechies wavelets. We also evaluate a new type of orthogonal wavelet with dilation factor three which is both symmetric and compact in real space.

### 3:42PM V20.00005 How competitive are expansions in orbital products with explicitly correlated expansions

, KRZYSZTOF SZALEWICZ, University of Delaware — Helium dimer potential is of great importance for metrology since several future measurement standards will be based on helium gas. Such potential can be used to predict all thermodynamic properties of diffuse helium gas (nonadditive three-body potential is needed for higher densities). The accuracy required by these standards is so high, that in the past work of our group we had to include nonadiabatic, relativistic, and quantum electrodynamics effects. The current state is that the largest contribution to the uncertainty of the helium dimer potential is due to the Born-Oppenheimer (BO) part of this potential. This uncertainty was reduced and became comparable to other uncertainties in the new calculations that will be presented. These calculations used explicitly correlated Gaussian (ECG) basis sets and represent nearly exact solutions of the Schrödinger equation in the BO approximation. Similar calculations were also performed in orbital basis sets using a multilevel approach up to the full configuration interactions level. Largest existing basis sets were used at each level so that our calculations represent the best results that can currently be obtained using orbitals. These results will be critically compared with those obtained using ECG bases.

### 4:18PM V20.00006 New Types of Explicitly Correlated Gaussian Functions for Non-Born-Oppenheimer Molecular? Calculations.

, MARTIN FORMANEK, KEITH JONES, University of Arizona, SERGIY BUBIN, Nazarbayev University, LUDWIK ADAMOWICZ, University of Arizona — In this work we explore the possibility of using a new functional form of Explicitly Correlated Gaussian-type functions (ECGs) for performing non-Born-Oppenheimer calculations of diatomic molecular systems. Namely we focus our attention on ECGs with pre-exponential factors in the form of sin/cos functions of the square of the internuclear distance (sin/cos-ECGs). These ECGs can be generated as linear combinations of ECGs with complex exponential parameters (complex-ECGs) The complex-ECGs were previously used to calculate energy levels of He atom [1] and with the sin/cos-ECGs the vibrational energy levels for the H<sub>2</sub> molecule described by an effective Morse potential were calculated [2]. The focus of this study is ab-initio description of a real diatomic molecule, namely HD<sup>+</sup>, within the framework where the BO approximation is not assumed using these basis sets. The aim is to compare their accuracy and efficiency with ECGs with pre-exponential factors in the form of even powers of the internuclear distance and to assess their potential usefulness in non-BO calculations of molecules with more than two nuclei. [1] S. Bubín and L. Adamowicz, J. Chem. Phys. 124, 224317 (2006) [2] M. Formanek, K.L. Sharkey, N. Kirnosov and L. Adamowicz, J. Chem. Phys. 141, 154103 (2014)

### 4:30PM V20.00007 Complex explicitly correlated Gaussians for non-Born–Oppenheimer calculations of small molecules<sup>1</sup>

, SERGIY BUBIN, Nazarbayev University, LUDWIK ADAMOWICZ, University of Arizona — Non-Born–Oppenheimer calculations of molecular systems, where all particles are properly treated on an equal footing, represents a big challenge for the theory. Due to the huge difference in the masses of the electrons and nuclei the latter move more slowly and their correlation functions have distinct localization around the equilibrium internuclear separations. This feature is hard to implement in explicitly correlated variational approaches with Gaussian type basis functions while maintaining an analytic integrability of all necessary matrix elements. In this work we demonstrate that the difficulties can be overcome by using complex Gaussians. In our benchmark calculations on HD<sup>+</sup> molecular ion we have achieved excellent performance of this simple complex basis set that is on par or better than what was seen in previous Non-BO calculations of small diatomic molecules.

#### 4:42PM V20.00008 How Large are Nonadiabatic Effects in Atomic and Diatomic Systems?<sup>1</sup>

YUBO YANG, University of Illinois Urbana Champaign, ILKKA KYLANPAA, Tampere University of Technology, NORM TUBMAN, University of California, Berkeley, JARON KROGEL, Oak Ridge National Laboratory, SHARON HAMMES-SCHIFFER, DAVID CEPERLEY, University of Illinois Urbana Champaign — We have developed a fixed-node quantum Monte Carlo method to simulate atoms and molecules without the Born-Oppenheimer approximation with sub milli-Hartree accuracy [1]. For this purpose, we construct trial wave functions with nodes that depend on both the electronic and ionic positions. We report ground-state energies and the ionization energies for the first-row atoms and atomization energies for the first-row hydrides. The latter show effects of the nonadiabatic coupling between electrons and nuclei. We discuss how the method scales to larger systems. [1] Y. Yang, I. Kylänpää, N. M. Tubman, J. T. Krogel, S. Hammes-Schiffer, D. M. Ceperley, J. Chem. Phys. **143**(12), 2015.

#### 4:54PM V20.00009 The structure of the second-order non-Born-Oppenheimer density matrix

**D2:**<sup>1</sup> EDUARDO LUDENA, CIDNA-ESPOL, Guayaquil, Ecuador, PETER IZA, Department of Physics, ESPOL, Guayaquil, Ecuador, YOSSLEN ARAY, MAURICIO CORNEJO, CIDNA-ESPOL, Guayaquil, Ecuador, DIK ZAMBRANO, Department of Physics, ESPOL, Guayaquil, Ecuador — Properties of the non-Born-Oppenheimer 2-matrix are examined. Using a coordinate system formed by internal translationally invariant plus the total center-of-mass coordinates it is shown that regardless of the point of reference selected, the operator for the reduced second order density matrix, 2-RDM, solely depends upon the translationally invariant internal coordinates. We apply this result to examine the nature of the 2-RDM extracted from the exact analytical solutions for model non-Born-Oppenheimer four-particle systems of the Coulomb-Hooke and Moshinsky types. We obtain for both these models explicit closed-form analytic expressions for the electron and nuclear 2-RDM. An explicit expression is also obtained for the electron-nuclear 2-RDM in the Moshinsky case, which shows coupling between the electron and nuclear coordinates.

#### 5:06PM V20.00010 Extracting g tensor values from experimental data with Markov Chain

**Monte Carlo methods**, ANAGHA KULKARNI, Department of Electrical and Computer Engineering, University of Delaware, WEIWEN LIU, Department of Material Sciences and Engineering, University of Delaware, RYAN ZURAKOWSKI, Department of Biomedical Engineering, University of Delaware, MATTHEW DOTY, Department of Material Sciences and Engineering, University of Delaware — Quantum Dot Molecules (QDMs) have emerged as a new platform for optoelectronic and spintronic devices. QDMs consist of multiple Quantum Dots (QDs) arranged in close proximity such that interactions between them can tailor their optical and spin properties. These properties can be tuned during growth and in-situ by applying electric fields that vary the coupling between QDs, which controls the formation of delocalized molecular-like states. Engineering the formation of molecular states in QDMs can be used to achieve new functionalities unavailable with individual QDs. Using molecular engineering approaches to tailor QDMs require precise knowledge of parameters such as binding energies of charge complexes, magnitude of many body interactions or components of the g tensor. Precise values of these parameters are difficult to extract from either experimental measurements or theoretical calculations. We develop and demonstrate a Markov Chain Monte Carlo method for extracting elements of the g tensor for a single hole confined in a QDM from photoluminescence data obtained as a function of electric and magnetic fields. This method can be applied to extract precise quantitative values of other physical parameters from sparse experimental data on a variety of systems.

#### 5:18PM V20.00011 QUANTUM MONTE CARLO METHOD FOR HEAVY ATOMIC AND MOLECULAR SYSTEMS WITH SPIN-ORBIT INTERACTIONS<sup>1</sup>

**CODY MELTON, LUBOS MITAS, North Carolina State Univ** — We present a new quantum Monte Carlo (QMC) method that can treat spin-orbit and other types of spin-dependent interactions explicitly. It is based on generalization of the fixed-phase and projection of the nonlocal operators with spinor trial wave functions. For testing the method we calculate several atomic and molecular systems such as Bi, W, Pb, PbH and PbO, some of them with both large- and small-core pseudopotentials. We validate the quality of the results against other correlated methods such as configuration interaction in two-component formalism. We find excellent agreement with extrapolated values for the total energies and we are able to reliably reproduce experimental values of excitation energies, electron affinity and molecular binding. We show that in order to obtain the agreement with experimental values the explicit inclusion of the spin-orbit interactions is crucial.

Session V21 GSCCM DCOMP DMP: Materials at Extremes: Warm Dense Matter 320 - Arianna Gleason, Los Alamos National Laboratory

#### 2:30PM V21.00001 Study of the Warm Dense Matter with XANES spectroscopy - Applications to planetary interiors

ADRIEN DENOEUDE, CEA — With the recent discovery of many exoplanets, modelling the interior of these celestial bodies is becoming a fascinating scientific challenge. In this context, it is crucial to accurately know the equations of state and the macroscopic and microscopic physical properties of their constituent materials in the Warm Dense Matter regime (WDM). Moreover, planetary models rely almost exclusively on physical properties obtained using first principles simulations based on density functional theory (DFT) predictions. It is thus of paramount importance to validate the basic underlying mechanisms occurring for key planetary constituents (metallization, dissociation, structural modifications, phase transitions, etc....) as pressure and temperature both increase<sup>1,2</sup>.

In this work, we were interested in two materials that can be mainly found in the Earth-like planets: silica, or SiO<sub>2</sub>, as a model compound of the silicates that constitute the major part of their mantles, and iron, which is found in abundance in their cores. These two materials were compressed and brought to the WDM regime by using strong shock created by laser pulses during various experiments performed on the LULI2000 (Palaiseau, France) and the JLF (Livermore, US) laser facilities and on the LCLS XFEL (Stanford, US). In order to penetrate this dense matter and to have access to its both ionic and electronic structures, we have probed silica and iron with time-resolved X-ray Absorption Near Edge Structure (XANES)<sup>3</sup>. In parallel with these experiments, we performed quantum molecular dynamics simulations based on DFT at conditions representative of the region investigated experimentally so as to extract the interesting physical processes and comprehend the limits of the implemented models<sup>4</sup>. In particular, these works allowed us to highlight the metallization processes of silica in temperature<sup>5</sup> and the structural changes of its liquid in density, as well as to more constrain the melting curve of iron at very high pressures.

**3:06PM V21.00002 Free-electron x-ray laser measurements in isochorically heated warm dense matter** , PHILIPP SPERLING, SLAC National Accelerator Laboratory, HYUN CHUNG, International Atomic Energy Agency, LUKE FLETCHER, ERIC GALTIER, ELISEO GAMBOA, HAE JA LEE, SLAC National Accelerator Laboratory, YULTUZ OMARBAKIYEVA, HEIDI REINHOLZ, GERD RPKE, Rostock University, ULF ZASTRAU, European XFEL GmbH, SIEGFRIED GLENZER, SLAC National Accelerator Laboratory — We present the highly-resolved measurements of inelastic x-ray scattering spectra in an ultrafast heated solid. The obtained spectra from the isochorically heated foils permit a direct temperature dependent determination of plasma properties, e.g. transport coefficient. X-ray pulses from the seeded Linac Coherent Light Source delivering an average of 0.3 mJ of 8 keV x-ray photons in a 0.005% bandwidth pulse, have been focused to micrometer diameter focal spots isochorically heating solid materials to temperatures up to several eV. The inelastic forward scattering spectra resolve electronic plasma oscillations that directly allow an accurate determination of the electron temperature and density indicating a warm dense matter state. This accuracy enable us to extract plasma properties, e.g. the electrical conductivity, and enables the validation of existing theories.

**3:18PM V21.00003 Hot-dense hydrogen study up to 300 GPa** , CHANG-SHENG ZHA, Carnegie Institution of Washington — Hydrogen study under extreme pressure-temperature conditions has fundamental importance for the development of condensed physics. The prediction of insulator to metallic state transition at sufficient high pressure has been a long-standing open question for the high pressure physics community. Recently, more experimental and theoretical interests were focused on the hot-dense state of hydrogen. A numerous investigations indicated a turnover melting line with a maximum point around ~100 GPa. First-principle theoretical models indicate that the metallization could be a liquid-liquid transition just above the melting line. Experiments for these studies were mostly conducted in shock compression or pulsed laser heating in static compression resulted in large controversy observations. Hydrogen study also has been one of the engines driving the advance of static pressure-temperature technologies. New developments in hydrogen study have brought static pressure generation and signal probing technique into 300 ~400 GPa range, leading to more new phases found. New experimental results using static pressure-temperature DAC techniques demonstrate that hydrogen has much more complicated phase behaviors at multiple megabar pressure range than that expected previously.

**3:30PM V21.00004 Hydrogen Deuteride to 3.4 Megabar Mixed Isotopes and New Phases<sup>1</sup>** , RANGA DIAS, ORI NOKED, ISAAC SILVERA, Lyman Laboratory of Physics, Harvard University, Cambridge, MA 02138 — We present infrared absorption studies of solid hydrogen deuteride to pressures as high as 3.4 megabar in a diamond anvil cell and temperatures in the range 5 to 295 K. Above 198 GPa the sample transforms to a mixture of , and, interpreted as a process of dissociation and recombination. Three new phases-lines are observed, two of which differ remarkably from those of the high-pressure homonuclear species, but none are metallic. The time-dependent spectral changes are analyzed to determine the molecular concentrations as a function of time.y.

**3:42PM V21.00005 A Transition to Metallic Hydrogen: Evidence of the Plasma Phase Transition<sup>1</sup>** , ISAAC SILVERA, MOHAMED ZAGHOO, Lyman Laboratory of Physics, Harvard University, Cambridge, MA 02138, ASHKAN SALAMAT, Department of Physics, Univ. of Nevada at Las Vegas — The insulator-metal transition in hydrogen is one of the most outstanding problems in condensed matter physics. The high-pressure metallic phase is now predicted to be liquid atomic from T=0 K to very high temperatures. We have conducted measurements of optical properties of hot dense hydrogen in the region of 1.1-1.7 Mbar and up to 2200 K in a diamond anvil cell using pulsed laser heating of the sample. We present evidence in two forms: a plateau in the heating curves (average laser power vs temperature) characteristic of a first-order phase transition with latent heat, and changes in transmittance and reflectance characteristic of a metal for temperatures above the plateau temperature. For thick films the reflectance saturates at ~0.5. The phase line of this transition has a negative slope in agreement with theories of the so-called plasma phase transition.

**3:54PM V21.00006 High pressure hydrogen stabilised by quantum nuclear motion<sup>1</sup>** , RICHARD NEEDS, BARTOMEU MONSERRAT, CHRIS PICKARD, University of Cambridge — Hydrogen under extreme pressures is of fundamental interest, as it might exhibit exotic physical phenomena, and of practical interest, as it is a major component of many astrophysical objects. Structure searches have been successful at identifying promising candidates for the known phases of high pressure hydrogen. However, these searches have so far been restricted to the location of minima of the potential energy landscape. In this talk, we will describe a new structure searching method, “saddle-point ab initio random structure searching” (sp-AIRSS), that allows us to identify structures associated with saddle points of the potential energy landscape. Using sp-AIRSS, we find two new high-pressure hydrogen structures that exhibit a harmonic dynamical instability, but quantum and thermal anharmonic motion render them dynamically stable. These structures are formed by mixed layers of strongly and softly bound hydrogen molecules, and become thermodynamically competitive at the highest pressures reached in experiment. The experimental implications of these new structures will also be discussed.

**4:06PM V21.00007 Warm dense iron equation of state from quantum molecular dynamics** , TRAVIS SJOSTROM, SCOTT CROCKETT, Los Alamos National Laboratory — Through quantum molecular dynamics (QMD), utilizing both Kohn-Sham (orbital-based) and orbital-free density functional theory, we calculate the equation of state of warm dense iron in the density range 7-30 g/cm<sup>3</sup> and temperatures from 1 to 100 eV. A critical examination of the iron pseudopotential is made, from which we find the previous QMD calculations of Wang *et al.* [Phys. Rev. E 89, 023101 (2014)] to be in error. Our results also significantly extend the ranges of density and temperature which are attempted in that prior work. We calculate the shock Hugoniot and find very good agreement with experimental results to pressures over 20 TPa. Additionally we have utilized the QMD results to generate a new SESAME tabular equation of state for fluid iron, accurate in the warm dense matter region, and also extending to much broader regions of density and temperature than can be accessed by the QMD alone.

**4:18PM V21.00008 Overview of Warm Dense Matter Experiments at LCLS** , ERIC GALTIER, SLAC - Natl Accelerator Lab, ANNA LEVY, Sorbonne Universits, UPMC, CNRS, INSP, GARETH WILLIAMS, GoLP/IPFN-Laboratorio Associado, IST, LUKE FLETCHER, SLAC - Natl Accelerator Lab, FABIEN DORCHIES, JRME GAUDIN, Universit de Bordeaux, CNRS, CEA, CELIA, PHILIPP SPERLING, SLAC - Natl Accelerator Lab — Warm Dense Matter (WDM) is found in numerous astrophysical systems, from giant planets to brown dwarves or cool dense stars. Being this intermediate regime where condensed matter or plasma theories do not apply, it can be produced in all laser-induced plasma experiments on Earth. As a consequence, understanding its properties is fundamental and the whole community is investigating this extreme state of matter. With the advent of the 4th generation of light sources, namely the Free Electron Lasers (FELs), a new way of producing and diagnosing WDM becomes available. In 2009, the Linac Coherent Light Source (LCLS) at SLAC was the first FEL to produce X-ray photons to be used by the user community. Since then, various experiments took place at LCLS to produce and measure specific physical properties of WDM. In this talk, we will present an overview of key experiments performed at LCLS to study WDM. The LCLS has been used in a variety of configuration: as the main heating mechanism, as a probe or both at the same time. When used as a probe, high power lasers have been used to shock matter and excite it into the WDM regime. Finally, we will describe exciting perspectives on the WDM research, as the LCLS-II will become available in about 5 years.

**4:30PM V21.00009 First-principles equation of state and electronic properties of warm dense oxygen**, SHUAI ZHANG, KEVIN DRIVER, FRANÇOIS SOUBIRAN, BURKHARD MILITZER, University of California, Berkeley — We perform all-electron path integral Monte Carlo (PIMC) and density functional theory molecular dynamics (DFT-MD) calculations to explore warm dense matter states of oxygen. Our simulations cover a wide density-temperature range of  $1\text{--}100\text{ g cm}^{-3}$  and  $10^4\text{--}10^9\text{ K}$ . By combining results from PIMC and DFT-MD, we are able to compute pressures and internal energies from first-principles at all temperatures and provide a coherent equation of state. We compare our first-principles calculations with analytic equations of state, which tend to agree for temperatures above  $8 \times 10^6\text{ K}$ . Pair-correlation functions and the electronic density of states reveal an evolving plasma structure and ionization process that is driven by temperature and density. As we increase the density at constant temperature, we find that the ionization fraction of the  $1s$  state decreases while the other electronic states move towards the continuum. Finally, the computed shock Hugoniot curves show an increase in compression as the first and second shells are ionized. This work is funded by the DOE (DE-SC0010517).

**4:42PM V21.00010 Nuclear quantum effects in high-pressure ice**, Yael Bronstein, Philippe Depondt, Fabio Finocchi, Université Pierre et Marie Curie — Because of their mass, hydrogen nuclei are subjected to nuclear quantum effects (NQE), mainly tunneling and zero-point energy. They can be crucial to describe correctly the properties of H-containing systems, even at room temperature. A prototypical example of the importance of NQE is the transition from asymmetric H-bonds in phase VII to symmetric bonds in phase X of high-pressure ice, in which NQE drastically reduce the transition pressure<sup>1</sup>. However, natural ice is rarely pure and even small concentrations of salt (LiCl or NaCl) in ice have a strong effect on the phase diagram: the VII to X transition is shifted to higher pressures, questioning the resilience of NQE in the presence of ionic impurities<sup>2</sup>. We investigate these questions using the Quantum Thermal Bath<sup>3</sup>, a semi-classical Langevin dynamics, taking into account both NQE and thermal effects in pure and salty ices. We show why NQE can be sensitive to the presence of impurities and that non-trivial phenomena could result, such as the spectacular upshift of the transition pressure and the peculiar motion of ions.

**4:54PM V21.00011 Influence of exchange-correlation temperature effects on electric conductivity of aluminum in WDM regime**<sup>1</sup>, VALENTIN KARASIEV, LÁZARO CALDERÍN, SAM TRICKEY, Physics Dept., Univ. Florida — Calculation of transport properties in the warm dense matter (WDM) regime and comparison with experiment is an important development challenge. Computationally affordable, reliable theoretical methods are required. Current best practice is Kohn-Sham molecular dynamics (KS-MD) to sample ionic configurations and Kubo-Greenwood (KG) conductivity calculations at selected configurations. Relevant aspects are (i) the very high computational cost and unfavorable cost-scaling of the KS-MD at WDM temperatures, and (ii) neglect of explicit temperature effects in the ground state exchange-correlation (XC) functionals often used to approximate the XC free energy. We address both issues. We sample configurations of aluminum ions in the WDM regime with drastically lowered MD cost via finite-temperature orbital-free MD, including explicitly T-dependent XC [1]. Then we delineate the XC T-effects by comparing KG conductivities calculated with and without explicit XC T-dependence. The result is that explicitly T-dependent XC gives an unequivocal improvement with respect to experiment for aluminum at low material density and elevated temperatures. [1] V.V. Karasiev, T. Sjostrom, J. Dufty, and S.B. Trickey, Phys. Rev. Lett. 112, 076403 (2014)

**5:06PM V21.00012 Orbital-free Molecular Dynamics Simulations to Characterize the Liquid-vapor Critical Point of Aluminum**<sup>1</sup>, DEBAJIT CHAKRABORTY, VALENTIN KARASIEV, QTP, Department of Physics, U. Florida, Gainesville, FL 32611, SAMUEL TRICKEY, QTP, Department of Physics and Chemistry, U. Florida, Gainesville, FL 32611 — Aluminum is frequently used in warm-dense matter (WDM) experiments. However, experimental diagnostic limitations make computational exploration of the Al liquid-vapor transition important[1]. The elevated temperature and low-density make ab initio molecular dynamics (AIMD) with Kohn-Sham (KS) density functional theory (DFT) searches for the divergent compressibility extremely time consuming. Orbital free DFT (OFDFT) in principle is a cost-effective alternative. Here we report on calculations utilizing the PROFESS@QuantumEspresso interface [2] to explore suitable pseudo-potentials [3], the limitations of our wholly constraint-based VT84F [4] non-interacting free-energy functional as exposed in the low-density regime, and possible extensions or extrapolations via tunable non-interacting free energy functionals [5]. **5:18PM V21.00013 Accurate exchange-correlation energies for the warm dense electron gas**, FIONN MALONE, Imperial College London, NICHOLAS BLUNT, Cambridge University, JAMES SHEPHERD, Massachusetts Institute of Technology, DEREK LEE, JAMES SPENCER, MATTHEW FOULKES, Imperial College London — The accurate treatment of matter at high temperatures and densities is of increasing importance to many fields in physics and chemistry, with applications ranging from planetary physics to inertial confinement fusion and plasmonic catalysis. Faithfully including the effects of temperature in density functional theory simulations of warm dense matter requires accurate results for the uniform electron gas (UEG) across the whole temperature-density plane. While accurate ground state quantum Monte Carlo data have existed for over 30 years<sup>1</sup>, there remains significant disagreement between results obtained using different path integral Monte Carlo methods at finite temperature<sup>2,3</sup>. To resolve this disagreement, we use the systematically improvable density matrix quantum Monte Carlo method<sup>4,5</sup> to calculate the exchange-correlation energy of the UEG. We also demonstrate how the evaluation of free energies emerges naturally from our method.

**Session V22 DCOMP: Classical Monte Carlo and Molecular Dynamics** 321 - Paul Kent, Oak Ridge National Laboratory

**2:30PM V22.00001 Monte Carlo Simulation of a Novel Classical Spin Model with a Tricritical Point** , TYLER CARY, RICHARD SCALETTAR, RAJIV SINGH, University of California, Davis — Recent experimental findings along with motivation from the well known Blume-Capel model has led to the development of a novel two-dimensional classical spin model defined on a square lattice. This model consists of two Ising spin species per site with each species interacting with its own kind as perpendicular one dimensional Ising chains along with complex and frustrating interactions between species. Probing this model with Mean Field Theory, Metropolis Monte Carlo, and Wang Landau sampling has revealed a rich phase diagram which includes a tricritical point separating a first order magnetic phase transition from a continuous one, along with three ordered phases. Away from the tricritical point, the expected 2D Ising critical exponents have been recovered. Ongoing work focuses on finding the tricritical exponents and their connection to a supersymmetric critical point.

**2:42PM V22.00002 Molecular dynamics simulations of Leidenfrost droplets on a vibrating nano ratchet** , ABHISHEK KUMAR, NICKOLAY LAVRIK, MIGUEL FUENTES-CABRERA, Oak Ridge National Laboratory — Asymmetrically nanostructured surfaces can function as Brownian ratchets, that is, create a bias in mass or energy flows in response to thermal noise or in a more general case, isotropic excitations. Recently, experimental studies have shown that it is possible to induce directional movement of water droplets deposited on a vertically vibrating hydrophobic substrate made of inclined nanopillars. To investigate this issue, we have performed large-scale molecular dynamics (MD) simulations of a water droplet on a pillared graphitic substrate. We have found that our results not only reproduce the experimental behavior but also reveal new phenomena. In particular, it was found that at certain critical amplitude and frequency, the motion of the droplet transits from circular to linear-oscillatory along the substrate. The transition ultimately depends on the relative size of droplet and pillars, suggesting new ways of controlling the movement of water droplets on superhydrophobic substrates.

**2:54PM V22.00003 Observation of 2D Ising criticality of liquid-gas transition by the flowgram method<sup>1</sup>** , MAX YARMOLINSKY, ANATOLY KUKLOV, CSI and the Graduate Center, CUNY — We study the critical properties of the transition in 2D liquid-gas system with the square-well potential interaction by Monte Carlo simulations in the grand canonical ensemble. Due to lack of the underlying Ising symmetry, the analysis cannot be done reliably by the standard methods applicable to lattice systems. In contrast, the analysis based on the flowgram method<sup>2</sup> allowed us to find the critical point to significantly higher (and controllable) accuracy than in previous studies by other authors. Simulations were performed in a progression of sizes  $L$  up to size  $L = 84$ , with the particle numbers varying over 3 orders of magnitude and the subcritical behavior not extending beyond  $L = 10 - 15$ . The finite size scaling analysis of the critical exponents and their ratio,  $\mu$  and  $\gamma/\nu$ , gives values consistent with the 2D Ising universality class within 1-2% of errors. Our result essentially closes proposals that the nature of the liquid-gas transition might be different from the Ising model in systems with short-range interactions.

**3:06PM V22.00004 Heat Transfer in Porous Crystals Containing Adsorbed Gases** , HASAN BABAEI, CHRISTOPHER WILMER, University of Pittsburgh — Using molecular modeling, we investigated heat transfer phenomena in a porous crystal containing gases. This study was motivated by the challenge of quickly dissipating heat generated in metal-organic frameworks (MOFs) during gas adsorption. Our study reveals that thermal conductance is dominated by lattice thermal conductivity in the crystal, and that conductance decreases as the density of gas in the pores increases. We show that the observed decreased conductivity is due to phonon scattering in the crystal due to interactions with gas molecules. We have also investigated the effect of pore size and shape on thermal transport in these structures. We show that thermal conductivity of pure nanoporous crystals decreases with pore size. For nanoporous crystals with small pores, gas adsorption reduces thermal conductivity due to more phonon scatterings, whereas for larger pores, the increase in gas loading does not affect lattice thermal conductivity. We show that the probability of gas-crystal collisions is smaller for larger pores, which explains why loaded gases do not significantly affect thermal conductivity of large pore structures.

**3:18PM V22.00005 Renormalized Multicanonical Sampling in Two-Dimensional Systems** , YONG HWAN LEE, DAVID YEVIK, Univ of Waterloo — This presentation considers the relative speed and accuracy of the recently introduced renormalized multicanonical sampling method [D. Yevick, Int. J. Mod. Phys. C, 1650033] in the context of the 2 dimensional Ising model. In particular, the technique is compared to a method in which the transition matrix is constructed during a multicanonical determination of the density of states. In the comparison, the simulation speed is significantly increased by the renormalized sampling and the calculations with the transition matrices obtained from the multicanonical refinement steps of the renormalized algorithm improves the simulation speed and accuracy further.

**3:30PM V22.00006 Dynamic Algorithms for Transition Matrix Generation<sup>1</sup>** , DAVID YEVIK, YONG HWAN LEE, University of Waterloo — The methods of [D. Yevick, Int. J. Mod. Phys. C, 1650041] for constructing transition matrices are applied to the two dimensional Ising model. Decreasing the system temperature during the acquisition of the matrix elements yields a reasonably precise specific heat curve for a 32x32 spin system for a limited number (50-100M) of realizations. If the system is instead evolved to first higher and then lower energies within a restricted interval that is steadily displaced in energy as the computation proceeds, a modification which permits backward displacements up to a certain lower bound for each forward step ensures acceptable accuracy. Additional constraints on the transition rule are also investigated.

**3:42PM V22.00007 “Binless Wang-Landau sampling” - a multicanonical Monte Carlo algorithm without histograms<sup>1</sup>** , YING WAI LI, MARKUS EISENBACH, National Center for Computational Sciences, Oak Ridge National Laboratory — Inspired by the very successful Wang-Landau (WL) sampling<sup>2</sup>, we innovated a multicanonical Monte Carlo algorithm to obtain the density of states (DOS) for physical systems with continuous state variables. Unlike the original WL scheme where the DOS is obtained as a numerical array of finite resolution, our algorithm assumes an analytical form for the DOS using a well chosen basis set, with coefficients determined iteratively similar to the WL approach. To avoid undesirable artificial errors caused by the discretization of state variables, we get rid of the use of a histogram for keeping track of the number of visits to energy levels, but store the visited states directly for the fitting of coefficients. This new algorithm has the advantage of producing an analytical expression for the DOS, while the original WL sampling can be readily recovered.

**3:54PM V22.00008 Critical nonequilibrium relaxation in cluster algorithms in the BKT and weak first-order phase transitions**, YOSHIHIKO NONOMURA, Computational Materials Science Unit, National Institute for Materials Science (NIMS), Tsukuba, Ibaraki 305-0044, Japan, YUSUKE TOMITA, College of Engineering, Shibaura Institute of Technology, Saitama 337-8570, Japan — Recently we showed that the critical nonequilibrium relaxation in cluster algorithms is widely described by the stretched-exponential decay of physical quantities in the Ising [1] or Heisenberg [2] models. Here we make a similar analysis in the Berezinsky-Kosterlitz-Thouless (BKT) phase transition in the 2D XY model (simple exponential decay) and in the weak first-order phase transition in the 2D  $q = 5$  Potts model (power-law decay) [3], which means that these phase transitions can clearly be characterized by the present analysis. These relaxation behaviors are compared with those in the 3D and 4D XY models (second-order phase transition) and in the 2D  $q$ -state Potts models ( $2 \leq q \leq 4$  for second-order and  $q \geq 6$  for strong first-order phase transitions).

**4:06PM V22.00009 Real Space Alternatives to the Ewald: Shifted Electrostatics for Multipoles**, MADAN LAMICHHANE, THOMAS PARSONS, KATHIE NEWMAN, J. DANIEL GEZELTER, Univ of Notre Dame — We have developed three real-space methods for computing electrostatic interactions in Molecular Dynamics (MD): Gradient Shifted Force (GSF), Shifted Potential (SP), and Taylor Shifted Force (TSF) [1]. Electrostatic interaction energies, forces, and torques of the molecules obtained from these methods were tested against an analytical as well as a reference method in a variety of condensed phase environments. Tests show that electrostatic energies, forces, and torques evaluated from our real-space methods show excellent agreement with the computationally expensive Ewald method. Total energy is conserved in molecular systems interacting using GSF and TSF methods. Different structural and dynamical properties of the multipolar fluids have been investigated. Recently, we have developed methods for evaluating dielectric properties for dipolar and quadrupolar fluids. Results for the dielectric constant of dipolar and quadrupolar fluids evaluated using the fluctuation and perturbation method will also be discussed. [1] M. Lamichhane *et al.*, J. Chem. Phys **141**, 134109 (2014); **141**, 134110 (2014).

**4:18PM V22.00010 A robust high-order ideal magnetohydrodynamic solver**, DAVID SEAL, U.S. Naval Academy, ANDREW CHRISTLIEB, XIAO FENG, Michigan State University, QI TANG, Rensselaer Polytechnic Institute — In this work we present a robust high-order numerical method for the ideal magnetohydrodynamics (MHD) equations. Our method is single-stage and single-step, and hence amenable to adaptive mesh refinement (AMR) technology. The numerical robustness of the scheme is realized by accomplishing a total of two unrelated tasks: we retain positivity of the density and pressure by limiting fluxes similar to what happens in a flux corrected transport method, and we obtain divergence free magnetic fields by implementing an unstaggered transport method for the evolution of the magnetic potential. We present numerical results in two and three dimensions that indicate the utility of the scheme. These results include several classical test problems such as Orszag-Tang, cloud shock interactions and blast wave problems.

Session V23 DCMP: Superconductors: STM of Fe-based, Cuprates, and others 322 -

**2:30PM V23.00001 STM/S study on the role of Arsenic in Iron-based Superconductivity at Atomic Scale**, S. H. PAN, Inst. of Physics, CAS; TcSUH, Univ. of Houston, J. X. YIN, Institute of Physics, CAS, ZHENG WU, TcSUH, Univ. of Houston, ANG LI, TcSUH, Univ. of Houston, J. H. WANG, TcSUH, Univ. of Houston, X. J. LIANG, Institute of Physics, CAS, C. L. ZHANG, Rice Univ, P. C. DAI, Rice University, C. -S. TING, TcSUH, Univ of Houston, J. P. HU, Institute of Physics, CAS, Z. Q. WANG, Boston College, H. P. HOR, TcSUH, Univ. of Houston, G. F. CHEN, HONG DING, Institute of Physics, CAS — We use scanning tunneling microscopy /spectroscopy to investigate the role of Arsenic in superconducting Ba<sub>0.4</sub>K<sub>0.6</sub>Fe<sub>2</sub>As<sub>2</sub> by directly breaking and repairing the local Fe-As structure. After the up-As-layer peeled away, the tunneling spectrum of the exposed Fe surface reveals a shallow incoherent gap, indicating a severe suppression of superconductivity without As covering. When an As-dimer is placed on the same Fe surface, a localized topographic feature is formed due to p-d orbital hybridization and the superconducting coherent peaks recover locally with the superconducting gap size exactly the same as the Fe-layer with a complete As-coverage. These observations unravel the Fe-As interactions on an atomic scale and imply its essential roles in the Fe-based superconductivity.

**2:42PM V23.00002 Surface effect of epitaxially grown BaFe<sub>2</sub>As<sub>2</sub> surface – Scanning Tunneling Microscopy and Photoemission spectroscopy study**, SUNGMIN KIM, SUNWOUK YI, MINJUN LEE, HANHO LEE, HOYEON JEON, YONGCHAN YOO, INHAE ZOH, CHAO ZHANG, MYUNGCHUL OH, YOUNG KUK, Department of Physics and Astronomy, Seoul National University — The electronic properties of Co-doped BaFe<sub>2</sub>As<sub>2</sub> (BFCA) iron pnictide superconductors were studied using scanning tunneling microscopy and spectroscopy. BFCA samples with superconducting transition temperatures 22-27 K, were grown on SrTiO<sub>3</sub>(100) by pulsed laser deposition (PLD) growth under ultrahigh vacuum condition. As-grown surfaces revealed  $2 \times 2$  or  $2\sqrt{2} \times 2\sqrt{2}$  structures as a function of bias voltage at 4.3 K. Missing row structures were also observed on as-grown samples, suggesting many nucleation sites and resultant antiphase boundaries. The I-V and dI/dV spectra were deviated from the bulk spectrum obtained by contact conductance measurement. After removing surface layers by ion beam sputtering, different spectra were observed. The obtained spectra were explained with the surface state effect in BFCA samples as compared with DFT calculations.

**2:54PM V23.00003 Elasto-Scanning Tunneling Microscopy: Visualizing the Coupling of Strain to Electronic Nematicity in NaFeAs**, ERICK ANDRADE, AYELETE NOTIS, Columbia Univ, LINGYI XING, XIANCHENG WANG, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, ABHAY PASUPATHY, Columbia Univ — Electronic nematicity is a widely observed phenomenon in the pnictide superconductors. In this phenomenon, the electronic structure breaks four-fold rotational symmetry and displays anisotropic behavior that can be observed in several transport and spectroscopic measurements. Understanding the driving force for the nematicity and its relationship to superconductivity remains a key goal in these materials. Motivated by transport measurements that indicate that the nematicity is strongly coupled to crystal strain, we developed a new experimental technique by which tunable uniaxial strain can be applied to a crystal while scanning tunneling microscopy is performed on the crystal surface. The technique allows us to track the same atomically resolved area of the sample as a function of strain. Using this new technique, we measure the response of the local density of states to strain in the tetragonal and orthorhombic phases of the crystal. In the orthorhombic phase, we find that strain can move structural domain walls but does not affect the magnitude of the electronic nematicity. On the other hand, in the tetragonal phase we find that strain controls the magnitude of the electronic nematicity, indicating that the material is in a paranematic state above the structural transition.

**3:06PM V23.00004 Quantum phase transition in Fe<sub>1+x</sub>(Te,Se) induced by Single-atomic Impurities studied by STM/S**, J. X. YIN, Institute of Physics, CAS, ZHENG WU, TcSUH University of Houston, XIONG HUANG, Z. Y. YE, RUI WU, X. J. LIANG, H. Q. MAO, JIAN LI, Institute of Physics, CAS, C. -S. TING, TcSUH University of Houston, J. P. HU, Institute of Physics, CAS, Z. Q. WANG, Boston College, P.-H. HOR, TcSUH University of Houston, HONG DING, S. H. PAN, Institute of Physics, CAS; Collaborative Innovation Center of Quantum Matter — Previously we discovered a robust zero-energy bound state at an interstitial Fe impurity (IFIs) in Fe<sub>1+x</sub>(Te,Se), which resembles the Majorana mode (Nature Physics **11**, 543, (2015)). Here we report our comprehensive study, using scanning tunneling microscopy/spectroscopy technique, of the global effect of IFIs on the ground state of Fe<sub>1+x</sub>(Te,Se) over a wide range of IFI concentration  $x$ . Our high resolution tunneling spectroscopy and quasi-particle interference data at very low temperature demonstrate that IFIs do not affect the electron pairing strength, while they cause significant dephasing effect, which eventually drives the ground state of the system from strong-coupling-superconductivity to diffusive-Bose-metal.

**3:18PM V23.00005 Reconciling STS and ARPES data for the correlated superconductor LiFeAs**, JONGBAE HONG, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, DAVID ABERGEL, Nordita, KTH Royal Institute of Technology and Stockholm University, Roslagstullsbacken 23, SE-106 91 Stockholm, Sweden — The inconsistency between the density of states revealed by scanning tunneling spectroscopy (STS) and that given by angle-resolved photoemission spectroscopy (ARPES) is a substantial problem for understanding the nature of strongly correlated superconductors such as Fe-based LiFeAs and the cuprates. We reveal that the two side peaks commonly appearing in both pnictide and cuprate superconductors are the result of the non-equilibrium behavior associated with singlet cotunneling from the tip to the strongly correlated sample [1]. We accurately reproduce the STS line shape of the Fe-based LiFeAs using a sample density of states which coincides with ARPES data, thereby producing a unified description for these materials. [1] Jongbae Hong and D.S.L. Abergel, arXiv:1411.5532.

**3:30PM V23.00006 Anticorrelation between the parent charge transfer gap and maximum transition temperature in cuprates**, WEI RUAN, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, CHENG HU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, PENG CAI, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, YINGYING PENG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, XINTONG LI, ZHENQI HAO, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, XINGJIANG ZHOU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, ZHENG-YU WENG, Institute for Advanced Studies, Tsinghua University, YAYU WANG, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University — We use scanning tunneling spectroscopy to measure the electronic structure of the parent Mott insulator of three different types of cuprates. The charge transfer gap size exhibits pronounced variations, and more interestingly it shows an anticorrelation with the maximum superconducting transition temperature achieved at the optimal doping of each cuprate. This result suggests that the Mottness in parent cuprate plays a crucial role in determining the superconducting properties. In particular, reducing the electron correlation strength enhances superconductivity, which is consistent with the pairing mechanism based on the doped Mott insulator picture.

**3:42PM V23.00007 STM sub-gap structure in cuprates is a consequence of density waves, according to Mean-Field Theory and CDMFT<sup>1</sup>**, SIMON VERRET, Université de Sherbrooke, JYOTIRMOY ROY, TIFR Mumbai India, DAVID SÉNÉCHAL, A.-M. S. TREMBLAY, Université de Sherbrooke — Much work has been done to find how the pseudogap is related to charge density waves in cuprates. In scanning tunneling microscopy (STM) measurements, the superconducting gap and pseudogap of cuprates are sometimes accompanied by a small *sub-gap structure* at very low energy. This was documented early in vortex cores studies, and has now been reported at zero field for YBCO.(1) Here, we show that this can be caused by density waves, first through a standard mean-field approach, and then with Cellular Dynamical Mean-Field Theory for the Hubbard model using an exact diagonalization solver. We comment on the implication of these results for the relation between pseudogap and charge order. (1) Jens Bruér et al. arXiv:1507.06775

<sup>1</sup>Supported by NSERC, CIFAR and the Tier I Canada Research Chair Program

**3:54PM V23.00008 Theoretical visualization of charge order in cuprates**, PEAYUSH CHOUBEY, University of Florida, WEI-LIN TU, National Taiwan University, TING-KUO LEE, Institute of Physics, Academia Sinica, Taiwan., PETER HIRSCHFELD, University of Florida — The anti-phase charge density wave (AP-CDW) state obtained in [1] by solving the renormalized mean-field theory of the t-J model was shown to have a dominant d-form factor for the bond order. However, the local density of states (LDOS) is only defined at the Cu lattice site. In order to compare with scanning tunneling microscopy (STM) experiments [2] in detail, we compute the continuum LDOS in the AP-CDW state at typical STM tip heights using Bi<sub>2</sub>Sr<sub>2</sub>Ca<sub>2</sub>CuO<sub>2</sub> Wannier functions obtained from first principles [3]. The resulting spatial patterns compare very well with experimental results, and show the important role of the planar O2p states filtered through the BiO and SrO layers. In addition, we compute the Cu and O sublattice LDOS and Fourier transform it to obtain the amplitudes of s, s' and d-form factors actually reported in an STM experiment [4]. References:

**4:06PM V23.00009 Direct Local Measurement of the Superconducting Energy Gap of Nb doped SrTiO<sub>3</sub>**, JEONGHOON HA, Center for Nanoscale Science and Technology/NIST, Maryland NanoCenter/UMCP, Natl High Magnetic Field Lab/FSU, GURU KHALSA, FABIAN NATTERER, Center for Nanoscale Science and Technology/NIST, HONGWOO BAEK, Center for Nanoscale Science and Technology/NIST, Dept. of Phys. and Astro./SNU, Natl High Magnetic Field Lab/FSU, WILLIAM G. CULLEN, Center for Nanoscale Science and Technology/NIST, Maryland NanoCenter/UMCP, YOUNG KUK, Dept. of Phys. and Astro./ Seoul Natl Univ., JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology/NIST — Strontium titanate (STO) is a perovskite metal oxide insulator that can be electron doped by substitution of Ti or Sr sites with Nb or La, respectively, or by oxygen vacancies. When doped to high electron densities with concentration in the range of  $5 \times 10^{19} \text{ cm}^{-3}$  to  $2 \times 10^{20} \text{ cm}^{-3}$ , STO becomes superconducting with a transition temperature below 400 mK, at a value highly dependent on the doping concentration. Previous observations were made on bulk crystals or films of doped STO by measuring the transitions in resistivity, magnetic susceptibility or thermal conductivity as a function of temperature or magnetic field. In this work, we use an ultra-low temperature scanning tunneling microscope (STM) to investigate the local electronic structure of the surface of Nb doped STO. The tunneling spectra taken at a sample temperature of  $\approx 10$  mK reveal a BCS energy gap of  $\Delta = 40$   $\mu\text{eV}$ . Temperature and magnetic field dependent tunneling measurements show a critical temperature of  $\approx 250$  mK and upper critical field of  $\approx 0.07$  T. This is the first report of direct measurement of superconducting STO using an STM.

#### 4:18PM V23.00010 Multiband superconductivity in $2H\text{-NbSe}_2$ probed by Doppler-modulated scanning tunneling spectroscopy<sup>1</sup>

, I. FRIDMAN, Quantum Applied Science and Research, Inc., C. KLOC, Nanyang Technological University, Singapore, C. PETROVIC, Brookhaven National Laboratory, J. Y. T. WEI, University of Toronto and Canadian Institute for Advanced Research — Cooper pairing in multiband superconductors can involve carriers from bands having different dimensionalities, and the interband coupling can provide for novel pairing interactions. In addition to  $\text{MgB}_2$ , recent experiments on  $2H\text{-NbSe}_2$  have studied the Fermi surface topology using angle- and temperature-dependent scanning tunneling spectroscopy.[1] We present another novel method for probing multiband pairing: using a field-induced diamagnetic supercurrent, applied along different crystal axes, to perturb the quasiparticle density-of-states spectrum. By measuring the evolution of the quasiparticle spectrum under finite superfluid momentum, we characterize the pairing gaps and gap anisotropies. This approach is demonstrated on  $2H\text{-NbSe}_2$  at 300 mK with a magnetic field of up to 9 T applied in the *ab*-plane.[2] The STM measurements revealed unambiguous evidence for multiband pairing, and evidence for a novel transition of the in-plane vortex lattice. We discuss the characteristics of this transition in light of data from other probes. [1] Y. Noat *et al.*, Phys. Rev. B 92, 134510 (2015). [2] I. Fridman *et al.*, Applied Physics Letters 99, 192505 (2011).

#### 4:30PM V23.00011 Coherent long-range magnetic bound states in a superconductor

, GERBOLD MENARD, Univ Pierre et Marie Curie, SEBASTIEN GUISSART, Laboratoire de physique des solides, CHRISTOPHE BRUN, STEPHANE PONS, VASILY STOLYAROV, FRANCOIS DEBONTRIDDER, MATTHIEU LECLERC, Institut des nanosciences de Paris, ETIENNE JANOD, LAURENT CARIO, Institut des Materiaux Jean Rouxel, DIMITRI RODITCHEV, Institut des nanosciences de Paris, PASCAL SIMON, Laboratoire de physique des solides, TRISTAN CREN, Institut des nanosciences de Paris — Using low temperature scanning tunneling spectroscopy we accessed to localized states called Shiba states associated to magnetic impurities as well as their spatial dependence [1]. We studied samples of superconducting  $\text{NbSe}_2$  containing a really small concentration of native magnetic impurities. We observed the appearance of star-shaped structures around individual impurities with a size of the order of the coherence length of the superconductor ( $\approx 10$  nm). The fine study of our data revealed an oscillation of the density of states along the star branches. To further analyze our results, we performed tight-binding calculations which reproduced the observed spatial symmetry. A semi-analytical calculation also enabled us to establish a relation between the different spatial scales observed and the physical quantities associated to superconductivity, and to understand the role of dimensionality in such systems. [1] Nature Physics (2015), DOI:10.1038/NPHYS3508

#### 4:42PM V23.00012 Creating nanostructured superconductors on demand by local current annealing

, HONGWOO BAEK, Center for Nanoscale Science and Technology/NIST, Dept. of Phys. and Astro./SNU, JEONGHOON HA, DUMING ZHANG, BHARATH NATARAJAN, Center for Nanoscale Science and Technology/NIST, Maryland NanoCenter/UMCP, RONGWEI HU, KEFENG WANG, STEVEN ZIEMAK, JOHNPIERRE PAGLIONE, Dept. of Phys./UMCP, YOUNG KUK, Dept. of Phys. and Astro./SNU, JONATHAN P. WINTERSTEIN, RENU SHARMA, NIKOLAI B. ZHITENEV, JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology/NIST — When the effective size of a superconductor becomes comparable to the characteristic length scales, dramatic changes can occur in the superconducting properties that allow various applications in quantum devices. However, challenges remain in controlling the shape and size of specific superconducting materials. Here, we report on a method to create nanostructured superconductors by partial crystallization of the half-Heusler material,  $\text{YPtBi}$  using scanning tunneling microscopy. Superconducting islands, with diameters in the range of 100 nm, were reproducibly created by local current annealing of disordered  $\text{YPtBi}$  in the tunneling junction. Tunneling spectra measured on the islands showed non-Bardeen-Cooper-Schreffer behavior with different energy gaps and critical values as a function of spatial position. With increasing magnetic field, conductance maps showed the sequential addition of single vortices in the nanostructure, which fused into a giant vortex ring at 1.25 T. These results demonstrate an interesting method of creating tailored superconductors with complex materials for future applications [1]. [1] H. Baek *et al.*, Phys. Rev. B 92, 094510 (2015).

#### 4:54PM V23.00013 Magnetic field dependence of the density of states and tilted vortex lattice in the superconductor $\beta\text{-Bi}_2\text{Pd}$

, EDWIN HERRERA-VASCO, ISABEL GUILLAMON, ANTON FENTE, Universidad Autonoma de Madrid, JOSE GALVIS, Universidad Central, ALEXANDRE CORREA, ROBERTO LUCCAS, FEDERICO MOMPEAN, MAR GARCIA HERNANDEZ, Instituto de Ciencia de Materiales, Consejo Superior de Investigaciones Cientificas, JEAN P. BRISON, Universite Grenoble Alpes, CEA, INAC-SPSMS, SEBASTIAN VIEIRA, HERMANN SUDEROW, Universidad Autonoma de Madrid — We present very low-temperature scanning tunneling microscopy (STM) experiments on the superconductor  $\beta\text{-Bi}_2\text{Pd}$ . We find a single superconducting gap from the zero-field tunneling conductance. We also find that the hexagonal vortex lattice is locked to the square atomic lattice. The magnetic field dependence of the intervortex tunneling conductance is higher than the one expected in a single-gap superconductor. Such an increase in the intervortex tunneling conductance has been found in superconductors with multiple superconducting gaps. We fit the upper critical field  $H_{c2}(T)$  and show that multiband Fermi surface is needed to explain the observed behavior. We propose that  $\beta\text{-Bi}_2\text{Pd}$  is a single-gap multiband superconductor. We have measured the tilted vortex lattice (TVL) using a three axis superconducting magnet. Our results give first real space imaging of the TVL in a nearly isotropic s-wave BCS superconductor. From a detailed study of the TVL varying polar and azimuthal angles, we find correlations between the square atomic lattice and the TVL.

#### 5:06PM V23.00014 Josephson STM at mK temperatures: Coupling to the electronic environment<sup>1</sup>

, MICHAEL DREYER, RAMI DANA, WAN-TING LIAO, CRIS LOBB, FRED WELLSTOOD, BOB ANDERSON, University of Maryland — Ultra-small Josephson junctions can couple to modes in the electronic environment. This leads to sub-gap peaks in the  $I(V)$  curve in addition to the phase diffuse supercurrent. The  $I(V)$  curve can - in principle - be explained by  $P(E)$  theory [1] which describes the probability of tunneling at energy  $E$ . A recent study [2] showed that antenna modes of the STM tips could be responsible for the observed sideband structures. In our case the explanation appears to be less simple. We employ a dual tip STM at a temperature of 30 mK [3]. The  $I(V)$  spectra of the two tips show distinct patterns with only one shared mode. While the supercurrent branch for the "inner" tip is visible, it is obscured by a resonance for the outer tip. Possible causes and applications to other systems will be discussed. [1] G.-L. Ingold, H. Grabert, U. Eberhardt, PRB 50(1), 395 (1994) [2] Berthold Jäck, *et. al.*, Appl. Phys. Lett. 106, 013109 (2015) [3] Anita Roychowdhury, *et. al.*, Rev. Sci. Inst., 85, 043706 (2014)

#### 5:18PM V23.00015 Friedel oscillations and quasiparticle interference: Complementary STM and REXS approach

, PEGOR AYNANIAN, Binghamton University, ANDRS GYENIS, Princeton University, EDUARDO DA SILVA NETO, University of British Columbia, FEIZHOU HE, RONNY SUTARTO, Canadian Light Source, ENRICO SCHIERLE, EUGEN WESCHKE, BESSY, MARIAM KAVAI, Binghamton University, RYAN BAUMBACH, Florida State University, JOE THOMPSON, ERIC BAUER, LANL, ZACHARY FISK, UC Irvine, ANDREA DAMASCELLI, University of British Columbia, ALI YAZDANI, Princeton University — The origin of a competing charge ordering in the high-temperature superconducting cuprates has recently been subject to intense experimental and theoretical debates. Dalla Torre *et al* theoretically proposed that Friedel oscillations can reproduce the experimentally observed scattering peak in the resonant elastic x-ray scattering (REXS) of cuprates [NJP, 17 022001 2015]. Using complementary spectroscopic imaging with the scanning tunneling microscope and REXS on the heavy fermion compound  $\text{CeMn}_5$  ( $M=\text{Co, Rh}$ ) we observe a scattering peak in REXS, similar, yet broader than that found in cuprates. Through temperature and doping dependent experiments, we demonstrate this enhanced peak to originate from the scattering of hybridized heavy *f*-electrons. We discuss the origin of this phenomenon and its relation to Friedel oscillations and charge ordering.

## 2:30PM V24.00001 Ligand engineering of nanoparticle solar cells<sup>1</sup>, MARTON VOROS, Argonne Natl Lab —

Semiconductor nanoparticles (NP) are promising materials to build cheap and efficient solar cells. One of the key challenges in their utilization for solar energy conversion is the control of NP surfaces and ligand-NP interfaces. Recent experiments have shown that by carefully choosing the ligands terminating the NPs, one can tailor electronic and optical absorption properties of NP assemblies, along with their transport properties.[1] By using density functional theory based methods, we investigated how the opto-electronic properties of lead chalcogenide NPs may be tuned by using diverse organic and inorganic ligands. We interpreted experiments, and we showed that an essential prerequisite to avoid detrimental trap states is to ensure charge balance at the ligand-NP interface, possibly with the help of hydrogen treatment. [1] R. Crisp et al., Scientific Reports 5, 9945 (2015); C. Giansante et al., J. Am. Chem. Soc. 137, 1875 (2015).

## 3:06PM V24.00002 The effect of Ta "oxygen scavenger layer" on HfO<sub>2</sub>-based resistive switching behavior: thermodynamic stability, electronic structure, and low-bias transport, XIAOLIANG ZHONG,

Argonne Natl Lab, IVAN RUNGGER, Materials Division, National Physical Laboratory, TW11 0LW, UK, PETER ZAPOL, Argonne National Laboratory, HISAO NAKAMURA, YOSHIHIRO ASAI, National Institute of Advanced Industrial Science and Technology (AIST) Japan, OLLE HEINONEN, Argonne National Laboratory and Northwestern University — Metal-oxide-metal heterostructures are promising candidates for next-generation random access memories, which exhibit reversible resistive switching between high- and low-conductance states. Recent experimental work showed that inserting a metallic 'oxygen scavenger layer' between TiN electrode and HfO<sub>2</sub> significantly improves device switching performance. We show, using atomistic modeling within the GGA+U scheme of Density Functional Theory, that a Ta oxygen scavenger layer significantly enhances the thermodynamic stability of depleting oxygen from the oxide. Furthermore, the presence of a Ta layer reduces the dependence of the Schottky barrier heights on the location of the oxygen removed from the oxide matrix. Finally, the Schottky barrier height has a very small effect on the on-state low-bias conductance; this is more sensitive to the location of the depleted oxygen. We gratefully acknowledge the computing resources provided on Blues, a high-performance computing cluster operated by the Laboratory Computing Resource Center at Argonne National Laboratory. Work at Argonne was supported by U. S. DOE, Office of Science under Contract No. DE-AC02-06CH11357.

## 3:18PM V24.00003 Band alignment study on Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface with the presence of point defect<sup>1</sup>, JIANQIU HUANG<sup>2</sup>, ERIC TEA<sup>3</sup>, CELINE HIN<sup>4</sup>, Virginia Tech —

Metal-Oxide interface has a wide use in electronic devices. Currently, technological development is aiming on the shrinkage of electronic devices' size. Based on the knowledge of electron tunneling effect, the reduction of dielectric thickness would cause an exponential increase on electron tunneling probability which contributes to current leakage. It might cause dielectric breakdown, which could make a severe and irreversible damage to the devices. Therefore, the main purpose of this study is to explore the possible factors that can lead to dielectric breakdown at metal-oxide interface. Density functional theory *ab initio* calculation has been applied to study the Al/SiO<sub>2</sub> and Cu/SiO<sub>2</sub> metal-oxide interface. Results on oxygen (di)vacancies at the interface will be presented and compared with the defect free model. The band alignment has been constructed to describe the variation of potential barrier height due to defect at interface. Results show the oxygen (di)vacancies at interface might trap electron and reduce potential barrier height. Moreover, the potential barrier height has a significant dependence on defects charge states.

## 3:30PM V24.00004 Voltage mediated metal to insulator transition in VO<sub>2</sub> and V<sub>2</sub>O<sub>3</sub> nanodevices<sup>1</sup>, ILYA VALMIANSKI, Physics Department, UC San Diego, J. GABRIEL RAMIREZ, Physics Department, Universidad de los Andes,

SIMING WANG, Livermore Berkeley National Laboratory, STEFAN GUENON, Physics Department, University of Tuebingen, IVAN K. SCHULLER, Physics Department, UC San Diego — We investigate the mechanism of the voltage mediated MIT in a series of vanadium oxides (VO<sub>2</sub> and V<sub>2</sub>O<sub>3</sub>) nano-scopc devices. All films presented ~4 orders of magnitude resistance change at the MIT. The devices consist of in-plane gold electrodes with 200 nm wide tip on top of lithographically defined vanadium oxide films. The gap size between electrodes was fixed at 140 nm. Unlike micron-scale devices, the current-voltage characteristics in nano-scale V<sub>2</sub>O<sub>3</sub> cannot be accounted solely by an inhomogeneous joule-heating model, suggesting additional mechanisms may be playing a role in the switching behavior. However, in the case of nano-scopc VO<sub>2</sub> devices, it may be possible to explain the results with only inhomogeneous heating. We perform detailed electrical and thermal Finite Element Method (FEM) calculations on both the VO<sub>2</sub> and V<sub>2</sub>O<sub>3</sub> devices. We couple the FEM analysis with a variety of theoretical models, which can shed light on the nanoscopic nature of the MIT in VO<sub>2</sub> and V<sub>2</sub>O<sub>3</sub>.

## 3:42PM V24.00005 Ferroelectric Modulation of Two-dimensional Electron Gas Conductivity at Oxide Interfaces, WENXIONG ZHOU, JUN ZHOU, KUN HAN, SHENGWEI ZENG, ZHEN HUANG, THIRUMALAI VENKATESAN, ARIANDO

ARIANDO, Natl Univ of Singapore, NUSNNI-NANOCORE, NATIONAL UNIVERSITY OF SINGAPORE, SINGAPORE 117411 TEAM, DEPARTMENT OF PHYSICS, NATIONAL UNIVERSITY OF SINGAPORE, SINGAPORE 117542 TEAM, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, NATIONAL UNIVERSITY OF SINGAPORE, SINGAPORE 11757 TEAM — In this report, by inserting a ferroelectric Ba<sub>0.2</sub>Sr<sub>0.8</sub>TiO<sub>3</sub> layer between LaAlO<sub>3</sub>/SrTiO<sub>3</sub> heterostructure, a two-dimensional electron gas (2DEG) was found at LaAlO<sub>3</sub>/Ba<sub>0.2</sub>Sr<sub>0.8</sub>TiO<sub>3</sub> interface. With electrical, optical, piezoresponse force microscopic measurements and first-principle calculations, we studied the impact of this ferroelectric Ba<sub>0.2</sub>Sr<sub>0.8</sub>TiO<sub>3</sub> layer on the 2DEG. Both carrier density and mobility of the 2DEG can be modulated by changing the thickness of the ferroelectric layer. We also observed that Ba<sub>0.2</sub>Sr<sub>0.8</sub>TiO<sub>3</sub> layer can suppress oxygen vacancy formation, leading to observation of temperature-independent polarization-induced carrier density. These results indicate that the 2DEG at oxide interfaces can be ferroelectrically modulated.

## 3:54PM V24.00006 Energy Level Alignment at the Interface between Linear-Structured Benzenediamine Molecules and Au(111) Surface, GUO LI, TONATIUH RANGEL, ZHENFEI LIU, Lawrence Berkeley Natl Lab,

VALENTINO COOPER, Oak Ridge Natl Lab, JEFFREY NEATON, Lawrence Berkeley Natl Lab; UC-Berkeley; Kavli Energy NanoSciences Institute at Berkeley — Using density functional theory with model self-energy corrections, we calculate the adsorption energetics and geometry, and the energy level alignment of benzenediamine (BDA) molecules adsorbed on Au(111) surfaces. Our calculations show that linear structures of BDA, stabilized via hydrogen bonds between amine groups, are energetically more favorable than monomeric phases. Moreover, our self-energy-corrected calculations of energy level alignment show that the highest occupied molecular orbital energy of the BDA linear structure is deeper relative to the Fermi level relative to the isolated monomer and agrees well with the values measured with photoemission spectroscopy. This work supported by DOE.

**4:06PM V24.00007 Theory of work function tuning via mixed-monolayers on functional surfaces<sup>1</sup>**, MICHELE KOTIUGA, Physics Department, UC Berkeley & The Molecular Foundry, LBNL, PIERRE DARANCET, The Center for Nanoscale Materials, ANL, JEFFREY B. NEATON, Physics Department, UC Berkeley, The Molecular Foundry, LBNL & Kavli Energy NanoSciences Institute at Berkeley, Berkeley, CA — Self-assembled monolayers (SAMs) provide both stability and functionality of surfaces useful in optoelectronic nanoscale devices. The work function, level alignment and other electronic properties of functionalized surfaces can be tuned with the choice of molecule and an even finer control of the properties can be obtained with a SAM comprised of multiple types of molecules [1]. Modeling the effect on electronic properties of mixed-monolayers via ab initio calculations poses a challenge due to the large supercell required to capture a range of relative concentrations between the two types of molecules. Here, we present an implicit model - fit from density functional theory calculations - capturing local electrostatic interactions within the SAM primarily due to depolarization of the induced dipoles formed upon binding [2]. This quantitative model allows us to explore supercells with a large number of molecules and, thus, surface concentrations that are inhomogeneous in nature. We compare to experimental results of thiol terminated carboranes on gold [1]. [1] Kim et al., Nano Lett. 14, 2946 (2014) [2] Kotiuga et al., Nano Lett. 15, 4498 (2015)

**4:18PM V24.00008 Giant spatially-resolved self-assembled donor-acceptor molecular heterojunctions<sup>1</sup>**, JEFFREY R. GUEST, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL, USA, JOSEPH A. SMERDON, Jeremiah Horrocks Institute of Mathematics, Physics and Astronomy, University of Central Lancashire, Preston, UK, NOEL C. GIEBINK, Department of Electrical Engineering, The Pennsylvania State University, University Park, PA, USA, NATHAN P. GUISENGER, PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL, USA — Despite theoretical models predicting that rectification ratios (RR) >1000 should be achievable in molecular rectifiers, demonstrations of this have been rare. It has also been extremely challenging to unravel the structure-function relationships on the nanometer length scales that determine their behavior. Using scanning tunneling microscopy (STM) and spectroscopy (STS), we show that RRs >1000 at biases <500 mV are realized in the two-molecule limit for self-assembled donor-acceptor bilayers of pentacene on C<sub>60</sub> on Cu. We show that the system behaves as a molecular analog to a Schottky diode due to strong electronic coupling of C<sub>60</sub> to the metallic substrate, and electronic transport is dominated by sequential tunneling from semiconducting pentacene to metallic C<sub>60</sub>. Furthermore, we demonstrate the extreme sensitivity of the low-bias  $I(V)$  characteristics to the molecularly-resolved structure of the heterojunction (HJ), which leads to negative differential resistance and  $\sim 100\times$  variation in the rectification ratio within 2 nm of the edge of the molecular HJ.

**4:30PM V24.00009 Transient magnetization of core excited organic molecules adsorbed on graphene<sup>1</sup>**, ABHILASH RAVIKUMAR, ANU BABY, HE LIN, GIAN PAOLO BRIVIO, Department of Materials Science, University of Milano-Bicocca, Milano, Italy, GUIDO FRATESI, Department of Physics, University of Milano, Milano, Italy — This work presents a density functional theory based computational investigation of electronic and magnetic properties of physisorbed and chemisorbed organic molecules on graphene in the ground state and core excited one at low molecular coverage. For physisorbed molecules, where the interaction with graphene is dominated by van der Waals forces and the system is non-magnetic in the ground state, it is found that the valence electrons relax towards a spin polarized configuration upon excitation of a core-level electron. The magnetism depends on efficient electron transfer from graphene on the femtosecond time scale. On the contrary, when graphene is covalently functionalized, the system is magnetic in the ground state presenting two spin dependent mid gap states localized around the adsorption site. At variance with the physisorbed case upon core-level excitation, the LUMO of the molecule and the mid gap states of graphene hybridize and the relaxed valence shell is not magnetic anymore.

**4:42PM V24.00010 Probing the molecular structure of doped sites within crystals by Pyroelectricity and Dispersion Corrected DFT modeling**, ELENA MEIRZADEH, IDO AZURI, DAVID EHRE, Weizmann Institute of Science, ANDREW M. RAPPE, University of Pennsylvania, MEIR LAHAV, LEEOR KRONIK, IGOR LUBOMIRSKY, Weizmann Institute of Science — We describe the analysis of polar architectures at the nanoscale by pyroelectric measurements and DFT. Controlled doping of crystals is a primary tool for modification of the properties of materials. Doping of non-polar molecular crystals with “tailor-made” auxiliaries often reduces their symmetry, and converts them into polar mixed crystals. Such crystals are pyroelectric, *i.e.* they display temporary surface charge if subjected to a temperature change. When the non-polar crystals of the amino-acids are doped with different amino acids of concentrations as low as <0.2%, they display measurable pyroelectric effect. Since such minute amount of guest creates measurable macroscopic polarization, implies a local polar dislocation of the neighboring host molecules. We demonstrate here, that the value and the temperature dependence of the pyroelectric coefficient, provides intimate information on the molecular packing arrangement of the doped sites. Different amino acids as dopants induce different pyroelectric effects: The pyroelectric coefficient is a) not temperature dependent; b) changes its sign upon heating. These differences were explained by the determination of the polar domains at the molecular level by the DFT.

**4:54PM V24.00011 ABSTRACT WITHDRAWN —**

**5:06PM V24.00012 Theory of Giant Rectification in Molecular Schottky Diodes<sup>1</sup>**, PIERRE DARANCET, Argonne Natl Lab — Following early theoretical models [1], efforts towards the synthesis and characterization of more efficient molecular diodes have consisted into attempts to increase the electron rich/poor characters of the donor/acceptor moieties, decrease their conjugation, and imbalance their coupling to the electrodes. The experimental poor performance of single-molecule diodes – with the notable exception of environment-induced diodes [2] – suggests that these physical parameters tend to be mutually exclusive in most molecular systems [3]. In this talk, inspired by recent observations of large rectification ratios at organic bilayers [4], we will show how molecules with a moiety strongly coupled to a metal electrode can, in principle, be used to optimize these different aspects simultaneously. Using first-principles calculations, we will show that this class of molecular systems –analog to macroscopic Schottky diodes, can display large rectification ratios at low operating voltages. **2:30PM V25.00001 Negative magneto resistance and anisotropic transport in DC biased superconducting Ta films**, JUNGHYUN SHIN, SUNGYU PARK, EUNSEONG KIM, Center for Supersolid & Quantum Matter Research and Department of Physics, KAIST, Daejeon, 305-701, Republic of Korea — We investigated the field-tuned superconductor-insulator transition in DC biased Ta thin films. Differential resistance in direction parallel (x axis) and perpendicular (y axis) to DC bias (x axis) was measured simultaneously as functions of DC bias and magnetic field. The DC biased magneto-resistance,  $dV/dI$ , showed anisotropy; differential magneto-resistance exhibited peaks at high DC bias in the parallel measurements while monotonic increase in  $dV/dI$  was obtained in the perpendicular measurements. Besides, the critical fields determined by magneto-resistance isotherms cross-over reveal substantially different values depending on the measurement directions. Furthermore, the E-field scaling exponents show different values of 1.33 in perpendicular direction and of 0.82 in parallel direction which cannot be simply understood by the temperature scaling with electron heating.

**2:42PM V25.00002 Signature of Cooper pairs in the Metallic and Insulating Phases of Homogeneously Disordered Superconducting Ta Films<sup>1</sup>**, YIZE STEPHANIE LI, California State University, Bakersfield — With the increase of magnetic field or the decrease of sample thickness, homogeneously disordered superconducting Ta films undergo a superconductor-metal-insulator phase transition [1][2]. Each phase displays remarkably different nonlinear current-voltage (I-V) characteristics. The evolution of the nonlinear transport in the insulating phase exhibits a non-monotonic behavior as the magnetic field is increased, which could be evidence of the presence of localized Cooper pairs in the insulating phase [3]. As the metallic phase intervenes the superconducting and insulating states in Ta films, we further suggest that Cooper pairs also exist in the metallic ground state. References: [1] Y. Qin et al., Phys. Rev. B 73, 100505(R) (2006). [2] Y. Li et al., Phys. Rev. B 81, 020505 (R) (2010). [3] Y. S. Li, Supercond. Sci. Technol. 28, 025002 (2015).

**2:54PM V25.00003 Superconductor-Insulator Transition and Fermi-Bose Crossovers<sup>1</sup>**, NANDINI TRIVEDI, The Ohio State University, YEN LEE LOH, University of North Dakota, MOHIT RANDEIRA, The Ohio State University, CHIA-CHEN CHANG, RICHARD SCALETTAR, University of California, Davis — The direct transition from an insulator to a superconductor (SC) in Fermi systems is a problem of long-standing interest, which necessarily goes beyond the standard BCS paradigm of superconductivity as a Fermi surface instability. We introduce here a simple, translationally-invariant lattice fermion model that undergoes a SC-insulator transition (SIT) and elucidate its properties using analytical methods and quantum Monte Carlo simulations. We show that there is a fermionic band insulator to bosonic insulator crossover in the insulating phase and a BCS-to-BEC crossover in the SC. The SIT is always found to be from a bosonic insulator to a BEC-like SC, with an energy gap for fermions that remains finite across the SIT. The energy scales that go critical at the SIT are the gap to pair excitations in the insulator and the superfluid stiffness in the SC. In addition to giving insights into important questions about the SIT in solid state systems, our model should be experimentally realizable using ultracold fermions in optical lattices. Ref: arXiv:1507.05641

**3:06PM V25.00004 Critical Exponents of Dynamical Conductivity in 2D Percolative Superconductor-Insulator Transitions: Three Universality Classes**, PRAGALV KARKI, YEN LEE LOH, Univ of North Dakota — We simulate three types of random inductor-capacitor (LC) networks on 4000x4000 lattices. We calculate the dynamical conductivity using an equation-of-motion method in which timestep error is eliminated and windowing error is minimized [1]. We extract the critical exponent  $a$  such that  $\sigma(\omega) \propto \omega^{-a}$  at low frequencies. The results suggest that there are three different universality classes. The  $L_{ij}C_i$  model, with capacitances from each site to ground, has  $a = 0.32$ . The  $L_{ij}C_{ij}$  model, with capacitances along bonds, has  $a = 0$ . The  $L_{ij}C_iC_{ij}$  model, with both types of capacitances, has  $a = 0.30$ . This implies that classical percolative 2D superconductor-insulator transitions (SITs) generically have  $\sigma(\omega) \rightarrow \infty$  as  $\omega \rightarrow 0$ . Therefore, experiments that give a constant conductivity as  $\omega \rightarrow 0$  must be explained in terms of quantum effects. [1. Yen Lee Loh, Rajesh Dhakal, John F. Neis and Evan M. Moen, "Divergence of dynamical conductivity at certain percolative superconductor-insulator transitions", Journal of Physics: Condensed Matter 26, 50 (2014)]

**3:18PM V25.00005 The phase diagram and Bose metal in superconducting nanowires<sup>1</sup>**, TYLER MORGAN-WALL<sup>2</sup>, HANNAH HUGHES<sup>3</sup>, NIKOLAUS HARTMAN<sup>4</sup>, NINA MARKOVIC<sup>5</sup>, Johns Hopkins University — We experimentally investigated the transport properties of thin, narrow superconducting aluminum nanowires as a function of magnetic field and temperature. We characterized the full superconducting phase diagram with respect to magnetic field and temperature, and show the onset of a flux-flow phase for certain values of temperature and magnetic field. The flux-flow resistance follows the Bardeen-Stephen model and it is shown that the resistance increases linearly with respect to magnetic field in this region of the phase diagram. In addition, we show the saturation to a non-zero finite resistance state below the normal state resistance for certain magnetic fields as the temperature decreases to zero.

**3:30PM V25.00006 Shrinking of the Cooper Pair Insulator Phase in Thin Films with Ultrasmall Superconducting Islands**, J.C. JOY, X. ZHANG, C. ZHAO<sup>1</sup>, J.M. VALLES, JR., Department of Physics- Brown University, G. FERNANDES, J.M. XU, Division of Engineering- Brown University — The ubiquity of the bosonic Cooper Pair Insulator (CPI) phase near the two-dimensional superconductor to insulator transition (SIT) is a long standing question. While a number of two dimensional materials exhibit bosonic insulating phases similar to the Mott Insulator in arrays of ultrasmall, Josephson coupled superconducting islands, others show behaviors consistent with a fermionic insulating phase. Utilizing specially prepared anodized aluminum oxide substrates, we are able to fabricate films reminiscent of arrays of superconducting islands whose properties are tunable by varying the substrate morphology. Our recent work has focused on arrays of islands which possess an energy level spacing comparable to the mean field superconducting gap, where one expects pair breaking followed by fermionic Anderson Localization as the dominant mechanism by which superconductivity is destroyed. Early results show that the paradigmatic bosonic insulator exists only very near the disorder tuned SIT, while films only marginally deeper in the insulating phase exhibit transport distinct from the CPIs reentrant, activated transport. We are grateful for the support of NSF Grant No. DMR-1307290, the AFOSR, and the AOARD.

**3:42PM V25.00007 Disorder induced superconductor-insulator transition in epitaxial  $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$  thin films**, HAN-BYUL JANG, CHAN-HO YANG, KAIST —  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$  is a well-known superconducting system showing various electronic properties as a function of Sr content. Especially, epitaxial thin layers of the compound show enormous increase of superconducting critical temperature ( $T_c$ ) by a compressive strain. It has been reported that  $T_c$  can be controlled by misfit strain, thickness, and oxygen annealing. In this study, we report structural and transport properties of high quality epitaxial  $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$  thin films. According to x-ray diffraction study, *c*-axis lattice parameter shows no significant change for various film thicknesses and the in-plane lattice parameters of the films are coherently matched with that of substrate. Electronic transport measurements show a clear superconductor-to-insulator transition (SIT), accompanying variation of  $T_c$  depending on film thickness. These results are analyzed by using the McMillan equation to find the relation between the  $T_c$  and a disorder correlating with film thickness. We have found the disorder exhibits an explicit power-law behavior with respect to film thickness in our  $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$  thin films.

**3:54PM V25.00008 Origin and consequences of the disorder-induced inhomogeneities in cuprate superconductors**, DEBMALYA CHAKRABORTY, Indian Institute of Science Education and Research Kolkata, Mohanpur Campus, India-741246, RAJDEEP SENSARMA, Department of Theoretical Physics, Tata Institute of Fundamental Research, Mumbai-400005, India, AMIT GHOSAL, Indian Institute of Science Education and Research Kolkata, Mohanpur Campus, India-741246 — The effect of potential impurities on cuprate superconductors are investigated within a formalism suitable for addressing the complex interplay of the bare repulsive electronic correlations and disorder, both being strong. We show that the mechanism governing the demise of superconductivity is rather subtle and differs from the conventional weak-coupling descriptions. While the superconductivity remains surprisingly robust for up to moderate disorder, it crashes down sharply at stronger disorders. The initial robustness is attributed to the strong repulsive correlations that smear out charge inhomogeneities by reorganizing the hopping on the bonds prohibiting formation of superconducting "islands". However, with increasing strength of disorder, the potential difference across some bonds reach the scale of the bandwidth and the overall energy of the system is reduced by prohibiting hopping on such links. Integrating this concept within our formalism, we show that the correlations fail to homogenize the system across these "cut-bonds". This produces Mott-insulating, Anderson-insulating, as well as locally superconducting regions interspersed among each other at strong disorder, eventually destroying the global superconductivity.

**4:06PM V25.00009 The half-filling paradox in  $\text{Pr}_2\text{CuO}_{4+\delta}$** , YOSHIHARU KROCKENBERGER, AI IKEDA, HIROSHI IRIE, HIDEKI YAMAMOTO, NTT Basic Research Labs — In a type-II superconductor, the onset of the superconducting state as a function of decreasing magnetic field  $H$  occurs at the upper critical magnetic field  $H_{c2}$ , dictated by the pairing gap  $\Delta$  through the coherence length  $\xi_0 \sim \nu_F/\Delta$ , via  $H_{c2} = \Phi_0/2\pi\xi_0^2$ . We show that the mean-free length  $\ell$  in superconducting  $\text{Pr}_2\text{CuO}_4$  can be as large as 85nm, or 200 unit cell lengths. Such large  $\ell$  values are directly related to residual resistivity ratios. While  $\text{Pr}_2\text{CuO}_{4+\delta}$  is commonly known as an antiferromagnetic insulator (AFI), we show that synthesis and annealing conditions govern  $\delta$ . For AFI  $\text{Pr}_2\text{CuO}_4$ , i.e.  $\ell \ll 2\text{nm}$ ,  $\delta$  is larger than 0.10 whereas  $\delta \ll 0.04$  in the superconducting state. In fact, this de-intercalation of apical oxygen is mandatory for the induction of superconductivity and is counter to early conclusions that all cuprate superconductors are AFI in their undoped state. It is not surprising that the AFI state found in cuprates with 5- and 6-fold coordinated copper is not established in cuprates with 4-fold coordinated copper, i.e.  $\delta < 0.04$ . Such coordination-driven phase transition is at the core of the long-term assumed half-filling paradox.

**4:18PM V25.00010 Investigating Links Between Enhanced Inhomogeneity and Robustness of the Superconducting State in Severely Underdoped, Ultrathin  $\text{CaYBCO}$** , STANLEY STEERS, THOMAS LEMBERGER, BRIAN BAKER, The Ohio State University — Multiple experiments in recent years have shown evidence for intrinsic inhomogeneity in the cuprate superconductors upon approach to the superconductor to insulator transition (SIT). We present experimental evidence of anomalous suppression of both the diamagnetic response and the resistivity in ultrathin Ca-doped YBCO over tens of Kelvin. We then present further experiments to investigate to what extent this suppression is related to increased inhomogeneity upon approach to the SIT. Finally, we compare these results in  $\text{CaYBCO}$  to experiments in other cuprate compounds from the literature.

**4:30PM V25.00011 Modulation of Superconductor-Insulator Transition in  $\text{NdBa}_2\text{Cu}_3\text{O}_{7-x}$  through Oxygen Migration by Electrolyte Gating**, LINGCHAO ZHANG, S.W. ZENG, D.Y. WAN, K. HAN, L.K. JIAN, A. ARIANDO, T. VENKATESAN, NATIONAL UNIVERSITY OF SINGAPORE, NUSNNI-NANOCORE TEAM — The technique of electric double layer transistor (EDLT) has been applied to several HTS, such as LSCO and YBCO. The interpretation of SIT in all these studies are attributed to electrostatically induced carriers. However, in several electrolyte gating experiments recently, the effect is mainly attributed to oxygen vacancy formation, with migration of oxygen from the film into ionic liquid. In this study, the modulation of SIT is performed in a 7uc NBCO EDLT. By applying positive  $V_g$ , the SC NBCO gradually transits to insulating. When  $V_g$  changes back to 0V, it remains insulating. If the mechanism is electrostatically induced carriers, it should recover SC. However, it is only when applying a reverse negative  $V_g$  that it can gradually recover SC. Meanwhile, after SIT and  $V_g$  back to 0V, another sample is taken out from PPMS. After careful remove of ionic liquid, it remains insulating. After annealing at  $\text{O}_2$  atmosphere, it recovers SC. These strongly support the underlying mechanism is oxygen migration, instead of electrostatically induced carriers. The  $R_c$  is extracted to be about 5320 $\Omega$ , suggestive of quantum phase fluctuation.

**4:42PM V25.00012 Phase Transitions in a Two-dimensional Electron System at Oxide Interface with Dual Gate Tuning**, ZHUOYU CHEN, HISASHI INOUE, HYEOK YOON, DI LU, TYLER MERZ, SEUNG SAE HONG, ADRIAN SWARTZ, YANWU XIE, Stanford University, HONGTAO YUAN, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HAROLD HWANG, Stanford University and SLAC National Accelerator Laboratory — The ground state of a two-dimensional (2D) electron system can be controlled by parameters including disorder, carrier density, and magnetic field. Using the conducting channel formed at the  $\text{LaAlO}_3/\text{SrTiO}_3$  (001) heterointerface, we performed magnetotransport measurements with simultaneous electric field effect gating from both the top epitaxial  $\text{LaAlO}_3$  layer and the back  $\text{SrTiO}_3$  (001) substrate. Besides conventional carrier density tuning, the structural asymmetry inherent to the dual-gate device also enables independent modulation of the disorder level in the conduction channel probed through carrier mobility. Under different top and back gate voltages and magnetic field combinations, the interface channel showed strikingly different conducting states including zero resistance (superconductor), saturating small finite resistance ("metal"), and increasing resistance (insulator), when approaching zero temperature. These results provide a unique opportunity for understanding the quantum phase transitions in 2D superconducting systems with continuously tunable parameters.

**4:54PM V25.00013 Behavior of an Amorphous Superconducting Thin Film in a Tunable Dissipative Environment<sup>1</sup>**, ILANA PERCHER, ALLEN GOLDMAN, University of Minnesota — It has been shown that a dissipative electrical environment supports superconductivity. This is particularly true for low-dimensional systems of disordered and granular superconductors close the insulating state, where Ohmic dissipation can damp the order parameter fluctuations that would otherwise destroy global phase coherence. We will present the latest results from experiments in which a homogeneously disordered indium oxide film is placed in very close proximity to a two dimensional electron gas (2DEG) within a gallium arsenide/aluminum gallium arsenide heterostructure. The dissipation provided by the 2DEG depends on its carrier concentration, which is varied electrostatically by means of a back gate. We are grateful to the groups of Prof. Rachel Goldman at University of Michigan and Prof. Aviad Frydman at Bar Ilan University for growing heterostructures and superconducting films (respectively) for this experiment.

**5:06PM V25.00014 The role of disorder and electron-electron interactions in the superconductor-insulator transition of molybdenum disulfide**, JOSEPH PRESTIGIACOMO, NRC Postdoctoral Fellow: US Naval Research Laboratory, ANINDYA NATH, George Mason University, ANTHONY BOYD, ASEE Postdoctoral Fellow: US Naval Research Laboratory, QINGFENG LIU, JUDY WU, Kansas State University, THOMAS SUTTO, MICHAEL OSOFSKY, US Naval Research Laboratory — The 2D layered transition-metal dichalcogenide, MoS<sub>2</sub>, first garnered interest over 40 years ago when it was discovered that it becomes a superconductor (SC) after electrochemical intercalation with alkali- or alkali-earth metals. Recently, however, a superconductor-insulator (SI) transition was observed in MoS<sub>2</sub> by electric-field gating with ionic liquid (IL) dielectrics, substances that enable induced charge-carrier concentrations (n) much larger than are possible using conventional solid-state dielectric gate barriers. Despite this feat, detailed studies of gate-tuned metal-insulator transitions in MoS<sub>2</sub> have mainly focused on the understanding the various mobility-reducing scattering mechanisms thought to contribute to the smaller than predicted on/off ratios observed in MoS<sub>2</sub>-based FETs. In this presentation, we discuss the results of an investigation into the role of disorder and electron-electron interactions in the SI transition of mechanically-exfoliated multilayer and CVD-grown few-layer MoS<sub>2</sub> probed by carefully examining their low temperature magneto-transport properties as a function of charge carrier-concentration via IL-gating.

**2:30PM V26.00001 Variable Temperature Scanning Tunneling Microscopy of WTe<sub>2</sub>, MoTe<sub>2</sub> and alloyed MoWTe<sub>2</sub>**, DREW EDELBERG, DANIEL CHENET, LIOR EMBON, NATHAN ZHAO, AYELET NOTIS, ERICK ANDRADE, ABHAY PASUPATHY, Columbia Univ — The transition metal dichalcogenides MoTe<sub>2</sub> and WTe<sub>2</sub> grow in a Van der Waals layered structure and can be produced down to monolayer thickness. These materials exhibit multiple crystal structures with drastically differing electronic properties including semiconductor (2H) and metal (1T'). Nanoscale phase engineering has been proposed as a way to create a variety of device architectures. This phase engineering can be achieved by strain, chemical doping or alloying. Alloying in particular has been proposed as a facile technique to continuously tune the structural phase of the resultant material and thus lower the barrier for transitions between the insulating and metallic states. In this study we use variable temperature scanning tunneling microscopy to image both parent compounds MoTe<sub>2</sub>, WTe<sub>2</sub> and alloyed crystals MoWTe<sub>2</sub>. Using dI/dV spectroscopy we determine the nature of the insulating and metallic states of both the parent compounds as well as use this technique to characterize the properties of the alloyed material.

**2:42PM V26.00002 Local Spectroscopic Characterization of Spin and Layer Polarization in WSe<sub>2</sub>**, DEVIN MCKENZIE, MATTHEW YANKOWITZ, BRIAN LEROY, University of Arizona — Semiconducting transition metal dichalcogenides, such as WSe<sub>2</sub>, exhibit very strong spin-orbit coupling (SOC) at certain band extrema due to large in-plane dipole moments formed by their heavy constituent atoms. The strong SOC links the spin and valley degrees of freedom in monolayers. In bilayers, interlayer hopping is suppressed by this SOC, leading to a spontaneous layer polarization and a coupling of the layer pseudospin with the spin and valley degrees of freedom. We examine these effects by tracking allowed and forbidden electronic scattering pathways in monolayer and bilayer WSe<sub>2</sub> using scanning tunneling spectroscopy. Specifically, we observe a strong suppression of intervalley scattering in both monolayer and bilayer WSe<sub>2</sub> indicative of these band polarizations.

**2:54PM V26.00003 Resolving 2D Amorphous Materials with Scanning Probe Microscopy<sup>1</sup>**, KRISTEN M. BURSON, CHRISTIN BUECHNER, ADRIAN LEWANDOWSKI, MARKUS HEYDE, HANS-JOACHIM FREUND, Fritz-Haber Institute of the Max Planck Society — Novel two-dimensional (2D) materials have garnered significant scientific interest due to their potential technological applications. Alongside the emphasis on crystalline materials, such as graphene and hexagonal BN, a new class of 2D amorphous materials must be pursued. For amorphous materials, a detailed understanding of the complex structure is necessary. Here we present a structural study of 2D bilayer silica on Ru(0001), an insulating material which is weakly coupled to the substrate. Atomic structure has been determined with a dual mode atomic force microscopy (AFM) and scanning tunneling microscopy (STM) sensor in ultra-high vacuum (UHV) at low temperatures, revealing a network of different ring sizes. Liquid AFM measurements with sub-nanometer resolution bridge the gap between clean UHV conditions and the environments that many material applications demand. Samples are grown and characterized in vacuum and subsequently transferred to the liquid AFM. Notably, the key structural features observed, namely nanoscale ring networks and larger holes to the substrate, show strong quantitative agreement between the liquid and UHV microscopy measurements. This provides direct evidence for the structural stability of these silica films for nanoelectronics and other applications.

**3:06PM V26.00004 Measurement of electrostatic potential variations between 2D materials using low-energy electron microscopy<sup>1</sup>**, SERGIO DE LA BARRERA, PATRICK MENDE, JUN LI, RANDALL FEENSTRA, Carnegie Mellon University, Department of Physics, YU-CHUAN LIN, JOSHUA ROBINSON, Pennsylvania State University, Materials Science and Engineering, SURESH VISHWANATH, HUILI XING, Cornell University, Electrical and Computer Engineering — Among the many properties that evolve as isolated 2D materials are brought together to form a heterostructure, rearrangement of charges between layers due to unintentional doping results in dipole fields at the interface, which critically affect the electronic properties of the structure. Here we report a method for directly measuring work function differences, and hence electrostatic potential variations, across the surface of 2D materials and heterostructures thereof using low energy electron microscopy (LEEM). Study of MoSe<sub>2</sub> grown by molecular beam epitaxy on epitaxial graphene on SiC with LEEM reveals a large work function difference between the MoSe<sub>2</sub> and the graphene, indicating charge transfer between the layers and a subsequent dipole layer. In addition to quantifying dipole effects between transition metal dichalcogenides and graphene, direct imaging of the surface, diffraction information, and the spectroscopic dependence of electron reflectivity will be discussed.

**3:18PM V26.00005 Scanning tunneling spectroscopy of tungsten disulfide<sup>1</sup>**, MICHAEL LODGE, CAMERON GLASSCOCK, MASA ISHIGAMI, University of Central Florida — Atomically thin layers of tungsten disulfide possess interesting optoelectronic properties characterized by strong photoluminescence. Here we perform scanning tunneling microscopy and spectroscopy measurements of 2H WS<sub>2</sub> on silicon oxide substrates to understand how electronic properties are affected by defects and substrate-induced disorder. Specifically, the electronic property of tungsten disulfide is probed as a function of gate-induced carrier density.

<sup>1</sup>This work is based upon research supported by the National Science Foundation under Grant No. 0955625.

**3:30PM V26.00006 Structure and Electronic Properties of Single- to Few Layers Molybdenum Disulfide Films<sup>1</sup>**, D. TRAINER, A. PUTILOV, M. WOLAK, R. U. CHANDRASENA, Department of Physics, Temple University, Philadelphia, PA 19122, F. KRONAST, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, D-12489 Berlin, Germany, A. X. GRAY, X. X. XI, M. IAVARONE, Department of Physics, Temple University, Philadelphia, PA 19122 — Using high resolution scanning tunneling microscopy and spectroscopy (STM/STS) we have investigated the electronic properties of mono- to few layers molybdenum disulfide films grown on HOPG using ambient pressure chemical vapor deposition (APCVD). Atomic force microscopy and STM show that this growth technique produces crystalline triangular and hexagonal islands with varying thicknesses in 1 ML increments. The films exhibited a suppression of quasiparticle band-gap as a function of layer number as measured by local spectroscopy. Changes in the valence band edge were supported by photoemission electron microscopy (PEEM) measurements. We also report on a strain-induced contraction of the quasiparticle band-gap in proximity to grain boundaries and defects.

**3:42PM V26.00007 Scanning tunneling microscopy on CVD grown lateral graphene molybdenum disulfide heterostructures**, ALEXANDER KERELSKY, MINGHAO CHENG, XINJUE ZHONG, XIAODONG ZHAO, ALI DADGAR, DA WANG, Columbia Univ, HUI GAO, MARCOS GUIMARAES, KIBUM KANG, Cornell Univ, XIAOYANG ZHU, Columbia Univ, JIWOONG PARK, Cornell Univ, ABHAY N. PASUPATHY, Columbia Univ — We investigate the interface of single layer graphene, molybdenum disulfide lateral heterostructures using scanning tunneling microscopy (STM). Samples are fabricated using chemical vapor deposition to deposit graphene, photolithography to pattern graphene and metal-organic chemical vapor deposition to grow molybdenum disulfide in patterned areas. The lateral junction of the two materials allows investigation of structural and electronic properties at the interface of the two materials, an interface usually buried in conventional stacked heterostructures. STM is used to image the stitching of the two materials with nanoscale resolution. STM is also used to perform local spectroscopy, probing the local density of states on an atomic scale across the junction. Interesting phenomena such as the charge transfer and atomic bonding are investigated. The spatially changing chemical potential between the two materials is also examined at different gate voltages.

**3:54PM V26.00008 Monolayer MoS<sub>2</sub> on HOPG Studied by Scanning Tunneling Microscopy / Spectroscopy<sup>1</sup>**, CHUN-I LU, Department of Physics, National Taiwan University; National Synchrotron Radiation Research Center, C. BUTLER, Y.-H. CHU, H.-H. YANG, Department of Physics, National Taiwan University, C.-M. WEI, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan, L.-J. LI, Physical Sciences and Engineering, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia., M.-T. LIN, Department of Physics, National Taiwan University; Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan, DEPARTMENT OF PHYSICS, NATIONAL TAIWAN UNIVERSITY TEAM, INSTITUTE OF ATOMIC AND MOLECULAR SCIENCES, ACADEMIA SINICA TEAM — Chemical Vapor Deposition (CVD) is a promising way to prepare 2D material such as graphene and MoS<sub>2</sub> for  $\mu\text{m}$ -scale. In this report, we deposit monolayer MoS<sub>2</sub> by CVD method on HOPG to create the heterojunction. We observe that, the alignment of triangle MoS<sub>2</sub> islands shows the tendency that they have some preferred directions from AFM morphology. From STM atomic resolution images, the moiré superstructures analysis could summarize that the MoS<sub>2</sub> lattice tends to have a small angle with graphite's lattice. On the other hand, we also take the tunneling spectra from the different moiré domains and the moiré hills, moiré valleys of the single moiré domain. The results reveal the extraordinary states, which appear in the band gap range of MoS<sub>2</sub>. We consider these states are the consequence of hybridized of two layers and be detected from the interlayer space.

**4:06PM V26.00009 STM/STS Study of Surface Modification Effect on Bandgap Structure of Ti<sub>2</sub>C with -OH, -F, and -H.<sup>1</sup>**, SEONG JUN JUNG, SHEN LAI, TAEHWAN JEONG, SUNGJOO LEE, YOUNG JAE SONG, Sungkyunkwan Univ — In this presentation, we present Scanning Tunneling Microscopy (STM) and Spectroscopy (STS) study of bandgap structures of surface-modified Ti<sub>2</sub>C with -OH, -F, and -O in atomic scale. Since the discovery of new two dimensional (2D) materials like graphene, various 2D materials including transition metal dichalcogenide (TMD) have been intensively investigated. There are, however, still scientific issues to apply them to the device fabrications for controlling the appropriate bandgap structure with high field effect mobility. Recently another 2D materials of transition metal carbide (TMC), Ti<sub>2</sub>CT<sub>x</sub> with modifiable surface group T<sub>x</sub> (-OH, -F, and -O) was suggested. [S. Lai et. al, Nanoscale (2015), DOI: 10.1039/C5NR06513E]. This 2D material shows that the mobility at room temperature is less sensitive to the measured transport bandgap, which can imply that Ti<sub>2</sub>CT<sub>x</sub> can be a strong candidate of 2D TMC for application to the future electronic devices. Surface modification on the electronic structure of Ti<sub>2</sub>C by -OH, -F, and -O is, therefore, investigated by STM and STS in atomic scale. More scientific results will be further discussed in the presentation.

**4:18PM V26.00010 An ARPES investigation of band evolution of MoS<sub>2</sub> in presence of high pressure hydrogen gas<sup>1</sup>**, SOOHYUN CHO, Yonsei University, BEOM SEO KIM, Seoul National University, BEOM YOUNG KIM, YEONGKWAN KIM, Lawrence Berkeley National Laboratory, BYUNG HOON KIM, Incheon National University, CHANGYONG KIM, Seoul National University, SEUNGRYONG PARK, Incheon National University, INCHEON NATIONAL UNIVERSITY COLLABORATION, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION — The monolayer MoS<sub>2</sub>, has a large direct band gap and spin band splitting in K-point which make it a good candidate for several applications such as solar cell, valley Hall transistor and so on. When it has more than two layers, turns into a semiconductor with indirect band gap. Theoretical predictions have revealed that the number of layers is directly related to number of bands. Also, it was recently reported that the resistivity of MoS<sub>2</sub> decreases when exposed to high pressure hydrogen gas for few hours. To investigate the evolution of energy bands as a function of high pressure hydrogen exposure, we performed angle resolved photoemission spectroscopy (ARPES) experiment on pristine and hydrogen treated bulk MoS<sub>2</sub>. Our result, is suggestive for quantum well state in the treated sample case, and impurity state induced by sulphur vacancy between valence and conduction band at K-point. We argue that the impurity state depending on momentum mediate decrease in resistivity.

<sup>1</sup>An ARPES investigation of band evolution of MoS<sub>2</sub> in presence of high pressure hydrogen gas

**4:30PM V26.00011 Investigation of the Spatially Resolved Electronic Structure of Single Layer WS<sub>2</sub> on Transition Metal Oxide Surfaces**, JYOTI KATOCH, THE OHIO STATE UNIVERSITY, SREN ULSTRUP, ROLAND KOCH, DANIEL SCHWARZ, Advanced Light Source, Lawrence Berkeley National Laboratory, SIMRANJEET SINGH, THE OHIO STATE UNIVERSITY, KATHY MCCREARY, Naval Research Laboratory, HYANG KEUN YOO, Advanced Light Source, Lawrence Berkeley National Laboratory, JINSONG XU, THE OHIO STATE UNIVERSITY, BERRY JONKER, Naval Research Laboratory, ROLAND KAWAKAMI, THE OHIO STATE UNIVERSITY, AARON BOSTWICK, ELI ROTENBERG, CHRIS JOZWIAK, Advanced Light Source, Lawrence Berkeley National Laboratory — The family of semiconducting single layer (SL) transition metal dichalcogenides (TMDs) have lately been intensely studied, owing to the strong coupling between spin and valley degrees of freedom as well as the presence of strongly bound excitons. The choice of supporting substrate is known to strongly influence these properties. We set out to investigate the electronic properties of CVD grown SL WS<sub>2</sub> transferred onto the dielectric oxide materials SrTiO<sub>3</sub> and TiO<sub>2</sub>. By using a combination of photoemission electron microscopy (PEEM) and angle-resolved photoemission (ARPES) with micrometer focus we obtain simultaneous spatial, momentum and energy-resolved information about SL WS<sub>2</sub> on a polar (SrTiO<sub>3</sub>) and a nonpolar (TiO<sub>2</sub>) surface for the first time.

**4:42PM V26.00012 Graphene protected surface state on Ir(111) with adsorbed lithium**, PREDRAG LAZIC, Institute Ruder Bokovic, PETAR PERVAN, MARIN PETROVIC, IVA SRUT-RAKIC, Institute of Physics, Zagreb, IVO PLETIKOSIC, Brookhaven National Laboratory, MARKO KRALJ, MILORAD MILUN, Institute of Physics, Zagreb, TONICA VALLA, Brookhaven National Laboratory — It is well known that electronic surface states (SS) get strongly perturbed upon the chemical adsorption of very small amount of adsorbates. Adsorption of lithium atoms on Ir(111) is no exception to that rule. Iridium SS gets strongly perturbed and is practically eradicated - it can not be seen as a sharp peak in the ARPES measurement. However, if the system is prepared with graphene on top of Ir/Li system, the iridium SS reappears. We present a combined experimental and theoretical study of the described system. Using the density functional theory calculations for large unit cells with disordered lithium atoms geometries on the (111) surface of iridium we were able to reproduce the results of the ARPES measurements - showing clearly that the SS signal is strongly suppressed when lithium is adsorbed, while it is almost unchanged when lithium is intercalated (i.e. with graphene on top of it). Looking at the projected density of states we constructed a rather simple model explaining this behavior which seems to be general.

**4:54PM V26.00013 Semiconducting graphene and its incommensurate SiC interface<sup>1</sup>**, MATTHEW CONRAD, MEREDITH NEVIUS, FENG WANG, Georgia Tech, KATHERINE JINKINS, Univ Wisconsin, ARLENSI CELIS, Univ Paris-Sud, MAYA NAIR, ALESSANDRO COATI, AMINA TALEB-IBRAHIMI, SOLEIL, ANTONIO TEJEDA, Univ Paris-Sud, PAUL MICELI, Univ Missouri, EDWARD CONRAD, Georgia Tech — The development of a viable form of semiconducting graphene has been the goal since the onset of graphene research. Using improved growth techniques, we show that the first epitaxial graphene layer grown on SiC(0001) (the buffer layer) is semiconducting. With ARPES, we found that the buffer layer has a band gap > 0.5eV. At present, no existing theory explains the observed band structure. This is in part due to a corresponding lack of detailed structural studies of the buffer. Using SXRD, we show that the buffer layer is not the commensurate ( $6\sqrt{3} \times 6\sqrt{3}$ )R30° structure assumed for the past four decades. Rather, it is tensile strained and interacts with a strongly modulated SiC interface layer. The buffer-interface layer pair is well ordered, yet incommensurate with bulk SiC. We also find that the buffer evolves during the growth process and reverts to a near commensurate phase with a large RMS roughness when a monolayer forms. These structural changes correspond with changes in the band structure that demonstrate the importance of the incommensurate phase in producing semiconducting graphene.

**5:06PM V26.00014 Band parameters of 2D semiconductor heterostructures determined by micro-ARPES**, PAUL NGUYEN, Department of Physics, University of Washington, NEIL WILSON, Department of Physics, University of Warwick, PASQUAL RIVERA, KYLE SEYLER, Department of Physics, University of Washington, ALEXEY BARINOV, Sincrotrone Elettra Trieste, GEETHA BALAKRISHNAN, Department of Physics, University of Warwick, XIAODONG XU, DAVID COBDEN, Department of Physics, University of Washington — Heterostructures made by stacking monolayers of different 2D materials can have unique properties, such as hosting long-lived polarized interlayer excitons. Understanding these depends on knowledge of the band parameters of both the separate monolayers and the hetero-bilayer. Interlayer hybridization can also produce distinct electronic structure dependent on the relative monolayer crystal orientation. The most powerful technique for determining such properties is angle-resolved photoemission (ARPES), which can now be applied to micron-scale samples at the Spectromicroscopy Elettra Trieste beamline. Using this new facility, combined with careful sample design, we have studied heterostructures of WSe<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub> and graphene. We determined band offsets, effective masses, and spin-orbit splittings with an energy resolution <50 meV. Interestingly, the bands near the gamma-point in hetero-bilayers oriented near zero degrees are not a superposition of those in the isolated monolayers, but exhibit an additional higher band. However, the valence band edge remains at the K-point, which together with the band offsets is consistent with measurements of strong luminescence from interlayer excitons in MoSe<sub>2</sub>/WSe<sub>2</sub>.

**5:18PM V26.00015 Angle- and spin-resolved photoemission spectroscopy study of monolayer semiconducting transition metal dichalcogenides**, WEI YAO, ERYIN WANG, HUAQING HUANG, Tsinghua Univ, TAICHI OKUDA, Hiroshima Synchrotron Radiation Center, CHAOXIN LIU, Pennsylvania State University, WENHUI DUAN, SHUYUN ZHOU, Tsinghua Univ — Monolayer transition-metal dichalcogenides (TMDs) receive significant attention due to their intriguing physical properties for both fundamental research and potential applications in electronics, optoelectronics, spintronics, and so on. In particular, the multiple degrees of freedom in these materials (e.g. spin, valley and layer) are coupled with each other, providing various ways to control their properties. Here we report the electronic and spin structural studies of a monolayer semiconducting transition metal dichalcogenide thin film using Angle-resolved photoemission spectroscopy (ARPES) and Spin-Resolved ARPES.

## 2:30PM V27.00001 The isostructural $\alpha-\gamma$ phase transition in Cerium: a DFT+DMFT study.

BERNARD AMADON, THOMAS APPLENCOURT, ALEXIS GEROSSIER, JORDAN BIEDER, CEA, DAM, DIF, F-91297 Arpajon, France, FABIEN BRUNEVAL, CEA, DEN, Service de Recherches de Metallurgie Physique, F-91191 Gif-sur-Yvette, France, JULES DENIER, CEA, DAM, DIF, F-91297 Arpajon, France — We present a study of the electronic structure and structural properties of the  $\alpha-\gamma$  isostructural first order phase transition in cerium. Because of strong local electronic interactions due to 4f electrons, Density Functional Theory is not able to describe it. We thus use the combination of DFT and Dynamical Mean Field Theory, as implemented in ABINIT to understand and describe the transition:

Firstly, we use the constrained Random Phase Approximation to compute the effective interaction in cerium and discuss the validity of this approximation [1]. Secondly, we use this interaction to clarify the orbital mechanism of the transition: we thus discuss the validity of different models [2].

Thirdly, we compute the electronic free energy for the transition and discuss the role of entropy and spin orbit coupling [3,4].

Finally, we put in perspective our results with respect to recent calculations.

## 2:42PM V27.00002 Simulation of the X-ray Emission Spectrum from Early Lanthanides<sup>1</sup>, WEI-

TING CHIU, University of California, Davis, CHUNJING JIA, BRIAN MORITZ, TOM DEVEREAUX, SIMES, SLAC National Accelerator Laboratory and Stanford University, MAGNUS LIPP, Condensed Matter and Materials Division, LLNL, DEVON MORTENSEN, GERALD SEIDLER, University of Washington, RICHARD SCALETTAR, University of California, Davis — For decades it has been known that certain Lanthanide metals, such as cerium and praseodymium, exhibit a volume collapse transition at a critical pressure. The volume change correlates with charge transfer from 4f orbitals to higher energy conduction bands due small differences in energy. To date, high pressure X-ray emission measurements have enabled the determination of the bare 4f moment of Lanthanide metals.<sup>2</sup> In particular at the  $L_{\gamma_1}$  emission line, the intensity of a satellite peak captures the behavior of the 4f electrons across the volume collapse transition. Here we use exact diagonalization for an atomic model of the Lanthanides, including orbital site energies and core-, valence-, and conduction-band multiplet interactions to simulate the x-ray emission spectrum. The multiple interactions are derived from atomic structure calculations, augmented by effective 4f-to-conduction-band hybridization term. The Kondo screening effect from the conduction electrons at high pressure changes the 4f occupation, resulting in a change of the satellite peak intensity, which well reproduces the experimental findings in the early Lanthanide metals.

## 2:54PM V27.00003 Systematic investigation of structural, transport, magnetic and thermodynamic properties of hexagonal $R_2Pt_6Al_{15}$ ( $R = Y, La-Nd, Sm-Lu$ ) series.<sup>1</sup>, SOHAM MANNI, Q. LIN,

S. L. BUD'KO, P. C. CANFIELD, Ames Laboratory/ Iowa State University, Ames, IA 50011, USA — We have synthesized single crystals of new hexagonal intermetallic series of compounds  $R_2Pt_6Al_{15}$  with  $R = Y, La-Nd, Sm-Lu$ . Structural analysis have confirmed hexagonal  $P6_3/mmc$  crystal structure with ordered R-site. Magnetic, transport and heat capacity measurements show that most of the members of the series order antiferromagnetically at low temperature with highest  $T_N = 7.5$  K for  $Gd_2Pt_6Al_{15}$  and moments are along c-axis except  $Dy_2Pt_6Al_{15}$  and  $Ho_2Pt_6Al_{15}$ .  $Ce_2Pt_6Al_{15}$  does not order, but shows insulating behavior with a strong divergence in heat capacity divided by temperature ( $C/T$ ). Mixed valence state of  $Eu^{2+}/Eu^{3+}$  state has been observed in  $Eu_2Pt_6Al_{15}$  with antiferromagnetic ordering below 3 K. Magnetic entropy and crystal electric field are analyzed for all the members from the magnetic contribution of heat capacity. This series of compounds serves a unique example of a rare earth series with only one rare earth (R) site having hexagonal point-symmetry.

## 3:06PM V27.00004 Epitaxial growth and *in situ* ARPES of ultrathin $YbAl_3$ thin films, SHOVIK

CHATTERJEE, DARRELL SCHLOM, KYLE SHEN, Cornell Univ —  $YbAl_3$  is a well-known intermediate valence compound that shows emergence of Fermi liquid behavior below a coherence temperature of  $\sim 34K - 40K$ . Transport, thermodynamic and photoemission measurements have established limitations of Single Impurity Anderson model in describing this material system, suggesting the importance of lattice effects. However, microscopic mechanisms underlying these properties are yet to be properly understood, one reason being that the direct experimental determination of its electronic band structure is still lacking. In this talk I will present our recent efforts in stabilizing thin films of  $YbAl_3$  and *in situ* angle-resolved photoemission spectroscopy (ARPES) of these films. With the aid of an Al buffer layer crystalline, phase pure and fully oriented epitaxial thin films can be grown with sub-nm surface roughness. By using ARPES, we, for the first time have been able to map out its band structure and Fermi surface. Moreover, by growing ultra thin films we have been able to drive this material system towards its 2D limit. Evolution of its electronic structure with temperature and dimensionality will be discussed.

## 3:18PM V27.00005 Entanglement entropy near Kondo-destruction quantum critical points,

TATHAGATA CHOWDHURY, CHRISTOPHER WAGNER, KEVIN INGERSANT, Univ of Florida, JEDEDIAH PIXLEY, University of Maryland — Entanglement entropy is a measure of quantum-mechanical entanglement across the boundary created by partitioning a system into two subsystems. We study this quantity in Kondo impurity models that feature Kondo-destruction quantum critical points (QCPs). Recent work [1] has shown that the entanglement entropy between a Kondo impurity of spin  $S_{imp}$  and its environment is pinned at its maximum possible value  $S_e = \ln(2S_{imp} + 1)$  throughout the Kondo phase. In the Kondo-destroyed phase, where the impurity spin acquires a nonzero expectation value  $M_{loc}$ ,  $S_e = \ln(2S_{imp} + 1) - a(S_{imp})M_{loc}^2$  irrespective of the properties of the host. Here, we report numerical renormalization-group results for Kondo models with a pseudogapped density of states under a different partition that separates the impurity and on-site conduction electrons from the rest of the system. Now, the entanglement entropy is affected by the nature of the environment beyond the information contained in  $M_{loc}$ , but  $S_e$  still contains a critical part that exhibits power-law behavior in the vicinity of the Kondo-destruction QCP. [1] J. H. Pixley *et al.*, Phys. Rev. B **91**, 245122 (2015).

## 3:30PM V27.00006 Entanglement across different cuts along the Wilson chain for the pseudo-gap Anderson model, CHRISTOPHER WAGNER, TATHAGATA CHOWDHURY, KEVIN INGERSANT, University of Florida, JEDEDIAH PIXLEY,

University of Maryland — Entanglement entropy measures the quantum entanglement of a pure state across the boundary created by partitioning a system into two subsystems. The entanglement entropy between an Anderson impurity and a pseudogapped conduction band displays nonuniversal behavior near the Kondo-destruction quantum critical point (QCP), but in the ordered phase contains a critical component proportional to the square of the order parameter [1]. Here we report calculations of the entanglement entropy for other partitions of the system. Specifically, within the numerical renormalization group formulation of the problem, we consider partitions where one subsystem is composed of the impurity plus the first few sites in the Wilson-chain representation of the conduction band, sites that represent the electronic states spatially localized closest to the impurity. By calculating the reduced density matrix for the subsystem containing the impurity, we study the behavior of the entanglement entropy across the parameter space of the model, with particular focus on the vicinity of the Kondo-destruction QCP. [1] J. H. Pixley, T. Chowdhury, M. T. Mienikowski, J. Stephens, C. Wagner, and K. Ingersant, Phys. Rev. B **91**, 245122 (2015)

**3:42PM V27.00007 Skyrmion defects of antiferromagnet and competing singlet orders of a Kondo-Heisenberg model on honeycomb lattice** , CHIA-CHUAN LIU, Rice Univ, PALLAB GOSWAMI, University of Maryland, QIMIAO SI, Rice Univ — The competition between antiferromagnetism and proximate singlet orders is the common feature of many heavy fermion compounds. Depending on the context, the singlet order can be described by static Kondo singlets, unconventional superconductivity, site or bond centered charge orders, or more exotic density waves. This competition between singlet and triplet orders can give rise to exotic quantum critical points or even an intervening non-Fermi liquid phase. It is a fundamentally important but challenging problem to develop a general scheme for identifying the competing singlet orders from the antiferromagnetically ordered side and vice versa. We study this problem on a honeycomb lattice, and approach it starting from the Kondo-destroyed antiferromagnetic phase. We show how the topological defects of the antiferromagnetic order parameter can give rise to competing singlet orders in the presence of itinerant fermions. We identify translational symmetry breaking singlet orders and static Kondo singlets as gapped collective excitations inside the skyrmion core. Our results provide non-perturbative insight into the global phase diagram of heavy fermion compounds.

**3:54PM V27.00008 Charge density wave instability in the periodic Anderson model with electron-phonon interaction<sup>1</sup>** , ENZHI LI, Department of Physics and Astronomy, Louisiana State University , PENG ZHANG, Xi'an Jiaotong University, KA-MING TAM, SHUXIANG YANG, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University — We study the periodic Anderson model with the conduction electrons coupled to phonons. It has been shown by using the dynamical mean field theory that the model contains two phases, the Kondo singlet phase for strong hybridization and the local moment phase for weak hybridization. In the hybridization-temperature plane, these two phases are separated by a first order phase transition line which terminates at a second order phase transition point. We calculated the susceptibilities for various possible orderings for the model. We found that the charge density wave ordering is robust at low temperature and for weak hybridization. The second order critical point is screened out by the formation of CDW. It is probable that the two phases should be Kondo singlet phase and CDW phase.

**4:06PM V27.00009 The entanglement structure of the Kondo singlet in energy space** , CHUN YANG, ADRIAN FEIGUIN, Physics department of Northeastern University — We unveil the entanglement structure of the Kondo singlet in energy space by studying the contribution of each individual free electron eigenstate. This is a problem of two spins coupled to a bath, where the bath is formed by the remaining conduction electrons. Being a mixed state, we resort to the "concurrence" as a good measure of entanglement. Using the density matrix renormalization group and analytical variational calculations with the Yoshida wave-function, and slave bosons, we find a distinct transition between weak and strong coupling regimes characterized by very different entanglement distributions. We discuss implications to the theory of the Kondo cloud.

**4:18PM V27.00010 Kondo phase shift at the zero-bias anomaly of quantum point contacts** , BORIS BRUN, CNRS, Institut Neel & Univ. Grenoble Alpes, Grenoble, France, FREDERICO MARTINS, SBASTIEN FANIEL, BENOIT HACKENS, IMCN/NAPS, Univ. catholique de Louvain, Belgium, ANTONELLA CAVANNA, CHRISTIAN ULYSSE, ALBDELKARIM OUEGHY, ULF GENNSER, DOMINIQUE MAILLY, CNRS, Laboratoire de photonique et de nanostructures, Marcoussis, France, PASCAL SIMON, Laboratoire de Physique des solides, Univ. de Paris-Sud, Orsay, France, SERGE HUANT, CNRS, Institut Neel & Univ. Grenoble Alpes, Grenoble, France, VINCENT BAYOT, IMCN/NAPS, Univ. catholique de Louvain, Belgium, MARC SANQUER, CEA, INAC-SPSMS & Univ Grenoble Alpes, Grenoble, France, HERMANN SELLIER, CNRS, Institut Neel & Univ. Grenoble Alpes, Grenoble, France — The Kondo effect is the many-body screening of a local spin by a cloud of electrons at very low temperature. It has been proposed as an explanation of the zero-bias anomaly in quantum point contacts where interactions drive a spontaneous charge localization. However, the Kondo origin of this anomaly remains under debate, and additional experimental evidence is necessary. Here we report on the first phase-sensitive measurement of the zero-bias anomaly in quantum point contacts using a scanning gate microscope to create an electronic interferometer. We observe an abrupt shift of the interference fringes by half a period in the bias range of the zero-bias anomaly, a behavior which cannot be reproduced by single-particle models. We instead relate it to the phase shift experienced by electrons scattering off a Kondo system. Our experiment therefore provides new evidence of this many-body effect in quantum point contacts.

**4:30PM V27.00011 Full counting statistics for current through each channel of orbital degenerate Anderson impurity with exchange interactions** , RUI SAKANO, ISSP, the university of Tokyo, AKIRA OGURI, YUNORI NISIKAWA, Department of physics, Osaka city university — We study non-equilibrium currents, current fluctuations and cross-correlations of the currents through Kondo-correlated quantum dots at low applied bias-voltages, using full counting statistics. To elucidate impact of dot-site interaction to these current properties in crossover between noninteracting and some Kondo states, renormalized perturbation theory or local Fermi liquid theory are employed. The exact form of the cumulant generating function up to third order of bias-voltage is derived in term of renormalized parameters. Specifically, crossover behavior of the Fano factor (ratio between noise and current) and current crosscorrelations for two-fold orbital case is discussed with using computed renormalized parameters by numerical renormalization group.

**4:42PM V27.00012 Voltage quench dynamics of a Kondo system** , ANDREY ANTIPOV, QIAOYUAN DONG, EMANUEL GULL, Univ of Michigan - Ann Arbor — We examine the dynamics of a correlated quantum dot in the mixed valence regime. We perform numerically exact calculations of the current after a quantum quench from equilibrium by rapidly applying a bias voltage in a wide range of initial temperatures. The current exhibits short equilibration times and saturates upon the decrease of temperature at all times, indicating Kondo behavior both in the transient regime and in steady state. The time-dependent current saturation temperature connects the equilibrium Kondo temperature to a substantially increased value at voltages outside of linear response. These signatures are directly observable by experiments in the time-domain.

**4:54PM V27.00013 NMR spin relaxation rates in the Heisenberg bilayer** , TIAGO MENDES, UFRJ / UC Davis, NICHOLAS CURRO, RICHARD SCALETTAR, UC Davis, THEREZA PAIVA, RAIMUNDO R. DOS SANTOS, UFRJ — One of the striking features of heavy fermions is the fact that in the vicinity of a quantum phase transition these systems exhibit the breakdown of Fermi-liquid behavior and superconductivity. Nuclear magnetic resonance (NMR) experiments play an important role in the study of these phenomena. Measurements of NMR spin relaxation rates and Knight shift, for instance, can be used to probe the electronic spin susceptibility of these systems. Here we studied the NMR response of the Heisenberg bilayer model. In this model, it is well known that the increase of the interplane coupling between the planes,  $J_{\text{perp}}$ , suppresses the antiferromagnetic order at a quantum critical point (QCP). We use stochastic series expansion (SSE) and the maximum-entropy analytic continuation method to calculate the NMR spin lattice relaxation rate  $1/T_1$  and the spin echo decay  $1/T_{2G}$  as function of  $J_{\text{perp}}$ . The spin echo decay,  $T_{2G}$  increases for small  $J_{\text{perp}}$ , due to the increase of the order parameter, and then vanishes abruptly in the QCP. The effects of  $J_{\text{perp}}$  dilution disorder in the QCP and the relaxation rates are also discussed. This research was supported by the NNSA grant number DE-NA 0002908, and Ciência sem fronteiras program/CNPQ.

**5:06PM V27.00014 4f metals (compounds) under High Pressure (and Temperature): f-electron Correlation Physics**, MAGNUS LIPP, ZSOLT JENEI, HYUNCHAE CYNN, WILLIAM EVANS, Lawrence Livermore National Laboratory, PHYSICS DIVISION TEAM — The physics of 4f-electron correlation governs the behavior of the most interesting group in the periodic table, the rare-earth elements. Arguably the most celebrated example is cerium with its iso-structural (fcc) volume collapse (VC) from the  $\gamma$ - to the  $\alpha$ -phase ending in a critical point. Close to the VC cerium is even auxetic since its Poisson's ratio becomes negative. Radiography tells us that both phases continue on into the melt, possibly separated by a first order transition. The presence of the f-electron can be interrogated via X-ray emission spectroscopy of the satellite intensity of the  $L\gamma$  radiation. Across the VC it experiences a step-like drop which could be interpreted as a discontinuous decrease of the 4f-moment or occupancy. The theoretical models (Hubbard-Mott or Kondo) explain these phenomena with the behavior of the f-electrons themselves or their spin but the contribution of the lattice-phonons also plays an important part. However, its share in the entropy change across the VC decreases with temperature. This work was performed under the auspices of the US DOE by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. The X-ray studies were performed at HPCAT (Sector 16), APS/ANL. HPCAT is supported by CIW, CDAC, UNLV and LLNL through funding from DOE-NNSA, DOE-BES and NSF. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

**5:18PM V27.00015 Multi-pole orders and Kondo screening: Implications for quantum phase transitions in multipolar heavy-fermion systems**, HSIN-HUA LAI, EMILIAN NICA, QIMIAO SI, Department of Physics and Astronomy, Rice University — Motivated by the properties of the heavy-fermion  $\text{Ce3Pd20Si6}$  compound [1] which exhibits both antiferro-magnetic (AFM) and antiferro-quadrupolar (AFQ) orders, we study a simplified quantum non-linear sigma model for spin-1 systems [2], with generalized multi-pole Kondo couplings to conduction electrons [3]. We first consider the case when an  $\text{SU}(3)$  symmetry relates the spin and quadrupolar channels. We then analyze the effect of breaking the  $\text{SU}(3)$  symmetry, so that the interaction parameters in the spin and quadrupolar sectors are no longer equivalent, and different stages of Kondo screenings are allowed. A renormalization group analysis [4] is used to analyze the interplay between the Kondo effect and the AFM/AFQ orders. Our work paves the way for understanding the global phase diagram in settings beyond the prototypical spin- cases. We also discuss similar considerations in the non-Kramers systems such as the heavy fermion compound  $\text{PrV2Al20}$  [5]. [1]Custers et al, Nat.Mater. 11, 189 (2012). [2]A. Smerald et. al., Phys. Rev. B 88, 184430 (2013); Phys. Rev. B 91, 174402 (2015). [3]O. Parcollet et. al., Phys. Rev. Lett. 79, 4665 (1997); Phys. Rev. B 58, 3794 (1998) [4]Yamamoto S.J. and Q. Si, Phys. Rev. ## Thursday, March 17, 2016 2:30PM - 5:30PM – Session V28 DCMF: Josephson and Superconducting Proximity Effect 327 -

**2:30PM V28.00001 Topological phase transition of a Josephson junction and its dynamics**, JIMMY HUTASOIT, MARCO MARCIANI, BRIAN TARASINSKI, CARLO BEENAKKER, Lorentz Institute, Leiden University — A Josephson junction formed by a superconducting ring interrupted by a semiconductor nanowire can realize a zero-dimensional class D topological superconductor. By coupling the Josephson junction to a ballistic wire and altering the strength of the coupling, one can drive this topological superconductor through a topological phase transition. We study the compressibility of the junction as a probe of the topological phase transition. We also study the dynamics of the phase transition by studying the current pulse injected into the wire.

**2:42PM V28.00002 Combined gate-tunable Josephson junctions and normal state transport in  $\text{Bi}_2\text{Te}_3$  topological insulator thin films<sup>1</sup>**, PROSPER NGABONZIZA, MARTIN, P STEHNO, University of Twente, HIROAKI MYOREN, Saitama University, ALEXANDER BRINKMAN, University of Twente — In recent years, extensive efforts have been made to improve the coupling between topological insulators and s-wave superconductors in topological insulator Josephson devices (TIJDs). Despite significant progress, essential questions remain open such as the bulk contribution to the Josephson critical current or the existence (and number) of  $4\pi$ -periodic bound states (Majoranas) in TIJDs. To address these issues, we fabricated  $\text{Nb}/\text{Bi}_2\text{Te}_3/\text{Nb}$  Josephson junctions alongside Hall bar devices on MBE-grown  $\text{Bi}_2\text{Te}_3$  topological insulator thin films. Using the  $\text{SrTiO}_3$  [111] substrate as a gate dielectric, we tuned the carrier density electrostatically and measured the Josephson supercurrent and the normal state transport properties of our thin film devices. We identify three gate voltage ranges with distinct behavior: A region of intermediate gate bias where the measured quantities change rapidly with the applied electric field, and two saturation regions for large bias of either polarity. We discuss carrier distribution and band alignment in the material as well as implications for the effective Josephson coupling in TIJDs.

**2:54PM V28.00003 Quantum Phase Slips in Topological Josephson Junction Rings**, ROSA RODRIGUEZ MOTA, McGill University, SMITHA VISHVESHVARA, University of Illinois at Urbana-Champaign, TAMI PEREG-BARNEA, McGill University — We study quantum phase slip processes (QPS) in a ring of N topological superconducting islands joined by Josephson junctions and threaded by magnetic flux. In this array, neighboring islands interact through the usual charge  $2e$  Josephson tunneling and the Majorana assisted charge  $e$  tunneling.<sup>1</sup> When the charging energy associated with the island's capacitance is zero, the energy vs. flux relation of the system is characterized by parabolas centered around even or odd multiples of the superconducting flux quantum, depending on the parity of the system. For small but non-zero charging energy, quantum fluctuations can lead to tunneling between these classical states.<sup>2</sup> In this work, we calculate the amplitude of these tunneling processes, commonly known as quantum phase slips. We also add gate voltages to our system and study how the amplitude of QPS in these topological Josephson array is modified by Aharonov-Casher interference effects.

**3:06PM V28.00004 Detecting evidence for chiral superconductivity in  $\text{Sr}_2\text{RuO}_4$  through the use of Josephson junctions**, BRIAN ZAKRZEWSKI, Y. A. YING, XINXIN CAI, SHAUN MILLS, N. E. STALEY, Pennsylvania State University, Y. XIN, National High Magnetic Field Laboratory, DAVID FOBES, TIJIANG LIU, ZHI-QIANG MAO, Tulane University, YING LIU, Pennsylvania State University —  $\text{Sr}_2\text{RuO}_4$  is predicted to be an odd-parity, spin-triplet superconductor, possibly featuring a doubly degenerate chiral order parameter, which leads to the presence of chiral edge currents, domains, and domain walls. We fabricated Josephson junctions on ramps cut by focused ion beam as well as on naturally cleaved edges of micron thick crystals of  $\text{Sr}_2\text{RuO}_4$  using Al as the conventional superconductor electrode. The sensitivity of these Josephson junctions to a magnetic flux penetrating the junction and the domain dependent intrinsic phase of the superconducting order parameter make them a powerful tool for probing the effects of chiral superconductivity mentioned above. We will present the methodology as well as preliminary measurements and discuss the implications of our results.

**3:18PM V28.00005 Switching Current Distributions in Superconductor–Topological Insulator–Superconductor Junctions**, ANDREW MURPHY, CAN ZHANG, ERIK HUERMILLER, Univ of Illinois - Urbana, SEONGSHIK OH, Rutgers University, JAMES ECKSTEIN, DALE VAN HARLINGEN, ALEXEY BEZRYADIN, Univ of Illinois - Urbana — It has been proposed that localized Majorana fermion (MF) modes can exist in lateral Josephson junctions with a 3D-topological insulator barrier at locations at which the phase difference across the junction is an odd multiple of  $\pi$ . These states enter the junctions bound to the nodes of the Josephson vortices as a perpendicular magnetic field is increased. Each mode contributes a local  $4\pi$ -periodic  $\sin(\varphi/2)$ -component to the junction's current-phase relation, adding to the usual  $\sin(\varphi)$  dependence. The sign of this new term encodes the parity of the Majorana pair. As a way to detect these states and measure their parity, we study the distribution of switching currents in Nb-Bi<sub>2</sub>Se<sub>3</sub>-Nb junctions fabricated on thin Bi<sub>2</sub>Se<sub>3</sub> films in which the superconductivity is induced by a pair of closely spaced Nb electrodes. We expect that such measurements will be sensitive to the parity of the MFs, yielding a splitting of the distribution. Preliminary measurements of the critical current distributions show the onset of unusual features when the magnetic field is increased which we are analyzing to determine if they may arise from Majorana fermions in the junctions.

**3:30PM V28.00006 Signature of topological transition in InAs nanowire Josephson junctions**, ELIA STRAMBINI, J. PAAJASTE, M. AMADO, S. RODDARO, NEST, CNR-NANO and Scuola Normale Superiore, Pisa, Italy, P. SAN-JOSE, R. AGUADO, ICMN-CSIC, Madrid, Spain, S. BERGERET, CFM-MPC, San Sebastian, Spain, D. ERCOLANI, L. SORBA, F. GIAZZOTTO, NEST, CNR-NANO and Scuola Normale Superiore, Pisa, Italy — The coupling of a conventional s-wave superconductors to semiconductors with strong spin-orbit (SO) coupling, like e. g. InAs or InSb nanowires (NWs), gives rise to unconventional p-wave superconductivity that may become a topological superconductor (TS), which is a natural host for exotic edge modes with Majorana character. Recently the enhancement of the critical supercurrent  $I_c$  in a strong SO semiconducting Josephson junction (JJ) have been proposed as a new evidence of the sought-after Majorana bound states.<sup>1</sup> Here we report on the first observation of the colossal  $I_c$  enhancement induced by an external magnetic field on a mesoscopic JJ formed by InAs NWs and Ti/Al leads. This anomalous enhancement appears precisely above a threshold magnetic field  $B_{th}$  orthogonal to the substrate and in junctions of different lengths, suggesting that the origin of the enhancement is intrinsic, i.e. it is not related to geometrical resonances in the junction. None of the standard phenomenon known in JJ, including e. g. Fraunhofer patterns or  $\pi$ -junction behavior, can explain this colossal enhancement while a topological transition at  $B_{th}$  is qualitatively compatible with the observed phenomenology.

<sup>1</sup>Phys.Rev.Lett. **112**, 137007 (2014)

**3:42PM V28.00007 Band structure of topological insulators from noise measurements in tunnel junctions**, JUAN PEDRO CASCALES SANDOVAL, Massachusetts Institute of Technology, ISIDORO MARTINEZ, Universidad Autnoma de Madrid, RUBEN GUERRERO, IMDEA-Nanociencia, CUI-ZU CHANG, FERHAT KATMIS, JAGADEESH MOODERA, Massachusetts Institute of Technology, FARKHAD ALIEV, Universidad Autnoma de Madrid — The unique properties of spin-polarized surface or edge states in topological insulators (TIs) make these quantum coherent systems interesting from the point of view of both fundamental physics and their implementation in low power spintronic devices. Here we present such a study in TIs, through tunnelling and noise spectroscopy utilizing TI/Al<sub>2</sub>O<sub>3</sub>/Co tunnel junctions with bottom TI electrodes of either Bi<sub>2</sub>Te<sub>3</sub> or Bi<sub>2</sub>Se<sub>3</sub>. We demonstrate that features related to the band structure of the TI materials show up in the tunnelling conductance and even more clearly through low frequency noise measurements. The bias dependence of  $1/f$  noise reveals peaks at specific energies corresponding to band structure features of the TI. TI tunnel junctions could thus simplify the study of the properties of such quantum coherent systems that can further lead to the manipulation of their spin-polarized properties for technological purposes.

**3:54PM V28.00008 Quantum interferences and edge states in Bismuth based Josephson junctions**, ANIL MURANI, SHAMASHIS SENGUPTA, ALIK KASUMOV, SOPHIE GUERON, HLENE BOUCHIAT, Laboratoire de Physique des Solides, MESO GROUP TEAM — We have investigated proximity induced superconductivity in single crystal bismuth nanowires connected to superconducting electrodes with a high critical field. I will specially report recent results on nanowires whose crystalline orientation could be determined by electron diffraction. At low temperature a supercurrent is measured which persists up to the critical field of the electrodes and exhibits sample dependent fast squid-like oscillations (period one to few hundred gauss) modulated by slower (few thousand Gauss) oscillations. We attribute this striking result to the appearance of 1D topological edge channels on special surfaces of Bi due to its strong spin-orbit coupling, in addition to a strong Zeeman effect caused by an unusually high g-factor.

**4:06PM V28.00009 Quantum transport in topological insulator nanoribbon field effect and Josephson devices**, MORTEZA KAYYALHA, Purdue University, LUIS JAUREGUI, Purdue University, Harvard University, ALEKSANDER KAZAKOV, Purdue University, MICHAEL PETTES, University of Connecticut, IRENEUSZ MIOTKOWSKI, Purdue University, LI SHI, University of Texas at Austin, LEONID ROKHINSON, YONG CHEN, Purdue University — The spin-helical topological surface states (TSS) of topological insulators have attracted great attention in the past few years as an excellent platform to study topological transport and other exotic physics such as Majorana fermions. Here we present experiments studying quantum transport of TSS in topological insulator nanoribbon (TINR) field effect devices with normal as well as superconducting contacts. In Bi<sub>2</sub>Te<sub>3</sub> NRs with normal contacts, we observe that the conductance vs. axial magnetic field exhibits Aharonov-Bohm (AB) oscillations with an alternating phase of zero and  $\pi$ , depending periodically on the Fermi momentum  $k_F$  tuned by an applied back-gate voltage, consistent with the 1D sub-band structure formed by circumferentially quantized TSS [1]. We also investigated the Josephson effects in BiSbTeSe<sub>2</sub> TINRs with superconducting Nb contacts. We measured the gate voltage and temperature dependence of the supercurrent and multiple Andreev reflections (MAR), to probe phase coherent transport via TSS. [1] L. A. Jauregui et al., arxiv:1503.00685.

**4:18PM V28.00010 Multi-terminal Josephson junctions as topological matter**, ROMAN-PASCAL RIWAR, MANUEL HOUZET, JULIA S. MEYER, Univ. Grenoble Alpes & CEA, INAC-SPSMS, F-38000 Grenoble, France, YULI V. NAZAROV, Kavli Institute of Nanoscience, TU Delft, NL-2628 CJ, Delft, The Netherlands — Topological materials and their unusual transport properties are now at the focus of modern experimental and theoretical research. Their topological properties arise from the bandstructure determined by the atomic composition of a material and as such are difficult to tune and naturally restricted to  $\leq 3$  dimensions. Here we demonstrate that  $n$ -terminal Josephson junctions with conventional superconductors may provide novel realizations of topology in  $n - 1$  dimensions, which have similarities, but also marked differences with existing 2D or 3D topological materials. For  $n \geq 4$ , the Andreev subgap spectrum of the junction can accommodate Weyl singularities in the space of the  $n - 1$  independent superconducting phases, which play the role of bandstructure quasimomenta. The presence of these Weyl singularities enables topological transitions that are manifested experimentally as changes of the quantized transconductance between two voltage-biased leads, the quantization unit being  $4e^2/h$ .

**4:30PM V28.00011 Towards all electrical control of topological Josephson junctions and Majorana zero modes via spin-orbit interactions**, XIN LIU, School of Physics and Wuhan National High Magnetic Field Center, Huazhong University of Science and Technology, Wuhan, Hubei 430074, China, XIAOPENG LI, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA, XIONG-JUN LIU, International Center for Quantum Materials and School of Physics, Peking University, Beijing 100871, China, DONG-LING DENG, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, College Park, MD 20742-4111, USA — We study the current-phase relation of topological Josephson junctions with spin-orbit interactions, and show that the coupling between Majorana zero modes (MZMs) can be controlled via gate tunable spin-orbit couplings (SOCs). The spin-triplet pairings in the presence of MZMs at the two ends of a one-dimensional topological superconductor, are shown to have a  $\pi$  phase difference, from which a Josephson  $\pi$ -junction can be created. This  $\pi$  phase is unambiguously manifested to be a spin-dependent superconducting phase, dubbed spin-phase. We demonstrate that SOC can induce such spin-phase in spin-triplet superconducting condensates which can tune the MZM coupling energy and allow a finite topological Josephson current without a magnetic flux in superconducting circuits. We further establish the linkage between this Josephson current and the fermion parity in a topological Josephson junction and propose an all-electronically controlled superconductor-semiconductor hybrid circuit to detect the non-Abelian nature of MZMs.

**4:42PM V28.00012 Mean-field description of topological charge  $4e$  superconductors**, VICTORIA GABRIELE, JING LUO, JEFFREY C. Y. TEO, University of Virginia — BCS superconductors can be understood by a mean-field approximation of two-body interacting Hamiltonians, whose ground states break charge conservation spontaneously by allowing non-vanishing expectation values of charge  $2e$  Cooper pairs. Topological superconductors, such as one-dimensional  $p$ -wave wires, have non-trivial ground states that support robust gapless boundary excitations. We construct a four-body Hamiltonian in one dimension and perform a mean-field analysis. The mean-field Hamiltonian is now quartic in fermions but is still exactly solvable. The ground state exhibits 4-fermion expectation values instead of Cooper pair ones. There also exists a topological phase, where the charge  $4e$  superconductor carries exotic zero energy boundary excitations.

**4:54PM V28.00013 Scattering states of the Majorana-bound-state-supporting vortices at the interface of a topological insulator and an s-wave superconductor**, ADAM DURST, Hofstra University — We consider an isolated vortex in the 2D proximity-induced superconducting state formed at the interface of a 3D topological insulator (TI) and an s-wave superconductor (sSC). Prior calculations of the bound states of this system famously revealed a zero-energy state that is its own conjugate, a Majorana fermion bound to the vortex core. We calculate, not the bound states, but the scattering states of this system, and ask how the spin-momentum-locked massless Dirac form of the single-particle Hamiltonian, inherited from the TI surface, affects the cross section for scattering Bogoliubov quasiparticles from the vortex. As in the case of an ordinary superconductor, this is a two-channel problem with the vortex mixing particle-like and hole-like excitations. And as in the ordinary case, the same-channel differential cross section diverges in the forward direction due to the Aharonov-Bohm effect, resulting in an infinite total cross section but finite transport and skew cross sections. We calculate the transport and skew cross sections numerically, via a partial wave analysis, as a function of both quasiparticle excitation energy and chemical potential. Novel effects emerge as particle-like or hole-like excitations are tuned through the Dirac point.

**5:06PM V28.00014 Observation of superconductivity induced by a point contact on 3D Dirac semimetal  $\text{Cd}_3\text{As}_2$  crystals.**<sup>1</sup>, HE WANG, HUICHAO WANG, HAIWEN LIU, HONG LU, WUHAO YANG, SHUANG JIA, XIONGJUN LIU, XINCHENG XIE, JIAN WEI, JIAN WANG, Peking Univ — The 3D Dirac semimetal state is located at the topological phase boundary and can potentially be driven into other topological phases including topological insulator, topological metal and the long-pursuit topological superconductor states. Crystalline  $\text{Cd}_3\text{As}_2$  has been proposed and proved to be one of 3D Dirac semimetals which can survive in atmosphere. By precisely controlled point contact (PC) measurements, we observe the exotic superconductivity in the vicinity of the point contact region on the surface of  $\text{Cd}_3\text{As}_2$  crystal, which might be induced by the local pressure in the out-of-plane direction from the metallic tip for PC. The observation of zero bias conductance peak (ZBCP) and double conductance peaks (DCPs) symmetric to zero bias further reveals  $p$ -wave like unconventional superconductivity in  $\text{Cd}_3\text{As}_2$ . Considering the special topological property of the 3D Dirac semimetal, our findings may indicate that the  $\text{Cd}_3\text{As}_2$  crystal under certain conditions is a candidate of topological superconductor, which is predicted to support Majorana zero modes or gapless Majorana edge/surface modes on the boundary depending on the dimensionality of the material.

**5:18PM V28.00015 Induced gap in topological materials from the superconducting proximity effect**, CHING-KAI CHIU, WILLIAM COLE, Condensed Matter Theory Center, University of Maryland — Topological superconductivity has been of considerable interest lately, with several proposed experimental realizations in solid state systems. A heterostructure of s-wave superconductor and 3D topological insulator is one of the more promising platforms, with topological superconductivity realized on the "naked" surface of the topological insulator through the superconducting proximity effect. We theoretically study the induced superconducting gap on the naked surface. Adjusting the Fermi level above the bulk gap (which is the case in experiments), our results for the induced superconducting gap are in agreement with that probed in thin topological insulators ( $<10\text{nm}$ ) in the experiments (Nat. Phys. 10, 943-950 (2014) and Phys. Rev. Lett. 112, 217001 (2014)). We further predict the gap in thick topological insulators ( $>10\text{nm}$ ). This work is supported by LPS-MPO-CMTC, Microsoft Q, and JQI-NSF-PFC.

**Thursday, March 17, 2016 2:30PM - 5:30PM —**

**Session V29 DCMP: Weyl Semimetals: Theory and Experiments** 328 - Rudro Biswas, Purdue University

**2:30PM V29.00001 Topological Nodal-Line Fermions in the Non-Centrosymmetric Spin-Orbit Metal  $\text{PbTaSe}_2$ .**<sup>1</sup>, GUANG BIAN, Princeton University, PRINCETON TEAM — We report on the existence of topological nodal-line states in the non-centrosymmetric compound single-crystalline  $\text{PbTaSe}_2$  with strong spin-orbit coupling. Remarkably, the spin-orbit nodal lines in  $\text{PbTaSe}_2$  are not only protected by the reflection symmetry but also characterized by an integer topological invariant. Our detailed angle-resolved photoemission measurements, first-principles simulations and theoretical analysis illustrate the physical mechanism underlying the formation of the topological nodal-line states and associated surface states. Our work paves the way towards exploring the exotic properties of the topological nodal-line fermions in condensed matter systems and, potentially, the rich physics arising from the interplay between the topological nodal-line states and the emergent superconductivity in this compound.

<sup>1</sup>Work at Princeton University and Princeton-led synchrotron-based ARPES measurements were supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.

**2:42PM V29.00002 Magnetic structure and its role in the possible Weyl state in topological semimetal  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$  ( $0 < y, z < 0.1$ )**<sup>1</sup>, QIANG ZHANG, Louisiana State Univ - Baton Rouge, HUIBO CAO, Oak Ridge National Laboratory, JINYU LIU, Tulane University, ALAN TENNANT, Oak Ridge National Laboratory, JOHN DITUSA, Louisiana State Univ - Baton Rouge, ZHIQIANG MAO, Tulane University — Very recently, Liu et al ([arxiv.org/pdf/1507.07978](https://arxiv.org/pdf/1507.07978), (2015)) discovered the first magnetic topological semimetal  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$  ( $0 < y, z < 0.1$ ), in which a possible Weyl state arising from time reversal symmetry breaking is expected. However, the origin of ferromagnetic (FM) behavior of this material has not been clarified. By employing the neutron diffraction at the four-circle diffractometer HB3A, HFIR, we found a long-range FM order with Mn moments along  $b$ -axis below  $T_C = 565$  K, followed by another magnetic transition to a canted  $C$ -type antiferromagnetic (AFM) order at  $T_{FM-AFM} = 304$  K. In the canted  $C$ -type AFM state, the Mn moments are aligned with the  $a$ -axis along with a canting toward the  $b$ -axis, leading to a net FM moment lying along the  $b$ -axis. The Mn moments along the  $a$ - and  $b$ -axes at 5 K are found to be 3.789(3) and 0.741(4)  $\mu_B$ , respectively. The discovered FM order in  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$ , either the FM ordering at  $304 < T < 565$  K or the FM component of the canted AFM order for  $T < 304$  K, is sufficient to break time-reversal symmetry likely creating a Weyl semimetal.

**2:54PM V29.00003 An optical investigation of the Magnetic Weyl semi-metal candidate  $\text{YbMnBi}_2$** , DIPANJAN CHAUDHURI, BING CHENG, Department of Physics and Astronomy, Johns Hopkins University, QUINN D. GIBSON, ROBERT J. CAVA, Department of Chemistry, Princeton University, N. PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University — The discovery of Dirac and Weyl fermions in condensed matter systems has sparked tremendous interest in both condensed matter and high energy physics communities alike. While the existence of Dirac electrons in graphene and topological insulator materials is now well established, only a handful of experiments provide direct evidence of Weyl fermions in non-centrosymmetric systems. Moreover, the theoretically predicted Weyl fermions in magnetic materials with strong spin-orbit coupling have continued to be elusive. A potent candidate for a Weyl semimetal with broken time reversal symmetry (TRS) and antiferromagnetic ordering is the newly discovered  $\text{YbMnBi}_2$  compound. Although the complete magnetic structure of this material is still unknown, preliminary ARPES measurements are consistent with TRS breaking and a Weyl fermionic band dispersion. In this work, we investigate  $\text{YbMnBi}_2$  single crystal with FTIR spectroscopy and study its low energy electrodynamic response. The energy scale of IR light is ideally suited to probe for the linear band dispersion of these materials close to the Weyl points. Temperature dependent optical conductivity calculations reveal crucial information on the fundamental scattering processes in these materials.

**3:06PM V29.00004 Scanning tunneling microscopic investigation of the topological surface of a Weyl semimetal**<sup>1</sup>, HAO ZHENG, department of Physics, Princeton University — Weyl semimetals are believed to open the next era of condensed matter physics after graphene and topological insulators because they provide the first ever realization of Weyl fermions in all physics and extend the classification of topological phases beyond insulators. For many years, experimental studies have been held back due to the absence of material realization of the Weyl semimetal state. Very recently, the first Weyl semimetal has been experimentally discovered in TaAs class of materials. So far only preliminary ARPES and transport experiments have been reported. In this talk, we will present some interesting results of the scanning tunneling microscopy/spectroscopy (STM/STS) study on a Weyl semimetal.

<sup>1</sup>The work at Princeton were supported by the Gordon and Betty Moore Foundations EPIQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200

**3:18PM V29.00005 SdH oscillations and pressure effect of the Weyl semimetal NbAs**, YONGKANG LUO, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, N. J. GHIMIRE, Argonne National Laboratory, Argonne, Illinois 60439, USA, M. WARTENBE, HONGCHUL CHOI, M. NEUPANE, R. D. MCDONALD, E. D. BAUER, JIANXIN ZHU, J. D. THOMPSON, F. RONNING, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — Via angular Shubnikov-de Hass (SdH) quantum oscillations measurements, we determine the Fermi surface topology of NbAs. The SdH oscillations consist of two frequencies, corresponding to two Fermi surface extrema: 20.8 T ( $\alpha$ -pocket) and 15.6 T ( $\beta$ -pocket). The analysis shows that the  $\beta$ -pocket has a Berry phase of  $\pi$  and a small effective mass 0.033  $m_0$ , indicative of a nontrivial topology; whereas the  $\alpha$ -pocket has a trivial Berry phase of 0 and a heavier effective mass 0.066  $m_0$ . Subtle changes can be seen in the  $\rho_{xx}(T)$  profiles with pressure up to 2.31 GPa. The Fermi surfaces undergo an anisotropic evolution under pressure, while the topological features of the two pockets remain unchanged. Specific heat measurements reveal a small Sommerfeld coefficient  $\gamma_0 = 0.09(1)$  mJ/(mol $\cdot$ K<sup>2</sup>) and a large Debye temperature,  $\Theta_D = 450(9)$  K, confirming a “hard” crystalline lattice that is stable under pressure. We also studied the Kadowaki-Woods ratio of this low-carrier-density massless system,  $R_{KW} = 3.210^4 \Omega \text{ cm mol}^{-1} \text{ K}^2 \text{ J}^{-2}$ . After accounting for the small carrier density in NbAs, this  $R_{KW}$  indicates a suppressed transport scattering rate relative to other metals. **References:** [1] N. J. Ghimire et al., J. Phys.: Condens. Matter **27**, 152201 (2015) [2] Y. Luo et al., arXiv: 1506.01751 (2015) [3] Y. Luo et al., arXiv: 1510.08538 (2015)

**3:30PM V29.00006 Topological semimetal  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$** , JINYU LIU, JIN HU, Tulane Univ, DAVID GRAF, National High Magnetic Field Lab, S.M.A. RADMANESH, D.J. ADAMS, Univ. of New Orleans, Y.L. ZHU, G.F. CHEN, X. LIU, J. WEI, Tulane Univ, I. CHIORESCU, National High Magnetic Field Lab & Florida State Univ., L. SPINU, Univ. of New Orleans, Z.Q. MAO, Tulane Univ — Recent discoveries of topological Weyl semimetals in noncentrosymmetric monpnictides TX ( $T=\text{Ta/Nb}$ ,  $X=\text{As/P}$ ) [1-4] and photonic crystals [5] have generated immense interests since they represent new topological states of quantum matter. Time reversal symmetry (TRS) breaking Weyl semimetal was also recently reported in  $\text{YbMnBi}_2$  [6]. In this talk, we report a new type of topological semimetal phase arising from two-dimensional Sb layers in  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$  ( $y, z < 0.1$ ), which coexists with ferromagnetism. Through quantum transport measurements on this material, we reveal remarkable signatures of relativistic fermions, including light effective quasiparticle mass, high carrier mobility, a  $\pi$  Berry phase and valley polarized interlayer conduction. Given  $\text{Sr}_{1-y}\text{Mn}_{1-z}\text{Sb}_2$  shows ferromagnetism, it offers a wonderful opportunity to explore the TRS breaking Weyl state. [1]. H. Weng et al., Phys. Rev. **3:42PM V29.00007 Chiral magnetic effect in  $\text{ZrTe}_5$** , QIANG LI, CHENG ZHANG, GENDA GU, T. VALLA, Brookhaven National Lab, DMITRI KHARZEEV, Brookhaven National Lab and Stony Brook University, I. PLETIKOSIC, Princeton University — The chiral magnetic effect is the generation of electric current induced by chirality imbalance in the presence of magnetic field. Here we report on the measurement of magneto-transport in zirconium pentatelluride,  $\text{ZrTe}_5$  that provides a strong evidence for the chiral magnetic effect. Our angle-resolved photoemission spectroscopy experiments show that this material's electronic structure is consistent with a 3D Dirac semimetal. We observe a large negative magnetoresistance when magnetic field is parallel with the current. The measured quadratic field dependence of the magnetoresistance is a clear indication of the chiral magnetic effect. The observed phenomenon stems from the effective transmutation of Dirac semimetal into a Weyl semimetal induced by the parallel electric and magnetic fields that represent a topologically nontrivial gauge field background. We expect that chiral magnetic effect may emerge in a wide class of materials that are near the transition between the trivial and topological insulators.

**3:54PM V29.00008 Optical evidence for a Weyl semimetal state in pyrochlore  $\text{Eu}_2\text{Ir}_2\text{O}_7$** <sup>1</sup>, ANDREI SUSHKOV, JOHANNES HOFMANN, GREGORY JENKINS, DENNIS DREW, Department of Physics, University of Maryland, USA, JUN ISHIKAWA, SATORU NAKATSUJI, Institute for Solid State Physics, University of Tokyo, Japan — Possible realization of a Weyl semimetallic state with the broken time-reversal symmetry in pyrochlore iridates is still under debate. In the absence of ARPES and neutron data, optical evidence become very important. We found that the THz optical conductivity and temperature dependence of the free carrier response in pyrochlore  $\text{Eu}_2\text{Ir}_2\text{O}_7$  match the predictions for a Weyl semimetal and suggest novel Dirac liquid behavior. The interband optical conductivity vanishes continuously at low frequencies signifying a semimetal. The metal-semimetal transition at  $T_N = 110$  K is manifested in the Drude spectral weight, which is independent of temperature in the metallic phase, and which decreases smoothly in the ordered phase. The temperature dependence of the free carrier weight below  $T_N$  is in good agreement with theoretical predictions for a Weyl semimetal. The fit of experimental Drude weight yields a Fermi velocity  $4 \times 10^7$  cm/s, a logarithmic renormalization scale  $\Lambda_L \approx 600$  K, and require a Fermi temperature of  $\sim 100$  K associated with residual unintentional doping to account for the low temperature optical response and dc resistivity.

<sup>1</sup>This work was supported by grants: NSF DMR-1104343 and 1066293, DOE ER46741-SC0005436, LPS-MPO-CMTC, the Japanese Society for the Promotion of Science R2604, and Grants-in-Aid for Scientific Research 25707030.

**4:06PM V29.00009 Weak Topological Insulators and Composite Weyl Semimetals:  $\beta\text{-Bi}_4\text{X}_4$  ( $\text{X}=\text{Br}, \text{I}$ )**, FAN ZHANG, CHENG-CHENG LIU, Univ of Texas, Dallas, JIN-JIAN ZHOU, YUGUI YAO, Beijing Institute of Technology — While strong topological insulators (STI) have been experimentally realized soon after their theoretical predictions, a weak topological insulator (WTI) has yet to be unambiguously confirmed. A major obstacle is the lack of distinct natural cleavage surfaces to test the surface selective hallmark of WTI. With a new scheme, we discover that  $\text{Bi}_4\text{X}_4$  ( $\text{X}=\text{Br}, \text{I}$ ), stable or synthesized before, can be WTI with two natural cleavage surfaces, where two anisotropic Dirac cones stabilize and annihilate, respectively. We further find four surface state Lifshitz transitions under charge doping and two bulk topological phase transitions under uniaxial strain. Near the WTI-STI transition, there emerges a novel Weyl semimetal phase, in which the Fermi arcs generically appear at both cleavage surfaces whereas the Fermi circle only appears at one selected surface.

**4:18PM V29.00010 STM studies of Weyl semimetals**, HIROYUKI INOUE, ANDRAS GYENIS, SEONG WOO OH, JIAN LI, ZHI JUN WANG, ANDREI BERNEVIG, Princeton University, NI NI, University of California at Los Angeles, ALI YAZDANI, Princeton University — Weyl semimetal exhibits a new gapless topological phase, which is characterized by an even number of band touching points of two non-degenerate bands in the bulk, called Weyl nodes. The surfaces of these compounds are expected to harbor topologically protected surface states with disconnected Fermi surfaces, called Fermi arcs, which connect surface projections of the Weyl nodes with opposing Chern numbers. Among the theoretically predicted Weyl semimetals, there have been several experimental reports on the presence of Fermi arcs in inversion-symmetry-broken monoarsenides, such as TaAs. In this talk, we will present atomic-scale imaging and spectroscopic mapping of the electronic properties of TaAs and other Weyl semimetal candidates. Such measurements have the potential to directly visualize the Fermi arc surface states of these compounds and to probe their properties. This work is supported by ARO and NSF.

**4:30PM V29.00011 Noncentrosymmetric Line-Node Dirac semimetal  $\text{CaAgX}$  ( $\text{X}=\text{P}, \text{As}$ )**, AI YAMAKAGE, Department of Applied Physics, Nagoya University, YUICHI YAMAKAWA, Department of Physics, Nagoya University, YUKIO TANAKA, YOSHIHIKO OKAMOTO, Department of Applied Physics, Nagoya University — Noncentrosymmetric ternary pnictide  $\text{CaAgX}$  ( $\text{X}=\text{P}, \text{As}$ ) is shown to be a topological line-node semimetal protected solely by mirror-reflection symmetry. The band gap vanishes on a circle in momentum space and surface states emerge within the circle. The  $Z_2$  topological invariant  $\nu$  related to the surface states is defined from the Berry phase and mirror-reflection symmetry. Extending this study to spin-orbit coupled systems reveals that, compared with  $\text{CaAgP}$ , a substantial band gap is induced in  $\text{CaAgAs}$  by large spin-orbit interaction. The resulting states are a topological insulator, in which the  $Z_2$  topological invariant is given by 1;000. We have found that the  $Z_2$  topological invariants  $\nu_0, \nu_1, \nu_2$ , and  $\nu_3$  for time-reversal-invariant insulators without spatial-inversion symmetry and with mirror-reflection symmetry are calculated from the  $Z_2$  invariant  $\nu$  for a line node in the absence of spin-orbit interaction. Namely, line-node Dirac semimetals protected by mirror-reflection symmetry turn into strong topological insulators owing to spin-orbit interaction. [AY, Y. Yamakawa, Y. Tanaka, and Y. Okamoto, arXiv:1510.00202]

**4:42PM V29.00012 Signature of Instability of Chiral Fermion in Ultraquantum Weyl Semimetal TaAs**, CHENGLONG ZHANG, BING-BING TONG, ZHUJUN YUAN, SHUANG JIA, CHI ZHANG, Peking University — In the compound of Tantalum Monoarsenide (TaAs), the novel Weyl fermions are hosted. In our high mobility single crystal samples, the Shubnikov-de Haas oscillations are distinct below the quantum limit ( $B \sim 10$  T). Beyond the quantum limit, within the configuration-B (electric field  $\mathbf{E} \parallel \mathbf{B}$ -fields), we observed the novel quantum phase transitions in the  $\rho_{zz}$ -measurements, which may come from the nesting of the vector over a wide range of B-T plane. Due to the similarity to those observed density wave phases or the excitonic states in three-dimensional graphite semimetal, the novel phase may from many body effect beyond the quantum limit. However, in the other measurements ( $R_{xx}$  in configuration-A:  $\mathbf{E} \perp \mathbf{B}$ -fields), the novel quantum phase transition does not exist. In general, our results on the density wave phase support its non-trivial topological order.

**4:54PM V29.00013 Optical spectroscopy study of Weyl Semimetal NbP**, JEREMY YANG, YUXUAN JIANG, Georgia Institute of Technology, ZHILING DUN, HAIDONG ZHOU, University of Tennessee, DMITRY SMIRNOV, National High Magnetic Field Laboratory, ZHIGANG JIANG, Georgia Institute of Technology — Weyl semimetals have attracted much interest lately because of its unique band structure, where conduction band and valence band touch at discrete points. Here, we report on optical spectroscopy study of Weyl semimetal NbP, seeking evidence for the existence of Weyl fermions. Specifically, using Raman spectroscopy we investigate the anisotropic response of Raman-active phonon modes in NbP and compare with Quantum Espresso simulations. Using magneto-infrared spectroscopy in a high magnetic field up to 17.5T, we observe several Landau level transitions and compare with the theoretical model of three-dimensional massless Dirac/Weyl fermions. By combining our data with low-temperature magneto-transport measurement, the magnetic field dispersion of Landau levels in NbP is obtained.

**5:06PM V29.00014 Non-stoichiometry and Defects in the Weyl Semimetals TaAs, TaP, NbAs, and NbP**<sup>1</sup>, TIGLET BESARA, DANIEL A. RHODES, KUAN-WEN CHEN, QUI ZHANG, BIN ZHENG, YAN XIN, LUIS BALICAS, RYAN E. BAUMBACH, THEO SIEGRIST, National High Magnetic Field Laboratory / Florida State University — We report on a structural study of the Weyl semimetals TaAs, TaP, NbAs, and NbP, utilizing diffraction techniques (single crystal x-ray diffraction and energy dispersive spectroscopy) and imaging techniques (transmission electron microscopy). We observe defects of various degrees, leading to non-stoichiometric single crystals of all four semimetals. While TaP displays a very large pnictide deficiency with composition  $\text{TaP}_{0.83(3)}$  and stacking faults accompanied by anti-site disorder and site vacancies, TaAs displays transition metal deficiency with composition  $\text{Ta}_{0.92(2)}\text{As}$  and a high density of stacking faults. NbP also displays pnictide deficiency, yielding composition  $\text{NbP}_{0.95(2)}$ , and lastly, NbAs display very little deviation from a 1:1 composition,  $\text{NbAs}_{1.00(3)}$ , and is therefore recommended to serve as the model compound for these semimetals.

<sup>1</sup>DOE-BES #DE-SC0008832 (TB & TS), NSF DMR-1157490 (NHMFL)

**5:18PM V29.00015 Chiral Magnetic Effect in Condensed Matter<sup>1</sup>**, TONICA VALLA, QIANG LI, Brookhaven National Laboratory, DMITRI KHARZEEV, Brookhaven National Laboratory and Stony Brook University, CHENG ZHANG, YUAN HUANG, Brookhaven National Laboratory, IVO PLETIKOSIC, Brookhaven National Laboratory and Princeton University, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, RUIDAN ZHONG, JOHN SCHNEELOCH, GENDA GU, Brookhaven National Laboratory — The chiral magnetic effect (CME) is the generation of electric current induced by chirality imbalance in the presence of magnetic field - a macroscopic manifestation of the quantum anomaly in relativistic field theory of chiral fermions. The recent discovery of Dirac and Weyl semimetals opened a fascinating possibility to study this phenomenon in condensed matter experiments. Magneto-transport in  $\text{ZrTe}_5$  shows a strong evidence for CME. Our ARPES experiments show that this material's electronic structure is consistent with a highly anisotropic 3D Dirac semimetal. We observe a large negative magnetoresistance in parallel magnetic field, with the quadratic field dependence of the magneto-conductance - a clear indication of the CME.

**Session V30 DMP: Charge Transfer and Electron Gases at Oxide Interfaces** 329 - Uli Aschauer, ETH Zurich

**2:30PM V30.00001 Charge transfer and emergent phenomena of oxide heterostructures<sup>1</sup>**, HANGHUI CHEN, Columbia Univ — Charge transfer is a common phenomenon at oxide interfaces. We use first-principles calculations to show that via heterostructuring of transition metal oxides, the electronegativity difference between two dissimilar transition metal ions can lead to high level of charge transfer and induce substantial redistribution of electrons and ions. Notable examples include i) enhancing correlation effects and inducing a metal-insulator transition [1]; ii) tailoring magnetic structures and inducing interfacial ferromagnetism [2]; iii) engineering orbital splitting and inducing a non-cuprate single-orbital Fermi surface [3]. Utilizing charge transfer to induce emergent electronic/magnetic/orbital properties at oxide interfaces is a robust approach. Combining charge transfer with quantum confinement and epitaxial strain provides an appealing prospect of engineering electronic structure of artificial oxide heterostructures. [1] H. Chen, A. J. Millis and C. A. Marianetti, PRL 111, 116403 (2013) [2] H. Chen, H. Park, A. J. Millis and C. A. Marianetti, PRB 90, 245138 (2014) [3] H. Chen, D. P. Kumah, A. S. Disa, F. J. Walker, C. H. **3:06PM V30.00002 Structural and electronic properties of  $\text{Sr}(\text{Zr,Ti})\text{O}_3$  alloys for use in oxide heterostructures<sup>1</sup>**, LEIGH WESTON, University of California, Santa Barbara, ANDERSON JANOTTI, University of Delaware, Newark, XIANGYUAN CUI, The University of Sydney, BURAK HIMMETOGLU, University of California, Santa Barbara, CATHERINE STAMPFL, The University of Sydney, CHRIS G. VAN DE WALLE, University of California, Santa Barbara —  $\text{Sr}(\text{Ti,Zr})\text{O}_3$  alloys are promising materials for use in oxide heterostructures, however the fundamental properties of this system have not yet been characterized. Using hybrid density functional calculations, we study the electronic and structural properties of ordered  $\text{SrTi}_x\text{Zr}_{1-x}\text{O}_3$  alloys at  $x=0, 0.25, 0.5, 0.75$ , and 1. As Ti is added to  $\text{SrZrO}_3$ , the lattice parameter is reduced according to Vegard's law, while the band gap shows a large bowing and is sensitive to the Ti distribution. For  $x=0.5$ , arranging the Ti and Zr atoms into a  $1\times 1$   $\text{SrZrO}_3/\text{SrTiO}_3$  superlattice along the [001] direction leads to a highly dispersive single band at the conduction-band minimum (CBM) that is absent in the parent compounds, and a direct gap close to that of pure  $\text{SrTiO}_3$ . This is explained by the splitting of the Ti  $3d\ t_{2g}$  states in the reduced symmetry of the superlattice, lowering the band originating from the Ti  $3d_{xy}$  orbitals. The lifting of the orbital degeneracy around the CBM suppresses scattering due to electron-phonon interactions. We propose that short-period  $\text{SrZrO}_3/\text{SrTiO}_3$  superlattices could be exploited to engineer the band structure and improve carrier mobility compared to bulk  $\text{SrTiO}_3$ .

<sup>1</sup>This work was supported by NSF, ONR and ARC.

**3:18PM V30.00003 Direct observation of induced ferromagnetism in  $\text{SrTiO}_3$  quantum wells confined in  $\text{GdTiO}_3$  heterostructures**, RYAN NEED, BRANDON ISAAC, University of California Santa Barbara, Materials Department, BRIAN KIRBY, JULIE BORCHERS, NIST Center for Neutron Research, SUSANNE STEMMER, STEPHEN WILSON, University of California Santa Barbara, Materials Department — Complex oxide thin film heterostructures with charge transfer at the interface provide a uniquely tunable environment in which to study the physics of highly-correlated and quantum-confined electron systems. Previous studies using magnetoresistance measurements had suggested that thin  $\text{SrTiO}_3$  layers become ferromagnetic when grown between thicker  $\text{GdTiO}_3$  layers. Here we report the direct observation of induced ferromagnetism in  $\text{SrTiO}_3$  quantum wells using polarized neutron reflectometry (PNR). Four  $\text{GdTiO}_3/\text{SrTiO}_3$  superlattice structures with varying  $\text{SrTiO}_3$  layer thickness were grown epitaxially on LSAT (001) substrates by hybrid molecular beam epitaxy. Chemical and magnetic depth-profiles were refined using a combination of x-ray and polarized neutron reflectivity measurements taken at temperatures ranging from 4-300K. We observed a critical thickness below which the  $\text{SrTiO}_3$  layer have non-zero magnetism in the center of the well. These results are in excellent agreement with the previous magnetoresistance measurements and provide the first direct observation of induced-magnetism in this system.

**3:30PM V30.00004 Intrinsic Electronic Confinement at Conducting Oxide Interfaces**, DANFENG LI, STEFANO GARIGLIO, WEI LIU, ALEXANDRE FTE, MARGHERITA BOSELLI, DQMP, University of Geneva, MARC GABAY, LPS, Universit Paris-Sud, JEAN-MARC TRISCONE, DQMP, University of Geneva, DQMP COLLABORATION, LPS COLLABORATION — The discovery of a two-dimensional electron liquid (2DEL), confined at the interface between the two band insulators  $\text{LaAlO}_3$  (LAO) and  $\text{SrTiO}_3$  (STO) has generated tremendous research interest [1]. The 2DEL confinement lifts the degeneracy of Ti  $t_{2g}$  orbitals and promotes exotic physical properties [2]. A previous study [3] has demonstrated that a 2DEL is also observed when LAO is alloyed with STO ( $(\text{La,Al})_{1-x}(\text{Sr,Ti})_x\text{O}_3$  (LASTO: $x$ )). The threshold thickness required for the onset of conductivity scales with  $x$ . We present here a study of magnetotransport and superconductivity at the (LASTO:0.5)/STO interface. The thickness of the 2DEL, measured using perpendicular and parallel critical fields is larger than the one at the LAO/STO interface. This change is due to a modification on the confining potential linked to a reduced charge transfer that is scaling as  $1/x$ . This study supports an intrinsic origin to the formation of the 2DEL in the LAO/STO system. [1] A. Ohtomo, H. Y. Hwang, Nature **427**, 423 (2004). [2] P. Zubko, S. Gariglio, M. Gabay, P. **3:42PM V30.00005 Beyond GaAs: Room-Temperature Intersubband Absorption in SrTiO<sub>3</sub>/LaAlO<sub>3</sub> Multiple Quantum Wells**, JOHN ORTMANN, NISH NOOKALA, University of Texas at Austin, QIAN HE, Oak Ridge National Lab, AGHAM POSADAS, University of Texas at Austin, ALBINA BORISEVICH, Oak Ridge National Lab, MIKHAIL BELKIN, ALEX DEMKOV, University of Texas at Austin — With the recent advancements in oxide thin film fabrication, it is possible to design and grow oxide quantum well heterostructures whose well depths far exceed those of traditional GaAs-based quantum wells. Here, we discuss the design, fabrication, structural quality, and optical properties of MBE-grown SrTiO<sub>3</sub>/LaAlO<sub>3</sub> multiple quantum wells. These oxide quantum wells have a conduction band offset of greater than 2eV, as measured by X-ray photoelectron spectroscopy. We present simulations of the confined states within the wells and demonstrate the feasibility of driving intersubband transitions whose energies exceed 1eV. Furthermore, we demonstrate the excellent crystalline quality of these heterostructures via X-ray diffraction spectra and STEM-HAADF imaging and present evidence of atomic-scale control of the structures. Finally, we present room-temperature FTIR spectra demonstrating the first-reported evidence of intersubband absorption in SrTiO<sub>3</sub>/LaAlO<sub>3</sub> multiple quantum wells and discuss the possibility of oxide quantum well-based devices.

**3:54PM V30.00006 Constriction based superconducting quantum interference devices at the LaAlO<sub>3</sub>/SrTiO<sub>3</sub> interface**, EMRE MULAZIMOGLU, SRIJIT GOSWAMI, ANA M. R. V. L. MONTEIRO, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, ROMAN WOELBING, DIETER KOELLE, REINHOLD KLEINER, Physikalisches Institut - Experimentalphysik II, Eberhard Karls Universität Tuebingen, Germany, YAROSLAV BLANTER, LIEVEN M. K. VANDERSYPEN, ANDREA D. CAVIGLIA, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands — The two-dimensional (2D) superconductor formed at the interface between LaAlO<sub>3</sub> (LAO) and SrTiO<sub>3</sub> (STO) has been studied extensively and shows many intriguing properties. However, to date there exist no measurements which are sensitive to the phase of the superconducting order parameter, a fundamental prerequisite to understand the microscopic mechanism of the superconductivity. Here, we realize superconducting quantum interference devices (SQUIDs) at the LAO/STO interface. Using nanoscale patterning, we define sub-100 nm physical constrictions, which serve as weak links between superconducting reservoirs. The SQUIDs show clear flux-periodic oscillations in the critical current. Back gate and temperature dependent studies, in combination with numerical simulations, show that the low superfluid density of this 2D superconductor results in an exceptionally large, gate controllable kinetic inductance of the SQUID. This ability to perform phase-sensitive measurements opens up a completely new approach to study this unique interfacial superconductor.

**4:06PM V30.00007 Electrostatically defined superconducting quantum interference devices at the LaAlO<sub>3</sub>/SrTiO<sub>3</sub> interface**, SRIJIT GOSWAMI, EMRE MULAZIMOGLU, ANA MONTEIRO, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, ROMAN WOELBING, DIETER KOELLE, REINHOLD KLEINER, Physikalisches Institut - Experimentalphysik II, Eberhard Karls Universität Tuebingen, Germany, YAROSLAV BLANTER, LIEVEN VANDERSYPEN, ANDREA CAVIGLIA, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands — Two-dimensional superconductivity at the LaAlO<sub>3</sub> (LAO)/ SrTiO<sub>3</sub> (STO) interface can be controlled via the field effect, whereby a global back gate can be used to systematically tune the critical temperature ( $T_c$ ) of the bulk superconductor. Here, we exploit this sensitivity of  $T_c$  to the field effect to create an electrostatically defined superconducting quantum interference device (SQUID) at the LAO/STO interface. The device consists of a superconducting loop with nanoscale local top gates on each arm. By controllably depleting carriers below the gates we create a SQUID with two identical Josephson junctions (JJs), giving rise to flux-periodic oscillations in the critical current. Furthermore, by independently tuning the two JJs we create an asymmetric SQUID, which allows us to accurately estimate an extremely large kinetic inductance of about 60nH. While other examples of gate-tunable JJs do exist, they necessarily involve physical interfaces between two dissimilar materials. In contrast, our gate-defined SQUIDs are unique in that the entire device is made from a single superconductor with purely electrostatic interfaces.

**4:18PM V30.00008 Aharanov-Bohm quantum interference in LaAlO<sub>3</sub>/SrTiO<sub>3</sub> Hall bar structures<sup>1</sup>**, PATRICK IRVIN, SHICHENG LU, ANIL ANNADI, GUANGLEI CHENG, MICHELLE TOMCZYK, MENGCHEN HUANG, JEREMY LEVY, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison — Aharanov-Bohm (AB) interference can arise in transport experiments when magnetic flux threads through two or more transport channels. The existence of this behavior requires long-range ballistic transport and is typically observed only in exceptionally clean materials. We observe AB interference in wide ( $w \sim 100$  nm) channels created at the LaAlO<sub>3</sub>/SrTiO<sub>3</sub> interface using conductive AFM lithography. Interference occurs above a critical field  $B \sim 4$  T and increases in magnitude with increasing magnetic field. The period of oscillation implies a ballistic length that greatly exceeds the micron-scale length of the channel, consistent with Fabry-Perot interference in 1D channels. The conditions under which AB oscillations are observed will be discussed in the context of the electron pairing mechanism in LaAlO<sub>3</sub>/SrTiO<sub>3</sub>.

**4:30PM V30.00009 Dimensionality effects on superconductivity in LaAlO<sub>3</sub>/SrTiO<sub>3</sub> nanostructures<sup>1</sup>**, ANIL ANNADI, SHICHENG LU, GUANGLEI CHENG, MICHELLE TOMCZYK, MENGCHEN HUANG, PATRICK IRVIN, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, JEREMY LEVY, University of Pittsburgh — We investigate electron transport, especially superconductivity, in LaAlO<sub>3</sub>/SrTiO<sub>3</sub> nanostructures with respect to the dimensionality by creating channels with widths varying from nanometers to micrometers using c-AFM lithography. Superconducting properties such as upper critical magnetic field and critical current are compared as a function of electron doping (gating) and temperature. The superconducting properties among these devices show a marked deviation from naive scaling expectations. We discuss the results in regard to ferroelastic domains and possible edge/boundary mode transport scenarios.

**4:42PM V30.00010 Quantum Oscillations at LaTiO<sub>3</sub>/SrTiO<sub>3</sub> Interfaces<sup>1</sup>**, MICHAEL VEIT, YURI SUZUKI, Stanford University — Emergent metallic behavior at the interface of the Mott insulator LaTiO<sub>3</sub> and the band insulator SrTiO<sub>3</sub> was observed for the first time more than a decade ago. Since then the metallicity has been explained in terms of charge redistribution at the interface combined with lattice relaxation. However to date, Shubnikov de Haas oscillations have not been reported in this two dimensional metallic system. For ultrathin (3-4 unit cells) LaTiO<sub>3</sub> thin films on SrTiO<sub>3</sub>, we report the observation of Shubnikov-de Haas oscillations whose frequency corresponds to a small Fermi pocket. Surprisingly the oscillation are only observed between 1 and 4 T. Above this range, the quantum limit is reached for this pocket so no more oscillations are observed. A Berry's phase of  $\pi$  is also detected in these oscillations. Additionally a strong in-plane anisotropic magnetoresistance was measured in the heterostructures which, along with the Berry's phase, is attributed to a giant Rashba coupling at the interface.

**4:54PM V30.00011 Impact of electric-field-dependent dielectric constants on two-dimensional electron gases in complex oxides<sup>1</sup>**, CHRIS VAN DE WALLE, HARTWIN PEELAERS, KARTHIK KRISHNASWAMY, LUKE GORDON, DANIEL STEIAUF, ANNA SARWE, ANDERSON JANOTTI, Univ of California - Santa Barbara — A high-density two-dimensional electron gas (2DEG) can be formed at interfaces of complex oxides. The electric field in the vicinity of the interface depends on the dielectric properties of the material as well as on the electron distribution. However, electric fields can strongly modify the dielectric constant of SrTiO<sub>3</sub> (STO) as well as other complex oxides. Solving the electrostatic problem thus requires a self-consistent approach in which the dielectric constant varies according to the local magnitude of the field. We have implemented the field dependence of the dielectric constant in a Schrodinger-Poisson solver and use the SrTiO<sub>3</sub>/GdTiO<sub>3</sub> interface as an example to discuss the importance of taking this field dependence into account when modeling interfaces of complex oxides [1].

**5:06PM V30.00012 Nanomechanical probes of sketched LaAlO<sub>3</sub>/SrTiO<sub>3</sub> single-electron transistors<sup>1</sup>**, JESSICA MONTONE, FENG BI, MENGCHEN HUANG, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison — The interface of LaAlO<sub>3</sub>/SrTiO<sub>3</sub> presents a locally tunable metal-insulator transition that can be utilized to create complex nanostructures. Using conducting AFM lithography techniques, we can create a variety of nanoscale devices such as sketched single-electron transistors (SketchSETs)<sup>2</sup>. Due to the piezoelectric properties of LaAlO<sub>3</sub>/SrTiO<sub>3</sub>, there exists the possibility of locally modulating the local electron density using the pressure applied by an AFM tip. Some of the most interesting properties are only observed at cryogenic temperature. For this purpose we utilize a cryogenic AFM system. I will describe our efforts to perform nanomechanical imaging of conductive structures, which can be helpful in mapping the electronic properties of oxide nanostructures.

**5:18PM V30.00013 Density-functional modelling of electron energy-loss spectra for LaAlO<sub>3</sub>/SrTiO<sub>3</sub> quantum well**, MIRI CHOI, LINGYUAN GAO, The University of Texas, QIAN HE, ALBINA BORISEVICH, Oak Ridge National Laboratory, ALEXANDER A. DEMKOV, The University of Texas — LaAlO<sub>3</sub>/SrTiO<sub>3</sub> quantum wells (QW) are grown by molecular beam epitaxy (MBE). The conduction band alignment is investigated using electron energy loss spectroscopy (EELS). We model the EELS spectrum using first-principle calculations. To account for the core-hole effect, the Z+1 approximation is adopted. Site-projected unoccupied p and d densities of states (pDOS) are extracted and compared with the experimental O K and Ti L edges that correspond to 1s to 2p and 2p to 3d transitions, respectively. Results for bulk LaAlO<sub>3</sub> (LAO) and SrTiO<sub>3</sub> (STO) are discussed first and then the quantum well case is analyzed. We investigate the orbital character of the conduction band states in a QW. We find that in LAO/STO QW, there are evanescent Ti-originated states in the LAO layer and relate them with the peak at EELS front edge.

**2:30PM V31.00001 Three-dimensional topological insulator based nanospaser**, HARI PAUDEL, VADYM APALKOV, MARK STOCKMAN, Georgia State Univ — After the discovery of spaser, now it has been possible to deliver optical energy beyond the diffraction limit and generate an intense source of optical field. Spaser is a nanoplasmonic counter part of laser. One of the major advantages of spaser is the size: spaser is truly a nanoscopic device whose size can be made smaller than skin depth of the material to a size as small as the nonlocality radius. Recently, an electrically pumped graphene based nanospaser has been proposed that operates in the mid-infrared frequency (Apalkov & Stockman). Here we propose an optically pumped nanospaser based on 3-dimensional topological insulator (3D TI) materials such as Bi<sub>2</sub>Se<sub>3</sub> that operates at an energy equal to the bulk bandgap energy and uses the surface as a source for plasmons and its bulk as a gain medium. The population inversion is obtained in the bulk and radiative energy of exciton recombination is transferred to surface plasmons of the same material to stimulate spasing action. As this spaser operates in the mid-infrared spectral region, it can be a useful device for number of applications such as nanoscopy, nanolithography, nanospectroscopy, and semi-classical information processing.

**2:42PM V31.00002 Light Scattering by Spheroids<sup>1</sup>**, YA-MING XIE, Beijing Computational Science Research Center, Beijing 100094, China, XIA JI, LSEC, Institute of Computational Mathematics, Chinese Academy of Sciences, Beijing 100190, China — Nowadays, with the development of technology, particles with size at nanoscale have been synthesized in experiments. It is noticed that anisotropy is an unavoidable problem in the production of nanospheres. Besides, nonspherical nanoparticles have also been extensively used in experiments. Comparing with spherical model, spheroidal model can give a better description for the characteristics of nonspherical particles. Thus the study of analytical solution for light scattering by spheroidal particles has practical implications. By expanding incident, scattered, and transmitted electromagnetic fields in terms of appropriate vector spheroidal wave functions, an analytic solution is obtained to the problem of light scattering by spheroids. Unknown field expansion coefficients can be determined with the combination of boundary conditions and rotational-translational addition theorems for vector spheroidal wave functions. Based on the theoretical derivation, a Fortran code has been developed to calculate the extinction cross section and field distribution, whose results agree well with those obtained by FDTD simulation.

**2:54PM V31.00003 Optical response of metal nanojunctions driven by single atom motion: influence of quantized electron transport on nanoplasmonics<sup>1</sup>**, DANIEL SANCHEZ-PORTAL, FEDERICO MARCHESIN, Centro de Física de Materiales de San Sebastián CSIC-UPV/EHU and DIPC, Spain, PETER KOVAL, Donostia International Physics Center (DIPC), Spain, MARC BARBRY, JAVIER AIZPURUA, Centro de Física de Materiales de San Sebastián CSIC-UPV/EHU and DIPC, Spain — The correlation between transport properties across sub-nanometric metallic gaps and the optical response of the system is a complex effect that, similarly to the near-field enhancement [1], is determined by fine atomic-scale details in the junction structure. Using ab initio calculations, we present here a study of the simultaneous evolution of the structure and the optical response of a plasmonic junction as the two Na<sub>380</sub> clusters forming the cavity approach and retract. Atomic reorganizations are responsible for a large hysteresis of the optical response. The system exhibits a jump-to-contact instability during the approach, and the formation of an atom-sized neck across the junction during retraction. Due to the quantization of the conductance in metal nanocontacts, atomic-scale reconfigurations play a crucial role in determining the optical response. We observe abrupt changes in the intensities and spectral positions of the dominating plasmon resonances, and find a one-to-one correspondence between these jumps and those of the quantized transport across the neck. These results point out to an unforeseen connection between transport and optics at the atomic scale, which is at the frontier of current optoelectronics. [1] M. Barbry, et al., Nano Letters **354**, 216 (2015)

**3:06PM V31.00004 Condensed Matter in Ultrafast and Superstrong Fields: Attosecond Phenomena**, MARK STOCKMAN, Center for Nano-Optics (CeNO) and Department of Physics and Astronomy, Georgia State University, Atlanta, GA 30302 — We present our latest results for a new class of phenomena in condensed matter optics when a strong optical field 1-3 V/Å changes a solid within optical cycle [1-7]. Such a pulse drives ampere-scale currents in dielectrics and adiabatically controls their properties, including optical absorption and reflection, extreme UV absorption, and generation of high harmonics [8] in a non-perturbative manner on a 100-as temporal scale. Applied to a metal, such a pulse causes an instantaneous and, potentially, reversible change from the metallic to semimetallic properties. We will also discuss our latest theoretical results on graphene that in a strong ultrashort pulse field exhibits unique behavior [9, 10]. New phenomena are predicted for buckled two-dimensional solids, silicene and germanene [11]. These are fastest phenomena in optics unfolding within half period of light. They offer potential for petahertz-bandwidth signal processing, generation of high harmonics on a nanometer spatial scale, etc.

**3:42PM V31.00005 Nobel metal alloyed thin-films with optical properties on demand**, CHEN GONG, MARINA S. LEITE, Department of Materials Science and Eng., Institute for Research in Electronics and Applied Physics, Univ. of Maryland, College Park, MD 20742 — Metallic materials with tunable optical responses can enable the unprecedented control of optoelectronic and nanophotonic devices with enhanced performance, such as thin-film solar cells, metamaterials and metasurfaces for tunable absorbers and optical filters, among others. Here we present the alloying of noble metals, Ag, Au and Cu, to develop a novel class of material with optical response not achieved by pure metals. We fabricate binary mixtures with controlled chemical composition by co-sputtering. Ellipsometry and surface plasmon polariton coupling angle measurements are in excellent agreement when determining the real part of the dielectric function ( $\epsilon_1$ ). Surprisingly, in some cases, a mixture provides a material with higher surface plasmon polariton quality factor than the corresponding pure metals. Our approach paves the way to implement metallic nanostructures with tunable absorption/transmission, overcoming the current limitation of the dielectric function of noble metals.

**3:54PM V31.00006 Metal alloyed nanostructures with tunable optical properties.**, MARIAMA REBELLO SOUSA DIAS, CHEN GONG, GARRETT WESSLER, MARINA LEITE, Department of Material Science and Eng. Institute for Research in Electronics and Applied Physics - Univ. of Maryland, College Park, MD 20742 — Pure metal nanostructures (Ns) have been widely used to enhance the optical response of optoelectronic devices, ranging from photovoltaics to broadband absorbers. However, their use is limited by their fixed optical properties. The development of metallic materials with modulated optical response could lead to a new class of Ns for optoelectronic devices with enhanced performance. In this work, we simulated and measured the optical response of binary mixtures of silver (Ag), gold (Au) and aluminum (Al) nanoparticles. We resolved the broadband forward scattering of these alloyed nanoparticles when applied to solar cells by finite-difference time-domain (FDTD) calculations. For a realistic prediction, we used the measured dielectric function of thin-films with identical chemical composition. We demonstrate that, in some cases, an alloy can outperform their pure metal counterparts, e.g.  $\text{Ag}_{0.5}\text{Au}_{0.5}$  shows increased light absorption at 800 nm than pure Au and Ag. The optical response of the alloyed Ns and its dependence with size and composition is measured by transmission and near-field scanning optical microscopy (NSOM). The use of alloyed metals as building blocks for broadband absorbers, where a large imaginary part of the dielectric function is desired, will also be discussed.

**4:06PM V31.00007 Emission and propagation of hyperbolic phonon polaritons in hexagonal boron nitride**, SIYUAN DAI, University of California, San Diego, QIONG MA, YAFANG YANG, Massachusetts Institute of Technology, JEREMY ROSENFELD, MICHAEL GOLDFLAM, ALEX MCLEOD, University of California, San Diego, TROND ANDERSEN, Massachusetts Institute of Technology, ZHE FEI, MENGKUN LIU, ZHIYUAN SUN, YINMING SHAO, University of California, San Diego, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, MARK THIEMENS, University of California, San Diego, FRITZ KEILMANN, Ludwig-Maximilians-Universitt and Center for Nanoscience, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, MICHAEL FOGLER, D. N. BASOV, University of California, San Diego — Using scattering-type scanning near-field optical microscope (s-SNOM), we studied various kinds of emission and propagation of hyperbolic phonon polaritons (HP2s) in hexagonal boron nitride (hBN). The systematic study via real-space nano-imaging reveals the emission mechanisms and propagating properties of HP2s excited by crystal edges, artificial structures, surface defects and impurities. Compared with traditional s-SNOM tip emitter, the polaritons from new emitters reported in this work possess longer propagation length and can be artificially manipulated on the hBN surface. Our work may benefit the future applications and engineering of HP2s using convenient emitters which are analogous to collective modes in other materials.

**4:18PM V31.00008 Nano-photonic phenomena in van der Waals atomic layered materials**, DMITRI BASOV, UCSD — Layered van der Waals (vdW) crystals reveal diverse classes of light-matter modes (polaritons) including: surface plasmon polaritons in graphene, hyperbolic phonon polaritons in boron nitride, exciton polaritons in  $\text{MoS}_2$ , Cooper pair plasmon polaritons in high-Tc cuprates, topological plasmon polaritons and many others. Polaritons in vdW materials are of considerable technological interest. For example, polaritonic modes enable sub diffractional focusing and imaging in infrared frequencies. Applications apart, infrared nano-imaging of propagating polaritons facilitates experimental access to new physics of vdW materials not attainable with conventional spectroscopic methods. I will discuss two recent experiments performed in our group that utilize unique virtues of polaritons. Nano-imaging of plasmon polaritons in moire superlattices formed in graphene on boron nitride has allowed us to establish the important features of the electronic structure of this interesting from of graphene. Pump-probe hyper-spectral images of non-equilibrium plasmon polaritons in graphene revealed novel aspects of carrier relaxation.

**4:54PM V31.00009 Unveiling nanometric plasmons optical properties with advanced electron spectroscopy in the Scanning Transmission Electron Microscope**, MATHIEU KOCIAK, Centre National de la Recherche Scientifique — Since the pioneering work of Yamamoto[1], the use of electron spectroscopy such as Cathodoluminescence (CL) and Electron Energy Loss Spectroscopy (EELS) in a Scanning (Transmission) Electron Microscope (STEM) has considerably helped improving our understanding of the optical properties of metallic nanoparticles. The resemblance of spectroscopic signals from electron and pure optical techniques leads to the intuition that both types of techniques are very close, an idea theoretically discussed by F.J. Garcia de Abajo and coworkers[2]. However, it is also quite intuitive that CL and EELS should be different. For example, EELS helps detecting any sort of modes while CL can only detect radiative ones. On the other hand, even between optical spectroscopy techniques, clear differences such as energy shifts or spectral shapes changes are expected in the case of plasmons. The lack of adapted instrumentation capable of performing combined EELS and CL, as well as theoretical developments allowing to account for the generic difference between EELS and CL and their optical counterparts impeached a comprehensive understanding of plasmons physics with the otherwise amazing electron spectroscopies. In this talk, I will present recent experimental results showing combined EELS and CL spectral mapping of plasmonic properties for nanoparticles with several shapes (triangles [3], cubes, stars) and composition (gold, silver, aluminum). Helped with different theoretical tools [3,4], I will try to show how these results can be related to their optical counterparts (extinction, scattering), and what type of physical insights can be gained from these combined measurements. Finally, if time allows, pointing the weaknesses of state-of-the-art CL and EELS (in terms of spectral range and/or spectral resolution), I will present EELS results obtained on highly monochromated electron beams that could cope with these limitations. [1] N. Yamamoto, K. Araya, and F. Garca de Abajo, Phys. Rev. B 64, (2001). [2] F. Garca de Abajo and M. Kociak, Phys. Rev. Lett. 100, (2008). [3] A. Losquin, L. F. Zagonel, V. Myroshnychenko, B. Rodriguez-Gonzalez, M. Tenc, L. Scarabelli, J. Frstner, L. M. Liz-Marzn, F. J. G. de Abajo, O. Stphan, and M. Kociak, Nano Lett. 15, 1229 (2015). [4] A. Losquin and M. Kociak, ACS Photonics 2, 1619 (2015).

**5:30PM V31.00010 GaAs/InAs quantum dot exciton and trion excitation via nearby plasmonic waveguides**, MATT SEATON, YANWEN WU, USC Columbia, DAN GAMMON, ALLAN BRACKER, NRL, WU OPTICS GROUP TEAM, NRL TEAM — An open area of research in quantum plasmonics is the detailed characterization of the interaction between plasmonic structures and single quantum emitters. We observe the indirect excitation of excitons and trions in MBE grown GaAs/InAs quantum dots embedded in a Schottky structure by nearby plasmons. The samples, grown on heavily doped N-type GaAs, were coated with a thin Cr layer to provide an electrical gate, through which we observe the photoluminescence spectrum of the different exciton charge states. Through spatially resolved photoluminescence spectroscopy, we verify the QD signature by laser pumping of surface plasmons in Ag thin film plasmonic waveguides near the dots. The waveguides were lithographically defined and embedded in the QD layer of the substrate via wet chemical etching and thermal vapor deposition. The characteristic PL spectra of the dots were collected and observed a large distance away from the excitation point, on the order of ten microns.

**2:30PM V32.00001 Kinetics, mechanisms and products of reactions of Criegee intermediates.**<sup>1</sup>, ANDREW ORR-EWING, University of Bristol — The atmospheric ozonolysis of alkenes such as isoprene produces Criegee intermediates which are increasingly recognized as important contributors to oxidation chemistry in the Earth's troposphere. Stabilized Criegee intermediates are conveniently produced in the laboratory by ultraviolet photolysis of diiodoalkanes in the presence of O<sub>2</sub>, and can be detected by absorption spectroscopy using their strong electronic bands in the near ultraviolet region. We have used these techniques to study a wide range of reactions of Criegee intermediates, including their self-reactions, and reactions with carboxylic acids and various other trace atmospheric constituents. In collaboration with the Sandia National Laboratory group led by Drs C.A. Taatjes and D.L. Osborn, we have used photoionization and mass spectrometry methods, combined with electronic structure calculations, to characterize the products of several of these reactions. Our laboratory studies determine rate coefficients for the Criegee intermediate reactions, many of which prove to be fast. In the case of reactions with carboxylic acids, a correlation between the dipole moments of the reactants and the reaction rate coefficients suggests a dipole-capture controlled reaction and allows us to propose a structure-activity relationship to predict the rates of related processes. The contributions of these various Criegee intermediate reactions to the chemistry of the troposphere have been assessed using the STOCHEM-CRI global atmospheric chemistry model.

**3:06PM V32.00002 Direct Measurement of the Unimolecular Decay Rate of Criegee Intermediates to OH Products.**<sup>1</sup>, FANG LIU, YI FANG, University of Pennsylvania, STEPHEN KLIPPENSTEIN, Argonne National Laboratory, ANNE MCCOY, University of Washington Seattle, MARSHA LESTER, University of Pennsylvania — Ozonolysis of alkenes is an important non-photolytic source of OH radicals in the troposphere. The production of OH radicals proceeds through formation and unimolecular decay of Criegee intermediates such as syn-CH<sub>3</sub>CHOO and (CH<sub>3</sub>)<sub>2</sub>CCOO. These alkyl-substituted Criegee intermediates can undergo a 1,4-H transfer reaction to form an energized vinyl hydroperoxide species, which breaks apart to OH and vinoxy products. Recently, this laboratory used IR excitation in the C-H stretch overtone region to initiate the unimolecular decay of syn-CH<sub>3</sub>CHOO and (CH<sub>3</sub>)<sub>2</sub>CCOO Criegee intermediates, leading to OH formation. Here, direct time-domain measurements are performed to observe the rate of appearance of OH products under collision-free conditions utilizing UV laser-induced fluorescence for detection. The experimental rates are in excellent agreement with statistical RRKM calculations using barrier heights predicted from high-level electronic structure calculations. Accurate determination of the rates and barrier heights for unimolecular decay of Criegee intermediates is essential for modeling the kinetics of alkene ozonolysis reactions, a significant OH radical source in atmospheric chemistry, as well as the steady-state concentration of Criegee intermediates in the atmosphere.

**3:18PM V32.00003 Probing neutral atmospheric collision complexes with anion photoelectron imaging.**<sup>1</sup>, CAROLINE JARROLD, None — Photodetachment of anionic precursors of neutral collision complexes offers a way to probe the effects of symmetry-breaking collision events on the electronic structure of normally transparent molecules. We have measured the anion photoelectron imaging (PEI) spectra of a series of O<sub>2</sub><sup>-</sup> · X complexes, where X is a volatile organic molecule with atmospheric relevance, to determine how the electronic properties of various X molecules affect the low-lying electronic structure of neutral O<sub>2</sub> undergoing O<sub>2</sub> – X collisions. The study was motivated by the catalog of vibrational and electronic absorption lines induced by O<sub>2</sub>–O<sub>2</sub>, O<sub>2</sub>–N<sub>2</sub>, and other collisions. The energies of electronic features observed in the anion PEI spectra of O<sub>2</sub><sup>-</sup> · X (X = hexane, hexene, isoprene and benzene) relative to O<sub>2</sub><sup>-</sup> PEI spectroscopic features indicate that photodetachment of the anion does indeed access a repulsive part of the O<sub>2</sub> – X potential. In addition, the spectra of the various complexes show an interesting variation in the intensities of transitions to the excited O<sub>2</sub>(<sup>1</sup>Δ<sub>g</sub>) · X and O<sub>2</sub>(<sup>1</sup>Σ<sub>g</sub><sup>+</sup>) · X states relative to the ground O<sub>2</sub>(<sup>3</sup>Σ<sub>g</sub><sup>-</sup>) · X state. With X = non-polar species such as hexane, the relative intensities of transitions to the triplet and singlet states of O<sub>2</sub> · X are very similar to those of isolated O<sub>2</sub>, while the relative intensity of the singlet band decreases and becomes lower in energy relative to the triplet band for X = polar molecules. A significant enhancement in the intensities of the singlet bands is observed for complexes with X = isoprene and benzene, both of which have low-lying triplet states. The role of the triplet states in isoprene and benzene, and the implications for induced electronic absorption in O<sub>2</sub> undergoing collisions with these molecules, are explored.

**3:54PM V32.00004 Photoelectron Spectroscopy of Transition Metal Hydride Cluster Anions and Their Roles in Hydrogenation Reactions**, XINXING ZHANG, KIT BOWEN, Johns Hopkins University — The interaction between transition metals and hydrogen has been an intriguing research topic for such applications as hydrogen storage and catalysis of hydrogenation and dehydrogenation. Special bonding features between TM and hydrogen are interesting not only because they are scarcely reported but also because they could help to discover and understand the nature of chemical bonding. Very recently, we discovered a PtZnH<sub>5</sub><sup>-</sup> cluster which possessed an unprecedented planar pentagonal coordination between the H<sub>5</sub><sup>-</sup> moiety and Pt, and exhibited special σ-aromaticity. The H<sub>5</sub><sup>-</sup> kernel as a whole can be viewed as a η<sup>5</sup>-H<sub>5</sub> ligand for Pt. As the second example, an H<sub>2</sub> molecule was found to act as a ligand in the PdH<sub>3</sub><sup>-</sup> cluster, in which two H atoms form a η<sup>2</sup>-H<sub>2</sub> type of ligation to Pd. These transition metal hydride clusters were considered to be good hydrogen sources for hydrogenation. The reactions between Pth<sub>n</sub><sup>-</sup> and CO<sub>2</sub> were investigated. We observed formate in the final product H<sub>2</sub>Pt(HCO<sub>2</sub>)<sup>-</sup>.

**4:06PM V32.00005 Total Cross Section Measurements and Velocity Distributions of Hyper-thermal Charge Transfer in  $\text{Xe}^{2+} + \text{N}_2^1$** , MICHAEL HAUSE, Boston College Institute of Scientific Research, BENJAMIN PRINCE, RAYMOND BEMISH, Air Force Research Laboratory — Guided-ion beam measurements of the charge exchange (CEX) cross section for  $\text{Xe}^{2+} + \text{N}_2$  are reported for collision energies ranging from 0.3 to 100 eV in the center-of-mass frame. Measured total XS decrease from  $69.5 \pm 0.3$  Angstroms<sup>2</sup> (Angs.) at the lowest collision energies to 40 Angs.<sup>2</sup> at 100 eV. The product  $\text{N}_2^+$  CEX cross section is similar to the total CEX cross section while those of the dissociative product,  $\text{N}^+$ , are less than 1Angs.<sup>2</sup> for collision energies above 9 eV. The product  $\text{N}_2^+$  CEX cross section measured here are much larger than the total optical emission-excitation cross sections for the  $\text{N}_2^+$  (*A*) and (*B*) state products determined previously in the chemiluminescence study of Prince and Chiu suggesting that most of the  $\text{N}_2^+$  products are in the *X* state. Time-of-flight (TOF) spectra of both the  $\text{Xe}^+$  and  $\text{N}_2^+$  products suggest two different CEX product channels. The first leaves highly-vibrationally excited  $\text{N}_2^+$  products with forward scattered  $\text{Xe}^+$  (LAB frame) and releases between 0.35 to 0.6 eV translational energy for collisions below 17.6 eV. The second component decreases with collisional energy and leaves backscattered  $\text{Xe}^+$  and low-vibrational states of  $\text{N}_2^+$ . At collision energies above 17.6 eV, only charge exchange involving minimal momentum exchange remains in the TOF spectra.

**4:18PM V32.00006 Aerosol droplets: Nucleation dynamics and photokinetics<sup>1</sup>**, RUTH SIGNORELL, Laboratory of Physical Chemistry, ETH Zurich — This talk addresses two fundamental aerosol processes that play a pivotal role in atmospheric processes: The formation dynamics of aerosol particles from neutral gas phase precursors and photochemical reactions in small aerosol droplets induced by ultraviolet and visible light. Nucleation is the rate determining step of aerosol particle formation. The idea behind nucleation is that supersaturation of a gas leads to the formation of a critical cluster, which quickly grows into larger aerosol particles. We discuss an experiment for studying the size and chemical composition of critical clusters at the molecular level. Much of the chemistry happening in planetary atmospheres is driven by sunlight. Photochemical reactions in small aerosol particles play a peculiar role in this context. Sunlight is strongly focused inside these particles which leads to a natural increase in the rates of photochemical reactions in small particles compared with the bulk. This ubiquitous phenomenon has been recognised but so far escaped direct observation and quantification. The development of a new experimental setup has finally made it possible to directly observe this nanofocusing effect in droplet photokinetics.

**4:54PM V32.00007 Single Scattering Albedo of fresh biomass burning aerosols measured using cavity ring down spectroscopy and nephelometry<sup>1</sup>**, SOLOMON BILILIGN, SUJEETA SINGH, MARC FIDDLER, NCAT State University, DAMON SMITH, High Point University, BILILIGN RESEARCH GROUP TEAM — An accurate measurement of optical properties of aerosols is critical for quantifying the effect of aerosols on climate. Uncertainties still persist and measurement results vary significantly. The factors that affect measurement accuracy and the resulting uncertainties of the extinction-minus-scattering method are evaluated using a combination of cavity ring-down spectroscopy (CRDS) and integrating nephelometry and applied to measure the optical properties of fresh soot (size 300 and 400 nm) produced from burning of pine, red oak and cedar. We have demonstrated a system that allows measurement of optical properties at a wide range of wavelengths, which can be extended over most of the solar spectrum to determine “featured” absorption cross sections as a function of wavelength. SSA values measured were nearly flat ranging from 0.45 to 0.6. The result also demonstrates that SSA of fresh soot is nearly independent of wavelength of light in the 500-680 wavelength range with a slight increase at longer wavelength. The values are within the range of measured values both in the laboratory and in field studies for fresh soot

**5:06PM V32.00008 Catching Conical Intersections in the Act; Monitoring Transient Electronic Coherences by Attosecond Stimulated X-Ray Raman Signals<sup>1</sup>**, KOCHISE BENNETT, MARKUS KOWALEWSKI, KONSTANTIN DORFMAN, SHAUL MUKAMEL, University of California, Irvine — Conical intersections (CIs) dominate the pathways and outcomes of virtually all photochemical molecular processes. Despite extensive experimental and theoretical effort, CIs have not been directly observed yet and the experimental evidence is inferred from fast reaction rates and vibrational signatures. We show that short X-ray pulses can directly detect the passage through a CI with the adequate temporal and spectral sensitivity. The non-adiabatic coupling that exists in the region of a CI redistributes electronic population but also generates electronic coherence. This coherent oscillation can then be detected via a coherent Raman process that employs a composite femtosecond/attosecond X-ray pulse. This technique, dubbed Transient Redistribution of Ultrafast Electronic Coherences (TRUECARS) is reminiscent of Coherent Anti-Stokes Raman Spectroscopy (CARS) in that a coherent oscillation is set in motion and then monitored, but differs in that the dynamics is electronic (CARS generally observes nuclear dynamics) and the coherence is generated internally by passage through a region of non-adiabatic coupling rather than by an externally applied laser.

**Session V33 DPOLY: Block Copolymer Thin Films: Directed Self-Assembly** 336 - Gila Stein, University of Houston

**2:30PM V33.00001 Log-rolling block copolymers cylinders**, SO YOUN KIM, YE CHAN KIM, DONG HYUP KIM, NA KYUNG KWON, Ulsan National Institute of Science and Technology, RICHARD A. REGISTER, Princeton University — Shear has been the most effective method to create long range order of micro- or nano- structures in soft materials. When shear is applied, soft particles or polymers tend to align along the shear direction to minimize the viscous dissipation, thus transverse (so-called log-rolling) alignment is unfavored. In this study, for the first time we report the transverse alignment of cylinder-forming block copolymers. Poly(styrene-*b*-methyl methacrylate), PS-PMMA, can form a metastable hemicylinder structure when confined in a thin film, and this hemicylinder structure can align either along the shear direction, or transverse to the shear direction (log-rolling), depending on the shearing temperature. This unusual log-rolling behavior is explained by the different chain mobility of the two blocks in PS-PMMA; the rigidity of core cylinder is the critical parameter determining the direction of shear alignment.

**2:42PM V33.00002 Laser Zone Annealing - Accelerated Route to Self-Assembled Nanostructures<sup>1</sup>**, PAWEL MAJEWSKI, KEVIN YAGER, ATIKUR RAHMAN, CHARLES BLACK, Brookhaven National Laboratory — We present Laser Zone Annealing – a novel technique of accelerated self-assembly of block copolymer thin films utilizing laser light. In our approach, the laser beam, focused to a narrow line, is rastered across the polymer film coated on the light-absorbing substrate, inducing rapid and highly localized temperature transients in the film. By coupling our method with soft-shear, we demonstrate monolithic alignment of various cylinder-forming block copolymers over extremely short timescales. We utilize the aligned block copolymer films as templates for inorganic nanomaterials patterning. After delivery of inorganic precursors via aqueous or gaseous route, the polymer matrix is ashed leading to extremely well-ordered arrays of inorganic, metallic or semiconducting nanowires. Subsequently, we demonstrate how more complex nanostructures can be created with LZA including multilayered nanomeshes with symmetries beyond the conventional motifs accessible by native block copolymers. We investigate a perspective use of the inorganic arrays as transparent conductors or chemical sensors and characterize their anisotropic electro-optical properties.

**2:54PM V33.00003 Block Copolymer Directed Self-Assembly Approaches for Doping Planar and Non-Planar Semiconductors.**, BHOOSHAN POPERE, Univ of California - Santa Barbara, BORIS RUSS, Univ of California - Berkeley, ANDREW HEITSCH, The Dow Chemical Company, PETER TREFONAS, Dow Electronic Materials, RACHEL SEGALMAN, Univ of California - Santa Barbara — As electronic circuits continue to shrink, reliable nanoscale doping of functional devices presents new challenges. While directed self-assembly (DSA) of block copolymers (BCPs) has enabled excellent pitch control for lithography, controlling the 3D dopant distribution remains a fundamental challenge. To this end, we have developed a BCP self-assembly approach to confine dopants to nanoscopic domains within a semiconductor. This relies on the supramolecular encapsulation of the dopants within the core of the block copolymer (PS-*b*-P4VP) micelles, self-assembly of these micelles on the substrate, followed by rapid thermal diffusion of the dopants into the underlying substrate. We show that the periodic nature of the BCP domains enables precise control over the dosage and spatial position of dopant atoms on the technologically relevant length scales (10-100 nm). Additionally, as the lateral density of 2D circuit elements approaches the Moore's limit, novel 3D architectures have emerged. We have utilized our BCP self-assembly approach towards understanding the self-assembly of our micelles directed by such nanoscale non-planar features. We show that the geometric confinement imposed by the hard feature walls directs the assembly of these micelles.

**3:06PM V33.00004 Directed Nanoscale Assembly of Graphene Based Materials**, SANG OUK KIM, National Creative Research Initiative Center for Multi-Dimensional Directed Nanoscale Assembly, Department of Materials Science & Engineering, KAIST — Graphene based materials, including fullerene, carbon nanotubes and graphene, are two-dimensional polymeric materials consisting of sp<sup>2</sup> hybrid carbons. Those carbon materials have attracted enormous research attention for their outstanding material properties along with molecular scale dimension. The optimized utilization of those materials in various application fields inevitably requires the subtle controllability of their structures and properties. In this presentation, our research achievements associated to directed nanoscale assembly of B- or N-doped graphene based materials will be introduced. Graphene based materials can be efficiently processed into various three-dimensional structures via self-assembly principles. Those carbon assembled structures with extremely large surface and high electro-conductivity are potentially useful for energy and environmental applications. Aqueous dispersion of graphene oxide shows liquid crystalline phase, whose spontaneous molecular ordering is useful for display or fiber spinning. Along with the structure control by directed nanoscale assembly, substitutional doping of graphene based materials with B- or N- can be attained via various chemical treatment methods. The resultant chemically modified carbon materials with tunable workfunction, charge carrier density and enhanced surface activity could be employed for various nanomaterials and nanodevices for improved functionalities and performances.

**3:42PM V33.00005 Direct Immersion Solvent Annealing of Nano-filled Block Copolymer Films**, MELANIE LONGANECKER, ARVIND MODI, Univ of Akron, GUANGCUI YUAN, SUSHIL SATIJA, National Institute of Standards and Technology, JOONA BANG, Korea University, ALAMGIR KARIM, Univ of Akron, UNIVERSITY OF AKRON TEAM, NATIONAL INSTITUTE OF TECHNOLOGY COLLABORATION, KOREA UNIVERSITY COLLABORATION — The addition of nanoparticles to polymer films is a strategic approach to enhance film properties such as optical, thermal, hardness, conductivity, permeability etc. with inorganic components while maintaining an easily processable polymer matrix. To this end, the “annealing” of block copolymers while immersed directly in a chamber of solvent is examined to determine its efficacy in ordering nano-filled block copolymer films. Previously we have shown that it is possible to order neat block copolymer films in a mixture of solvents, and this research follows up that work. Specifically, we observe and utilize the effects of direct immersion solvent annealing (DIA) on lamellar poly(styrene-*b*-methyl methacrylate) thin films with loadings of gold nanoparticles as high as 25 percent by mass. Neutron reflection confirms that DIA is a viable technique applicable to ordering these highly loaded, nano-filled block copolymer systems. Some notable differences exist with respect to results on conservation of domain spacing that may be beneficial to film barrier properties, accomplished with minimal disruption of order and fast kinetics that is compatible with roll-to-roll techniques.

**3:54PM V33.00006 Effects of ultra-fast solvent evaporation in solvent vapor annealed cylinder-forming block polymer thin films**, A. BARUTH, G. NELSON, C. DRAPES, J. WONG, M. GRANT, Creighton Univ, Omaha, NE — Despite continued advances in directed self-assembly of block polymer thin films via solvent vapor annealing, a standardized process remains absent. There remain several complicating factors, notably solvent evaporation rate. Recent theoretical models point to this rate dominating the propagation of a given morphology into the bulk of a thin film following nucleation from the free surface. During this drying process, the film undergoes a competition between thermodynamically driven phase separation and kinetically controlled chain mobility. We, among others, have demonstrated that faster solvent removal can enhance propagation down to the substrate. Perpendicularly aligned cylinders are one illustrative example. To further quantify this effect, and look at ultra-fast time scales, we have constructed a solvent vapor annealing chamber that computer-controls evaporation times down to 15 ms. *In situ* spectral reflectance, with 10 ms temporal resolution, monitors the swelling and evaporation. We will present results on cylinder-forming polystyrene-*block*-polylactide thin films swollen to near disorder with tetrahydrofuran, followed by immediate solvent evaporation. Our data reveals control over evaporation times, ranging from 15 ms to several seconds, and the discovery of various evaporation types, previously undetected, including linear, exponential and combinations. Furthermore, atomic force micrographs correlate surface morphologies (both free and substrate) of the resultant films with each evaporation condition. Funded by Nebraska EPSCoR.

**4:06PM V33.00007 Fabrication of nanoporous block copolymer films using highly selective solvents and non-solvent extraction**, CHANGHUI YE, BRYAN VOGT, The University of Akron — Nanoporous polymeric films with high porosity are necessary for some applications, such as anti-reflective coating. A simple and relatively environmental benign method is developed to fabricate nanoporous block copolymer thin film with tunable porosity up to 69% based on selective solvent swelling of the majority phase and subsequent rapid extraction with a miscible non-solvent (water). Poly(butylnorbornene)-*block*-poly(hydroxyhexafluoroisopropyl norbornene) (BuHFA) is used to generate these porous thin films due to its high T<sub>g</sub> (>300 °C) and the selectivity of primary alcohols towards HFA. The porosity of these nanoporous films is highly dependent on the solvent quality for HFA. The modulus of the as-prepared nanoporous BuHFA thin films with the porosity from 0% to 69% was investigated by surface wrinkling and a scaling law of modulus versus density was obtained. These nanoporous thin films act as anti-reflective coatings and an increase in transmittance from approximately 92% to 99.1% (average for the full range of visible light) was obtained for double-side coated glass slides. This methodology is simple and highly tunable; extension to other block copolymer systems is likely possible if sufficient solubility contrast between segments exists.

**4:18PM V33.00008 Tracking Solvent Distribution in Block Polymer Thin Films with In Situ Solvent Vapor Annealing during Neutron Scattering**, CAMERON SHELTON, University of Delaware, RONALD JONES, JOSEPH DURA, National Institute of Standards and Technology, THOMAS EPPS, University of Delaware — Solvent vapor annealing (SVA) is a potential route to controlling the self-assembly of block polymer nanostructures in thin film geometries as it harnesses the ability to tune substrate surface, free surface, and polymer-polymer interactions simultaneously. However, the effect of parameters such as solvent preference and solvent partial pressure on nanostructure self-assembly is still poorly understood. Herein, we quantified the degree of preferential segregation of d-benzene into polystyrene domains of cylinder-forming poly(styrene-*b*-isoprene-*b*-styrene) as a function of film thickness and solvent partial pressure. Additionally, measurable changes in lateral domain spacing, vertical layer spacing, film thickness, and the number of stacked domains at set partial pressures were used to determine how solvent-polymer interactions affected nanostructure reorganization. These in situ experiments were conducted with a combination of small-angle neutron scattering (SANS) and neutron reflectivity (NR), which allowed us to obtain a 3-D profile of solvent distribution and nanostructure self-assembly. By studying the underlying solvent-polymer interactions, this work provides an improved understanding of the mechanisms responsible for nanostructure reorganization during SVA.

**4:30PM V33.00009 Continuous and patterned deposition of functional block copolymer thin films using electrospray**, KRISTOF TOTH, HANQIONG HU, Yale University, MYUNGWOONG KIM, Inha University, PADMA GOPALAN, University of Wisconsin, MICHAEL LOEWENBERG, CHINEDUM OSUJI, Yale University — The delivery of sub-micron droplets of dilute polymer solutions to a heated substrate by electrospray deposition (ESD) enables precisely controlled and continuous growth of block copolymer (BCP) thin films. The ESD process overcomes many shortcomings of spin coating deposition, including the batch nature of the process, loss of potentially valuable polymer, limitations of solvent choice, and large time scales of annealing. We report that high substrate temperatures led to vertically oriented cylindrical microdomains of poly(styrene-*b*-methyl methacrylate) (PS-*b*-PMMA) at the film surface independent of the solvent composition and deposition rates utilized. Conversely, low substrate temperatures resulted in morphologies that were more sensitive to these parameters, with poorly ordered films of globular structures. We also report on the new possibility for patterned deposition of BCP films by spatially varying the electric field at the substrate using an underlying charged grid. To overcome surface charging, a novel alternating current electrospray process is proposed for deposition on non-conductive surfaces.

**4:42PM V33.00010 Formation of Lamellar Heterolattices in Block Copolymer Thin Films by Sequential Electrospray Deposition**<sup>1</sup>, YOUNGWOONG CHOO, HANQIONG HU, KRISTOF TOTH, CHINEDUM OSUJI, Yale University — Electrospray deposition (ESD) of block copolymers (BCPs) on a heated substrate provides precise control over the formation of BCP thin films. This continuous deposition process allows one to fabricate heterogeneously assembled thin films by altering the deposition materials. Here, we demonstrate such the sequential ESD of lamellae-forming poly(styrene-*b*-4-vinylpyridine) BCPs with differing molecular weights and explore the morphology of the composite films. The resulting structure of the heterolattice interface was a strong function of temperature. Sharp interfaces with abrupt changes in the lamellar period ( $L_0$ ) were observed at lower deposition temperatures (150 - 170 °C), while higher temperature (190 °C) produced a smooth variation in the lamellar period from one molecular weight to the next. Furthermore, the ordering kinetics of a secondary layer which was deposited onto the primary layer could be substantially enhanced depending on the molecular weight of the polymer present in the underlying primary layer. We elucidate these findings in the context of temperature and molecular weight dependent diffusion dynamics of the polymers in the melt which control the inter-mixing of the layers.

**4:54PM V33.00011 Hierarchical assembled nanostructures of hydrogen-bonded supramolecular block copolymer thin films.**<sup>1</sup>, XIAOFANG CHEN, YONGCHEN CAI, Soochow University — Controlling the microdomain orientation and long-range ordering in block copolymer thin films is very important in a number of applications, such as nanotemplate, nanoporous thin film, and data storage media. The hierarchical assemblies of block copolymers PS-*b*-P4VP with dendronized small molecules (DM) hydrogen-bonded onto P4VP blocks were investigated in thin films after solvent vapor annealing. P4VP/DM could form lamellar or hexagonal columnar structure with the periodicity around 8 nm, depending on the stoichiometry of the complex. Hierarchical assemblies of PS-*b*-P4VP(DM)<sub>x</sub>, including lamellae-within-lamellae, cylinder-within-lamellae, and cylinder-within-cylinder, were simultaneously ordered and oriented in thin films, which have been studied systematically with the help of AFM, TEM and GISAXS technologies. The orientation of supramolecular assembly depends on the P4VP(DM) fraction and can be tailored by varying the DM to P4VP ratio. Structural transitions from cylinders of (P4VP/DM), lamellae, to cylinders of PS could be achieved by simply increasing the ratio of DM to 4VP units in block copolymer systems.

**5:06PM V33.00012 Azobenzene photoswitching as a tool for controlling block copolymer self-assembly in dip-coated thin films**, JAANA VAPAAVUORI, JOSU GROSRENAUD, KATERYNA BOROZENKO, CHRISTIAN PELLERIN, GERALDINE BAZUIN, University of Montreal, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF MONTREAL TEAM — Understanding how to control the characteristics of microphase-separated block copolymer thin films is of crucial importance for developing nanotechnological applications, such as producing nanoscale lithography templates for the electronics industry. The supramolecular complexation of small molecules selectively to one of the blocks in suitable block copolymers enables modulating the block volume fractions and thereby controlling the type of surface morphology obtained in thin films. In this contribution, we show that the morphology of dip-coated polystyrene-*b*-poly(4-vinylpyridine) polymer films containing a hydrogen-bonding azobenzene guest can be further controlled using light as an external in situ stimulus during the dip-coating procedure. A change from spherical to cylindrical morphology was demonstrated when the geometry of the azobenzene units was switched by illumination at 365 nm. Film thickness measurements revealed that the thickness of the films can also be tailored by light, since films prepared under irradiation are significantly thicker than non-irradiated ones. The photochemical requirements to guide the choice of azobenzene molecule and the nature of the solvent used will be discussed in view of an optimal material combination for easily directable systems.

**5:18PM V33.00013 Crystallization induced block copolymer assembly at curved liquid-liquid interface**, HAO QI, TIAN ZHOU, HAO ZHOU, CHRISTOPHER LI, Drexel University, SOFT MATERIALS LAB TEAM — In a selected solvent, amphiphilic block copolymers can self-assemble into various micelle structures which find widespread applications in nanomedicine. Herein we report a directed assembly of poly(L-lactide acid)-*b*-poly(ethylene glycol) (PLLA-*b*-PEG) at curved oil/water interfaces. Oil droplets were dispersed in water phase upon sonication with amphiphilic PLLA-*b*-PEG as the surfactant. Subsequent crystallization of PLLA segments resulted in the formation of lamellosomes consisting of crystalline PLLA shell and densely-grafted (approx. 1 chain/nm<sup>2</sup>) PEG layer. The structure, morphology, and mechanical properties of these unique polymer ensembles were investigated using transmission electron microscopy and atomic force microscopy. Detailed formation mechanism will be discussed in detail.

**2:30PM V34.00001 What drives hydrophobic polymer collapse and re-entry transitions in miscible good solvents?**<sup>1</sup> , FRANCISCO RODRIGUEZ ROPERO, TIMIR HAJARI, NICO F. A. VAN DER VEGT, Tech Univ Darmstadt — Herein, we study co-nonsolvency of poly(*N*-isopropylacrylamide) (PNiPAM) in methanol aqueous solutions. Our results show that both the coil-to-globule transition at low methanol concentrations and the globule-to-coil re-entrance at high methanol concentrations are entropy driven. At low alcohol content, methanol preferentially binds to the PNiPAM globule and drives polymer collapse. Rather than being driven by electrostatic, hydrogen bonding or bridging-type interactions with the globule, preferential methanol binding is found to result from a significant increase of the chain configurational entropy, stabilizing methanol-enriched globular structures over wet globular structures in neat water. The globule-to-coil re-entrance at high methanol concentrations is instead driven by changes in solvent-excluded volume of the coil and globular states imparted by a decrease in solvent density with increasing methanol content of the solution. The co-nonsolvency mechanism proposed in this contribution provides a new angle on how to develop Coarse Grained simulation models for responsive soft matter systems. Moreover, several of the solvation effects described in this contribution can be incorporated in theories for cosolvent-induced conformational transitions in dilute polymer solutions.

<sup>1</sup>This research was supported by the German Research Foundation (DFG) within the Collaborative Research Center "Multiscale Simulation Methods for Soft Matter Systems" (SFB-TRR146).

**2:42PM V34.00002 Co-non-solvency: Depletion forces or preferential adsorption?** , CARLOS MARQUES, Institut Charles Sadron, CNRS, TIAGO OLIVEIRA, PAULO NETZ, Universidade Federal do Rio Grande do Sul, Brazil, TORSTEN STUEHN, DEBASHISH MUKHERJI, KURT KREMER, Max-Planck-Institute for Polymer Research, Germany — Co-non-solvency is a phenomenon that occurs when a polymer is added to a mixture of two (perfectly) miscible and competing good solvents. As a result, the same polymer collapses into a globule within intermediate mixing ratios. More interestingly, polymer collapses despite the fact that the solvent quality remains good or even gets increasingly better by the addition of the better cosolvent [1]. This puzzling phenomenon, where the solvent quality is completely decoupled from the polymer conformation, is driven by strong local preferential adsorption of the better cosolvent to the polymer [1,2,3]. Because a polymer collapses in good solvent, the depletion forces, that are responsible for standard poor solvent collapse, do not play any role in describing co-non-solvency [4]. [1] D. Mukherji and K. Kremer, *Macromolecules* (2013). [2] D. Mukherji, C. M. Marques, and K. Kremer, *Nature Communications* (2014). [3] D. Mukherji, C. M. Marques, T. Stuehn and K. Kremer, *Journal of Chemical Physics* (2015). [4] T. E. de Oliveira, P. A. Netz, D. Mukherji, and K. Kremer, *Soft Matter* (2015).

**2:54PM V34.00003 Depleting depletion: Polymer swelling in poor solvent mixtures** , DEBASHISH MUKHERJI, Max-Planck-Institute for Polymer Research, CARLOS MARQUES, Institut Charles Sadron, CNRS, TORSTEN STUEHN, KURT KREMER, Max-Planck-Institute for Polymer Research — A polymer collapses in a solvent when the solvent particles dislike monomers more than the repulsion between monomers. This leads to an effective attraction between monomers, also referred to as depletion induced attraction. This attraction is the key factor behind standard polymer collapse in poor solvents. Strikingly, even if a polymer exhibits poor solvent condition in two different solvents, it can also swell in mixtures of these two poor solvents. This collapse-swelling-collapse scenario is displayed by poly(methyl methacrylate) (PMMA) in aqueous alcohol. Using molecular dynamics simulations of a thermodynamically consistent generic model and theoretical arguments, we unveil the microscopic origin of this phenomenon. Our analysis suggests that a subtle interplay of the bulk solution properties and the local depletion forces reduces depletion effects, thus dictating polymer swelling in poor solvent mixtures.

**3:06PM V34.00004 Effects of dipolar interactions in polymer brushes** , RAJEEV KUMAR, Oak Ridge National Laboratory — Effects of dipolar interactions on structure of polymer brushes are studied using a combination of semi-analytical theory, numerical simulations based on the self-consistent field theory (SCFT) and experiments. In this talk, insights obtained by studying brushes in the presence and absence of various polar solvents will be discussed. Possibility of vertical phase segregation in planar polymer brushes immersed in polar solvents and interpenetration as well as forces between opposing brushes will be discussed.

**3:42PM V34.00005 Molecular dynamics simulations of poly (ethylene oxide) hydration and conformation in solutions.**<sup>1</sup> , UDAYA DAHAL, DDept. of Physics and Inst. of Mat. Sci., Univ of Connecticut, ELENA DORMIDONTOVA, Dept. of Physics and Inst. of Mat. Sci., Univ of Connecticut — Polyethylene oxide (PEO) is one of the most actively used polymers, especially in biomedical applications due to its high hydrophilicity, biocompatibility and potency to inhibit protein adsorption. PEO solubility and conformation in water depends on its capability to form hydrogen bonds. Using atomistic molecular dynamics simulations we investigated the details of water packing around PEO chain and characterized the type and lifetime of hydrogen bonds in aqueous and mixed solvent solutions. The observed polymer chain conformation varies from an extended coil in pure water to collapsed globule in hexane and a helical-like conformation in pure isobutyric acid or isobutyric acid –water mixture in agreement with experimental observations. We'll discuss the implications of protic solvent arrangement and stability of hydrogen bonds on PEO chain conformation and mobility.

**3:54PM V34.00006 A Coarse-Grained Model for Thermoresponsive Poly(*N*-isopropylacrylamide)** , LAUREN J ABBOTT, MARK J STEVENS, Sandia National Laboratories — Poly(*N*-isopropylacrylamide) (PNIPAM) is a thermoresponsive polymer that undergoes a phase transition at its lower critical solution temperature (LCST). Although atomistic simulations have been effective to study PNIPAM single chains in solution, they are limited in reaching longer length- and time-scales. In this work, a coarse-grained (CG) model is developed for PNIPAM that captures its thermoresponsive behavior. Nonbonded parameters are fit to experimental thermodynamic data, with minor adjustments to provide better agreement with radial distribution functions from atomistic simulations. Bonded parameters are fit to probability distributions from atomistic simulations using multi-centered Gaussian-based potentials. The temperature-dependent potentials derived for the CG model in this work properly capture the coil-globule transition of PNIPAM single chains and yield a chain-length dependence consistent with atomistic simulations and experiment. The self-assembly of PNIPAM surfactants is also explored. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**4:06PM V34.00007 A Coarse Grained Model for Methylcellulose: Spontaneous Ring Formation at Elevated Temperature**, WENJUN HUANG, RONALD LARSON, Univ of Michigan - Ann Arbor — Methylcellulose (MC) is widely used as food additives and pharma applications, where its thermo-reversible gelation behavior plays an important role. To date the gelation mechanism is not well understood, and therefore attracts great research interest. In this study, we adopted coarse-grained (CG) molecular dynamics simulations to model the MC chains, including the homopolymers and random copolymers that models commercial METHOCEL A, in an implicit water environment, where each MC monomer modeled with a single bead. The simulations are carried using a LAMMPS program. We parameterized our CG model using the radial distribution functions from atomistic simulations of short MC oligomers, extrapolating the results to long chains. We used dissociation free energy to validate our CG model against the atomistic model. The CG model captured the effects of monomer substitution type and temperature from the atomistic simulations. We applied this CG model to simulate single chains up to 1000 monomers long and obtained persistence lengths that are close to those determined from experiment. We observed the chain collapse transition for random copolymer at 600 monomers long at 50C. The chain collapsed into a stable ring structure with outer diameter around 14nm, which appears to be a precursor to the fibril structure observed in the methylcellulose gel observed by Lodge *et al.* in the recent studies. Our CG model can be extended to other MC derivatives for studying the interaction between these polymers and small molecules, such as hydrophobic drugs.

**4:18PM V34.00008 Modeling helical polymer brushes using self-consistent field theory (SCFT)**<sup>1</sup>, JYOTI MAHALIK, BOBBY SUMPTER, RAJEEV KUMAR, Oak Ridge National Lab — We investigate structure of helical polymer brushes in terms of segment density distribution and local helical ordering using SCFT. A flexible chain model with vector potential was used to model liquid crystalline-like ordering in the brushes. The effects of surface grafting density, polymer molecular weight and the solvent quality on the brush structure were investigated. For densely grafted polymer brushes or the brushes made up of high molecular weight polymers, immersed in good quality solvent, stronger orientational ordering was found near the edge of the brushes (i.e., far from the grafting surface). Furthermore, an increase in the orientational ordering near the grafted end was found with decrease in solvent quality or decrease in molecular weight and decrease in surface grafting density.

**4:30PM V34.00009 The effects of bonded interactions on the structural phase properties of flexible elastic homopolymer**, KAI QI, BENJAMIN LIEWEHR, TOMAS KOCI, BUSARA PATTANASIRI, MATTHEW WILLIAMS, MICHAEL BACHMANN, The Univ of Georgia — By means of advanced parallel-tempering replica-exchange Monte Carlo methods we systematically examine the effects of an asymmetric bond potential between the bonded monomers on the structural formations of an elastic flexible polymer model. Employing microcanonical inflection-point analysis and conformational analysis based on a suitable set of structural order parameters, we identify diverse structural phases in the low-temperature region of the microcanonical hyperphase diagram. In addition to the icosahedral phase occurring if the symmetry of the bonded interaction is broken by strong bonded Lennard-Jones potential, amorphous structures with bihexagonal cores appear for small values of the asymmetry control parameter in the bond potential. Another remarkable feature is the observation of the hierarchy of freezing transitions associated with the formation of the surface layer after nucleation.

**4:42PM V34.00010 Crystal Growth in Lennard-Jones Mixtures: A Model System to Study Generic Effects in Biomineralization Processes**, MARC RADU, KURT KREMER, Max Planck Institute for Polymer Research — In various scientific fields regulating the growth of crystalline structures and tuning their morphologies plays an important role. E.g. in pharmaceutical delivery the crystallization of a supersaturated drug solution is inhibited by the addition of stimuli-responsive polymers. While past simulation studies rather focused on a detailed understanding of the binding modes of specific additives to likewise specific crystal surfaces here we investigate the characteristics of a generic model system in which we modify the growth mechanisms and the emerging shapes of Lennard-Jones crystallites by tuning the specific interaction parameters and/or adding polymer chains - represented by linear bead-spring molecules - to the system. We performed molecular dynamics simulations on samples containing a crystalline phase embedded in a supersaturated solution applying an adaptive simulation scheme in order to keep the chemical potential difference between the solid and the surrounding liquid constant. We report on different crystal properties depending on a systematic variation of simulation parameters as the solvent content, the solubility and the density of polymer chains. We analyze our results by means of various approaches within the framework of non-equilibrium statistical physics.

**4:54PM V34.00011 ABSTRACT WITHDRAWN** —

**5:06PM V34.00012 Thermodynamics of polymer nematics described with a worm-like chain model: particle-based simulations and SCF theory calculations**, CRISTINA GRECO, Max Planck Institute for Polymer Research, Mainz, Germany, YING YIANG, School of Chemistry and Environment, Center of Soft Matter Physics and Its Applications, BeiHang University, Beijing, China, KURT KREMER, Max Planck Institute for Polymer Research, Mainz, Germany, JEFF CHEN, Department of Physics and Astronomy, University of Waterloo, Canada, KOSTAS DAOULAS, Max Planck Institute for Polymer Research, Mainz, Germany — Polymer liquid crystals, apart from traditional applications as high strength materials, are important for new technologies, e.g. Organic Electronics. Their studies often invoke mesoscale models, parameterized to reproduce thermodynamic properties of the real material. Such top-down strategies require advanced simulation techniques, predicting accurately the thermodynamics of mesoscale models as a function of characteristic features and parameters. Here a recently developed model [1] describing nematic polymers as worm-like chains interacting with soft directional potentials is considered. We present a special thermodynamic integration scheme delivering free energies in particle-based Monte Carlo simulations of this model, avoiding thermodynamic singularities. Conformational and structural properties, as well as Helmholtz free energies are reported as a function of interaction strength. They are compared with state-of-art SCF calculations [2] invoking a continuum analog of the same model, demonstrating the role of liquid-packing and fluctuations. [1] P. Gemnden and K.Ch. Daoulas, Soft Matter 2015, 11, 532; [2] Y. Jiang and J.Z.Y. Chen, Macromolecules 2010, 43, 10668.

**5:18PM V34.00013 Molecular Dynamics Modeling of Dielectric Polarization and Ferroelectricity in Poly(vinylidene fluoride) and Related Polymers**<sup>1</sup>, JEFFREY CALAME, Naval Research Laboratory, Washington, DC 20375 — Molecular dynamics studies of the dielectric polarization response of a constrained bond length and bond angle, united-atom-based model of lamellar crystals of poly(vinylidene fluoride) (PVDF) are reported. Classical ferroelectricity is observed in PVDF, and when variations in the basic PVDF-like interaction parameters are allowed, a transition between classical and relaxor ferroelectricity is found to depend systematically on the polymer repeat unit dipole moment and on the united atom radius of the non-CH<sub>2</sub> functional group. The effects of step and ramp electric field reversal are studied. A complicated sequence of reorientation processes occurs over a wide range of time scales, including a weak, temperature-independent response of 1-2 ps duration associated with local torsional motion, followed by a slow-rising delay regime lasting 10s of ns or longer that involves trans-gauche (TG) transitions in the amorphous phase. After the delay, a large-amplitude primary reorientation occurs over a relatively short additional duration (0.1 to 2 ns), which is due to rotation of large sub-segments in the crystalline phase with few TG transitions. The overall sequence concludes with a slow terminal rise lasting several 100s of ns involving an improvement in crystalline order.

**Session V35 DBIO GSOF GSNP: Active Matter: Collective Phenomena in Living Systems V**

338 - Thierry Mora, ENS and CNRS

**2:30PM V35.00001 Questioning the activity of active matter: the case of bird flocks** , THIERRY MORA, ALEKSANDRA WALCZAK, Ecole normale supérieure and CNRS, LORENZO DEL CASTELLO, University of Rome and CNR, FRANCESCO GINELLI, University of Aberdeen, STEFANIA MELILLO, LEONARDO PARISI, MASSIMILIANO VIALE, ANDREA CAVAGNA, IRENE GIARDINA, University of Rome and CNR — Animal flocking is a natural instance of active matter. What makes flocks active is the rearrangement of neighborhoods, which constantly remodels the network of interactions between individuals in the group, keeping the system out of equilibrium. Despite the predicted importance of this reshuffling, its true impact for natural flocks is not well understood. Here we analyse films of flocks of starlings with a novel statistical inference technique based on dynamical maximum entropy to measure the parameters of flock alignment - alignment strength, interaction range, and noise. We show that birds align their flight orientations must faster than they change neighbors. In the statistical mechanics sense, this means that flocks remain adiabatically in equilibrium, allowing for a rigorous analogy with equilibrium systems of interacting spins, and we show that an inference method based on equilibrium assumptions gives fully consistent results.

**2:42PM V35.00002 Linear response to leadership, effective temperature and decision making in flocks.** , DANIEL PEARCE, LUCA GIOMI, Univ of Leiden — The Vicsek model is the prototypical system for studying collective behavior of interacting self propelled particles (SPPs). It has formed the basis for models explaining the collective behavior of many active systems including flocks of birds and swarms of insects. To the standard Vicsek model we introduce a small angular torque to a subset of the particles and observe how this effects the direction of polarisation of the entire swarm. This is analogous to a few informed birds trying to lead the rest of a large flock by initiating a turn. We find a linear response to this perturbation and fluctuations that are in agreement with fluctuation dissipation theorem. This allows the identification of an effective temperature for the Vicsek model that follows a power law with the noise amplitude. The linear response can also be extended to the process of decision-making, wherein flocks must decide between the behaviors of two competing subgroups of individuals.

**2:54PM V35.00003 Fluctuation Spectra Underlie the Behavior of Non-equilibrium Systems** , ALPHA LEE, Harvard University, DOMINIC VELLA, University of Oxford, JOHN WETTLAUFER, Yale University — A diverse set of important physical phenomena, ranging from hydrodynamic turbulence to the collective behaviour of bacteria, are intrinsically far from equilibrium. Despite their ubiquity, there are few general theoretical results that describe these non-equilibrium steady states. Here we argue that a generic signature of non-equilibrium systems is nontrivial fluctuation spectra. Based on this observation, we derive a general relation for the force exerted by a non-equilibrium system on two embedded walls. We find that for a narrow, unimodal spectrum, the force depends solely on the width and the position of the peak in the fluctuation spectrum, and will oscillate between repulsion and attraction. We demonstrate the generality of our framework by examining two apparently disparate examples: the Maritime Casimir effect and recent simulations of active Brownian particles. A key implication of our work is that important non-equilibrium interactions are encoded within the fluctuation spectrum. In this sense the noise becomes the signal.

**3:06PM V35.00004 Visual perturbations and the collective dynamics of fish schools** , JULIA GIANNINI, JAMES PUCKETT, Gettysburg College — We investigate the dynamics of the collective behaviors exhibited in a laboratory fish school. Using an artificial light gradient with varies both spatially and temporally, we investigate the competition between individual locomotion and local polarization arising from social interactions between individuals. We will discuss how our work informs current agent-based models on the interplay between social interactions and heterogeneous environments.

**3:18PM V35.00005 The influence of following on bidirectional flow through a doorway<sup>1</sup>** , AMY GRAVES, RACHEL DIAMOND, EDUARD SAAKASHVILI, Swarthmore College — Pedestrian dynamics is a subset of the study of self-propelled particles. We simulate two species of pedestrians undergoing bidirectional flow through a narrow doorway. Using the Helbing-Monlr-Farkas-Vicsek Social Force Model, our pedestrians are soft discs that experience psychosocial and physical contact forces. We vary the following parameter which determines the degree to which a pedestrian matches its direction of movement to the average of nearby, same-species pedestrians. Current density, efficiency and statistics of bursts and lags are calculated. These indicate that choosing different following parameters for each species affects the efficacy of transport - greater following being associated with lower efficacy. The information entropy associated with velocity and the long time tails of the complementary CDF of lag times are additional indicators of the dynamical consequences of following during bidirectional flow.

**3:30PM V35.00006 Collective dynamics of sperm in viscoelastic fluid<sup>1</sup>** , CHIH-KUAN TUNG, <sup>1,2</sup>, BENEDICT B. HARVEY, <sup>2</sup>, ALYSSA G. FIORE, <sup>1</sup>, FLORENCIA ARDON, SUSAN S. SUAREZ, <sup>2</sup>, MINGMING WU, Depts of <sup>1</sup>Biological and Environmental Engineering; <sup>2</sup>Biomedical Sciences, Cornell University — Collective dynamics in biology is an interesting subject for physicists, in part because of its close relations to emergent behaviors in condensed matter, such as phase separation and criticality. However, the emergence of order is often less drastic in systems composed of the living cells, sometimes due to the natural variability among individual organisms. Here, using bull sperm as a model system, we demonstrate that the cells migrate collectively in viscoelastic fluids, exhibiting behavior similar to flocking. This collectiveness is greatly reduced in similarly viscous Newtonian fluids, suggesting that the cell-cell interaction is primarily a result of the elastic property or the memory effect of the fluids, instead of pure hydrodynamic interactions. Unlike bacterial swarming, this collectiveness does not require a change in phenotype of the cells; therefore, it is a better model system for physicists.

**3:42PM V35.00007 To be decided by speaker** , MADAN RAO, National Centre for Biological Sciences(TIFR) — No abstract available.

**4:18PM V35.00008 Critical phenomena in active matter<sup>1</sup>**, MATTEO PAOLUZZI, M CRISTINA MARCHETTI, Syracuse Univ, CLAUDIO MAGGI COLLABORATION, UMBERTO MARINI BETTOLO MARCONI COLLABORATION, NICOLETTA GNAN COLLABORATION — A collection of active agents can organize in phases with structural properties remarkably similar to those of ordinary materials, such as active gases, liquids and glasses. These phases are formed, however, out of equilibrium, where the machinery of equilibrium statistical mechanics cannot be applied. It has recently been shown that models of particles with Gaussian colored noise can capture some of the nonequilibrium behavior of active Brownian particles, including motility-induced phase separation. By using the Unified Gaussian Colored Noise Approximation (UCNA) it has been possible to obtain an equilibrium-like probability distribution function and an effective free energy for active Brownian particles. Here we employ UCNA to examine the effect of colored noise on mean-field order-disorder transitions. Starting with a  $\varphi^4$  Landau model that undergoes a second-order phase transition as a function of a tuning parameter, we calculate the shift in transition due to colored noise as a function of the noise amplitude and correlation time  $\tau$ . We find that the transition line exhibits reentrance as a function of  $\tau$ . The mean-field theoretical predictions are compared with Molecular Dynamics simulations of active Lennard-Jones particles.

**4:30PM V35.00009 Long-range Acoustic Interactions in Insect Swarms: An Adaptive Gravity Model**, DAN GORBONOS, REUVEN IANCONESCU, Department of Chemical Physics, The Weizmann Institute of Science, JAMES G. PUCKETT, Department of Physics, Gettysburg College, RUI NI, Department of Mechanical and Nuclear Engineering, The Pennsylvania State University, NICHOLAS T. OUELLETTE, Department of Civil and Environmental Engineering, Stanford University, NIR S. GOV, Department of Chemical Physics, The Weizmann Institute of Science — The collective motion of groups of animals emerges from the net effect of the interactions between individual members of the group. In many cases, such as birds, fish, or ungulates, these interactions are mediated by sensory stimuli that predominantly arise from nearby neighbors. But not all stimuli in animal groups are short range. Here, we consider mating swarms of midges, which interact primarily via long-range acoustic stimuli. We exploit the similarity in form between the decay of acoustic and gravitational sources to build a model for swarm behavior. By accounting for the adaptive nature of the midges acoustic sensing, we show that our adaptive gravity model makes mean-field predictions that agree well with experimental observations of laboratory swarms. Our results highlight the role of sensory mechanisms and interaction range in collective animal behavior. The adaptive interactions that we present here open a new class of equations of motion, which may appear in other biological contexts.

**4:42PM V35.00010 Synchronization of self-propelled units carrying an internal oscillator**, DEMIAN LEVIS, IGNACIO PAGONABARRAGA, ALBERT DIAZ-GUILERA, Univ de Barcelona — We address the question of how self-propulsion, and the dynamical patterns emerging from it, affects the synchronization of motile physical entities, like moving cells synchronizing their intracellular genetic oscillators. In order to do that, we introduce a simple model of self-propelled hard disks moving in 2D carrying an internal variable which follows a Kuramoto dynamics. We find that, in the absence of particle-particle interactions, self-propulsion promotes the synchronization of the particles up to a saturation threshold that we identify with the parameters of the model. However, the presence of steric interactions give rise to an optimal self-propulsion for synchronization as a consequence of the clustering of the particles. This new effect shows that the interplay between the oscillators coupling and the topology of the underlying network, arising from particle interactions, plays an important role for the performance of mobile systems. We single out several dynamic regimes controlled by different processes that we describe. We analyse the relaxation of the system and show that synchronization proceeds through a mechanism that, despite being out-of-equilibrium, verifies the dynamical scaling hypothesis.

**4:54PM V35.00011 Statistical Mechanics of Collective Transport by Ants**, ITAI PINKOVIEZKY, Department of Chemical Physics, Weizmann Institute of Science, AVIRAM GELBLUM, EHUD FONIO, Department of Physics of Complex Systems, Weizmann Institute of Science, ABHIJIT GHOSH, NIR GOV, Department of Chemical Physics, Weizmann Institute of Science, OFER FEINERMAN, Department of Physics of Complex Systems, Weizmann Institute of Science — Collective decisions and cooperation within groups are essential for the survival of many species. Conflicts within the group must be suppressed but conformism may render the system unresponsive to new information. Collective transport by ants is therefore an ideal model system to study how animal groups optimize these opposing requirements. We combine experiments and theory to characterize the collective transport. The ants are modeled as binary Ising spins, representing the two roles ants can perform during transport. It turns out that the ants poise themselves collectively near a critical point where the response to a newly attached ant is maximized. We identify the size as being proportional to an inverse effective temperature and thus the system can exhibit a mesoscopic transition between order and disorder by manipulating the size. Constraining the cargo with a string makes the system behave as a strongly non-linear pendulum. Theoretically we predict that a Hopf bifurcation occurs at a critical size followed by a global bifurcation where full swings emerge. Remarkably, these theoretical predictions were verified experimentally.

**5:06PM V35.00012 Dynamics of fire ant aggregations**, MICHAEL TENNENBAUM, DAVID HU, ALBERTO FERNANDEZ-NIEVES, Georgia Inst of Tech — Fire ant aggregations are an inherently active system. Each ant harvests its own energy and can convert it into motion. The motion of individual ants contributes non-trivially to the bulk material properties of the aggregation. We have measured some of these properties using plate-plate rheology, where the response to an applied external force or deformation is measured. In this talk, we will present data pertaining to the aggregation behavior in the absence of any external force. We quantify the aggregation dynamics by monitoring the rotation of the top plate and by measuring the normal force. We then compare the results with visualizations of 2D aggregations.

**5:18PM V35.00013 Extensional Rheology of Fire Ant Aggregates<sup>1</sup>**, SCOTT FRANKLIN, MATTHEW KERN, Rochester Institute of Technology, SULISAY PHONEKEO, DAVID HU, Georgia Tech — We explore the extensional rheology and self-healing of fire ant (*Solenopsis invicta*) aggregations, mechanically entangled ensembles used to form rafts, bivouacs or bridges. Macroscopic experiments create quasi-two dimensional piles and measure the force required to impose a constant end-velocity. This force fluctuates, reminiscent of similar experiments on geometrically cohesive granular materials. Heterogeneous chains develop, with isolated ants often the sole link between top and bottom. Finally, the maximum pile strength scales sub-linearly with the number of ants, with the maximum force per ant decreasing as the pile grows. We reproduce these behaviors with a simple model that represents ants feet as discs connected by a spring (the "leg"). Discs move randomly, and stick to one another when in contact. Discs in contact un-stick at random with a probability that decreases as the spring (leg) is stretched, modeling an ant's tendency to hold on longer when stretched. Simulations qualitatively reproduces the fluctuating force, chain formation and sublinear scaling of maximum force with particle number and give insight into underlying mechanisms that govern the ants' behaviors.

**Session V36 GSOF: Disordered and Glassy Systems (Non-Polymeric)** 339 - Colm Kelleher, New York University

**2:30PM V36.00001 Injecting a droplet into a quasi-2D jammed emulsion: Fluctuations and rearrangements**, ERIC R. WEEKS, XIA HONG, Physics Dept., Emory University — We experimentally study the dynamic response of a quasi-two-dimensional emulsion to a slowly growing injected droplet. Our area fractions range from  $\phi = 0.77 - 0.99$ , such that the droplets are in most cases in contact with one another and are in many cases highly deformed. There is no dependence of the average flow behavior on distance to the inflation droplet, or on polydispersity or packing fraction of the emulsions. However, the fluctuations of velocity increase as the packing fraction increases. The magnitude of the fluctuations appears similar in both monodisperse, moderately ordered samples and bidisperse, disordered samples.

**2:42PM V36.00002 Densest packings of hard spheres in a cylinder**, LIN FU, WILLIAM STEINHARDT, HAO ZHAO, JOSHUA SOCOLAR, PATRICK CHARBONNEAU, Duke University — Densely packing hard spheres (HS) within a cylinder is remarkably complex. Little is known about the densest achievable packings when the cylinder diameter,  $D$ , is larger than 2.85 times the sphere diameter,  $s$ . Here, we extend the identification of the densest packings up to  $D = 4.00s$  by adapting Torquato-Jiao's adaptive-shrinking-cell formulation and sequential-linear-programming technique to this geometry. We identify 17 new structures, almost all of them chiral. Beyond  $D$ , approx  $2.85s$ , most of the structures consist of an outer shell and of an inner core that compete for being close packed. In some cases the shell adopts a periodic configuration that is optimal and the stacking of core spheres within it is quasiperiodic, while in other cases a direct interplay between the two layers is observed. For some packings the very distinction between the core and shell vanishes, which results in exotic geometries, including some that are a three-dimensional extension of packing hard disks in a circle. In order to connect our results with experiments on comparable systems, we also consider the ease with which these structures assemble. Using kinetic Monte Carlo simulations, we find that some of the structures promptly assemble while others simply do not.

**2:54PM V36.00003 Labyrinthine phase and slow dynamics in a driven magnetic granular medium**, SIMON MERMINOD, TIMOTHEE JAMIN, ERIC FALCON, MICHAEL BERHANU, Matter and Complex Systems (MSC), University Paris Diderot, CNRS, Paris, DIVISION OF NON-EQUILIBRIUM PHYSICS TEAM — Labyrinthine patterns arise in two-dimensional physical systems submitted to competing interactions, ranging from the fields of solid-state physics to hydrodynamics. Here we experimentally investigate a labyrinthine phase in an out-of-equilibrium system constituted of vibrated granular particles. Once sufficiently magnetized, they self-organize into short chains of particles in contact and randomly orientated. We quantitatively characterize the transition from a granular gas state to a labyrinthine phase, and we explain the formation of these chains using a simple model. Interestingly, the labyrinthine phase does not display any steady state: its morphology evolves with the aging time on very long timescales. Experiments suggest that here, slow dynamics involves strong structural rearrangements and therefore is comparable to slow dynamics in structural glasses. We characterize this aging process and evaluate to what extent this analogy holds.

**3:06PM V36.00004 From Gelation and Glass Transition of Colloidal Systems to Polymers**, CHARLES HAN, ICCAS and IAS of SZU, GUANGCUI YUAN, ICCAS, HE CHENG, ICCAS and IHEP — Charles C. Han, Guangcui Yuan and He Cheng Joint Laboratory of Polymer Science and Materials, ICCAS, Beijing, China and Institute for Advanced Study, Shenzhen University, Shenzhen, China Aggregation and gelation behavior of mixed suspensions of polystyrene microspheres and poly(N-isopropylacrylamide) microgels have been studied. In dilute microsphere suspensions, with increasing concentration of microgel (MG), microspheres (MS) first aggregated with each other through the bridging of the microgels, then dispersed individually when saturated adsorption was achieved, and finally depletion clusters formed at even higher concentrations of microgel. In concentrated microsphere suspensions, with saturated MG adsorption, a state transition from attractive glass to repulsive glass can be observed. This type of system can be viewed as a molecular model system which has a long range repulsive interaction potential and a short range attractive potential. A comparison between the glass transition of the colloidal systems and the glass transition of polymeric systems can be made.

**3:18PM V36.00005 Relaxation and self-diffusion of supercooled liquids derived from picosecond timescale dynamics**, MARCUS CICERONE, MIAOCHAN ZHI, BRANDON BLAKELY, MADHUSUDAN TYAGI, NIST — We use neutron scattering and nonlinear optical measurements to investigate ps-ns timescale dynamics in liquid, supercooled liquid, and glassy states. The experimental observables show evidence of dynamic heterogeneity on this timescale that supports a facilitated dynamics picture. We obtain a direct measure of the concentration of molecular excitations, or mobile regions, as a function of time and temperature. Using a model [1] broadly consistent with that proposed by Chandler and co-workers [2], we are able to quantitatively predict self-diffusion rates and Stokes Einstein violation deep in the supercooled regime directly from ps timescale and Angstrom - nanometer length scale measurements for all systems we have investigated. The model we employ also provides a clear physical mechanism for the Johari-Goldstein relaxation process. [1] M.T. Cicerone, Q. Zhong & M. Tyagi, PRL 113 117801 (2014). [2] J. P. Garrahan & D. Chandler, Coarse-grained microscopic model of glass formers, PNAS 100, 9710 (2003).

**3:30PM V36.00006 In search of a Corresponding state description of the thermodynamics and dynamics of complex fluids.**, TAMOGHNA DAS, National Institute of Standards and Technology & University of Maryland, MAHESH BANDI, Okinawa Institute of Science and Technology Graduate University, JACK DOUGLAS, National Institute of Standards and Technology — Long ago, Pitzer introduced a scheme for characterizing the relative "complexity" of fluids based on a consideration of the temperature dependence of the second virial coefficient at low temperature, where this property is sensitive to the form of the inter-molecular potential. "Simple" fluids, in this classification scheme, are those that satisfy a common "corresponding states" in which the properties (eg. shape of the phase boundary, surface tension etc.) obey a universal reduced variable scaling description. This idea was pioneered by van der Waals based on his equation of states describing the pressure of gases. Many real fluids are not "simple" in the sense that the molecules have complex shapes and interact with a combination of short-range and long-range directional interactions having different spatial interaction ranges. These features lead to these fluids being classified as "complex". We show that an effective reduced variable description for a model complex fluid can be achieved by defining a reduced variable involving the second virial coefficient. We further show that a recent reduced variable description of the dynamics and thermodynamics of glass-forming liquids derives from the same principle.

**3:42PM V36.00007 Short-Time Glassy-like Dynamics Observed in Viscous Protein Solutions with Competing Potential Features.**, NORMAN WAGNER, DOUG GODFRIN, University of Delaware, YUN LIU, University of Delaware/NCNR NIST — Structures in concentrated protein solutions caused by the combination of short-range attraction (SA) and long-range repulsion (LR) have been extensively studied due to their importance in understanding therapeutic protein formulations and the phase behavior in general. Despite extensive studies of kinetically arrested states in colloidal systems with short-range attraction, less is understood for the effect of an additional longer-range repulsion on model colloidal systems with a SA interaction. Highly purified lysozyme is used as a model experimental system due to its stable globular structure and SALR interactions at low ionic strength that can be quantitatively modeled. The fluid microstructure and protein short time self diffusion are measured across a broad range of conditions by small angle neutron scattering (SANS) and neutron spin echo (NSE), respectively. Newtonian liquid behavior is observed at all concentrations, even with an increase of zero shear viscosity by almost four orders of magnitude with increasing concentration. However, dynamic measurements demonstrate a sub-diffusive regime at relatively short time scales for concentrated samples at low temperature. The formation of a heterogeneous density distribution is shown to produce localized regions of high density that reduce protein motion, giving it a glassy-like behavior at the short time scale. This heterogeneity occurs at the length scale associated with the intermediate range order driven by the competing potential features, distinguishable from heterogeneous colloidal gels.

### **3:54PM V36.00008 Combined Effects of Media Disorderedness and Tracer Shape on the Trend of Translation-Rotation Decoupling in Two-Dimensional Binary Colloids**

**YOUNGHOON OH, JEONGMIN KIM, BONG JUNE SUNG**, Department of Chemistry, Sogang University, Seoul 987-654, Korea — While translational diffusion of tracers often violates the Stokes-Einstein relation, the rotational diffusion of tracers follows the Debye-Stokes-Einstein relation faithfully in the glass-forming materials. A previous study revealed that in two-dimensional (2D) monodisperse colloids, as the dynamics of media became heterogeneous in 2D hexatic phase, the tracer shape and the local media structure affected the translation-rotation decoupling trend significantly [1]: the rotation of tracers was enhanced compared to the translation for square tracers but was rather suppressed for diamond tracers. The shape dependency of rotation originated from the similarity in structure between the local hexagonal media structure and the tracer shape. Unlike in 2D monodisperse colloids where the liquid-to-hexatic phase transition takes place, in 2D binary colloids, a phase transition from the liquid to either solid or glass depends on the disorderedness that is controlled by size and number ratios. We present simulation results on the combined effects of the tracer shape and the local media disorderedness on the translation-rotation decoupling, which relates closely to the nature of glass transition. ### **4:06PM V36.00009 Spatio-temporal correlations in Coulomb clusters**

**AMIT GHOSAL, BISWARUP ASH**, Indian Institute of Science Education and Research-Kolkata, Mohanpur Campus, India-741246, **JAYDEB CHAKRABARTI**, S. N. Bose National Centre for Basic Sciences, Kolkata, India-700098 — Dynamical response of Coulomb-particles in nanoclusters are investigated at different temperatures characterizing their solid-like (Wigner molecule) and liquid-like behavior. The density correlations probe spatio-temporal relaxation, uncovering distinct behavior at multiple time scales in these systems. They show a stretched-Gaussian or stretched-exponential spatial decay at long times in circular and irregular traps. Interplay of confinement and long-range nature of interactions yields spatially correlated motion of the particles in string-like paths, leaving the system heterogeneous even at long times. While particles in a 'solid' flow producing dynamic heterogeneities, their random motion in 'liquid' defies central limit theorem. Distinguishing the two confinements, temperature dependent motional signatures serve as a criterion for the crossover between 'solid' and 'liquid'. The irregular Wigner molecule turns into a nearly homogeneous liquid over a much wider temperature window compared to the circular case. The temperature dependence of different relaxation time scales builds crucial insights. A phenomenological model, relating the unusual dynamics to the heterogeneous nature of the diffusivities in the system, captures much of the subtleties of our numerical simulations.

### **4:18PM V36.00010 Glassy Spin Dynamics in Buckled Colloidal Crystal<sup>1</sup>**

**DI ZHOU, FENG WANG, YILONG HAN**, Department of Physics, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong — Geometric frustration arises when lattice structure prevents simultaneous minimization of local interaction energies. It leads to highly degenerate ground states and complex behaviors in frustrated magnetic materials. Here we experimentally studied buckled 1.5-layer colloidal NIPA microgel crystals confined between parallel plates. Spheres buckled up and down are analogous to antiferromagnetic Ising spins. These spins on the distorted triangular lattice exhibit glassy dynamics at low temperatures. In particular, a spin only has 13 nearest-neighbor configurations, which enables to reveal the correlation between structures and dynamical heterogeneity. Soft modes also localize at high-energy regions. Further, we compared the colloidal spin system with kinetic constrained models (KCMs) and observed dynamical facilitation behaviors including excitations lines in space-time. Similar structures and glassy dynamics are also observed in our simulation of Coulomb charges on a triangular lattice.

### **4:30PM V36.00011 Experiments reveal different dynamics in two and three dimensions near the colloidal glass transition**

**SKANDA VIVEK**, Emory University, **COLM KELLEHER, PAUL CHAIKIN**, New York University, **ERIC WEEKS**, Emory University — We use microscopy to study both 3D and quasi-2D colloidal systems as they approach their glass transitions. We use two different bidisperse 2D systems, one of which has hard particles and the other which has particles interacting with long range dipolar interactions. The 3D system also has hard interactions (3D data obtained from Narumi, et al. Soft Matter 2011). In the 3D data, we observe significant plateaus in the mean square displacement curves, in contrast to 2D. This indicates stronger transient localization in 3D. In both 2D systems, as we approach the glass transition, we observe decoupling between translational time scales and time scales for structural reorientation. In 3D, these time scales always remain coupled. Finally, in 2D we observe large clusters of particles moving in parallel directions, but similar clusters are markedly smaller in 3D. In both 2D systems, these clusters become larger on approaching the glass transition. We attribute the observed decoupling of translational and bond-orientational times in 2D to the presence of these large directional clusters. Overall, our results are in good qualitative agreement with recent simulation results [Flenner and Szamel, Nature Communications 2015].

### **4:42PM V36.00012 Measuring heterogenous stress fields in a 3D colloidal glass**

**NEIL LIN, MATTHEW BIERBAUM**, Cornell University, **MAX BI**, Rockefeller University, **JAMES SETHNA**, **ITAI COHEN**, Cornell University — Glass in our common experience is hard and fragile. But it still bends, yields, and flows slowly under loads. The yielding of glass, a well documented yet not fully understood flow behavior, is governed by the heterogenous local stresses in the material. While resolving stresses at the atomic scale is not feasible, measurements of stresses at the single particle level in colloidal glasses, a widely used model system for atomic glasses, has recently been made possible using Stress Assessment from Local Structural Anisotropy (SALSA). In this work, we use SALSA to visualize the three dimensional stress network in a hard-sphere glass during start-up shear. By measuring the evolution of this stress network we identify local-yielding. We find that these local-yielding events often require only minimal structural rearrangement and as such have most likely been ignored in previous analyses. We then relate these micro-scale yielding events to the macro-scale flow behavior observed using bulk measurements.

### **4:54PM V36.00013 Mean-field description of plastic flow in amorphous solids**

**JIE LIN**, New York University, **MATTHIEU WYART**, EPFL — Failure and flow of amorphous materials are central to various phenomena including earthquakes and landslides. There is accumulating evidence that the yielding transition between a flowing and an arrested phase is a critical phenomenon, but the associated exponents are not understood, even at a mean-field level where the validity of popular models is debated. Here we solve a mean-field model that captures the broad distribution of the mechanical noise generated by plasticity, whose behavior is related to biased Lévy flights near an absorbing boundary. We compute the exponent  $\theta$  characterizing the density of shear transformation  $P(x) \sim x^\theta$ , where  $x$  is the stress increment beyond which they yield. We find that after an isotropic thermal quench,  $\theta = 1/2$ . However,  $\theta$  depends continuously on the applied shear stress, this dependence is not monotonic, and its value at the yield stress is not universal. The model rationalizes previously unexplained observations, and captures reasonably well the value of exponents in three dimensions. These results support that it is the true mean-field model that applies in large dimension, and raise fundamental questions on the nature of the yielding transition.

**5:06PM V36.00014 Rearrangement dynamics in colloidal particle packings identified through local structure and machine-learning<sup>1</sup>**, ZOEY S. DAVIDSON, TIM STILL, MATTHEW D. GRATALE, XIAO GUANG MA, SAMUEL S. SCHOENHOLZ, DANIEL M. SUSSMAN, A.J. LIU, A.G. YODH, University of Pennsylvania — We explore the connection between measures of local structure and particle rearrangements in soft thermal quasi-two-dimensional colloidal systems employing a machine learning approach. Local structure is characterized by two and three point structure functions that measure radial and angular distributions of particles, and rearrangements are identified by a measure of change in average colloidal particle position. By generating labeled training data, we can extract the features of these functions that contribute to the likelihood of a rearrangement. In particular, we use a machine-learning algorithm to construct a decision function in the form of a scalar field we call softness that with high accuracy labels regions of particles more likely to rearrange. Thus, we can predict dynamic rearrangements from the instantaneous local structure. The softness field remains a good predictor when we vary the packing fraction between training and test data sets. In glassy samples, the softness field can identify aging as particles become less likely to undergo cage rearrangements.

**5:18PM V36.00015 A Generic Microscopic Theory for the Universality of TTLS Meissner-Berret Ratio of Amorphous Solid**, DI ZHOU, ANTHONY LEGGETT, Univ of Illinois - Urbana — Tunneling-two-level-system (TTLS) has successfully explained several experimental results for amorphous solid which do not exist in crystalline counterparts. However longitudinal and transverse phonon-TTLS coupling constants' ratio  $\gamma_l/\gamma_t$  has been found to lie between 1.5 and 1.6 for 13 different amorphous solids which cannot be explained within TTLS model. In this paper by developing an interacting generic block model with random stress tensors, we show the universality essentially comes from interaction between generic blocks, independent of the material's microscopic structure. In the appendix we also give a detailed correction for non-elastic stress-stress interaction coefficient  $\Lambda_{ijkl}^{(ss')}$  derived by Joffrin and Levelut.

**Thursday, March 17, 2016 2:30PM - 5:30PM –**

**Session V37 GSOF DBIO: Soft Mechanics in Biological Systems** 340 - Itai Cohen, Cornell University

**2:30PM V37.00001 State transitions of actin cortices in vitro and in vivo**, TZER HAN TAN, Massachusetts Inst of Tech-MIT, KINNERET KEREN, Technion-Israel Institute of Technology, FRED MACKINTOSH, University of Amsterdam, CHRISTOPH SCHMIDT, Goettingen University, NIKTA FAKHRI, Massachusetts Inst of Tech-MIT — Most animal cells are enveloped by a thin layer of actin cortex which governs the cell mechanics. A functional cortex must be rigid to provide mechanical support while being flexible to allow for rapid restructuring events such as cell division. To satisfy these requirements, the actin cortex is highly dynamic with fast actin turnover and myosin-driven contractility. The regulatory mechanism responsible for the transition between a mechanically stable state and a restructuring state is not well understood. Here, we develop a technique to map the dynamics of reconstituted actin cortices in emulsion droplets using IR fluorescent single-walled carbon nanotubes (SWNTs). By increasing crosslinker concentration, we find that a homogeneous cortex transitions to an intermediate state with broken rotational symmetry and a globally contractile state which further breaks translational symmetry. We apply this new dynamic mapping technique to cortices of live starfish oocytes in various developmental stages. To identify the regulatory mechanism for steady state transitions, we subject the oocytes to actin and myosin disrupting drugs.

**2:42PM V37.00002 Direct measurement of local material properties within living embryonic tissues**, FRIEDHELM SERWANE, ALESSANDRO MONGERA, PAYAM ROWGHANIAN, DAVID KEALHOFER, ADAM LUCIO, ZACHARY HOCKENBERRY, OTGER CAMPÀS, University of California, Santa Barbara — The shaping of biological matter requires the control of its mechanical properties across multiple scales, ranging from single molecules to cells and tissues. Despite their relevance, measurements of the mechanical properties of sub-cellular, cellular and supra-cellular structures within living embryos pose severe challenges to existing techniques. We have developed a technique that uses magnetic droplets to measure the mechanical properties of complex fluids, including in situ and in vivo measurements within living embryos across multiple length and time scales. By actuating the droplets with magnetic fields and recording their deformation we probe the local mechanical properties, at any length scale we choose by varying the droplets' diameter. We use the technique to determine the subcellular mechanics of individual blastomeres of zebrafish embryos, and bridge the gap to the tissue scale by measuring the local viscosity and elasticity of zebrafish embryonic tissues. Using this technique, we show that embryonic zebrafish tissues are viscoelastic with a fluid-like behavior at long time scales. This technique will enable mechanobiology and mechano-transduction studies in vivo, including the study of diseases correlated with tissue stiffness, such as cancer.

**2:54PM V37.00003 The role of anisotropy in cell morphology**, KOEN SCHAKENRAAD, WIM POMP, Univ of Leiden, ROELAND MERKS, Univ of Leiden, Centrum Wiskunde en Informatica Amsterdam, THOMAS SCHMIDT, LUCA GIOMI, Univ of Leiden — The shape of adhering cells is determined by the interplay between contractile forces, arising from the cytoskeleton, and the resistance of the underlying substrate. In particular, experiments with fibroblasts on an elastic micro-pillar array show that fibroblasts possess a high degree of orientational order of the actin stress fibers. This anisotropy causes the shape of the cell edge to deviate from the shape of cells with an isotropic cytoskeleton. We present a model that describes the contractility of the cytoskeleton as a combination of directed forces, in the direction of stress fibers, and isotropic forces. We found that cell morphology is described by an anisotropic generalization of the Young-Laplace law, which describes the cell edges as parts of an ellipse. Experiments on the shape of and adhesion forces on fibroblasts show good agreement with our model. Our work highlights the strong coupling between the organization of the internal cytoskeleton and the shapes and forces on the outside of the cell.

**3:06PM V37.00004 Role of forces and of micromechanics of biopolymers in the cellular process of cell division**, MARIA KILFOIL, University of Massachusetts, Amherst — No abstract available.

**3:42PM V37.00005 Hydraulic fracture and resilience of epithelial monolayers under stretch**, MARINO ARROYO, Univ Politecnica de Catalunya, ALESSANDRO LUCANTONIO, GIOVANNI NOSELLI, SISAInternational School for Advanced Studies, LAURA CASARES, Institute for Bioengineering of Catalonia (IBEC) / Univ Politecnica de Catalunya, ANTONIO DESIMONE, SISAInternational School for Advanced Studies, XAVIER TREPAT, Institute for Bioengineering of Catalonia (IBEC) — Epithelial monolayers are very simple and prevalent tissues. Their functions include delimiting distinct physicochemical containers and protecting us from pathogens. Epithelial fracture disrupts the mechanical integrity of this barrier, and hence compromises these functions. Here, we show that in addition to the conventional fracture resulting from excessive tissue tension, epithelia can hydraulically fracture under stretch as a result of the poroelastic nature of the matrix [1]. We will provide experimental evidence of this counterintuitive mechanism of fracture, in which cracks appear under compression. Intriguingly, unlike tensional fracture, which is localized and catastrophic, hydraulic epithelial fracture is distributed and reversible. We will also describe the active mechanisms responsible for crack healing, and the physical principles by which the poroelastic matrix contributes to this resilient behavior [2]. [1] Casares et al., Nature Materials, 14, 343-351 (2015) [2] Lucantonio et al., Physical Review Letters, 115, 188105 (2015)

**3:54PM V37.00006 Mechanics and crack formation in the extracellular matrix with articular cartilage as a model system<sup>1</sup>**, SARAH KEARNS, Rochester Institute of Technology, JESSE SILVERBERG, Harvard University, LAWRENCE BONASSAR, ITAI COHEN, Cornell University, MOUMITA DAS, Rochester Institute of Technology — We investigate the mechanical structure-function relations in the extracellular matrix (ECM) with focus on crack formation and failure. As a model system, our study focuses on the ECM in articular cartilage (AC), the tissue that covers the ends of bones, and distributes load in joints including in the knees, shoulders, and hips. The strength, toughness, and crack resistance of native articular cartilage is unparalleled in materials made by humankind. This mechanical response is mainly due to its ECM. The ECM in AC has two major mechanobiological components: a network of the biopolymer collagen and a flexible aggrecan gel. We model this system as a biopolymer network embedded in a swelling gel, and investigate the conditions for the formation and propagation of cracks using a combination of rigidity percolation theory and energy minimization approaches. Our results may provide useful insights into the design principles of the ECM as well as of biomimetic hydrogels that are mechanically robust and can, at the same time, easily adapt to cues in their surroundings.

**4:06PM V37.00007 Fiber networks amplify active stress**, MARTIN LENZ, PIERRE RONCERAY, LPTMS, CNRS, Univ. Paris-Sud, Universit Paris-Saclay, 91405 Orsay, France, CHASE BROEDERSZ, Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-Universitt, Mnchen, Theresienstrasse 37, D-80333 — Large-scale force generation is essential for biological functions such as cell motility, embryonic development, and muscle contraction. In these processes, forces generated at the molecular level by motor proteins are transmitted by disordered fiber networks, resulting in large-scale active stresses. While fiber networks are well characterized macroscopically, this stress generation by microscopic active units is not well understood. I will present a comprehensive theoretical study of force transmission in these networks. I will show that the linear, small-force response of the networks is remarkably simple, as the macroscopic active stress depends only on the geometry of the force-exerting unit. In contrast, as non-linear buckling occurs around these units, local active forces are rectified towards isotropic contraction and strongly amplified. This stress amplification is reinforced by the networks' disordered nature, but saturates for high densities of active units. I will show that our predictions are quantitatively consistent with experiments on reconstituted tissues and actomyosin networks, and that they shed light on the role of the network microstructure in shaping active stresses in cells and tissue.

**4:18PM V37.00008 A micro-mechanical model to determine changes of collagen fibrils under cyclic loading**, MICHELLE L CHEN, Johns Hopkins University, MONICA E. SUSILO, JEFFREY A. RUBERTI, Northeastern University, THAO D. NGUYEN, Johns Hopkins University — Dynamic mechanical loading induces growth and remodeling in biological tissues. It can alter the degradation rate and intrinsic mechanical properties of collagen through cellular activity. Experiments showed that repeated cyclic loading of a dense collagen fibril substrate increased collagen stiffness and strength, lengthened the substrate, but did not significantly change the fibril areal fraction or fibril anisotropy (Susilo, et al. Collagen Network Hardening Following Cyclic Tensile Loading, Interface Focus, submitted). We developed a model for the collagen fibril substrate (Tonge, et al. A micromechanical modeling study of the mechanical stabilization of enzymatic degradation of collagen tissues, Biophys J, in press.) to probe whether changes in the fibril morphology and mechanical properties can explain the tissue-level properties observed during cyclic loading. The fibrils were modeled as a continuous distribution of wavy elastica, based on experimental measurements of fibril density and collagen anisotropy, and can experience damage after a critical stress threshold. Other mechanical properties in the model were fit to the stress response measured before and after the extended cyclic loading to determine changes in the strength and stiffness of collagen fibrils.

**4:30PM V37.00009 Confined semiflexible biopolymers suppress fluctuations of soft membrane tubes**, STEVEN ABEL, SINA MIRZAEIFARD, University of Tennessee, Knoxville — Membrane nanotubes are tubular membrane structures that contain actin and connect cells over long distances. Disrupting the actin cytoskeleton abrogates membrane nanotubes, making them an interesting model system for studying membrane-biopolymer interactions. In this study, we use Monte Carlo computer simulations to investigate tubular, elastic membrane structures with and without semiflexible polymers confined inside. At small values of membrane bending rigidity, fluid membranes adopt irregular, highly fluctuating shapes while non-fluid membranes maintain extended tube-like structures. With increasing bending rigidity, fluid membranes exhibit a local maximum in specific heat that is coincident with a transition to extended tube-like structures. We further find that confining a semiflexible polymer within a fluid membrane tube suppresses membrane shape fluctuations and reduces the specific heat of the membrane. Polymers with a sufficiently large persistence length can significantly deform the membrane tube, leading to localized bulges in the membrane that accommodate regions in which the polymer forms loops. Analytical calculations of the energies of idealized polymer-membrane configurations provide additional insight into the formation of polymer-induced membrane deformations.

**4:42PM V37.00010 Force distributions in disordered fiber networks**, KNUT HEIDEMANN, Institute for Numerical and Applied Mathematics, Georg-August-Universitaet, Goettingen, ABHINAV SHARMA, FLORIAN REHFELDT, CHRISTOPH F SCHMIDT, Third Institute of Physics – Biophysics, Georg-August-Universitaet, Goettingen, MAX WARDETZKY, Institute for Numerical and Applied Mathematics, Georg-August-Universitaet, Goettingen — Disordered filamentous networks determine the mechanical response of many materials in nature. Due to the filamentous character of these networks, the strain field, and hence the force distributions, can be highly inhomogeneous. Large local stresses can result in an increased susceptibility for local rearrangements due to rupture or unbinding events. In our study, we introduce a quantitative measure to characterize the emergence of highly stressed one-dimensional paths, so-called force chains, in three-dimensional nonlinear fiber networks. Furthermore, we provide an analytical approach, based on graph theory, that quantitatively describes the force distributions in one-dimensional periodic spring networks. Our analytical results are in excellent agreement with our extensive numerical simulations.

**4:54PM V37.00011 Role of differential physical properties in the collective mechanics and dynamics of tissues<sup>1</sup>**, MOUMITA DAS, Rochester Institute of Technology — Living cells and tissues are highly mechanically sensitive and active. Mechanical stimuli influence the shape, motility, and functions of cells, modulate the behavior of tissues, and play a key role in several diseases. In this talk I will discuss how collective biophysical properties of tissues emerge from the interplay between differential mechanical properties and statistical physics of underlying components, focusing on two complementary tissue types whose properties are primarily determined by (1) the extracellular matrix (ECM), and (2) individual and collective cell properties. I will start with the structure-mechanics-function relationships in articular cartilage (AC), a soft tissue that has very few cells, and its mechanical response is primarily due to its ECM. AC is a remarkable tissue: it can support loads exceeding ten times our body weight and bear 60+ years of daily mechanical loading despite having minimal regenerative capacity. I will discuss the biophysical principles underlying this exceptional mechanical response using the framework of rigidity percolation theory, and compare our predictions with experiments done by our collaborators. Next I will discuss ongoing theoretical work on how the differences in cell mechanics, motility, adhesion, and proliferation in a co-culture of breast cancer cells and healthy breast epithelial cells may modulate experimentally observed differential migration and segregation. Our results may provide insights into the mechanobiology of tissues with cell populations with different physical properties present together such as during the formation of embryos or the initiation of tumors.

**Thursday, March 17, 2016 2:30PM - 5:30PM —**  
Session V38 DPOLY DBIO: Mechanics of Biopolymers: Single Polymer Dynamics 341 - Alex Levine, UCLA

**2:30PM V38.00001 Non-continuum correlated intermolecular dynamical displacements in entangled biopolymer solutions.** , KENNETH S. SCHWEIZER, ZACHARY E. DELL, BOYCE TSANG, LINGXIANG JIANG, University of Illinois at Urbana-Champaign, STEVE GRANICK, IBS Center for Soft and Living Matter — Understanding correlated intermolecular motion is important in biology and of fundamental interest in polymer physics. We performed real space measurements of the correlated dynamical displacements of a pair of biopolymers in entangled F-actin solutions over mesoscopic and continuum length scales, and on time scales beyond the entanglement crossover but much shorter than the reptation time. A microscopic theory is constructed based on generalizing a recent force-level statistical mechanical approach for predicting the separation-dependent, non-hydrodynamic relative friction of a pair of colloids in polymer melts [1] and in dense suspensions [2]. In the mesoscopic time regime, individual biopolymers move by reptation, and the dynamically-emergent intermolecular correlation hole is proposed as the mechanism for inducing non-hydrodynamic collective Fickian motion. Non-continuum cross correlations are predicted to dominate for inter-polymer separations up to the rod length (~15 microns), beyond which a crossover to hydrodynamic behavior occurs. The theoretical results agree well with our measurements at different observation times and physical mesh values. [1] Yamamoto, Schweizer, J.Chem.Phys.139,064907(2013); [2] Dell, Tsang, Jian, Granick, Schweizer, Phys.Rev.E, in press, 2015

**2:42PM V38.00002 Force fluctuation in a semiflexible loop** , JAMES WATERS, HAROLD KIM, Georgia Institute of Technology, HAROLD KIM TEAM — DNA-binding proteins can regulate genetic expression by holding two sites in close proximity, forming a closed loop. Such complexes may require strong bending of DNA segments on the order of one persistence length or less. Both this elastic bending and the thermal fluctuations of the DNA molecule are necessary to describe the resulting behavior. To explore this problem, we consider a discrete model of a wormlike chain, kept in the fixed extension ensemble. By using a novel method to sample conformations in both position and momentum space, we can obtain a distribution of constraint forces as a function of chain length, extension, and flexibility. Our coarse-grained model allows us to explore the space of these parameters more efficiently than a detailed molecular dynamics approach. We find that increasing contour length decreases average force by relieving bending stress, but that the additional freedom allows fluctuations in the constraint force to increase. This implies that the probability of large forces may go up even as the mean goes down, impacting the lifetime of such bound states in a way unforeseen by purely equilibrium methods.

**2:54PM V38.00003 Watching entangled circular DNA in real time with super-resolution** , AH-YOUNG JEE, HYEONGJU KIM, STEVE GRANICK, Institute for Basic Science — In this talk, we will show how we unraveled the conformational dynamics of entangled ring-shaped polymers in network, which is one of the most well-known problems in polymer physics, using deep imaging based on super-resolution fluorescence imaging, stimulated emission depletion (STED) microscopy. By using home-written software, we obtained the statistics of each of the hundreds of molecules, mapping out a large statistical distribution. Through inspection we not only found some aspects of the classic understanding of polymers, but some surprising aspects as well.

**3:06PM V38.00004 Single Molecule Dynamics of Branched DNA Polymers** , DANIELLE MAI, CHARLES SING, CHARLES SCHROEDER, Univ of Illinois - Urbana — This work focuses on extending the field of single polymer dynamics to topologically complex polymers. Here, we report the direct observation of DNA-based branched polymers. Recently, we recently demonstrated a two-step synthesis method to generate star, H-shaped, and comb polymers for single molecule visualization. Following synthesis, we use single-color or dual-color single molecule fluorescence microscopy to directly visualize branched polymer dynamics in flow, in particular tracking side branches and backbones independently. In this way, our imaging method allows for characterization of molecular properties, including quantification of polymer contour length and branch distributions. Moving beyond characterization, we use molecular rheology and single molecule techniques to study the dynamics of single branched polymers in flow. Here, we utilize precision microfluidics to directly observe branched DNA polymer conformations during transient stretching, steady-state extension, and relaxation from high stretch. We specifically measure backbone end-to-end distance as a function of time. Experiments and Brownian dynamics simulations show that branched polymer relaxation is a strong function of the number of branches and position of branch points along the main chain backbone.

**3:18PM V38.00005 Single polymer dynamics of linear and architecturally complex chains in semi-dilute solutions** , KAIWEN HSIAO, Univeristy of Illinois at Urbana Champaign, YANFEI LI, GREGORY MCKENNA, Texas Tech University, CHARLES SCHROEDER, Univeristy of Illinois at Urbana Champaign — The interplay between polymer topology and concentration gives rise to complex dynamics due to inter- and intramolecular interactions. We use a molecular level approach to study the threading behavior for linear and ring polymers near equilibrium and in non-linear flows. A semi-dilute solution of linear DNA chains is doped with fluorescently labeled ring polymers (circular DNA plasmids), and this material is used to study the dynamics of rings in semi-dilute solutions of linear chains. Single molecule fluorescence microscopy in combination with a custom-built microfluidic trapping system is used to study collective polymer dynamics at the molecular level, which allows us to precisely control flow rates and accumulated fluid strain applied to single polymer. We performed step-strain experiments on ring polymer in linear semi-dilute polymer solutions undergoing deformation in planar extensional flow. In comparison to our previous work on semi-dilute linear chains, ring polymers exhibit large fluctuations in fractional extension at steady state extension, indicating strong interactions with the background polymer solution. Transient stretching dynamics of ring polymer is inhibited in semi-dilute linear background, similar to our previous observation in linear systems. Our findings show that topology and concentration play a strong role on polymer chain dynamics in non-equilibrium flow.

**3:30PM V38.00006 Study of mechanical properties of DNA in E. coli cells by fluorescence correlation spectroscopy** , RUDRA KAFLE, Worcester Polytechnic Institute, MOLLY LIEBESKIND, JENS-CHRISTIAN MEINERS, University of Michigan — Mechanical quantities like the elasticity of cells are conventionally measured by directly probing them mechanically. Measurements of these quantities for subcellular structures in living cells are almost impossible this way. We use fluorescence correlation spectroscopy (FCS) to measure such mechanical quantities in chromosomal DNA in *E. coli* cells. We present methods to address complexities of live-cell FCS such as photobleaching, and calculate the viscoelastic moduli from the FCS data. We compare the measured viscoelastic moduli of live cells with those that are ATP-depleted to stop all molecular motor action and find substantial differences. Active processes are stopped in ATP-depleted cells and hence the bacterial DNA appears to become stiffer and the surrounding intracellular medium more viscous. We also compare our results with the FCS data obtained from the lambda DNA solution in various concentrations to mimic the cellular environment.

**3:42PM V38.00007 Single Polymer Dynamics under Large (LAOE) Flow** , YUECHENG ZHOU<sup>1</sup>, CHARLES M. SCHROEDER, Univ of Illinois - Urbana — Imaging and particle manipulation have enabled the direct observation of single polymer dynamic flow. The vast majority of single polymer studies, however, has focused on chain dynamics using single polymer dynamics in non-idealized model flows, there is a clear need to implement more complicated amplitude oscillatory shear (LAOS) was widely used to study the linear and nonlinear viscoelasticity. In this work, we directly probe single polymer dynamics using oscillatory extensional flow in precisely large and small amplitude sinusoidal oscillatory extensional flow in a cross-slot microfluidic device where polymer chains are trapped at the stagnation point. In this flow, polymer chains are stretched, squeezed, and rotated in a transient manner. Using this technique, we studied the dynamics and coil-stretch transition of polymer chains as a function of the Weissenberg number (Wi) and Deborah number (De). Moreover, we use Brownian dynamics simulation to map a wide range of conditions to non-linear unsteady-states. Our results reveal a critical Wi at the coil-stretch transition.

**3:54PM V38.00008 Large-scale structural transitions in supercoiled DNA revealed by coarse-grained simulations**, BRAD KRAJINA, ANDREW SPAKOWITZ, Stanford Univ — Topological constraints, such as DNA supercoiling, play an integral role in genomic regulation and organization in living systems. However, physical understanding of the principles that underlie DNA structure and organization at biologically-relevant length-scales remains a formidable challenge. We develop a coarse-grained simulation approach for predicting equilibrium conformations of supercoiled DNA. With this approach, we study the conformational transitions that arise due to supercoiling across the full range of supercoiling densities that are commonly explored by living systems. Simulations of ring DNA molecules with lengths up to the scale of topological domains in the E. coli chromosome (~10 kilobases) reveal large-scale structural transitions elicited by supercoiling, resulting in 3 supercoiling conformational regimes: chiral coils, extended plectonemes, and branched hyper-supercoils. These results capture the non-monotonic relationship of size versus degree of supercoiling observed in experimental sedimentation studies of supercoiled DNA, and our results provide a physical explanation of the structural transitions underlying this behavior.

**4:06PM V38.00009 Jamming of Knots along a Tensioned Chain**, PATRICK DOYLE, VIVEK NARSIMHAN, C. BENJAMIN RENNER<sup>1</sup>, Massachusetts Institute of Technology — In the limit of very long chains, coiled polymers almost always self-entangle and form knots. In this study, we characterize the motion of these knots along the chain contour when the chain is under very high tension. In this regime, we find that the knot exhibits glassy physics. For example, instead of moving continuously along the contour, the knot becomes kinetically trapped in long-lived, metastable states. This caging phenomenon follows Poisson statistics, and thus the long-time dynamics of the knot are diffusive. We quantify the long-time diffusivity of knots of various topologies, and we find that the diffusivity decays exponentially with increasing chain tension. The rate-of-decay of these transport properties is relatively insensitive to the knot's topology, which can be explained by examining the energy landscape of the self-reptation moves of the knot along the chain. Finally, we examine the role of bending and excluded volume interactions on this jamming phenomenon. Bending plays the biggest role in determining the onset of jamming, but the corrugation of the excluded volume interactions solely determines the rate-of-decay of the knot's transport properties.

<sup>1</sup>Now at Liquiglide

**4:18PM V38.00010 Activity induced phase separation in particles and (bio)polymers**, ALEXANDER GROSBERG, New York University — It was recently shown that the non-equilibrium steady state of the mixture of two types of particles exposed to two different thermostats can phase separate (A.Y.Grosberg, J.-F.Joanny, PRE, v. **91**, 032118, 2015). similar result is valid also in the case when particles in question are monomers of two different polymer chains, or blocks of a co-polymer. We discuss the implications of these results for the physics of chromatin.

**4:54PM V38.00011 Electrophoresis of semiflexible heteropolymers and the “hydrodynamic Kuhn length”**, MYKYTA V. CHUBYNSKY, GARY W. SLATER, Department of Physics, University of Ottawa, Canada — Semiflexible polymers, such as DNA, are rodlike for short lengths and coil-like for long lengths. For purely geometric properties, such as the end-to-end distance, the crossover between these two behaviors occurs when the polymer length is on the order of the Kuhn length. On the other hand, for the hydrodynamic friction coefficient it is easy to see by comparing the expressions for a rod and a coil that the crossover should occur at the polymer length, termed by us the *hydrodynamic Kuhn length* [1], which is larger than the ordinary Kuhn length by a logarithmic factor that can be quite significant. We show that for the problem of electrophoresis of a heteropolymer consisting of several blocks of (in general) different stiffnesses, both of these length scales can be important depending on the details of the problem. [1] M. V. Chubynsky and G. W. Slater, *Macromolecules* 48 (2015) 5899.

**5:06PM V38.00012 Viscoelastic dynamics in a system of two actin filaments under stress**, ARJAN ERIK BOERMA, ERIK VAN DER GIESSEN, Univ of Groningen, STEFANOS PAPANIKOLAOU, Johns Hopkins University — The viscoelasticity of cytoskeleton networks is experimentally well-established but still lacks a consistent theoretical description. We present a novel minimal model that consists of two semi-flexible filaments coupled by cross-linkers, whose dynamics are described by Grand Canonical Monte Carlo. The mechanical properties are captured in the continuum and solved through an athermal finite-element approach. We discuss the phase diagram of the model and the emergence of viscoelastic behavior: the variation of the dynamic modulus as a function of loading frequency and density of cross-linkers, in thermodynamically and biologically realistic settings.

**5:18PM V38.00013 How to Concentrate Genomic Length DNA in a Microfabricated Array**, YU CHEN, Princeton University, EZRA ABRAMS, CHRISTIAN BOLES, Sage Science Inc., JONAS PEDERSEN, HENRIK FLYVBJERG, Danish Technical University, JAMES STURM, ROBERT AUSTIN, Princeton University — We demonstrate that a microfabricated bump array can concentrate genomic-length DNA molecules efficiently at continuous, high flow velocities, up to 40  $\mu\text{m/s}$ , if the single-molecule DNA globule has a sufficiently large shear modulus.. Increase in the shear modulus is accomplished by compacting the DNA molecules to minimal coil-size using polyethylene glycol (PEG) derived depletion forces. We map out the sweet spot where concentration occurs as a function of PEG concentration, flow speed, and bump array parameters using a combination of theoretical analysis and experiment. Purification of DNA from enzymatic reactions for next-generation DNA-sequencing libraries will be an important application of this development.

**2:30PM V39.00001 Self-Organized Information Processing in Neuronal Networks: Replacing Layers in Deep Networks by Dynamics**, CHRISTOPH KIRST, Rockefeller University — It is astonishing how the sub-parts of a brain co-act to produce coherent behavior. What are mechanism that coordinate information processing and communication and how can those be changed flexibly in order to cope with variable contexts? Here we show that when information is encoded in the deviations around a collective dynamical reference state of a recurrent network the propagation of these fluctuations is strongly dependent on precisely this underlying reference. Information here 'surfs' on top of the collective dynamics and switching between states enables fast and flexible rerouting of information. This in turn affects local processing and consequently changes in the global reference dynamics that re-regulate the distribution of information. This provides a generic mechanism for self-organized information processing as we demonstrate with an oscillatory Hopfield network that performs contextual pattern recognition. Deep neural networks have proven to be very successful recently. Here we show that generating information channels via collective reference dynamics can effectively compress a deep multi-layer architecture into a single layer making this mechanism a promising candidate for the organization of information processing in biological neuronal networks.

**2:42PM V39.00002 The learnability of critical distributions**, DAVID SCHWAB, Northwestern University, JOHANNAH TORRENCE, University of Chicago, GIACOMO TORLAI, ROGER MELKO, University of Waterloo, STEPHANIE PALMER, University of Chicago — Many biological systems, including some neural population codes, have been shown empirically to sit near a critical point. Here we study the learnability of such codes. We first construct networks of interacting binary neurons with random, sparse interactions (i.e. a Erdos-Renyi graph) of uniform strength. We then characterize the discriminability of those interactions from data samples by performing a direct coupling analysis and thresholding the direct information between each pair of neurons to predict the presence or absence of an interaction. By sweeping through threshold values, we compute the area under the ROC curve as a measure of discriminability of the interactions. We show that the resulting discriminability is maximized when the original distribution is at its critical point. We next trained deep neural networks to discriminate between samples drawn from two nearby temperatures in the 2D Ising model. We find distinct signatures of decoding performance in the vicinity of the critical point. This technique may be useful for detecting phase transitions in models without an a priori identified order parameter.

**2:54PM V39.00003 Machine learning phases of matter**, JUAN CARRASQUILLA, MILES SToudenMIRE, Perimeter Inst for Theo Phys, ROGER MELKO, Perimeter Inst for Theo Phys and University of Waterloo — We show how the technology that allows automatic teller machines read hand-written digits in cheques can be used to encode and recognize phases of matter and phase transitions in many-body systems. In particular, we analyze the (quasi-)order-disorder transitions in the classical Ising and XY models. Furthermore, we successfully use machine learning to study classical Z2 gauge theories that have important technological application in the coming wave of quantum information technologies and whose phase transitions have no conventional order parameter.

**3:06PM V39.00004 Using chaos to model random symbols for improved unsupervised information processing**<sup>1</sup>, SUMONA MUKHOPADHYAY<sup>2</sup>, HENRY LEUNG<sup>3</sup>, Department of Electrical and Computer Engineering, University of Calgary — We present theoretical analyses that may allow strengthening the connection between chaotic dynamical system and information processing. The analytical and empirical studies prove that computing with chaos and nonlinear characterization of information improves unsupervised information processing. Traditional supervised techniques for information retrieval from noisy environment achieve optimal performance. However, the need for training symbols is an inefficient strategy. We prove that with a chaotic generator as an information source, unsupervised performance is close to that of supervised with a white Gaussian stochastic process. Analytical results show that unsupervised technique using chaotic symbolic dynamics is equivalent to that of supervised when using random symbolic information. We conclude from the concepts of measure theory and ergodic theory, that random symbolic information can be modeled by a chaotic dynamical system via symbolic dynamics. We observe that the performance of unsupervised information retrieval is equivalent to that of supervised, when random symbolic information and a dynamical representation of it are used in conjunction. This fact enables to apply nonlinear dynamics to design improved communication systems.

**3:18PM V39.00005 Anatomy of a Spin: The Information-Theoretic Structure of Classical Spin Systems**, RYAN JAMES, VIKRAM VIJAYARAGHAVAN, JAMES CRUTCHFIELD, Univ of California - Davis — Collective organization in matter plays a significant role in its expressed physical properties. Typically, it is detected via an order parameter, appropriately defined for a given system's observed emergent patterns. Recent developments in information theory suggest how to quantify collective organization in a system- and phenomenon-agnostic way: decompose the system's thermodynamic entropy density into a localized entropy, that solely contained in the dynamics at a single location, and a bound entropy, that stored in space as domains, clusters, excitations, or other emergent structures. We compute this decomposition and related quantities explicitly for the nearest-neighbor Ising model on the 1D chain, the Bethe lattice with coordination number  $k = 3$ , and the 2D square lattice, illustrating its generality and the functional insights it gives near and away from phase transitions. In particular, we consider the roles that different spin motifs play (cluster bulk, cluster edges, and the like) and how these affect the dependencies between spins.

**3:30PM V39.00006 Global Characterization of Model Parameter Space Using Information Topology**, MARK TRANSTRUM, Brigham Young University — A generic parameterized model is a mapping between parameters and data and is naturally interpreted as a prediction manifold embedded in data space. In this interpretation, known as Information Geometry, the Fisher Information Matrix (FIM) is a Riemannian metric that measures the identifiability of the model parameters. Varying the experimental conditions (e.g., times at which measurements are made) alters both the FIM and the geometric properties of the model. However, several global features of the model manifold (e.g., edges and corners) are invariant to changes in experimental conditions as long as the FIM is not singular. Invariance of these features to changing experimental conditions generates an "Information Topology" that globally characterizes a model's parameter space and reflects the underlying physical principles from which the model was derived. Understanding a model's information topology can give insights into the emergent physics that controls a system's collective behavior, identify reduced models and describe the relationship among them, and determine which parameter combinations will be difficult to identify for various experimental conditions.

**3:42PM V39.00007 Statistical Physics of High Dimensional Inference**<sup>1</sup>, MADHU ADVANI, SURYA GANGULI, Stanford University — To model modern large-scale datasets, we need efficient algorithms to infer a set of  $P$  unknown model parameters from  $N$  noisy measurements. What are fundamental limits on the accuracy of parameter inference, given limited measurements, signal-to-noise ratios, prior information, and computational tractability requirements? How can we combine prior information with measurements to achieve these limits? Classical statistics gives incisive answers to these questions as the measurement density  $\alpha = \frac{N}{P} \rightarrow \infty$ . However, modern high-dimensional inference problems, in fields ranging from bio-informatics to economics, occur at finite  $\alpha$ . We formulate and analyze high-dimensional inference analytically by applying the replica and cavity methods of statistical physics where data serves as quenched disorder and inferred parameters play the role of thermal degrees of freedom. Our analysis reveals that widely cherished Bayesian inference algorithms such as maximum likelihood and maximum a posteriori are suboptimal in the modern setting, and yields new tractable, optimal algorithms to replace them as well as novel bounds on the achievable accuracy of a large class of high-dimensional inference algorithms.

**3:54PM V39.00008 Compression and regularization with the information bottleneck**, DJ STROUSE, Princeton University, DAVID SCHWAB, Northwestern University — Compression fundamentally involves a decision about what is relevant and what is not. The information bottleneck (IB) by Tishby, Pereira, and Bialek formalized this notion as an information-theoretic optimization problem and proposed an optimal tradeoff between throwing away as many bits as possible, and selectively keeping those that are most important. The IB has also recently been proposed as a theory of sensory gating and predictive computation in the retina by Palmer et al. Here, we introduce an alternative formulation of the IB, the deterministic information bottleneck (DIB), that we argue better captures the notion of compression, including that done by the brain. As suggested by its name, the solution to the DIB problem is a deterministic encoder, as opposed to the stochastic encoder that is optimal under the IB. We then compare the IB and DIB on synthetic data, showing that the IB and DIB perform similarly in terms of the IB cost function, but that the DIB vastly outperforms the IB in terms of the DIB cost function. Our derivation of the DIB also provides a family of models which interpolates between the DIB and IB by adding noise of a particular form. We discuss the role of this noise as a regularizer.

**4:06PM V39.00009 A novel method for the precise determination of step times and sizes in counting large numbers of photobleaching events** , KONSTANTINOS TSEKOURAS, STEVE PRESSE, Indiana University - Purdue University Indianapolis — Counting of photobleaching steps is of importance in the investigation of many open problems in biophysics. Current methods of counting photo- bleaching steps cannot directly account for fluorophore photophysical behaviors such as fluorophore self-quenching, blinking and flickering. Our Bayesian approach to the counting problem allows for fluorophore blinking and reactivation as well as for multiple simultaneous photobleaching events and is neither computational resource- nor time- heavy. We detail the methods applicability and limitations and present examples of application in photobleach event counting.

**4:18PM V39.00010 Assessing the limits of hidden Markov model analysis for multi-state particle tracks in living systems** , DYLAN YOUNG, Clarkson Univ — Particle tracking offers significant insight into the molecular mechanics that govern the behavior of living cells. The analysis of molecular trajectories that transition between different motive states, such as diffusive, driven and tethered modes, is of considerable importance, with even single trajectories containing significant amounts of information about a molecule's environment and its interactions with cellular structures such as the cell cytoskeleton, membrane or extracellular matrix. Hidden Markov models (HMM) have been widely adopted to perform the segmentation of such complex tracks, however robust methods for failure detection are required when HMMs are applied to individual particle tracks and limited data sets. Here, we show that extensive analysis of hidden Markov model outputs using data derived from multi-state Brownian dynamics simulations can be used for both the optimization of likelihood models, and also to generate custom failure tests based on a modified Bayesian Information Criterion. In the first instance, these failure tests can be applied to assess the quality of the HMM results. In addition, they provide critical information for the successful design of particle tracking experiments where trajectories containing multiple mobile states are expected.

**4:30PM V39.00011 Inferring phenomenological models of Markov processes from data<sup>1</sup>** , CATALINA RIVERA, ILYA NEMENMAN, Emory Univ — Microscopically accurate modeling of stochastic dynamics of biochemical networks is hard due to the extremely high dimensionality of the state space of such networks. Here we propose an algorithm for inference of phenomenological, coarse-grained models of Markov processes describing the network dynamics directly from data, without the intermediate step of microscopically accurate modeling. The approach relies on the linear nature of the Chemical Master Equation and uses Bayesian Model Selection for identification of parsimonious models that fit the data. When applied to synthetic data from the Kinetic Proofreading process (KPR), a common mechanism used by cells for increasing specificity of molecular assembly, the algorithm successfully uncovers the known coarse-grained description of the process. This phenomenological description has been noticed previously, but this time it is derived in an automated manner by the algorithm.

**4:42PM V39.00012 Probing self similar structures by studying the frequency of directional changes<sup>1</sup>** , ALI TABELI, University of Northern Iowa, STANISLAV BUROV, Bar Ilan University, ANDREW MILBRANDT, KYLE SPURGEON, University of Northern Iowa — It has been shown that in two and higher dimension, when the time series of individual particle trajectories exist, the distribution of relative angles of motion between successive time intervals of random motions provides information about stochastic processes, which is beyond the information obtained from studying mean squared displacement. We show that this distribution is a useful measure, which provides supplementary information about the structural properties of the media that a random walker is diffusing. We compare the behavior of this measure for common self-similar structures. We show that the distribution of relative angles is a good measure to discriminate different complex structural geometries.

**4:54PM V39.00013 Diffusion, Backward In Time: A Universal Inversion Scheme** , DERVIS VURAL, VU NGUYEN, University of Notre Dame — A sugar cube placed in a cup of tea will erode and eventually dissolve. Given the initial shape of the sugar block, it is trivial to predict its final distribution. However, the opposite problem of determining the initial state, given a final one is extremely difficult. A surprising number of seemingly unrelated topics in biology are the same one in disguise: Inverting diffusion on a network. Here we present a method that will identify the origin of a stochastic biological diffusion process, regardless of the forward model. We will then discuss potential implications to evolution, neuroscience, aging biology, and epidemiology.

**5:06PM V39.00014 Inferring biological dynamics in heterogeneous cellular environments** , STEVE PRESS, IUPUI — In complex environments, it often appears that biomolecules such as proteins do not diffuse normally. That is, their mean square displacement does not scale linearly with time. This anomalous diffusion happens for multiple reasons: proteins can bind to structures and other proteins; fluorophores used to label proteins may flicker or blink making it appear that the labeled protein is diffusing anomalously; and proteins can diffuse in differently crowded environments. Here we describe methods for learning about such processes from imaging data collected inside the heterogeneous environment of the living cell. "A data-driven alternative to the fractional Fokker-Planck equation" Steve Press\*, J. Stat. Phys.: Th. and Exptl. , P07009 (2015).

**5:18PM V39.00015 Discovering cell types in flow cytometry data with random matrix theory** , YANG SHEN, Chemical Physics Graduate Program, University of Maryland, ROBERT NUSSENBLATT, Laboratory of Immunology, National Eye Institute, National Institutes of Health, WOLFGANG LOSERT<sup>1</sup>, Chemical Physics Graduate Program, University of Maryland — Flow cytometry is a widely used experimental technique in immunology research. During the experiments, peripheral blood mononuclear cells (PBMC) from a single patient, labeled with multiple fluorescent stains that bind to different proteins, are illuminated by a laser. The intensity of each stain on a single cell is recorded and reflects the amount of protein expressed by that cell. The data analysis focuses on identifying specific cell types related to a disease. Different cell types can be identified by the type and amount of protein they express. To date, this has most often been done manually by labelling a protein as expressed or not while ignoring the amount of expression. Using a cross correlation matrix of stain intensities, which contains both information on the proteins expressed and their amount, has been largely ignored by researchers as it suffers from measurement noise. Here we present an algorithm to identify cell types in flow cytometry data which uses random matrix theory (RMT) to reduce noise in a cross correlation matrix. We demonstrate our method using a published flow cytometry data set. Compared with previous analysis techniques, we were able to rediscover relevant cell types in an automatic way.

**2:30PM V40.00001 Geometric mechanics for modelling bioinspired robots locomotion: from rigid to continuous (soft) systems**, FREDERIC BOYER, MATHIEU POREZ, Ecole des Mines de Nantes, FEDERICO RENDA, Khalifa University — This talk presents recent geometric tools developed to model the locomotion dynamics of bio-inspired robots. Starting from the model of discrete rigid multibody systems we will rapidly shift to the case of continuous systems inspired from snakes and fish. To that end, we will build on the model of Cosserat media. This extended picture of geometric locomotion dynamics (inspired from fields' theory) will allow us to introduce models of swimming recently used in biorobotics. We will show how modeling a fish as a one-dimensional Cosserat medium allows to recover and extend the Large Amplitude Elongated Body theory of J. Lighthill and to apply it to an eel-like robot. In the same vein, modeling the mantle of cephalopods as a two dimensional Cosserat medium will build a basis for studying the jet propelling of a soft octopus like robot.

**2:42PM V40.00002 Geometric Mechanics Reveals Optimal Complex Terrestrial Undulation Patterns**, CHAOHUI GONG, Carnegie Mellon University, HENRY ASTLEY, PERRIN SCHIEBEL, Georgia Institute of Technology, JIN DAI, MATTHEW TRAVERS, Carnegie Mellon University, DANIEL GOLDMAN, Georgia Institute of Technology, HOWIE CHOSSET, Carnegie Mellon University, CMU TEAM, GT TEAM — Geometric mechanics offers useful tools for intuitively analyzing biological and robotic locomotion. However, utility of these tools were previously restricted to systems that have only two internal degrees of freedom and in uniform media. We show kinematics of complex locomotors that make intermittent contacts with substrates can be approximated as a linear combination of two shape bases, and can be represented using two variables. Therefore, the tools of geometric mechanics can be used to analyze motions of locomotors with many degrees of freedom. To demonstrate the proposed technique, we present studies on two different types of snake gaits which utilize combinations of waves in the horizontal and vertical planes: sidewinding (in the sidewinder rattlesnake *C. cerastes*) and lateral undulation (in the desert specialist snake *C. occipitalis*). *C. cerastes* moves by generating posteriorly traveling body waves in the horizontal and vertical directions, with a relative phase offset equal to  $\pm \frac{\pi}{2}$  while *C. occipitalis* maintains a  $\frac{\pi}{2}$  offset of a frequency doubled vertical wave. Geometric analysis reveals these coordination patterns enable optimal movement in the two different styles of undulatory terrestrial locomotion. More broadly, these examples demonstrate the utility of geometric mechanics in analyzing realistic biological and robotic locomotion.

**2:54PM V40.00003 Optimal bipedal interactions with dynamic terrain: synthesis and analysis via nonlinear programming**, CHRISTIAN HUBICKI, DANIEL GOLDMAN, AARON AMES, Georgia Institute of Technology — In terrestrial locomotion, gait dynamics and motor control behaviors are tuned to interact efficiently and stably with the dynamics of the terrain (i.e. terradynamics). This controlled interaction must be particularly thoughtful in bipeds, as their reduced contact points render them highly susceptible to falls. While bipedalism under rigid terrain assumptions is well-studied, insights for two-legged locomotion on soft terrain, such as sand and dirt, are comparatively sparse. We seek an understanding of how biological bipeds stably and economically negotiate granular media, with an eye toward imbuing those abilities in bipedal robots. We present a trajectory optimization method for controlled systems subject to granular intrusion. By formulating a large-scale nonlinear program (NLP) with reduced-order resistive force theory (RFT) models and jamming cone dynamics, the optimized motions are informed and shaped by the dynamics of the terrain. Using a variant of direct collocation methods, we can express all optimization objectives and constraints in closed-form, resulting in rapid solving by standard NLP solvers, such as IPOPT. We employ this tool to analyze emergent features of bipedal locomotion in granular media, with an eye toward robotic implementation.

**3:06PM V40.00004 Geometric Mechanics for Continuous Swimmers on Granular Material**, JIN DAI, Carnegie Mellon Univ, HOSSEIN FARAJI, Oregon State University, PERRIN SCHIEBEL, Georgia Institute of Technology, CHAOHUI GONG, MATTHEW TRAVERS, Carnegie Mellon Univ, ROSS HATTON, Oregon State University, DANIEL GOLDMAN, Georgia Institute of Technology, HOWIE CHOSSET, Carnegie Mellon Univ, THE BIOROBOTICS LAB COLLABORATION, LABORATORY FOR ROBOTICS AND APPLIED MECHANICS (LRAM) COLLABORATION, COMPLEX RHEOLOGY AND BIOMECHANICS LAB COLLABORATION — Animal experiments have shown that *Chionactis occipitalis* (N=10) effectively undulating on granular substrates exhibits a particular set of waveforms which can be approximated by a sinusoidal variation in curvature, i.e., a serpenoid wave. Furthermore, all snakes tested used a narrow subset of all available waveform parameters, measured as the relative curvature equal to 5.00.3, and number of waves on the body equal to 1.80.1. We hypothesize that the serpenoid wave of a particular choice of parameters offers distinct benefit for locomotion on granular material. To test this hypothesis, we used a physical model (snake robot) to empirically explore the space of serpenoid motions, which is linearly spanned with two independent continuous serpenoid basis functions. The empirically derived height function map, which is a geometric mechanics tool for analyzing movements of cyclic gaits, showed that displacement per gait cycle increases with amplitude at small amplitudes, but reaches a peak value of 0.55 body-lengths at relative curvature equal to 6.0. This work signifies that with shape basis functions, geometric mechanics tools can be extended for continuous swimmers.

**3:18PM V40.00005 A Cosserat-based formulation for elastic, axisymmetric shells with implications to the pulsed-jetting propulsion of soft-bodied aquatic vehicles**, FEDERICO RENDA, Khalifa University Robotics Institute, Khalifa University, FRANCESCO GIORGIO-SERCHI, Southampton Marine and Maritime Institute, University of Southampton, FREDERIC BOYER<sup>1</sup>, Institut de Recherche en Communication et Cybernetique de Nantes, Ecole des Mines de Nantes — We take the cue from recent development in geometric-based modelling in order to describe the dynamics of a novel soft-structured aquatic vehicle. The Cosserat-like formulation for an axisymmetric, elastic shell subject to concentrated dynamic loadings lends itself to the case of this new vehicle, recently designed by the authors, which consists of a shell of rubber-like materials undergoing sequential stages of inflation and deflation in order to propel itself in water via pulsed-jetting. The experiments performed on the existing robotic prototypes are used for the validation of the geometric model. This is eventually employed for deriving an accurate measure of the efficiency of propulsion which explicitly accounts for the elastic energy involved during the propulsion routine. The model yields a-priori estimations of swimming efficiency based on vehicle specifications and mode of actuation. These provide invaluable information for both design optimization and control, as well as a means to study the biomechanics of soft-bodied aquatic organisms.

<sup>1</sup>Presenting author

**3:30PM V40.00006 Reverse engineering the euglenoid movement: from unicellular swimmers to bio-inspired robots.**<sup>1</sup>, ANTONIO DESIMONE, GIOVANNI NOSELLI, SISSA-International School for Advanced Studies, MARINO ARROYO, Universitat Politècnica de Catalunya — Euglenids are unicellular organisms living in freshwater, which are capable of moving either by beating a flagellum, or by executing dramatic shape changes. These are accomplished thanks to a complex structure made of interlocking pellicle strips, microtubules, and motor proteins. Relative sliding of the pellicle strips, suitably orchestrated, can cause the propagation of a bulge along the body, hence generating a propulsive force. We study the mechanisms by which the sliding of pellicle strips leads to shape control and locomotion, by means of both theory (through the mechanics of active surfaces and its coupling to computational fluid dynamics for the surrounding fluid) and experimental observations. Moreover, we implement them into a new concept of a surface with programmable shape, obtained by assembling 3d-printed strips in a construct mimicking the biological template. We explore the range of possible geometries achievable by actuating these surfaces, to assess their potential in soft robotics applications. The subtle balance between constraints and flexibility leads to a wide variety of shapes that can be obtained with relatively simple controls, similar to the notion of morphological computation in biological systems.

### **3:42PM V40.00007 Robotics and Biology: Lets get Physical** , HOWIE CHOSET, Carnegie Mellon University —

Our research group investigates the core fundamentals of locomotion as it exists in biology and as it applies to locomoting robotic systems. Initially, our work advanced techniques found in geometric mechanics to design cyclic controllers, often called gaits, for snake robots, highly articulated mechanisms that can thread through tightly packed spaces to access locations people cannot. We had considerable success in designing snake robot gaits, but found our systems stymied in terrains characterized by sandy substrates. Sandy terrains and other granular media pose a challenge to snake robots because it is unclear how the mechanism interacts with environment: we cannot simply assume the robot is on hard-ground nor in a fluid. Simulating granular interactions can prove to be computationally intractable for real-time use on the robots. Therefore, we developed experimental tools that allowed us to sieve out models of the locomoting systems operating on granular media. We were then able to bring these models into harmony with the elegant formulation of our geometric mechanics approach. This allowed us to derive adaptive controllers for our snake robots in sandy terrains, and enabled us to gain deeper insight into of how biological systems move over similar terrains as well.

### **4:18PM V40.00008 Bio-inspired robot design for viscous fluids** , GRACE MA, TYLER LIPMAN, SUNGHWAN

JUNG, Virginia Tech — Many modern micro-robots are designed for biomedical applications to transport drugs to targets or to operate tests in the body for diagnosis. However, most micro-robots simply mimic the morphology and the propulsive mechanism of micro-organisms without understanding the underlying physics of low-Re swimming. Two types of swimming motions have been observed in micro-organisms; stresslet and source-dipole swimming. The stresslet swimmer (e.g. *E. coli*) uses a rotating helical appendage, whereas the source-dipole swimmer (e.g. *Paramecium*) creates surface velocity for propulsion. Using this principle, we designed a robot to swim in very viscous fluids either by rotating a helix or creating surface velocity, simply by changing the orientation of the appendage. Further, we will discuss the performance of this robot (swimming speed and rotation speed) with respect to the number, winding angle, and radius of helices in a very viscous fluid.

### **4:30PM V40.00009 A microfluidic two-pump system inspired by liquid feeding in mosquitoes**

, ANDREW MARINO, Virginia Tech, ANGELA GOAD, Carroll County High School, MARK STREMLER, JOHN SOCHA, SUNGHWAN JUNG, Virginia Tech — Mosquitoes feed on nectar and blood using a two-pump system in the head—a smaller cibarial pump in line with a larger a pharyngeal pump, with a valve in between. To suck, mosquitoes transport the liquid (which may be a multi-component viscous fluid, blood) through a long micro-channel, the proboscis. In the engineering realm, microfluidic devices in biomedical applications, such as lab-on-a-chip technology, necessitate implementing a robust pump design to handle clogging and increase flow control compared to a single-pump system. In this talk, we introduce a microfluidic pump design inspired by the mosquito's two-pump system. The pumping performance (flow rate) in presence of impurities (air bubbles, soft clogs) is quantified as a function of phase difference and volume expansion of the pumps, and the elasticity of the valve.

### **4:42PM V40.00010 Propulsion of a two-sphere swimmer** , DAPHNE KLOTS, Department of Applied and Physical

Sciences, University of North Carolina at Chapel Hill, KYLE BALDWIN, RICHARD HILL, ROGER BOWLEY, MICHAEL SWIFT, School of Physics and Astronomy, University of Nottingham, UK — We describe experiments and simulations demonstrating the propulsion of a neutrally-buoyant macroscopic swimming robot that consists of a pair of spheres attached by a spring, immersed in a vibrating fluid. The vibration of the fluid induces relative motion of the spheres which, for sufficiently large amplitudes, can lead to motion of the center of mass of the two spheres. We find that the swimming speed obtained from both experiment and simulation agree and collapse onto a single curve if plotted as a function of the streaming Reynolds number, suggesting that the propulsion is related to streaming flows. There appears to be a critical onset value of the streaming Reynolds number for swimming to occur. We observe a change in the streaming flows as the Reynolds number increases, from that generated by two independent oscillating spheres to a collective flow pattern around the swimmer as a whole. The mechanism for swimming is traced to a strengthening of a jet of fluid in the wake of the swimmer.

### **4:54PM V40.00011 Microstructural view of burrowing with a bioinspired digging robot** , KERSTIN

NORDSTROM, Mount Holyoke College, DAN DORSCH, Massachusetts Institute of Technology, WOLFGANG LOSERT, University of Maryland, AMOS WINTER, V, Massachusetts Institute of Technology — RoboClam is a burrowing technology inspired by *Ensis directus*, the Atlantic razor clam. Atlantic razor clams should only be strong enough to dig a few centimeters into the soil, yet they burrow to over 70 cm. The animal uses a clever trick to achieve this: by contracting its body, it agitates and locally fluidizes the soil, reducing the drag and energetic cost of burrowing. RoboClam technology, which is based on the digging mechanics of razor clams, may be valuable for subsea applications that could benefit from efficient burrowing, such as anchoring, mine detonation, and cable laying. We directly visualize the movement of soil grains during the contraction of RoboClam, using a novel index-matching technique along with particle tracking. We show that the size of the failure zone around contracting RoboClam can be theoretically predicted from the substrate and pore fluid properties, provided that the timescale of contraction is sufficiently large. We also show that the nonaffine motions of the grains are a small fraction of the motion within the fluidized zone, affirming the relevance of a continuum model for this system, even though the grain size is comparable to the size of RoboClam.

### **5:06PM V40.00012 Bipedal locomotion in granular media** , MARK KINGSBURY, TINGNAN ZHANG, DANIEL

GOLDMAN, Georgia Inst of Tech — Bipedal walking, locomotion characterized by alternating swing and double support phase, is well studied on ground where feet do not penetrate the substrate. On granular media like sand however, intrusion and extrusion phases also occur. In these phases, relative motion of the two feet requires that one or both feet slip through the material, degrading performance. To study walking in these phases, we designed and studied a planarized bipedal robot (1.6 kg, 42 cm) that walked in a fluidized bed of poppy seeds. We also simulated the robot in a multibody software environment (Chrono) using granular resistive force theory (RFT) to calculate foot forces. In experiment and simulation, the robot experienced slip during the intrusion phase, with the experiment presenting additional slip due to motor control error during the double support phase. This exaggerated slip gave insight (through analysis of ground reaction forces in simulation) into how slip occurs when relative motion exists between the two feet in the granular media, where the foot with higher relative drag forces (from its instantaneous orientation, rotation, relative direction of motion, and depth) remains stationary. With this relationship, we generated walking gaits for the robot to walk with minimal slip.

### **5:18PM V40.00013 Obstacle traversal and self-righting of bio-inspired robots reveal the physics of multi-modal locomotion** , CHEN LI, RONALD FEARING, ROBERT FULL, University of California, Berkeley —

Most animals move in nature in a variety of locomotor modes. For example, to traverse obstacles like dense vegetation, cockroaches can climb over, push across, reorient their bodies to maneuver through slits, or even transition among these modes forming diverse locomotor pathways; if flipped over, they can also self-right using wings or legs to generate body pitch or roll. By contrast, most locomotion studies have focused on a single mode such as running, walking, or jumping, and robots are still far from capable of life-like, robust, multi-modal locomotion in the real world. Here, we present two recent studies using bio-inspired robots, together with new locomotion energy landscapes derived from locomotor-environment interaction physics, to begin to understand the physics of multi-modal locomotion. (1) Our experiment of a cockroach-inspired legged robot traversing grass-like beam obstacles reveals that, with a terradynamically “streamlined” rounded body like that of the insect, robot traversal becomes more probable by accessing locomotor pathways that overcome lower potential energy barriers. (2) Our experiment of a cockroach-inspired self-righting robot further suggests that body vibrations are crucial for exploring locomotion energy landscapes and reaching lower barrier pathways. Finally, we posit that our new framework of locomotion energy landscapes holds promise to better understand and predict multi-modal biological and robotic movement.

**5:30PM V40.00014 Swarming Bristle-Bots: Exploring Properties of Active Matter** , MARTIN B. FORSTNER, DAMIAN BEASOCK, Syracuse University — Active Matter describes an ubiquitous class of non-equilibrium systems that encompasses a diverse range of phenomena in the living and non-living realm. Examples are microscopic bio-filaments and their associated motor proteins, flocks of birds and fish, vibrated rods and disks, or nanoscale colloids actuated by catalytic activity on their surface. What unifies these systems is that they are all composed of self-driven units. In consequence, these systems are not driven into non-equilibrium by energy input at their boundary, but by local energy injection. As fascinating as these systems are, there are currently barely any laboratory systems that allow for controlled experiments in dry active matter. That is, systems not immersed in a fluid that can be observed without specialized equipment. Here we present a two-dimensional 'active matter' system consisting of hundreds of macroscopic (~0.05 m long), modified, commercially available bristle-bots. We show that this swarm of toys classifies as active matter as it exhibits properties such as dynamic phase separation. Because of their straight forward implementation, their size and controllability, such swarms can not only answer scientific questions, but they have great potential as educational tools in teaching labs and classrooms.

**Session V41 DBIO DPOLY DCOMP: Physics of Proteins: Mechanics and Forces** 344 - Tom Chou,  
University of California, Los Angeles

**2:30PM V41.00001 Rationally designing the mechanical properties of protein hydrogels** , YI CAO, Nanjing University — Naturally occurring biomaterials possess diverse mechanical properties, which are critical to their unique biological functions. However, it remains challenging to rationally control the mechanical properties of synthetic biomaterials. Here we provide a bottom-up approach to rationally design the mechanical properties of protein-based hydrogels. We first use atomic force microscope (AFM) based single-molecule force spectroscopy to characterize the mechanical stability of individual protein building blocks. We then rationally design the mechanical properties of hydrogels by selecting different combination of protein building blocks of known mechanical properties. As a proof-of-principle, we demonstrate the engineering of hydrogels of distinct extensibility and toughness. This simple combinatorial approach allows direct translation of the mechanical properties of proteins from the single molecule level to the macroscopic level and represents an important step towards rationally designing the mechanical properties of biomaterials.

**3:06PM V41.00002 Nonlinear elasticity of disordered fiber networks** , JINGCHEN FENG, Bioengineering Department and Center for Theoretical Biological Physics, Rice University, Houston TX, 77251-1892, USA., HERBERT LEVINE, Bioengineering Department and Center for Theoretical Biological Physics, Rice University, Houston TX, 77251-1892, USA, XIAOMING MAO, Department of Physics, University of Michigan, Ann Arbor MI 48109-1040, USA., LEONARD M. SANDER, Physics & Complex Systems, University of Michigan, Ann Arbor MI 48109-1040, USA. — One of the most striking mechanical properties in disordered biopolymer gels is strong nonlinearities. In the case of athermal gels (such as collagen- I) the nonlinearity has long been associated with a crossover from a bending dominated to a stretching dominated regime of elasticity. The physics of this crossover is related to the existence of a central-force isostatic point and to the small bending modulus for most gels. This crossover induces scaling behavior for the elastic moduli. In particular, for linear elasticity such a scaling law has been demonstrated by Broedersz et al. We generalize the scaling to the nonlinear regime with a two-parameter scaling law involving three critical exponents. We do numerical testing of the scaling law for two disordered lattice models, and find a good scaling collapse for the shear modulus in both the linear and nonlinear regimes. We compute all the critical exponents for the two lattice models and discuss the applicability of our results to real systems.

**3:18PM V41.00003 Mechanosensing by tethered membrane channels** , BENEDIKT SABASS, HOWARD A. STONE, Mechanical and Aerospace Engineering, Princeton University — Force-gated membrane channels are a paradigm of biological mechanosensing. These channels are often tethered to cytoskeletal elements, which allows direct transmission of the mechanical signal. How force at tethers leads to channel opening is unknown. Here, we focus on the generic role of membrane-channel interaction for gating. We propose a scaling relation, linking protein deformation under force to membrane energy. A minute conical deformation during gating leads to an elastic energy gain that far exceeds the thermal energy. Force thresholds for gating are in the experimentally inferred range and are robust against changes of membrane tension. We also study a detailed model for membrane-mediated interactions among channels. In general, interactions reduce the force threshold, leading to cooperatively enhanced gating.

**3:30PM V41.00004 Group transfer theory of single molecule imaging experiments in the F-ATPase biomolecular motor** , SANDOR VOLKAN-KACSO, RUDOLPH MARCUS, California Institute of Technology — I describe a chemo-mechanical theory to treat single molecule imaging and "stalling" experiments on the F-ATPase enzyme. This enzyme is an effective stepping biomolecular rotary motor with a rotor shaft and a stator ring. Using group transfer theoretical approach the proposed structure-based theory couples the binding transition of nucleotides in the stator subunits and the physics of torsional elasticity in the rotor. The twisting of the elastic rotor domain acts as a perturbation upon the driving potential, the Gibbs free energy. In the theory, without the use of adjustable parameters, we predict the rate and equilibrium constant dependence of steps such as ATP binding and phosphate release as a function of manipulated rotor angle. Then we compare these predictions to available data from stalling experiments. Besides treating experiments, the theory can provide guides for atomistic simulations, which could calculate the reorganization parameter and the torsional spring constant. The framework is generic and I discuss its application to other single molecule experiments, such as controlled rotation and other biomolecular motors, including motor-DNA complexes and linear motors.[PNAS, Early Edition, Oct. 19, 2015, doi: 10.1073/pnas.1518489112]

**3:42PM V41.00005 Fluorescent ATP analog mant-ATP reports dynein activity in the isolated *Chlamydomonas* axoneme** , MARIA FEOFILOVA, JONATHON HOWARD, Yale University — Eukaryotic flagella are long rod-like extensions of cells, which play a fundamental role in single cell movement, as well as in fluid transport. Flagella contain a highly evolutionary conserved mechanical structure called the axoneme. The motion of the flagellum is generated by dynein motor proteins located all along the length of the axoneme. How the force production of motors is controlled spatially and temporally is still an open question. Therefore, monitoring dynein activity in the axonemal structure is expected to provide novel insights in regulation of the beat. We use high sensitivity fluorescence microscopy to monitor the binding and hydrolysis kinetics of the fluorescently labeled ATP analogue mant-ATP (2'-(3')-O-(N-methylanthraniloyl) adenosine 5'-triphosphate), which is known to support dynein activity. By studying the kinetics of mant-ATP fluorescence, we identified distinct mant-ATP binding sites in the axoneme. The application of this method to axonemes with reduced amounts of dynein, showed evidence that one of the sites is associated with binding to dynein. In the future, we would like to use this method to find the spatial distribution of dynein activity in the axoneme.

**3:54PM V41.00006 Limiting Speed of the Bacterial Flagellar Motor** , JASMINE NIRODY, University of California, Berkeley, RICHARD BERRY, University of Oxford, GEORGE OSTER, University of California, Berkeley — The bacterial flagellar motor (BFM) drives swimming in a wide variety of bacterial species, making it crucial for several fundamental biological processes including chemotaxis and community formation. Recent experiments have shown that the structure of this nanomachine is more dynamic than previously believed. Specifically, the number of active torque-generating units (stators) was shown to vary across applied loads. This finding invalidates the experimental evidence reporting that limiting (zero-torque) speed is independent of the number of active stators. Here, we put forward a model for the torque generation mechanism of this motor and propose that the maximum speed of the motor increases as additional torque-generators are recruited. This is contrary to the current widely-held belief that there is a universal upper limit to the speed of the BFM. Our result arises from the assumption that stators disengage from the motor for a significant portion of their mechanochemical cycles at low loads. We show that this assumption is consistent with current experimental evidence and consolidate our predictions with arguments that a processive motor must have a high duty ratio at high loads.

**4:06PM V41.00007 A mechanochemical model for myosin VI**, RIINA TEHVER, AMANDA JACK, Denison University, IAN LOWE, University of Pennsylvania — Myosin VI is a motor protein that transports cellular cargo along actin filaments. This transport takes place as a result of a coordinated mechano-chemical cycle that is controlled by external variables including imposed force and nucleotide concentrations. We present a model that captures the different dynamic pathways that myosin VI can take in response to these variables. The results of our model for experimentally observable quantities, such as the motor velocity or run length, agree with available experimental data, and we can also make predictions beyond the tested regimes. Using the model, we study how myosin VI reacts to its environment and test its operational efficiency.

**4:18PM V41.00008 Talin mediated force transmission and mechanosensing<sup>1</sup>**, JIE YAN, Department of Physics and Mechanobiology Institute, Natl Univ of Singapore, MINGXI YAO, Mechanobiology Institute, Natl Univ of Singapore, BENJAMIN GOULT, School of Biosciences, University of Kent, UK, MICHAEL SHEETZ, Department of Biological Sciences, Columbia University; Mechanobiology Institute, Natl Univ of Singapore — Cells adhere to extracellular matrix (ECM) through focal adhesion. Talin is a cytoplasmic adapter protein that links the actin cytoskeleton to focal adhesion, playing a central role in regulation of cell spreading and migration. Talin's functions depend on the binding of talin rod domains to a cytoplasmic protein vinculin in a force dependent manner. By stretching full-length talin rod using magnetic tweezers, we have determined the force-dependent unfolding and refolding rates of subdomains in talin rod. Kinetics simulations based on these rates have revealed that talin rod can serve as a force buffer, capable of maintaining tension in talin in a range of 5-10 pN over a wide range of extension change of talin rod from 50 nm to 400 nm. Further, this level of force is found able to expose the cryptic vinculin-binding sites, promoting subsequent binding of the head domain of vinculin with a nano Molar affinity. Such a force-sensitive interaction between talin rod and vinculin is described by a force-dependent dissociation constant derived based on the mechanical stability of the talin rod domains. Together, these results provide important insights into the mechanosensing at focal adhesion that is crucial for cells to sense and respond to their microenvironments.

**4:30PM V41.00009 Directly measuring single molecule heterogeneity in proteins and RNA using force spectroscopy**, MICHAEL HINCZEWSKI, Case Western Reserve University, CHANGBONG HYEON, Korea Institute for Advanced Study, DEVARAJAN THIRUMALAI, Institute For Physical Science and Technology, University of Maryland, College Park — One of the most intriguing results of single molecule experiments on proteins and nucleic acids is the discovery of functional heterogeneity: the observation that complex cellular machines exhibit multiple, biologically active conformations. The structural differences between these conformations may be subtle, but each distinct state can be remarkably long-lived, with stochastic interconversions occurring only at macroscopic timescales, fractions of a second or longer. Though we now have proof of functional heterogeneity in a handful of systems—enzymes, motors, adhesion complexes—identifying and measuring it remains a formidable challenge. We show that evidence of this phenomenon is more widespread than previously known, encoded in data collected from some of the most well-established single molecule techniques: AFM or optical tweezer pulling experiments. We present a theoretical procedure for analyzing distributions of rupture/unfolding forces recorded at different pulling speeds. This results in a single parameter, quantifying the degree of heterogeneity, and also leads to bounds on the equilibration and conformational interconversion timescales. Our work suggests experimental approaches for estimating the timescales of these fluctuations with unprecedented accuracy.

**4:42PM V41.00010 Bayesian Uncertainty Quantification for Bond Energies and Mobilities Using Path Integral Analysis**, PAK-WING FOK, University of Delaware, JOSHUA CHANG, Ohio State University, TOM CHOU, UCLA, UCLA-OSU-UD BIOMATH GROUP COLLABORATION — Dynamic single-molecule force spectroscopy is often used to distort bonds. The resulting responses, in the form of rupture forces and trajectories of displacements, are used to reconstruct bond potentials. Such approaches often rely on simple parameterizations of one-dimensional bond potentials and/or large amounts of trajectory data. Parametric approaches typically fail at inferring complicated bond potentials with multiple minima, while piecewise estimation may not guarantee smooth results. Existing techniques also do not address spatial variations in the diffusivity that may arise from inhomogeneous coupling to other degrees of freedom in the macromolecule. To address these challenges, we develop an empirical Bayesian approach that incorporates data and regularization terms into a path integral. All experimental and statistical parameters in our method are estimated from the data. Upon testing our method on simulated data, our regularized approach requires less data and allows simultaneous inference of both complex bond potentials and diffusivities. We show that the accuracy of the reconstructed bond potential is sensitive to the spatially varying diffusivity and accurate reconstruction can be expected only when both are simultaneously inferred.

**4:54PM V41.00011 Base-by-Base Counting of Nucleotide Incorporations by DNA Polymerase**, MACKENZIE W. TURVEY, O. TOLGA GUL, KAITLIN M. PUGLIESE, DENYS O. MARUSHCHAK, ARITH J. RAJAPAKSE, GREGORY A. WEISS, PHILLIP G. COLLINS, University of California, Irvine — Previously, the catalytic cycle of DNA polymerase has been recorded by tethering single polymerase molecules to single-walled carbon nanotube field effect transistors (FETs) [1]. As the polymerase incorporates nucleotides into a single-stranded DNA template, it generates electrical signals in the SWCNT-FET. Here, we investigate the accuracy of this electronic method by using low concentrations (<10 nM) of DNA template, such that the signal consists of long, diffusion-limited pauses interrupted by template binding and a burst of nucleotide incorporation events. By counting the events generated by as few as 10 template molecules, template length has been correctly determined with <1 base pair resolution. Furthermore, differing template lengths can be identified and correctly enumerated in solutions containing mixtures of templates. Processivity of the Klenow Fragment of DNA polymerase currently limits read lengths to 50-100 base pairs, but the FET technique should work equally well with longer-processivity polymerases. 1. T.J. Olsen, et. al., "Electronic Measurements of Single-Molecule Processing by DNA polymerase I (Klenow fragment)," JACS 135, 7855 (2013).

**5:06PM V41.00012 Sequence and Structure Dependent DNA-DNA Interactions**, BENJAMIN KOPCHICK, XIANGYUN QIU, The George Washington University — Molecular forces between dsDNA strands are largely dominated by electrostatics and have been extensively studied. Quantitative knowledge has been accumulated on how DNA-DNA interactions are modulated by varied biological constituents such as ions, cationic ligands, and proteins. Despite its central role in biology, the sequence of DNA has not received substantial attention and "random" DNA sequences are typically used in biophysical studies. However, ~50% of human genome is composed of non-random-sequence DNAs, particularly repetitive sequences. Furthermore, covalent modifications of DNA such as methylation play key roles in gene functions. Such DNAs with specific sequences or modifications often take on structures other than the canonical B-form. Here we present series of quantitative measurements of the DNA-DNA forces with the osmotic stress method on different DNA sequences, from short repeats to the most frequent sequences in genome, and to modifications such as bromination and methylation. We observe peculiar behaviors that appear to be strongly correlated with the incurred structural changes. We speculate the causalities in terms of the differences in hydration shell and DNA surface structures.

**5:18PM V41.00013 *In vivo* Studies of VEGFR2 Interactions in the Presence and Absence of VEGF<sup>1</sup>**, CHRISTOPHER KING, DR. KALINA HRISTOVA, Johns Hopkins Univ — Vascular Endothelial Growth Factor Receptor 2 (VEGFR2) is a receptor tyrosine kinase (RTK) that is critical for vasculogenesis and angiogenesis. Enhanced VEGFR2 signaling is often correlated with malignancy. Recently, it was shown that full-length VEGFR2 exists in a monomer-dimer equilibrium in the absence of bound VEGF. Thus, the canonical model of RTK activation does not seem to adequately describe the behavior of VEGFR2 in the cell membrane. In order to understand the role that VEGFR2 extracellular domain plays in unliganded dimerization in live cells, we utilize Fully Quantified Spectral Imaging (FSI) to probe the interactions of VEGFR2 mutant constructs with rationally truncated EC domains. In addition, we investigate the stoichiometry of ligand binding to VEGFR2 EC domain as a function of VEGF concentration and total receptor expression.

#### 2:30PM V42.00001 Melt structure and self-nucleation of ethylene copolymers<sup>1</sup>, RUFINA G ALAMO,

Florida State University, FAMU-FSU College of Engineering, Tallahassee, FL 32310 USA — A strong memory effect of crystallization has been observed in melts of random ethylene copolymers well above the equilibrium melting temperature. These studies have been carried out by DSC, x-ray, TEM and optical microscopy on a large number of model, narrow, and broad copolymers with different comonomer types and contents. Melt memory is correlated with self-seeds that increase the crystallization rate of ethylene copolymers. The seeds are associated with molten ethylene sequences from the initial crystals that remain in close proximity and lower the nucleation barrier. Diffusion of all sequences to a randomized melt state is a slow process, restricted by topological chain constraints (loops, knots, and other entanglements) that build in the intercrystalline region during crystallization. Self-seeds dissolve above a critical melt temperature that demarcates homogeneity of the copolymer melt. There is a critical threshold level of crystallinity to observe the effect of melt memory on crystallization rate, thus supporting the correlation between melt memory and the change in melt structure during copolymer crystallization. Unlike binary blends, commercial ethylene-1-alkene copolymers with a range in inter-chain comonomer composition between 1 and about 15 mol % display an inversion of the crystallization rate in a range of melt temperatures where narrow copolymers show a continuous acceleration of the rate. With decreasing the initial melt temperature, broadly distributed copolymers show enhanced crystallization followed by a decrease of crystallization rate. The inversion demarcates the onset of liquid-liquid phase separation (LLPS) and a reduction of self-nuclei due to the strong thermodynamic drive for molecular segregation inside the binodal. The strong effect of melt memory on crystallization rate can be used to identify liquid-liquid phase separation in broadly distributed copolymers, and offers strategies to control the state of copolymer melts in ways of technological relevance for melt processing of LLDPE and other random olefin copolymers. #### 3:06PM V42.00002 Crystal Structures of Precise Functional Copolymers: Atomistic Molecular Dynamics Simulations and Comparisons with Experiments, EDWARD B. TRIGG, University of Pennsylvania, MARK J. STEVENS, Sandia National Laboratories, KAREN I. WINEY, University of Pennsylvania — Layered crystal structures have been observed in linear poly(ethylene-co-acrylic acid) in which the carboxylic acid groups are placed precisely every 21 carbon atoms along the backbone. The alkane segments form structures resembling orthorhombic polyethylene crystals, while the acid groups form continuous domains that may act as pathways for ion conduction. Further details of the crystal structure have been difficult to elucidate experimentally, but could be important for understanding structure-property relationships. Here, two classes of crystal structures are evaluated via atomistic molecular dynamics: extended chain structures, wherein the polymer backbones are highly extended in near-trans conformations, and adjacent reentry structures, wherein the polymer backbones conform in adjacent reentry loops near the site of each covalently-bonded acid group. Energies of relaxed structures and hydrogen bonding states are compared, and X-ray scattering and other experimental data is compared with the simulation results.

#### 3:18PM V42.00003 Modeling neutron scattering in disperse, nonuniformly labeled commercial polyolefins, BRIAN HABERSBERGER, KYLE HART, DAVID GILLESPIE, TIANZI HUANG, Dow Chemical Co — In spite of their chemically simple monomer elements, understanding of many structural, thermodynamic, and other aspects of polyolefins has remained elusive. Scattering studies on polyolefins are challenged by their nearly identical density in the melt, requiring the use of deuterium-labeling to provide contrast for small-angle neutron scattering (SANS). Until recently, labeling of commercial polyolefins has been prohibitively costly, leading SANS investigations on polyolefins to focus on non-disperse model systems. Commercial polyolefins often have broad molecular weight and composition distributions, and such dispersity plays an important role in their rheology, crystallization, and mechanical properties. Recent reports have described facile hydrogen-deuterium exchange reactions that preserve the chain architecture of polyolefins. However, such exchange is not uniformly distributed across the chain population. Here, we report a generalized application of the Random Phase Approximation prediction for SANS from homogeneous polymer blends to account for such dispersity. A Monte-Carlo method is used to calculate the deuterium distribution that corresponds to SANS measurements. These methods provide powerful tools for probing the structure of disperse polymer architectures.

#### 3:30PM V42.00004 Time-resolved WAXD studies on the crystallization of semicrystalline/graphene nanocomposites, MAYA ENDOH, Stony Brook Univ, SHOTARO NISHITSUJI, Yamagata Univ, TAD KOGA, MIRIAN RAFAILOVICH, Stony Brook Univ — Graphene is one layer of carbon atoms, which has good electronic, thermal conductivity, and mechanical properties. By adding graphene to semicrystalline polymers such as polyethylene (PE) and isotactic polypropylene (iPP), the mechanical and electrical properties of the polymers are significantly improved. To further achieve high performance of semicrystalline polymer/graphene nanocomposites, it is important to investigate the relationship between the crystalline structure of the polymer and the mechanical property of the nanocomposites. In this study, the effect of graphene on the crystallization behavior of PE and iPP was investigated by using time-resolved wide angle X-ray diffraction (WAXD). The in situ WAXD results on the melt-crystallization process showed that the crystalline structures of all the samples remained the same as the pure bulk, while both the rate and degree of the crystallinity increased. We will discuss the detailed structure information along with DSC and mechanical test results.

#### 3:42PM V42.00005 Porous Polyolefin Films via Polymer Blends, CHRIS MACOSKO, University of Minnesota — Porous polymer films have broad application including battery separators, membrane supports and filters. Polyolefins are attractive for these applications because of their solvent resistance, low electrical and thermal conductivity, easy fabrication and cost. We will describe fabrication of porous films using cocontinuous blends of a polyolefin with another polymer which can be readily removed with a solvent. Methods to image and control the cocontinuous morphology will be presented. Bell, J. R., K. Chang, C. R. Lopez-Barron, C. W. Macosko, and D. C. Morse, "Annealing of cocontinuous polymer blends: effect of block copolymer molecular weight and architecture," *Macromolecules* 43, 5024-5032 (2010). Lopez-Barron, C. R., and C. W. Macosko, "Direct measurement of interface anisotropy of bicontinuous structures via 3D image analysis," *Langmuir* 26, 14284-14293 (2010). Trifkovic, M., A. T. Hedegaard, K. Huston, M. Macosko, "Effect of Extensional Viscosity on Cocontinuity of Immiscible Polymer Blends" *J. Rheol.* 59, 1397-1417 (2015).

#### 4:18PM V42.00006 Quantifying tie-molecule content in semicrystalline polymers, AMANDA MCDERMOTT, CHAD SNYDER, NIST - Natl Inst of Stds & Tech, PAUL DESLAURIERS, Chevron Phillips Chemical Co., RONALD JONES, NIST - Natl Inst of Stds & Tech — Tie molecules bridging adjacent crystalline lamellae in semicrystalline polymers strongly impact mechanical properties, but they remain difficult to characterize. We demonstrate a new method of measuring tie-chain content: applying equilibrium swelling theory to small-angle neutron scattering patterns from semicrystalline polyethylene films whose interlamellar amorphous regions are swollen with deuterated organic solvent in a vapor-flow sample environment. To aid in validating the measurement, measured tie-chain content is compared with a primary structural parameter (PSP2) that is calculated from molecular architecture and correlates with slow crack growth behavior. Agreement is favorable for a linear polyethylene and a series of ethylene-hexene copolymers. Recent applications of the technique are also discussed.

## 4:30PM V42.00007 ABSTRACT WITHDRAWN —

### 4:42PM V42.00008 Understanding the Evolution in Meso/Nanostructure in UHMWPE Fibers

, PRESTON MCDANIEL, JOSEPH DEITZEL, JOHN GILLESPIE, Univ of Delaware — Ultra-high-molecular-weight polyethylene (UHMWPE) fibers are increasingly used in composite armor applications. Understanding the complex sub-filament structure which ultimately dictates macroscopic mechanical performance is important as a materials by design approach is taken. In this work, the meso/nanostructure of fibers is studied through a series of atomic force microscopy, X-ray diffraction, and tomography techniques. Fibers with varying thermomechanical processing histories and macroscopic mechanical properties are examined to correlate the evolution of structure with fiber mechanical response in both tension and transverse compression. This work spotlights the sub-filament structural hierarchy in the fiber. The study of nanoscale fibril geometry and crystal structure provides some insight into the load pathways within the fiber, while the identification of a three-dimensional fibrillar network indicates the presence of complex mechanical interactions throughout. The presence and geometry of mesoscale voids in highly drawn fibers is discussed, and tomography results are presented to further understand their distribution throughout the fiber. Finally, the presence of these features are explored in the context of their influence on the energy dissipative capabilities at the fiber level.

### 4:54PM V42.00009 Unfolding of Isotactic Polypropylene under Uniaxial Stretching

, JIA KANG, TOSHIKAZU MIYOSHI, Univ of Akron, AKIHIRO KAMIMURA, AKIHIRO OTSUBO COLLABORATION — Despite numerous investigations on polymer processing, understanding the deformation mechanisms of semicrystalline polymer under uniaxial stretching is still challenging. In this work,  $^{13}\text{C}$ - $^{13}\text{C}$  Double Quantum (DQ) NMR was applied to trace the structural evolution of  $^{13}\text{C}$ -labeled isotactic polypropylene (iPP) chains inside the crystallites stretched to engineering strain ( $\epsilon$ ) of 21 at 100 C. DQ NMR based on spatial proximity of  $^{13}\text{C}$  labeled nuclei proved conformational changes from the folded chains to the locally extended chains induced by stretching. By combining experimental findings with literature results on molecular dynamics, it was concluded that transportation of the crystalline chains plays a critical role to achieve large deformability of iPP.

### 5:06PM V42.00010 Deformation across length scales in polyolefines: effect of the chain microstructure on the polymorphism, phase transitions and morphological changes.

, FINIZIA AURIEMMA, CLAUDIO DE ROSA, ROCCO DI GIROLAMO, ANNA MALAFRONTÉ, MIRIAM SCOTI, Dipartimento di Scienze Chimiche- Universit di Napoli Federico II-Complesso Monte Sant' Angelo- via Cintia-80126 Napoli — The transformations related to phase changes of the crystals, and at lamellar length scales by effect of tensile deformation are studied in the case of some isotactic polypropylene samples having high molecular mass, polydispersity index  $\approx 2$ , and stereodefects at different concentrations and with a uniform distribution. The stress induced transformations are followed in real time during stretching through wide and small angle X-ray scattering measurements. The data analysis evidences that during the transformations of the spherulitic into the fibrillar morphology, stress-induced phase transitions occurring during plastic deformation are regulated by the same factors that govern the textural and morphological changes, that is the ability of the entangled amorphous chains to transmit the stress and the intrinsic stability of the lamellar crystals. Since the relative stability of the different polymorphic forms involved in the structural transformations and the intrinsic flexibility of the chains depend on the stereoregularity, precise correlations between the stereoregularity of the chains, and the deformation behavior are outlined, paving the way for understanding the material properties at molecular level.

### 5:18PM V42.00011 Topological Constraints on Chain-Folding Structure of Semicrystalline Polymer as Studied by $^{13}\text{C}$ - $^{13}\text{C}$ Double Quantum NMR<sup>1</sup>

, YOULEE HONG, TOSHIKAZU MIYOSHI, The university of akron — Chain-folding process is a prominent feature of long polymer chains during crystallization. Over the last half century, much effort has been paid to reveal the chain trajectory. Even though various chain-folding models as well as theories of crystallization at molecule levels have been proposed, they could be not reconciled due to the limited experimental evidences. Recent development of double quantum NMR with selective isotope labeling identified the chain-trajectory of  $^{13}\text{C}$  labeled *isotactic* poly(1-butene). The systematic experiments covered a wide range of parameters, i.e. kinetics, concentration, and molecular weight ( $M_w$ ). It was demonstrated that i) adjacent re-entry site was invariant as a function of crystallization temperature ( $T_c$ ), concentration, and  $M_w$ , ii) long-range order of adjacent re-entry sequence is independence of kinetics at a given concentration while it decreased with increasing the polymer concentration at a given  $T_c$  due to the increased interruption between the chains, and iii) high  $M_w$  chains led to the multilayer folded structures in single crystals, but the melt state induced the identical short adjacent sequences of long and short polymer over a wide range of  $T_c$  due to the entanglements. The behaviors indicated that the topological restriction plays significant roles in the chain-folding process rather than the kinetics. The proposed framework to control the chain-folding structure presents a new perspective into the chain organization by either the intra- or inter-chain interaction.

Session V43 GSNP: Wave Chaos: Theory and Applications 346 - Gabriele Gradoni, University of Nottingham

### 2:30PM V43.00001 Modeling Transmission Line Networks Using Quantum Graphs<sup>1</sup>

, TRYSTAN KOCH, THOMAS ANTONSEN, Univ of Maryland-College Park — Quantum graphs—one dimensional edges, connecting nodes, that support propagating Schrödinger wavefunctions—have been studied extensively as tractable models of wave chaotic behavior (Smilansky and Gnutzmann 2006, Berkolaiko and Kuchment 2013). Here we consider the electrical analog, in which the graph represents an electrical network where the edges are transmission lines (Hul et. al. 2004) and the nodes contain either discrete circuit elements or intricate circuit elements best represented by arbitrary scattering matrices. Including these extra degrees of freedom at the nodes leads to phenomena that do not arise in simpler graph models. We investigate the properties of eigenfrequencies and eigenfunctions on these graphs, and relate these to the statistical description of voltages on the transmission lines when driving the network externally. The study of electromagnetic compatibility, the effect of external radiation on complicated systems with numerous interconnected cables, motivates our research into this extension of the graph model.

### 2:42PM V43.00002 Experimental Study of Quantum Graphs with Microwave Networks<sup>1</sup>

, ZIYUAN FU, TRYSTAN KOCH, THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, University of Maryland, College Park, WAVE CHAOS TEAM — An experimental setup consisting of microwave networks is used to simulate quantum graphs. The networks are constructed from coaxial cables connected by T junctions. The networks are built for operation both at room temperature and superconducting versions that operate at cryogenic temperatures. In the experiments, a phase shifter is connected to one of the network bonds to generate an ensemble of quantum graphs by varying the phase delay. The eigenvalue spectrum is found from S-parameter measurements on one-port graphs. With the experimental data, the nearest-neighbor spacing statistics and the impedance statistics of the graphs are examined. It is also demonstrated that time-reversal invariance for microwave propagation in the graphs can be broken without increasing dissipation significantly by making nodes with circulators. Random matrix theory (RMT) successfully describes universal statistical properties of the system.

## **2:54PM V43.00003 Numerical and experimental studies of the elastic enhancement factor of 2D open systems<sup>1</sup>**

, LESZEK SIRKO, MAŁGORZATA BIAŁOUS, VITALII YUNKO, SZYMON BAUCH, MICHAŁ ŁAWNICZAK, Institute of Physics Polish Academy of Sciences, al. Lotników 32/46, 02-668 Warszawa, Poland — We present the results of numerical and experimental studies of the elastic enhancement factor  $W$  for microwave rough and rectangular cavities simulating two-dimensional chaotic and partially chaotic quantum billiards in the presence of moderate absorption strength. We show that for the frequency range  $\nu = 15.0 - 18.5$  GHz, in which the coupling between antennas and the system is strong enough, the values of  $W$  for the microwave rough cavity lie below the predictions of random matrix theory and on average they are above the theoretical results of V. Sokolov and O. Zhirov, Phys. Rev. E, **91**, 052917 (2015). We also show that the enhancement factor  $W$  of a microwave rectangular cavity coupled to the external channels via microwave antennas, simulating a partially chaotic quantum billiard [1], calculated by applying the Potter-Rosenzweig model with  $\kappa = 2.8 \pm 0.5$  is close to the experimental one. Our numerical and experimental results suggest that the enhancement factor can be used as a measure of internal chaos which can be especially useful for systems with significant openness or absorption. [1] M. Ławniczak, M. Białous, V. Yunko, S. Bauch, and L. Sirko, Phys. Rev. E **91**, 032925 (2015).

## **3:06PM V43.00004 Statistical Model of Wave Transport in Systems with Coexisting Chaotic and Regular Phase Space Regions.**

, EDWARD OTT, University of Maryland — We study the statistics of the input-output properties of wave systems in which ray trajectories that are regular and chaotic coexist (i.e., ‘mixed systems’). The transport is expressed as a summation over eigenmodes (energy states) where the eigenmodes can typically be classified as either regular or chaotic. By appropriate characterization of regular and chaotic contributions, we obtain predictions for the transport as characterized by impedance or scattering matrices. We test these predictions by comparison with numerical calculations for a specific example. [Collaborators: M.-J. Lee, T.M. Antonsen, and K. Ma]

## **3:42PM V43.00005 Radiation of complex and noisy sources within enclosures<sup>1</sup>**

, GABRIELE GRADONI, STEPHEN CREAGH, GREGOR TANNER, University of Nottingham — Predicting the radiation of complex electromagnetic sources inside semi-open cavities and resonators with arbitrary geometry is a challenging topic both for physics and for engineering. We have exploited a Perron-Frobenius operator to propagate field-field correlation functions of complex and extended sources in free-space. The formula is based on a phase-space picture of the electromagnetic field, using the Wigner distribution function, and naturally captures evanescent as well as diffracted waves. This approach can be extended to study the propagation of correlation functions within cavities, with the ray-dynamical map given by the geometry of the cord connecting a point of the boundary to another. While ray methods provide an efficient way to predict average values of the correlation matrix elements, the use of random matrix theory approaches allows efficient characterisation of statistical fluctuations around these averages. Universal relations are derived and tested in the presence of dissipation for quantum maps and billiard systems. The use of this formalism is discussed in the contexts of open systems with surface roughness. The theory and achieved results are of interest in the simulation of next-generation of wireless communications.

## **3:54PM V43.00006 FDTD simulations of the losses in complex electromagnetic cavities<sup>1</sup>**

, FRANCO MOGLIE, LUCA BASTIANELLI, VALTER MARIANI PRIMIANI, Università Politecnica delle Marche - DII, Ancona, EMC TEAM — The simulations of complex electromagnetic cavities like reverberation chambers (RC) require a massive parallel computer to accurately account the complex three dimensional geometry. A parallel finite-difference time-domain (FDTD) code optimized for a massive parallel computer could lose its efficiency if the losses are concentrated in some part of the computation volume. For example, the simulation of the finite conductivity of the cavity metallic walls requires a significant overcharge for the computer processors that handle the boundary part of the global computational domain. Our in-house parallel FDTD code replaces the volumetric losses in every cell of the grid instead of the Ohmic losses on the walls. In this contribution, we evaluate the difference in the field distribution inside the cavity due to this replacement. Moreover, we compare the common RC statistics like the number of stirrer uncorrelated positions and the field uniformity, and the resources required for the two methods are reported and discussed. Finally, the numerical results will be compared with the measurements of the RC in our laboratory with a volume of 60 m<sup>3</sup> and plated steel walls in the frequency range 0.2-1.0 GHz, that includes the transition from the undermoded to the overmoded region.

## **4:06PM V43.00007 Conductance and Transmittance of waves through a chaotic cavity (or, equivalently, quantum dot) results in regularization of tunneling rates**

, LOUIS PECORA, DONG HO WU, CHRISTOPHER KIM, Naval Research Lab — Tunneling rates in closed, double well quantum or wave systems in two dimensions or higher are radically different between wells with classically regular or chaotic behavior [1]. Wells with regular dynamics have tunneling rates that fluctuate by several orders of magnitude as a function of energy or frequency. Wells with chaotic dynamics have fluctuations smaller than one order of magnitude (a regularization of the fluctuations). We examine a more realistic experimental system, a single well with two channels with tunneling barriers at their junctions with the wells. Former theories for conductance in quantum dots will not apply here. We developed a theory, which uses proper boundary conditions at the barriers and yields the scattering matrix. Results show that the transmission rates fluctuate by orders of magnitude in the regular-shaped well, but are greatly reduced (regularized) for the chaotic-shaped well. We will show experimental results that test these theoretical findings for microwave transmission through a chaotic-shaped cavity, which is made of copper and has two ports with tunneling barriers. [1] Chaos regularization of quantum tunneling rates, L. M. Pecora, H. Lee, D-H. Wu, T. Antonsen, M-J. Lee, and E. Ott, Phys. Rev. E **83**, 065201(R) (2011)

## **4:18PM V43.00008 Time Reversed Electromagnetics as a Novel Method for Wireless Power Transfer**

, ANU CHALLA, ECE Department, University of Maryland, STEVEN M. ANLAGE, Physics and ECE Departments, University of Maryland, TESLA TEAM<sup>1</sup> — Taking advantage of ray-chaotic enclosures, time reversal has been shown to securely transmit information via short-wavelength waves between two points, yielding noise at all other sites. In this presentation, we propose a method to adapt the signal-focusing technique to electromagnetic signals in order to transmit energy to portable devices. Relying only on the time-reversal invariance properties of waves, the technique is unencumbered by the inversely-proportional-to-distance path loss or precise orientation requirements of its predecessors, making it attractive for power transfer applications. We inject a short microwave pulse into a complex, wave-chaotic chamber and collect the resulting long time-domain signal at a designated transceiver. The signal is then time reversed and emitted from the collection site, collapsing as a time-reversed replica of the initial pulse at the injection site. When amplified, this reconstruction is robust, as measured through metrics of peak-to-peak voltage and energy transfer ratio. We experimentally demonstrate that time reversed collapse can be made on a moving target, and propose a way to selectively target devices through nonlinear time-reversal.

**4:30PM V43.00009 Enhancement of coherent terahertz beam with chaotic electrodes in a photoconductive antenna**, DONG HO WU, BENJAMIN GRABER, LOUIS PECORA, CHRISTOPHER KIM, U.S. Naval Research Laboratory — We investigated terahertz beam emission from photoconductive antennas containing various shapes of electrodes. With a pair of curved (e.g. concave shape) electrodes it appears that electrons (mostly thermal electrons) follow chaotic trajectories, which keep the electrons away from the surface plasma so that the surface plasma can coherently oscillates without being disrupted by thermal electrons, resulting a slightly increased coherent terahertz power. For an emitter with a pair of ripple electrodes, the classical Poincare surface section map using Birkoff coordinate tends to exhibit chaotic sea and KAM islands if the ripple amplitude becomes comparable to the electrode gap, indicating considerable electron bunching in between the ripple electrodes. Our data show that, when the bunched electrons are stimulated by terahertz pulses, the emitter produces additional spontaneous coherent terahertz beams, which is known as Dicke effect. We will discuss details of our experiments and results.

**4:42PM V43.00010 Controlling and enhancing high frequency collective electron dynamics in superlattices by chaos-assisted miniband transport**, MARK FROMHOLD, MARK GREENAWAY, NATALIA ALEXEEVA, University of Nottingham, ALEXANDER BALANOV, Loughborough University, OLEG MAKAROVSKY, AMALIA PATANE, University of Nottingham, MARAT GAIFULLIN, FEO KUSMARTSEV, Loughborough University — We show in both measurements and calculations that a tilted magnetic field can transform the structure and THz dynamics of charge domains in a biased semiconductor superlattice (SL) [1]. In SLs, at critical field values, when the Bloch frequency equals the cyclotron frequency corresponding to the magnetic field component along the SL axis, the semiclassical electron motion changes abruptly from localized stable trajectories to unbounded chaotic paths, which propagate rapidly through the SL. This delocalisation of the electron creates a series of sharp resonant peaks in drift velocity-field characteristics, which were detected in previous DC current-voltage measurements. We show that these additional peaks can create multiple propagating charge domains, shaped by both the strength and tilt angle of the magnetic field. As a result, the tilted magnetic field generates AC currents whose magnitude and frequencies are far higher than with no magnetic field applied. Chaos-assisted single-electron transport induced by the interplay between cyclotron and Bloch motion therefore provides a mechanism for controlling the collective dynamics of miniband electrons, and thus enhancing the high frequency response of SLs. **4:54PM V43.00011 Light transport in dense composite media: role of near-field coupling**, ROXANA REZVANI NARAGHI, CREOL and Department of Physics, University of Central Florida, SERGEY SUKHOV, CREOL, University of Central Florida, JUAN JOS SENZ, Condensed Matter Physics Center, Universidad Autnoma de Madrid and Donostia International Physics Center, Paseo Manuel Lardizabal 4, ARISTIDE DOGARIU, CREOL, University of Central Florida — In scattering media, optical waves comprise both homogeneous and evanescent components. At very high concentrations of scatterers, particles are located in close proximity and interact through evanescent near fields. Thus, in this regime the energy is not only carried by propagating waves but it also evolves through evanescent coupling between individual scatterers. We have shown that in dense composite media additional transmission channels open because of these near-field interactions between close proximity scatterers and, consequently, a new regime of transport emerges. This is clearly beyond simple descriptions of scatterers acting independently of their environment and framed in terms of far-field characteristics such as Mie cross-sections. We will show that, because in the dense media the energy can transfer through both diffusion and evanescent channels, the total transmittance is  $T = T_{CS} + T_{NF} = 1/L(l_{CS}^* + l_{NF}^*)$ . Correcting the total transmission in this manner is appealing because it is done in terms of physically meaningful and measurable quantities such a near-field (NF) scattering cross-section  $\sigma_{NF}$ .

**5:06PM V43.00012 Complexity of knotting in chaotic 3D eigenfunctions**, ALEXANDER TAYLOR, MARK DENNIS, University of Bristol — Quantised vortices occur generically in disordered 3D complex scalar fields, forming a geometrically complex and statistically random large scale tangle even in systems with very different origins of complexity such as turbulent superfluids, optical volume speckle, the quantum eigenfunctions of chaotic 3D cavities, and liquid crystal phases. Although all such systems are random and fractal on large scales [1], it has previously been established that topological measures such as the probability of vortices knotting or linking with one another are sensitive to the local physics. We use the wave chaos as a universal model system with just one physical lengthscale, the wavelength, beyond which its vortices are Brownian. To access finite-volume realisations of wavefields, vortices are traced numerically in three different random degenerate eigenfunction systems, each approximating the random isotropic limit but with different constraints and symmetries that significantly impact topological statistics even at high energies. By a simple mode counting argument, we observe that the probability of a generic eigenfunction containing a knotted vortex line reaches 50% by around its 1000-3000th mode. [1] A J Taylor and M R Dennis, *J Phys A* **47** 465101 (2014)

**5:18PM V43.00013 Supersymmetric sigma model of disordered, isotropic, elastic media<sup>1</sup>**, DOUGLAS PHOTIADIS, Naval Research Laboratory — The supersymmetry method proposed by Efetov in 1983 has been enormously successful at describing a broad range of phenomena involving disorder, providing a framework for understanding and going beyond the successes of random matrix theory and allowing a calculation of the slowing of diffusion as the Anderson transition is approached. The original model described the propagation of a scalar wave in a disordered medium, and subsequent work extended these ideas to classical waves, optical or elastic, with the approximation that the wave propagation can be similarly described by a scalar theory. Such a theory cannot however account correctly for scattering between different polarizations. A direct attempt to derive a supersymmetric model describing elastic waves results in a non-renormalizable field theory, and poses substantial difficulties. We have obtained a supersymmetric sigma model by considering the dual model which describes a generalized superstress field. The model enables one to fully account for the different wave types and polarizations in the medium. We will present our recent results in this area, including model predictions for the obtained diffusion constants, and the effects of renormalization to first order.

**2:30PM V44.00001 Second-Order Asymptotics for the Classical Capacity of Image-Additive Quantum Channels**, MARCO TOMAMICHEL, University of Sydney — We study non-asymptotic fundamental limits for transmitting classical information over memoryless quantum channels, i.e. we investigate the amount of classical information that can be transmitted when a quantum channel is used a finite number of times and a fixed, non-vanishing average error is permissible. Specifically we consider the classical capacity of quantum channels that are image-additive, including all classical to quantum channels, as well as the product state capacity of arbitrary quantum channels. In both cases we show that the non-asymptotic fundamental limit admits a second-order approximation that illustrates the speed at which the rate of optimal codes converges to the Holevo capacity as the blocklength tends to infinity. The behavior is governed by a new channel parameter, called channel dispersion, for which we provide a geometrical interpretation.

**3:06PM V44.00002 Quantum Coding with Finite Resources** , MARIO BERTA, Caltech — The quantum capacity of a memoryless channel determines the maximal rate at which we can code reliably over asymptotically many uses of the channel. Here we argue that this asymptotic characterization is often insufficient in practice where decoherence severely limits our ability to manipulate large quantum systems in the encoder and decoder. For all practical purposes we should instead focus on the optimal trade-off between three parameters: the rate of the code, the size of the quantum devices at the encoder and decoder, and the fidelity of the transmission. Towards this goal, we find approximate and exact characterizations of this tradeoff for various channels, including dephasing, depolarizing and erasure channels. In each case the tradeoff is parametrized by the capacity and a second channel parameter, the quantum channel dispersion. In the process we develop several general bounds that are valid for all finite-dimensional quantum channels and can be computed efficiently.

**3:42PM V44.00003 Experimental loophole-free Bell inequality violation using electron spins separated by 1.3 km** , B HENSEN, H BERNIEN, A E DRÉAU, A REISERER, N KALB, M S BLOK, J RUITENBERG, R F L VERMEULEN, R N SCHOUTEN, QuTech & Kavli Inst. of Nanoscience, Delft Univ. of Tech. The Netherlands, C ABELLÁN, W AMAYA, V PRUNERI, M W MITCHELL, ICFO-Institut de Ciències Fotoniques, The Barcelona Inst. of Sc. and Tech., Spain, M MARKHAM, D J TWITCHEN, Element Six Innovation, Didcot, Oxfordshire, UK, D ELKOUS, S WEHNER, QuTech, Delft Univ. of Tech., The Netherlands, T H TAMINIAU, R HANSON, QuTech & Kavli Inst. of Nanoscience, Delft Univ. of Tech. The Netherlands — 50 years ago[1], John Bell proved that no theory of nature that obeys locality and realism can reproduce all the predictions of quantum theory. Numerous Bell inequality tests have been reported, however, all experiments reported so far required additional assumptions to obtain a contradiction with local realism, resulting in loopholes. Here we will present[2] a Bell experiment that is free of any such additional assumption. We use an event-ready scheme that enables the generation of robust entanglement between distant electron spins. Efficient spin read-out avoids the fair-sampling assumption, while the use of fast random-basis selection and spin read-out combined with a spatial separation of 1.3 km ensure the required locality conditions. We performed 245 trials that tested the CHSH-Bell inequality  $S \leq 2$  and found  $S = 2.42 \pm 0.20$ . A null-hypothesis test yields a probability of  $P \leq 0.039$  that a local-realist model for space-like separated sites could produce data with a violation at least as large as we observe, even when allowing for memory in the devices. [1] J.S. Bell, Physics 1, 195-200, (1964) [2] Hensen et al. Nature 526, 682 (2015)

**3:54PM V44.00004 Beating the Classical Limits of Information Transmission using a Quantum Decoder** , AKIB KARIM, ZIXIN HUANG, ROB CHAPMAN, University of Sydney, RMIT University, MARCO TOMAMICHEL, STEVE FLAMMIA, University of Sydney, ALBERTO PERUZZO, University of Sydney, RMIT University — Reliable transmission of information over a noisy channel is a fundamental challenge in communication theory. The emergence of quantum technologies has created a new class of strategies that allow for message recovery greater than purely classical methods. Despite this, for minimal uses of the channel, finding such schemes remains a challenge. We investigate the amplitude damping channel which describes physical systems that suffer energy loss such as in cavity quantum electrodynamics or spin chain excitations. We derive and experimentally demonstrate the fundamental limit for message recovery possible with only classical methods. We then propose a quantum decoder and experimentally demonstrate message recovery past this classical limit. We use polarisation-encoded photonic qubits. The post-amplitude damping states are generated by an unbalanced Mach-Zehnder interferometer and entanglement is accomplished with a linear optical probabilistic controlled z gate. Our quantum decoder uses a single entangling gate at the receiver where other similar schemes rely on both the sender and the receiver having quantum devices. Our results present an advance in discovering the quantum capabilities of finite resource communications, with specific regard to the amplitude damping channel.

**4:06PM V44.00005 Quantum Key Distribution based on Silicon Integrated Photonic Devices** , DARIUS BUNANDAR, NICHOLAS HARRIS, ZHESHEN ZHANG, Massachusetts Inst of Tech-MIT, RAN DING, TOM BAEHR-JONES, MICHAEL HOCHBERG, Coriant Advanced Technology Group, JEFFREY SHAPIRO, FRANCO WONG, DIRK ENGLUND, Massachusetts Inst of Tech-MIT — We present a compact quantum key distribution (QKD) transmitter near a 1550-nm wavelength using microring modulators implemented on a silicon-on-insulator photonics platform. The transmitter generates time-bin based qubits with a temporal FWHM of 940 ps and an extinction ratio beyond 16 dB. We prove the feasibility of the transmitter with a coherent one-way QKD protocol, where the bit string is encoded in the arrival time of the time-bin qubits and possible eavesdropping is monitored via the interference visibility of neighboring time-bin qubits<sup>1</sup>. The receiver consists of an asymmetric beamsplitter, which provides a random choice of measurement basis, followed by either a superconducting nanowire single-photon detector (SNSPD) or an unbalanced Michelson interferometer with SNSPDs. This experiment demonstrates the feasibility of high-speed QKD based on CMOS-compatible silicon photonics integrated circuits.

<sup>1</sup>B. Korzh, C. C. W. Lim, R. Houlmann, N. Gisin, M. J. Li, D. Nolan, B. Sanguinetti, R. Thew, and H. Zbinden, Nature Photonics **9**, 163–168 (2015)

**4:18PM V44.00006 Quantum Versus Classical Advantages in Secret Key Distillation (and Their Links to Quantum Entanglement)** , ERIC CHITAMBAR, BENJAMIN FORTESCUE, Southern Illinois University Carbondale, MIN-HSIU HSIEH, University of Technology Sydney — We consider the extraction of shared secret key from correlations that are generated by either a classical or quantum source. In the classical setting, two honest parties (Alice and Bob) use public discussion and local operations to distill secret key from some distribution  $p_{XYZ}$  that is shared with an unwanted eavesdropper (Eve). In the quantum settings, the correlations  $p_{XYZ}$  are delivered to the parties as either an incoherent mixture of orthogonal quantum states or as coherent superposition of such states. Here we demonstrate that the classical and quantum key rates are equivalent when the correlations are generated incoherently in the quantum setting. For coherent sources, we next show that the rates are incomparable, and in fact, their difference can be arbitrarily large in either direction. However, we identify a large class of non-trivial distributions that possess the following properties: (i) Eve's advantage is always greater in the quantum source than classically, and (ii) for the entanglement shared in the coherent source, the so-called entanglement cost/squashed entanglement/relative entropy of entanglement can all be computed. We thus present a rare instance in which various entropic entanglement measures of a quantum state can be explicitly computed.

**4:30PM V44.00007 Unstructured quantum key distribution** , PATRICK COLES, ERIC METODIEV, NORBERT LUTKENHAUS, University of Waterloo — Quantum key distribution (QKD) allows for communication with security guaranteed by quantum theory. The main theoretical problem in QKD is to calculate the secret key rate for a given protocol. Analytical formulas are known for protocols with a high degree of symmetry, since symmetry simplifies the analysis. However, experimental imperfections break symmetries, hence the effect of imperfections on key rates is difficult to estimate. Furthermore, it is an interesting question whether (intentionally) asymmetric protocols could outperform symmetric ones. In this work, we develop a robust numerical approach for calculating the key rate for arbitrary discrete-variable QKD protocols. Ultimately this will allow researchers to study “unstructured” protocols, i.e., those that lack symmetry. Our approach relies on transforming the key rate calculation to the dual optimization problem, which dramatically reduces the number of parameters and hence the calculation time. We illustrate our method by investigating some unstructured protocols for which the key rate was previously unknown.

#### 4:42PM V44.00008 A Contextuality Based Quantum Key Distribution Protocol<sup>1</sup> , JAMES TROUPE,

The University of Texas at Austin — In 2005 Spekkens presented a generalization of noncontextuality that applies to imperfect measurements (POVMs) by allowing the underlying hidden variable model to be indeterministic. In addition, unlike traditional Bell-Kochen-Specker noncontextuality, HV models of a single qubit were shown to be *contextual* under this definition. Thus, not all single qubit POVM measurement outcomes can be modeled classically. Recently M. Pusey showed that, under certain conditions, exhibiting an anomalous weak value (i.e. values outside the eigenspectrum of the observable) implies contextuality. We will present a new single qubit prepare and measure QKD protocol that uses observation of anomalous weak values of particular observables to estimate the quantum channel error rate and certify the security of the channel. We also argue that it is the “degree” of contextuality of the noisy qubits exiting the channel that fundamentally determine the secure key rate. A benefit of this approach is that the security does not depend on the fair sampling assumption, and so is not compromised by Eve controlling Bob’s measurement devices. Thus, it retains much of the benefit of “Measurement Device Independent” QKD protocols while only using single photon preparations and measurements.

#### 4:54PM V44.00009 Investigation of physical implementation of one-way quantum repeaters with multilevel systems , SRERAMAN MURALIDHARAN, CHANG-LING ZOU, LINSHU LI, JIANMING WEN, LIANG JIANG, Yale University

— Error correcting codes of multilevel systems have been shown to be resource efficient for the correction of erasure errors. One way quantum repeaters based on multilevel systems offer ultrafast key generation rates, while consuming lower resources than qubit based schemes (arxiv:1504.08054). On the other hand, they are technologically demanding. Here, we identify the key technological requirements needed for the implementation of quantum repeaters with multilevel systems and propose different experimental techniques that can be used to overcome the difficulties. We propose a generalized Duan-Kimble scheme for the generation of error correcting codes of multilevel systems with time-bin qudits.

#### 5:06PM V44.00010 Long distance quantum communication using continuous variable encoding

, LINSHU LI, VICTOR V. ALBERT, Yale University, MARIOS MICHAEL, Cambridge University, SRERAMAN MURALIDHARAN, CHANGLING ZOU, LIANG JIANG, Yale University — Quantum communication enables faithful quantum state transfer between different parties and protocols for cryptographic purposes. However, quantum communication over long distances (>1000km) remains challenging due to optical channel attenuation. This calls for investigation on developing novel encoding schemes that correct photon loss errors efficiently. In this talk, we introduce the generalization of multi-component Schrödinger cat states [1] and propose to encode quantum information in these cat states for ultrafast quantum repeaters [2,3]. We detail the quantum error correction procedures at each repeater station and characterize the performance of this novel encoding scheme given practical imperfections, such as coupling loss. A comparison with other quantum error correcting codes for bosonic modes will be discussed. [1] M. Mirrahimi, Z. Leghtas, V. V. Albert, S. Touzard, R. J. Schoelkopf, L. Jiang, and M. H. Devoret, New J. Phys. 16, 045014 (2014). [2] S. Muralidharan, J. Kim, N. Lütkenhaus, M. D. Lukin, and L. Jiang, Phys. Rev. Lett. 112, 250501 (2014). [3] S. Muralidharan, L. Li, J. Kim, N. #### 5:18PM V44.00011 Quantum Secure Direct Communication in a noisy environment: Theory and Experiment<sup>1</sup> , GUI LU LONG, Tsinghua University

— Quantum communication holds promise for absolutely security in secret message transmission. Quantum secure direct communication (QSDC) is an important branch of the quantum communication in which secret messages are sent directly over a quantum channel with security[Phys. Rev. A 65 , 032302 (2002)]. QSDC offers higher security and is instantaneous in communication, and is a great improvement to the classical communication mode. It is also a powerful basic quantum communication primitive for constructing many other quantum communication tasks such as quantum bidding, quantum signature and quantum dialogue and so on. Since the first QSDC protocol proposed in 2000, it has become one of the extensive research focuses. In this talk, the basic ideas of QSDC will be reviewed, and major QSDC protocols will be described, such as the efficient-QSDC protocol, the two-step QSDC protocol, the one-time-pad QSDC protocol, the high-dimensional QSDC protocol and so on. Experimental progress is also developing steadily, and will also be reviewed. In particular, the quantum one-time-pad QSDC protocol has recently been successfully demonstrated experimentally[arXiv:1503.00451].

#### 2:30PM V45.00001 Generation of heralded entanglement between distant quantum dot hole spins , AYMERIC DELTEIL, Institute of Quantum Electronics, ETH Zurich

— Entanglement plays a central role in fundamental tests of quantum mechanics as well as in the burgeoning field of quantum information processing. Particularly in the context of quantum networks and communication, some of the major challenges are the efficient generation of entanglement between stationary (spin) and propagating (photon) qubits, the transfer of information from flying to stationary qubits, and the efficient generation of entanglement between distant stationary (spin) qubits. In this talk, I will present such experimental implementations achieved in our team with semiconductor self-assembled quantum dots.

Not only are self-assembled quantum dots good single-photon emitters, but they can host an electron or a hole whose spin serves as a quantum memory, and then present spin-dependent optical selection rules leading to an efficient spin-photon quantum interface. Moreover InGaAs quantum dots grown on GaAs substrate can profit from the maturity of III-V semiconductor technology and can be embedded in semiconductor structures like photonic cavities and Schottky diodes.

I will report on the realization of heralded quantum entanglement between two semiconductor quantum dot hole spins separated by more than five meters. The entanglement generation scheme relies on single photon interference of Raman scattered light from both dots. A single photon detection projects the system into a maximally entangled state. We developed a delayed two-photon interference scheme that allows for efficient verification of quantum correlations. Moreover the efficient spin-photon interface provided by self-assembled quantum dots allows us to reach an unprecedented rate of 2300 entangled spin pairs per second, which represents an improvement of four orders of magnitude as compared to prior experiments carried out in other systems. Our results extend previous demonstrations in single trapped ions or neutral atoms, in atom ensembles and nitrogen vacancy centers to the domain of artificial atoms in semiconductor nanostructures that allow for on-chip integration of electronic and photonic elements. This work lays the groundwork for the realization of quantum repeaters and quantum networks on a chip.

### 3:06PM V45.00002 Polarisation singularities in disordered photonic crystal waveguides for on-chip spin-photon entanglement.

, DARYL BEGGS, BEN LANG, ANDREW YOUNG, RUTH OULTON, University of Bristol — A polarisation singularity occurs at a position in a vector field where one of the parameters of the local polarisation ellipse (handedness, eccentricity or orientation) becomes singular. With the vector nature of electromagnetic fields, optics is an obvious place for the study of polarisation singularities, and they can be found in systems ranging from tightly focused beams to speckle fields. Here we demonstrate that photonic crystal waveguides support on-chip polarisation singularities. As Bloch waves, the eigenmodes of photonic crystal waveguides possess a strong longitudinal, as well as transverse, component of their electric field. The spatial dependence of both these components and the phase between them ensures a rich and complex polarisation landscape in the waveguide. Recently, the use of polarisation singularities found in photonic crystal waveguides is generating much interest for integrated quantum information applications, as they can couple the spin-states of electrons confined to quantum dots to the optical modes of the waveguide. For example, at a circular-point (C-point), the sign of the local helicity is governed by the propagation direction of the optical mode, which allows for spin-photon coupling to one direction only. However, any real system will inevitably contain imperfections, and it is not obvious that the polarisation singularities will persist in the disordered waveguides. Here, we use calculations of the eigenmodes of disordered waveguides to demonstrate that the polarisation singularities persist far beyond realistically expected levels of disorder.

**3:18PM V45.00003 Optical control of Berry phase in a diamond spin qubit<sup>1</sup>**, CHRISTOPHER G. YALE, F. JOSEPH HEREMANS, BRIAN B. ZHOU, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, ADRIAN AUER, GUIDO BURKARD, Department of Physics, University of Konstanz — Geometric phase, a fascinating quantum mechanical phenomenon that arises from cyclic state evolution, is a promising avenue to realize fault-tolerant quantum information processing. Here, we demonstrate an all-optical approach to accumulate a geometric phase, or Berry phase, within a solid-state spin qubit, the nitrogen-vacancy center in diamond<sup>2</sup>. With stimulated Raman adiabatic passage (STIRAP), we evolve two light fields to cycle the resulting dark state of a low temperature lambda system in a 'tangerine slice' trajectory that we examine through time-resolved state tomography. This type of trajectory acquires a Berry phase which we then measure through phase comparison to a reference state. We then probe the limits of this control as a result of adiabatic breakdown for short timescales and unintended excitation driven by far-detuned optical fields that accumulate for long timescales. We also investigate the intrinsic resilience of this Berry phase to noise introduced into the system, which is the focus of the following talk. As an all-optical approach, this geometric control represents a pathway to the development of optical geometric gates in the solid state.

### 3:30PM V45.00004 Robustness of optically-controlled Berry phase in a diamond spin qubit<sup>1</sup>

BRIAN B. ZHOU, CHRISTOPHER G. YALE, F. JOSEPH HEREMANS, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, Chicago, IL 60637, ADRIAN AUER, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — The intrinsic noise resilience of geometric phases has motivated their application as an alternative protocol for realizing high fidelity quantum operations. Using stimulated Raman adiabatic passage (STIRAP) to cyclically evolve the dark state of a lambda system, we demonstrate all-optical control over Berry phase for a single spin in the solid state, the nitrogen vacancy center in diamond [1]. Here we introduce both phase and amplitude noise into the optical control fields for a class of 'tangerine slice' trajectories on the Bloch sphere. We examine the response of Berry phase to scaling of the noise amplitude and adiabatic cycle time, finding Berry phase to be unaffected by deviations parallel to the trajectory and to increase in robustness for long cycle times. Moreover, our noise resilience is independent of the value of the accumulated Berry phase, a property that differs from the behavior of circular trajectories investigated by prior microwave techniques. We also discuss potential improvements to our work.

### 3:42PM V45.00005 Quantum nanophotonics: Controlling a photon with a single spin<sup>1</sup>

EDO WAKS, Univ of Maryland-College Park — The implementation of quantum network and distributive quantum computation relies on strong interactions between stationary matter qubits and flying photons. The spin of a single electron confined in a quantum dot is considered as a promising matter qubit as it possesses microsecond coherence time and allows picosecond timescale control using optical pulses. The quantum dot spin can also interact with a photon by controlling the optical response of a strongly coupled cavity. In this talk I will discuss our recent work on an experimental realization of a spin-photon quantum phase switch using a single spin in a quantum dot strongly coupled to a photonic crystal cavity. We show large modulation of the cavity reflection spectrum by manipulating the spin states of the quantum dot, which enables us to control the quantum state of a reflected photon. We also show the complementary effect where the presence of a single photon switches the quantum state of the spin. The reported spin-photon quantum phase operation can switch spin or photon states in picoseconds timescale, representing an important step towards GHz semiconductor based quantum logic devices on-a-chip and solid-state implementations of quantum networks.

### 4:18PM V45.00006 A quantum phase switch between a solid state spin and a photon

, SHUO SUN, HYOCHUL KIM, University of Maryland College Park, GLENN SOLOMON, National Institute of Standards and Technology, EDO WAKS, University of Maryland-College Park — The implementation of quantum network and distributive quantum computation relies on strong interactions between stationary matter qubits and flying photons. The spin of a single electron confined in a quantum dot is considered as a promising matter qubit as it possesses microsecond coherence time and allows picosecond timescale control using optical pulses. The quantum dot spin can also interact with a photon by controlling the optical response of a strongly coupled cavity. In this talk I will discuss our recent work on an experimental realization of a spin-photon quantum phase switch using a single spin in a quantum dot strongly coupled to a photonic crystal cavity. We show large modulation of the cavity reflection spectrum by manipulating the spin states of the quantum dot, which enables us to control the quantum state of a reflected photon. We also show the complementary effect where the presence of a single photon switches the quantum state of the spin. The reported spin-photon quantum phase operation can switch spin or photon states in picoseconds timescale, representing an important step towards GHz semiconductor based quantum logic devices on-a-chip and solid-state implementations of quantum networks.

### 4:30PM V45.00007 Efficient generation of indistinguishable single photons on-demand at telecom wavelengths

, JEHYUNG KIM, TAO CAI, Univ of Maryland-College Park, CHRISTOPHER RICHARDSON, RICHARD LEAVITT, Laboratory for Physical Science, EDO WAKS, Univ of Maryland-College Park — Highly efficient single photon sources are important building blocks for optical quantum information processing. For practical use and long-distance quantum communication, single photons should have fiber-compatible telecom wavelengths. In addition, most quantum communication applications require high degree of indistinguishability of single photons, such that they exhibit interference on a beam splitter. However, deterministic generation of indistinguishable single photons with high brightness remains a challenging problem in particular at telecom wavelengths. We demonstrate a telecom wavelength source of indistinguishable single photons using an InAs/InP quantum dot in a nanophotonic cavity. To obtain the efficient single quantum dot emission, we employ the higher order mode in L3 photonic crystal cavity that shows a nearly Gaussian transverse mode profile and results in out-coupling efficiency exceeding 46 % and unusual bright single quantum dot emission exceeding 1.5 million counts per second at a detector. We also observe Purcell enhanced spontaneous emission rate as large as 4 and high linear polarization ratio of 0.96 for the coupled dots. Using this source, we generate high purity single photons at 1.3  $\mu\text{m}$  wavelength and demonstrate the indistinguishable nature of the emission using a two-photon interference measurement.

**4:42PM V45.00008 Quantum Dot Device Design Optimization for Resonator Coupling<sup>1</sup>**, CAMERON KING, S. N. COPPERSMITH, MARK FRIESEN, University of Wisconsin, Madison — Coupling a semiconductor quantum dot qubit to a superconducting resonator broadens the possibilities for interqubit communication and potentially allows integration of quantum dots with other qubit systems. The major technological hurdle that must be overcome is reaching the strong coupling limit, where the coupling frequency between the resonator and the qubit is larger than both the qubit decoherence rate and the photon loss rate of the resonator. In this work, we examine optimization of the quantum dot device design. Using the Thomas-Fermi approximation in conjunction with a metallic dot capacitive model, we focus on improving the capacitive coupling between a resonator gate and a quantum dot while decreasing the cross-coupling to nearby dots. Through these simulations, we find that the optimization follows an intuitive geometric relation.

**4:54PM V45.00009 A Dressed Spin Qubit in Silicon<sup>1</sup>**, ARNE LAUCHT, RACHPON KALRA, JUAN DEHOLLAIN, STEPHANIE SIMMONS, JUHA MUHONEN, FAHD MOHIYADDIN, SOLOMON FREER, FAY HUDSON, UNSW Australia, KOHEI ITOH, Keio University, DAVID JAMIESON, JEFF MCCALLUM, University of Melbourne, ANDREW DZURAK, ANDREA MORELLO, UNSW Australia — Coherent dressing of a quantum two-level system has been demonstrated on a variety of systems, including atoms, self-assembled quantum dots, and superconducting quantum bits, and can be demonstrated by measuring Rabi oscillations, or a Mollow triplet in the spectrum. It can be used to gain access to a new quantum system with improved properties - a different and tunable level splitting, faster and easier control, and longer coherence times. In our work we investigate the properties of the dressed, donor-bound electron spin in silicon, and probe its potential for the use as quantum bit in scalable architectures. Here, the two dressed spin-polariton levels constitute the quantum bit. The dressed qubit can be coherently driven with an oscillating magnetic field, an oscillating electric field, by frequency modulating the driving field, or by a simple detuning pulse. We measure coherence times of  $T_2^* = 2.4$  ms and  $T_2 = 9$  ms (Hahn echo), one order of magnitude longer than those of the undressed qubit.

**5:06PM V45.00010 Gate sensing coherent charge oscillations in a silicon field-effect transistor.<sup>1</sup>**, M. FERNANDO GONZALEZ-ZALBA, Hitachi Cambridge Laboratory, UK, SERGEY SHEVCHENKO, B. Verkin Institute for Low Temperature Physics and Engineering, Ukraine, SYLVAIN BARRAUD, CEA-LETI, France, J. ROBERT JOHANSSON, CEMS, RIKEN, Japan, ANDREW FERGUSON, Cavendish Laboratory, UK, FRANCO NORI, CEMS, RIKEN, Japan, ANDREAS BETZ, Hitachi Cambridge Laboratory, UK — We report the observation of coherent charge oscillations in a double quantum dot formed in a silicon nanowire transistor detected via its dispersive interaction with a radio-frequency resonant circuit coupled via the gate. Differential capacitance changes at the inter-dot charge transitions allow us to monitor the state of the system in the strong-driving regime where we observe the emergence of Landau-Zener-Stückelberg-Majorana interference on the phase response of the resonator. A theoretical analysis of the dispersive signal demonstrates that quantum and tunnelling capacitance changes must be included to describe the qubit-resonator interaction. Furthermore, a Fourier analysis of the interference pattern reveals a charge coherence time,  $T_2 = 100$  ps. Our results demonstrate charge coherent control and readout in a simple silicon transistor and open up the possibility to implement charge and spin qubits in existing complementary metal-oxide-semiconductor technology.

**5:18PM V45.00011 Coplanar photonic bandgap resonators for low temperature electron and nuclear magnetic resonance spectroscopy**, A. J. SIGILLITO, A. M. TYRYSKHIN, S. A. LYON, Department of Electrical Engineering, Princeton University — In recent years, superconducting coplanar waveguide (CPW) resonators have become a useful tool for low temperature pulsed electron spin resonance (ESR), even at dilution refrigerator temperatures. Their small mode volumes make CPW resonators particularly well suited to measuring small numbers of spins near the resonator surface, since in this region the spin sensitivity is very high. While these resonators have proven useful for ESR at single microwave frequencies, it is difficult to also manipulate nuclear spins in electron-nuclear-double resonance (ENDOR) experiments, since manipulation of nuclear spins requires radio frequency (RF) magnetic fields. Ideally one would simply generate these fields by passing RF currents through the CPW, but because conventional CPW resonators are capacitively coupled, they will not transmit low-frequency RF currents. In this talk, we discuss the use of one dimensional photonic bandgap (PBG) resonators to overcome this challenge. PBG resonators are a promising alternative to conventional CPW resonators since they offer high quality factors at microwave frequencies, while simultaneously allowing transmission of nonresonant RF currents below the photonic bandgap. Here, we will discuss PBG resonator designs and present data showing their use for low temperature ESR of donors in <sup>28</sup>Si. Initial ENDOR results will also be presented.

**5:30PM V45.00012 Theory of nuclear spin dephasing and relaxation by optically illuminated nitrogen vacancy center.**, PING WANG, WEN YANG, Zhongguancun Software Park II, No. 10 West Dongbeiwang Road, Haidian District, Beijing 100094, China — Dephasing and relaxation of the nuclear spins coupled to the nitrogen-vacancy (NV) center during optical initialization and readout is an important issue for various applications of this hybrid quantum register. Here we present both an analytical description and a numerical simulation for this process, which agree reasonably with the experimental measurements. For the NV center under cyclic optical transition, our analytical formulas not only provide a clear physics picture, but also allows controlling the nuclear spin dissipation by tuning an external magnetic field. For more general optical pumping, our analytical formulas reveal significant contribution to the nuclear spin dissipation due to electron random hopping into/out of the  $m = 0$  (or  $m = \pm 1$ ) subspace. This contribution is not suppressed even under saturated optical pumping and/or vanishing magnetic field, thus providing a possible solution to the puzzling observation of nuclear spin dephasing in zero perpendicular magnetic field [M. V. G. Dutt *et al.*, Science **316**, 1312 (2007)]. It also implies that enhancing the degree of spin polarization of the nitrogen-vacancy center can reduce the effect of optical induced nuclear spin dissipation.

**2:30PM V46.00001 Optimum Noise Reduction Methods for the Interior of Vehicles and Aircraft Cabins**, HASSON M. TAVOSSI, PH.D., Valdosta State University, Department of Physics, Astronomy & Geosciences — The most effective methods of noise reduction in vehicles and Aircraft cabins are investigated. The first goal is to determine the optimal means of noise mitigation without change in external shape of the vehicle, or aircraft cabin exterior such as jet engine or fuselage design, with no significant added weight. The second goal is to arrive at interior designs that can be retrofitted to the existing interiors, to reduce overall noise level for the passengers. The physical phenomena considered are; relaxation oscillations, forced vibrations with non-linear damping and sub-harmonic resonances. The negative and positive damping coefficients and active noise cancelations methods are discussed. From noise power-spectrum for a prototype experimental setup, the most energetic vibration modes are determined, that require the highest damping. The proposed technique will utilize the arrangement of uniformly distributed open Helmholtz resonators, with sound absorbing surface. They are tuned to the frequencies that correspond to the most energetic noise levels. The resonators dissipate noise energy inside the vehicle, or aircraft cabin, at the peak frequencies of the noise spectrum, determined for different vehicle or aircraft cabin, interior design models.

**2:42PM V46.00002 A Noninvasive In Vivo Glucose Sensor Based on Mid-Infrared Quantum Cascade Laser Spectroscopy**, ALEXANDRA WERTH, Princeton University, SABBIR LIAKAT, SRI International, LAURA XU, Yahoo Inc., CLAIRE GMACHL, Princeton University — Diabetes affects over 387 million people worldwide; a number which grows every year. The most common method of measuring blood glucose concentration involves a finger prick which for some can be a harrowing process. Therefore, a portable, accurate, noninvasive glucose sensor can significantly improve the quality of life for many of these diabetics who draw blood multiple times a day to monitor their glucose levels. We have implemented a noninvasive, mobile glucose sensor using a mid-infrared (MIR) quantum cascade laser (QCL), integrating sphere, and thermal electrically (TE) cooled detector. The QCL is scanned from 8 - 10 microns wavelength over which are distinct absorption features of glucose molecules with little competition of absorption from other molecules found in the blood and interstitial fluid. The obtained absorption spectra are analyzed using a neural network algorithm which relates the small changes in absorption to the changing glucose concentration. The integrating sphere has increased the signal-to-noise ratio from a previous design, allowing us to use the TE-cooled detector which increases mobility without loss of accuracy.

**2:54PM V46.00003 Temperature Coefficient of Secondary Electron Emission: A Novel Thermal Metrology**, MD. IMRAN KHAN, SEAN DANIEL LUBNER, University of California at Berkeley, DAVID FRANK OGLETREE, ED WONG, Molecular Foundry (Lawrence Berkeley National Laboratory), CHRIS DAMES, University of California at Berkeley — State of the art nanoscale temperature mapping techniques include Scanning Thermal Microscopy (SThM) and optical thermorefectance, though these have the challenges of requiring sample contact and being diffraction limited, respectively. Near field scanning optical microscopy (NSOM) can beat the diffraction limit but still cannot measure temperature at 10s of nanometer resolution. SEM is well known for topographic imaging but has not been previously used for thermal mapping. Past literature suggested that secondary electron yields might have a small temperature dependence due to electron-phonon scattering and/or temperature dependence of work function. We previously measured the temperature coefficient of secondary electron emission of several group IV and III-V semiconductors and found it to range from around 100 to 1000 ppm/K. Here, we utilize this to map a spatial temperature gradient in an SEM image. We implement a double-heater structure to produce a temperature gradient along the plane of a substrate. The primary electron beam is scanned across the sample's surface while the emitted (secondary plus backscattered) electron current and net absorbed sample currents are simultaneously recorded. The results demonstrate the ability to map a spatial temperature gradient.

**3:06PM V46.00004 Tomographic Reconstruction of Circularly Polarized High Harmonic Fields: 3D Attosecond Metrology**, CONG CHEN, ZHENSHENG TAO, JILA, University of Colorado Boulder, CARLOS HERNANDEZ-GARCA, Universidad de Salamanca, Spain, PIOTR MATYBA, ADRA CARR, RONNY KNUT, JILA, University of Colorado Boulder, OFER KFIR, Technion, Haifa, Israel, DIMITRY ZUSIN, CHRISTIAN GENTRY, PATRICK GRYCHTOL, JILA, University of Colorado Boulder, OREN COHEN, Technion, Haifa, Israel, LIUS PLAJA, Universidad de Salamanca, Spain, ANDREAS BECKER, AGNIESZKA JARON-BECKER, HENRY KAPTEYN, MARGARET MURNANE, JILA, University of Colorado Boulder — Bright, circularly polarized, extreme ultraviolet (EUV) and soft X-ray high harmonic beams can now be produced using counter-rotating circularly polarized driving laser fields. In the time domain, the field is predicted to emerge as a complex series of rotating linearly polarized bursts, varying rapidly in amplitude, frequency and polarization. Here, we extend attosecond metrology techniques to circularly polarized light for the first time by simultaneously irradiating a copper surface with circularly polarized high harmonic and linearly polarized infrared laser fields. The resulting temporal modulation of the photoelectron spectra carries essential phase information about the EUV field. Utilizing the polarization selectivity of the solid surface and by rotating the circularly polarized EUV field in space, we fully retrieve the amplitude and phase of the circularly polarized harmonics, allowing us to reconstruct one of the most complex coherent light fields produced to date.

**3:18PM V46.00005 Enhancement of photocurrent on few-layered  $p$ -WSe<sub>2</sub> FET by multi-terminal measurement<sup>1</sup>**, CARLOS GARCIA, Florida State University/NHMFL, NIHAR PRADHAN, NHMFL, JOSHUA HOLLEMAN, DANIEL RHODES, Florida State University/NHMFL, LUIS BALICAS, STEPHEN MCGILL, NHMFL — Recently, two dimensional materials particularly transition metal dichalcogenides (TMDs) have been extensively studied because of their strong light-matter interactions and extraordinary electrical and optical properties in field-effect transistors (FETs). We investigated the photocurrent response on few-layered  $p$ -WSe<sub>2</sub> and MoSe<sub>2</sub> FETs in a multi-terminal configuration using a 532 nm laser. Photogenerated current  $I_{ph}$  ( $= I_{light} - I_{dark}$ ) was measured as a function of optical power incident on the sample with varying source-drain bias,  $V_{ds}$ , and back gate voltage,  $V_{bg}$ . We observed a large enhancement of photocurrent in a four-terminal configuration compared to a two-terminal configuration. The measured two-terminal photoresponsivity ( $R$ ) and external quantum efficiency ( $EQE$ ) from our ~10 layers  $p$ -WSe<sub>2</sub> at applied  $V_{ds}$  = 1V and  $V_{bg}$  = 10V were ~18A/W and ~4000%, respectively. The  $R$  and  $EQE$  values increased to ~85 A/W and ~20000% respectively using a four-terminal configuration. Thus by using a multi-terminal configuration, one can observe an enhanced photocurrent response on few-layered TMDs for potential applications in photo-detection and optoelectronic circuits.

**3:30PM V46.00006 Cavities for electron spin resonance: predicting the resonant frequency**, JOHN COLTON, KYLE MILLER, MICHAEL MEEHAN, ROSS SPENCER, Brigham Young University — Microwave cavities are used in electron spin resonance to enhance magnetic fields. Dielectric resonators (DRs), pieces of high dielectric material, can be used to tailor the resonant frequency of a cavity. However, designing cavities with DRs to obtain desired frequencies is challenging and in general can only be done numerically with expensive software packages. We present a new method for calculating the resonant frequencies and corresponding field modes for cylindrically symmetric cavities and apply it to a cavity with vertically stacked DRs. The modes of an arbitrary cavity are expressed as an expansion of empty cavity modes. The wave equation for  $D$  gives rise to an eigenvalue equation whose eigenvalues are the resonant frequencies and whose eigenvectors yield the electric and magnetic fields of the mode. A test against theory for an infinitely long dielectric cylinder inside an infinite cavity yields an accuracy better than 0.4% for nearly all modes. Calculated resonant frequencies are also compared against experiment for quasi-TE<sub>011</sub> modes in resonant cavities with ten different configurations of DRs; experimental results agree with predicted values with an accuracy better than 1.0%. MATLAB code is provided at <http://www.physics.byu.edu/research/coltonlab/cavityresonance>.

**3:42PM V46.00007 High magnetic field calibration using de Haas-van Alphen oscillations in polycrystalline copper<sup>1</sup>**, WILLIAM A. CONIGLIO, National High Magnetic Field Laboratory, ALAN F. WILLIAMS, ANNA YANNAKOPOULOS, Florida State University/National High Magnetic Field Laboratory, AUDREY GROCKOWIAK, STAN TOZER, National High Magnetic Field Laboratory — We provide a calibration for the de Haas-van Alphen (dHvA) frequency in polycrystalline copper, which may be used to standardize the measurement of magnetic fields, particularly in pulsed field environments, where direct observation of NMR is challenging. Using a reliable single-crystal model of the Fermi surface from coefficients that are traceable to a powder Al NMR reference, we computed Fermi surface extremal areas for evenly spaced directions around a sphere. Summing the peaks corresponding to extremal orbits according to the Lifshitz-Kosevich model, we arrive at a dHvA spectrum that corresponds to experimental observation. We find that actual maximum fields reached at the NHMFL-Pulsed Field Facility are slightly larger than previously determined.

<sup>1</sup>We appreciate generous primary support from the U. S. Department of Energy NNSA SSAA DE-NA0001979. The National High Magnetic Field Laboratory is supported by the National Science Foundation, U. S. Department of Energy, and the State of Florida.

**3:54PM V46.00008 NANONIS TRAMEA – A Quantum Transport Measurement System**, THORSTEN KAMPEN, ANDREAS THISSEN, OLIVER SCHAFF, ALESSANDRO PIODA, SPECS Surface Nano Analysis GmbH — Nanonis Tramea is a quantum leap with respect to increased speed for transport measurements taking research onto a new level. Measurements which took several hours in the past can now be done in minutes without compromising signal quality. Tramea uses its fast, high-resolution, high-precision and ultra-low-noise outputs and inputs to generate and acquire up to 20000 data points per second on 24 channels in parallel. This is not only up to 1000 × faster than typical measurement systems but it is also time deterministic with highest precision. Here, the time separation between points is constant so that artefacts caused by unequal point spacings in non-deterministic measurement systems are avoided. The emphasis here is the real-time relation. Tramea comes with a built-in interface which allows for control of the instruments' basic functions from any programming environment. For users requiring more functionality and higher speeds a full-featured LabVIEW-based programming interface or scripting module are available as add-on modules. Due to the modularity and flexibility of the hardware and software architecture of Tramea upgrades with standardized add-on modules are possible. Non-standard requests can still be handled by the various programming options.

**4:06PM V46.00009 Construction and  $^{13}\text{C}$  NMR signal-amplification efficiency of a dynamic nuclear polarizer at 6.4 T and 1.4 K<sup>1</sup>**, ANDHIKA KISWANDHI, PETER NIEDEBALSKI, CHRISTOPHER PARISH, SARAH FERGUSON, DAVID TAYLOR, GEORGE MCDONALD, LLOYD LUMATA, Univ of Texas, Dallas — Dissolution dynamic nuclear polarization (DNP) is a rapidly emerging technique in biomedical and metabolic imaging since it amplifies the liquid-state nuclear magnetic resonance (NMR) and imaging (MRI) signals by >10,000-fold. Originally used in nuclear scattering experiments, DNP works by creating a non-Boltzmann nuclear spin distribution by transferring the high electron ( $\gamma = 28,000 \text{ MHz/T}$ ) thermal polarization to the nuclear spins via microwave irradiation of the sample at high magnetic field and low temperature. A dissolution device is used to rapidly dissolve the frozen sample and consequently produces an injectable hyperpolarized liquid at physiologically-tolerable temperature. Here we report the construction and performance evaluation of a dissolution DNP hyperpolarizer at 6.4 T and 1.4 K using a continuous-flow cryostat. The solid and liquid-state  $^{13}\text{C}$  NMR signal enhancement levels of  $^{13}\text{C}$  acetate samples doped with trityl OX063 and 4-oxo-TEMPO free radicals will be discussed and compared with the results from the 3.35 T commercial hyperpolarizer.

**4:18PM V46.00010 Comparative Analysis of two Methods for High-Resolution Differential Conductance Measurement<sup>1</sup>**, DAVID CUSICK, Taylor University, MICHIO NAITO, Tokyo University of Agriculture and Technology, ROBERTO RAMOS, University of the Sciences — We compare two methods of differential conductance measurement. The first is a traditional method in which current and voltage data is acquired via four-wire measurement, then averaged and differentiated numerically. The second method calculates  $dI/dV$  in real time by superimposing a small DC signal  $dI$  on the input step function, alternating between addition and subtraction of the signal with each step, then averaging the small signal voltage response over three steps to obtain  $dV$ . This requires two instruments: a DC current source and a high-resolution voltmeter. Keithley Instruments has commercially promoted the Keithley 622x current source and 2182A nanovoltmeter as means to achieve this measurement; we therefore refer to it as the Keithley method. We compare the two methods by performing high-resolution measurements of the energy gap of  $\text{MgB}_2$  thin film Josephson junctions. We show that the Keithley method has advantages of cleaner data, easier implementation, and overall faster data collection, but may lack the traditional method's high resolution.

**2:30PM V47.00001 Area Determination of Electrodeposited Ni, Co, and NiCo Thin Films<sup>1</sup>**, MATTHEW GIRA, KEVIN TKACZ<sup>2</sup>, JENNIFER HAMPTON, Hope College — The surface area of electrodeposited thin films of Ni, Co, and NiCo was evaluated using electrochemical double-layer capacitance, electrochemical area measurements using the  $[\text{Ru}(\text{NH}_3)_6]^{3+}/[\text{Ru}(\text{NH}_3)_6]^{2+}$  redox couple, and topographic atomic force microscopy (AFM) imaging. The methods were compared to each other for each composition separately and for all the samples regardless of composition. Double-layer capacitance measurements were found to be positively correlated to the roughness factors determined by AFM topography. Electrochemical area measurements were less correlated with measured roughness factors and applicable only to two of the three compositions studied. The results indicate that *in situ* double-layer capacitance measurements are a practical, versatile technique for estimating the accessible surface area of a metal sample.

**2:42PM V47.00002 Structure and Dynamics of the Au(111) Surface in an Electrochemical Environment<sup>1</sup>**, JOHN COLLINI, Rochester Institute of Technology, YIHUA LIU, Argonne National Laboratory, BRYANNE MCDONOUGH, MICHAEL PIERCE, Rochester Institute of Technology, HOYDOO YOU, Argonne National Laboratory, VLADIMIR KOMANICKY, Safarik University, ANDI BARBOUR, Brookhaven National Laboratory — The Au(111) surface possesses a well-known herringbone surface reconstruction pattern. However, the character of the reconstruction's response to external variables is not completely understood due to the limited amount of kinetics and dynamics studies of the surface in different environments. Here, we present *in-situ* x-ray scattering measurements from the Advanced Photon Source at Argonne National Laboratory of the Au(111) surface in a controllable electrochemical environment of weak NaF solution. Crystal truncation rod (CTR) measurements were taken to examine how the average surface properties and overall structure change with cell voltage. X-ray photon correlation spectroscopy (XPCS) measurements were also taken to examine how the dynamics of the surface change with voltage. The relation between applied potential, average kinetics, and microstate dynamics will be discussed.

**2:54PM V47.00003 Atomic diffusion processes in heteroepitaxial metallic systems using SLKMC-II**, SYED ISLAMUDDIN SHAH, ALTAF KARIM, Department of Physics, COMSATS Institute of information technology, Park Road, Tar-lai Kalan, Islamabad 45550, Pakistan — We have examined the diffusion of small islands of Cu on Ag(111) surface using a self-learning kinetic Monte Carlo (SLKMC-II) [1] method with an improved pattern recognition scheme. Due to strain generated at the interface between metals with different bulk lattice constants, interesting single atom, multi-atom and concerted diffusion processes are automatically revealed in the simulations. Here we will report various processes for small islands in the case of Cu/Ag(111) system. Key processes responsible for island diffusion and their energetics together with trends in effective energy barriers as well as diffusion constants for small islands will also be provided. In addition to 2-D diffusion processes, as an application of SLKMC-II to the 3-dimensional heteroepitaxial systems, we will also report energy barriers of some of the 3-dimensional processes including down the A- and B-steps and exchange processes. [1] Syed Islamuddin Shah, et al., J. Phys.: Condens. Matter 24, 354004 (2012)

**3:06PM V47.00004 Nanotribological properties of water films adsorbing atop, and absorbing below, graphene layers supported by metal substrates<sup>1</sup>**, ZIJIAN LIU, C.K. CURTIS, North Carolina State University, R. STINE, P. SHEEHAN, Naval Research Laboratory, J. KRIM, North Carolina State University — The tribological properties of graphite, a common lubricant with known sensitivity to the presence of water, have been studied extensively at the macroscopic and microscopic scales. Although far less attention has been devoted to the tribological properties of graphene, it has been established that the tribological response to the presence of water is dissimilar from that of graphite.[1] We report here a quartz crystal microbalance study of the nanotribological properties of water films adsorbed/absorbed on graphene layers prepared by either chemical decomposition on nickel(111) substrates or transfer of freestanding graphene layers to aluminum substrates. Sliding friction levels of the water films were also measured for metal surfaces in the absence of a graphene layer. We observe very high friction levels for water adsorbed atop graphene on Ni(111) and very low levels for water on aluminum. For the case of graphene/aluminum, the data indicate that the water is absorbing between the graphene layer and the aluminum. Dissipation levels moreover indicate the presence of an interstitial water increases sliding friction between the graphene and the aluminum substrate. [1] D. Berman et al., Materials Today 17, 31 (2014)

**3:18PM V47.00005 Interfacial Assembly of Graphene Oxide Films.**, CAIN VALTIERREZ, Department of Physics, Augsburg College, ISSAM ISMAIL, CHRISTOPHER MACOSKO, Department of Chemical Engineering and Materials Science, University of Minnesota Twin Cities, BENJAMIN STOTTRUP, Department of Physics, Augsburg College — Controlled assembly of monolayer graphene-oxide (GO) films at the air/water interface is of interest for the development of transparent conductive thin films of chemically-derived graphene. We present experimental results from investigations of the assembly of polydisperse GO sheets at the air-water interface. GO nanosheets with lateral dimensions of greater than 10 microns were created using a modified Tour synthesis (Dimiev and Tour, 2014). GO films were generated with conventional Langmuir trough techniques to control lateral packing density. Film morphology was characterized *in situ* with Brewster angle microscopy. Films were transferred unto a substrate via the Langmuir-Blodgett deposition technique and imaged with fluorescence quenching microscopy. Through pH modulation of the aqueous subphase, it was found that GO's intrinsic surface activity to the interface increased with increasing subphase acidity. Finally, we found a dominant elastic contribution during uniaxial film deformation as measured by anisotropic pressure measurements. A. M. Dimiev, and J. M. Tour, "Mechanism of GO Formation," ACS Nano, 8, (2014)

**3:30PM V47.00006 Tuning friction with an external magnetic field: A Quartz Crystal Microbalance study of physisorbed oxygen monolayers and multilayers sliding on nickel substrates.<sup>1</sup>**, Z.B. FREDRICKS, K.M. STEVENS, B. ACHARYA, J. KRIM, North Carolina State University — The sliding friction levels of oxygen monolayer and multilayer films adsorbed on nickel close to the oxygen monolayer solid-liquid melting transition temperature have been monitored by means of a Quartz Crystal Microbalance (QCM) technique in the presence and absence of a weak external magnetic field. Friction levels for the monolayers in the presence of the field were observed to be half of those observed in the absence of a field. For thick films, the reduction was proportionately less, indicating an interfacial effect as the source of the magnetic sensitivity. While the presence of the field is expected to increase the normal force between the paramagnetic oxygen overlayer and the ferromagnetic substrate, the impact of this mechanism on friction appears to be minimal, or possibly masked by more dominant mechanisms. These include magnetically induced structural reorientation (magnetostriction), and/or realignment of adlayer spins in response to the applied field, both of which would reduce the physical or magnetic interfacial commensurability, thus lowering friction levels.

**3:42PM V47.00007 Effect of charges on the interaction of water with hematite<sup>1</sup>**, FABIO NEGREIROS RIBEIRO, LUANA PEDROZA, GUSTAVO DALPIAN, Universidade Federal do ABC — Hematite is one of the many types of iron oxide that is easily found in nature. It is most commonly used in catalysis and it is rarely present in its pristine form. The influence of charged defects in its properties is very important for the correct geometrical/electronic characterization in more realistic operative conditions, but very few studies focus explicitly on these defects in this system. In this work we perform first principles DFT+U calculations to determine the properties of a hematite slab when both dopant and electrons/holes are added. We focus on the differences between the geometrical/electronic properties between the neutral/charged surfaces and also study their interaction with water (molecule and liquid) by performing molecular dynamics simulations at room temperature. Our results indicate that electric charges strongly influence the properties of these surfaces, changing the binding energies and the molecular arrangement of the water molecules adsorbed on hematite. Negative charges induce a larger binding and favor the partial water dissociation, whereas positive charges weaken the binding energy. We will provide comparative results for different configurations of this system.

**3:54PM V47.00008 Novel Transrotational Solid State Order Discovered by TEM in Crystallizing Amorphous Films<sup>1</sup>**, VLADIMIR KOLOSOV, Ural Federal University — Exotic thin crystals with unexpected **transrotational** microstructures [1] have been discovered by transmission electron microscopy (TEM) for crystal growth in thin (10-100 nm) amorphous films of different chemical nature (oxides, chalcogenides, metals and alloys) prepared by various methods. Primarily we use our TEM bend contour technique. The unusual phenomenon can be traced **in situ** in TEM column: dislocation independent regular internal bending of crystal lattice planes in a growing crystal. Such **transrotation** (unit cell **translation** is complicated by small **rotation** realized round an axis lying in the film plane) can result in strong regular lattice orientation gradients (up to 300 degrees per micrometer) of different geometries: cylindrical, ellipsoidal, toroidal, saddle, etc. Transrotation is increasing as the film gets thinner. Transrotational crystal resembles ideal single crystal enclosed in a curved space. Transrotational micro crystals have been eventually recognized by other authors in some vital thin film materials, i.e. PCMs for memory, silicides, SrTiO<sub>3</sub>. Atomic model and possible mechanisms of the phenomenon are discussed. New transrotational nanocrystalline model of amorphous state is also proposed. [1] V.Yu. Kolosov and A.R.Tholen, Acta Mater., 48 (2000) 1829.

#### 4:06PM V47.00009 Successively Thresholded Domain Boundary Roughening Driven by Pinning Centers and Missing Bonds: Hard-Spin Mean-Field Theory Applied to $d=3$ Ising Magnets

, TOLGA CAGLAR, Sabanci University, A. NIHAT BERKER, Sabanci University and MIT — Hard-spin mean-field theory has recently been applied to Ising magnets, correctly yielding the absence and presence of an interface roughening transition respectively in  $d = 2$  and  $d = 3$  dimensions and producing the ordering-roughening phase diagram for isotropic and anisotropic systems. The approach has now been extended to the effects of quenched random pinning centers and missing bonds on the interface of isotropic and anisotropic Ising models in  $d = 3$  [1]. We find that these frozen impurities cause domain boundary roughening that exhibits consecutive thresholding transitions as a function of interaction anisotropy. For both missing-bond and pinning-center impurities, for moderately large values of the anisotropy, the systems saturate to the "solid-on-solid" limit, exhibiting a single universal curve for the domain boundary width as a function of impurity concentration.

#### 4:18PM V47.00010 Atomic-Scale Mechanism for Hydrogenation of *o*-Cresol on Pt Catalysis<sup>1</sup>

, YAPING LI, University of Tulsa, ZHIMIN LIU, University of Oklahoma, WENHUA XUE, University of Tulsa, STEVEN CROSSLEY, University of Oklahoma, FRIEDERIKE JENTOFT, University of Massachusetts Amherst, SANWU WANG, University of Tulsa — Biofuels derived from lignocellulosic biomass have received significant attention lately due to increasing environmental concerns. With first-principles density-functional theory and *ab initio* molecular dynamic simulations, we investigated the atomic-scale mechanism of *o*-cresol hydrogenation on the Pt(111) surface. The formation of 2-methyl-cyclohexanone (the intermediate product) was found to involve two steps. The first step is the dehydrogenation, that is, the H atom in the hydroxyl group moves to the Pt surface. The second step is the hydrogenation, that is, the H atoms on Pt react with the carbon atoms in the aromatic ring. The first step involves a smaller barrier, suggesting that dehydrogenation occurs first, followed by hydrogenation of the ring. In particular, tautomerization is found to occur via a two-step process over the catalyst. On the other hand, 2-methyl-cyclohexanol (the final product) is produced through two paths. One is direct hydrogenation of the aromatic ring. Another pathway includes partial hydrogenation of the ring, dehydrogenation of -OH group, finally hydrogenation of remaining C atoms and the O atom. Our theoretical results agree well with the experimental observations.

#### 4:30PM V47.00011 Multidisciplinary Investigation of the Structural and Electronic Properties of the Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> interface

, JUDITH YANG, QING ZHU, CECILE BONIFACIO, University of Pittsburgh, JOSH KAS, University of Washington, HENRY AYOOLA, University of Pittsburgh, KIM KISSLINGER, DONG SU, Brookhaven National Laboratory, FERNANDO VILA, University of Washington, STEPHEN HOUSE, University of Pittsburgh, ERIC STACH, Brookhaven National Laboratory, JOHN REHR, University of Washington, WISSAM SAIDI, University of Pittsburgh, UNIVERSITY OF PITTSBURGH TEAM, UNIVERSITY OF WASHINGTON TEAM, BROOKHAVEN NATIONAL LABORATORY TEAM — Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> is arguably the most important heterogeneous catalyst system. Despite the numerous studies on this system, the detailed structural and electronic properties of this interface remain uncertain. Through controlled oxidation of NiAl (110), we were able to obtain single crystalline Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> thin films. We also prepared Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> samples. STEM observations show that use of cryo-electron microscopy techniques prevented electron-beam damage, including direct sample damage, and changes in the EELS oxygen K pre-peak (~532 eV). The oxygen K pre-peak was consistently present in spectra taken at the Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> interface at cryo-temperatures, but not in those acquired at room temperature. The theoretically calculated EELS oxygen K signals for the Pt on (110) Pt/ $\gamma$ -Al<sub>2</sub>O<sub>3</sub> exhibited a similar pre-peak at 532 eV correlating to the experimental EELS oxygen K data, and we attribute to this feature to the formation of Pt-O complex. This points out an important factor in understanding the reactivity of this catalysis.

#### 4:42PM V47.00012 First Principles Study of a-U<sub>2</sub>N<sub>3</sub> Surfaces and its Anti-oxidant Mechanism

, MENGTING JIN, YANNING ZHANG, Chengdu Green Energy and Green Manufacturing Technology RD Center — With the advantages over oxides as fuel materials for fast nuclear reactors, actinide nitrides have been extensively studied in experiments. In particular, a-U<sub>2</sub>N<sub>3</sub> is also the main composition of surface layer obtained by surface nitriding for the enhancement of oxidation resistance of uranium in ambient conditions.[1-4] However, the anti-oxidant mechanism behind is still unclear, which hinders the further development of surface treatment technologies for uranium. Here we perform extensive *ab initio* studies on the geometric, magnetic and electronic properties of a-U<sub>2</sub>N<sub>3</sub> bulk and (001) surfaces. Then the adsorption and diffusion of O<sub>2</sub> near the stable a-U<sub>2</sub>N<sub>3</sub>(001) surface will be discussed, focusing on the local atomic arrangements of U-N and U-N-O that cannot be observed easily in experiments. Our theoretical results may give some insights in understanding the anti-oxidant mechanism of surface nitriding.

#### 4:54PM V47.00013 Laser driven solid-state diffusional mixing in a Ni-Pt multilayer film probed by hard x-ray diffraction<sup>1</sup>

, AARON LOETHER, BRIAN KELLY, Department of Physics and Astronomy, University of Delaware, ANTHONY DICHARA, ROBERT HENNING, Advanced Photon Source, Argonne National Laboratory, KARL UNRUH, MATTHEW DECAMP, Department of Physics and Astronomy, University of Delaware — Intense optical excitation has been utilized for decades to modify atomic scale structure in the condensed phase. When the optically excited systems are probed by hard x-ray radiation, one can reconstruct the modified atomic structure on a sub-angstrom spatial scale. In this work we utilize sub-picosecond optical radiation to rapidly drive atomic diffusion in a Ni-Pt multilayer film. Transient atomic diffusion was measured using hard x-ray diffraction, thereby directly observing the formation of a new metallic alloy as a function of laser excitation. Our observations demonstrate that the diffusional mixing in the multilayer can be completed in only a few individual laser shots, allowing us to directly probe the dynamics of the atomic scale motion.

#### 5:06PM V47.00014 NMR Studies of the Dynamics of HD Adsorbed on MCM-41<sup>1</sup>

, CHAO HUAN, JAHAMAMIDA, NEIL SULLIVAN, University of Florida — We report the results of measurements of the nuclear spin-spin and spin-lattice relaxation times of a monolayer of HD molecules adsorbed on MCM-41 for temperatures  $1.5 < T < 20$  K. Two distinct characteristic relaxation times are observed. A slow diffusion process for  $5 < T < 8.8$  K and a faster rate with a distinctly different activation energy for  $8.9 < T < 12$  K. The behavior is fluid-like above 12 K. We discuss the results in terms of an expected cluster formation at low temperatures followed by the diffusion of single molecules at high temperatures.

**5:18PM V47.00015 Noble gas adsorption in two-dimensional zeolites: a combined experimental and density functional theory study<sup>1</sup>**, MENGGEN WANG, Stony Brook University, JIANQIANG ZHONG, JORGE ANIBAL BOSCOBONIN, DEYU LU, Brookhaven National Laboratory — Zeolites are important industrial catalysts with porous three-dimensional structures. The catalytically active sites are located inside the pores, thus rendering them inaccessible for surface science measurements. We synthesized a two-dimensional (2D) zeolite model system, consisting of an (alumino)silicate bilayer weakly bound to a Ru (0001) surface. The 2D zeolite is suitable for surface science studies; it allows a detailed characterization of the atomic structure of the active site and interrogation of the model system during the catalytic reaction. As an initial step, we use Ar adsorption to obtain a better understanding of the atomic structure of the 2D zeolite. In addition, atomic level studies of rare gas adsorption and separation by zeolite are important for its potential application in nuclear waste sequestration. Experimental studies found that Ar atoms can be trapped inside the 2D-zeolite, raising an interesting question on whether Ar atoms are trapped inside the hexagonal prism nano-cages or at the interface between the (alumino)silicate bilayer and Ru(0001), or both. DFT calculations using van der Waals density functionals were carried out to determine the preferred Ar adsorption sites and the corresponding adsorption energies.

**Session V48 GQI: Readout and Trajectories in Superconducting Circuits** 349 - Kater Murch, Washington University, St. Louis

**2:30PM V48.00001 Probing the Speed Limits of Transmon Dispersive Readout**, THEO WALTER, PHILIPP KURPIERS, MINTU MONDAL, MAREK PECHAL, ANDREAS WALLRAFF, S. GASPARINETTI, ETH Zurich — In circuit QED, faster and more accurate measurement of a qubit's state is necessary to achieve better feedback control, to accomplish more complex quantum algorithms and simulations, and to cross the threshold for fault tolerant quantum computing. In this talk, we discuss our experimental progress to minimize the time needed to readout the state of a dispersively coupled transmon qubit with high fidelity. We outline a signal-to-noise ratio model, illuminate the constraints and find optimal parameters for maximizing measurement speed, while maintaining high readout fidelity. Utilizing a Purcell Filter increases the generality of our results as it becomes possible to reach these speeds with a broader set of system parameters.

**2:42PM V48.00002 Fast Quantum Nondemolition Readout by Parametric Modulation of Longitudinal Qubit-Oscillator Interaction**, JÉRÔME BOURASSA, Cégep de Granby, NICOLAS DIDIER<sup>1</sup>, McGill University and Université de Sherbrooke, ALEXANDRE BLAIS, Université de Sherbrooke and Canadian Institute for Advanced Research — For quantum information processing, qubit readout must be fast, of high-fidelity and ideally quantum non-demolition (QND). To rapidly reuse the measured qubit, fast reset of the measurement pointer states is also needed. Combining these characteristics is essential to meet the stringent requirements of fault-tolerant quantum computation. For superconducting qubits, a common strategy is the dispersive readout where the qubit is coupled to an oscillator acting as pointer. In this talk, we present an alternative strategy based on parametric modulation of longitudinal qubit-oscillator interaction. We show that compared to dispersive readout it leads to a faster, high-fidelity and ideally QND qubit readout with a simple reset mechanism [1]. We moreover show how to exponentially improve the signal-to-noise ratio (SNR) of this measurement with the help of single-mode squeezed input state on the oscillator. We present an implementation of this longitudinal parametric readout in circuit quantum electrodynamics along with results using realistic experimental parameters. [1] N. Didier, J. Bourassa and A. Blais, Phys. Rev. Lett., In Print (2015)

**2:54PM V48.00003 Non-QNDness of Dispersive Measurement in Superconducting Qubits, Part I: Theory**, MOSTAFA KHEZRI, University of California, Riverside, DANIEL SANK, Google, ZIJUN CHEN, University of California, Santa Barbara, RAMI BARENDTS, YU CHEN, AUSTIN FOWLER, ROBERT GRAFF, EVAN JEFFREY, JULIAN KELLY, ERIK LUCERO, ANTHONY MEGRANT, JOSH MUTUS, PEDRAM ROUSHAN, TED WHITE, MATTHEW NEELEY, Google, BROOKS CAMPBELL, BENJAMIN CHIARO, ANDREW DUNSWORTH, CHARLES NEILL, PETER O'MALLEY, CHRISTOPHER QUINTANA, AMIT VAINSENER, JAMES WENNER, University of California, Santa Barbara, JOHN M. MARTINIS, Google, University of California, Santa Barbara, ALEXANDER N. KOROTKOV, University of California, Riverside — We theoretically analyze the dispersive measurement of an Xmon qubit in the circuit QED setup at moderately high power, so that the number of photons in the resonator exceeds the so-called critical number by up to an order of magnitude. Our results show an abrupt change of the qubit state when the number of photons reaches a certain threshold, which depends on the detuning between the qubit and the resonator. The simulation results are in agreement with experimental findings for Xmon measurement at moderately high power. We will discuss the physical mechanism causing an abrupt deterioration of the measurement QNDness at the threshold.

**3:06PM V48.00004 Non-QNDness of Dispersive Measurement in Superconducting Qubits, Part II: Experiment**, DANIEL SANK, Google Inc - Santa Barbara, Z. CHEN, UC Santa Barbara, M. KHEZRI, UC Riverside, R. BARENDTS, Google Inc - Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google Inc - Santa Barbara, B. CHIARO, A. DUNSWORTH, UC Santa Barbara, A. FOWLER, R. GRAFF, E. JEFFREY, J. KELLY, E. LUCERO, A. MEGRANT, J. MUTUS, M. NEELEY, Google Inc - Santa Barbara, C. NEILL, P. J. J. O'MALLEY, UC Santa Barbara, C. QUINTANA, P. ROUSHAN, Google Inc - Santa Barbara, A. VAINSENER, J. WENNER, UC Santa Barbara, T. WHITE, Google Inc - Santa Barbara, A. KOROTKOV, UC Riverside, J. M. MARTINIS, Google Inc - Santa Barbara — Modern quantum state measurement in transmon qubits uses the interaction between the qubit and a harmonic oscillator. In the dispersive limit of the interaction, the coupling operator  $n\sigma_z$  commutes with the qubit Hamiltonian and should be perfectly QND. However, previous experiments have indicated that sufficiently high resonator drive power causes unwanted qubit state transitions, producing errors. We investigate these errors in detail, connect the results with theory, and comment on the implications for quantum computer design.

**3:18PM V48.00005 Dependence of transmon qubit relaxation rate on readout drive power<sup>1</sup>**, S.O. MUNDHADA, S. SHANKAR, A. NARLA, E. ZALYS-GELLER, S.M. GIRVIN, M.H. DEVORET, Department of Applied Physics, Yale University — In circuit QED experiments, microwave drives are applied to the readout mode for qubit measurement, control and to realize various multi-photon processes. These microwave drives have been observed to detrimentally affect the qubit mode by increasing the qubit relaxation rates for both upward and downward transitions. These transitions demolish the qubit state during a measurement, limiting the maximum measurement strength and thus the readout fidelity and speed. Here, we experimentally investigate this effect for transmon qubits coupled to different realizations of the readout mode: 3-dimensional microwave cavities, strip-line resonators and nonlinear readout modes in a waveguide.

<sup>1</sup>Work supported by: NSF, ARO, AFOSR and YINQE.

**3:30PM V48.00006 A balanced, superconducting multiplier circuit for fast-switching and multiplexed qubit readout: Design and modeling**, ERIC I. ROSENTHAL, BENJAMIN J. CHAPMAN, BRAD A. MOORES, JILA, University of Colorado, Boulder, JOSEPH KERCKHOFF, HRL Laboratories, JILA, University of Colorado, Boulder, K. W. LEHNERT, JILA, University of Colorado, Boulder, National Institute of Standards and Technology, Boulder — Superconducting qubits hold great promise for the development of new quantum-information technology. Coherence times of individual transmon qubits in microwave cavities are consistently improving. While qubits are becoming well developed tools, scaling qubit readout for many-qubit architectures remains prohibitively complex and expensive. Here, we present a concept for a multi-purpose device that enables time or code domain multiplexing of qubit readout. It is a two-port, microwave device that can be switched rapidly between three modes of operation: transmission, reflection and inversion. The design is based on a Wheatstone bridge-like structure of tunable inductors, which we realize with arrays of SQUIDS. A single bias line modulates the flux through the SQUIDS, and hence the imbalance of the bridge, putting the device in one of its three modes of operation. This talk will discuss the theory, design and layout behind the device and its potential use for multiplexing of qubit networks. The device is designed to operate over a broad bandwidth (4-8 GHz), and to have low dissipation, appropriate for integration with superconducting qubit networks.

**3:42PM V48.00007 A balanced, superconducting multiplier circuit for fast-switching and multiplexed qubit readout: Performance and demonstration<sup>1</sup>**, BRAD A. MOORES, BENJAMIN J. CHAPMAN, ERIC I. ROSENTHAL, JILA, University of Colorado, Boulder, JOSEPH KERCKHOFF, HRL Laboratories, JILA, University of Colorado, Boulder, K. W. LEHNERT, JILA, University of Colorado, Boulder — A major challenge of scaling the promising transmon qubits into a quantum information processing machine is the classical hardware burden required to readout many qubits. Within the cavity QED architecture, qubit states are measured by detecting the transmission through microwave cavities. A multiplexing scheme could allow the classical hardware burden of generating and measuring a readout tone to be shared among several cavity-qubit systems. In this talk, we will present measurements of a recently designed superconducting multiplier circuit intended to accomplish time and code domain multiplexed readout. In particular, we characterize three modes of microwave operation: transmission, reflection and inversion. The device can be switched between these modes approximately 100 times faster than typical qubit coherence times. Exploiting this performance, we demonstrate a code domain multiplexing scheme with classical signals created to simulate typical qubit signals. The scheme operates with near unity fidelity at microwave powers comparable to typical qubit tones.

**3:54PM V48.00008 Frequency and sensitivity tunable microresonator array for high-speed quantum processor readout**, EMILE HOSKINSON, J. D. WHITTAKER, L. J. SWENSON, M. H. VOLKMANN, P. SPEAR, F. ALTOMARE, A. J. BERKLEY, D-Wave Systems, B. BUMBLE, Jet Propulsion Laboratory, P. BUNYK, D-Wave Systems, P. K. DAY, B. H. EOM, Jet Propulsion Laboratory, R. HARRIS, J. P. HILTON, M. W. JOHNSON, D-Wave Systems, A. KLEINSASSER, Jet Propulsion Laboratory, E. LADIZINSKY, T. LANTING, T. OH, I. PERMINOV, E. TOLKACHEVA, J. YAO, D-Wave Systems — Frequency multiplexed arrays of superconducting microresonators have been used as detectors in a variety of applications. The degree of multiplexing achievable is limited by fabrication variation causing non-uniform shifts in resonator frequencies. We have designed, implemented and characterized a superconducting microresonator readout that incorporates two tunable inductances per detector, allowing independent control of each detector frequency and sensitivity. The tunable inductances are adjusted using on-chip programmable digital-to-analog flux converters, which are programmed with a scalable addressing scheme that requires few external lines.

**4:06PM V48.00009 Simple quantum trajectories for transmon measurement with moderate bandwidth**, ALEXANDER N. KOROTKOV, University of California, Riverside — So far, most experiments on the continuous quantum measurement of superconducting qubits in a circuit QED setup have been well described by the Quantum Bayesian formalism, which assumes the "bad cavity limit": the resonator bandwidth is assumed to be much larger than the measurement-induced dephasing. However, in some experiments this assumption is not applicable, and then the Quantum Bayesian formalism should be extended. We discuss a relatively simple generalization to the case of arbitrary resonator bandwidth, which can be applied when there is no significant qubit evolution due to Rabi oscillations. We also discuss how to include Rabi oscillations and energy relaxation into the simulation of quantum trajectories.

**4:18PM V48.00010 Mapping quantum state dynamics of spontaneous emission**, MAHDI NAGHILOO, NEDA FROUZANI, DIAN TAN, KATER MURCH, Washington University, St. Louis — Controlling the dynamics of spontaneous emission for quantum emitters is relevant to many novel applications in quantum computation and quantum optics. In this work we use homodyne measurements of the spontaneous emission of a superconducting qubit to track its quantum evolution. A resonant pulse is used to prepare the qubit in the excited state and the emission from the system into this environment is monitored with a near-quantum-limited Josephson parametric amplifier acting as a homodyne detector. By an appropriately chosen phase of amplification, we execute weak measurements in the  $\sigma_x$  basis of the qubit. We use the measurement results to track individual quantum trajectories as the qubit evolves from its excited to ground state, revealing rich dynamics that occur in the process of spontaneous emission.

**4:30PM V48.00011 Tracking Multi-State Quantum Jumps in a Superconducting Circuit**, NEDA FOROUZANI, DIAN TAN, MAHDI NAGHILOO, KATER MURCH, Washington University, St. Louis — Quantum measurements are known to be crucial for quantum error-correction and state initialization. Continuous measurements can be used for state tracking and real-time quantum feedback. If the measurements are strong, the state dynamics are described by quantum jumps between states. Using continuous measurements, we track the quantum state of a transmon circuit initially in its lowest energy state. We observe spurious jumps between five observable states of the circuit and use a Bayesian update formalism to estimate state occupation probabilities as well as transition rates over time. Our analysis reveals switching between different quantum jump statistics. Resolving the energy distribution of spurious jumps will help characterize this decoherence process.

**4:42PM V48.00012 Theory and practice of dressed coherent states in circuit QED<sup>1</sup>**, FRANK WILHELM, Saarland University, LUKE C.G. GOVIA, McGill University — In the dispersive regime of qubit-cavity coupling, classical cavity drive populates the cavity, but leaves the qubit state unaffected. However, the dispersive Hamiltonian is derived after both a frame transformation and an approximation. Therefore, to connect to external experimental devices, the inverse frame transformation from the dispersive frame back to the lab frame is necessary. We show that in the lab frame the system is best described by an entangled state known as the dressed coherent state, and thus even in the dispersive regime, entanglement is generated between the qubit and the cavity. Also, we show that further qubit evolution depends on both the amplitude and phase of the dressed coherent state. This provides a limitation to readout in the dispersive regime. We show that only in the limit of infinite measurement time is this protocol QND, as the formation of a dressed coherent state in the qubit-cavity system applies an effective rotation to the qubit state. We show how this rotation can be corrected by a unitary operation, leading to improved qubit initialization by measurement and unitary feedback.] L.C.G. Govia and F.K. Wilhelm Phys. Rev. Applied 4, 054001 (2015) L.C.G. Govia and F.K. Wilhelm, arXiv: 1506.04997

**4:54PM V48.00013 Design and initial tests of a superconducting circulator for quantum microwave systems<sup>1</sup>**, BENJAMIN J. CHAPMAN, ERIC I. ROSENTHAL, BRAD A. MOORES, JILA, University of Colorado, Boulder, JOSEPH KERCKHOFF, HRL Laboratories, JILA, University of Colorado, Boulder, KEVIN LALUMIÈRE, ALEXANDRE BLAIS, University of Sherbrooke, K.W. LEHNERT, JILA, University of Colorado, Boulder, National Institute of Standards and Technology, Boulder — Microwave circulators enforce a single propagation direction for signals in an electrical network. Unfortunately, commercial circulators are bulky, lossy, and cannot be integrated close to superconducting circuits because they emit large stray magnetic fields. Here we report progress toward the development of a lossless, on-chip, active circulator for superconducting microwave circuits in the 4-8 GHz band. Non-reciprocity is achieved by actively modulating circuit elements on a slow time scale (10 – 100 ns). Our circulator's active components are dynamically tunable inductors constructed with arrays of dc-SQUIDS in series. The array inductance is tuned by varying the magnetic flux through the SQUIDS with fields weaker than 1 Oe. Initial tests show that the device exhibits non-reciprocity, but performance is degraded by trapped magnetic flux in the circuit. Nevertheless, the device meets many design goals including a tunable center frequency between 4-8 GHz and a high (-93 dBm) saturation power. This presentation will describe these tests and a new layout designed to avoid trapped flux.

**5:06PM V48.00014 Squeezing-enhanced superconducting qubit measurement using driven nonlinear resonators**, LUKE C. G. GOVIA, BENJAMIN LEVITAN, AASHISH A. CLERK, McGill University — Dispersive measurement of a superconducting qubit is a key ingredient in many contemporary protocols in circuit quantum electrodynamics, and high measurement fidelity has recently been achieved. However, as the number of qubits on chip and the complexity of protocols increases, so too does the required measurement fidelity. To reach higher fidelity, it has been proposed that squeezed microwave fields injected into the resonator can be used to reduce the noise in the measured field quadrature<sup>1,2</sup>. However, creating, preserving, and injecting a squeezed microwave field is a technologically challenging task. Here, we theoretically analyze the dispersive measurement of a qubit coupled to one or more driven nonlinear resonators, which provide an in situ source of microwave field squeezing. This is potentially a more flexible way of harnessing the physics that leads to the increase in measurement fidelity seen for both single-mode and two-mode squeezed states<sup>1</sup>, without the drawback of having to independently create and inject these states.

**5:18PM V48.00015 Closing a quantum feedback loop for a superconducting qubit inside a cryostat**, CHRISTIAN KRAGLUND ANDERSEN, Aarhus University, JOSEPH KERCKHOFF, KONRAD W LEHNERT, BENJAMIN J CHAPMAN, JILA, University of Colorado, Boulder, KLAUS MLMER, Aarhus University — Several quantum information protocols relies upon efficient feedback (or feed-forward) schemes. Recently, within the field of superconducting qubits, many experiments have shown tremendous progress towards high fidelity quantum feedback scheme. Some experiments work by traditional measurement based schemes where the classical output is processed on a classical "computer" before a signal is fed back to the qubits. Other approaches are working in a continuous coherent manner, where the full quantum description of the system creates an effective bath that relaxes the system into the desired state. This talk will present a different approach that aims to close a measurement based feedback loop inside a cryostat and, thus, the scheme works completely autonomous. This approach sidesteps many of the inefficiencies inherent in two-way communication between temperature stages in typical systems with room temperature controllers, and avoids increasing the cryogenic heat load. This controller may find a broad range of uses in multi-qubit systems, but here I analyze two specific demonstrative cases in single qubit-control and show simulations of the time evolution for the full system dynamics.

Session V50 DAMOP: Quantum Gases in Optical Lattices Hilton Baltimore Holiday Ballroom 1 - B. Svistunov, University of Massachusetts Amherst

**2:30PM V50.00001 Phase diagram of ferromagnetic spinor bosons in an optical lattice under an external magnetic field<sup>1</sup>**, KOHAKU H. Z. SO, Department of Physics, University of Tokyo, MASAHIITO UEDA, Department of Physics, University of Tokyo, and RIKEN Center for Emergent Matter Science (CEMS) — Recently, cold atoms with spin degrees of freedom have attracted considerable interest because of the possibility they offer of modelling quantum magnetism and exploring the interplay between spatial and spin degrees of freedom. While spinor bosons with antiferromagnetic interaction loaded in optical lattices have been widely studied in this context because of their properties such as an even-odd effect in the superfluid to Mott-insulator transition, those with ferromagnetic interaction has not been studied extensively. However, mean-field analysis in the continuum systems suggests that the competition between an external magnetic field and the ferromagnetic interaction could give rise to new and rich phases. We have studied ferromagnetic spinor bosons in an optical lattice under an external magnetic field. Using the decoupling mean-field approximation, we have obtained a rich ground-state phase diagram, in which, in addition to the well-known Mott-insulator and superfluid phases, polar and broken-axisymmetry superfluid phases arise. We also found that the transition between broken-axisymmetry superfluid phase and other phases is a first-order one across some part of the phase boundary, in remarkable contrast to the case without external magnetic fields.

**2:42PM V50.00002 Unconventional Bose-Einstein Condensations of Two-species Bosons in the  $p$ -orbital Bands in Optical Lattice**, JHIH-SHIH YOU, Department of Physics, Harvard University, I-KANG LIU, Department of Physics and Graduate Institute of Photonics, National Changhua University of Education, DAW-WEI WANG, Physics Department and Physics division, National Center for Theoretical Sciences, National Tsing-Hua University, SHIH-CHUAN GOU, Department of Physics and Graduate Institute of Photonics, National Changhua University of Education, CONGJUN WU, Department of Physics, University of California, San Diego — We investigate the unconventional Bose-Einstein condensations of two-species mixture with  $p$ -wave symmetry in the second band of a bipartite optical lattice. Different from the single-species case, the two-species boson mixture exhibits two non-equivalent complex BECs in the intraspecies-interaction-dominating regime, with one breaking time-reversal symmetry while the other not. When the interspecies interaction is tuned across the SU(2) invariant point, the system undergoes a quantum phase transition toward a real-valued checkerboard state characterized by a staggered spin density structure. An experimental scheme for phase measurement is presented. Finally, we will show strong coupling analysis on anti-Hund's rule, Mott-insulating states and the superfluid.

**2:54PM V50.00003 Phase diagram of strongly attractive  $p$ -orbital fermions on optical lattices**, THEJA DE SILVA, Augusta University — We examine a system of doubly degenerate  $p$ -orbital polarized fermions on a two-dimensional square lattice with a strong on-site interaction. For strong attractive interactions at the half filling density limit, a four-site square plaquette interaction term is generated from the directional tunneling dependence of  $p$ -orbitals. By treating both on-site interaction and the four-site square plaquette interaction term in fourth order perturbation theory, we derive an effective Hamiltonian for the system. We then map the resulting effective particle Hamiltonian into an effective spin-Hamiltonian and study the phase diagram of the system by using a variational mean field approach and a linear spin-wave theory. Further, we discuss the experimental signatures of the resulting phases within the context of current cold-atom experimental techniques.

**3:06PM V50.00004 Superfluidity of ultracold atomic gases of Fermi-Fermi mixtures on an optical lattice<sup>1</sup>**, JIBIAO WANG, QIJIN CHEN, Zhejiang University — Superfluidity of ultracold atomic gases of Fermi-Fermi mixtures has been under active investigation recently. Experimentally, mixtures of  $^6\text{Li}$ - $^{40}\text{K}$ ,  $^{171}\text{Yb}$ - $^{173}\text{Yb}$  and  $^6\text{Li}$ - $^{173}\text{Yb}$ , for example, have been prepared and cooled down to the quantum degeneracy regime, making the superfluid phase accessible in the near future. In this talk, we will address the superfluidity of ultracold Fermi-Fermi mixtures on 1D through 3D optical lattices, with varying mass and population imbalances and different densities, as they undergo BCS-BEC crossover, within a pairing fluctuation theory which includes self-consistently the important pseudogap effects at finite temperatures. We will present various phase diagrams and show the dramatic combined effects of mass and population imbalances and lattice periodicity. Implications for future experiment will be discussed. **3:18PM V50.00005 Magnetic-field-tunable Kondo effect in alkaline-earth cold atoms<sup>1</sup>**, LEONID ISAEV, ANA MARIA REY, JILA, NIST and Department of Physics, University of Colorado Boulder — We study quantum magnetism and emergent Kondo physics in strongly interacting fermionic alkaline-earth atoms in an optical lattice with two Bloch bands: one localized and one itinerant. For a fully filled narrow band (two atoms per lattice site) we demonstrate that an applied magnetic field provides an efficient control of the ground state degeneracy due to the field-induced crossing of singlet and triplet state of the localized atomic pairs. We exploit this singlet-triplet resonance, as well as magnetically tunable interactions of atoms in different electronic states via the recently-discovered inter-orbital Feshbach resonance, and demonstrate that the system exhibits a magnetic field-induced Kondo phase characterized by delocalization of local singlets and a large Fermi surface. We also determine the phase diagram of the system within an effective low-energy model that incorporates the above magnetic-field effect as well as atomic interactions in the two optical lattice bands. Our results can be tested with ultracold  $^{173}\text{Yb}$ , and provide a model for the magnetic field-induced heavy-fermion state in filled skutterudites such as  $\text{PrOs}_4\text{Sb}_{12}$ .

**3:30PM V50.00006 Cooling a Band Insulator with a Metal: Fermionic Superfluid in a Dimerized Holographic Lattice<sup>1</sup>**, ARIJIT HALDAR, VIJAY B. SHENOY, Indian Institute of Science Bangalore — A cold atomic realization of a quantum correlated state of many fermions on a lattice, eg. superfluid, has eluded experimental realization due to the entropy problem. Here we propose a route to realize such a state using holographic lattice and confining potentials. The potentials are designed to produce a *band insulating* state (low heat capacity) at the trap center, and a metallic state (high heat capacity) at the periphery. The metal “cools” the central band insulator by extracting out the excess entropy. The central band insulator can be turned into a superfluid by tuning an attractive interaction between the fermions. Crucially, the holographic lattice allows the emergent superfluid to have a *high transition temperature* – even twice that of the effective trap temperature. The scheme provides a promising route to a laboratory realization of a fermionic lattice superfluid, even while being adaptable to simulate other many body states. Reference: Scientific Reports 4, 6665 (2014).

**3:42PM V50.00007 Dirac and Weyl Rings in Three Dimensional Cold Atom Optical Lattices.**, YONG XU, CHUANWEI ZHANG, The University of Texas at Dallas — Recently three dimensional topological quantum materials with gapless energy spectra have attracted considerable interests in many branches of physics. Besides the celebrated example, Dirac and Weyl points which possess gapless point structures in the underlying energy dispersion, the topologically protected gapless spectrum can also occur along a ring, named Dirac and Weyl nodal rings. Ultra-cold atomic gases provide an ideal platform for exploring new topological materials with designed symmetries. However, whether Dirac and Weyl rings can exist in the single-particle spectrum of cold atoms remains elusive. Here we propose a realistic model for realizing Dirac and Weyl rings in the single-particle band dispersion of a cold atom optical lattice. Our scheme is based on previously experimentally already implemented Raman coupling setup for realizing spin-orbit coupling. Without the Zeeman field, the model preserves both pseudo-time-reversal and inversion symmetries, allowing Dirac rings. The Dirac rings split into Weyl rings with a Zeeman field that breaks the pseudo-time-reversal symmetry. We examine the superfluidity of attractive Fermi gases in this model and also find Dirac and Weyl rings in the quasiparticle spectrum.

**3:54PM V50.00008 The Detection of Massive Goldenstone (Higgs) Mode in Two-Dimensional Ultra-cold Atomic Lattice Systems**, KUN CHEN, University of Massachusetts, Amherst; University of Science and Technology of China, LONGXIANG LIU, University of Science and Technology of China, YOUJIN DENG, University of Science and Technology of China; University of Massachusetts, Amherst; MANUEL ENDRES, Harvard University; California Institute of Technology, LODÉ POLLET, Ludwig Maximilian University of Munich, NIKOLAY PROKOF'EV, University of Massachusetts, Amherst; Russian Research Center Kurchatov Institute — We discuss how to reveal the massive Goldstone mode, often referred to as the Higgs amplitude mode, near the Superfluid-to-Insulator quantum critical point (QCP) in a system of two-dimensional ultra-cold bosonic atoms in optical lattices. The spectral function of the amplitude response is obtained by analytic continuation of the kinetic energy correlation function calculated by Monte Carlo methods. Our results enable a direct comparison with the recent experiment [M. Endres, T. Fukuhara, D. Pekker, M. Cheneau, P. Schauß, C. Gross, E. Demler, S. Kuhr, and I. Bloch, Nature **487**, 454-458 (2012)], and demonstrate a good agreement for temperature shifts induced by lattice modulation. Based on our numerical analysis, we formulate the necessary conditions in terms of homogeneity, detuning from the QCP and temperature in order to reveal the massive Goldstone resonance peak in spectral functions experimentally. We also propose to apply a local modulation at the trap center to overcome the inhomogeneous broadening caused by the parabolic trap confinement.

**4:06PM V50.00009 Evolution of the Hofstadter butterfly in a tunable optical lattice**, MEHMET O. OKTEL, Bilkent Univ, NUR UNAL, Cornell Univ, FIRAT YILMAZ, Bilkent Univ — Advances in realizing artificial gauge fields on optical lattices promise experimental detection of topologically non-trivial energy spectra. Self-similar fractal energy structures, known as Hofstadter butterflies, depend sensitively on the geometry of the lattice, as well as the applied magnetic field [1]. The recent demonstration of an adjustable lattice geometry [L. Tarruell et al., Nature **483**, 302 (2012)] presents a unique opportunity to study this dependence. We calculate the Hofstadter butterflies that can be obtained in such an adjustable lattice and find three qualitatively different regimes. We show that the existence of Dirac points at zero magnetic field does not imply the topological equivalence of spectra at finite field. As the real-space structure evolves from the checkerboard to the honeycomb lattice, two square lattice Hofstadter butterflies merge to form a honeycomb lattice butterfly in a topologically non-trivial way, as it is accomplished by sequential closing of infinitely many gaps. We discuss the evolution of topological properties with underlying lattice geometry by calculating the Chern numbers and comment on the validity of simulating graphene in such an adjustable lattice. [1] F. Yilmaz, F. Nur Unal, and M. O. Oktel, Phys. Rev. A **91**, 063628 (2015).

**4:18PM V50.00010 Proposals for quantum simulating simple lattice gauge theory models using optical lattices<sup>1</sup>**, JIN ZHANG, University of California, Riverside, JUDAH UNMUTH-YOCKEY, University of Iowa, ALEXEI BAZAVOV, University of California, Riverside, YANNICK MEURICE, University of Iowa, SHAN-WEN TSAI, University of California, Riverside — We derive an effective spin Hamiltonian for the (1+1)-dimensional Abelian Higgs model in the strongly coupled region by integrating out the link variables. With finite spin truncations, the Hamiltonian can be matched with a 1-dimensional two-species Bose Hubbard model in the strong-coupling limit that can be implemented with cold atoms on an optical lattice. We study the phase diagram of the original Abelian Higgs model with Monte Carlo simulation and Tensor Renormalization Group methods. The results show a crossover line which terminates near the Kosterlitz-Thouless transition point. The effective quantum Hamiltonian is also studied with the DMRG method, and we find that they have a similar behavior. We discuss practical experimental implementations for our quantum simulator. Species-dependent optical lattices and ladder systems with double-well potentials are considered. We show how to obtain each of the interaction parameters required in the Bose-Hubbard model that we obtained, and confirm the possibility of tuning these interactions to the region in which our mapping is valid. We emphasize that this proposal for quantum simulating a gauge theory uses a manifestly gauge-invariant formulation and Gauss's Law is therefore automatically satisfied.

**4:30PM V50.00011 Topological Nodal-Line Superfluid in Spin-Orbit Coupled Cold Atomic Systems**, WEN-YU HE, DONG-HUI XU, TONG ZHOU, K. T. LAW, Hong Kong University of Science and Technology, HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — Topological nodal line superconductivity or superfluidity is a fascinating topological gapless phase which hosts bulk Weyl ring degeneracy in the quasiparticle excitation spectrum and supports Majorana zero bound modes with a large density of states at the edge. In this work, based on the experimentally realized 1D spin orbit coupling, we show the emergence of topological nodal line superfluid phase in Fermionic atoms trapped in 3D cubic optical lattice when the s wave pairing field is introduced through Feshbach resonance between the two atomic hyperfine spin states. The nodal line degeneracy is further found to evolve into Weyl nodes once another component of spin orbit coupling field enters to break the chiral symmetry. The momentum resolved radio frequency spectroscopy is suggested to manifest the topological nodal line superfluid phase.

**4:42PM V50.00012 Vacancy dynamics in the paramagnetic environment**, JOHAN CARLSTROM, BORIS SVISTUNOV, NIKOLAY PROKOFIEV, University of Massachusetts — We consider the motion of a single vacancy in a magnetic spin-1/2 lattice. Examples of realisations of this model include vacancies in a He3 solid or holes in the t-J model with J=0. This motion is ballistic when spins exhibit ferromagnetic order, with  $\langle |r(t)| \rangle$  growing linearly with time. However in the disordered paramagnet, the motion of the vacancy becomes highly nontrivial, and no exact solution to this outstanding problem is known. This scenario is known as the Brinkman-Rice problem. We report here numerical results for the spatial probability distribution of the vacancy obtained by integrating the time evolution operator through Monte Carlo and averaging over a large number of random spin realisations. We find highly counterintuitive results, with the probability of finding the vacancy at a given site oscillating in time. These results can be verified in experiments with ultra-cold fermions in optical lattice at a temperature high enough that the spins are disordered.

**4:54PM V50.00013 Scratched-XY Universality and Phase Diagram of Disordered 1D Bosons in Optical Lattice**, ZHIYUAN YAO, Department of Physics, University of Massachusetts, Amherst, MA 01003, USA, LODE POLLET, Department of Physics, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, University of Munich, Theresienstrasse 37, 80333 M, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, Amherst, MA 01003, USA — The superfluid-insulator quantum phase transition in a 1D system with weak links belongs to the so-called scratched-XY universality class, provided the irrenormalizable exponent  $\zeta$  characterizing the distribution of weak links is smaller than 2/3. With a combination of worm-algorithm Monte Carlo simulations and asymptotically exact analytics, we accurately trace the position of the scratched-XY critical line on the ground-state phase diagram of bosonic Hubbard model at unity filling. In particular, we reveal the location of the tricritical point separating the scratched-XY criticality from the Giamarchi-Schulz one.

**5:06PM V50.00014 Application of the DMRG in two dimensions: a parallel tempering algorithm<sup>1</sup>**, SHIJIE HU, Department of Physics and Research Center Optimas, Technical University Kaiserslautern, 67663 Kaiserslautern, Germany, JIZE ZHAO, Institute of Applied Physics and Computational Mathematics, Beijing 100088, China, XUEFENG ZHANG, SEBASTIAN EGGERT, Department of Physics and Research Center Optimas, Technical University Kaiserslautern, 67663 Kaiserslautern, Germany — The Density Matrix Renormalization Group (DMRG) is known to be a powerful algorithm for treating one-dimensional systems. When the DMRG is applied in two dimensions, however, the convergence becomes much less reliable and typically "metastable states" may appear, which are unfortunately quite robust even when keeping a very high number of DMRG states. To overcome this problem we have now successfully developed a parallel tempering DMRG algorithm. Similar to parallel tempering in quantum Monte Carlo, this algorithm allows the systematic switching of DMRG states between different model parameters, which is very efficient for solving convergence problems. Using this method we have figured out the phase diagram of the xxz model on the anisotropic triangular lattice which can be realized by hardcore bosons in optical lattices.

<sup>1</sup>SFB Transregio 49 of the Deutsche Forschungsgemeinschaft (DFG) and the Allianz für Hochleistungsrechnen Rheinland-Pfalz (AHRP)

**5:18PM V50.00015 Many-body physics of ultracold doublet sigma molecules in optical lattices<sup>1</sup>**, GAVRIIL SHCHEDRIN, DANIEL JASCHKE, WEI HAN, LINCOLN CARR, Colorado School of Mines, Golden, Colorado, USA, DERMOT G. GREEN, Durham University, Durham, UK, JESUS ALDEGUNDE, Universidad de Salamanca, Salamanca, Spain, JEREMY M. HUTSON, Durham University, Durham, UK — The creation of ultracold polar molecules provides a unique opportunity to discover and explore new regimes in strongly interacting many-body quantum systems. Polar molecules have strong long-range dipole-dipole interactions that allow one to realize exotic phenomena such as topological phases and quantum magnetism. We explore quantum many-body systems formed by molecules in doublet sigma ( $^2\Sigma$ ) states, with both electric dipole moments and electron spin  $S = 1/2$ , but without electronic orbital momentum. The Hamiltonian for doublet sigma molecules includes molecular rotation terms, spin-rotation interaction, hyperfine terms including both spin-spin and nuclear electric quadrupole interactions, and molecular dipole-dipole interactions. The complete control of the molecular quantum states can be accomplished by applying electric and magnetic fields to molecules trapped in optical lattices. We provide the complete theoretical treatment for experimentally relevant doublet sigma molecules such as SrF and CaF and discuss the associated single-body and many-body physics.

**2:30PM V51.00001 Accurate Electronic, Transport, and Bulk Properties of Wurtzite Beryllium Oxide (BeO)** , CHEICK OUMAR BAMBA, YURIY MALOZOVSKY, LASHOUNDA FRANKLIN, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813 — We present *ab-initio*, self-consistent density functional theory (DFT) description of electronic, transport, and bulk properties of wurtzite Beryllium oxide (w-BeO). We used a local density approximation potential (LDA) and the linear combination of atomic orbitals (LCAO) formalism. Our implementation of the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF), ensures the full, physical content of our local density approximation (LDA) calculations – as per the derivation of DFT [AIP Advances, 4, 127104 (2014)] We report the band gap, density of states, partial density of state, effective masses, and the bulk modulus. Our calculated band gap of 10.29 eV, using an experimental, room temperature lattice constant of 2.6979 Å at room temperature is in agreement with the experimental value of 10.6 eV. Acknowledgments: This work was funded in part the US National Science Foundation [NSF, Award Nos. EPS-1003897, NSF (2010-2015)-RII-SUBR, and HRD-1002541], the US Department of Energy, National Nuclear Security Administration (NNSA, Award No. DE-NA0002630), LaSPACE, and LONI-SUBR.

**2:42PM V51.00002 First principles studies of the stability and Schottky barriers of metal/CdTe(111) interfaces** , ZHEN LIU, Department of Physics, California State University Northridge, MASOEHNG MIAO, Department of Chemistry and Biochemistry, California State University Northridge, NICHOLAS KIOUSSIS, Department of Physics, California State University Northridge, FIKRI AQARIDEN, Y. CHANG, CHRISTOPH GREIN, Sivananthan Laboratories, 590 Territorial Dr, Unit H Bolingbrook — CdZnTe and CdTe based semiconductor X-Ray and Gamma-Ray detectors have been intensively studied recently due to their promising potentials for achieving high-resolution, high signal-to-noise ratios and low leakage current, all are desirable features in applications ranging from medical diagnostics to homeland security. Using density functional calculations, we systematically studied the stability, the atomic and electronic structures of the interfaces between CdTe (111) surfaces (Cd- and Te-terminated) and the selected metals (Cu, Al Ni, Pd and Pt). We also calculated the Schottky barrier height (SBH) by aligning the electrostatic potentials in semiconductor and metal regions. Our calculations revealed significant differences between the Cd- and Te- terminated interfaces. While metals tend to deposit directly on reconstructed Te-terminated surfaces, they form a Te-metal alloy layer at the Cd-Terminated metal/CdTe interface. For both Te- and Cd- terminated interfaces, the Schottky barrier heights do not depend much on the choice of metals despite the large variation of the work functions. On the other hand, the interface structure is found to have large effect on the SBH, which is attributed to the metal induced states in the gap.

**2:54PM V51.00003 Ab-initio Electronic, Transport and Related Properties of Zinc Blende Boron Arsenide (zb-BAs)** , IFEANYI H. NWIGBOJI, Department of Computational Science, University of Texas at El Paso, El-Paso, TX 79968 USA., YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813 — We present results from *ab-initio*, self-consistent density functional theory (DFT) calculations of electronic, transport, and bulk properties of *zinc blende* boron arsenide (zb-BAs). We utilized a local density approximation (LDA) potential and the linear combination of atomic orbital (LCAO) formalism. Our computational technique follows the Bagayoko, Zhao, and Williams method, as enhanced by Ekuma and Franklin. Our results include electronic energy bands, densities of states, and effective masses. We explain the agreement between these findings, including the indirect band gap, and available, corresponding, experimental ones. This work confirms the capability of DFT to describe accurately properties of materials, provided the computations adhere to the conditions of validity of DFT [AIP Advances, 4, 127104 (2014)]. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0002630), LaSPACE, and LONI-SUBR.

**3:06PM V51.00004 Ab-initio Density Functional Theory (DFT) Studies of Electronic, Transport, and Bulk Properties of Sodium Oxide (Na<sub>2</sub>O).** , DANIEL POLIN, Department of Physics New York University, New York, NY 10003, USA, JOSHUA ZIEGLER, Department of Physics Case Western Reserve University, Cleveland, OH 44106, USA., YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics Southern University and AM College, Baton Rouge, LA 70813, USA. — We present the findings of *ab-initio* calculations of electronic, transport, and structural properties of cubic sodium oxide (Na<sub>2</sub>O). These results were obtained using density functional theory (DFT), specifically a local density approximation (LDA) potential, and the linear combination of Gaussian orbitals (LCAO). Our implementation of LCAO followed the Bagayoko, Zhao, and Williams method as enhanced by the work of Ekuma and Franklin (BZW-EF). We describe the electronic band structure of Na<sub>2</sub>O with a direct band gap of 2.22 eV. Our results include predicted values for the electronic band structure and associated energy eigenvalues, the total and partial density of states (DOS and pDOS), the equilibrium lattice constant of Na<sub>2</sub>O, and the bulk modulus. We have also calculated the electron and holes effective masses in the  $\Gamma$  to L,  $\Gamma$  to X, and  $\Gamma$  to K directions. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0002630), LaSPACE, and LONI-SUBR.

**3:18PM V51.00005 Hybrid DFT calculations of the band structure of alpha-Sn** , ERIN DUPAY<sup>1</sup>, LUCAS DOMULEVICZ<sup>2</sup>, HENRY CASTEJON<sup>3</sup>, AMJAD NAZZAL<sup>4</sup>, Wilkes Univ — The electronic properties of bulk alpha-tin were revisited using first principles. The band structure, in addition to other properties, such as the absorption spectrum and density of states, were calculated using Density Functional Theory and the HSE06 hybrid functional. The direct and indirect band gaps obtained from these calculations are in better agreement with experimental results than previously reported calculations.

**3:30PM V51.00006 Ab-initio Calculation of Optoelectronic and Structural Properties of Cubic Lithium Oxide (Li<sub>2</sub>O).** , JOSHUA ZIEGLER, Department of Physics, Case Western Reserve University, Cleveland, OH 44106, USA, DANIEL POLIN, Department of Physics, New York University, New York City, NY 10003, USA, YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813, USA — Using the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF), we performed *ab-initio*, density functional theory (DFT) calculations of optoelectronic, transport, and bulk properties of Li<sub>2</sub>S. In so doing, we avoid “band gap” and problems plaguing many DET calculations [AIP Advances 4, 127104 (2014)]. We employed a local density approximation (LDA) potential and the linear combination of atomic orbitals (LCAO). With the BZW-EF method, our results possess the full, physical content of DFT and agree with available, corresponding experimental ones. In particular, we found a room temperature indirect band gap of 6.659 eV that compares favorably with experimental values ranging from 5 to 7.99 eV. We also calculated total and partial density of states (DOS and PDOS), effective masses of charge carriers, the equilibrium lattice constant, and the bulk modulus. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award Nos. DE-NA0001861 and DE- NA0002630), LaSPACE, and LONI-SUBR.

**3:42PM V51.00007 Comparisons of Accurate Electronic, Transport, and Bulk Properties of XP (X=B, Al, Ga, In).** , YURIY MALOZOVSKY, JOHN EJEMBI, Department of Physics Southern, University and AM College, Baton Rouge, LA 70813, USA, AZIZJON SALIEV, Department of Electrical and Computer Engineering, Binghamton University, NY 13902, USA, LASHOUNDA FRANKLIN, DIOLA BAGAYOKO, Department of Physics Southern, University and AM College, Baton Rouge, LA 70813, USA — We present comparisons of results from *ab-initio*, self-consistent local density approximation (LDA) calculations of accurate, electronic and related properties of zinc blende XP (X=B, Al, Ga, In) phosphides. We implemented the linear combination of atomic orbitals following the Bagayoko, Zhao, and Williams (BZW) method as enhanced by Ekuma and Franklin (BZW-EF). Consequently, our results have the full physical content of DFT and agree very well with corresponding experimental ones [AIP Advances, 4, 127104 (2014)]. Our calculated, indirect band gap of 2.02 eV for BP, 2.56 eV for AIP, and of 2.29 eV for GaP, from  $\Gamma$  to X-point, are in excellent agreement with experimental values. Our calculated direct band gap of 1.43 eV, at  $\Gamma$ , for InP is also in an excellent agreement with experimental value. We discuss calculated electron and hole effective masses, total (DOS) and partial (pDOS) densities of states, and the bulk modulus of these phosphides. Acknowledgments: NSF and the Louisiana Board of Regents, LASIGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, DOE – National, Nuclear Security Administration (NNSA) (Award Nos. DE-NA0001861 and DE- NA0002630), LaSPACE, and LONI-SUBR.

**3:54PM V51.00008 *Ab-initio* Calculations of Electronic Properties of Calcium Fluoride (CaF<sub>2</sub>)** , BIR BOHARA, LASHOUNDA FRANKLIN, YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813, USA — We have performed first principle, local density approximation (LDA) calculations of electronic and related properties of cubic calcium fluoride (CaF<sub>2</sub>). Our non-relativistic computations employed the Ceperley and Alder LDA potential and the linear combination of atomic orbitals (LCAO) formalism. The implementation of the LCAO formalism followed the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). We discuss the electronic energy bands, including the large band gap, total and partial density of states, electron and hole effective masses, and the bulk modulus. Our calculated, indirect (X- $\Gamma$ ) band gap is 12.98 eV; it is 1 eV above an experimental value of 11.8 eV. The calculated bulk modulus (82.89 GPa) is excellent agreement with the experimental result of 82.0  $\pm$  0.7. Our predicted equilibrium lattice constant is 5.42Å. Acknowledgments: This work is funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASIGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR], and NSF HRD-1002541, the US Department of Energy, National, Nuclear Security Administration (NNSA) (Award No. DE-NA-0002630), LaSPACE, and LONI-SUBR.

**4:06PM V51.00009 Direct detection of dark matter via single-electron excitations in semiconductors** , ROUVEN ESSIG, MARIVI FERNANDEZ-SERRA, Stony Brook University, JEREMY MARDON, Stanford University, ADRIAN SOTO, Stony Brook University, TOMER VOLANSKY, Tel Aviv University, TIEN-TIEN YU, Stony Brook University — Over the last several decades, there has been an enormous experimental effort to search for dark matter (DM). Traditionally, semiconductors have been used to detect DM via scattering with nuclei and the subsequent relaxation of the crystal. However, if DM has mass below order 10 GeV these methods lose detection sensitivity. This is because the DM is lighter than a typical nucleus and, since DM particles move at non-relativistic speeds, they cannot transfer enough energy and momentum to the crystal to produce observable signals. In our work [arXiv:1509.01598], we demonstrate that DM-electron scattering in semiconductors increases the sensitivity of DM detection in this mass regime by several orders of magnitude and is a viable avenue for the direct detection of sub-GeV DM. We use density functional theory (DFT) to calculate the crystal wavefunctions and the band energies, which we correct with an empirical scissor operator. These wavefunctions are used to do perturbation theory, which allows us to calculate the DM-electron scattering rates. In this talk we will focus on the computational and theoretical challenges, discuss future directions and present new expected limits for DM-electron scattering.

**4:18PM V51.00010 Raman spectra calculations for Si-Ge core-shell nanocrystals using *ab initio* real-space methods**<sup>1</sup> , N. SCOTT BOBBITT, JAMES R. CHELIKOWSKY, Univ of Texas, Austin — We use a real-space pseudopotential method within density functional theory to calculate Raman spectra for Si-Ge core-shell nanocrystals. We examine the lattice strain induced by the interface of the core and the shell. We calculate how this strain affects the vibrational modes and Raman spectra. We also find that the relative size of the Si and Ge peaks in the Raman spectrum is proportional to the size of the Si core and Ge shell regions, which suggests that Raman spectroscopy can be used to experimentally determine the relative size of the core and the outer shell in these nanocrystals.

<sup>1</sup>This work is supported by the DOE under grant number DE-FG02-06ER46286. Computations were performed on machines at TACC and NERSC.

**4:30PM V51.00011 *k.p* Parameters with Accuracy Control from Preexistent First-Principles Band Structure Calculations**<sup>1</sup> , GUILHERME SIPAHI, CARLOS M. O. BASTOS, FERNANDO P. SABINO, PAULO E. FARIA JUNIOR, TIAGO DE CAMPOS, JUAREZ L. F. DA SILVA, Universidade de So Paulo — The *k.p* method is a successful approach to obtain band structure, optical and transport properties of semiconductors. It overtakes the *ab initio* methods in confined systems due to its low computational cost since it is a continuum method that does not require all the atoms' orbital information. From an effective one-electron Hamiltonian, the *k.p* matrix representation can be calculated using perturbation theory and the parameters identified by symmetry arguments. The parameters determination, however, needs a complementary approach. In this paper, we developed a general method to extract the *k.p* parameters from preexistent band structures of bulk materials that is not limited by the crystal symmetry or by the model. To demonstrate our approach, we applied it to zinc blende GaAs band structure calculated by hybrid density functional theory within the Heyd-Scuseria-Ernzerhof functional (DFT-HSE), for the usual 8×8 *k.p* Hamiltonian. Our parameters reproduced the DFT-HSE band structure with great accuracy up to 20% of the first Brillouin zone (FBZ). Furthermore, for fitting regions ranging from 7-20% of FBZ, the parameters lie inside the range of values reported by the most reliable studies in the literature.

<sup>1</sup>The authors acknowledge financial support from the Brazilian agencies CNPq (grant #246549/2012-2) and FAPESP (grants #2011/19333-4, #2012/05618-0 and #2013/23393-8).

**4:42PM V51.00012 Transferable tight binding model for strained group IV and III-V heterostructures** , YAOHUA TAN, Dr, MICHEAL POVOLOTSKYI, TILLMANN KUBIS, TIMOTHY BOYKIN, GERHARD KLIMECK, Prof — Modern semiconductor devices have reached critical device dimensions in the range of several nanometers. For reliable prediction of device performance, it is critical to have a numerical efficient model that are transferable to material interfaces. In this work, we present an empirical tight binding (ETB) model with transferable parameters for strained IV and III-V group semiconductors. The ETB model is numerically highly efficient as it make use of an orthogonal sp<sup>3</sup>d<sup>5</sup>s\* basis set with nearest neighbor inter-atomic interactions. The ETB parameters are generated from HSE06 hybrid functional calculations. Band structures of strained group IV and III-V materials by ETB model are in good agreement with corresponding HSE06 calculations. Furthermore, the ETB model is applied to strained superlattices which consist of group IV and III-V elements. The ETB model turns out to be transferable to nano-scale hetero-structure. The ETB band structures agree with the corresponding HSE06 results in the whole Brillouin zone. The ETB band gaps of superlattices with common cations or common anions have discrepancies within 0.05eV.

**4:54PM V51.00013 Valley Physics in Tin (II) Sulfide**, ALEKSANDR RODIN, LIDIA GOMES, ALEXANDRA CARVALHO, ANTONIO CASTRO NETO, Natl Univ of Singapore — The field of 2D physics has experienced a rapid growth in recent years. Improved manipulation and growth techniques have resulted in isolation and characterization of novel materials with fascinating properties. A family of compounds that was described recently is transition metal monochalcogenides. Due to their non-trivial crystal structure, studying these materials is a challenging task. Using a combination of density functional theory (DFT) and analytical methods, we investigate the band structure of tin (II) sulfide, a naturally occurring material, to discover that SnS has two pairs of valleys positioned in perpendicular orientation to each other. DFT is employed to construct  $\mathbf{k} \cdot \mathbf{p}$  Hamiltonians around each of the valleys. Finally, we show that these individual valley pairs can be separated using linearly polarized light or by utilizing the nonlinear current response, making SnS a candidate for valleytronic applications.

**5:06PM V51.00014 Reduced-Density-Matrix Description of Single-Photon and Multi-Photon Processes in Quantized Many-Electron Systems<sup>1</sup>**, VERNE JACOBS, Naval Research Laboratory, ALEX KUTANA, Rice University — The frequency-dependent transition rates for single-photon and multi-photon processes in quantized many-electron systems are evaluated using a reduced-density-matrix approach. We provide a fundamental quantum-mechanical foundation for systematic spectral simulations. A perturbation expansion of the frequency-domain Liouville-space self-energy operator is introduced for detailed evaluations of the spectral-line shapes. In the diagonal-resolvent (isolated-line) and short-memory-time (Markov) approximations, the lowest-order contributions to the spectral-line widths and shifts associated with environmental electron-photon and electron-phonon interactions are systematically evaluated. Our description is directly applicable to electromagnetic processes in a wide variety of many-electron systems, without premature approximations. In particular, our approach can be applied to investigate quantum optical phenomena involving electrons in both bulk and nanoscale semiconductor materials entirely from first principles, using a single-electron basis set obtained from density functional theory as a starting point for a many-electron description.

**5:18PM V51.00015 Lifshitz Transitions in Bias-Resonant Twisted Bilayer Graphene**, STEVE CARTER, HRIDIS PAL, MARKUS KINDERMANN, Georgia Institute of Technology — Topological transitions of the Fermi surface (Lifshitz transitions) have been shown to cause discontinuities in materials properties. One such transition has been predicted to occur in AB-stacked bilayer graphene.<sup>[1]</sup> In this talk we discuss incommensurately twisted bilayer graphene with an interlayer bias energy.<sup>[2]</sup> New physics emerges when the bias energy is tuned into resonance with the kinetic energy cost of interlayer hopping due to the mismatch between the Dirac points of the twisted layers. We show that the system near resonance is described by relatively simple low-energy theories that nevertheless produce a vast number of Lifshitz transitions. An exhaustive description of the topological transitions in a universal regime at weak interlayer coupling will be presented. [1] Y. Lemonik et al. Phys. Rev. B, 82:201408 (2010). [2] H.K. Pal et al. arXiv:1409.1971 (2014).

## Thursday, March 17, 2016 2:30PM - 4:18PM – Session V53 DFD: Fluid Mechanics - General Hilton Baltimore Holiday Ballroom 4 -

**2:30PM V53.00001 Equivalence of Non-Equilibrium Ensembles and Representation of Friction in Turbulent Flows: The Lorenz '96 Model**, VALERIO LUCARINI, University of Hamburg, Hamburg, Germany, GIOVANNI GALLAVOTTI, Sapienza University of Roma — We construct different equivalent non-equilibrium ensembles in the Lorenz '96 model of atmospheric turbulence. The vector field can be decomposed into an energy-conserving, time-reversible part, plus a non-time reversible part, including forcing and dissipation. We construct a modified version of the model where viscosity varies with time, so that energy is conserved, and the dynamics is time-reversible. The statistical properties of the irreversible and reversible model are in excellent agreement, if in the latter the energy is kept constant at a value equal to the time-average realized with the irreversible model. The average contraction rate of the phase space of the time-reversible model agrees with that of the irreversible model, where it is constant by construction. We show that the phase space contraction rate obeys the fluctuation relation, and we interpret its finite time corrections. A local version of the fluctuation relation is explored and successfully checked. The equivalence between the two ensembles extends to the Lyapunov exponents. These results have relevance in motivating the importance of the chaotic hypothesis. In explaining that we have the freedom to model non-equilibrium systems using different but equivalent approaches.

**2:42PM V53.00002 Optimum design of vortex generator elements using Kriging surrogate modelling and genetic algorithm**, RITHWIK NEELAKANTAN, RAMAN BALU, ABHINAV SAJI, Ace College of Engineering — Vortex Generators (VGs) are small angled plates located in a span wise fashion aft of the leading edge of an aircraft wing. They control airflow over the upper surface of the wing by creating vortices which energise the boundary layer. The parameters considered for the optimisation study of the VGs are its height, orientation angle and location along the chord in a low subsonic flow over a NACA0012 airfoil. The objective function to be maximised is the L/D ratio of the airfoil. The design data are generated using the commercially available ANSYS FLUENT software and are modelled using a Kriging based interpolator. This surrogate model is used along with a Generic Algorithm software to arrive at the optimum shape of the VGs. The results of this study will be confirmed with actual wind tunnel tests on scaled models.

**2:54PM V53.00003 Predicting the Noise of High Power Fluid Targets Using Computational Fluid Dynamics**, MICHAEL MOORE, Jefferson Lab, Old Dominion University, SILVIU COVRIG DUSA, Jefferson Lab — The 2.5 kW liquid hydrogen (LH2) target used in the  $Q_{weak}$  parity violation experiment is the highest power LH2 target in the world and the first to be designed with Computational Fluid Dynamics (CFD) at Jefferson Lab. The  $Q_{weak}$  experiment determined the weak charge of the proton by measuring the parity-violating elastic scattering asymmetry of longitudinally polarized electrons from unpolarized liquid hydrogen at small momentum transfer ( $Q^2 = 0.025 \text{ GeV}^2$ ). This target satisfied the design goals of  $< 1\%$  luminosity reduction and  $< 5\%$  contribution to the total asymmetry width (the  $Q_{weak}$  target achieved  $2\%$  or 55ppm). State of the art time dependent CFD simulations are being developed to improve the predictions of target noise on the time scale of the electron beam helicity period. These predictions will be bench-marked with the  $Q_{weak}$  target data. This work is an essential component in future designs of very high power low noise targets like MOLLER (5 kW, target noise asymmetry contribution  $< 25 \text{ ppm}$ ) and MESA (4.5 kW).

### 3:06PM V53.00004 Fluid Dynamical Consequences of Current and Stress-Energy Conservation

, DILLON SCOFIELD, Dept Physics, Oklahoma State University, PABLO HUQ, College of Earth, Ocean, and Environment, Univ. Delaware — The dynamical consequences of fluid current conservation combined with the conservation of fluid stress-energy are used to develop the geometrodynamical theory of fluid flow (GTF). In the derivation of the GTF, we highlight the fact the continuity equation, equivalently the conservation of current density, implies the existence of the fluid dynamical vortex field. The vortex field transports part of the stress-energy; the other part of the stress-energy is transported by the fluid inertia field. Two channels of energy dissipation are determined by the GTF. One is an analog of the Joule heating found in electrodynamics. This follows from the conservation of stress-energy. The other dissipation channel arises from mechanisms leading to complex-valued constitutive parameters described in the electrodynamical analogy as due to a lossy medium. The dynamical consequences of the continuity equation, combined with the conservation of total stress-energy, then lead to a causal, covariant, theory of fluid flow, consistent with thermodynamics for all physically possible flow rates.

### 3:18PM V53.00005 The Geometry and Dynamics of a Propagating Front in a Chaotic Flow

Field, MARK PAUL, Virginia Tech — There are many important problems regarding transport in complex fluid flows with implications in science, nature, and technology. Examples include the combustion of pre-mixed gases in a turbulent flow, the complex patterns of reagents in a chemical system, the spread of a forest fire, and the outbreak of an epidemic. This talk explores the transport and dynamics of a reacting species in a chaotic fluid flow field. Large-scale parallel numerical simulations are used to explore the dynamics of propagating fronts in complex three-dimensional time-dependent fluid flows for the precise conditions of the laboratory. It is shown that a chaotic flow field enhances the front propagation when compared with a purely cellular flow field. This enhancement is quantified by computing measures of the spreading rate of the products and by quantifying the complexity of the three-dimensional front geometry for a range of chaotic flow conditions.

### 3:30PM V53.00006 Surface Acoustic Wave Transport and Mixing in Fluids in an Enclosed

Nanoslit, MORTEZA MIANSARIGAVZAN, JAMES FRIEND, University of California, San Diego — Non-laminar fluid flow was generated in a nanoslit using 20 MHz surface acoustic waves. A novel acoustic nanofluidic device was fabricated by a unique room-temperature, high-strength bonding method combining a 128-YX lithium niobate (LN) substrate with a second LN substrate containing a 1-cm long, 50–300-nm thick, 400  $\mu\text{m}$ -wide planar nanoslit. The nanoslit was verified to be extremely smooth (roughness  $< 5$  nm) and possess a uniformly rectangular shape. Despite an exceptionally low ( $\sim 10^{-5}$ ) hydrodynamic Reynolds number within the nanoslit, acoustic streaming induced by the SAW is found to drive filling of the *hydrophilic* nanoslit greatly in excess of the typical Washburn capillary filling rate, a unique ability to completely *drain* the hydrophilic nanoslit of fluid, induce rapid mixing of fluid within, and drive nanoparticle and early evidence of molecular separation from the fluid at the nanoslit exit as the fluid passes through. The unique physical phenomena may prove to be useful across a broad range of applications where it facilitates the use of nanofluidics in chemistry and medicine. It illuminates an extraordinary ability to use sound at ever smaller scales to manipulate fluids and particles within in unexpected ways.

### 3:42PM V53.00007 Electroosmotic Entry Flow with Joule Heating Effects.

, RAMA PRABHAKARAN, AKSHAY KALE, XIANGCHUN XUAN, Clemson University — Electrokinetic flow, which transports liquids by electroosmosis and samples by electrophoresis, is the transport method of choice in microfluidic chips over traditional pressure-driven flows. Studies on electrokinetic flows have so far been almost entirely limited to inside microchannels. Very little work has been done on the electroosmotic fluid entry from a reservoir to a microchannel, which is the origin of all fluid and sample motions in microchips. We demonstrate in this talk that strong vortices of opposite circulating directions can be generated in electroosmotic entry flows. We also develop a two-dimensional depth-averaged numerical model of the entire microchip to predict and understand the fluid temperature and flow fields at the reservoir-microchannel junction.

### 3:54PM V53.00008 Accounting for anomalous energy-dissipation in guided flows

, PABLO HUQ, College Earth, Ocean, and Environment, Univ. Delaware, DILLON SCOFIELD, Dept. of Physics, Oklahoma State University — The Navier-Stokes theory significantly underestimates energy-dissipation in time-dependent flows through flow guides such as ones with helical geometry. We show the geometrodynamical theory of fluids (GTF) accounts for this anomalous energy-dissipation by predicting the excitation of transverse modes of flow leading to such dissipation. According to the GTF, the transverse modes are composed of vorticity and swirl fields which together constitute a vortex field  $F$  which is a function of the swirl and vorticity fields. Analysis shows the energy-dissipation depends on the wave energy, the dot product of the swirl and the vorticity, as well as their cross product. These lead to heating of the fluid at a rate proportional to the work the current does against the swirl field. For the constitutive parameters of the theory we find the values for water to be  $\lambda = 0.01/(\text{cm/s})$ , and  $\kappa = 1$  [unitless]. A lower bound for the effective value of the speed of the first transverse modes is found to be 90 cm/sec. We determine that a dimensionless vortex number,  $R_v$ , usefully delineates the excitation of the transverse mode flow regime.

### 4:06PM V53.00009 Effect of Curvature Parameter on Non-Darcy Mixed Convective Flow in a Vertical Annulus: A LTNE Approach

, MOUMITA BHOWMIK, PREMANANDA BERA, Indian Institute of Technology Roorkee — The influence of curvature parameter on fully developed mixed convective flow in a vertical annulus filled with porous medium under local thermal non-equilibrium (LTNE) state has been addressed here. Since the curvature parameter ( $C$ ) describes the size of the enclosure, therefore the main emphasize is given to understand its impact on other controlling parameters. Based on computational results,  $C$  has a significant impact on both heat transfer rate as well as flow profiles for stably stratified flow. It has a tendency to reduce the magnitude of the maximum velocity. It is also observed that depending on other parameters, increment in  $C$  may have tendency to make the velocity profile free from back flow. The heat transfer rate is obtained maximum at a small value of  $C$  which is independent of media permeability and converges asymptotically on increasing  $C$ . At the end, the linear stability analysis based on normal mode technique has been used to verify the results obtained from basic flow study. Overall, from both basic flow as well as linear stability results, it is found that increment in  $C$  makes the flow profile smooth which means  $C$  has tendency to stabilize the flow.

**Thursday, March 17, 2016 2:30PM - 5:30PM –**

Session V55 DBIO GSNP DPOLY: DNA Physics and Chromatin Organization Hilton Baltimore Holiday Ballroom 6 - Alexandre V. Morozov, Rutgers University

## 2:30PM V55.00001 Micromechanical study of protein-DNA interactions and chromosomes<sup>1</sup>

JOHN MARKO<sup>2</sup>, Northwestern University — I will discuss micromechanics experiments that our group has used to analyze protein-DNA interactions and chromosome organization. In single-DNA experiments we have found that a feature of protein-DNA complexes is that their dissociation rates can depend strikingly on bulk solution concentrations of other proteins and DNA segments; I will describe experiments which demonstrate this effect, which can involve tens-fold changes in off-rates with submicromolar changes in solution concentrations. Second, I will discuss experiments aimed at analyzing large-scale human chromosome structure; we isolate metaphase chromosomes, which in their native form behave as remarkably elastic networks of chromatin. Exposure to DNA-cutting restriction enzymes completely eliminates this elasticity, indicating that there is not a mechanically contiguous protein "scaffold" from which the chromosome gains its stability. I will show results of siRNA experiments indicating that depletion of condensin proteins leads to destabilization of chromosome mechanics, indicating condensin's role as the major chromatin "cross-linker" in metaphase chromosomes. Finally I will discuss similar experiments on human G1 nuclei, where we use genetic and chemical modifications to separate the contributions of the nuclear lamina and chromatin to the mechanical stiffness of the nucleus as a whole.

<sup>1</sup>Supported by the NSF (DMR-1206868, MCB-1022117) and the NIH (GM105847, CA193419).

<sup>2</sup>I'd like to present my talk from my laptop (movies)

## 3:06PM V55.00002 Polymer models of chromosome (re)organization, LEONID MIRNY, MIT — Chromosome

Conformation Capture technique (Hi-C) provides comprehensive information about frequencies of spatial interactions between genomic loci. Inferring 3D organization of chromosomes from these data is a challenging biophysical problem. We develop a top-down approach to biophysical modeling of chromosomes. Starting with a minimal set of biologically motivated interactions we build ensembles of polymer conformations that can reproduce major features observed in Hi-C experiments. I will present our work on modeling organization of human metaphase and interphase chromosomes. Our works suggests that active processes of loop extrusion can be a universal mechanism responsible for formation of domains in interphase and chromosome compaction in metaphase.

## 3:42PM V55.00003 Action at a Distance in the Cell's Nucleus<sup>1</sup>, JANE KONDEV, Brandeis University — Various

functions performed by chromosomes involve long-range communication between DNA sequences that are tens of thousands of bases apart along the genome, and microns apart in the nucleus. In this talk I will discuss experiments and theory relating to two distinct modes of long-range communication in the nucleus, chromosome looping and protein hopping along the chromosome, both in the context of DNA-break repair in yeast. Yeast is an excellent model system for studies that link chromosome conformations to their function as there is ample experimental evidence that yeast chromosome conformations are well described by a simple, random-walk polymer model. Using a combination of polymer physics theory and experiments on yeast cells, I will demonstrate that loss of polymer entropy due to chromosome looping is the driving force for homology search during repair of broken DNA by homologous recombination. I will also discuss the spread of histone modifications along the chromosome and away from the DNA break point in the context of simple physics models based on chromosome looping and kinase hopping, and show how combining physics theory and cell-biology experiment can be used to dissect the molecular mechanism of the spreading process. These examples demonstrate how combined theoretical and experimental studies can reveal physical principles of long-range communication in the nucleus, which play important roles in regulation of gene expression, DNA recombination, and chromatin modification.

<sup>1</sup>This work was supported by the NSF DMR-1206146

## 4:18PM V55.00004 How, when, and where in pattern formation: Spying on embryonic development one molecule at a time., HERNAN GARCIA, Univ of California - Berkeley — An abiding mystery in the study of living matter

is how a single cell develops into a multicellular organism. As this cell divides, its progeny read the program encoded on their DNA and adopt different fates becoming familiar cell types such as those found in muscle, liver and our brains. We now know that the decisions that cells make during development are not so much based on which genes to express, but rather on when, where and how to express them. Despite advances in determining the identities of the molecules that mediate these decisions we are still incapable of predicting how simple physical parameters such as the number, position and affinity of binding sites for these molecules on the DNA determine developmental fates. Using the fruit fly, one of the classic model systems for embryonic development, I will show how a combination of new technologies, quantitative experiments, and statistical mechanics is providing new insights about cellular decision making during development. In particular, I will describe how the specification of macroscopic body parts in an organism is linked to the non-equilibrium molecular-scale processes inside single cells. The goal of this interdisciplinary research is to produce a predictive understanding of developmental programs which will enable the rational control of biological size, shape and function.

## 4:54PM V55.00005 Energy Landscapes of Folding Chromosomes, BIN ZHANG, Rice University — The genome,

the blueprint of life, contains nearly all the information needed to build and maintain an entire organism. A comprehensive understanding of the genome is of paramount interest to human health and will advance progress in many areas, including life sciences, medicine, and biotechnology. The overarching goal of my research is to understand the structure-dynamics-function relationships of the human genome. In this talk, I will be presenting our efforts in moving towards that goal, with a particular emphasis on studying the three-dimensional organization, the structure of the genome with multi-scale approaches. Specifically, I will discuss the reconstruction of genome structures at both interphase and metaphase by making use of data from chromosome conformation capture experiments. Computationally modeling of chromatin fiber at atomistic level from first principles will also be presented as our effort for studying the genome structure from bottom up.

## Friday, March 18, 2016 8:00AM - 10:24AM —

Session X1 DCMP GMAG: Complex Oxide Interfaces at the Nanoscale: Electronic, Magnetic and Superconducting Properties Ballroom I - Chang-Beom Eom, University of Wisconsin-Madison

## 8:00AM X1.00001 Electron pairing without superconductivity<sup>1</sup>, JEREMY LEVY, University of Pittsburgh —

Strontium titanate (SrTiO<sub>3</sub>) is the first and best known superconducting semiconductor. It exhibits an extremely low carrier density threshold for superconductivity, and possesses a phase diagram similar to that of high-temperature superconductors—two factors that suggest an unconventional pairing mechanism. Despite sustained interest for 50 years, direct experimental insight into the nature of electron pairing in SrTiO<sub>3</sub> has remained elusive. Here we perform transport experiments with nanowire-based single-electron transistors at the interface between SrTiO<sub>3</sub> and a thin layer of lanthanum aluminate, LaAlO<sub>3</sub>. Electrostatic gating reveals a series of two-electron conductance resonances—paired electron states—that bifurcate above a critical pairing field  $B_p$  of about 1–4 tesla, an order of magnitude larger than the superconducting critical magnetic field. For magnetic fields below  $B_p$ , these resonances are insensitive to the applied magnetic field; for fields in excess of  $B_p$ , the resonances exhibit a linear Zeeman-like energy splitting. Electron pairing is stable at temperatures as high as 900 millikelvin, well above the superconducting transition temperature (about 300 millikelvin). These experiments demonstrate the existence of a robust electronic phase in which electrons pair without forming a superconducting state. Key experimental signatures are captured by a model involving an attractive Hubbard interaction that describes real-space electron pairing as a precursor to superconductivity.

<sup>1</sup>Support from AFOSR, ONR, ARO, NSF, DOE and NSSEFF is gratefully acknowledged.

**8:36AM X1.00002 Magnetic coupling through lanthanum nickelate in non-metallic (111)  $\text{LaMnO}_3/\text{LaNiO}_3$  superlattices**, JEAN-MARC TRISCON, DQMP, University of Geneva — Perovskite nickelates ( $\text{RNiO}_3$ , RE = Rare Earth) are fascinating materials, well known for their metal to insulator transition (MIT) and unique antiferromagnetic (AFM) ground state [1]. In this presentation, I will first discuss how one can control the MIT and the magnetic properties of high quality epitaxial nickelate films through a variety of techniques [2-6]. I will then describe our work on heterostructures containing  $\text{LaNiO}_3$  – the only member of the family that is metallic and paramagnetic in the bulk down to low temperature – and ferromagnetic  $\text{LaMnO}_3$ . In this system we observed an unusual exchange bias in [111] oriented  $(\text{LaNiO}_3)/(\text{LaMnO}_3)$  superlattices [7] and an antiferromagnetic interlayer exchange coupling above the blocking temperature of the exchange biased state specifically in 7 unit cells  $\text{LaNiO}_3$ / 7 unit cells  $\text{LaMnO}_3$  superlattices. The antiferromagnetic coupling is attributed to the presence of a  $(1/4, 1/4, 1/4)$  wavelength AFM structure in  $\text{LaNiO}_3$ . The complex exchange bias observed in this  $(\text{LaNiO}_3)/(\text{LaMnO}_3)$  system is explained in this context also considering the presence of two types of interfaces [8]. [1] M.L. Medarde, Journal of Physics: Condensed Matter, 9, 1679 (1997). [2] R. Scherwitzl et al., Advanced Materials 22, 5517 (2010). [3] S. Catalano et al., Appl. Phys. Lett. Mat. 2, 116110 (2014). [4] S. Mat. 11, 195 (2012). [8] M. Gibert et al., Nanoletters in press (2015).

**9:12AM X1.00003 Emergent nanoscale superparamagnetism at oxide interfaces**, ELI ZELDOV, Weizmann Institute of Science — Atomically sharp oxide heterostructures exhibit a range of novel physical phenomena that do not occur in the parent bulk compounds. The most prominent example is the appearance of highly conducting and superconducting states at the interface between the band insulators  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$ . We present a new emergent phenomenon at the  $\text{LaMnO}_3/\text{SrTiO}_3$  interface in which an antiferromagnetic insulator abruptly transforms into a superparamagnetic state. Above a critical thickness of  $\text{LaMnO}_3$  of five unit cells, our scanning nanoSQUID-on-tip microscopy [1] shows spontaneous formation of isolated magnetic islands with in-plane moment of  $10^4$  to  $10^5 \mu_B$  with characteristic diameter of 10 to 50 nm [2]. The nanoscale islands display superparamagnetic dynamics of random moment reversals by thermal activation or in response to an in-plane magnetic field [1]. We propose a charge reconstruction model of the polar  $\text{LaMnO}_3/\text{SrTiO}_3$  heterostructure which describes a sharp emergence of thermodynamic phase separation leading to nucleation of metallic ferromagnetic islands in an insulating antiferromagnetic matrix. The model suggests that a gate tunable superparamagnetic-ferromagnetic transition can be induced, holding potential for applications in magnetic storage and spintronics. [1] D. Vasyukov et al., Nature Nanotechnology 8, 639 (2013). [2] Y. Anahory, L. Embon, C. J. Li, S. Banerjee, A. Meltzer, H. R. Naren, A. Yakovenko, J. Cuppens, Y. Myasoedov, M. L. Rappaport, M. E. Huber, K. Michaeli, T. Venkatesan, and E. Zeldov, arXiv:1509.01895

**9:48AM X1.00004 Spatially resolved ultrafast magnetic dynamics initiated at a complex oxide heterointerface.**, ANDREA CAVIGLIA, Kavli Institute of Nanoscience TU Delft — Static strain in complex oxide heterostructures has been extensively used to engineer electronic and magnetic properties at equilibrium. In the same spirit, deformations of the crystal lattice with light may be used to achieve functional control across heterointerfaces dynamically. Here, by exciting large-amplitude infrared-active vibrations in a  $\text{LaAlO}_3$  substrate we induce magnetic order melting in a  $\text{NdNiO}_3$  film across a heterointerface. Femtosecond resonant soft X-ray diffraction is used to determine the spatiotemporal evolution of the magnetic disordering. We observe a magnetic melt front that propagates from the substrate interface into the film, at a speed that suggests electronically driven motion. Light control and ultrafast phase front propagation at heterointerfaces may lead to new opportunities in optomagnetism.

**Friday, March 18, 2016 8:00AM - 11:00AM –**

**Session X2 DCMP DAMOP: Recent Advances in Many Body Localization** Ballroom II - Christopher Laumann, University of Washington

**8:00AM X2.00001 A rigorous result on many-body localization**, JOHN IMBRIE, University of Virginia — The mathematical theory of many-body localization is in its infancy. Lack of thermalization is associated with the existence of a complete set of quasi-local integrals of motion. I will discuss a proof that a particular one-dimensional spin chain with random local interactions exhibits many-body localization. The proof depends on a physically reasonable assumption that limits the amount of level attraction in the system. In a KAM-style construction, a sequence of local unitary transformations is used to diagonalize the Hamiltonian and connect the exact many-body eigenfunctions to the original basis vectors. This provides an explicit construction of integrals of motion via convergent expansions.

**8:36AM X2.00002 Many-body localization: Entanglement and efficient numerical simulations**, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems — Many-body localization (MBL) occurs in isolated quantum systems when Anderson localization persists in the presence of finite interactions. To understand this phenomenon, the development of new efficient numerical methods to find highly excited many-body eigenstates is essential. In this talk, we will discuss two complementary approaches to simulate MBL systems: First, we introduce a variant of the density-matrix renormalization group (DMRG) method that obtains individual highly excited eigenstates of MBL systems to machine precision accuracy at moderate to large disorder. This method explicitly takes advantage of the local spatial structure and the low entanglement which is characteristic for MBL eigenstates. Second, we propose an approach to directly find an approximate compact representation of the diagonalizing unitary by using a variational unitary matrix-product operator.

**9:12AM X2.00003 Dynamical Response of Many-Body Localized Systems**, VEDIKA KHEMANI, Princeton University — Many-body localization (MBL) is the long sought-after generalization of Anderson localization to interacting systems. Many-body localized systems fail to thermalize, and display a variety of novel properties and phases that have no equilibrium analog. In this talk, I will review our rapidly evolving understanding of the MBL phase before describing the eigenstate properties and dynamical response of these phases in some detail. In particular, I will show how a slow local perturbation surprisingly induces a highly non-local charge response despite the localized nature of the phase. This effect lies beyond linear response theory and has implications for numerous fields, including topological quantum computation in quantum Hall systems and quantum control in disordered environments. I will also discuss the low-frequency Kubo conductivity of MBL systems, and discuss the crossover from the linear to the non-linear response regime with an emphasis on the time-scales and amplitudes of the drive.

**9:48AM X2.00004 Universal dynamics across many-body localization phase transition** , MAKSYM SERBYN, Univ of California - Berkeley — Many body localization allows quantum systems to evade thermalization owing to the emergence of extensive number of local conserved quantities [1,2]. Many-body localized (MBL) systems exhibit universal dynamics, qualitatively distinct from dynamics in ergodic systems. In this talk I will survey recent progress in understanding the properties of the MBL phase, which follow from the picture of local conserved quantities. In particular, I will discuss the power-law relaxation of local observables [3], which gives an experimentally observable signatures of the MBL phase. In the second part of my talk, I will demonstrate how the delocalization transition can be probed by characterizing the breakdown of local conservation laws. Using statistics of matrix elements of local operators, I will introduce an analogue of many-body Thouless conductance which probes the response of the system to local perturbations [4]. Its scaling allows one to locate the MBL transition, and predicts the onset of logarithmically slow transport at the MBL transition, consistent with results from the renormalization group [5,6]. In addition, I will demonstrate how the properties of matrix elements govern the crossover of the level statistics across the MBL transition, and relate to the dynamics in the ergodic phase. I will conclude by discussing experimental implications and open challenges in understanding the MBL transition.

**10:24AM X2.00005 Many-body localisation of interacting fermions in a quasi-random optical lattice** , IMMANUEL BLOCH, Max Planck Institute of Quantum Optics — We experimentally observe many-body localization (MBL) of interacting fermions in a one-dimensional quasi-random optical lattice. We identify the many-body localization transition through the relaxation dynamics of an initially-prepared charge density wave. For sufficiently weak disorder the time evolution appears ergodic and thermalizing, erasing all remnants of the initial order. In contrast, above a critical disorder strength a significant portion of the initial ordering persists, thereby serving as an effective order parameter for localization. The stationary density wave order and the critical disorder value show a distinctive dependence on the interaction strength, in agreement with numerical simulations. I will also present recent results on the fate of an MBL system upon coupling to the environment through photon scattering or by coupling identical 1d systems. Finally, progress to observe MBL in a 2d setting of interacting bosons will be presented that can provide a new route for identifying and characterizing the MBL phase transition

**Friday, March 18, 2016 8:00AM - 11:00AM –**

**Session X3 DCMP GSOF: Design, Characterization and Assembly of Hyperuniform Materials**

Ballroom III - Dreyfus Remi, CNRS

**8:00AM X3.00001 Ensemble Theory for Stealthy Hyperuniform Disordered Ground States** , SALVATORE TORQUATO, Princeton University — Disordered hyperuniform many-particle systems [1] have been receiving recent attention because they are distinguishable exotic states of matter poised between a crystal and liquid that are endowed with novel thermodynamic and physical properties. It has been shown numerically that systems of particles interacting with “stealthy” bounded, long-ranged pair potentials (similar to Friedel oscillations) have classical ground states that are, counterintuitively, disordered, hyperuniform and highly degenerate. The task of formulating an ensemble theory that yields analytical predictions for the structural characteristics and other properties of stealthy degenerate ground states in d-dimensional Euclidean space is highly nontrivial because the dimensionality of the configuration space depends on the number density and there is a multitude of ways of sampling the ground-state manifold, each with its own probability measure for finding a particular ground-state configuration. A new type of statistical-mechanical theory had to be invented to characterize these exotic states of matter. I report on some initial progress that we have made in this direction [2]. We show that stealthy disordered ground states behave like “pseudo”-equilibrium hard-sphere systems in Fourier space. Our theoretical predictions for the structure and thermodynamic properties of the stealthy disordered ground states and associated excited states are in excellent agreement with computer simulations across dimensions. [1] Torquato and F. H. Stillinger, Local Density Fluctuations, Hyperuniform Systems, and Order Metrics, Physical Review E, 68, 041113 (2003); [2] S. Torquato, G. Zhang, and F. H. Stillinger, Ensemble Theory for Stealthy Hyperuniform Disordered Ground States, Physical Review X, 5, 021020 (2015).

**8:36AM X3.00002 Hyperuniformity Disorder Length Spectroscopy - Method and Applications** , DOUGLAS DURIAN, University of Pennsylvania — The original idea is that fluctuations in a hyperuniform system are controlled by particles on the surface of the measuring windows [Torquato and Stillinger, PRE 2003]. But particles live in a volume; therefore, we introduce a “hyperuniformity disorder length”  $h(L)$  such that the relevant particles are within a distance  $h(L)$  of the  $L^d$  measuring window boundaries. Then the asymptotic volume fraction variance scaling becomes dimensionally correct as  $\sigma_\phi^2(L) \propto \langle v \rangle h(L)/L^{d+1}$  where  $\langle v \rangle$  is the average particle volume. After giving the technical definition of  $h(L)$ , I'll discuss two bounds, and I'll show simulation results for crystal vacancy and Einstein patterns to help build intuition for scaling of  $h(L) \sim L$  in systems with liquid-like fluctuations and as  $h(L) = \text{constant}$  in strongly hyperuniform systems. Then, in terms of the real-space spectrum of  $h(L)$  versus  $L$ , I'll show how different kinds of packings become increasingly uniform on approach to jamming and reach hyperuniformity at jamming. An important theme is to bring meaning to the value, as well as the scaling, of density fluctuations. Various parts of this work are in collaboration with A. Chieco, R. Dreyfus, C. Goodrich, A.J. Liu, and S. Torquato.

**9:12AM X3.00003 Unusual Fluctuations in Absorbing State Models** , HEXNER DANIEL, Technion — No abstract available.

**9:48AM X3.00004 Emergent Hyperuniformity in Periodically Driven Emulsions** , DENIS BARTOLO, ENS Lyon — I will discuss the self-organization of microfluidic emulsions into anomalously homogeneous structures. Upon periodic driving confined emulsions undergo a first-order transition from a reversible to an irreversible dynamics. We evidence that this dynamical transition is accompanied by structural changes at all scales yielding macroscopic yet finite hyperuniform structures. Numerical simulations are performed to single out the very ingredients responsible for the suppression of density fluctuations. We show that, as opposed to equilibrium systems, the long-range nature of the hydrodynamic interactions are not required for the formation of hyperuniform patterns, thereby suggesting a robust relation between reversibility and hyperuniformity which should hold in a broad class of periodically driven materials.

**10:24AM X3.00005 Hyperuniform disordered photonic bandgap materials, from microwave to infrared wavelength regime.**<sup>1</sup> , WEINING MAN, SFSU — Recently, we have introduced a new class of hyperuniform disordered (HUD) photonic bandgap (PBG) materials enabled by a novel constrained optimization method for engineering the material's Fourier transform to be continuous, isotropic and stealthy. Their structure factor  $S(k)$  is equal to zero for small  $k$  and exhibits a broad ring of maximum values around a characteristic wave-length range. Experimentally, an isotropic complete PBG (at all angles and for all polarizations) in an alumina-based HUD structure and single-polarized PBGs for plastic-based HUD structure have been demonstrated. Using measured and simulated transmission and phase delay information through these HUD structures, we also unfolded their band structures and reconstructed the effective dispersion relations of propagating electromagnetic modes in them. The intrinsic isotropy in these disordered structures is an inherent advantage associated with the lack of crystalline order, offering unprecedented freedom for functional defect design impossible to achieve in photonic crystals. In the microwave regime, we have shown the creation of freeform waveguides, which can channel photons robustly along arbitrarily curved paths and around sharp bends, and be decorated with defects to produce sharply resonant structures useful for filtering and frequency splitting. Recent simulation and experimental results for waveguides and modulators based on submicron-scale planar hyperuniform disordered PBG structures further highlight their ability to serve as highly compact, flexible and energy-efficient platforms for photonic integrated circuits.

**Session X4 DPOLY: From Polymer Topology to Performance Materials** Ballroom IV - Chinedum Osuji, Yale University

**8:00AM X4.00001 Continuous Liquid Interface Production (CLIP)** , JOHN TUMBLESTON, Carbon3D, Inc. —

Continuous liquid interface production (CLIP) can rapidly produce 3D parts using a range of polymeric materials. A DLP-based form of additive manufacturing, CLIP proceeds via projecting a sequence of UV images through an oxygen-permeable, UV-transparent window below a liquid resin bath. A thin uncured liquid layer, or dead zone, is created above the window and maintains a liquid interface below the advancing part. Above the dead zone, the curing part is drawn out of the resin bath creating suction forces that renew reactive liquid resin. The dead zone is created due to oxygen inhibition of photopolymerization, a process that is traditionally a nuisance in other photopolymerization applications. However, for CLIP oxygen inhibition and creation of the dead zone allows for a continuous mode of printing where UV exposure, resin renewal, and part elevation are conducted simultaneously. This continual process is fundamentally different from traditional bottom-up stereolithography printers where these steps must be conducted in separate and discrete steps. Furthermore, the relatively gentle nature of CLIP due to the established dead zone enables the use of unique materials with a wide range of mechanical properties. This presentation will showcase the CLIP technology and provide a detailed picture of interactions between different resin and process parameters. New applications for 3D printing that span the micro- to macro-scale enabled by CLIP's combination of unique materials and part production speed will also be presented.

**8:36AM X4.00002 Polymer Grafted Nanoparticle Assemblies: From Optical to Mechanical Performance through Clusters, Monolayers and Monoliths**<sup>1</sup> , RICHARD VAIA, Air Force Research Laboratory — Solution or melt-based fabrication of large area, matrix-free, ordered assemblies of polymer grafted nanoparticles (PGN) will enable additive manufacturing of novel membrane, electronic, and photonic elements. Due to the single component nature of these hybrids, aggregation and phase separation common in blended polymer nanocomposites are avoided. Architecturally, PGNs combine characteristics of colloids, brushes and high molecular weight polymers. Thus the processing-structure-property relationship of the entangled PGN assembly is unique from analogous condensed nano-structures, such as ligand stabilized nanoparticles, hard-sphere colloids, star macromolecules and linear chain – nanoparticle blends. Here in, we will discuss the intermediate character of PGNs with respect to deformability, physical aging, and rapid fabrication of stable, large-area, ordered PGN monolayers. For example, processing via flow coating follows that of classic colloids; however local structure and order within the PGN assembly is determined by the canopy architecture and substrate interactions. From this insight, large-area (cm<sup>2</sup>), highly-ordered, monolayer polystyrene-Au nanoparticle films that are resistant to de-wetting can be fabricated on substrates with high interface energy (80 mN/m) within seconds using flow-coating and a volatile solvent (THF). Overall these findings imply intriguing parallels between PGN assemblies and other mesoscale ordered polymeric systems including hard-soft block copolymers and semi-crystalline polymers. With the appropriate corona architecture, PGNs afford opportunities to design high inorganic fraction hybrids that retain processibility and enable the creation of films and fibers for next generation optoelectronic applications.

**9:12AM X4.00003 Translating polymer physics from the lab to the field** , JAN GENZER, North Carolina State Univ — Recent years witnessed increased activity in the application of fundamental principles of polymer physics and polymer chemistry in helping solve pressing environmental issues using eco-friendly approaches. We will describe examples of two polymer material platforms, i.e., surface-anchored polymer grafts and silicone elastomers, and their utilization in 1) minimizing non-specific bioadsorption, and 2) removal of metals/toxins and volatile organic compounds (VOCs) from contaminated waters. Optimal performance of such materials requires detailed knowledge and tunability of their chemical composition and topology. We will demonstrate that non-specific bioadsorption is heavily reduced on substrates made of PEG-ylated or zwitterionic chemistries whose topologies comprise either gels or polymeric grafts with high areal densities. We will also present an effective method utilizing organic mimics of metalloproteins, high cysteine containing peptides, for removing heavy metals and toxins from contaminated waters. Finally, we will discuss a simple, yet powerful, method of removing VOCs from waters by utilizing silicone elastomers that act as effective “sponges”.

**9:48AM X4.00004 Using Polymer Confinement for Stem Cell Differentiation: 3D Printed vs Molded Scaffolds.**<sup>1</sup> , MIRIAM RAFAILOVICH, Stony Brook University — Additive manufacturing technologies are increasingly being used to replace standard extrusion or molding methods in engineering polymeric biomedical implants, which can be further seeded with cells for tissue regeneration. The principal advantage of this new technology is the ability to print directly from a scan and hence produce parts which are an ideal fit for an individual, eliminating much of the sizing and fitting associated with standard manufacturing methods. The question though arises whether devices which may be macroscopically similar, serve identical functions and are produced from the same material, interact in the same manner with cells and living tissue. Here we show that fundamental differences can exist between 3-D printed and extruded scaffolds which can impact stem cell differentiation and lineage selection. We will show how polymer confinement inherent in these methods affect the printed features on multiple length scales. We will also and how the differentiation of stem cells is affected by substrate heterogeneity in both morphological and mechanical features.

<sup>1</sup>NSF-Inspire award 1344267

**10:24AM X4.00005 Directed self-assembly of performance materials**, PAUL NEALEY, University of Chicago — Directed self-assembly (DSA) is a promising strategy for high-volume cost-effective manufacturing at the nanoscale. Over the past decades, manufacturing techniques have been developed with such remarkable efficiency that it is now possible to engineer complex systems of heterogeneous materials at the scale of a few tens of nanometers. Further evolution of these techniques, however, is faced with difficult challenges not only in feasibility of implementation at scales of 10 nm and below, but also in prohibitively high capital equipment costs. Materials that self-assemble, on the other hand, spontaneously form structures at the mesoscale, but the micrometer areas or volumes over which the materials self-assemble with adequate perfection in structure is incommensurate with the macroscopic dimensions of working devices and systems of devices of industrial relevance. Directed Self-Assembly (DSA) refers to the integration of self-assembling materials with traditional manufacturing processes. Here we will discuss DSA of block copolymers to revolutionize sub 10 nm lithography and the manufacture of integrated circuits and storage media, DSA of ex-situ synthesized nanoparticles for applications in nanophotonics, and DSA of liquid crystals for advanced optics.

**Friday, March 18, 2016 8:00AM - 11:00AM –**  
**Session X5 GMAG DMP: Frustrated Magnetism: Kagome Lattice** 301 - Oleg Tchernyshyov, Johns Hopkins University

**8:00AM X5.00001 A Dichotomy of the Spin Liquid and the Correlated Impurities in Herbertsmithite**, TIANHENG HAN, University of Chicago — It is debatable whether RVB spin liquids exist in kagome systems. Enthusiasm in spin-1/2 kagome antiferromagnets gained extra momentum from the observation of a spinon continuum in  $\text{ZnCu}_3(\text{OD})_6\text{Cl}_2$  (herbertsmithite). In low-energy limit, where insightful many-body theories exist, impurities complicate experimental interpretations. Two important progresses were made in the past year. Single-crystalline  $^{170}\text{Yb}$  NMR experiment provided evidence for pristine kagome layers and a spin gap. Below the spinon continuum's energies, neutron scattering measurements revealed 3 dimensional spin correlations, which likely originate from the impurities. I will present the intrinsic-extrinsic dichotomy in  $\text{ZnCu}_3(\text{OD})_6\text{Cl}_2$  as well as my thoughts on future directions.

**8:36AM X5.00002 Fractionalized spin-wave continuum in kagome spin liquids**, JIA-WEI MEI, Perimeter Institute for Theoretical Physics, XIAO-GANG WEN, Department of Physics, Massachusetts Institute of Technology and Perimeter Institute for Theoretical Physics — Motivated by spin-wave continuum (SWC) observed in recent neutron scattering experiments in Herbertsmithite, we use Gutzwiller-projected wave functions to study dynamic spin structure factor  $S(\mathbf{q}, \omega)$  of spin liquid states on the kagome lattice. Spin-1 excited states in spin liquids are represented by Gutzwiller-projected two-spinon excited wave functions. We investigate three different spin liquid candidates, spinon Fermi-surface spin liquid (FSL), Dirac spin liquid (DSL) and random-flux spin liquid (RSL). FSL and RSL have low energy peaks in  $S(\mathbf{q}, \omega)$  at  $K$  points in the extended magnetic Brillouin zone, in contrast to experiments where low energy peaks are found at  $M$  points. There is no obvious contradiction between DSL and neutron scattering measurements. Besides a fractionalized spin (*i.e.* spin-1/2), spinons in DSL carry a fractionalized crystal momentum which is potentially detectable in SWC in the neutron scattering measurements.

**8:48AM X5.00003 A mean-field study of the Hubbard model on the kagome lattice<sup>1</sup>**, MATTHEW ENJALRAN, Southern Connecticut State University — The experimental work on the herbertsmithite compound,  $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$ , almost a decade ago ignited intense interest in the field of frustrated magnetism because it represented the best material realization of a spin-1/2 Heisenberg antiferromagnet (AFM) on the kagome lattice and its ground state was a gapless spin liquid. Many theoretical and numerical studies of the quantum Heisenberg AFM on the kagome lattice have been performed since and have coalesced around the general consensus of a small gapped spin liquid ground state for the model. Although there is not currently a metallic kagome material system, the work on  $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$  has motivated theoretical and numerical investigations of itinerant electrons on the kagome lattice. We contribute to this pursuit by studying the single band Hubbard model on the kagome lattice, where the frustration can be tuned by adjusting the hopping along different bonds,  $t_1$  and  $t_2$ ; however, we are mainly interested in the isotropic limit,  $t_1 = t_2 = t$ . We report preliminary results on the low temperature correlations in the half filled model as a function of frustration and interaction strength in the mean-field, Hartree-Fock, limit.

<sup>1</sup>CSU Research Grant

**9:00AM X5.00004 Structure and Physical Properties of  $\text{SrNiRu}_5\text{O}_{11}$  Single Crystals: A New Frustrated R-type Ferrite Based on Ordered Kagome Nets<sup>1</sup>**, LANCE DE LONG, University of Kentucky, Department of Physics and Astronomy, LARYSA SHLYK, RAINER NIEWA, Universitt Stuttgart, Institut für Anorganische Chemie — Single crystals of the R-type ferrite  $\text{SrNiRu}_5\text{O}_{11}$  were grown from a chloride flux. The hexagonal crystal structure contains ruthenium located on Kagome nets, distorted due to formation of Ru–Ru dumbbells via metal-metal bonding.  $\text{SrNiRu}_5\text{O}_{11}$  does not show long-range magnetic order down to 4.5 K. The low-temperature magnetic susceptibilities,  $\chi_\perp$  and  $\chi_\parallel$  c-axis, diverge as  $T^{-0.3}$ , and the electric resistivity varies as  $T^{1.6}$  below 40 K, which is typical of non-Fermi liquid materials. This anomalous behavior might originate from the competition between residual magnetic interactions among  $\text{Ni}^{2+}$  ( $S = 1$ ) spins and geometrical frustration on the two-dimensional Kagome lattice of  $\text{Ru}^{3+}$  ( $S = 1/2$ ) spins. The transverse magnetoresistivity  $\rho_{xy}$ , of a  $\text{SrNiRu}_5\text{O}_{11}$  single crystal at constant temperature  $T = 5$  K for current-magnetic-field configurations,  $\mathbf{J} \perp \mathbf{H} \parallel \text{c-axis}$  and  $\mathbf{J} \parallel \mathbf{H} \perp \text{c-axis}$ , reveals no anomalous contribution, which is typical for non-magnetic materials. Fits of the heat capacity data below 10 K require a dominant, but unusual electronic term of the form  $C_{el} = \gamma T^{1.2}$ , which is expected for massless Dirac fermion states in topological insulators or spin liquid phases.

<sup>1</sup>Research at University of Kentucky supported by U.S. Department of Energy grant no. DE-FG02-97ER-45653.

**9:12AM X5.00005 Local probe study of Sr-Vesignieite**, AIM VERRIER, JEFFREY QUILLIAM, Universit de Sherbrooke, FABRICE BERT, PHILIPPE MENDELS, Laboratoire de physique des solides, Universit Paris-Sud XI, DAVID BOLDRIN, ANDREW WILLS, University College London — We discuss the results of local probe measurements (NMR and  $\mu\text{SR}$ ) on a powder sample of  $\text{SrCu}_3\text{V}_2\text{O}_8(\text{OH})_2$  (Sr-Vesignieite)[D. Boldrin and A. S. Wills, J. Mat. Chem. C 3, 4308(2015)], a spin-1/2 kagome lattice with antiferromagnetic interactions.<sup>63,65</sup>  $^{63,65}\text{Cu}$  zero-field NMR and  $^{51}\text{V}$  NMR (in-field) reveal static magnetism at low temperatures and allow us to measure the intrinsic local susceptibility of the kagome lattice. Muon spin rotation ( $\mu\text{SR}$ ) experiments also demonstrate static magnetism at low  $T$ . We discuss the possible role of the Dzyaloshinsky-Moriya interaction and the proximity of this material to a quantum critical point between ordered and quantum spin liquid phases.

**9:24AM X5.00006 Hidden Order in Spin-Liquid  $\text{Gd}_3\text{Ga}_5\text{O}_{12}$**  , JOSEPH PADDISON, School of Physics, Georgia Institute of Technology, USA, and Department of Chemistry, University of Oxford, UK, and STFC-ISIS, UK, HENRIK JACOBSEN, Nanoscience Center, University of Copenhagen, Denmark, and European Spallation Source, Sweden, OLEG PETRENKO, Department of Physics, University of Warwick, UK, MARIA TERESA FERNÁNDEZ-DÍAZ, Institut Max von Laue - Paul Langevin, France, PASCALE DEEN, Nanoscience Center, University of Copenhagen, Denmark, and European Spallation Source, Sweden, ANDREW GOODWIN, Department of Chemistry, University of Oxford, UK — Frustrated magnetic materials are promising candidates for new states of matter because lattice geometry suppresses conventional magnetic dipole order, potentially allowing non-dipole ("hidden") order to emerge in its place. However, an atomic-scale model of a hidden-order state has been difficult to obtain because microscopic probes are not directly sensitive to hidden order. We use a combination of neutron-scattering experiments and reverse Monte Carlo refinements to develop a model of the spin-liquid state in the canonical frustrated magnet  $\text{Gd}_3\text{Ga}_5\text{O}_{12}$ . We show that this state exhibits a hidden order which has three unusual properties. First, it is a collective phenomenon, in which multipoles are formed from ten-spin loops. Second, it is long-range, with a diverging correlation length. Third, it is a consequence of the interplay between antiferromagnetic spin correlations and local planar magnetic anisotropy, which allows it to be indirectly observed in our neutron-scattering experiments.

**9:36AM X5.00007 Topologically non-trivial electronic and magnetic states in doped copper Kagome lattices<sup>1</sup>** , DANIEL GUTERDING, HARALD O. JESCHKE, ROSER VALENTI, Institute for Theoretical Physics, University of Frankfurt, Frankfurt a.M., Germany — We present a theoretical investigation of doped copper kagome materials based on natural minerals Herbertsmithite  $[\text{ZnCu}_3(\text{OH})_6\text{Cl}_2]$  and Barlowite  $[\text{Cu}_4(\text{OH})_6\text{FBr}]$ . Using ab-initio density functional theory calculations we estimate the stability of the hypothetical compounds against structural distortions and analyze their electronic and magnetic properties. We find that materials based on Herbertsmithite present an ideal playground for investigating the interplay of non-trivial band-topology and strong electronic correlation effects. In particular, we propose candidates for the Quantum Spin Hall effect at filling 4/3 and the Quantum Anomalous Hall effect at filling 2/3. For the Barlowite system we point out a route to realize a Quantum Spin Liquid.

**9:48AM X5.00008 DMRG studies of the frustrated kagome antiferromagnets and the application to volborthite<sup>1</sup>** , SHOU-SHU GONG, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, USA, D. N. SHENG, Department of Physics and Astronomy, California State University, Northridge, California 91330, USA, KUN YANG, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, USA — Motivated by the recent magnetization measurements on the high-quality single crystals of the kagome antiferromagnet volborthite, we study the ground state and magnetization properties of two kagome models proposed from the electronic structure simulations, which treat the volborthite as either the coupled trimers or the coupled frustrated chains on the kagome lattice. We study the models using density-matrix renormalization group on the cylinder geometry with the system width up to 4 legs. We find a quantum phase diagram of the models with changing couplings, and identify the magnetic properties of each phase. In the antiferromagnetic phases, we also study the magnetization curve and the different phases in the magnetic field. Finally, we compare the magnetization properties of the models with the experimental observations of volborthite.

**10:00AM X5.00009 Spin-wave analysis of a broad magnetization plateau in volborthite** , EDWARD PARKER, LEON BALENTS, Univ of California - Santa Barbara — Volborthite  $(\text{Cu}_3\text{V}_2\text{O}_7(\text{OH})_2 \cdot 2\text{H}_2\text{O})$  is a system comprised of spin-1/2 ions forming quasi-2D layers of Kagomé lattices. It displays two striking experimental features: strong geometric frustration (with a magnetic ordering temperature more than two orders of magnitude below its Curie temperature), and an extremely broad  $m = \frac{1}{3}m_{\text{sat}}$  magnetization plateau extending over a range of more than 100 T. Density functional theory calculations suggest that it has a complicated anisotropic spin coupling structure with both ferromagnetic and antiferromagnetic first- and second-nearest-neighbor bonds. We present results for the classical phase diagram for this system, focusing on how the upper and lower critical fields of the magnetization plateau depend on the exchange couplings. We also present a semiclassical large- $S$  expansion, and show how including the leading quantum corrections in  $1/S$  gives a magnon self-energy that shifts the classical values for the plateau's critical fields.

**10:12AM X5.00010 Changing the Electron Count in Spin Liquids<sup>1</sup>** , ZACHARY KELLY, TYREL MCQUEEN, Johns Hopkins Univ — Materials which possess the resonating valence bond (RVB) "spin-liquid" state have been long sought after by scientists due to their predicted exotic properties. Several materials have been identified as potential spin liquid candidates and laboratory studies have only just begun to provide insight into the properties of these materials and their theoretical description. Recently theoretical calculations predict doping of a spin liquid could lead to a rich and unique phase diagram including complex magnetic states, Dirac metal behavior, and superconductivity. We report the results of structural and physical property characterizations of newly synthesized doped candidate spin liquids.

**10:24AM X5.00011 A Kagome Map of Spin Liquids<sup>1</sup>** , KARIM ESSAFI, OWEN BENTON, LUDOVIC D. C. JAUBERT, Okinawa Inst of Sci & Tech — Competing interactions in frustrated magnets prevent ordering down to very low temperatures and stabilize exotic highly degenerate phases where strong correlations coexist with fluctuations. We study a very general nearest-neighbour Heisenberg spin model Hamiltonian on the kagome lattice which consist of Dzyaloshinskii-Moriya, ferro- and antiferromagnetic interactions. We present a three-fold mapping which transforms the well-known Heisenberg antiferromagnet (HAF) and XXZ model onto two lines of time-reversal Hamiltonians. The mapping is exact for both classical and quantum spins, *i.e.* preserves the energy spectrums of the HAF and XXZ model. As a consequence, our three-fold mapping gives rise to a connected network of quantum spin liquids centered around the Ising antiferromagnet. We show that this quantum disorder spreads over an extended region of the phase diagram at linear order in spin wave theory, which overlaps with the parameter region of Herbertsmithite  $\text{ZnCu}_3(\text{OH})_6\text{Cl}_2$ . At the classical level, all the phases have an extensively degenerate ground-state which present a variety of properties such as ferromagnetically induced pinch points in the structure factor and spontaneous scalar chirality which was absent in the original HAF and XXZ models.

**10:36AM X5.00012 Nature of Possible  $Z_6$  symmetry breaking magnetic phases in frustrated hyperkagome iridate**, RYUICHI SHINDOU, School of Physics, Peking University — To obtain a comprehensive understanding of classical magnetism possible in frustrated hyperkagome iridate  $\text{Na}_4\text{Ir}_3\text{O}_8$  (Na-438), we postulated additional lattice symmetries other than an exact crystal symmetry, and introduced a relatively simpler effective spin model for Na-438. Using Monte Carlo simulation and Luttinger-Tisza analysis, we derived a classical magnetic phase diagram for Na-438. We show that a  $Z_6$  symmetry breaking magnetic phase is stabilized by the thermal order by disorder. Our finite-size scaling analysis reveals that the criticality of the ordering temperature of the  $Z_6$  phase is characterized by the 3D XY universality class, where the system acquires effectively a higher symmetry than high- $T$  disorder phase (dubbed as emergent U(1) symmetry). For a finite size system, an intermediate temperature regime appears below the ordering temperature, where the spin anisotropy term becomes effectively irrelevant and spin ordering develops in the U(1) symmetric way. We showed that this crossover phenomena can be well accounted for in terms of the 3-d ferromagnetic  $Z_6$  Potts model. Based on this crossover behavior, we introduced a possible phenomenology of low-temperature magnetic behaviors of polycrystalline Na-438. Reference: arXiv.1509.01002

**10:48AM X5.00013 Competing phases of  $S=1$  XXZ model on Kagome lattice<sup>1</sup>**, ZHENYUE ZHU, STEVEN WHITE, UC Irvine — We numerically study the  $S=1$  XXZ model on the kagome lattice with the Density matrix renormalization group. We focus on the two types of expected magnetic order,  $Q = 0$  and  $\sqrt{3} \times \sqrt{3}$ . As a function of the coupling  $\Delta$  for the  $S_z S_z$  terms, we find two possible phase transitions. For  $\Delta < \Delta_1$ , we find that the  $Q = 0$  state has lower energy, but the difference between these two magnetic ordered phase is very small. For  $\Delta_1 < \Delta < \Delta_2$ ,  $\sqrt{3} \times \sqrt{3}$  magnetic ordered state is the ground state. For  $\Delta > \Delta_2$ , we find that the magnetic ordered phases disappears, entering a magnetic disordered phase. We find a close competition between a trimerized phase and a hexagon singlet phase, which is consistent with recent numerical studies of  $S=1$  Heisenberg model on the Kagome lattice.

Session X6 GMAG DMP: Nanoparticles, Nanowires, and Clusters 302 - Deepak Singh, Univ. of Missouri

**8:00AM X6.00001 Using Magnetic Proximity Effects to Stabilize Magnetic Nanoparticles<sup>1</sup>**, JOSE A. DE TORO, Instituto Regional de Investigacin Cientfica Aplicada (IRICA) and Departamento de Fsica Aplicada, Universidad de Castilla-La Mancha — The current miniaturization trend in magnetic applications has led to a quest to suppress spontaneous thermal fluctuations (superparamagnetism) in ever-smaller nanostructures, which constitutes a clear example of the fundamental efforts of condensed matter physics to meet technological challenges (e.g., the continued growth of magnetic recording density). We have demonstrated that ferromagnetic (FM) Co nanoparticles with blocking temperature below 70 K become magnetically stable above 400 K when embedded in a high Neel temperature antiferromagnetic (AFM) NiO matrix [1]. This remarkable stabilization is due to a magnetic proximity effect between a thin CoO shell (with low Neel temperature and high anisotropy) surrounding the Co nanoparticles and the NiO matrix (with high Neel temperature but low anisotropy). This proximity effect yields an effective antiferromagnet with an apparent ordering temperature beyond that of bulk CoO, and an enhanced anisotropy compared to NiO. In turn, the Co core FM moment is stabilized against thermal fluctuations via core-shell exchange-bias coupling, leading to the observed increase in blocking temperature. A mean-field model, corrected for thermal activation effects, closely reproduces the experimental exchange-bias data, corroborating the above interpretation and providing a semi-quantitative understanding of the nature of the proposed proximity effect. The results presented in this study constitute a striking illustration of how a subtle combination of interactions may permit the occurrence of unique magnetic properties by exploiting proximity effects in magnetism. 1. **8:36AM X6.00002 Emergent  $1/f$  noise in collections of individually oscillating magnetic dots<sup>1</sup>**, BARRY COSTANZI, E DAN DAHLBERG, Univ of Minnesota - Twin Cities — We experimentally demonstrate an emergent  $1/f$  spectrum from a superposition of the noise from random telegraph noise (RTN) oscillators. The system consists of individual square magnetic permalloy dots with dimensions on the order of  $200\text{nm} \times 200\text{nm} \times 10\text{nm}$  that exhibit RTN in their magnetization at appropriate applied fields. The magnetization fluctuations are measured by the anisotropic magnetoresistance (AMR). AMR is used to find applied fields necessary to exhibit RTN, which result in Lorentzian spectra in the power spectral density of the measurement. A composite AMR measurement of multiple oscillating dots at once, however, shows an emergent  $1/f$  spectrum in the power spectral density. This agrees with the prediction of Van Der Ziel [1] that, for an appropriate distribution of oscillators showing Lorentzian spectra, the composite spectrum will have a  $1/f$  character. This experimental demonstration of  $1/f$  noise from a system of two-state oscillators indicates a possible mechanism for the origin of  $1/f$  spectra observed in both other magnetic systems, and potentially in other, more disparate systems. [1] A. van der Ziel, Physica 16, 359 (1950).

**8:48AM X6.00003 Magnetic and Structural Properties of  $\text{Mn}_5\text{Ge}_3$  Nanoparticles<sup>1</sup>**, ONUR TOSUN, MOHAMMAD SALEHI-FASHAMI, GEORGE C. HADJIPANAYIS, Univ of Delaware, DAVID J. SELLMYER, BALAMURUGAN BALASUBRAMANIAN, Univ of Nebraska-Lincoln, UNIV OF DELAWARE TEAM, UNIV OF NEBRASKA-LINCOLN COLLABORATION — Magnetic nanoparticles have unique and interesting properties which are scientifically important and attractive for numerous advanced technologies. In this work, we have used the cluster-beam deposition technique to synthesize  $\text{Mn}_5\text{Ge}_3$  nanoparticles with different size. The composition, crystal structure and magnetic properties of the nanoparticles have been characterized by energy dispersive x-ray spectroscopy (EDS), X-ray diffraction, high-resolution transmission electron microscopy (HR-TEM) and magnetometry, respectively. Particles made with 1.7 Torr Argon pressure, and power of 80 W had an average size of 14 nm. Selected area electron diffraction showed that the particles had a hexagonal  $\text{Mn}_5\text{Si}_3$ -type structure with space group  $P63/mcm$  which is the same as in bulk. Magnetic measurements showed that the nanoparticles are ferromagnetic with a Curie temperature near room temperature. The effects of particle size and temperature on the magnetic properties are currently being studied and the results will be reported and discussed.

**9:00AM X6.00004 Computational Atomistic Modeling of Bi-Magnetic Core-Shell Nanoparticles<sup>1</sup>**, RAHUL SAHAY, Sacred Heart Academy and Department of Physics, Central Michigan University, Mount Pleasant, MI, JUAN PERALTA, Department of Physics, Central Michigan University, Mount Pleasant, MI, 48859, GABRIEL CARUNTU, Department of Chemistry, Central Michigan University, Mount Pleasant, MI, 48859 — Since its discovery, there has been an increasing interest in the modeling of magnetic phenomena found in materials that present exchange bias. In particular, ferro-antiferromagnetic core-shell nanoparticles are an interesting case in which the magnetic properties of the nanostructure can be altered by adjusting their size, shape, and composition. Here we present a computational scheme that efficiently models the magnetic behavior of bi-magnetic core-shell nanostructures. Using a Heisenberg-Dirac-van Vleck Hamiltonian in combination with a continuous spin model, we simulate a wide range of hysteresis diagrams displaying exchange bias. Furthermore, we will demonstrate our efforts towards improving the efficiency of the simulation algorithms, aiming to afford magnetic atomistic simulations of large nanostructures by using a method based on a tessellated unit sphere to account for spin orientations. Our results allow for further semi-quantitative comparisons with existing experimental data and provide a means to discover new phenomena associated with these core-shell nanoparticles and other nanostructures.

**9:12AM X6.00005 Angular dependence of magnetization in single crystalline cobalt nanowires**, KINJAL GANDHA, KEVIN ELKINS, NARAYAN POUDYAL, J. PING LIU, University of Texas at Arlington — In this work, the magnetization behavior of Co nanowires has been investigated by applying the Stoner-Wohlfarth model. The single crystalline cobalt nanowires with a diameter of about 15 nm and a mean length of 200 nm were synthesized via a solvothermal chemical process that have high coercivity up to 12.5 kOe. It is found that the c-axis (002) or the easy magnetization direction of the single-crystalline wires is along the long axis of the nanowires. Particular attention has been paid to the angular dependence of magnetic properties on the applied magnetic field orientation with respect to the c-axis. The angular dependence of coercivity has been modeled and it was revealed that the coherent mode rotation gives the best fitting with the experimental observations. In addition, surface oxidized Co nanowires have also been studied that provided us a unique opportunity to understand the exchange bias in the aligned Co/CoO core-shell nanostructures. Ferromagnetic nanowires of this type are ideal building blocks for future bonded, consolidated and thin film magnets with high energy density and high thermal stability.

**9:24AM X6.00006 Chalcogenide Cobalt telluride nanotubes<sup>1</sup>**, BISHNU DAHAL, RAJENDRA DULAL, IAN L. PEGG, JOHN PHILIP, The Catholic University of America — Cobalt telluride nanotubes are grown using wet chemical and hydrothermal syntheses. Wet chemical synthesized nanotubes display nearly 1: 1 Co to Te ratio. On the other hand, CoTe nanotubes synthesized using hydrothermal method show excess Co content leading to the compound Co<sub>58</sub>Te<sub>42</sub>. Both CoTe and Co<sub>58</sub>Te<sub>42</sub> display magnetic properties, but with totally different characteristics. The Curie temperature of CoTe is higher than 400 K. However, the T<sub>c</sub> of Co<sub>58</sub>Te<sub>42</sub> is below 50 K. Transport properties of cobalt telluride (CoTe) nanotube devices show that they exhibit p-type semiconducting behavior. The magnetoresistance measured at 10 K show a magnetoresistance of 54%.

**9:36AM X6.00007 Effect of Bi Substitution on the FCC to L1<sub>0</sub> Phase Transformation in CoPt(Bi) Nanoparticles**, FRANK ABEL, Physics and Astronomy, University of Delaware, VASILIS TZITZIOS, Institute of Nanoscience and Nanotechnology, NCSR, DAVID SELLMYER, Physics and Astronomy and NCMN, University of Nebraska, GEORGE HADJIPANAYIS, Physics and Astronomy, University of Delaware — The transformation from the fcc to fct structure L1<sub>0</sub> in CoPt requires annealing at temperatures over 600<sup>0</sup> C, as compared to FePt which can occur at 550<sup>0</sup> C. In the past, similar attempts to lower the transformation temperature in CoPt have been unsuccessful. In this work, we report for the first time a decrease in the phase transformation temperature of chemically synthesized CoPt nanoparticles by the addition of a small amount of bismuth. Our studies have shown that the phase transformation occurs in as-made CoPt(Bi) nanoparticles at refluxing temperatures as low as 330<sup>0</sup> C, which is significantly lower than previously reported values in CoPt nanoparticles and thin films. The as-made CoPt nanoparticles with 5% atomic weight Bi show partial L1<sub>0</sub> ordering with an average size of 11.7 nm, as shown by TEM imaging, and have a coercivity of 1 kOe and saturation magnetization of 32 emu/g. Annealing of the CoPt(Bi) nanoparticles produced maximum coercivities of 12.4 kOe when annealed at 700<sup>0</sup> C for 1 hour. The effect of amount of Bi addition on the formation and ordering of L1<sub>0</sub> structure will be discussed.

**9:48AM X6.00008 Magnetic and Structural Properties of Co<sub>5</sub>Ge<sub>3</sub> Nanoparticles.<sup>1</sup>**, MOHAMMAD SALEHI-FASHAMI, VIMAL DEEPCHAND, University of Delaware, RALPH SKOMSKI, DAVID J. SELLMYER, University of NebraskaLincoln, GEORGE C. HADJIPANAYIS, University of Delaware — Magnetic semiconductor alloy nanostructures play a crucial role in advanced technologies due to their tunable band gaps and electronic properties. Among these magnetic semiconductor alloys, Co-Ge is important both scientifically and technologically. In this work, we studied the magnetic and transport properties of Co<sub>5</sub>Ge<sub>3</sub> nanoparticles(NPs) fabricated by cluster-beam deposition. The NPs were characterized by X-ray powder diffraction and the results demonstrated that they had the same hexagonal structure P6<sub>3</sub>/mm-type as in bulk. Transmission-electron-microscope observations revealed that the particles have a single crystalline structure with an average size of 8nm. Selected-area electron diffraction(SAED) confirmed the XRD data, showing clearly that the particles have the hexagonal structure mentioned above. High-resolution electron microscopy images show lattice fringes with spacing of 1.99Å and 2.02Å which correspond to the (102) and (110) superlattice reflections of the hexagonal ordered Co<sub>5</sub>Ge<sub>3</sub> structure. Magnetic properties showed that these nanoparticles are ferromagnetic at room temperature as-compared to bulk samples that are paramagnetic at all temperatures. This magnetic behavior in Co-Ge nanoparticles indicates new size-controlled spin structures in confined nanosize systems.

**10:00AM X6.00009 Evolution of Magnetic Moments in Cobalt and Nickel Clusters<sup>1</sup>**, MASAHIRO SAKURAI, JAIME SOUTO-CASARES, JAMES CHELIKOWSKY, University of Texas at Austin — Ferromagnetism in transition-metal clusters has attracted much interest owing to their enhanced magnetic moments as compared to those of bulk phases. Here, we investigate the stability and the magnetism of Co and Ni clusters with various structures using a real-space formalism of pseudopotentials within the spin-polarized density-functional theory, i.e., the PARSEC code. We will discuss how the calculated magnetic moments evolve as a function of cluster size and compare them to experiment.

<sup>1</sup>We acknowledge support by the National Science Foundation Grant No. DMR 14-35219.

**10:12AM X6.00010 Spin Moments and Stability of VCun+ Clusters: The curious case of VCu<sub>4</sub><sup>+</sup>, VCu<sub>8</sub><sup>+</sup>, and VCu<sub>12</sub><sup>+</sup>**, WILLIAM BLADES, ARTHUR REBER, SHIV KHANNA, VCU, LUIS SOSA, PATRIZIA CALAMINICI, ANDREAS KOSTER, Civestav — The atomic structures, bonding characteristics, magnetic spin moments, and stability of VCu<sub>n</sub><sup>+</sup> clusters have been examined within density functional theory. Our studies show that at small sizes, the spin moments of the vanadium atom (3d<sup>3</sup> 4s<sup>2</sup>) due to 3d electrons are unquenched as the bonding is primarily through 4s electrons. As the cluster grows, the 3d orbitals of the vanadium atom start to participate in hybridized bonding with the copper atoms, resulting in a quenching of the magnetic moment. Upon closer examination of the electronic structures, we observe shell closure at VCu<sub>5</sub><sup>+</sup>, VCu<sub>7</sub><sup>+</sup>, and VCu<sub>14</sub><sup>+</sup>. However, the observed abundances in the photofragmentation profile do not correspond to these shell closures and the subsequent electronic stability they provide. Instead, the enhanced abundances of VCu<sub>4</sub><sup>+</sup>, VCu<sub>8</sub><sup>+</sup>, and VCu<sub>12</sub><sup>+</sup> seen in the mass spectrum are justified through geometric means and a cluster growth mechanism is proposed. Through synergetic theoretical and experimental efforts, the unusual enhanced stability of VCu<sub>4</sub><sup>+</sup>, VCu<sub>8</sub><sup>+</sup>, VCu<sub>12</sub><sup>+</sup>, and their magnetic properties are probed and explained.

<sup>1</sup>We gratefully acknowledge support from Department of Energy under award number DE-SC0006420

**10:24AM X6.00011 Model for ferromagnetic behavior of metal cluster-fullerene superatomic solids.**, PALLABI SUTRADHAR, VIKAS CHAUHAN, SHIV KHANNA, JAYASIMHA ATULASIMHA, Virginia Commonwealth Univ — Recent work has explored the precise assembly of binary superatomic solids from metal clusters and fullerene [1] as well as experimentally demonstrated ferromagnetic behavior in such assemblies at low temperatures (less than 10K). However, the origin of this behavior is not yet completely understood and modeled rigorously. We report theoretical analyses and simulations that explain the origin of ferromagnetic behavior from super exchange mechanism and model the temperature dependent magnetic behavior of these superatomic solids. [1] X. Roy et al., Science, 341, 157, 2013. [2] C.H. Lee et al., J. Am. Chem. Soc. 136, 16926, 2014.

**10:36AM X6.00012 Transition metal doped semiconductor quantum dots: Optical and magnetic properties**, YURI DAHNOVSKY, VITALY PROSHCHENKO, ARTEM PIMACHEV, Department of Physics & Astronomy, University of Wyoming — We study optical and magnetic properties of CdSe and Cd-Mn-Se quantum dots (QD). We find that there are two luminescence lines, one is fast and another is slow (~1ms). With the increase of a QD diameter the slow luminescence disappears at some critical QD size, thus only one line (fast) remains. Using the SAC SI computational method we find that D = 3.2 nm and D = 2.7 nm if the Mn impurity is located inside a QD or on a QD surface, respectively. For two or four Mn atoms in the quantum dot, now absorption takes place because the transition is spin-allowed. The DFT calculations of the magnetic state reveal that it is an antiferromagnet. We also study other quantum dots such as Cd-Mn-Se, Zn-Mn-S, and Zn-Mn-Se, doped and undoped. We find the slow luminescence energies for low concentrations of Mn impurities for each QD type. The calculations indicate that two luminescence lines, fast and slow, should always take place. However for Pb-Mn-S quantum dots there are now Mn levels inside a HOMO-LUMO gap, i.e., the Mn-levels are located in a PbS conduction band. The presence of Mn dopants increases the band gap and also removes the exciton peak. This effect is different to the other quantum dots.

**10:48AM X6.00013 Anomalous Hall Effect and Electron Transport in Co<sub>2</sub>Si Nanocluster Films**, BALAMURUGAN BALASUBRAMANIAN, TOM GEORGE, BHASKAR DAS, RALPH SKOMSKI, DAVID SELLMYER, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy, University of Nebraska — Magnetic nanoparticles or clusters are of fundamental and technological importance, since they exhibit entirely different and/or improved magnetic and electronic properties as compared to bulk alloys. Our recent research shows large average magnetic moments of up to 0.70μ<sub>B</sub>/Co at 10K and 0.49μ<sub>B</sub>/Co at 300K for cluster-deposited Co<sub>2</sub>Si nanoparticles, in sharp contrast to the nearly vanishing bulk magnetization. In this talk, we present interesting electron-transport properties in Co<sub>2</sub>Si nanoparticle films. The film shows a room-temperature negative magnetoresistance (MR) of 0.14% at kOe, which become as high as 1.8% at low temperatures. We also observed anomalous field-dependent Hall resistivities (ρ<sub>xy</sub>) in the nanoparticle film, which corroborate the magnetic hysteresis loops. Interestingly, the longitudinal metallic resistivity (ρ<sub>xx</sub>) shows a resistivity minimum at around 10K, similar to Kondo effects observed in the case of non-magnetic metals due to dilute magnetic impurities. The transport properties will be discussed in terms of the underlying spin correlations in the Co<sub>2</sub>Si nanoparticle films. This work is supported by the U.S. DOE-BES-DMSE (Grant No. DE-FG02-04ER46152) and NCMN.

**8:00AM X7.00001 Electronic structure and scattering property of 4H-SiC(0001)/SiO<sub>2</sub> interface**, TOMOYA ONO, CHRISTOPHER KIRKHAM, Center for Computational Sciences, University of Tsukuba, Japan, SHIGERU IWASE, Department of Precision Science and Technology, Osaka University, Japan — SiC is attracted much attention as a promising material for the high-power electronics devices. We carried out a first-principles calculations to reveal the relationship between the electronic structure and the interface defects appearing in the thermal oxidation. We found interlayer states along the SiC conduction band edge (CBE), whose location changes depending on which of two possible lattice sites, *h* or *k*, is at the interface. Excess O atoms at the interface lead to defect structures which alter the electronic structure. Changes to the valence band edge are the same whether *h* or *k* sites are at the interface. On the other hand, defects remove the interlayer state of the CBE between the first and second SiC bilayers if an *h* site is at the interface, but have no effect when there is a *k* site. The scattering property of the defects was also examined by electron-transport calculations. Carriers at the CBE of the *h*-type interface are easily scattered by the defects because of the absence of the interlayer states while those at the *k*-type interface is not. Since recent SiC-MOSFETs mainly use the conduction band as a channel, the behavior of these interlayer states at the CBE might play an important role in the performance of these devices.

**8:12AM X7.00002 Measurements of depth dependent modification of optical constants arising from H<sup>+</sup> implantation in n-type 4H-SiC using coherent acoustic phonons<sup>1</sup>**, ANDREY BAYDIN, HALINA KRZYZANOWSKA, Vanderbilt University, M. DHANUNJAYA, S.V.S. NAGESWARA RAO, University of Hyderabad, JIMMY L. DAVIDSON, Vanderbilt University, LEONARD C. FELDMAN, Rutgers University, NORMAN H. TOLK, Vanderbilt University — Silicon carbide (SiC) is an ideal material for new electronics, such as high power/high temperature devices, and a candidate for advanced optical applications such as room temperature spintronics and quantum computing. Both types of applications may require the control of defects created by ion bombardment. In this work, we examine depth dependent modification of optical constants of 4H-SiC due to hydrogen implantation at 180keV and low doses ranging from 10<sup>14</sup> to 10<sup>16</sup> cm<sup>-2</sup> probed by coherent acoustic phonon (CAP) spectroscopy. For our studies, we used Si-face 10μm epilayers of n-type 4H-SiC grown by CVD on 4H-SiC substrate. A comprehensive analysis of the reference and implanted spectra shows a strong dependence of 4H-SiC complex refractive index shape versus depth on the H<sup>+</sup> fluence. We extract the complex refractive index as a function of depth and ion beam dose. Our results demonstrate that the implantation-modified refractive index is distributed over a greater depth range than Monte Carlo calculation predictions of the implantation induced structural damage. These studies provide insight into the application of hydrogen ion implantation to the fabrication of SiC-based photonic and optoelectronic devices.

**8:24AM X7.00003 Revealing Hidden Interfacial States in NO Passivated 4H-SiC/SiO<sub>2</sub> Structures using TEM-EELS and XPS<sup>1</sup>**, JOSHUA TAILLON, University of Maryland, College Park, SARIT DHAR, Auburn University, GANG LIU, LEONARD FELDMAN, Rutgers University, TSVETANKA ZHELEVA, AIVARS LELIS, US Army Research Laboratory, LOURDES SALAMANCA-RIBA, University of Maryland, College Park — The interface between 4H-SiC and SiO<sub>2</sub> in metal oxide semiconductor (MOS) devices contains a high density of electrically active defects, which adversely affect SiC microelectronic devices. Various treatments and altering the substrate's crystallographic orientation can improve electronic performance. We have previously shown an inverse relationship between nitric oxide (NO) anneal time and the width of the transition layer at this interface ( $w_{TL}$ ).<sup>2</sup> More recent work analyzing  $w_{TL}$  has revealed much narrower interfaces that do not appear to narrow when subjected to an NO post-oxidation anneal, contradicting expectations. To further explore these interfaces, high resolution transmission electron microscopy and spatially resolved electron energy-loss spectroscopy (EELS) have been used. In addition, X-ray photoemission spectroscopy measurements were taken at the interface. Advanced EELS analysis via machine learning techniques has revealed interfacial bonding states for different post-oxidation annealing processes. The nature of these interfacial states is compared for devices made on substrates with different orientations and for NO post-oxidation annealing. <sup>2</sup>J. Taillon *et al.*, *J. Appl. Phys.* **113**, 044517 (2013).

**8:36AM X7.00004 Generalization of the van der Pauw Method: Analyzing Longitudinal Magnetoresistance Asymmetry to Quantify Doping Gradients<sup>1</sup>**, M. GRAYSON, WANG ZHOU, HEUN-MO YOO, S. PRABHU-GAUNKAR, Northwestern University, L. TIEMANN, C. REICHL, W. WEGSCHEIDER, ETH Zurich, Switzerland — A longitudinal magnetoresistance asymmetry (LMA) between a positive and negative magnetic field is known to occur in both the extreme quantum limit and the classical Drude limit in samples with a nonuniform doping density. By analyzing the current stream function in van der Pauw measurement geometry, it is shown that the electron density gradient can be quantitatively deduced from this LMA in the Drude regime [1]. Results agree with gradients interpolated from local densities calibrated across an entire wafer, establishing a generalization of the van der Pauw method to quantify density gradients. Results will be shown of various semiconductor systems where this method is applied, from bulk doped semiconductors, to exfoliated 2D materials. [1] W. Zhou, H.M. Yoo, S. Prabhu-Gaunkar, L. Tiemann, C. Reichl, W. Wegscheider, and M. Grayson, *Phys. Rev. Lett.* **115**, 186804 (2015).

**8:48AM X7.00005 First principles modeling of grain boundaries in CdTe<sup>1</sup>**, MARIA K.Y. CHAN, FATIH SEN, Argonne National Laboratory, CHRISTOPHER BUURMA, EPIR, TADÁS PAULASKAS, University of Illinois Chicago, CE SUN, MOON KIM, University of Texas at Dallas, ROBERT KLIE, University of Illinois Chicago — The role of extended defects is of significant interest for semiconductors, especially photovoltaics since energy conversion efficiencies are often affected by such defects. In particular, grain boundaries in CdTe photovoltaics are enigmatic since the achievable efficiencies of CdTe photovoltaics are higher in polycrystalline devices as compared to single crystalline devices. Yet, despite recent advances, the efficiency of poly-CdTe devices are still substantially below the theoretical maximum. We carry out an atomistic-level study using Scanning Transmission Electron Microscopy (STEM), together with first principles density functional theory (DFT) modeling, in order to understand the properties of specific bicrystals, i.e. artificial grain boundaries, constructed using wafer bonding. We discuss examples of bicrystals, including some involving large scale DFT calculations, and trends in defect and electronic properties.

<sup>1</sup>This work was funded by DOE SunShot BRIDGE program.

**9:00AM X7.00006 Origin of High Electronic Quality in Solar Cell Absorber CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub>**, WANJIAN YIN, Soochow University, TINGTING SHI, University of Toledo, SUHUA WEI, Beijing Computational Science Research Center, YANFA YAN, University of Toledo — Thin-film solar cells based on CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> halide perovskites have recently shown remarkable performance. First-principle calculations and molecular dynamic simulations show that the structure of pristine CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> is much more disordered than the inorganic archetypal thin-film semiconductor CdTe. However, the structural disorders from thermal fluctuation, point defects and grain boundaries introduce rare deep defect states within the bandgaps; therefore, the material has high electronic quality. We have further shown that this unusually high electronic quality is attributed to the unique electronic structures of halide perovskite: the strong coupling between cation lone-pair Pb *s* orbitals and anion *p* orbitals and the large atomic size of constitute cation atoms. We further found that although CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> GBs do not introduce a deep gap state, the defect level close to the VBM can still act as a shallow hole trap state. Cl and O can spontaneously segregate into GBs and passivate those defect levels and deactivate the trap state.

**9:12AM X7.00007 Mn Doping Effects on the Electronic Band Structure of PbS Quantum Dot Thin Films: A Scanning Tunneling Microscopy Analysis<sup>1</sup>**, ANDREW J. YOST, GAURAB RIMAL, JINKE TANG, TEYU CHIEN, University of Wyoming — A thorough understanding of the phenomena associated with doping of transition metals in semiconductors is important for the development of semiconducting electronic technologies such as semiconducting quantum dot sensitized solar cells (QDSSC). Manganese doping is of particular interest in a PbS QD as it is potentially capable of increasing overall QDSSC performance [1]. Here we present scanning tunneling microscopy and spectroscopy studies about the effects of Manganese doping on the energy band structures of PbS semiconducting QD thin films, grown using pulsed laser deposition. As a result of Manganese doping in the PbS QD thin films, a widening of the electronic band gap was observed, which is responsible for the observed increase in resistivity. Furthermore, a loss of long range periodicity observed by XRD, upon incorporation of Manganese, indicates that the Manganese dopants also induce a large amount of grain boundaries. [1] Qilin Dai *et al.*, *APL* **104**, 183901 (2014).

**9:24AM X7.00008 Electronic structure and defect properties of selenophosphate Pb<sub>2</sub>P<sub>2</sub>Se<sub>6</sub> for  $\gamma$ -ray detection<sup>1</sup>**, OLEG Y. KONTSEVOI, JINO IM, BRUCE W. WESSELS, MERCOURI G. KANATZIDIS, ARTHUR J. FREEMAN, Northwestern University — Heavy metal chalcophosphate Pb<sub>2</sub>P<sub>2</sub>Se<sub>6</sub> has shown a significant promise as an X-ray and  $\gamma$ -ray detector material. To assess the fundamental physical properties important for its performance as detector, theoretical calculations were performed for the electronic structure, band gaps, electron and hole effective masses, and static dielectric constants. The calculations were based on first-principles density functional theory (DFT) and employ the highly precise full potential linearized augmented plane wave method and the projector augmented wave method and include nonlocal exchange-correlation functionals to overcome the band gap underestimation in DFT calculations. The calculations show that Pb<sub>2</sub>P<sub>2</sub>Se<sub>6</sub> is an indirect band gap material with the calculated band gap of 2.0 eV, has small effective masses, which could result in a good carrier mobility-lifetime product  $\mu\tau$ , and a very high static dielectric constant, which could lead to high mobility of carriers by screening of charged scattering centers. We further investigated a large set of native defects in Pb<sub>2</sub>P<sub>2</sub>Se<sub>6</sub> to determine the optimal growth conditions for application as  $\gamma$ -ray detectors. The results suggest that the prevalent intrinsic defects are selenium vacancies, followed by lead vacancies, then phosphorus vacancies and antisite defects. The effect of various chemical environments on defect properties was examined and the optimal conditions for material synthesis were suggested. <sup>1</sup>Supported by DHS (Grant No. 2014-DN-077-ARI086-01).

**9:36AM X7.00009 Challenges in p-type Doping of CdTe**, JEDIDIAH MCCOY, SANTOSH SWAIN, KELVIN LYNN, Center for Materials Research at Washington State University — We have made progress in defect identification of arsenic and phosphorous doped CdTe to understand the self-compensation mechanism which will help improve minority bulk carrier lifetime and net acceptor density. Combining previous measurements of un-doped CdTe, we performed a systematic comparison of defects between different types of crystals and confirmed the defects impacting the doping efficiency. CdTe bulk crystals have been grown via vertical Bridgman based melt growth technique with varying arsenic and phosphorous dopant schemes to attain p-type material. Furnace temperature profiles were varied to influence dopant solubility. Large carrier densities have been reproducibly obtained from these boules indicating successful incorporation of dopants into the lattice. However, these values are orders of magnitude lower than theoretical solubility values. Infrared Microscopy has revealed a plethora of geometrically abnormal second phase defects and X-ray Fluorescence has been used to identify the elemental composition of these defects. We believe that dopants become incorporated into these second phase defects as Cd compounds which act to inhibit dopant solubility in the lattice.

**9:48AM X7.00010 Diversity of surface conduction in pyrite FeS<sub>2</sub> single crystals**, CHRIS LEIGHTON, JEFF WALTER, XIN ZHANG, FRAZIER MORK, RYAN HOOL, MIKE MANNO, ERAY AYDIL, University of Minnesota — Pyrite FeS<sub>2</sub> has long been recognized as an attractive material for solar cells because of its high absorptivity, potential low cost, high abundance, and low toxicity. Despite having appropriate band gap (0.95 eV) and minority carrier diffusion length (100-1000 nm), low open circuit voltages ( $V_{oc} \leq 0.1$  V) have plagued FeS<sub>2</sub>-based cells. Surface conduction has been proposed as a contributing factor for the low  $V_{oc}$ , particularly a p-type surface inversion layer on n-type crystals [1]. Here we report a detailed electronic transport study of a large number of well-characterized CVT-grown n-FeS<sub>2</sub> single crystals. Abundant evidence of surface conduction is found from the  $T$  dependence of resistivity, resistance anisotropy, low  $T$  behavior at the 2D quantum resistance, thickness dependence, and the influence of contact metal work function. However, striking diversity in this surface conduction is found, even in nominally identical crystals at similar doping. The results cannot be understood by surface inversion alone, pointing to as yet uncontrolled surface factors. [1] Limpinsel *et al.* Energy Environ. Sci. (2014). Work supported by NSF.

**10:00AM X7.00011 Grain boundaries and surfaces in polycrystalline photovoltaics**, PAUL HANEY, National Institute of Standards and Technology, HEAYOUNG YOON, The University of Utah, NIKOLAI ZHITENEV, National Institute of Standards and Technology — Despite the fact that polycrystalline photovoltaics materials such as CdTe and CIGS are an established commercial technology, the precise role of grain boundaries in their performance remains poorly understood. The high defect density at grain boundaries is generally detrimental to carrier lifetime, however the electric fields surrounding charged grain boundaries may separate electrons and holes, effectively passivating the grain boundary. One difficulty in ascertaining the properties of grain boundaries is that high spatial resolution experimental techniques needed to probe individual grain boundaries are generally surface sensitive. For this reason, extracting quantitative grain boundary and other material properties from this data requires a quantitatively accurate model of the exposed surface. Motivated by these considerations, we present a theoretical analysis of the response of a polycrystalline semiconductor to a localized excitation near a grain boundary, and near the surface. We use our analytical results to interpret electron beam induced current (EBIC) data on polycrystalline CdTe solar cells.

**10:12AM X7.00012 Individual iso-electronic N and Bi centers in GaAs studied by Scanning Tunneling Microscopy.**, PAUL KOENRAAD, CHRISTIAN KRAMMEL, RIANNE PLANTENGA, Eindhoven University of Technology, VICTORIA KORTAN, MICHAEL FLATT, University of Iowa, FREDDY TILLEY, MERVIN ROY, PETER MAKSYM, University of Leicester, TAKASHI KITA, Kobe University — Nitrogen and bismuth iso-electronic doping centers in GaAs have received considerable interest in the last few years due to their peculiar behaviour in dilute nitrides and bismides. In these materials effects such as a strong band bowing and the formation of resonant states in respectively the conduction and valence band have been reported. In this contribution we will report our exploration of individual nitrogen and bismuth atoms in the outermost layers of a freshly cleaved (110) GaAs surface by STM. Depending on the tunnel conditions we are able to either visualise the lattice distortion or image the charge distribution of the resonant state. We clearly observe that nitrogen pulls its neighbouring atoms inwards whereas bismuth pushes its neighbouring atoms away. A straightforward geometrical model based on the covalent radii of the dopants and substrate atoms is used to interpret the observed crystal deformation seen in our STM images of nitrogen and bismuth under the appropriate tunnel conditions. At small positive voltages we could observe the charge distribution of the resonant state induced by iso-electronic nitrogen atoms in GaAs. Tight Binding Modelling (TBM) was used to explain the observed strongly anisotropic charge distribution.

**Session X8 DMP GMAG: Organic Inorganic Perovskite Spintronics** 304 - Oana Jurchescu, Wake Forest University

**8:00AM X8.00001 Organometal Trihalide Perovskite Spintronics<sup>1</sup>**, DALI SUN, University of Utah — The family of organometal trihalide perovskite (OTP), CH<sub>3</sub>NH<sub>3</sub>PbX<sub>3</sub> (where X is halogen) has recently revolutionized the photovoltaics field, and shows promise in applications such as solar energy harnessing, light emitting diodes, field effect transistors and laser action. The OTP spin characteristic properties are influenced by the large spin-orbit-coupling of the Pb atoms, and thus may offer a new class of semiconductors for spin-based applications. In this talk we will summarize the 'magnetic field effect' on photocurrent and electroluminescence in OTP optoelectronic devices, and photoluminescence from OTP films [1]; and report more recent studies of pure spin-current and spin-aligned carrier injection in OTP spintronics devices using 'spin-pumping' and 'spin-injection', respectively. We measured relatively large inverse-spin-Hall effect using pulsed microwave excitation in OTP devices at resonance with a ferromagnetic (FM) layer, and giant magnetoresistance in OTP-based spin-valves. Our studies launch the field of OTP spintronics. [1] C. Zhang *et al.* Nat. Phys. 11, 427-434 (2015)

<sup>1</sup>Research sponsored by the DOE, Office of Science, grant DE-SC0014579. Work done in collaboration with Chuang Zhang, Marzieh Kavand, Kipp J. van Schooten, Hans Malissa, Matthew Groesbeck, Ryan McLaughlin, Christoph Boehme, and Z. Vally Vardeny.

**8:36AM X8.00002 Magneto-optical properties of hybrid organic-inorganic perovskites**, ZHI-GANG YU, Washington State University — In semiconductors the k.p Hamiltonian played a central role in understanding material properties because the model parameters are directly related to experimental measurable properties. Here we construct a 8-band k.p Hamiltonian for tetragonal perovskites from both perturbation and group theories and determine the parameters from first-principles band-structure calculations and experiments. This Hamiltonian is then used to study conduction- and valence-band states as well as excitons under an arbitrary magnetic field. The calculated electron and hole g-factors can explain the exciton g-factors measured by magneto-absorption and magneto-luminescence and the field-dependent exciton energies are consistent with the high-field magneto-absorption experiment, which has been used to accurately determine the exciton binding energy.

**8:48AM X8.00003 Studies of Gilbert magnetization damping in NiFe/organometallic trihalide perovskite bilayers investigated by broadband ferromagnetic resonance<sup>1</sup>**, MATTHEW GROESBECK, DALI SUN, RYAN MCLAUGHLIN, CHUANG ZHANG, HAOLIANG LIU, ZEEV VALY VARDENY, University of Utah Dept. of Physics and Astronomy — Organo-metallic trihalide perovskites (OTP) have recently been suggested as promising candidates for spintronics applications, motivated by the presence of strong spin-orbit coupling, and recent studies of spin dynamics in  $\text{CH}_3\text{NH}_3\text{PbI}_3$ . To help elucidate the spin transport properties in these materials, we have studied the Gilbert magnetization damping parameter in NiFe ferromagnetic films related to spin-pumping into adjacent OTP layers under ferromagnetic resonance (FMR) excitation conditions, using a broadband FMR detection system. We found an increase of the damping parameter associated with spin-pumping into the OTP. The obtained thickness-dependent results are compared to those of NiFe/Cu and NiFe/Pt bilayer structures, where spin transport characteristics are well-known.

**9:00AM X8.00004 Optical Generation of Ballistic and Diffusive Spin Currents in Organic-Inorganic Lead Halide Perovskites**, JUNWEN LI, PAUL HANEY, National Institute of Standards and Technology — Organic-inorganic halide perovskite solar cells have attracted enormous attention in recent years due to their remarkable photovoltaic power conversion efficiency. These materials should exhibit interesting spin-dependent properties as well, owing to the strong spin-orbit coupling and the broken inversion symmetry present at room temperature. In this work, we consider the spin-dependent optical response of  $\text{CH}_3\text{NH}_3\text{PbI}_3$  on two distinct time scales. We first use density functional theory to compute the ballistic spin current injected by absorption of linearly polarized light. This spin current persists on a time scale of the momentum relaxation time. We then consider diffusive transport of photogenerated charge and spin for a thin perovskite layer with a passivated surface and an Ohmic, non-selective back contact. The spin densities and spin currents are evaluated by solving the drift-diffusion equations for a 3-dimensional Rashba model. We comment on the applications of optically excited spin densities and spin currents in these materials.

**9:12AM X8.00005 Exciton spin dynamics in  $\text{MAPbI}_3$  measured by Hanle effect**, WILLIAM TALMADGE, University of Utah Department of Physics and Astronomy, RUIZHI WANG, University of Utah Department of Physics and Astronomy, Nanjing University of Science and Technology, PATRICK ODENTHAL, NATHAN GUNDLACH, CHUANG ZHANG, DALI SUN, ZEEV VALY VARDENY, YAN (SARAH) LI, University of Utah Department of Physics and Astronomy — The organic-inorganic hybrid perovskites have emerged as a highly promising class of semiconductors for photovoltaic applications. The properties responsible for the high photoconversion efficiency are under extensive investigation. There have, however, been fewer investigations of spin-dependent effects in this class of materials. We present energy dependent photoinduced Faraday rotation in polycrystalline thin film  $\text{CH}_3\text{NH}_3\text{PbI}_3$ , which benefit from the band structure and optical selection rules. The Faraday rotation spectrum follows the exciton absorption band at low temperatures, indicating its excitonic origin. Through the Hanle effect, based on Faraday rotation, we found the coexistence of two spin components at 4 K, which was confirmed through time resolved measurements.

**9:24AM X8.00006 Photoexcited carrier spin dynamics in  $\text{CH}_3\text{NH}_3\text{PbI}_3$ <sup>1</sup>**, PATRICK ODENTHAL, NATHAN GUNDLACH, WILLIAM TALMADGE, University of Utah, RUIZHI WANG, Nanjing University of Science and Technology, CHUANG ZHANG, DALI SUN, ZEEV VALY VARDENY, YAN (SARAH) LI, University of Utah — Metal halide perovskites have shown great promise for the field of spintronics due to their large tunable spin-orbit coupling, spin dependent optical selection rules and predicted electrically tunable Rashba band. The spin sensitive optical transitions allow optical spin orientation of carriers using circularly polarized light, and detection of the spin polarization via optical Faraday rotation measurement. We study carrier spin dynamics on solution-processed polycrystalline  $\text{CH}_3\text{NH}_3\text{PbI}_3$  films using time-resolved Faraday rotation (TRFR). TRFR reveals unexpected long spin lifetimes exceeding 1ns at 4K. This is significant given that Pb and I exhibit large spin-orbit coupling, which usually lead to fast spin relaxation.

<sup>1</sup>Research supported by the NSF-MRSEC (DMR 1121252) at the University of Utah.

**9:36AM X8.00007 Composition, Temperature, and Electric Field Dependence of Magneto-Optical Properties of Lead Halide Perovskites<sup>1</sup>**, RYAN MCLAUGHLIN, CHUANG ZHANG, DALI SUN, Z. VALY VARDENY, University of Utah — Organometallic Perovskites have received much attention in recent years due to their remarkable efficiency in photovoltaic cells, along with their highly tunable optical and electrical properties. It is an important goal to quantify and understand the effects of Spin-Orbit Coupling in Perovskite-based optoelectronic devices, which can be characterized by magneto-optical properties such as Kerr rotation and Faraday rotation. Here we use the Verdet constant to investigate the tunability of the Spin-Orbit coupling parameters of Organometallic Perovskites as a function of chemical composition, temperature, and electric field.

<sup>1</sup>Research sponsored by the NSF (Grant No. DMR-1104495) and NSF-MRSEC (DMR 1121252).

**9:48AM X8.00008 ABSTRACT WITHDRAWN —**

**10:00AM X8.00009 Neutron and X-Ray Scattering Studies of Hybrid Perovskites for Photovoltaic Applications**, MICHAEL CRAWFORD, DuPont Company, PAMELA WHITFIELD, NIINA JALARVO, GEORG EHLERS, SNS, Oak Ridge National Laboratory, MADHUSUDAN TYAGI, NIST Center for Neutron Research, NORMAN HERRON, LYNDIA JOHNSON, DuPont Company, WILLIAM GUISE, DuPont Company and APS, Argonne National Laboratory, IVAN MILAS, DuPont Company, YONGQIANG CHENG, LUKE DAEMEN, ANIBAL RAMIREZ-CUESTA, KATHARINE PAGE, XIAOPING WANG, FENG YE, SNS, Oak Ridge National Laboratory — Hybrid perovskites ( $\text{ABX}_3$ ) have attracted a great deal of attention recently as light absorbers for photovoltaics. In these materials the A site is occupied by organic cations, for example methyl ammonium (MA) or formamidinium (FA) cations, the B site is occupied by metals, for example Pb or Sn, and the X anions are halogens (I, Br, or Cl). Typical of perovskites, these materials exhibit a series of structural phase transitions involving rotations or tilts of the  $\text{BX}_6$  octahedra, but with the added complexity that the inorganic framework is coupled to order-disorder transitions of the organic cations. We have used neutron scattering techniques to characterize the structures and dynamics of several of these compounds as a function of temperature. In addition, high resolution synchrotron x-ray diffraction measurements have been performed to investigate the structural phase transitions. These studies yield a detailed picture of the structures, dynamics, and structural phase transitions of these compounds, and provide a firm basis for understanding their excellent photovoltaic properties.

**10:12AM X8.00010 Electric Field Effects on Photoconductivity and Photoluminescence in  $\text{MAPbI}_3$  Perovskite<sup>1</sup>**, CHUANG ZHANG, DALI SUN, ZEEV VALY VARDENY, Department of Physics & Astronomy, University of Utah — The origin of “hysteresis behavior” in I-V response of  $\text{MAPbI}_3$  perovskite devices is still under debate. We characterized this electric field induced hysteresis by monitoring the changes of photoconductivity (E-PC) and photoluminescence (E-PL) from the  $\text{MAPbI}_3$  film deposited on inter-digital electrodes. Interestingly, we observed a “sign change” in both E-PC and E-PL effects, depending on the applied field and temperature. The E-PC/E-PL could be “frozen” when cooling the device under external field to lower temperature. These results reveal multiple possible reasons for the intrinsic hysteresis behavior in  $\text{MAPbI}_3$  perovskite devices. This work was supported by the Utah NSF-MRSEC program DMR 1121252.

<sup>1</sup>Electric Field Effects on Photoconductivity and Photoluminescence in  $\text{MAPbI}_3$  Perovskite

**10:24AM X8.00011 Nanoimprinting Perovskite by Hot Stamping for Improved Crystallinity and Morphology**, BALASUBRAMANIAM BALACHANDRAN, ROSS HAROLDSON, YIXIN REN, ANVAR ZAKHIDOV, WENCHUANG HU, JULIA CHAN, Univ of Texas - Dallas, UTD NANOIMPRINT TEAM — We present an innovative approach of using thermal nanoimprinting lithography (NIL by hot embossing) to pattern hybrid perovskites into ordered micro and nanostructures with improved crystallinity and morphology. The spin-coated thin films of organic-inorganic perovskite CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3</sub> have been embossed by large area stamps of highly periodic nanopatterns at the scale of 200 to 600 nm. XRD shows the larger and aligned grains, while SEM reveals much improved film morphology with no pin-holes and much less grain boundaries. The obtained ordered periodic micro- and nanostructures show iridescent coloration due to Bragg scattering in planar perovskite photonic crystals.

**10:36AM X8.00012 Spatially resolved optoelectronic characterization of perovskite lead iodide nanostructures**, RUI XIAO, XINGYU PENG, YASEN HOU, DONG YU, Univ of California - Davis — The high power conversion efficiency of organo-lead halide perovskite-based solar cells has attracted world-wide attention over the past few years. The high efficiency was believed to originate from the unusual properties including long carrier lifetimes and consequent long carrier diffusion lengths in these materials. Ion drift, ferroelectricity, and charge traps have been proposed to account for the efficient charge separation and photocurrent hysteresis. However, it remains unclear which mechanism is dominating. We fabricate field effect transistors (FETs) incorporating single nanoplates/nanowires of organic perovskite and perform scanning photocurrent microscopic (SPCM) measurements to extract carrier diffusion lengths as a function of gate voltage, source-drain bias. Spatially resolved optoelectronic investigations of single crystalline perovskite nanostructures provide valuable information and key evidence on distinguishing the dominating charge transport/separation mechanism.

**Friday, March 18, 2016 8:00AM - 11:00AM —**

**Session X11 DMP: New Fe-based Superconductors and Related Materials II** 307 - Xianhui Chen, University of Science and Technology of China

**8:00AM X11.00001 Interplay of structure, magnetism and superconductivity in the 112 Fe based superconducting family**, NI NI, Univ of California - Los Angeles — Both cuprates and Fe-based superconductors, the two known high T<sub>c</sub> superconducting families, show rich emergent phenomena near the superconductivity (SC). To understand the mechanism of unconventional SC, it is crucial to unravel the nature of these emergent orders. The 112 Fe pnictide superconductor (FPS), Ca<sub>1-x</sub>RE<sub>x</sub>FeAs<sub>2</sub> (CaRE112), shows SC up to 42 K, the highest bulk T<sub>c</sub> among all nonoxide FPS [2]. Being an exceptional FPS where the global C<sub>4</sub> rotational symmetry is broken even at room temperature, it is important to extract the similarities and differences between 112 and other FPS so that critical ingredients in inducing SC in FPS can be filtered. In this talk, I will review current progress in the study of 112. The comparison between Co doped CaLa112 and Co doped 10-3-8 will be made and the importance of interlayer coupling will be discussed. The work on 112 is supported by NSF while the work on 10-3-8 is supported by DOE.

**8:36AM X11.00002 Structural symmetries of the 112-type iron-based superconductor (Ca<sub>1-x</sub>La<sub>x</sub>)FeAs<sub>2</sub> studied using nonlinear and ultrafast optics**, JOHN HARTER, HAO CHU, Institute for Quantum Information and Matter, California Institute of Technology, SHAN JIANG, NI NI, Department of Physics & Astronomy, University of California, Los Angeles, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology — The crystal structure of the newly discovered 112-type iron-based superconductors contains symmetry-breaking arsenic chains, avoiding the need for local probes or uniaxial strain in order to study the ubiquitous electronic nematic state that exists in the vicinity of magnetic order in the iron pnictides. In addition, the 112-type materials are the first known high-temperature superconductors without a center of inversion, with interesting ramifications for Cooper pairing in the superconducting state. We present details of the structure of 112-type (Ca<sub>1-x</sub>La<sub>x</sub>)FeAs<sub>2</sub> using rotational anisotropy second harmonic generation and pump-probe transient reflectivity experiments. These all-optical techniques are complimentary to conventional diffraction measurements and enable a precise determination of crystallographic symmetries. Our measurements highlight the novel structural properties of the 112-type materials.

**8:48AM X11.00003 ABSTRACT WITHDRAWN —**

**9:00AM X11.00004 The Interplay of Fe and Ce Magnetism in Ca<sub>0.71</sub> Ce<sub>0.29</sub>(Fe<sub>1-x</sub>Co<sub>x</sub>)As<sub>2</sub> single crystals<sup>1</sup>**, SHAN JIANG, Univ of California - Los Angeles, LIAN LIU, Columbia University, HUIBO CAO, WEI TIAN, Oak Ridge National Lab, EVE EMMANUELIDU, AOSHUANG SHI, Univ of California - Los Angeles, YASUTOMO UEMURA, Columbia University, NI NI, Univ of California - Los Angeles — In this talk, we will present the synthesis and characterization of the Ca<sub>0.71</sub> Ce<sub>0.29</sub>(Fe<sub>1-x</sub>Co<sub>x</sub>)As<sub>2</sub> single crystals. Elastic neutron scattering complemented by resistivity, susceptibility and heat capacity measurements has revealed a paramagnetic-to-antiferromagnetic phase transition of the Fe sublattice at 69K and a monoclinic-to-triclinic structural phase transition at 73 K in Ca<sub>0.71</sub> Ce<sub>0.29</sub>FeAs<sub>2</sub>. In addition, Fe spin reorientation and Ce ordering at lower temperatures, reminiscent of the one in REFeAsO (RE=Ce, Pr, Nd) materials, exist. The Co substitution on the Fe sites completely suppresses the ordering of Fe sublattice at x=0.032. However, it only slightly affects the Ce ordering, which prevents the formation of superconductivity in Ca<sub>0.71</sub> Ce<sub>0.29</sub>(Fe<sub>1-x</sub>Co<sub>x</sub>)As<sub>2</sub>.

**9:12AM X11.00005 Thallium-doped BaFe<sub>2</sub>As<sub>2</sub> crystals: The unusual competition between magneto-elastic coupling and charge doping<sup>1</sup>**, ATHENA SEFAT, LI LI, HUIBO CAO, BRIAN SALES, MICHAEL MCGUIRE, RADU CUSTELCEAN, DAVID PARKER, Oak Ridge National Lab — We partially substitute thallium for barium and report the effects of interlayer coupling in Ba<sub>1-x</sub>Tl<sub>x</sub>Fe<sub>2</sub>As<sub>2</sub> crystals. We demonstrate the unusual competition between magneto-elastic coupling and charge doping in an iron-arsenide material, whereby T<sub>N</sub> temperature rises in BaFe<sub>2</sub>As<sub>2</sub>, and then falls with additional TI-doping. Evidence from temperature-dependent bulk thermodynamic and transport properties, and neutron diffraction results will be presented. Using LDA, we illustrate that small changes related to 3d transition-metal state can have profound effects on magnetism.

<sup>1</sup>The work is supported by the U.S. DOE, Office of Science, BES, Materials Sciences and Engineering Division, and Chemical Sciences, Geosciences, and Biosciences Division. The work at ORNLs HFIR is sponsored by the Scientific User Facilities Division.

**9:24AM X11.00006 Structural and antiferromagnetic properties of  $\text{Ba}(\text{Fe}_{1-x-y}\text{Co}_x\text{Rh}_y)_2\text{As}_2$  compounds**<sup>1</sup>, MIN GYU KIM, Lawrence Berkeley National Laboratory, T. W. HEITMANN, The Missouri Research Reactor, S. R. MULCAHY, University of California, Berkeley, E. D. BOURRET-COURCHESNE, Lawrence Berkeley National Laboratory, R. J. BIRGENEAU, University of California, Berkeley — We present a systematic investigation of the electrical, structural, and antiferromagnetic properties for the series of  $\text{Ba}(\text{Fe}_{1-x-y}\text{Co}_x\text{Rh}_y)_2\text{As}_2$  compounds with fixed  $x = 0.027$  and  $0 < y < 0.035$ . We compare our results for the Co-Rh doped  $\text{Ba}(\text{Fe}_{1-x-y}\text{Co}_x\text{Rh}_y)_2\text{As}_2$  compounds with  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  compounds. We demonstrate that the electrical, structural, antiferromagnetic, and superconducting properties of the Co-Rh doped compounds are similar to the properties of the Co doped compounds. We find that the overall behaviors of  $\text{Ba}(\text{Fe}_{1-x-y}\text{Co}_x\text{Rh}_y)_2\text{As}_2$  and  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  compounds are very similar when the total number of the extra electrons per Fe/*TM* (*TM* = transition metal) site is considered, which is consistent with the rigid band model. Despite the similarity, we find that the details of the transitions are different in between  $\text{Ba}(\text{Fe}_{1-x-y}\text{Co}_x\text{Rh}_y)_2\text{As}_2$  and  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  compounds.

**9:36AM X11.00007 Search for New Superconductors: An Electro-Magnetic Phase Transition in an Iron Meteorite Inclusion at 117 K**, STEFAN GUÉNON, PIT, Nano Atomoptics, University of Tuebingen, Germany, JUAN GABRIEL RAMIREZ, Department of Physics, Universidad de los Andes, Bogota, Colombia, ALI C. BASARAN, Department of Physics, Gebze Technical University, Turkey, JAMIE WAMPLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego, MARK THIEMENS, Department of Chemistry and Biochemistry, University of California San Diego, IVAN K. SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California San Diego — We investigated a natural iron sulfide based materials (Troilite) inclusion with its associated minerals in the iron meteorite Tlacotepec. The search for superconductivity in these heterogeneous materials requires a technique capable of detecting minute amounts of a superconducting phase embedded in a non-superconducting matrix. We used Magnetic Field Modulated Microwave Spectroscopy (MFMMS), a very sensitive, selective, and non-destructive technique, to search for superconductivity in heterogeneous systems. Here, we report the observation of an electro-magnetic phase transition at 117 K that causes a MFMMS-response typical of a superconductor. A pronounced and reproducible peak together with isothermal magnetic field sweeps proves the appearance of an electromagnetic phase below 117 K. This is very similar to the characteristic response due to flux trapping in a granular superconductor with a short coherence length. This work was supported by the AFOSR under the grant number AFOSR-MURI FA9550-14-1-0202.

**9:48AM X11.00008 Heisenberg Model Analysis on Inelastic Powder Neutron Scattering Data Using Pure and K doped  $\text{BaMn}_2\text{As}_2$  samples**<sup>1</sup>, MEHMET RAMAZANOGLU, Istanbul Technical University, A. SAPKOTA, A. PANDEY, D. JOHNSTON, ALAN GOLDMAN, A. KREYSSIG, Ames Lab. & Iowa State Univ., Ames, IA, 50011, D. ABERNATHY, J. NIEDZIELA, M. STONE, Oak Ridge National Lab., TN, 37831, R.J. MCQUEENEY, Ames Lab. & Iowa State Univ., Ames, IA, 50011 — Low temperature powder inelastic neutron scattering measurements (INS) were performed on powders of  $\text{Ba}(1-x)\text{KxMn}_2\text{As}_2$  with  $x=0$ (BMA), 0.125 and 0.25. BMA is a G type antiferromagnet (AFM) which has local magnetic modulations bridging between the pnictide and cuprate superconductors. Hole doping (K) introduces more metallic behavior. The magnetic contribution to the intensities were retrieved by subtracting the estimated phonon background obtained at high momentum transfers from the raw. The resultant estimated magnetic intensities were analyzed by using damped harmonic oscillator model. The K doping effects create a broadening in the magnetic peak profiles consistent with expected weak FM fluctuations. We also analyzed the INS data using a powder integration routine which is based on J1-J2-Jz Heisenberg Model. The Monte Carlo integration technique is used to obtain the powder-averaged  $S(\mathbf{Q}, E)$  for a series of Js. The representative values (with lowest chi-squared) obtained for BMA are in agreement with previous results. The values obtained for K doped samples were found in the close proximity to the parent ones. Overall we conclude that the original AFM structure seen in BMA retained its character even in the K doped samples with minimal differences.

**10:00AM X11.00009 A new class of half-metallic ferromagnets based on the pnictide superconductors from first principles.**<sup>1</sup>, SINEAD GRIFFIN, JEFFREY NEATON, Lawrence Berkeley Natl Lab/UC Berkeley — Most theoretical and experimental efforts in the Fe-pnictide class of superconductors aim to optimize the superconducting  $T_c$ . Significant substitution with other transition-metal ions is detrimental to superconductivity, however recent experiments on doped  $\text{BaMn}_2\text{As}_2$  point to its potential as a half-metallic ferromagnet. Using ab initio calculations we investigate Mn-based structures as a new family of half-metallic ferromagnets, and discuss tuning the chemical composition and physical parameters for optimal device performance.

**10:12AM X11.00010 Antiferromagnetism in  $\text{CaAl}_2\text{Si}_2$ -type  $\text{CaMn}_2\text{As}_2$  and  $\text{SrMn}_2\text{As}_2$  single crystals**<sup>\*</sup>, N. S. SANGEETHA, ABHISHEK PANDEY, ZACKERY A. BENSON, D. C. JOHNSTON, Ames Laboratory, Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011 — Magnetic susceptibility versus temperature  $\chi(T)$  measurements of  $\text{CaMn}_2\text{As}_2$  and  $\text{SrMn}_2\text{As}_2$  crystals show clear antiferromagnetic (AFM) transitions at  $T_N \approx 65$  K and 120 K,<sup>1</sup> respectively. The anisotropic behaviors in  $\chi(T \leq T_N)$  suggest that both compounds are noncollinear antiferromagnets which may result either from an intrinsic noncollinear structure or from multiple collinear AFM domains that are not aligned collinearly.<sup>2</sup> The  $\chi(T)$  data at  $T > T_N$  reveal that both compounds exhibit strong short-range AFM ordering, evidently associated with quasi-two-dimensional spin lattices. The electrical resistivities show insulating ground states with activation energies of  $\approx 63$  meV in  $\text{CaMn}_2\text{As}_2$  and 44 meV in  $\text{SrMn}_2\text{As}_2$ . The experimental results thus reveal that both (Ca, Sr) $\text{Mn}_2\text{As}_2$  materials are AFM insulators at low temperatures and in analogy with the high  $T_c$  cuprates, may be potential parent compounds for  $\text{CaAl}_2\text{Si}_2$ -type superconductors.

**10:24AM X11.00011 Resistivity Anisotropy in Single Crystals of  $\text{CaCo}_{1.86}\text{As}_2$** <sup>1</sup>, M. A. TANATAR, V. K. ANAND, A. PANDEY, N. S. SANGEETHA, D.C. JOHNSTON, R. PROZOROV, Ames Laboratory and Iowa State University — In-plane and inter-plane resistivity was measured in single crystals of type A antiferromagnet  $\text{CaCo}_{2-x}\text{As}_2$  ( $x = 0.14$ ). Clear anomalies in the temperature dependent resistivity are observed at the magnetic ordering at  $T_N \approx 50$  K. The transition shifts to lower temperatures upon application of 9 T magnetic field both along tetragonal (001) axis,  $H \parallel c$ , and transverse to it,  $H \perp c$ . The temperature - magnetic field phase diagrams determined from the resistivity measurements are in good agreement with magnetization measurements [1]. No additional anomalies are found at the spin-flip transition in the compound, suggesting that the direction of the spin does not play an appreciable role in the spin-disorder scattering in this compound. [1] V. K. Anand *et al.* Phys. Rev B **89**, 214409 (2014).

**10:36AM X11.00012 Wall-like spin excitations in A-type antiferromagnetic  $\text{CaCo}_2\text{As}_2$** <sup>1</sup>, A. SAPKOTA, B. G. UELAND, ABHISHEK PANDEY, D. C. JOHNSTON, A. KREYSSIG, R. J. MCQUEENEY, A. I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, V. K. ANAND, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, J. L. NIEDZIELA, D. L. ABERNATHY, Oak Ridge National Laboratory — The  $\text{ACo}_2\text{As}_2$  ( $A = \text{Ca, Sr, Ba}$ ) compounds are structurally and chemically similar to  $\text{AFe}_2\text{As}_2$  and possess some interesting similarities and differences in their magnetism. We recently discovered that  $\text{SrCo}_2\text{As}_2$  has stripe antiferromagnetic (AFM) spin correlations similar to stripe-ordered  $\text{AFe}_2\text{As}_2$ . On the other hand,  $\text{CaCo}_2\text{As}_2$  orders in an A-type AFM structure with ferromagnetic correlation of the spins in the square-lattice Co-layer and AFM correlations between layers. Despite the A-type order, our recent inelastic neutron scattering measurements show that spin excitations in  $\text{CaCo}_2\text{As}_2$  are not associated with either the A-type or stripe-type order. Instead, we observe broad excitations that extend longitudinally (along (1,1,0) in reciprocal space), but remain sharply defined in the transverse direction. These excitations seem to be best characterized as a “wall” of scattering and suggest that  $\text{CaCo}_2\text{As}_2$  has quasi-one-dimensional spin dynamics very different than in  $\text{AFe}_2\text{As}_2$  and  $\text{SrCo}_2\text{As}_2$ .

<sup>1</sup>Work at Ames Laboratory was supported by US DOE, Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-07CH11358. Work at ORNL was supported by US DOE, Office of Basic Energy Sciences, Scientific User Facilities Division.

**10:48AM X11.00013 Pressure-induced collapsed-tetragonal phase in  $\text{SrCo}_2\text{As}_2$  at ambient temperature**, W. T. JAYASEKARA, U. S. KALUARACHCHI, B. G. UELAND, A. PANDEY, Y. B. LEE, V. TAUFOR, A. SAPKOTA, K. KOTHAPALLI, N. S. SANGEETHA, S. L. BUD'KO, B. N. HARMON, P. C. CANFIELD, D. C. JOHNSTON, A. KREYSSIG, A. I. GOLDMAN, Ames Lab., Dept. of Physics and Astronomy, Iowa State Univ., G. FABBRIS, Y. FENG, L. S. I. VEIGA, Argonne Natl. Lab., A. M. DOS SANTOS, Oak Ridge Natl. Lab. — Our recent high-energy (HE) high-pressure (HP) x-ray powder diffraction measurements on tetragonal (T)  $\text{SrCo}_2\text{As}_2$  have revealed a first-order pressure-induced structural phase transition to a collapsed tetragonal (cT) phase with a reduction in  $c$  by -7.9% and the  $c/a$  ratio by -9.9%. The T and cT phases coexist for applied pressures 6 GPa to 18 GPa at 7 K. Resistance measurements up to 5.9 GPa and down to 1.8 K signatures likely associated with the cT phase above 5.5 GPa and found no evidence for superconductivity. Neutron diffraction data show no evidence of magnetic order up to 1.1 GPa. Here, we show that the T to cT transition occurs around 6.8 GPa at ambient temperature, and that the transition is nearly temperature-independent from 300 K down to 7 K, which indicates a steep  $p - T$  phase line.

Work at Ames Lab. was supported by US DOE, BES, DMSE under DE-AC02-07CH11358. This research used resources at the APS and ORNL, US DOE, SC, User Facilities.

## Friday, March 18, 2016 8:00AM - 11:00AM – Session X12 DCMP DMP: Topological Materials: Theory and Experiment 308 -

**8:00AM X12.00001 Phase diagram of disordered, time reversal invariant topological superconductors in two and three dimensions**, SUDIP CHAKRAVARTY, UCLA, PALLAB GOSWAMI, University of Maryland — In the absence of spin rotational invariance, time reversal symmetric topological superconducting states (belonging to the class DIII) can be realized in all three spatial dimensions. We construct the global phase diagrams of disordered, class DIII superconductors in two and three dimensions. In both spatial dimensions the Bogoliubov de Gennes quasiparticles can exhibit two topologically distinct localized (gapped) phases, in addition to a diffusive (gapless) phase that possesses metallic thermal conductivity. We also obtain exact localization length exponents and approximate crossover scaling functions for the relevant topological quantum phase transitions. For sufficiently weak disorder, we show that the direct topological transition between two gapped states is described by a four component, massless Dirac fermion with a dynamical exponent  $z = 1$  and a correlation/localization length exponent  $\nu_M = 1$ . For stronger disorder, we demonstrate how two topologically distinct localized states and the delocalized diffusive phase meet at a line of disorder controlled fixed points, which governs the nature of the localization-delocalization transitions. We show the existence of a universal localization length exponent  $\nu_M = 2/d$  and a nonuniversal dynamical exponent for the localization

**8:12AM X12.00002 Converting a topologically trivial superconductor into a chiral topological superconductor via diluted magnetic doping**<sup>1</sup>, WEI QIN, University of Science and Technology of China, DI XIAO, Carnegie Mellon University, KAI CHANG, Chinese Academy of Sciences, SHUN-QING SHEN, University of Hong Kong, ZHENYU ZHANG, University of Science and Technology of China — We employ two complementary theoretical approaches to explore the feasibility of altering the topological properties of two-dimensional Rashba spin-orbit coupled superconductors by proper introduction of magnetic disorders. First, using the self-consistent Born approximation, we show that a topologically trivial superconductor can be driven into a chiral topological superconductor upon diluted doping of isolated magnetic disorders, which gradually narrow, close, and reopen the quasi-particle gap of the paired electrons in a nontrivial manner. Such a topological phase transition is further characterized by the change in the corresponding topological invariant. The central predictions made here are then confirmed using the complementary numerical approach by solving the Bogoliubov-de Gennes equations self-consistently within a tight-binding model. We also discuss the validity of the present model studies in connection with existing experimental findings. Collectively, the present study offers appealing new schemes for potential experimental realization of topological superconductors.

**8:24AM X12.00003 Quantum Monte Carlo study of strange correlator in interacting topological insulators**, HAN-QING WU, YUAN-YAO HE, Renmin Univ of China, YI-ZHUANG YOU, CENKE XU, Department of Physics, University of California, Santa Barbara, California, ZI YANG MENG, Institute of Physics, Chinese Academy of Sciences, ZHONG-YI LU, Renmin Univ of China — Distinguishing the nontrivial symmetry-protected topological (SPT) phase from the trivial insulator phase in the presence of electron-electron interaction is an urgent question to the study of topological insulators. In this work, we demonstrate that the strange correlator is a sensitive diagnosis to detect SPT states in interacting systems. Employing large-scale quantum Monte Carlo (QMC) simulations, we investigate the interaction-driven quantum phase transition in the Kane-Mele-Hubbard model. The transition from the quantum spin Hall insulator at weak interaction to an antiferromagnetic Mott insulator at strong interaction can be readily detected by the momentum space behavior of the strange correlator in single-particle, spin, and pairing sectors. The interaction effects on the symmetry-protected edge states in various sectors are well captured in the QMC measurements of strange correlators. Moreover, we demonstrate that the strange correlator is technically easier to implement in QMC and more robust in performance than other proposed numerical diagnoses for interacting topological states, as only static correlations are needed. The attempt in this work paves the way for using the strange correlator to study interaction-driven topological phase transitions.

**8:36AM X12.00004 Avoided quantum criticality in disordered three-dimensional Dirac semi-metals**, JEDEDIAH PIXLEY, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, DAVID HUSE, Princeton University — We study the effects of short-range random potential disorder on three-dimensional Dirac semi-metals. We focus on the proposed quantum critical point (QCP) separating a semi-metal and diffusive metal phase driven by disorder. We will briefly review the existing evidence of such a QCP. We will then explore the non-perturbative effects of rare regions using Lanczos and the kernel polynomial method, from which we establish the existence of two distinct types of excitations in the weak disorder regime. The first are perturbatively renormalized dispersive Dirac states and the second are weakly dispersive quasi-localized “rare” eigenstates. We establish that these rare eigenstates contribute an exponentially small but non-zero density of states at zero energy, thus converting the semi-metal to diffusive metal transition into an avoided quantum critical point.

**8:48AM X12.00005 Explicit derivation of duality between a free Dirac cone and quantum electrodynamics in  $(2+1)$  dimensions**, DAVID F. MROSS, JASON ALICEA, OLEXEI I. MOTRUNICH, Caltech — A single Dirac cone of (free) electrons famously arises on the surface of a 3D topological insulator. Recent work proposed that these metallic surfaces can alternatively be described by quantum electrodynamics in  $(2+1)$  dimensions (QED<sub>3</sub>), where charge-neutral ‘dual fermions’ strongly couple to an emergent photon. We explicitly derive this duality via an exact, non-local mapping from electrons to dual fermions on the level of path integrals. This mapping allows us to construct Hamiltonians for exotic topological-insulator surface phases, and to derive the particle-hole-symmetric field theory of a half-filled Landau level. By running the duality ‘in reverse’ we can constrain scaling dimensions for operators in QED<sub>3</sub> and establish duality between bosonic topological insulator surfaces and QED<sub>3</sub> with two fermion flavors.

**9:00AM X12.00006 Correlation effects in 3D triple-Weyl semimetals**, SHI-XIN ZHANG, Tsinghua University, SHAO-KAI JIAN, HONG YAO, Institute for Advanced Study, Tsinghua University — We study interaction effects, including short-range interactions and long-range Coulomb interactions, in three-dimensional topological triple-Weyl semimetals whose triple-Weyl points are protected by crystalline symmetries. In the low-energy effective field theory of triple-Weyl semimetals, by considering symmetries and utilizing Fierz identity, we find that there are only four independent short-range interaction terms. We then perform Wilsonian renormalization group analysis to determine the effect of short-range interactions at low energy and long distance by finding fixed points as well as stable strong-coupling limits. For those strong-coupling limits due to short-range interactions, spontaneous symmetry-breaking ordering is expected and is analyzed by self-consistent mean-field calculations combined with RG flow. For long-range Coulomb interactions, we find anisotropic screening effect, similar with the one in double-Weyl semimetals, and hence a qualitatively different fixed point from the Gaussian one.

**9:12AM X12.00007 First-Principles Design of a Half-Filled Flat Band of the Kagome Lattice in Two-Dimensional Metal-Organic Frameworks**, MASAHIKO G. YAMADA, Institute for Solid State Physics, University of Tokyo, TOMOHIRO SOEJIMA, Department of Chemistry, Massachusetts Institute of Technology, NAOTO TSUJI, RIKEN Center for Emergent Matter Science (CEMS), DAISUKE HIRAI, Department of Physics, University of Tokyo, MIRCEA DINCĂ, Department of Chemistry, Massachusetts Institute of Technology, HIDEO AOKI, Department of Physics, University of Tokyo — Metal-organic frameworks (MOFs) are crystalline materials composed of metal ions and bridging organic molecules, which have been the subject of numerous investigations in inorganic and materials chemistry. Owing to their typically trivial electronic states, MOFs have not attracted much attentions from condensed-matter physicists. However, recent experimental success in fabricating two-dimensional (2D) MOFs with kagome lattice structures is bridging the gap between condensed-matter physics and chemistry. Then, we design from first principles a new type of 2D MOFs with phenalenyl-based ligands to realize a half-filled flat band of the kagome lattice, which belongs to the lattice family that shows Lieb-Mielke-Tasaki’s flat-band ferromagnetism. We find that *trans*-Au-THTAP(trihydroxytriaminophenalenyl) has an ideal band structure, where the Fermi energy is adjusted right at the nearly flat band. The spin-orbit coupling opens a band gap and gives a non-zero Chern number to the nearly flat band. This is a novel and realistic example of a system in which a nearly flat band is both ferromagnetic and topologically non-trivial. See arXiv:1510.00164.

**9:24AM X12.00008 Nernst and magneto-thermal conductivity in a lattice model of Weyl fermions<sup>1</sup>**, GIRISH SHARMA, Clemson University, PALLAB GOSWAMI, University of Maryland, College Park, MD, SUMANTA TEWARI, Clemson University — Weyl semimetals (WSM) are topologically protected three dimensional materials whose low energy excitations are linearly dispersing massless Dirac fermions, possessing a non-trivial Berry curvature. Using semi-classical Boltzmann dynamics in the relaxation time approximation for a lattice model of time reversal (TR) symmetry broken WSM, we compute both magnetic field dependent and anomalous contributions to the Nernst coefficient. In addition to the magnetic field dependent Nernst response, which is present in both Dirac and Weyl semimetals, we show that, contrary to previous reports, the TR-broken WSM also has an anomalous Nernst response due to a non-vanishing Berry curvature. We also compute the thermal conductivities of a WSM in the Nernst ( $\nabla T \perp \mathbf{B}$ ) and the longitudinal ( $\nabla T \parallel \mathbf{B}$ ) set-up and confirm from our lattice model that in the parallel set-up, the Wiedemann-Franz law is violated between the longitudinal thermal and electrical conductivities due to chiral anomaly.

**9:36AM X12.00009 Topological edge states in pnictides<sup>1</sup>**, CODY YOUMANS, City College of New York; The Graduate Center, CUNY, POUYAN GHAEMI, City College of New York, MEHDI KARGARIAN, University of Maryland — In some members of the ferro-pnictides, non-trivial topology in the bulk band-structure is related to potentially observable gapless edge states. We study these states numerically and analytically for a range of parameters, with and without superconductivity and antiferromagnetic SDW ordering, and their relation to the symmetries and topologically non-trivial aspects of our model Hamiltonian.

<sup>1</sup>Support was provided by the Doctoral Student Research Grant program at the Graduate Center, CUNY.

**9:48AM X12.00010 Symmetry-enriched topological invariants from tensor network representations**, BRAYDEN WARE, Univ of California - Santa Barbara, MENG CHENG, BELA BAUER, Microsoft Station Q — We examine topologically ordered quantum phases in  $2+1$  dimensions where in the presence of symmetries the topological phase splits into multiple symmetry enriched topological (SET) phases. These SET phases become adiabatically connected when the symmetry is broken, but are separated by phase transitions when symmetry is enforced. Using tensor network representations of representative wavefunctions for certain SET phases, we demonstrate the calculation of the extended modular matrices, a generalization of the well-known modular matrices that have been used to robustly characterize topological phases in numerical calculations. Here, the crucial extension is to systems with symmetry defects. The extended modular matrices are used to form symmetry-enriched topological invariants which distinguish different SET phases.

**10:00AM X12.00011 Electronic structure studies of topological materials**, SHUYUN ZHOU, Department of Physics, Tsinghua University — Three-dimensional (3D) Dirac fermions are a new class of topological quantum materials. In 3D Dirac semimetals, the conduction and valence bands touch each other at discrete points in the momentum space and show linear dispersions along all momentum directions, forming 3D Dirac cones which are protected by the crystal symmetry. Here I will present our recent studies of the electronic structures of novel materials which host 3D Dirac fermions by using angle-resolved photoemission spectroscopy.

**10:12AM X12.00012 Propagation of Surface Plasmon Polaritons in Thin Films of Topological Insulators<sup>1</sup>**, YURY DESHKO, ZHIYI CHEN, LIA KRUSIN-ELBAUM, VINOD MENON, City College of New York – CUNY, JACOB TREVINO, Advanced Science Research Center – CUNY, ALEXANDER KHANIKAEV, Queens College – CUNY — Surface Plasmon Polaritons (SPP) are coupled collective oscillations of surface charges and electromagnetic waves confined to the interface between a metal and a dielectric. Three dimensional topological insulators (TI), such as Bi<sub>2</sub>Se<sub>3</sub>, Bi<sub>2</sub>Te<sub>3</sub>, and Sb<sub>2</sub>Te<sub>3</sub> are narrow band-gap semiconductors in the bulk while having conducting surface with the linear energy dispersion for the surface electronics states. Similar to double-layered graphene a thin single film of TI supports two SPP modes in the far-infrared range. We study the propagation of these modes in thin films of Bi<sub>2</sub>Se<sub>3</sub>, Bi<sub>2</sub>Te<sub>3</sub>, and Sb<sub>2</sub>Te<sub>3</sub>. The dispersion curves and the propagation lengths are estimated for all three materials. The explanation of the discrepancy between the theory [1] and the first experimental observation of standing wave SPPs in Bi<sub>2</sub>Se<sub>3</sub> [2] is proposed. Finally, the possibilities of tuning the SPP dispersion relations in thin films of TI are discussed.

**10:24AM X12.00013 Observation of a topologically non-trivial surface state in half-Heusler PtLuSb (001) thin films**, JOHN LOGAN, SAHIL PATEL, SEAN HARRINGTON, Univ of California - Santa Barbara, CRAIG POLLEY, Max IV Laboratory, BRIAN SCHULTZ, Univ of California - Santa Barbara, T. BALASUBRAMANIAN, Max IV Laboratory, ANDERSON JANOTTI, University of Delaware, ANDERS MIKKELSEN, Lund University, CHRIS PALMSTRM, Univ of California - Santa Barbara — Topological insulators are a recently discovered new quantum state of matter that has a bulk band gap but also possesses cross-gap surface states which are protected by time-reversal symmetry. The experimental realization of topologically non-trivial surface states (TSSs) in materials such as Bi<sub>2</sub>Se<sub>3</sub> has generated widespread interest in identifying other material systems that exhibit TSSs due to their many uses including spintronic devices. In particular, recent theory calculations suggest that TSSs may be found in certain half-Heusler ternary compounds. If experimentally realizable, this would provide an opportunity for the creation of entirely new heterostructure spintronic devices that make use of the structurally-identical but electronically-varied nature of Heusler compounds. Here, we show the presence of a TSS in the half-Heusler compound PtLuSb. Spin and angle-resolved photoemission spectroscopy reveals a surface state with linear dispersion and a helical tangential spin texture consistent with theoretical predictions and the expectation for a topological insulator.

**10:36AM X12.00014 Predicted Growth of Two-Dimensional Topological Insulators Consisting of Hydrogenated III-V Thin films on Si(111) Substrate**, FENG-CHUAN CHUANG, CHRISTIAN CRISOSTOMO, LIANG-ZI YAO, CHUN-CHEN YEH, SHU-MING LAI, ZHI-QUAN HUANG, CHIA-HSIU HSU, Natl. Sun Yat-sen U., HSIN LIN, Natl. U. of Singapore, MARVIN ALBAO, U. of the Philippines Los Baos College, ARUN BANSIL, Northeastern U. — We have carried out systematic first-principles electronic structure calculations of growth of ultrathin films of compounds of group III (B, Al, In, Ga and Tl) with group V (N, P, As, Sb and Bi) elements on Si(111) substrate, including effects of hydrogenation. A total of six compounds (GaBi, InBi, TlBi, TIAs, TISb and TIN) are identified to be nontrivial in unhydrogenated case; whereas for hydrogenated case, only four (GaBi, InBi, TlBi and TISb) remains nontrivial. The band gap is found to be as large as 855 meV for the hydrogenated TlBi film, making this class of III-V materials suitable for room temperature applications. TlBi remains topologically nontrivial with a large band gap at various hydrogen coverages, indicating the robustness of its band topology against bonding effects of substrates. Two bilayers (BLs) of AlBi, InBi, GaBi, TIAs and TISb are found to support a topological phase over a wide range of strains, in addition to BBi, TIN and TlBi which can be driven into the nontrivial phase via strain. One and two BL films of GaBi and 2 BL films of InBi and TIAs on Si(111) surface possess nontrivial phases with a band gap as large as 121 meV in the case of 2 BL film of GaBi. Persistence of the nontrivial phase upon hydrogenations in the III-V thin films suggests that these films are suitable for growing on various substrates.

**10:48AM X12.00015 Transport properties of superconducting high indium-doped SnTe single crystals**, CHENG ZHANG, RUIDAN ZHONG, GENDA GU, QIANG LI, Brookhaven National Laboratory — The discovery of topological crystalline insulator SnTe has ignited a search for the predicted topological superconductors. Recently, we performed the transport measurement on a series of indium-doped SnTe single crystals (Sn<sub>1-x</sub>In<sub>x</sub>Te). Hall measurement shows that carrier type changes when indium doping level is between  $x = 0.2$  and  $0.3$ . Weak anti-localization effect and Shubnikov-de Hass oscillations was found in  $x = 0.45$  samples, which have the highest superconducting transition temperature at 4.5 K. Both superconducting and normal state properties of high indium-doped SnTe will be discussed.

**Friday, March 18, 2016 8:00AM - 11:00AM –**

**Session X13 GMAG DMP: Hall-Bar Structure for the Detection of Spin/Valley Hall Effect** 309  
- Wei Han, Peking University

**8:00AM X13.00001 Topological Superconductivity in HgTe-based Devices**, LAURENS MOLENKAMP, Wuerzburg University — Suitably structured HgTe has been shown to be a topological insulator in both 2- (a quantum well wider than some 6.3 nm) and 3 (an epilayer grown under tensile strain) dimensions with favorable properties for quantum transport studies, i.e. a good mobility and a complete absence of bulk carriers. In this talk I will summarize the results of our efforts (in collaboration with colleagues all over the globe) to induce superconductivity in the topological surface states of these materials. Special emphasis will be given to recent results on the ac Josephson effect. We will present data on Shapiro step behavior that is a very strong indication for the presence of a gapless Andreev mode in our Josephson junctions.

**8:36AM X13.00002 Origins of Nonlocality Near the Neutrality Point in Graphene**, JOSHUA FOLK, University of British Columbia — Nonlocal measurements are an effective experimental tool for probing non-charge characteristics of carriers using a (charge) transport measurement. For example, nonlocal signals in a Hall bar geometry can indicate spin currents, or valley currents, or heat currents flowing through a sample without an accompanying charge current. We present an experimental study of nonlocal electrical signals near the Dirac point in graphene, with the goal of disentangling the various types of current that might give rise to nonlocality. The in-plane magnetic field dependence of the nonlocal signal confirms the role of spin in this effect, as expected from predictions of the Zeeman spin Hall effect in graphene, but our experiments show that thermo-magneto-electric effects also contribute to nonlocality, and the effect is sometimes stronger than that due to spin.

## 9:12AM X13.00003 Spin Hall effect and spin transport in graphene and 2D heterostructures

, BARBAROS OEZYILMAZ<sup>1</sup>, National University of Singapore — Semiconducting 2D materials offer new opportunities in both alternative technologies and fundamental discoveries by using the spin degree freedom of electrons. One of the main challenges in this field is to identify new materials which allow the control of spin currents by means of the electric field effect. This requires either a sizeable spin-orbit coupling strength or a sizeable bandgap or both. Unfortunately, pristine graphene has a negligibly small spin-orbit coupling strength. Recently we have addressed this problem in three distinct ways. First we have used chemical functionalization to introduce locally sp<sup>3</sup> type bonding. Next we used metal ad-atoms to increase spin-orbit coupling via local enhancement of the spin-orbit coupling strength due to resonant scattering. Finally, I will show that the proximity of graphene on transition metal dichalcogenides can also lead to a significant enhancement of the spin-orbit coupling strength. I will complete my talk with a brief discussion on the possibility of all electrical spin injection into complementary 2D crystals such as WS<sub>2</sub>, MoS<sub>2</sub> or black phosphorus.

## 9:48AM X13.00004 Electron transport nonlocality in monolayer graphene modified with hydrogen silsesquioxane polymerization<sup>1</sup>

, ALEXEY KAVERZIN, Univ of Groningen — Physical properties of electrons in graphene offer not only functionality in terms of conventional charge transport, but also allow to explore spin and valley degrees of freedom. The presence of internal coupling between the nontrivial current states and normal charge current provides the effective mechanism for studying these properties. At the same time a nonlocal geometry of the transport experiments allows to separate the useful signal associated with either spin or valley degree of freedom from trivial charge contribution. In this work using the nonlocal geometry we study the transport properties of hydrogenated graphene Hall bar devices. The observed nonlocal signal is seen to substantially exceed the background ohmic contribution and, therefore, has to be understood in terms of nontrivial mediative current. The channel length dependence of the useful signal falls into direct/inverse spin Hall effect description, however, the absence of the modulation of the measured effect with the applied in plane magnetic field discredits the spin nature of the observed phenomenon. Our findings cannot be explained with the existing models suggesting that further investigation is required.

## 10:24AM X13.00005 Spin Hall Angle in Gold thin films: large or small?

, XIAOFENG JIN, Fudan University — Most of the methods so far adopted to determine the spin Hall angle are involved with the interface between a ferromagnetic (FM) and a nonmagnetic (NM) material, which would inevitably produce some complications in the analysis. Here, we report a new method using simply nanoscale H-pattern of gold, which is free from any interface between FM/NM, to obtain the spin Hall angle in gold thin films. A spin Hall angle around 0.1 is obtained for 10nm gold film but negligibly small for 60 nm gold. This result has not only clarified the controversy about the spin hall angle in gold thin film, but also proved the feasibility of using H-pattern to measure SHE in metallic system.

## 8:00AM X14.00001 van der Waals Heterostructures Grown by MBE

, CHRISTOPHER HINKLE, University of Texas at Dallas — In this work, we demonstrate the high-quality MBE heterostructure growth of various layered 2D materials by van der Waals epitaxy (VDWE). The coupling of different types of van der Waals materials including transition metal dichalcogenide thin films (e.g., WSe<sub>2</sub>, WTe<sub>2</sub>, HfSe<sub>2</sub>), insulating hexagonal boron nitride (h-BN), and topological insulators (e.g., Bi<sub>2</sub>Se<sub>3</sub>) allows for the fabrication of novel electronic devices that take advantage of unique quantum confinement and spin-based characteristics. The relaxed lattice-matching criteria of van der Waals epitaxy has allowed for high-quality heterostructure growth with atomically abrupt interfaces, allowing us to couple these materials based primarily on their band alignment and electronic properties. We will discuss the impact of sample preparation, surface reactivity, and lattice mismatch of various substrates (sapphire, graphene, TMDs, Bi<sub>2</sub>Se<sub>3</sub>) on the growth mode and quality of the films and will discuss our studies of substrate temperature and flux rates on the resultant growth and grain size. Structural and chemical characterization was conducted via reflection high energy electron diffraction (RHEED), X-ray diffraction (XRD), transmission electron microscopy (TEM), scanning tunneling microscopy/spectroscopy (STM/S), atomic force microscopy (AFM), X-ray photoelectron spectroscopy (XPS), and Raman spectroscopy. Experimentally determined band alignments have been determined and compared with first-principles calculations allowing the design of novel low-power logic and magnetic memory devices. Initial results from the electrical characterization of these grown thin films and some simple devices will also be presented. These VDWE grown layered 2D materials show significant potential for fabricating novel heterostructures with tunable band alignments and magnetic properties for a variety of nanoelectronic and optoelectronic applications.

## 8:36AM X14.00002 Direct growth of single- and few-layer MoS<sub>2</sub> on h-BN by CVD method<sup>1</sup>

, AIMING YAN, JAIRO VELASCO, JR., SALMAN KAHN, Univ of California - Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, FENG WANG, MICHAEL CROMMIE, Univ of California - Berkeley, ALEX ZETTL, Univ of California - Berkeley; Materials Sciences Division, LBNL; Kavli Energy NanoSciences Institute at the Univ of California, Berkeley and LBNL — As a promising candidate for the next-generation electronics, large-scale single- and few-layer molybdenum disulfide (MoS<sub>2</sub>) grown by CVD method is an important advancement towards technological implementation of this material. However, the choice of substrate can significantly affect the performance of MoS<sub>2</sub> based devices. An attractive insulating substrate or mate for MoS<sub>2</sub> (and related materials such as graphene) is hexagonal boron nitride (h-BN). Stacked heterostructures of MoS<sub>2</sub> and h-BN have been produced by manual transfer methods, but a more efficient and scalable assembly method is needed. Here we demonstrate the direct growth of single- and few-layer MoS<sub>2</sub> on h-BN by chemical vapor deposition (CVD) method. The growth mechanisms for single- and few-layer samples are found to be distinct, and for single-layer samples low relative rotation angles (<5°) between the MoS<sub>2</sub> and h-BN lattices prevail. In addition, MoS<sub>2</sub> directly grown on h-BN maintains its intrinsic 1.89 eV bandgap. Our CVD synthesis method presents a viable path towards high-quality MoS<sub>2</sub> based field effect transistors in a controllable and scalable fashion.

## 8:48AM X14.00003 Spiral Growth of Few-Layer MoS<sub>2</sub> by Chemical Vapor Deposition<sup>1</sup>

, XI DONG, DUSHYANT TOMER, LIAN LI, Univ of Wisconsin, Milwaukee — Monolayer and few-layer transition metal dichalcogenide MoS<sub>2</sub> are grown by chemical vapor deposition on SiO<sub>2</sub>/Si substrates using MoO<sub>3</sub> and S powder as precursors. Before growth, the substrates are pretreated with perylene-3, 4, 9, 10-tetracarboxylic acid tetrapotassium salt to promote nucleation. Monolayer MoS<sub>2</sub> islands are triangularly shaped with sizes ranging from a few to tens of micrometers, which also exhibits the characteristic Raman bands at 403.36 and 385.05 cm<sup>-1</sup> corresponding to the A<sub>1g</sub> and E<sub>2g</sub> modes, respectively. Atomic force microscopy imaging further confirms the monolayer thickness to be 0.8 nm. For few-layer MoS<sub>2</sub> films, triangular spirals are observed with both left- and right-handed chirality. Raman spectra showed interesting features of these growth spirals, the details of which will be presented at the meeting.

<sup>1</sup>NSF DMR-1508560.

**9:00AM X14.00004 Controlled synthesis of single-layer MoSe<sub>2</sub> nanostructures**, YUXUAN CHEN, CHEN-DONG ZHANG, Univ of Texas, Austin, PING CUI, ZHENYU ZHANG, Univ. of Science and Technology of China, CHIH-KANG SHIH<sup>1</sup>, Univ of Texas, Austin — Group VIB transition metal dichalcogenides (TMD), such as MoSe<sub>2</sub>, WS<sub>2</sub>, etc., are a family of layered materials with weak van der Waals (vdW) interaction between neighboring layers. A transition from indirect to direct bandgap semiconductor takes place for most of these materials when they become single layer (SL), and the values of these direct band gap are comparable to visible light. This makes SL TMDs attractive candidates for 2D electronic and optoelectronic devices. Though epitaxial SL TMDs have been successfully prepared, there is controversy in their growth conditions and in their edge structures. Moreover, some intriguing theoretical predictions about the finite-size effect on SL TMDs are still awaiting experimental proof. Here we report systematic studies of the thermodynamics/ kinetics of SL MoSe<sub>2</sub> formation on a vdW surface (namely, highly oriented pyrolytic graphite) using molecular beam epitaxy (MBE). We also report the controlled creation of various nanostructures of MBE SL MoSe<sub>2</sub>. The edge properties and the influence of the in-plane confinement on the electronic structure are addressed by in-situ STM and STS. Theoretical calculations have been carried out to help understanding the experimental discoveries.

**9:12AM X14.00005 Large Area Synthesis of 2D Materials**, ERIC VOGEL, Georgia Inst of Tech — Transition metal dichalcogenides (TMDs) have generated significant interest for numerous applications including sensors, flexible electronics, heterostructures and optoelectronics due to their interesting, thickness-dependent properties. Despite recent progress, the synthesis of high-quality and highly uniform TMDs on a large scale is still a challenge. In this talk, synthesis routes for WSe<sub>2</sub> and MoS<sub>2</sub> that achieve monolayer thickness uniformity across large area substrates with electrical properties equivalent to geological crystals will be described. Controlled doping of 2D semiconductors is also critically required. However, methods established for conventional semiconductors, such as ion implantation, are not easily applicable to 2D materials because of their atomically thin structure. Redox-active molecular dopants will be demonstrated which provide large changes in carrier density and workfunction through the choice of dopant, treatment time, and the solution concentration. Finally, several applications of these large-area, uniform 2D materials will be described including heterostructures, biosensors and strain sensors.

**9:48AM X14.00006 Thermal stability of MBE-grown epitaxial MoSe<sub>2</sub> and WSe<sub>2</sub> thin films<sup>1</sup>**, YOUNG JUN CHANG, BYOUNG KI CHOY, Department of Physics, University of Seoul, Seoul, 130-743, Korea, SOO-HYON PHARK, Center for Nanometrology, Korea Research Institute of Standards & Science, Korea, MINU KIM, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Seoul 151-747, Republic of Korea — Layered transition metal dichalcogenides (TMDs) draw much attention, because of its unique optical properties and band structures depending on the layer thicknesses. However, MBE growth of epitaxial films demands information about thermal stability of stoichiometry and related electronic structure for high temperature range. We grow epitaxial MoSe<sub>2</sub> and WSe<sub>2</sub> ultrathin films by using molecular beam epitaxy (MBE). We characterize stoichiometry of films grown at various growth temperature by using various methods, XPS, EDX, and TOF-MEIS. We further test high temperature stability of electronic structure for those films by utilizing in-situ ellipsometry attached to UHV chamber. We discuss threshold temperatures up to 700~1000°C, at which electronic phases changes from semiconductor to metal due to selenium deficiency. This information can be useful for potential application of TMDs for fabrication of Van der Waals multilayers and related devices.

**10:00AM X14.00007 Synthesis and Optical Control of Circular Polarization in monolayer Tungsten Disulfide.<sup>1</sup>**, KATHLEEN MCCREARY, AUBREY HANBICKI, BEREND JONKER, MARC CURRIE, Naval Research Laboratory, GEORGE KIOSEOGLOU, University of Crete, Greece — The unique electronic band structure in single layer WS<sub>2</sub> provides the ability to selectively populate a desired valley by exciting with circularly polarized light. The valley population is reflected through the circular polarization of photoluminescence (PL). We investigate the circularly polarized PL in WS<sub>2</sub> monolayers synthesized using chemical vapor deposition (CVD). The resulting polarization is strongly dependent on the sample preparation. As-grown CVD WS<sub>2</sub> (still on the growth substrate) exhibits low polarized emission, regardless of laser excitation or laser power. Removing WS<sub>2</sub> from the growth substrate and repositioning on the same substrate significantly impacts the optical properties. In transferred films, the excitonic state is optically controlled via high-powered laser exposure such that subsequent PL is solely from either the charged exciton state or the neutral exciton state. Neutral excitonic emission exhibits zero polarization whereas the trion polarization can exceed 25% at room temperature. The removal process may modify the strain, sample-to-substrate distance, and chemical doping in the WS<sub>2</sub> monolayer, and work is underway to determine how these factors influence the valley populations. These results demonstrate a new method to control the excitonic state and PL polarization in monolayer WS<sub>2</sub>.

**10:12AM X14.00008 Atomically flat Ge buffer layers and alternating shutter growth of CaGe<sub>2</sub> for large area germanane<sup>1</sup>**, JINSONG XU, JYOTI KATOCH, ADAM AHMED, IGOR PINCHUK, ROBERT WILLIAMS, DAVID MCCOMB, ROLAND KAWAKAMI, Ohio State University — Germanane (GeH), which is converted from CaGe<sub>2</sub> by soaking in HCl acid, has recently attracted interest because of its novel properties, such as large band gap (1.56eV), spin orbit coupling and predictions of high mobility (18000 cm<sup>2</sup>/Vs). Previously CaGe<sub>2</sub> was successfully grown on Ge(111) substrates by molecular beam epitaxy (MBE) growth. But there were cracks between m-sized islands, which is not desirable for scientific study and application, and limits the material quality. By growing atomically flat Ge buffer layers and using alternating shutter MBE growth, we are able to grow crack-free, large area films of CaGe<sub>2</sub> films. Reflection high energy electron diffraction (RHEED) patterns of Ge buffer layer and CaGe<sub>2</sub> indicates high quality two dimensional surfaces, which is further confirmed by atomic force microscopy (AFM), showing atomically flat and uniform Ge buffer layer and CaGe<sub>2</sub>. The appearance of Laue oscillation in X-ray diffraction (XRD) and Kiessig fringes in X-ray reflectivity (XRR) proves the uniformity of CaGe<sub>2</sub> film and the smoothness of the interface. The high quality of CaGe<sub>2</sub> film makes it promising to explore novel properties of GeH.

**10:24AM X14.00009 Synthesis and Properties of Group IV Graphane Analogues**, JOSHUA GOLDBERGER, The Ohio State University — Similar to how carbon networks can be sculpted into low-dimensional allotropes such as fullerenes, nanotubes, and graphene with fundamentally different properties, it is possible to create similar ligand terminated sp<sup>3</sup>-hybridized honeycomb graphane derivatives containing Ge or Sn that feature unique and tunable properties. Here, we will describe our recent success in the creation of hydrogen and organic-terminated group IV graphane analogues, from the topochemical deintercalation of precursor Zintl phases, such as CaGe<sub>2</sub>. We will discuss how the optical, electronic, and thermal properties of these materials can be systematically controlled by substituting either the surface ligand or via alloying with other Group IV elements. Additionally, we have also developed an epitopotaxial approach for integrating precise thicknesses of germanane layers onto Ge wafers that combines the epitaxial deposition of CaGe<sub>2</sub> precursor phases with the topotactic interconversion into the 2D material. Finally, we will describe our recent efforts on the synthesis and crystal structures of Sn-containing graphane alloys in order to access novel topological phenomena predicted to occur in these graphanes.

## 8:00AM X15.00001 Electrons and phonons in layered and monolayer vanadium pentoxide.<sup>1</sup>

WALTER R. L. LAMBRECHT, Case Western Reserve University — Vanadium pentoxide ( $V_2O_5$ ) is a layered material with the potential for interesting new properties when made in 2D mono- or few-layer form. Its band structure is characterized by a split-off conduction band. The lowest conduction band is separated from the rest of the conduction bands by about 1 eV and consists of  $V-d_{xy}$  orbitals, non-bonding to the oxygens by symmetry. This narrow band has dispersion essentially along the direction of chains occurring in the layer. When this band becomes half-filled by doping, spin-splitting occurs accompanied by an antiferromagnetic coupling between nearest neighbors along the chain direction. This situation is well known to occur in the so-called ladder compound  $NaV_2O_5$ , which was extensively studied in the late 90s as a potential spin-Peierls or charge ordering compound. However, the monolayer form of  $V_2O_5$  may allow for other ways to control the doping by gating, removing vanadyl oxygens, adsorption of alkali metals, nanoribbon formation, etc. Our calculations predict a switch from antiferromagnetic to ferromagnetic coupling for doping slightly less than half filling of the split-off band. In this talk we will discuss our recent work on the electronic band structure of both bulk and monolayer  $V_2O_5$  as well as the phonons. We find that the quasi-particle self-consistent  $GW$  method strongly overestimates the band gap. Lattice polarization corrections of the screening are required because of the large LO/TO phonon frequency ratios. Excitonic effects may also be expected to be fairly large. We find that some of the vibrational modes, notably the vanadyl-oxygen bond stretch perpendicular to the layer, unexpectedly shows a strong blue shift. This is explained in terms of reduced screening affecting the long-range dipole components of the force constants.

## 8:36AM X15.00002 Doping effects on the electronic and magnetic properties of $V_2O_5$ <sup>1</sup>

CHURNA BHANDARI, WALTER R.L. LAMBRECHT, Case Western Reserve University — We study doping of the  $V_2O_5$  split-off conduction band using different methods: by adding electrons compensated by an artificial homogeneous background, a virtual crystal approximation (VCA), by changing the atomic number  $Z_v$ , and explicitly by intercalating Na as a dopant. The former two are mathematical models to simulate injected charge by gating, the latter occurs in the vanadium bronze  $NaV_2O_5$ . We also study  $Na_{1-x}V_2O_5$  using the VCA by changing  $10 \leq Z_{Na} \leq 11$ . We discuss the electronic band structure and the optical conductivity using the quasiparticle self-consistent QSGW method including a lattice polarization effect and the local density functional method with Hubbard- $U$  correction (LSDA+ $U$ ) for all these models. We show that the ground state prefers anti-ferromagnetic order along the chain (crystallographic  $b$ ) direction and extract various near neighbor exchange interactions from total energy differences of different spin configurations. We find that the coupling between the nearest V-neighbors changes from anti-ferromagnetic to ferromagnetic when the electron concentration is reduced from half filling of the band (1e/V atom) to about 0.88 e/V atom. The magnetic moment gradually decreases with decreasing electron concentration.

## 8:48AM X15.00003 ABSTRACT WITHDRAWN —

## 9:00AM X15.00004 Two-dimensional, ordered, double transition metals carbides (MXenes)

PAUL KENT, Oak Ridge National Lab, BABAK ANASORI, Drexel University, YU XIE, Oak Ridge National Lab, MAJID BEIDAGHI, Drexel University, JUN LU, Linköping University, Sweden, BRIAN HOSLER, Drexel University, LARS HULTMAN, Linköping University, Sweden, YURY GOGOTSI, MICHEL BARSQUM, Drexel University — We use [1] density functional theory to predict the existence of two new families of 2D ordered carbides (MXenes),  $M'_2M''C_2$  and  $M'_2M''C_3$ , where each M is a different early transition metal. Synthesizing  $Mo_2TiC_2T_x$ ,  $Mo_2Ti_2C_3T_x$ , and  $Cr_2TiC_2T_x$  (where T is a surface termination), we validated the DFT predictions. Since the Mo and Cr atoms are on the outside, they control the 2D flakes' chemical and electrochemical properties. The latter was proven by showing quite different electrochemical behavior of  $Mo_2TiC_2T_x$  and  $Ti_3C_2T_x$ . This work further expands the family of 2D materials, offering additional choices of structures, chemistries, and ultimately useful properties. [1] B. Anasori et al. ACS Nano 9 9507 (2015). DOI: 10.1021/acsnano.5b03591

## 9:12AM X15.00005 Unusual electronic and magnetic responses from sulfur-decorated graphene.

CHOONGYU HWANG, Materials Sciences Division, Lawrence Berkeley Natl. Lab. and Department of Physics, Pusan National University, South Korea, S. A. CYBART, S. M. WU, R. C. DYNES, Materials Sciences Division, Lawrence Berkeley Natl. Lab. and Department of Physics, University of California, San Diego, CA, S. J. SHIN, E. E. HALLER, Department of Materials Science and Engineering, University of California, Berkeley, CA and Materials Sciences Division, Lawrence Berkeley Natl. Lab., S. KIM, K. KIM, B. I. MIN, Department of Physics, Pohang University of Science and Technology, South Korea, T. G. RAPPOPORT, Instituto de Física, Universidade Federal do Rio de Janeiro, Brazil, C. JOZWIAK, A. V. FEDOROV, S. -K. MO, Advanced Light Source, Lawrence Berkeley Natl. Lab., A. H. CASTRO NETO, Graphene Research Centre, National University of Singapore, D. -H. LEE, A. LANZARA, Department of Physics, University of California, Berkeley, CA, and Materials Sciences Division, Lawrence Berkeley Natl. Lab. — Interactions between two different materials can produce strong electronic correlations that do not exist when each material stands alone. We search for such correlations from graphene, a non-magnetic semi-metal, decorated by sulfur, a diamagnetic insulator, using angle-resolved photoemission spectroscopy and magneto-transport measurements. Sulfur-decorated graphene exhibits unusual electronic and magnetic responses that are clearly distinguished from clean graphene. Our findings provide intriguing insights on the search for novel quantum phases in graphene-based compounds.

## 9:24AM X15.00006 Electronic correlations in monolayer $VS_2$

ERIC B. ISAACS, CHRIS A. MARIANETTI, Department of Applied Physics and Applied Mathematics, Columbia University — The layered transition metal dichalcogenide vanadium disulfide ( $VS_2$ ), which nominally has 1 electron in the  $3d$  shell, is potent for strong correlation physics and is possibly another realization of the one-band Hubbard model beyond the cuprates. Here we investigate the octahedral (OCT) and trigonal prismatic (TP) phases of monolayer  $VS_2$  using density functional theory plus Hubbard  $U$  calculations. Unlike the OCT phase, the TP phase has an isolated low-energy band due to the crystal field splitting and the nearest-neighbor V-V hopping. Within DFT, ferromagnetism spin splits this band leading to a low-band-gap  $S = 1/2$  ferromagnetic insulating TP phase, which is lower in energy than the OCT phase. The on-site interaction  $U$ , which we find to be approximately 4 eV via linear response, increases the band gap, leads to Mott insulating behavior, and for sufficiently high values stabilizes the ferromagnetic OCT phase. We explore the impact of charge density waves in monolayer  $VS_2$  and discuss the possibility to experimentally realize the TP phase.

## 9:36AM X15.00007 Competing antiferromagnetism in a quasi-2D itinerant ferromagnet:

$Fe_3GeTe_2$ , ZHENG GAI, JIEYU YI, HOULONG ZHUANG, S.A. CALDER, P.R.C. KENT, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee, Knoxville, TN, OAK RIDGE NATIONAL LABORATORY COLLABORATION, UNIVERSITY OF TENNESSEE, KNOXVILLE, TN COLLABORATION —  $Fe_3GeTe_2$  is known as an air-stable layered metal with itinerant ferromagnetism with a transition temperature of about 220 K. From extensive dc and ac magnetic measurements, we have determined that the ferromagnetic layers of  $Fe_3GeTe_2$  order antiferromagnetically along the  $c$ -axis below 152 K. The antiferromagnetic state was further substantiated by theoretical calculation to be the ground state. A magnetic structure model was proposed to describe the antiferromagnetic ground state as well as competition between antiferromagnetic and ferromagnetic states.  $Fe_3GeTe_2$  shares many common features with pnictide superconductors and may be a promising system in which to search for unconventional superconductivity.

**9:48AM X15.00008 Many-body effects in doped graphene on a piezoelectric substrate.<sup>1</sup>** , F. SOLS, D. G. GONZALEZ, I. ZAPATA, Universidad Complutense de Madrid (Spain), J. SCHIEFELE, IMDEA Nanociencia (Madrid, Spain) , F. GUINEA, IMDEA Nanociencia (Madrid, Spain) and University of Manchester (UK) — We study theoretically the role of piezoelectric acoustic phonons in the context of piezoelectric substrates covered by graphene. They are responsible for effective, substrate dependent electron-electron interactions which can be strong and give rise to novel many-body effects. We present a new derivation of the electron-phonon interaction matrix element which generalizes previous calculations made within the simpler and not always justified isotropic approximation. We study several many-body effects, including the temperature-dependent phonon renormalization due to the electron cloud surrounding the lattice vibration, as well as the electron self-energies arising from the effective electron-electron interactions in the perturbative  $G_0W$  approximation. We also perform calculations of the graphene electron mobility on substrates with various levels of piezoelectricity. Finally, we discuss how these piezoelectric phonons can influence the superconducting instability. For completeness, we compare our results with the situation found for the two-dimensional electron gas and for conventional three-dimensional BCS superconductors.

<sup>1</sup>Work supported by MINECO (Spain), CEI Moncloa UCM-UPM, ERC (EU), and the European Commission Graphene Flagship.

**10:00AM X15.00009 Electrochemical intercalation of lithium ions into NbSe<sub>2</sub> nanosheets** , EMILY HITZ, JIAYU WAN, (UMD), ANAND PATEL, (NIST), YUE XU, (UMD), LOUISA MESHI, (NIST), JIAQI DAI, YANAN CHEN, (UMD), ALBERT DAVYDOV, Materials Science and Engineering Division, National Institute of Standards and Technology, Gaithersburg, Maryland 20878, USA, LIANGBING HU, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742, USA — Transition metal dichalcogenides (TMDCs) have been known for decades to have unique properties and recently attracted broad attention for their two-dimensional (2D) characteristics. One TMDC that has been studied for its charge density wave transition behavior and superconductivity is metallic NbSe<sub>2</sub>, yet it is still largely unexplored for device applications in electronics, optics, and batteries. Through this work, we demonstrate successful electrochemical intercalation of lithium ions into layered NbSe<sub>2</sub>. We present evidence of lithium intercalation as a technique capable of modifying the material properties of hexagonal NbSe<sub>2</sub> for further study. We confirm our result through X-ray diffraction, showing a unit cell size increase in NbSe<sub>2</sub> after intercalation from 12.57 Å to 13.57 Å in the “c” lattice dimension. Additionally, planar half-cell micro-battery devices are fabricated using ultra-thin NbSe<sub>2</sub> from platelets to observe Li-ion intercalation through an increase in the optical transmittance of the material in the visible range. At 550 nm wavelength light, we observed an increase in the optical transmittance of the material by 26% due to electrochemical intercalation.

**10:12AM X15.00010 Electronic and magnetic properties of nanoribbons<sup>1</sup>** , GAYANATH FERNANDO, ZHIWEI ZHANG, Univ of Connecticut - Storrs, ARMEN KOCHARIAN, California State Univ - Los Angeles — We have performed tight-binding calculations with open boundary conditions on a set of twisted nanoribbons (4x100), monitoring the band structure as a function of the twist angle  $\theta$ . When this angle is zero, the ribbon is rectangular and when it is 60 degrees, the ribbon is cut from a honeycomb lattice. Depending on the parameters of the tight-binding model and the filling factor, semi-metallic or insulating behavior is observed. We have also studied the electronic structure of such ribbons due to the adsorption of small atoms such as nitrogen, a magnetic field and the Rashba spin-orbit interaction. The role of the adsorbed atoms and the Rashba term with regard to the conducting properties and the symmetry breaking of the ribbons will be discussed in some detail. In addition, the effects of electronic correlations on selected small ribbons will be examined.

<sup>1</sup>The authors acknowledge the computing facilities provided by the Center for Functional Nanomaterials, Brookhaven National Laboratory supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No.DE-AC02-98CH10886.

**10:24AM X15.00011 SU(4) quantum spin liquids in critical Coulomb impurity lattices on MoS<sub>2</sub>** , X. DOU, University of Oklahoma, V. N. KOTOV, University of Vermont, BRUNO UCHOA, University of Oklahoma — In the critical regime, massive Dirac fermions are known to form a bound state in the vicinity of a Coulomb impurity. We find that in the presence of electron-electron interactions, the electrons in this bound state will valley and spin polarize. We show that the interaction of the spin and valley polarized electrons bounded to two different Coulomb impurities naturally maps into a Heisenberg model with SU(4) symmetry. We propose that quantum spin-orbital liquids with that symmetry can be engineered in artificial Coulomb impurity lattices on the surface of MoS<sub>2</sub> monolayer. We discuss possible experiments to detect those states.

**10:36AM X15.00012 Crystalline topological insulators in ultrashort optical pulse<sup>1</sup>** , SEYYEDEL AZAR OLIAEIMOTLAGH, VADYM APALKOV, MARK STOCKMAN, Georgia State University — We study theoretically interaction of ultrashort and ultrashort optical pulse with crystalline topological insulators, which have quadratic band degeneracy at the surface. Coherent electron surface dynamics in such optical pulse is determined by interband dipole coupling, which is highly anisotropic in these materials. Within two-band  $k \cdot p$  model of the surface states of topological insulator the electron dynamics is described in terms of the mixing of two (valence and conduction) bands. Such mixing is characterized by residual, i.e., after the pulse, conduction band population. Residual electron momentum distribution in the conduction band is highly anisotropic and follows the profile of the interband dipole coupling. Depending on polarization of the optical pulse, the residual conduction band population has one or two strong peaks in the momentum space, where the shapes of the peaks change with the amplitude of the pulse. The conduction band population is almost one at these peaks.

<sup>1</sup>Crystalline topological insulators in ultrashort optical pulse

**10:48AM X15.00013 Gate tunable magneto-optical effects in layered antiferromagnets<sup>1</sup>** , NIKHIL SIVADAS, Department of Physics, Carnegie Mellon University, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, DI XIAO, Department of Physics, Carnegie Mellon University — It has long been believed that the Faraday and the magneto-optic Kerr effects are absent in collinear antiferromagnets due to their vanishing net magnetic moment. To the contrary, using first-principles calculations we demonstrate that these effects can be controlled by a perpendicular voltage in bilayer MnPSe<sub>3</sub>, which has a collinear AF-Néel spin texture. The Kerr rotation can be as high as 10 mrad, and is reversed on the reversal of the polarity of gate voltage. The tunable nature of the magneto-optic effects can result in novel optoelectronic device applications. It also provides a nondestructive way to characterize the magnetic ground state of 2D materials.

**Friday, March 18, 2016 8:00AM - 10:48AM –**  
**Session X16 DCMP DMP: Two-Dimensional Material Heterostructures** 315 - Masa Ishigami, University of Central Florida

**8:00AM X16.00001 Interlayer Hybridization in van der Waals Heterostructures.** , NAM LE, University of South Florida, Department of Physics, HUAN TRAN, University of Connecticut, Institute of Materials Science, LILIA WOODS, University of South Florida, Department of Physics — Van der Waals heterostructures composed of chemically inert dissimilar layers are of great interest for fundamental science and applications. The weak interplanar interactions and orbital overlap are expected to bring modifications to the constituent materials. By using first principles simulations, we investigate the properties of several heterostructures, including graphene/silicene, graphene/MoS<sub>2</sub>, and silicene/MoS<sub>2</sub>. The calculations reveal superlattice characteristic points in the Brillouin zone associated with the different stacking patterns. Band structures projected on each of the constituents show hybridization features related to specific orbital overlap for each heterostructure. Phonon dispersion spectra for the considered heterostructures are also investigated.

**8:12AM X16.00002 Vertically Stacked Graphene/Transition-Metal-Dichalcogenides/Graphene Heterojunction Devices for High Performance Photodetectors** , JINSEONG HEO, HEEJEONG JEONG, JAEHO LEE, KIYOUNG LEE, EUN-KYU LEE, SANGYEON LEE, YEONCHOO CHO, KYUNG-EUN BYUN, CHANG-WON LEE, SEONGJUN PARK, SUNGWOO HWANG, Samsung Advanced Institute of Technology — Photodetectors based on vertically stacked graphene heterojunctions have advantages of short transit length for photo-generated carriers and large sensing area, thus implying fast response time and high responsivity. Previously, vertically stacked Graphene (Gr)/Transition-Metal-Dichalcogenide (TMDC)/Gr junctions were introduced for optoelectronic devices, showing high current on and off ratio as well as photoresponsivity. But for high performance photodetectors, both thorough and comparative study in terms of the figures of merit such as photoresponse time and photoresponsivity depending on different TMDC materials is crucial. Here, we report fast response time (28 us) and high responsivity (20 A/W) from Gr/WS<sub>2</sub> and MoS<sub>2</sub>/Gr, respectively. At the same time, those devices operate as p- and n-type barrier-variable transistors, respectively, being a potential building block for optoelectronic system on a chip.

**8:24AM X16.00003 Ab initio Mapping of Interlayer Coupling in Transition Metal Dichalcogenides and Graphene<sup>1</sup>** , SHIANG FANG, EFTHIMIOS KAXIRAS, Harvard University — Two-dimensional layered materials cover a wide variety of physics phenomena, such as topological phases, superconductivity, magnetism and charge density waves. Owing to the layered geometry and the van der Waals interactions in between, stacks of these van der Waals layered materials provide a venue to create a heterostructure with various physics properties. The interaction between different physics properties is particularly interesting to engineer the material with the desired properties. One of the crucial ingredients in understanding the heterostructure is the interlayer coupling in between. In the literature, such kind of coupling has been proposed in various empirical forms. However, a true ab initio coupling model is still lacking. For the first time, here we have derived such interlayer coupling model from the first principle calculations based on the Wannier transformation of graphene stacks. We further investigate the Fermi velocity renormalization, van Hove singularities and the moiré pattern for electron localization. Such microscopic understanding of the interlayer coupling would shed light on orbital hybridization and transport in multilayer stacks.

**8:36AM X16.00004 The Interlayer Resistance of a Misoriented Bilayer MoS<sub>2</sub> Interface** , KUAN ZHOU, UC Riverside, DARSHANA WICKRAMARATNE, UC Santa Barbara, SUPENG GE, ROGER LAKE, UC Riverside — The performance of electrical and opto-electronic devices with vertically stacked transition metal dichalcogenides (TMDCs) has been found to be degraded by the rotated interface between bilayer system. The band properties and interlayer coupling have been researched experimentally and computationally, however, the dependence of the interlayer resistance on the disorientation angle of the two layers forming bilayer MoS<sub>2</sub> remains unknown. Ab-initio methods combined with non-equilibrium Greens functions are used to calculate the transport properties of the misoriented bilayer MoS<sub>2</sub> system. The energy and angle dependence of the interlayer resistivity is determined. The difference between the electron and hole transmission properties is analyzed. The influence of spin polarization in the K valleys of the TMDC system is also been discussed.

**8:48AM X16.00005 Probing in-plane anisotropy and interlayer interactions in ReS<sub>2</sub> and ReSe<sub>2</sub> by Raman spectroscopy** , ETIENNE LORCHAT, GUILLAUME FROELICHER, STÉPHANE BERCAUD, IPCMS (CNRS - Université de Strasbourg) — We address the intriguing Raman response of rhenium disulfide (ReS<sub>2</sub>) and rhenium diselenide (ReSe<sub>2</sub>). These layered semiconductors belong to the family of transition metal dichalcogenides and exhibit significant in-plane anisotropy and can be represented as a distorted 1T-phase (octahedral), with considerably lower symmetry than the more extensively studied 2H-phase (trigonal prismatic) compounds based on molybdenum or tungsten. Nevertheless, we will demonstrate that the low-frequency rigid layer vibrational modes of *N*-layer ReS<sub>2</sub> and ReSe<sub>2</sub> can, on the one hand, be described using a linear chain model but, on the other hand, make it possible to directly probe the in-plane anisotropy and to determine the crystal orientation. Since in-plane anisotropy also has a direct impact on the optical and electron transport properties, our work opens avenues for engineering novel optoelectronic devices relying on ReS<sub>2</sub> and ReSe<sub>2</sub>.

**9:00AM X16.00006 Twisted Van der Waals Systems<sup>1</sup>** , SATRIO GANI, ENRICO ROSSI, William and Mary College — Van der Waals systems formed by two-dimensional (2D) crystals and nanostructures possess electronic properties that make them extremely interesting for basic science and for possible technological applications. By tuning the relative angle (the twist angle) between the layers, or nanostructures, forming the Van der Waals systems experimentalists have been able to control the stacking configuration of such systems. We study the dependence on the twist angle of the electronic properties of two classes of Van der Waals systems: double layers formed by two, one-atom thick, layers of a metal dichalcogenide such as molybdenum disulfide (MoS<sub>2</sub>), and graphene nanoribbons on a hexagonal boron nitride substrate. We present results that show how, for both classes of systems, the electronic properties can be strongly tuned via the twist angle.

**9:12AM X16.00007 Epitaxial MoS<sub>2</sub>/GaN structures to enable vertical 2D/3D semiconductor heterostructure devices** , D. RUZMETOV, US Army Research Laboratory, K. ZHANG, Pennsylvania State University, G. STAN, B. KALANYAN, NIST, S. EICHFELD, PSU, R. BURKE, P. SHAH, T. O'REGAN, F. CROWNE, A.G. BIRDWELL, ARL, J. ROBINSON, PSU, A. DAVYDOV, NIST, T. IVANOV, ARL — MoS<sub>2</sub>/GaN structures are investigated as a building block for vertical 2D/3D semiconductor heterostructure devices that utilize a 3D substrate (GaN) as an active component of the semiconductor device without the need of mechanical transfer of the 2D layer. Our CVD-grown monolayer MoS<sub>2</sub> has been shown to be epitaxially aligned to the GaN lattice which is a pre-requisite for high quality 2D/3D interfaces desired for efficient vertical transport and large area growth. The MoS<sub>2</sub> coverage is nearly 50 % including isolated triangles and monolayer islands. The GaN template is a double-layer grown by MOCVD on sapphire and allows for measurement of transport perpendicular to the 2D layer. Photoluminescence, Raman, XPS, Kelvin force probe microscopy, and SEM analysis identified high quality monolayer MoS<sub>2</sub>. The MoS<sub>2</sub>/GaN structures electrically conduct in the out-of-plane direction and across the van der Waals gap, as measured with conducting AFM (CAFM). The CAFM current maps and I-V characteristics are analyzed to estimate the MoS<sub>2</sub>/GaN contact resistivity to be less than 4 Ω-cm<sup>2</sup> and current spreading in the MoS<sub>2</sub> monolayer to be approx. 1 μm in diameter. Epitaxial MoS<sub>2</sub>/GaN heterostructures present a promising platform for the design of energy-efficient, high-speed vertical devices incorporating 2D layered materials with 3D semiconductors.

**9:24AM X16.00008 ABSTRACT WITHDRAWN —**

**9:36AM X16.00009 Raman spectrum of MoS<sub>2</sub>/WS<sub>2</sub> heterostructure from first-principles calculation of phonon electron coupling<sup>1</sup>**, JUN JIANG, XIAO GUANG ZHANG, Univ of Florida - Gainesville, LIANGBO LIANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, GEORGIOS D. BARMPPARIS, Crete Center for Quantum Complexity and Nanotechnology, Department of Physics, University of Crete, Heraklion 71003, Greece, YEVGENIY S. PUZYREV, SOKRATES T. PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235, USA — We present a first-principles method to calculate Raman spectrum of MoS<sub>2</sub>/WS<sub>2</sub> heterostructure due to electron excitation. The first step is to calculate the ground state phonon modes and the displacements of the atoms from the ground state to the excited states. In the next step, inelastic multi-phonon relaxation for the excited electron is considered to produce the Raman spectrum quantitatively. The relative Raman intensity, peak width and shape are obtained directly from a sum over trillions of configurations of multiple phonon modes using a Monte Carlo scheme. Alternatively, we also calculate the overlap between the ground state phonon mode eigenvectors and the excited state atomic displacements, which provides a quick and qualitative description for the Raman shifting due to electron excitation.

**9:48AM X16.00010 Optical properties of few-layer MoS<sub>2</sub>-based heterostructures**, ASMA ALKABSH, HASSANA SAMASSEKOU, ANDREW WALKER, DIPANJAN MAZUMDAR, SAIKAT TALAPATRA, Southern IL Univ-Carbondale — 2D materials such as Transition metal dichalcogenides (TMDs) are promising for a number of electronic/optoelectronic applications. In particular, semiconducting MoS<sub>2</sub>, is considered as one of the most interesting 2D material due to its direct band gap at the monolayer level [1]. For device applications, such desirable properties have to translate when MoS<sub>2</sub> is layered with other materials and substrates. In this research, the optical properties of select MoS<sub>2</sub>-based heterostructures are investigated. In particular, the effect of various insulating underlayers such as BN, SiO<sub>2</sub> on few-layer MoS<sub>2</sub> are examined using spectroscopic ellipsometry. The angles  $\Psi$  and  $\Delta$ , as well as layer specific optical constants such as extinction coefficient (k) and refractive index (n) shall be extracted using Tauc-Lorentz oscillator model and as a function of MoS<sub>2</sub> layer thickness and underlayer structure. The band gap properties of few-layer MoS<sub>2</sub> will be analyzed using optical spectroscopy

**10:00AM X16.00011 The vertical transport properties of misoriented graphene/hexagonal-boron-nitride/graphene heterostructure devices<sup>1</sup>**, SUPENG GE, MASUM HABIB, ROGER LAKE, Univ of California - Riverside, LATTE TEAM — Hexagonal boron nitride (hBN) has an atomically smooth surface free of dangling bonds, minimal lattice mismatch with graphene and a wide band gap, which makes it an ideal insulator material for graphene devices. Recently, transistor devices made with the few layers of hBN sandwiched between two layers of graphene has attracted attention since interesting phenomenon such as negative differential resistance has been observed. In experiment, the device fabrication usually gives rise to random orientation of interfaces. To have a better understanding of the effect of misorientation, we employed non-equilibrium Greens function (NEGF) method to calculate transmission across graphene/hBN/graphene heterostructures devices. We find that the rotation can cause the transmission to change by more than one order of magnitude. The resistance and current as functions of h-BN layer thickness, commensurate rotation angles, gating voltage, and bias voltage are described.

**10:12AM X16.00012 Characterization of Graphene Transferred onto Hydrated "Soft" Substrates<sup>1</sup>**, M. BLADES, P. VENDOLA, W. PIERRE, S. JEDLICKA, S.V. ROTKIN, Lehigh University — Graphene's unique properties have recently found application in the fields of biosensing and bioimaging. Substrate selection is an important step in the use of graphene for this purpose; however, choices are usually limited to hard, dry surfaces such as silicon dioxide. Here we demonstrate a modified procedure, based on the H<sub>2</sub> bubbling method, for transferring graphene to the soft hydrogel polyacrylamide. Widefield imaging and confocal Raman mapping were performed to characterize the quality of the transfer.

**10:24AM X16.00013 The effects of quenched disorder on high-order sideband generation in GaAs/AlGaAs quantum wells<sup>1</sup>**, HUNTER BANKS, DARREN VALOVICIN, Physics Department, UCSB, SHAWN MACK, Naval Research Lab, ARTHUR GOSSARD, Materials Department, UCSB, LOREN PFEIFFER, Department of Electrical Engineering, Princeton University, MARK SHERWIN, Physics Department, UCSB — When a near-IR laser resonantly pumps excitons into a strong terahertz field, individual excitons tunnel ionize and the resulting electrons and holes are driven apart and then back together by the terahertz field. Resulting recollisions create a large number of sidebands around the pump frequency, in the process of high-order sideband generation (HSG) [1]. The high kinetic energy of the electron-hole recollisions yields substantial information about the underlying structure of the individual excitons as well as the interaction of energetic single electrons and holes with each other, the lattice, and quenched disorder at sub-micron length scales. We present a comparison of smooth-walled GaAs quantum wells with 5[1] B. Zaks, et al., Nature 483 (7391), 580 (2012) and H. Banks, et al., Physical Review Letters 111, 267402 (2013)

**10:36AM X16.00014 Passivation of CdSe Quantum Dots by Graphene and MoS<sub>2</sub> Monolayer Encapsulation**, DATONG ZHANG, DENNIS ZI-REN WANG, RICHARD C. CRESWELL, Columbia University, CHENGUANG LU, National Center for Nanoscience and Technology, IRVING P. HERMAN, Columbia University — The encapsulation of a monolayer of CdSe quantum dots (QDs) by one-to-three layer graphene and MoS<sub>2</sub> sheets protects the QDs from oxidation. Photoluminescence (PL) from the QD cores shows a much slower decrease in core diameter over time due to slower oxidation in regions where the QDs are covered by van der Waals (vdW) layers than in those where they are not, for chips stored both in the dark and in the presence of light. PL mapping shows that the CdSe QDs under the central part of the vdW sheet age slower than those near its edges, because oxidation of the covered QDs is limited by transport of oxygen from the edges of the vdW sheets and not transport across the vdW layers. This encapsulation effect is also tested with other environments. Preliminary results show that vdW materials could be promising candidates for nano-coating materials for devices operating in extreme environments.

**8:00AM X17.00001 Enhanced Valley Zeeman Splitting in MoS<sub>2</sub>/EuS due to interfacial exchange field**, CHUAN ZHAO, THOMAS SCRACE, PAYAM TAHERI, PEIYAO ZHANG, TENZIN NORDEN, BRETT BLIZZARD, ATHOS PETROU, HAO ZENG, Department of Physics, University at Buffalo, SUNY, PUQIN ZHAO, Nanjing Tech University, GEORGE KIOSEOGLOU, University of Crete, Greece — A monolayer transition metal dichalcogenides such as MoS<sub>2</sub> with broken inversion symmetry possesses two degenerate yet inequivalent valleys that can be selectively excited by circularly polarized light. The ability to manipulate valley degrees of freedom with light or external magnetic field makes them attractive for optoelectronic and spintronic applications. On the other hand, it has been demonstrated recently that a magnetic insulator such as EuS can induce magnetic exchange field (MEF) on graphene through proximity effect. Thus, construction of a magnetic insulator/TMDC heterostructure may induce large MEF on TMDC, which may lead to giant valley Zeeman splitting. In this work, we report the observation of valley Zeeman splitting in monolayer MoS<sub>2</sub> and other TMDCs due to the MEF from EuS substrates. Using magneto-reflectivity, we measured a Zeeman splitting of valley exciton of 2 meV at 7 tesla and 4 K, for monolayer MoS<sub>2</sub> on a SiO<sub>2</sub> substrate. This is consistent with values reported in monolayer WSe<sub>2</sub>. However, when EuS is used as the substrate, we observed an increase of valley splitting from 2 to 10 meV. We attribute this enhanced valley splitting to the MEF from the EuS substrate. Utilizing MEF of a magnetic insulator can induce magnetic ordering and giant Zeeman splitting in 2D TMDCs, which might enable novel spintronics applications.

**8:12AM X17.00002 Exciton diamagnetic shifts and valley Zeeman effect in monolayer WS<sub>2</sub> and MoS<sub>2</sub> to 65Tesla**, A. V. STIER, NHMFL, Los Alamos, K. A. MCCREARY, B. T. JONKER, Naval Research Laboratory, J. KONO, Rice University, S. A. CROOKER, NHMFL, Los Alamos — We report circularly-polarized optical reflection spectroscopy of monolayer WS<sub>2</sub> and MoS<sub>2</sub> at low temperatures (4 K) and in high magnetic fields to 65 T [1]. Both the A and the B exciton transitions exhibit a clear and very similar Zeeman splitting of approximately  $-230 \mu\text{eV/T}$  ( $g \simeq -4$ ), providing the first measurements of the valley Zeeman effect and associated g-factors in monolayer transition-metal disulphides. These results complement and are compared with recent low-field photoluminescence measurements of valley degeneracy breaking in the monolayer diselenides MoSe<sub>2</sub> and WSe<sub>2</sub>. Further, the very large magnetic fields used in our studies allows us to observe the small quadratic diamagnetic shifts of the A and B excitons in monolayer WS<sub>2</sub> (0.32 and 0.11  $\mu\text{eV/T}^2$ , respectively), from which we calculate exciton radii of 1.53 nm and 1.16 nm. When analyzed within a model of non-local dielectric screening in monolayer semiconductors, these diamagnetic shifts also constrain and provide estimates of the exciton binding energies (410 meV and 470 meV for the A and B excitons, respectively), further highlighting the utility of high magnetic fields for understanding new 2D materials. [1] A. V. Stier et al., submitted, arxiv:1510.07022 (2015)

**8:24AM X17.00003 Valley selective high field magneto-spectroscopy of monolayer MoSe<sub>2</sub>**, JONATHAN LUDWIG, Florida State University and National High Magnetic Field Lab, Y. LI, Stanford University and SLAC National Accelerator Lab, Z. LU, Florida State University and National High Magnetic Field Lab, X.X. ZHANG, Stanford University and SLAC National Accelerator Lab, X. CUI, J. HONE, Columbia University, T.F. HEINZ, Stanford University and SLAC National Accelerator Lab, D. SMIRNOV, National High Magnetic Field Lab — Monolayer transition metal dichalcogenides (TMDs) have recently emerged as a new class of direct bandgap 2D semiconductors with valleys at the  $\pm K$  points in the Brillouin zone. Due to the broken inversion symmetry in monolayer TMDs, this valley degree of freedom can be selectively addressed by optical helicity. We report on circularly polarized resolved photoluminescence on gated monolayer MoSe<sub>2</sub> in perpendicular and parallel magnetic fields up to 30T. In a perpendicular field at low carrier density, the PL energies of both the trion and exciton experience a linear shift with a slope of  $\approx \pm 2\mu_B/T$  for the  $\pm K$  valleys, demonstrating valley degeneracy lifting. This is in contrast to the measurements in parallel field, where no such linear splitting occurs. In addition, we report quadratic corrections to the linear magnetic field dependence of the trion and exciton energy in the perpendicular configuration.

**8:36AM X17.00004 Valley-selective optical Stark effect in monolayer WS<sub>2</sub>**, NUH GEDIK, MIT — Monolayer semiconducting transition-metal dichalcogenides (TMDs) have a pair of valleys that, by time-reversal symmetry, are energetically degenerate. Lifting the valley degeneracy in these materials is of great interest because it would allow for valley specific band engineering and offer additional control in valleytronic applications. In this talk, I will show that circularly polarized light, which breaks time-reversal symmetry, can be used to lift the valley degeneracy by means of the optical Stark effect [1]. We demonstrate that this effect is capable of raising the exciton level in monolayer TMD WS<sub>2</sub> by as much as 18 meV in a controllable valley-selective manner. The resulting energy shift is extremely large, comparable to the shift that would be obtained using a very high magnetic field (approximately 100 Tesla). These results offer a novel way to control valley degree of freedom, and may provide a means to realize new valley-selective Floquet topological state of matter. [1] E J Sie, J W McIver, Y H Lee, L Fu, J Kong and N Gedik, Nature Materials 14, 290 (2015)

**9:12AM X17.00005 Valley-Polarized Interlayer Excitons in 2D Semiconductor Heterostructures**, PASQUAL RIVERA, KYLE SEYLER, Univ of Washington, HONGYI YU, University of Hong Kong, JOHN SCHAIBLEY, Univ of Washington, JIAQIANG YAN, DAVID MANDRUS, University of Tennessee, XIAODONG XU, Univ of Washington — Vertically stacked monolayers of MoSe<sub>2</sub> and WSe<sub>2</sub> feature a type-II band alignment causing the formation of interlayer excitons, where the Coulomb bound hole and electron reside in different layers. This species of exciton has lifetime many orders of magnitude longer than intralayer valley excitons, providing a unique and advantageous system for investigating valley exciton physics. Here, we optically pump the MoSe<sub>2</sub>-WSe<sub>2</sub> heterostructure with circularly polarized light, creating interlayer valley excitons with gate-tunable spin-valley polarization lifetime up to 40 ns. This long valley lifetime enables the diffusion of the interlayer valley exciton gas to be visualized. Under increasing excitation power we observe the formation of a ring in the spatial distribution of the valley polarization, a manifestation of significant valley-selective exchange interactions at high exciton densities. The combination of long valley polarization and spatial diffusion makes the interlayer exciton in semiconductor heterostructures an exciting platform for studies of valley exciton physics.

**9:24AM X17.00006 Valley-Polarized Exciton-Polaritons in a Monolayer Semiconductor Embedded in a Microcavity**<sup>1</sup>, YEN-J. CHEN, TEODOR K. STANEV, NATHANIEL P. STERN, Department of Physics and Astronomy, Northwestern University, JEFFREY D. CAIN, VINAYAK P. DRAVID, Department of Materials Science and Engineering, Northwestern University — Two-dimensional transition metal dichalcogenides (TMDs) are semiconductors that exhibit degenerate, but inequivalent, valleys at their  $K$ -point band gaps which selectively couple to circularly-polarized light fields. Coherent hybrid states of light and matter, exciton-polaritons, have been observed when monolayer TMDs strongly interact with photon fields in a microcavity<sup>2</sup>. The degree of polarization is determined by the relative rates of exciton and intervalley relaxation, which can be modified for microcavity exciton-polaritons. Preservation of valley-polarization in a microcavity at room temperature is compared to the nearly zero polarization for bare monolayer MoS<sub>2</sub> on SiO<sub>2</sub>, demonstrating cavity-modified relaxation dynamics of the coherent valley-specific exciton-polaritons. These results suggest promising opto-electronic applications for valley-based polaritonic and photonic devices integrating monolayer TMDs.

**9:36AM X17.00007 Valley Polarization in Size-Tunable Monolayer Semiconductor Quantum Dots<sup>1</sup>**, GUOHUA WEI, Applied Physics Program, Northwestern University, DAVID A. CZAPLEWSKI, IL WOONG JUNG, Center for Nanoscale Materials, Argonne National Lab, ERIK J. LENFERINK, TEODOR K. STANEV, NATHANIEL P. STERN, Department of Physics, Northwestern University — Controlling the size of semiconductor nanostructures allows manipulation of the optical and electrical properties of band carriers. We show that laterally-confined monolayer MoS<sub>2</sub> quantum dots can be created through top-down nanopatterning of an atomically-thin two-dimensional semiconductor. Semiconductor-compatible nanofabrication processing allows for these low-dimensional materials to be integrated into complex systems that harness their controllable optical properties. Size-dependent exciton energy shifts and linewidths are observed, demonstrating the influence of quantum confinement. The patterned dots exhibit the same valley polarization characteristics as in a continuous MoS<sub>2</sub> sheet, suggesting that monolayer semiconductor quantum dots could have potential for advancing quantum information applications.

<sup>1</sup>This work is supported by ISEN, the DOE-BES (DE-SC0012130), the NSF MRSEC program (DMR-1121262), and the Center for Nanoscale Materials, DOE-BES (DE-AC02-06CH11357). N.P.S. is an Alfred P. Sloan Research Fellow.

**9:48AM X17.00008 Valley-selective harmonic generations in transition metal dichalcogenide monolayers**, JINGXIN CHENG, TAO JIANG, YUWEI SHAN, YINGGUO LI, Fudan University, XIANHUI CHEN, University of Science and Technology of China, Y.R. SHEN, Fudan University; University of California, Berkeley, WEITAO LIU, SHIWEI WU, Fudan University — Transition metal dichalcogenide monolayer has emerged as another star in the family of atomically thin two dimensional materials. Different from graphene, the two sublattices in its honeycomb-like structure are occupied by different atoms, leading to the reduced rotational symmetry from six fold to three fold. The reduced symmetry and dimension not only result in many intriguing physics such as valley and excitons, but also lead to rich nonlinear optical phenomena such as strong second harmonic generation. In this talk, we will present a systematic study on linearly and circularly polarized harmonic generations in this wonder material. We show that both the second and third harmonic generations follow the conservation of angular momentum and are valley-selective. Furthermore, these nonlinear optical processes could be used as a powerful imaging tool for studying transition metal dichalcogenide monolayers and other similar 2D materials.

**10:00AM X17.00009 Efficient evaluation of epitaxial MoS<sub>2</sub> on sapphire by direct band structure imaging<sup>1</sup>**, HOKWON KIM, DUMITRU DUMCENCO, MATHIEU FREGNAUX, Ecole Polytechnique Federale de Lausanne, ANASS BENAYAD, CEA, LETI, YEN-CHENG KUNG, ANDRAS KIS, Ecole Polytechnique Federale de Lausanne, OLIVIER RENAULT, CEA, LETI, LANES GROUP, EPFL TEAM, LETI, CEA TEAM — The electronic band structure evaluation of two-dimensional metal dichalcogenides is critical as the band structure can be greatly influenced by the film thickness, strain, and substrate. Here, we performed a direct measurement of the band structure of as-grown monolayer MoS<sub>2</sub> on single crystalline sapphire by reciprocal-space photoelectron emission microscopy with a conventional laboratory ultra-violet He I light source. Arrays of gold electrodes were deposited onto the sample in order to avoid charging effects due to the insulating substrate. This allowed the high resolution mapping ( $\Delta E = 0.2$  eV;  $\Delta k = 0.05$  Å<sup>-1</sup>) of the valence states in momentum space down to 7 eV below the Fermi level. The high degree of the epitaxial alignment of the single crystalline MoS<sub>2</sub> nuclei was verified by the direct momentum space imaging over a large area containing multiple nuclei. The derived values of the hole effective mass were 2.41 0.05 m<sub>0</sub> and 0.81 0.05 m<sub>0</sub>, respectively at  $\Gamma$  and K points, consistent with the theoretical values of the freestanding monolayer MoS<sub>2</sub> reported in the literature.

**10:12AM X17.00010 ABSTRACT WITHDRAWN —**

**10:24AM X17.00011 Nanoscale Photoconductivity Imaging of Thin-film Semiconductors by Laser-assisted Microwave Impedance Microscopy<sup>1</sup>**, ZHAODONG CHU, DI WU, YUAN REN, SEUNGCHEOL YANG, LIUYANG SUN, XIAOQIN LI, KEJI LAI, University of Texas at Austin — The photo-response of semiconductors is usually studied by detecting the photocurrent across source-drain electrodes under light illumination. By integrating the microwave impedance microscopy (MIM) technique with focused-laser stimulation, we are able to perform the real-space photoconductivity mapping of photo-sensitive materials without the need of patterning contact electrodes. Here, we report the MIM results of various thin-film materials, such as In<sub>2</sub>Se<sub>3</sub> nano-sheets and transition metal dichalcogenides (TMD) flakes, illuminated by laser beams of different wavelengths in the ambient condition. With no or below-gap illumination, the samples were highly resistive, as indicated by the low MIM signals. The MIM contrast emerges under above-gap light and increases as increasing laser intensity, which clearly demonstrates the local imaging of photoconductivity rather than the transport photocurrent. Interestingly, clear domain structures with mesoscopic length scales were seen in the data due to the coexistence of multiple phases in In<sub>2</sub>Se<sub>3</sub>. The unique combination of MIM and laser stimulation thus provides a new direction to explore the microscopic origin of various light-driven phenomena in complex systems.

**10:36AM X17.00012 High-harmonic generation from an atomically thin semiconductor**, HANZHE LIU, YILEI LI, Stanford Univ./SLAC national accelerator laboratory, SHAMBHU GHIMIRE, SLAC national accelerator laboratory, TONY HEINZ, DAVID REIS, Stanford Univ./SLAC national accelerator laboratory — The process of high-harmonic generation (HHG) from ultrashort laser pulses has recently been observed in bulk solids, complementing the well-established process in the gas phase. HHG is of interest both as a source of ultrashort pulses in the attosecond regime that has photon energies extending up to the soft x-ray region and as a method of probing material response outside the regime of perturbative nonlinear optics. In this paper, we present the observation of HHG from a single atomic layer of MoS<sub>2</sub> driven by a strong infrared pulse of 100 fs duration and 0.3 eV photon energy. We observe distinct harmonics up to the 13<sup>th</sup> order of the infrared excitation. The non-perturbative nature of the HHG process is demonstrated by the weak power dependence of the harmonic intensities. To gain further insight into the process, we have investigated the variation of the HHG signal with sample orientation and the ellipticity of pump excitation. We compare and contrast the process with that from the bulk MoS<sub>2</sub> crystal. We find significant differences in the response for the monolayer and bulk crystal, which can be understood in terms of the distinct crystallographic symmetries in the two cases.

**10:48AM X17.00013 Optical spectroscopy and imaging of the higher energy excitons and bandgap of monolayer MoS<sub>2</sub>**, NICHOLAS BORYS, WEI BAO, EDWARD BARNARD, Molecular Foundry, Lawrence Berkeley National Lab, CHANGHYUN KO, University of California Berkeley, SEFAATIN TONGAY, Arizona State University, JUNQIAO WU, University of California Berkeley, LI YANG, Washington University in St. Louis, P. JAMES SCHUCK, Molecular Foundry, Lawrence Berkeley National Lab — Monolayer MoS<sub>2</sub> (ML-MoS<sub>2</sub>) exhibits a rich manifold of excitons that dictate optoelectronic performance and functionality. Disentangling these states, which include the quasi-particle bandgap, is critical for developing 2D optoelectronic devices that operate beyond the optical bandgap. Whereas photoluminescence (PL) spectroscopy only probes the lowest-energy radiative state and absorption spectroscopy fails to discriminate energetically degenerate states, photoluminescence excitation (PLE) spectroscopy selectively probes only the excited states that thermalize to the emissive ground state exciton. Using PLE spectroscopy of ML-MoS<sub>2</sub>, we identify the Rydberg series of the exciton A and exciton B states as well as signatures of the quasi-particle bandgap and coupling between the indirect C exciton and the lowest-energy A exciton, which have eluded previous PLE studies. The assignment of these states is confirmed with density functional theory. Mapping the PLE spectrum reveals spatial variations of the higher-energy exciton manifold and quasi-particle bandgap which mirror the heterogeneity in the PL but also indicate variations in local exciton thermalization processes and chemical potentials.

Session X18 GMAG DMP: Bulk and Artificial Skyrmions 317 - Gong Chen, Berkeley National Laboratory

**8:00AM X18.00001 Emergence of skyrmions from rich parent phases in the molybdenum nitrides**, JIADONG ZANG, Univ of New Hampshire, WEI LI, Shanghai Institute of Microsystem and Information Technology, CAS, CHIMING JIN, High Magnetic Field Laboratory, CAS, RENCHAO CHE, Fudan University, WENSEN WEI, LANGSHENG LIN, LEI ZHANG, HAIFENG DU, MINGLIANG TIAN, High Magnetic Field Laboratory, CAS — We report a new family of skyrmion materials originated from the antisymmetric Dzyaloshinskii-Moriya (DM) interactions. Based on the symmetric tensor technique, the molybdenum nitrides with the  $\beta$ -manganese structure,  $A_2Mo_3N$  with  $A=Fe, Co, Rh$ , are predicted to support the skyrmion phase. This predication is directly proved in doped  $Fe_xCo_{1-x}Rh_{0.5}Mo_3N$  components by high resolution Lorentz transmission electron imaging. Interestingly, the parent compounds  $Fe_2Mo_3N$ ,  $Co_2Mo_3N$ , and  $Rh_2Mo_3N$  exhibit ferromagnetic, anti-ferromagnetic, and even superconducting orderings respectively. Magnetism in these parent phases is theoretically clarified by the first principle calculations, where the corrected nature of the magnetism is revealed..

**8:12AM X18.00002 Magnetic phase diagram of doped MnSi**, CHETAN DHITAL, MOJAMMEL KAHN, ADAM P. PHELAN, DAVID P. YOUNG, RONGYING JIN, JOHN DITUSA, Louisiana State University — The noncentrosymmetric chiral structure of cubic  $B20$  compound MnSi favors Dzyaloshinskii-Moria (DM) interaction ( $D$ ) where the broken inversion symmetry determines direction of  $D$  and the strength of spin-orbit coupling determines the magnitude of  $D$ . This relatively weak DM interaction  $D$  competes against the exchange interaction ( $J$ ) resulting in rather unusual long wavelength helimagnetism with the period set by the ratio  $(J/D)$ . Previous work has shown that both helimagnetic period ( $\lambda$ ) and the transition temperature ( $T_C$ ) are reduced as a result of either Fe or Co substitutions on Mn site [1, and references therein]. Recently we have started to investigate the effect on the helimagnetic/Skyrmion structure and the transition temperature by chemical substitutions on the Si site. I will present our preliminary magnetization and neutron scattering results where we have found clear evidence of increase in both  $T_C$  and helimagnetic period as a result of doping. The possible connection between carrier doping and the strength of DM interaction strength will be discussed.

**8:24AM X18.00003 First-principles simulation and low-energy effective modeling of three-dimensional skyrmion in MnGe**<sup>1</sup>, HONGCHUL CHOI, YUAN-YEN TAI, JIAN-XIN ZHU, Los Alamos National Laboratory, T-4 TEAM — The skyrmion spin textures are mostly observed in two-dimensional (2D) space, which can be topologically mapped onto the surface of the sphere with an integer multiple of topological winding number. Recently, MnGe has been reported as a candidate of 3D skyrmion crystal, showing the variation of the skyrmion size along the z-direction [1,2]. We have performed the first-principles simulation and constructed a tight-binding model with calculated electronic-structure information to investigate the 3D skyrmion phase in MnGe. Our first-principles study within density functional theory shows that the calculated magnetic moment is larger than that for MnSi (with different lattice constant), implying the possibility of a multiple magnetic transition under pressure [3]. We have also found that the small-sized skyrmion could be stabilized in a 2D structure. Such a high density of the skyrmion is in good agreement with the experimental finding of large topological Hall effect [1]. Finally, we will extend our study to consider the 3D skyrmion structure based on the constructed tight-binding model. [1] Y. Shiomi et al., Phys. Rev. B 88, 064409 (2013); [2] T. <sup>1</sup>This work was carried out under the auspices of the National Nuclear Security Administration of the U.S. Department of Energy at Los Alamos National Laboratory (LANL) under Contract No. DE-AC52-06NA25396, and was supported by the LANL LDRD Program.

**8:36AM X18.00004 Study of topological spin texture in B20 crystalline FeGe films**, EMRAH TURGUT, ALBERT PARK, KAYLA NGUYEN, ROBERT HOVDEN, School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853 USA, LENA KOURKOUTIS, DAVID MULLER, GREGORY FUCHS, School of Applied and Engineering Physics & Kavli Institute at Cornell in Nanoscale Science, Cornell University, Ithaca, NY 14853 USA — The possibility of efficient and robust information storage in B20-hellimagnet systems has been attracted significant interest. Although there have been promising transmission electron microscopy (TEM) and transport studies on bulk B20 crystalline materials, the development of applications motivates study of thin-film samples grown with scalable techniques such as magnetron sputtering. Here we report transport and characterization measurements of FeGe thin films grown on Si  $\langle 111 \rangle$  by magnetron co-sputtering. We obtain well-oriented but polycrystalline FeGe films with the B20 crystalline phase after post-growth annealing. Low temperature TEM imaging reveals that the lattice mismatch between the Si substrate and FeGe film introduces disordered helical magnetic phases. In addition, bulk susceptibility measurements of a continuous film and AMR measurements of micron-size wires indicate helical, conical, and ferromagnetic phases, but not an obvious skyrmion phase. Similar to recent reports, our measurements confirm that the observations of additional contributions to Hall effect measurements in B20 materials are not necessarily proof of magnetic skyrmion phase, and that more careful experimental studies are needed to understand thin film properties of B20 materials.

**8:48AM X18.00005 Skyrmion domains in Cu<sub>2</sub>OSeO<sub>3</sub>: Short-Range Order and Domain Wall Formation**, SHILEI ZHANG, Department of Physics, University of Oxford, ANDREAS BAUER, Physik Department, Technische Universität München, HELMUTH BERGER, Ecole Polytechnique Fédérale de Lausanne (EPFL), STAVROS KOMINEAS, Department of Mathematics and Applied Mathematics, University of Crete, DAVID BURN, Diamond Light Source, CHRISTIAN PFLEIDERER, Physik Department, Technische Universität München, GERRIT VANDER LAAN, Diamond Light Source, THORSTEN HESJEDAL, Department of Physics, University of Oxford — Cu<sub>2</sub>OSeO<sub>3</sub> is a chiral ferrimagnetic insulator carrying a long-range order magnetic skyrmion phase. Here, we report a short-range ordered equilibrium skyrmion state on the surface of Cu<sub>2</sub>OSeO<sub>3</sub> single crystal, studied by resonant soft x-ray scattering. Soft x-ray scattering at the  $L_{2,3}$  edge of  $3d$  compounds is an ideal tool to probe the magnetic order, and is only sensitive to 60-70 unit cells in depth of Cu<sub>2</sub>OSeO<sub>3</sub>. Our results show that under the arbitrary magnetic field directions that deviate from the cubic main axes, the six-fold-symmetric skyrmion order breaks into domains, and the initial, anisotropy-governed pinning of propagation directions is completely unwound. We show that uniform 360° Bloch domain walls form between the skyrmion domains. Our findings provide a new way to manipulate and engineer the skyrmion state locally, or even individually, on the surface which will enable applications in the future.

**9:00AM X18.00006 Transverse field muon-spin rotation in skyrmion-hosting materials**, TOM LANCASTER, FAN XIAO, ROBERT WILLIAMS, Durham University, ZAHER SALMAN, Paul Scherrer Institut, STEPHEN BLUNDELL, University of Oxford, FRANCIS PRATT, STFC ISIS Facility, IORWERTH THOMAS, Durham University, MONICA CIOMAGA HATNEAN, GEETHA BALAKRISHNAN, University of Warwick, SHILEI ZHANG, THORSTEN HESJEDAL, University of Oxford — We present the results of transverse field (TF) muon-spin rotation ( $\mu^+SR$ ) measurements on examples of materials that host a skyrmion lattice (SL) phase. In measurements on bulk Cu<sub>2</sub>OSeO<sub>3</sub>, we measure the response of the TF  $\mu^+SR$  signal in the SL phase along with the surrounding ones, and suggest how the phases might be distinguished using the results of these measurements. Dipole field simulations support the conclusion that the muon is sensitive to the SL via the TF lineshape and, based on this interpretation, our measurements suggest that the SL is quasistatic on a timescale  $\tau > 100$  ns. We also discuss TF  $\mu^+SR$  measurements on an epitaxially grown 40 nm-thick film of MnSi on Si(111) in the region of the field-temperature phase diagram where a skyrmion phase has been observed in the bulk. We identify changes in the quasistatic magnetic field distribution sampled by the muon, along with evidence for magnetic transitions around  $T \approx 40$  K and 30 K. Our results suggest that the cone phase is not the only magnetic texture realized in film samples for out-of-plane fields.

### 9:12AM X18.00007 Antiferromagnetic skyrmions<sup>1</sup> , OLEG TRETIAKOV, JOSEPH BARKER, IMR, Tohoku University —

Skyrmions are topologically protected entities in magnetic materials which have the potential to be used in spintronics for information storage and processing. However, skyrmions in ferromagnets have some intrinsic difficulties which must be overcome to use them for spintronic applications, such as the inability to move straight along current. We show that skyrmions can also be stabilized and manipulated in antiferromagnetic materials. An antiferromagnetic skyrmion is a compound topological object with a similar but of opposite sign spin texture on each sublattice, which e.g. results in a complete cancelation of the Magnus force. We find that the composite nature of antiferromagnetic skyrmions gives rise to different dynamical behavior, both due to an applied current and temperature effects.

### 9:24AM X18.00008 Creating Skyrmions Using Spin Transfer Torque , JENNIFER GRAB, ALISON RUGAR, DAVID MACNEILL, Cornell University, GIOVANNI FINOCCHIO, University of Messina, ROBERT BUHRMAN, DANIEL RALPH, Cornell University —

Finding efficient methods to read and write individual skyrmions under ambient conditions is an important first step toward realizing skyrmion-based applications, such as high density information storage and racetrack memory. Of recent interest experimentally are heavy metal /ferromagnet bilayers with a strong interfacial Dzyaloshinskii-Moriya Interaction and perpendicular magnetic anisotropy (PMA), which favor the formation of helical spin textures. Micromagnetic simulations of these materials suggest that an out of plane spin polarized current could be used to write isolated skyrmions and excite skyrmion breathing modes. In this project, we attempt to create skyrmions using a spin valve like device. Our devices consist of a PMA nanopillar on top of a bulk Co/Pt bilayer. The nanopillar generates a spin polarized current, which is expected to locally reverse the magnetization of the film underneath the pillar via spin transfer torque. We report measurements of the DC current and field dependence of the pillar resistance. By monitoring the magnetization state of the bilayer independently, these measurements can be used to isolate the resistive signatures of skyrmion formation.

### 9:36AM X18.00009 Generation of magnetic skyrmion bubbles by inhomogeneous spin-Hall currents<sup>1</sup> , OLLE HEINONEN, WANJUN JIANG, HAMOUD SOMAILY, SUZANNE G.E. TE VELTHUIS, AXEL HOFFMANN, Argonne Natl Lab —

Recent experiments have shown that magnetic skyrmion bubbles can be generated and injected at room temperature in thin films<sup>1</sup>. Here, we demonstrate, using micromagnetic modeling, that such skyrmions can be generated by an inhomogeneous spin Hall torque in the presence of Dzyaloshinskii-Moriya interactions (DMIs). In the experimental Ta-Co<sub>20</sub>Fe<sub>60</sub>B<sub>20</sub> thin films, the DMI is rather small; nevertheless, the skyrmion bubbles are stable, or at least metastable on observational time scales. We identify two different mechanisms, one in a low-current regime and the other in a high current regime, that destabilize a domain wall injected from a narrow region into an expanding region with inhomogeneous spin-Hall torque. In the first, asymmetric torques on the domain wall lead to a cascade of bubble formation and subsequent fragmentation. In the second, an approximately steady-state texture is injected into the wide region. When the current is turned off, the inhomogeneous spin texture relaxes and regions can coalesce into bubbles that attain a definite chirality because of the DMI. [1] W. Jiang *et al.*, Science **349**, 283 (2015).

### 9:48AM X18.00010 Tailoring the chiral magnetic interaction between two individual atoms<sup>1</sup> , J. WIEBE, Institute for Nanostructure and Solid State Research, Hamburg University, A. A. KHAJETOORIANS, Institute for Molecules and Materials, Radboud University, Nijmegen, M. STEINBRECHER, Institute for Nanostructure and Solid State Research, Hamburg University, M. TERNES, Max Planck Institute for Solid State Research, Stuttgart, M. BOUHASSOUNE, M. DOS SANTOS DIAS, S. LOUNIS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, R. WIESENDANGER, Institute for Nanostructure and Solid State Research, Hamburg University —

Chiral magnets are a promising route toward dense magnetic storage technology due to their inherent nano-scale dimensions and energy efficient properties. Engineering chiral magnets requires atomic-level control of the magnetic exchange interactions, including the Dzyaloshinskii-Moriya interaction, which defines a rotational sense for the magnetization of two coupled magnetic moments. Here we show that the indirect conduction electron mediated Dzyaloshinskii-Moriya interaction between two individual magnetic atoms on a metallic surface can be manipulated by changing the interatomic distance with the tip of a scanning tunneling microscope. We quantify this interaction by comparing our measurements to a quantum magnetic model and ab-initio calculations yielding a map of the chiral ground states of pairs of atoms depending on the interatomic separation. The map enables tailoring the chirality of the magnetization in dilute atomic-scale magnets.

### 10:00AM X18.00011 Collapse and control of the MnAu<sub>2</sub> spin spiral state through pressure and dopin , JAMES GLASBRENNER, National Research Council/Naval Research Lab —

MnAu<sub>2</sub> is a spin spiral material with ferromagnetic Mn layers that rotate from plane to plane. The spiral angle  $\theta$  decreases with pressure and collapses to a ferromagnetic state above a critical threshold, although different experiments do not agree on whether the collapse is first or second order. To resolve this contradiction, we employ density functional theory to calculate magnetic energies in the spiral state under both pressure and charge doping and fit the results to the  $J_1 - J_2 - J_3 - J_4$  Heisenberg model, which predicts either first or second order phase transitions depending on the set of exchange parameters. At ambient pressure, MnAu<sub>2</sub> sits very close to a dividing line separating first and second order transitions, and applying either pressure or electron doping shifts the system towards the second order region of parameter space. Our findings show how variations in material quality can impact how the spiral state collapses, which resolves the contradiction in pressure experiments. Our results also suggest that MnAu<sub>2</sub> is amenable to engineering via chemical doping and to controlling  $\theta$  using pressure and gate voltages, which holds potential for integration in spintronic devices.

### 10:12AM X18.00012 Neutron Study of Spiral Magnetism in Au<sub>2</sub>Mn , I-LIN LIU, MARIA PASCALE, University of Maryland, College Park, NICHOLAS BUTCH, NIST - Natl Inst of Stds & Tech —

The binary compound Au<sub>2</sub>Mn is known to order magnetically with a spiral structure. The pitch of the spiral has been previously shown to be dependent upon temperature and pressure. We will discuss the results of neutron diffraction measurements, in which we study the low temperature behavior of the spiral to higher pressure.

### 10:24AM X18.00013 Chiral Magnets Under a Tilted Magnetic Field: Noncircular Skyrmions , AVADH SAXENA, SHI-ZENG LIN, Los Alamos National Lab —

The equilibrium and dynamical properties of skyrmions in thin films of chiral magnets are studied in the presence of oblique magnetic fields. The shape of an individual skyrmion is found to be noncircular and the skyrmion density decreases with the tilt angle (from the normal of the film). Consequently, the interaction between two skyrmions depends on the relative angle between them besides their separation. Under a perpendicular magnetic field a triangular lattice of skyrmions is formed which is distorted into a centered rectangular lattice when the magnetic field is tilted. For low skyrmion densities a chainlike structure of skyrmions is formed. The dynamical response (including the Hall angle of motion) of the noncircular skyrmions is found to depend on the direction of external currents.

**10:36AM X18.00014 Anisotropy of Skyrmion Lattice in  $\text{Mn}_{0.9}\text{Fe}_{0.1}\text{Si}$  probed by magnetic field orientation dependence of the topological Hall effect and magnetoresistance**<sup>1</sup>, PETER SIEGFRIED, ANDREW TREGLIA, ALEXANDER BORNSTEIN, University of Colorado Boulder, THOMAS WOLF, Karlsruhe Institute of Technology, MINHUEA LEE, University of Colorado Boulder — We report the magnetic field orientation dependence of the topological Hall effect (THE) and magnetoresistance (MR) of  $\text{Mn}_{0.9}\text{Fe}_{0.1}\text{Si}$  in the *A*-phase within the applied magnetic field (*H*) temperature (*T*) phase diagram. In the *A*-phase a two dimensional Skyrmion lattice is formed in the plane perpendicular to the direction of *H*, which is responsible for the observed THE signal. At a given *T* within the *A*-phase, we investigated the angular dependence of THE and MR at a fixed *H* to probe the boundaries of the *A*-phase region. We find the MR signal exhibits a unique *H*-direction dependence at the entering and exiting of the *A*-phase, whereas, in the middle *H* range, i.e. in the core of *A*-phase, the angular dependence is consistent with what is expected from a perfect 2D Skyrmion lattice. However, THE signals show extreme sensitivity upon entering the *A*-phase and unexpected angular dependence, yet did not leave any trace through exiting. The discrepancy between the angular dependence of MR and THE signals at the *A*-phase boundaries indicates a crucial role of Fe impurities as pinning centers for the Skyrmions. We will discuss further our *H*-orientation dependence of the THE, compared to sweeping *H* at a fixed angle in Fe doped MnSi.

**10:48AM X18.00015 Critical phenomena of emergent monopoles in a chiral magnet**, XIAO-XIAO ZHANG, Univ. of Tokyo, NAOTO NAGAO, Univ. of Tokyo and RIKEN CEMS — A three-dimensional cubic Skyrmion crystal in the bulk, which is simultaneously a lattice of monopole-antimonopole pairs predicted theoretically, has been recently identified experimentally in MnGe. Adopting appropriate temperature Green's function technique for optical conductivity and devising a solvable phonon-magnon interaction, we systematically developed the theory of coupling spin-waves to both itinerant electrons and mechanical degrees of freedom in this chiral magnet, describing the latest experimental observations including anomalies and critical phenomena in magnetotransport and magnetoelasticity, which are identified as hallmarks of fluctuations of the emergent monopolar fields upon the nontrivial monopole dynamics and especially a topological phase transition signifying strong correlation. As a whole, they speak for a crucial role played by the monopole defects and hence the real-space spin topology in this material.

**Friday, March 18, 2016 8:00AM - 11:00AM –**  
**Session X19 GMAG DMP: Magnetic Oxide Thin Films and Heterostructures: Electrostatic, Ionic, and Magnetoelectric Coupling** 318 - Philip Ryan, Argonne National Laboratory

**8:00AM X19.00001 Electric-Field Coupling to Spin Waves in a Centrosymmetric Ferrite**, TIANYU LIU, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA — A systematic control of spin waves via external electric fields has been a long standing issue for the design of magnonic devices, and is of fundamental interest. One way to attain such control is to use multiferroics [1], whose electric and magnetic polarizations are inherently coupled. The lack of electric polarization in a centrosymmetric ferrite, however, makes direct coupling of its magnetization to external electric fields a challenge. Indirect electric control of spin waves has been accomplished by hybridizing yttrium iron garnet (YIG), a centrosymmetric ferrite, with a piezoelectric material [2]. Here, we predict direct control of spin waves in YIG by a *flexoelectric interaction*, which couples an electric field to the spatial gradient of the magnetization, and thus the spin waves [3]. Based on a superexchange model, which describes the antiferromagnetic coupling between two nearest neighbor iron ions through an oxygen ion, including spin-orbit coupling, we estimate the coupling constant and predict a phase shift linear in the applied electric fields [4]. The theory is then confirmed by experimental measurement of the electric-field-induced phase shift in a YIG waveguide [5]. In addition to the flexoelectric effect, another electric effect is observed, which couples the electric field directly with the magnetization of YIG. We call this a magnetoelectric effect. By adjusting the direction of the electric field, the two effects can be well separated. Experimental results agree quantitatively with the theoretical prediction. A phenomenological coupling constant for the magnetoelectric effect is also obtained. Our findings point to an important avenue for manipulating spin waves and developing electrically tunable magnonic devices. [1] P. Rovillain *et al.*, Nat. Mater. 9, 975 (2010). [2] M. Bao *et al.*, Appl. Phys. Lett. 101, 022409 (2012). [3] T. Liu and G. Vignale, J. Appl. Phys. 111, 083907 (2012). [4] T. Liu and G. Vignale, Phys. Rev. Lett. 106, 247203 (2011). [5] X. Zhang *et al.*, Phys. Rev. Lett. 113, 037202 (2014). [6] The author gratefully acknowledges collaborations with G. Vignale, M.E. Flatté, X. Zhang and H. X. Tang. **8:36AM X19.00002 Enhanced magneto-ionic switching of interface anisotropy in Pt/Co/GdOx films**, AIK JUN TAN, MAX MANN, UWE BAUER, GEOFFREY BEACH, MIT — Voltage control of magnetic anisotropy is of great interest for reducing the switching energy barrier in spintronic devices. It has recently been shown that electric field-driven oxygen ion migration near the interface of ferromagnet/oxide bilayers can lead to very large changes in magnetic anisotropy at elevated temperature. Here, we examine magneto-ionic switching in ultrathin Pt(3nm)/Co(0.9nm)/GdOx(*t<sub>ox</sub>*)/Au(*t<sub>Au</sub>*) films with perpendicular anisotropy, in which the GdOx layer and gate structure are optimized for efficient room-temperature oxygen conduction. We study voltage-induced switching dynamics as a function of the GdOx stoichiometry and the thickness of the Au gate layer. We find that for optimally oxidized GdOx, a positive bias voltage applied to the Au electrode results in a transition from PMA to in-plane magnetization, and at zero bias, the PMA spontaneously returns. The rate of this transition depends on the thickness of the Au gate which suggests that the rate-limiting step is removal and reintroduction of oxygen by gate voltage. This toggling of PMA under positive bias does not require oxidation of the Co layer, in contrast to earlier work by Uwe *et al.* We demonstrate that by optimizing the electrode materials, extremely fast room-temperature switching can be achieved in these devices.

**8:48AM X19.00003 Giant enhancement of magnetocrystalline anisotropy in ultrathin manganese films via nanoscale 1D periodic depth modulation**, ANIL RAJAPITAMAHUNI, LE ZHANG, VIJAY SINGH, JOHN BURTON, MAK KOTEN, JEFFREY SHIELD, EVGENY TSYMBAL, XIA HONG, University of Nebraska-Lincoln — We report a unusual giant enhancement of in-plane magnetocrystalline anisotropy (MCA) in ultrathin colossal magnetoresistive oxide films due to 1D nanoscale periodic depth modulation. High quality epitaxial thin films of  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$  (LSMO) of thickness 6 nm were grown on (001)  $\text{SrTiO}_3$  substrates via off-axis radio frequency magnetron sputtering. The top 2 nm of LSMO films are patterned into periodic nano-strips using e-beam lithography and reactive ion etching. The resulting structure consists of nano-strips of 2 nm height and 100-200 nm width on top of a 4 nm thick continuous base layer. We employed planar Hall effect measurements to study the in-plane magnetic anisotropy of the unpatterned and nanopatterned films. The unpatterned films show a biaxial anisotropy with easy axis along [110]. The extracted anisotropy energy density is  $\sim 1.1 \times 10^5$  erg/cm<sup>3</sup>, comparable to previously reported values. In the nanopatterned films, a strong uniaxial anisotropy is developed along one of the biaxial easy axes. The corresponding anisotropy energy density is  $\sim 5.6 \times 10^6$  erg/cm<sup>3</sup> within the nano-striped volume, comparable to that of Co. We attribute the observed uniaxial MCA to  $\text{MnO}_6$  octahedral rotations/tilts and the enhancement in the anisotropy energy density to the strain gradient within the nano-strips.

**9:00AM X19.00004 Magnetoelectric Dead Layer and Uncompensated Spins in Magnetic/Ferroelectric Heterostructures**, MIKEL HOLCOMB, CHIH-YEH HUANG, JINLING ZHOU, ROBBYN TRAPPEN, GUERAU CABRERA, West Virginia University, YING-HAO CHU, National Chiao Tung University, WEST VIRGINIA UNIVERSITY TEAM, NATIONAL CHIAO TUNG UNIVERSITY TEAM — Interfacial magnetoelectricity across a multilayer system is known to sometimes result in much larger coupling between electric and magnetism than in single phase systems. We compared the magnetic domains in  $\text{LaSrMnO}_3$  thin films, ferroelectric domains in  $\text{PbZrTiO}_3$  and observed uncompensated spin at the interface. Several techniques to quantify image contrast switching between left and right circularly polarized x-ray absorption spectra of magnetic domains and uncompensated spin were developed and gave similar results. Not surprisingly, the magnetic domain switching increased with magnetic film thickness, but the uncompensated spin did as well. This results suggests that there may be an effective magnetoelectric dead layer at the interface between coupled magnetic and ferroelectric layers, which is likely linked to at least the magnetic dead layer in the magnetic film. These measurements were taken by L-edge spectromicroscopy at the PEEM3 beamline of the Advanced Light Source.

**9:12AM X19.00005 Magnetoelectric Coupling Characteristics of the  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3/\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3(001)$  Interface<sup>1</sup>**, MAHMOUD HAMMOURI, DMITRY KARPOV, New Mexico State University, EDWIN FOHTUNG, New Mexico State University and Los Alamos National Laboratory, IGOR VASILIEV, New Mexico State University — Multiferroic heterostructures composed of thin layers of ferromagnetic and ferroelectric perovskites have attracted considerable attention in recent years. We apply *ab initio* computational methods based on density functional theory to study the characteristics of the magnetoelectric coupling at the (001) interface between  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$  (LSMO) and  $\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3$  (PZT). The calculations are carried out using the Quantum ESPRESSO electronic structure code combined with Vanderbilt ultrasoft pseudopotentials. Our study shows that the interfacial interaction between LSMO and PZT and the polarization of PZT have a strong influence on the distribution of magnetization within the LSMO layer. A significant change in the magnetization of the LSMO layer adjacent to PZT is observed after reversal of the direction of polarization of PZT.

**9:24AM X19.00006 Large enhancement of magnetic anisotropy and laser induced resistive switching effect in  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  films due to strain from  $\text{BaTiO}_3$  substrates<sup>1</sup>**, V KALAPPATTIL, R DAS, H SRIKANTH, M.H PHAN, Department of Physics, University of South Florida, X MOYA, Department of Materials Science, University of Cambridge, UK — Multifunctional oxide materials are interesting for their fundamental physical properties and technological applications. Epitaxial films of  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  (LSMO) on  $\text{BaTiO}_3$  (BTO) show intriguing properties such as a giant magnetoelectric effect due to strain from BTO substrate. The LSMO film shows sharp jumps in magnetization  $M(T)$  and resistance  $R(T)$  at first-order structural phase transitions of BTO ( $T_{R-O}$  200K and  $T_{O-T}$  270 K) due to strain coupling from BTO. A temperature evolution of effective in-plane anisotropy field ( $H_K$ ) measured using the radio-frequency transverse susceptibility (TS) shows a sharp increase in  $H_K$  around  $T_{R-O}$ , which vanishes around  $T_{O-T}$ . The in-plane magnetic anisotropy plays an important role in changing the magnetic and resistive states around  $T_{O-T}$ . A switchable laser-induced resistive change of up to 300 %, which is about 10 times greater than those of conventional oxide systems, has been achieved in LSMO films using a 0.5 W violet laser just below the  $T_{O-T}$ . The repeatability and stability of the laser-induced resistive switching effect reveal potential applications of LSMO/BTO heterostructures in developing new type of temperature sensors and memory devices.

**9:36AM X19.00007 Reversible Control of Magnetism in  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$  through Chemically-Induced Oxygen Migration**, ALEXANDER GRUTTER, DUSTIN GILBERT, BRIAN MARANVILLE, JULIE BORCHERS, BRIAN KIRBY, National Institute of Standards and Technology, ELKE ARENHOLZ, Lawrence Berkeley National Lab, URUSA ALAAN, YURI SUZUKI, Stanford University, KAI LIU, University of California, Davis — There has been a surge of interest in controlling magnetism through oxygen migration for applications in hybrid ionic/magnetoelectric device architectures. With a rich magnetic and electronic phase diagram, the colossal magnetoresistive perovskite  $(\text{La,Sr})\text{MnO}_3$  (LSMO) is an ideal candidate for achieving large modulations in magnetic properties with small changes in oxygen content. We demonstrate reversible control of magnetism in LSMO films through interfacial oxygen migration. Gd metal capping layers deposited onto LSMO leach oxygen from the film to form porous  $\text{Gd}_2\text{O}_3$ . X-ray absorption and polarized neutron reflectometry measurements show Mn valence alterations consistent with high oxygen vacancy concentrations, resulting in suppressed magnetization and increased coercive fields. Oxygen migration is observed both at the interface and also throughout the majority of a 40 nm thick film, suggesting extensive oxygen vacancy diffusion. After Gd-capped LSMO is exposed to atmospheric oxygen for a prolonged period of time, oxygen diffuses through the  $\text{Gd}_2\text{O}_3$  layer and the magnetization of the LSMO returns to the uncapped value. These findings showcase perovskite heterostructures as ideal candidates for developing functional interfaces through chemically-induced oxygen migration.

**9:48AM X19.00008 Detecting interfacial defects at magnetic/non-magnetic junctions<sup>1</sup>**, NICHOLAS HARMON, MICHAEL FLATTÉ, University of Iowa — Recent three terminal (3T) measurements in  $\text{Co/LaAlO}_3/\text{SrTiO}_3$  show that spin-dependent transport through an interfacial defect is occurring instead of Hanle dephasing [1]. We propose extending 3T measurements into a coherent regime where single defects are detected by their local fields. The setup involves defects being situated between biased non-magnetic (NM) and ferromagnetic (FM) contacts. Spin torque on the FM drives an AC magnetization. Due to the large exchange interaction, the ability for charge to enter the FM depends on its spin and FM's relative orientation. As the FM precesses, the spin is dynamically filtered and a precessing spin accumulation remains at the defect. Local fields also precess the defect spin and interfere with the dynamic spin filtering. If the AC and local field are resonant, the spin accumulation is locked anti-parallel to the FM and leads to a dip in current. By adjusting the AC frequency, information on the local field is ascertained which, for hyperfine local fields, tells which nuclei are present at the defect and aids in identifying the defect. In the DC limit, defect spin accumulation leads to modifications in Hanle signals. [1] H. Inoue, A.G. Swartz, N.J. Harmon, M.E. Flatté, T. Tachikawa, Y. Hikita, and H.Y. Hwang. In press at Phys. Rev. X.

**10:00AM X19.00009 Electronic and Magnetic Properties of Transition-Metal Oxide Nanocomposites: A Tight-Binding Modeling at Mesoscale.**<sup>1</sup>, YUAN-YEN TAI, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, JIAN-XIN ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — Transition metal oxides (TMOs) exhibit many emergent phenomena ranging from high-temperature superconductivity and giant magnetoresistance to magnetism and ferroelectricity. In addition, when TMOs are interfaced with each other, new functionalities can arise, which are absent in individual components. In this talk, I will present an overview on our recent efforts in theoretical understanding of the electronic and magnetic properties TMO nanocomposites. In particular, I will introduce our recently developed tight-binding modeling of these properties arising from the interplay of competing interactions at the interfaces of planar and pillar nanocomposites. Our theoretical tool package will provide a unique capability to address the emergent phenomena in TMO nanocomposites and their mesoscale response to such effects like strain and microstructures at the interfaces, and ultimately help establish design principles of new multifunctionality with TMOs.

**10:12AM X19.00010 Direct measurement of voltage-controlled reversal of the antiferromagnetic spin structure in magnetoelectric Cr<sub>2</sub>O<sub>3</sub>**<sup>1</sup>, JUNLEI WANG, CHRISTIAN BINEK, University of Nebraska-Lincoln — The frequency dependence of the electric field induced magneto-optical Faraday effect is investigated in the magnetoelectric antiferromagnet chromia. Two electrically induced Faraday signals superimpose in proportion to the linear magnetoelectric susceptibility and the antiferromagnetic order parameter. The relative strength of these contributions is determined by the frequency of the probing light beam. It allows tuning the Faraday signal between extreme characteristics which follow the temperature dependence of the magnetoelectric susceptibility or solely that of the antiferromagnetic order parameter. The frequency dependence is analyzed in terms of electric dipole transitions of perturbed Cr<sup>3+</sup> crystal-field states. The results lead to a table-top set-up allowing to measure voltage-controlled selection and temperature dependence of the antiferromagnetic order parameter. The Faraday rotation per applied voltage is independent of the sample thickness making the method scalable and versatile for thin film investigations. Scalability, compactness, and simplicity of the data analysis combined with low photon flux requirements make the Faraday approach advantageous for the investigation of the otherwise difficult to access voltage-controlled switching of antiferromagnetic domain states in magnetoelectric thin films.

**10:24AM X19.00011 Voltage Control of Exchange Bias in a Chromium Oxide Based Thin Film Heterostructure**<sup>1</sup>, WILL ECHTENKAMP, MIKE STREET, ATHER MAHMOOD, CHRISTIAN BINEK, Univ of Nebraska - Lincoln — Controlling magnetism by electrical means is a key challenge in the field of spintronics, and electric control of exchange bias is one of the most promising routes to address this challenge. Isothermal electric control of exchange bias has been achieved near room temperature using bulk, single crystal, magnetoelectric Cr<sub>2</sub>O<sub>3</sub> [1,2]. In this study the electrically-controlled exchange bias is investigated in an all thin film Cr<sub>2</sub>O<sub>3</sub>/PdCo exchange bias heterosystem where an MBE grown ferromagnetic and perpendicular anisotropic Pd/Co multilayer has been deposited on a PLD grown (0001) Cr<sub>2</sub>O<sub>3</sub> thin film. Prototype devices are fabricated using lithography techniques. Using a process of magnetoelectric annealing, voltage control of exchange bias in Cr<sub>2</sub>O<sub>3</sub> heterostructures is demonstrated with significant implications for scalability of ultra-low power memory and logical devices. In addition, the dependence of the exchange bias on the applied electric and magnetic fields are independently studied at 300K and isothermal voltage-controlled switching is investigated. [1] Xi He, et. al., Nature Mater.9, 579585 (2010). [2] W. Echtenkamp and Ch. Binek, Phys. Rev. Lett. 111, 187204 (2013).

**10:36AM X19.00012 Eliminating leakage current in voltage-controlled exchange-bias devices**<sup>1</sup>, ATHER MAHMOOD, WILL ECHTENKAMP, MICHAEL STREET, CHRISTIAN BINEK, Univ of Nebraska - Lincoln, MAGNETIC HETEROSTRUCTURES TEAM — Manipulation of magnetism by electric field has drawn much attention due to the technological importance for low-power devices, and for understanding fundamental magnetoelectric phenomena. A manifestation of electrically controlled magnetism is voltage control of exchange bias (EB). Robust isothermal voltage control of EB was demonstrated near room temperature using a heterostructure of Co/Pd thin film and an exchange coupled single crystal of the antiferromagnetic Cr<sub>2</sub>O<sub>3</sub> (Chromia) [1,2]. A major obstacle for EB in lithographically patterned Chromia based thin-film devices is to minimize the leakage currents at high electric fields (>10 kV/mm). By combining electrical measurements on patterned devices and conductive Atomic Force Microscopy of Chromia thin-films, we investigate the defects which form conducting paths impeding the application of sufficient voltage for demonstrating the isothermal EB switching in thin film heterostructures. Technological challenges in the device fabrication will be discussed. [1] Xi He, et.al, Nat. Mater. 9, 579-585 (2010) [2] W. Echtenkamp, Ch. Binek, Phys. Rev. Lett. 111, 187204 (2013)

**10:48AM X19.00013 Electrostatic doping limits and control of magnetism in electrolyte gated LaAlO<sub>3</sub>(001)/La<sub>0.5</sub>Sr<sub>0.5</sub>CoO<sub>3-δ</sub> thin films**, JEFF WALTER, HELIN WANG, CHRIS LEIGHTON, University of Minnesota — Recently developed ionic liquid/gel gating techniques have proven remarkably expedient in the study of charge density effects in a variety of conductors, ranging from organics to complex oxides. Here we present electrolyte gate control of magnetism in ultrathin (8 u.c.) La<sub>0.5</sub>Sr<sub>0.5</sub>CoO<sub>3-δ</sub> (LSCO) films, using ion gels in electric double layer transistors. The LSCO films are initially metallic and ferromagnetic ( $T_c \approx 170$  K), with anomalous Hall conductivity up to 40 S/cm, and strong perpendicular magnetic anisotropy. Based on extensive temperature and gate voltage dependences we first determined the limits for electrostatic vs. electrochemical operation, concluding that negative bias enables reversible hole accumulation, whereas positive bias irreversibly induces oxygen vacancies. Following this we demonstrated clear voltage-control of resistivity, magnetoresistance, and  $T_c$ . Utilizing the anomalous Hall conductivity as an exceptional probe of the magnetic order parameter in the gated surface region, a 12 K shift in  $T_c$  is obtained. This compares favorably to the state-of-the-art and exhibits potential for much larger modulation in films of lower Sr content. Work supported by NSF MRSEC.

Session X20 DMP: Van der Waals Bonding in Advanced Materials: Carbon Allotropes and Boron Nitride 319 - John Singleton, Los Alamos National Laboratory

**8:00AM X20.00001 Growth systematics for the controlled generation of nanostructured materials**, NICOLE GROBERT, University of Oxford — Whilst nanomaterials are well established in the research arena they are yet to be exploited at the industrial scale due to their limited availability. A series of bottlenecks must still be overcome before their outstanding properties can be fully unlocked. This fact applies to nanomaterials across the board including tailored 0D, 1D, 2D structures and combinations thereof. This talk addresses the challenges that need to be overcome related to up-scaling the production of novel nanomaterials, possible solutions and the necessity for the development of dedicated nanomaterials for end- user applications will also be discussed.

**8:36AM X20.00002 Investigation of intermolecular interactions between single walled nanotubes and conjugated oligomers using the dispersion-corrected DFT methods<sup>1</sup>**, JOLANTA B LAGOWSKI, SUAD ALJOHANI, M. ZAHIDUL H. KHAN, YUMING ZHAO, Memorial University — The area of carbon nanotubes (CNT)-polymer composites has been progressing rapidly in recent years. Pure CNT and CNT-polymer composites have many useful (industry related) properties: ranging from electronic electrical conductivity to superior strength. However the full potential of using CNTs as reinforcements (in say a polymer matrix) has been severely limited because of complications associated with the dispersion of CNTs. CNTs tend to entangle with each other forming materials that have properties that fall short of the expectations. The goal of this work is to identify the type of conjugated oligomers that are best suited for the dispersion of single walled CNT (SWCNT). For this purpose, various methods of dispersion corrected density functional theory (DFT-D/B97D, /WB97XD, /CAM-B3LYP) have been used to investigate the interaction between the SWCNT and the organic conjugated oligomers with different end groups (aldehyde (ALD) and dithiafulvenyl (DTF)). We investigate the effect of intermolecular interactions on the structure, polarity and energetics of the oligomers and SWCNT combinations. The comparison of results obtained using different DFT approximations is made. Our results show that DFT-endcapped oligomer interact more strongly with CNT than ALD-endcapped oligomer.

**8:48AM X20.00003 Probing moiré physics in low angle twisted bilayer graphene**, YUAN CAO, JASON LUO, Massachusetts Inst of Tech-MIT, JAVIER D. SANCHEZ-YAMAGISHI, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, Japan, PABLO JARILLO-HERRERO, Massachusetts Inst of Tech-MIT — When two sheets of honeycomb structured graphene are stacked together, a moiré pattern that depend on the twist angle forms. A gapped superlattice band structure is resulted when this angle is small enough so that the energy of moiré modulated hybridization between wave functions on the two sheets that are separated by only 0.34nm is low enough. Apart from the energy gaps, the superlattice band structure also manifests reduced Fermi velocity which implies comparatively higher density of states, multiple van Hove singularities below and above the gaps, and Hofstadter butterfly physics when magnetic field is applied. We show electronic transport measurements of high-quality low-angle twist bilayer graphene devices fabricated by a novel tear-and-stack technique, at zero, low and high magnetic fields. We also present angle dependence of the electronic structure along with magneto-transport features that possibly imply electron-electron interactions. A brief discussion about the transition between the low-twist and high-twist bilayer graphene, the physics of the latter of which is believed to be essentially based on decoupled monolayer graphene according to our previous work, is included.

**9:00AM X20.00004 Moire pattern interlayer potentials in van der Waals materials from high level ab initio calculations**, JEIL JUNG, NICOLAS LECONTE, University of Seoul, Korea, SEBASTIEN LEBEGUE, Université de Lorraine, France, TIMOTHY GOULD, Griffith University, Australia — Stacking-dependent interlayer interactions are important for understanding the structural and electronic properties in incommensurable two dimensional material assemblies where long-range moiré patterns arise due to small lattice constant mismatch or twist angles. We study the stacking-dependent interlayer coupling energies between graphene (G) and hexagonal boron nitride (BN) single layers for different possible combinations such as G/G, G/BN and BN/BN using high-level EXX+RPA *ab initio* calculations. The total energies differ substantially when compared with conventional LDA, but for stacking-dependent total energy differences we find that the dominance of short-range covalent-type binding over the longer-ranged van der Waals tails near equilibrium geometries renders the LDA as a reasonable starting point for ab initio calculation based analyses for the systems we have studied. Our calculations are useful input for study of strains originated by interlayer interactions in incommensurable 2D van der Waals crystals.

**9:12AM X20.00005 Near-field study in graphene/hBN moiré superlattices.**, GUANGXIN NI, University of California, San Diego, HAOMIN WANG, Shanghai Institute of Microsystem and Information Technology, JIHI-SHENG WU, ZHE FEI, MICHAEL GOLDFLAM, FRITZ KEILMANN, University of California, San Diego, BARBAROS ZYLMAZ, ANTONIO CASTRO NETO, National University of Singapore, XIAOMING XIE, Shanghai Institute of Microsystem and Information Technology, MICHAEL FOGLER, DIMITRI BASOV, University of California, San Diego — Moiré patterns are periodic superlattice structures that appear when two crystals with a minor lattice mismatch are superimposed. A prominent recent example is that of monolayer graphene placed on a crystal of hexagonal boron nitride (hBN). As a result of the moiré pattern superlattice created by this stacking, the electronic band structure of graphene is radically altered, acquiring satellite sub-Dirac cones at the superlattice zone boundaries. To probe dynamical response of the moiré graphene, we use infrared (IR) nano-imaging to explore propagation of surface plasmons, collective oscillations of electrons coupled to IR light. We show that interband transitions associated with the superlattice minibands in concert with free electrons in the Dirac bands produce two additive contributions to composite IR plasmons in graphene moiré superstructures. This novel form of collective modes is likely to be generic to other forms of moiré-forming superlattices, including van der Waals heterostructures.

**9:24AM X20.00006 Optical control of inter-layer distance of hBN: a TDDFT study**, YOSHIYUKI MIYAMOTO, AIST, HONG ZHANG, Sichuan University, TAKEHIDE MIYAZAKI, AIST, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — In this presentation, we introduce an idea to modify inter-layer distance of hBN by shining IR laser in resonance with the frequency of the optical phonon ( $A_{2u}$  mode). By performing the TDDFT-MD simulation under the IR laser, significant grow in an amplitude of the  $A_{2u}$  phonon mode was observed and inter-layer contraction over 11 % of the original distance was achieved. The source of the stronger attraction of hBN sheets was attributed with increase of dipole moment of each layer coming from the motions of boron (B) and nitrogen (N) atoms in opposite directions. Since the dipole moments of these layers remain as parallel throughout the  $A_{2u}$  phonon vibration, the increase of attractive force occurs between the two hBN sheets in analogy of the London force. In this talk, we will further discuss proper intensity of IR laser and potential applications of this phenomenon. This work was published in Phys. Rev. Lett **114**, 116102 (2015).

**9:36AM X20.00007 Using quantum Monte Carlo for the interaction of water with carbon and BN based substrates and assessing exchange-correlation functionals**, YASMINE AL-HAMDANI, Department of Chemistry, University College London and Thomas Young Centre, DARIO ALFE, Department of Earth Sciences, University College London and Thomas Young Centre, O. ANATOLE VON LILIENFELD, Argonne National Laboratories, Argonne, and Institute of Physical Chemistry, Chemistry Department, University of Basel, ANGELOS MICHAELIDES, Department of Physics, University College London and Thomas Young Centre — The interaction of water with the pure surfaces, graphene and hexagonal boron nitride (h- BN), has received a lot of attention because of interesting phenomena exhibited by these systems and their promising potential applications in clean energy, water purification, hydrogen storage, and bio-sensing. BN doped graphene can also now be made, opening the way to carefully designed hybrid materials. However, much of the fundamental mechanisms regarding the interaction between these surfaces and water is still not well understood. We use quantum Monte Carlo to establish accurate benchmarks for water on a number of carbonaceous and BN based substrates, including 2-dimensional periodic surfaces, for which van der Waals interactions play a key role. The benchmarks are then used to test and understand various exchange-correlation functionals in density functional theory. We find that the physisorption of water is poorly described in terms of the adsorption site and the interaction energy by a range of different classes of exchange- correlation functionals, including some that account for dispersion, and we show where these inadequacies might come from.

**9:48AM X20.00008 'Guanigma': the revised structure of biogenic anhydrous guanine**, ANNA HIRSCH, DVIR GUR, Weizmann Institute of Science, Israel, IRYNA POLISHCHUK, DAVIDE LEVY, BOAZ POKROY, Technion, Israel, AURORA J. CRUZ-CABEZA, University of Manchester, United Kingdom, LIA ADDADI, LEEOR KRONIK, LESLIE LEISEROWITZ, Weizmann Institute of Science, Israel — Living organisms display a spectrum of colors, produced by pigmentation, structural coloration, or both. A relatively well-studied system, which produces colors via an array of alternating anhydrous guanine crystals and cytoplasm, is responsible for the metallic luster of many fish. The structure of biogenic anhydrous guanine was believed to be the same as that of the synthetic one - a monoclinic polymorph. Here we re-examine the structure of biogenic guanine, using experimental X-ray and electron diffraction (ED) data exposing troublesome inconsistencies - namely, a 'guanigma'. To address this, we sought alternative candidate polymorphs using symmetry and packing considerations, then used first principles calculations to determine whether the selected candidates could be energetically stable. We identified theoretically a different monoclinic polymorph, were able to synthesize it, and to confirm using X-ray diffraction that it is this polymorph that occurs in biogenic samples. However, the ED data were still not consistent with this polymorph, but rather with a theoretically generated orthorhombic polymorph. This apparent inconsistency was resolved by showing how the ED pattern could be affected by crystal structural faults composed of offset molecular layers.

**10:00AM X20.00009 Sorption Properties of Halogen Containing Graphene Oxide Frameworks.**, JACOB BURRESS, ELIZABETH BAKER, DONALD BETHEA, KATHERINE FRANGOS, Univ of South Alabama — Physisorption of gases has applications in gas storage (e.g. methane, hydrogen for vehicles) and gas separation (carbon dioxide from flue gas). The van der Waals force in narrow pores is strong enough to condense even supercritical gases to much higher densities. Additionally, differences in the binding energy between different gases and the sorbent surface are sufficient to for gas separations. Beyond adsorption interactions, simple steric (size, shape) effects also play a role in gas separations. One class of materials currently being investigated for numerous gas storage/separation applications is graphene oxide frameworks (GOFs). GOFs consist of layers of graphene/graphene oxide separated by chemical linkers covalently bonded on both sides. This presentation will give results from boronic acid-based GOFs that contain halogen group elements. Effects of different linkers on pore shape will be presented. Physical behavior of the gases investigated (hydrogen, methane, carbon dioxide, nitrogen), including binding energies and steric effects for gas separation will also be presented. The physics mechanism behind pore breathing (expansion and contraction of pore volume) in these materials will be discussed.

**Session X21 GSCCM DCOMP DMP: Materials in Extremes: Metals at High Strain Rates** 320

- Tim Germann, Los Alamos National Laboratory

**8:00AM X21.00001 Elastic-plastic structure of shock waves in single crystal copper<sup>1</sup>**, R. RAVELO, Univ of Texas, El Paso, B.L. HOLIAN, T.C. GERMANN, Los Alamos National Laboratory — Large-scale atomistic simulations of shock wave propagation in defect-free copper single crystals exhibit an orientation dependent elastic limit and elastic-plastic two-wave regimes for shock propagation along the (110) and (111) low-index directions but not along (100). By contrast, no orientational difference in the Us-Up profiles of single crystals compared with polycrystalline samples has been reported in shock experiments. The elastic-plastic response of copper shocked along (111) was examined via large-scale non-equilibrium molecular dynamics (NEMD) simulations employing samples of up to 3.5 microns in length and particle velocities between 0.5 and 2.5 km/s (20- 130 GPa). The longer time and length scales allow for a more accurate determination of the elastic limit, longitudinal and plastic wave speeds. Results show a steady elastic precursor for particle velocities below 1.6 km/s, which does not decay in time. The NEMD data for the plastic wave velocity in the split-wave regime extrapolates linearly in particle velocity to the shear-wave speed at zero pressure.

**8:12AM X21.00002 Tantalum strength model incorporating temperature, strain rate and pressure**, HOJUN LIM, CORBETT BATTAILE, JUSTIN BROWN, MATT LANE, Sandia National Laboratories — Tantalum is a body-centered-cubic (BCC) refractory metal that is widely used in many applications in high temperature, strain rate and pressure environments. In this work, we propose a physically-based strength model for tantalum that incorporates effects of temperature, strain rate and pressure. A constitutive model for single crystal tantalum is developed based on dislocation kink-pair theory, and calibrated to measurements on single crystal specimens. The model is then used to predict deformations of single- and polycrystalline tantalum. In addition, the proposed strength model is implemented into Sandia's ALEGRA solid dynamics code to predict plastic deformations of tantalum in engineering-scale applications at extreme conditions, e.g. Taylor impact tests and Z machine's high pressure ramp compression tests, and the results are compared with available experimental data. Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**8:24AM X21.00003 Molecular simulation of dislocation motion in magnesium alloys under high strain rates**, PENG YI, ROBERT CAMMARATA, MICHAEL FALK, Johns Hopkins University — Dislocation motion of  $\langle a \rangle$ -dislocations on the basal and the prismatic planes under simple shear was studied using molecular simulations in Mg/Al and Mg/Y alloys. The critical resolved shear stress (CRSS) was calculated at temperature from 0K to 500K with solute concentrations from 0 to 7 at.%. The strain rates of  $10^6$ - $10^8$  s<sup>-1</sup> used in the simulation correspond to experimental strain rates of  $10^1$ - $10^5$  s<sup>-1</sup> based on Orowan's equation. Basal slip is dominated by the  $\langle a \rangle$ -edge dislocations. Solute hardening to the CRSS follows a power law,  $c^n$ , where  $c$  is the solute concentration. The exponent  $n$  transitions from close to 2/3 at low temperature to close to 1 at high temperature. Temperature and strain rate effects on the CRSS are captured by Kocks model based on thermally activated events. Prismatic slip is controlled by the  $\langle a \rangle$ -screw dislocation that cross-slips between the basal and the prismatic planes, in a locking-unlocking pattern. Temperature affects the slip kinetics through the diffusion of the screw dislocation on the basal plane, which leads to vacancy and loop generation. Solute softening was observed for both Mg/Al and Mg/Y alloys. The softening on prismatic slip is due to the solute pinning effect on the basal plane, and Al is more effective in softening.

**8:36AM X21.00004 Simulating the dynamic response of magnesium alloys**, JEFFREY LLOYD, RICHARD BECKER, US Army Research Laboratory — Unlike several conventional metals, the mechanical response of magnesium is severely anisotropic for quasistatic and dynamic loading conditions. In this work we present a crystal-based strength model that is the same order of magnitude in computational cost as rate-dependent isotropic strength models, yet is able to capture essential features exhibited by textured magnesium polycrystals. The model demarcates plastic deformation into contributions from basal slip, extension twinning, and non-basal slip mechanisms. Comparisons are made between model predictions and experiments for two magnesium alloys with differing processing histories. The model is then used to explore and quantify the dependence of metallurgical and processing variations for several dynamic experiments that probe propensity for localization and failure under complex loading conditions.

**8:48AM X21.00005 Deformation twinning in a polycrystalline magnesium alloy during dynamic compression**, CALEB HUSTEDT, Johns Hopkins University, JEFFREY LLOYD, Army Research Laboratory, PAUL LAMBERT, VIGNESH KANNAN, Johns Hopkins University, DANIEL CASEM, Army Research Laboratory, K.T. RAMESH, Johns Hopkins University, NICHOLAS SINCLAIR, Washington State University, RICHARD BECKER, Army Research Laboratory, TODD HUFNAGEL, Johns Hopkins University — We report the results of combined in situ x-ray diffraction studies and crystal plasticity modeling of deformation twinning in polycrystalline magnesium during dynamic compression. Diffraction experiments were conducted at the Dynamic Compression Sector (DCS) of the Advanced Photon Source, on magnesium alloy (AZ31B) specimens (with various crystallographic textures) loaded at strain rates of  $\sim 1000 \text{ s}^{-1}$  in a compression Kolsky bar. The diffraction patterns, recorded with temporal resolution of 5-10 microseconds, provide information about the evolution of crystallographic texture during deformation, which we interpret in terms of the twinning mechanism (so-called “extension” or “tensile” twinning). We compare our observations quantitatively with predictions of the evolution of crystallographic texture from an efficient reduced crystal plasticity model. This model explicitly accounts for basal slip and extension twinning on a rate-independent basis, but treats other mechanisms (pyramidal and prismatic slip) as isotropic, rate-dependent functions. This combination yields substantial improvements in efficiency over full crystal-plasticity models while retaining key aspects of the most important deformation mechanisms.

**9:00AM X21.00006 Deformation twinning activated  $\alpha \rightarrow \omega$  transformation in titanium under shock compression.**, HONGXIANG ZONG, TURAB LOOKMAN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — Materials dynamics, especially the behavior of solids under extreme compression, is a topic of broad scientific and technological interest. However, less is known of the role of grain boundary structures on the shock response of hexagonal-close-packed metals. We use molecular dynamics simulations to study deformation mechanisms in shock compressed Ti bicrystals containing three types of grain boundary (GB) microstructures, i.e., coherent twin boundaries (CTBs), symmetric incoherent twin boundaries (ITB) and  $\{1\text{-}210\}$  asymmetric tilt grain boundaries. Our results show that both dislocation activity and the  $\alpha \rightarrow \omega$  phase transformation in Ti are sensitive to the GB characteristics. In particular, we find that the elastic shock wave can readily trigger the  $\alpha \rightarrow \omega$  transformation at CTBs but not at the other two GBs, and the activation of the  $\alpha \rightarrow \omega$  transformation at CTBs leads to considerable wave attenuation (i.e., the elastic precursor decay). Combined with first principle calculations, we find that CTBs can facilitate the overcoming of the energy barrier for the  $\alpha \rightarrow \omega$  transformation. Our findings have potential implications for interface engineering and materials design under extreme conditions.

**9:12AM X21.00007 Microstructural Effects on Materials under Extreme Dynamic Environments**, CYRIL WILLIAMS, U.S. Army Research Laboratory — Studies have shown that microstructure and microstructure evolution can play a major role on the shock response of metals and metallic alloys. When metals and metallic alloys are deformed during shock compression, large numbers of lattice defects such as dislocations can be introduced in the material. These dislocations can lead to strengthening effects such as hardening and/or softening such as dynamic recovery which may consequently change the material behavior. Therefore, to better understand the effects of microstructure and microstructure evolution on the spall response of metals, both in-situ and end-state gas gun plate impact experiments were employed to study 1100-O aluminum. The results show a sharp increase in pullback velocity for 1100-O aluminum with increase in peak shock stress between 4.0 and 8.3 GPa due to shock hardening, followed by a decrease for peak shock stresses up to 12.0 GPa due to softening induced by dynamic recovery. In addition, the effects of microstructure on the spall properties of two magnesium alloys fabricated via ECAE (AZ31B-4E) and SWAP (AMX602) were also investigated. The pullback velocities were found to decrease by approximately 15% for AZ31B-4E between 1.7 GPa to 4.6 GPa shock stress. On the contrary, the pullback velocities for AMX602 were found to be random for the same shock stress range studied. Residual microstructure of the post-shocked AZ31B-4E magnesium shows that aluminum-manganese intermetallic inclusions were perhaps responsible for the reduction in pullback velocity. Also, the post-shocked residual microstructure of the AMX602 magnesium revealed features that may have been responsible for its random response.

**9:24AM X21.00008 Damage Tolerant Microstructures for Shock Environments**, ELLEN CERRETA, DARCIE DENNIS-KOLLER, LANL, JUAN PABLO ESCOBEDO, University of New South Wales, SARYU FENSIN, STEVE VALONE, CARL TRUJILLO, CURT BRONKHORST, RICARDO LEBENSOHN, LANL — While dynamic failure, due to shock loading, has been studied for many years, our current ability to predict and simulate evolving damage during dynamic loading remains limited. One reason for this is due to the lack of understanding for the linkages between process-induced as well as evolved microstructure and damage. To this end, the role of microstructure on the early stages of dynamic damage has been studied in high purity Ta and Cu. This work, which utilizes plate-impact experiments to interrogate these effects, has recently been extended to a subset to Cu-alloys (Cu-Pb, Cu-Nb, and Cu-Ag). These multi-length scale studies, have identified a number of linkages between damage nucleation and growth and microstructural features such as: grain boundary types, grain boundary orientation with respect to loading direction, grain orientation, and bi-metal interfaces. A combination of modeling and simulation techniques along with experimental observation has been utilized to examine the mechanisms for the ductile damage processes such as nucleation, growth and coalescence. This work has identified differing features of importance for damage nucleation in high purity and alloyed materials, lending insight into features of concern for mitigating shock induced damage in more complicated alloy systems.

**9:36AM X21.00009 Rate-dependent scaling laws for spall failure**, JUSTIN WILKERSON, University of Texas at San Antonio, KT RAMESH, Hopkins Extreme Materials Institute — Here we derive simple bounds on the growth rate of voids considering the combined retarding effects of micro-inertia and dislocation kinetics. We make use of these bounds to derive simple scaling laws capable of predicting the strong rate-dependence of spall strength. We show that the rate-sensitivity exponent for spall strength is bounded to below  $6/7$  when micro-inertia is the dominant retarding effect on void growth. However, under conditions in which the void growth is predominately governed by dislocation kinetics the rate-sensitivity exponent may rise to a maximum value of 1. With these scaling laws in hand, we go on to further explore the role of microstructure on spall strength. Though simple, the derived scaling laws compare well with experimental measurements and prove useful in shedding light on some of the more perplexing observations associated with spall failure. In particular, the scaling laws are helpful in understanding the somewhat anomalous dependence of spall strength on pre-existing microstructure, e.g. grain size and purity content.

**9:48AM X21.00010 Diffusion of Dissipative Correlation in the Dynamic Failure of Solids**, DENNIS GRADY, Applied Research Associates — A property identified as the dissipative action has found application as a unifying attribute underlying the dynamic failure of solid materials. Failure modes include tensile spall, impact-induced dynamic shear, shock compaction and steady shock-wave compression. The present work explores the possible application of Langevin dynamics and related statistical mechanical implications as underlying the extreme dynamic failure of solids.

**10:00AM X21.00011 A model for ductile metal friction at high velocities<sup>1</sup>** , J. E. HAMMERBERG, Los Alamos National Laboratory, R.J. RAVELO, Univ. of Texas - El Paso, T.C. GERMANN, Los Alamos National Laboratory — We describe a meso-macro scale model for the frictional force at ductile metal interfaces for high velocities and large compressions. The model incorporates the micro-mesoscopic growth and refinement of material microstructure in a highly strained region at the sliding interface and incorporates both rate dependent plasticity and thermal conduction. The model compares favorably with recent large scale (1.8 billion atom) simulations to 50 ns of 3-dimensional polycrystalline 13-50 nm grain size Al-Al interfaces at pressures of 15 GPa using the SPaSM NonEquilibrium Molecular Dynamics (NEMD) simulation code.

<sup>1</sup>This work was performed under the auspices of the U.S. Dept. of Energy under contract DE-AC52-06NA25396. The support of the LANL ASC-PEM program is gratefully acknowledged.

**10:12AM X21.00012 Novel Feed-through Richtmyer-Meshkov Instability (RMI) Experiment for Characterization of Dynamic Material Response<sup>1</sup>** , SAUL OPIE, SUDRISHTI GAUTAM, ELIZABETH FORTIN, JENNA LYNCH, Arizona State University, ERIC LOOMIS, Los Alamos National University, PEDRO PERALTA, Arizona State University — Hydrodynamic instabilities occur often in applications where forces act across a bimaterial interface. In Rayleigh-Taylor (RT) instabilities, surface perturbations grow exponentially under opposing pressure and density gradients. In the closely related Richtmyer-Meshkov (RM) instability, the same perturbations grow linearly due to an impulsive acceleration, e.g., a passing shock wave. These effects are often analyzed with linear fluid theory, but it is well known that for materials possessing shear strength the perturbation evolution can be significantly affected. A challenge in modeling these effects is that existing knowledge of the interplay between strength and hydrodynamic instabilities in solids is limited for the loads and strain rates that are typically used to study them. We have developed novel feed-through RM instability experiments that are useful to understand and model this interplay. We will describe the experimental setup and show simulations that agree well with experimental results in two materials, one-phase copper, and iron loaded above and below the alpha-epsilon phase boundary, where modeling used a phase-aware strength model. In copper, the growth of surface perturbations is quite sensitive to strength model parameters, and so is the amplitude of the shock front perturbations. This is also observed in iron, along with an additional sensitivity in the modeling results to the parameters used to describe phase change kinetics.

**10:24AM X21.00013 A method using the surface perturbation to determine the strength of materials** , JIANWEI YIN, HAO PAN, ZIHUI WU, XIAOMIAN HU, Institute of Applied Physics and Computational Mathematics, Beijing — The determination of the dynamic strength of materials at high pressure and strain rate has been focused by the shock dynamics community for many years. This paper simulated the surface perturbation problems under high pressure and strain rate loading. By adjusting the characteristic geometric variables as wave number, amplitude of initial perturbation at the free surface, we studied the growth of the perturbations in the improved forms of the theoretical results given by Piriz et al. (Phys. Rev. E 78, 056401, 2008). The critical condition that the surface perturbation was restrained from unstable growth was also deduced. In the stable region of perturbation growth, the relationship among the relative velocities, displacements of the key positions at the perturbed surface and the material strength was studied. The experimental feasibility of using the improved relationship to determine the strength of materials was also discussed.

**10:36AM X21.00014 Dynamic Failure Mode Transitions in 7075Al Expanding rings driven by Electromagnetic loading** , MINGTAO LIU, TIEGANG TANG, ZHAOLIANG GUO, CHENG FAN, Institute of Fluid Physics, China Academy of Engineering Physics, Mianyang 621900, Sichuan, China — Dynamic failure mode transitions are observed in 7075Al electromagnetic expanding rings with a typical size of 3mm in thickness and 0.5mm in height. The rings are driven to maximum expanding velocities ranged from 60m/s to 180m/s, corresponding to strain rates of about 3000 to 9000 per second. At lower strain rates, the fractures of the rings are dominated by the hoop tensile stress, and the cracks are along the radial direction. At higher strain rates, the fractures of the rings are dominated by the maximum shear stress, and the cracks are lie along with an angle of about 45 degree with the radial direction. While the rings deform at medium strain rates, a mixed failure mode is observed, which simultaneously consists of tensile fracture and shear fracture. The failure strains of the specimen and the numbers of the fragmentations were measured after testing. The failure strains show a maximum value as the strain rate increasing, but the numbers of the fragmentations increase firstly, then decrease and then increase again. These phenomena were found to have a close relationship with the dynamic failure mode transitions.

**10:48AM X21.00015 Study of expanding fracture behavior of a copper cylinder under hollow explosive loading.<sup>1</sup>** , CHENG FAN, ZHAOLIANG GUO, MINGTAO LIU, TIEGANG TANG, None — We study the expanding fracture behavior of a copper cylinder under hollow explosive loading. Besides the tensile fracture along the circumferential direction, spall fracture along radial direction occurs, which is evidenced by the step-like behavior with three velocity jumps in the free surface velocity curves and microstructure study of the soft recovered fragments. After considering the spall fracture mechanism, a numerical simulation is carried out and the result shows good agreement with the experiment data.

**11:00AM X21.00016 Compressible Heating in the Condense Phase due to Pore Collapse in HMX<sup>1</sup>** , JU ZHANG, Florida Institute of Technology, THOMAS JACKSON, University of Florida — Axisymmetric pore collapse in HMX is studied numerically by solving multi-phase reactive Euler equations. The generation of hot spots in the condense phase due to compressible heating is examined. The motivation is to improve the understanding of the role of embedded cavities in the initiation of reaction in explosives, and to investigate the effect of hot spots in the condense phase due to compressible heating alone, complementing previous study on hot spots due to the reaction in the gas phase and at the interface. It is found that the shock-cavity interaction results in pressures and thus temperatures that are substantially higher than the post-shock values in the condense phase. However, these hot spots in the condense phase due to compressible heating alone do not seem to be sufficiently hot to lead to ignition at shock pressures of 1-3 GPa. Thus, compressible heating in the condense phase may be excluded as a mechanism for initiation of explosives. It should be pointed out that the ignition threshold for the temperature, the so-called "switch-on" temperature, of hot spots depend on chemistry kinetics parameters. Switch-on temperature is lower for faster reaction rate. The current chemistry kinetics parameters are based on previous experimental work.

**Friday, March 18, 2016 8:00AM - 10:48AM –  
Session X22 DCMF: Mott Physics Model Calculations 321 -**

**8:00AM X22.00001 Dimensional reduction in spin dynamics at Mott quantum criticality**, JAE-HO HAN, YONG-HEUM CHO, KI-SEOK KIM, Department of Physics, POSTECH, Pohang, Gyeongbuk 790-784, Korea — One physical picture in describing metal-insulator transitions driven by strong interactions starts from a UV fixed point. Here, localized magnetic moments play the role of a source of strong inelastic scattering in Mott quantum criticality, which seems quite successful description at high temperature (e.g. anomalous scaling in electric resistivity). However, it has somewhat fundamental difficulty in explaining the low energy physics of a particular class of Mott insulators such as organic salts, where emergent localized magnetic moments are believed to form a spin liquid state. Here, starting from this spin-liquid IR fixed point, we investigate the Mott quantum criticality in (2+1) dimension (D). Our renormalization group analysis suggests that (2+1) D critical spin dynamics turns into (1+1) D dynamics, which originates from gauge invariance at Mott quantum criticality. Applying the bosonization framework, we find that critical spin dynamics is described by SU(2)  $k=1$  Wess-Zumino-Witten theory in (1+1) D and critical charge dynamics is in the XY universality class of (2+1) D. We discuss speculations for the high temperature Mott quantum criticality based on this critical field theory.

**8:12AM X22.00002 Quasi-soliton scattering in quantum spin chains**, DAVIDE FIORETTO, Institut für Theoretische Physik, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany, ROGIER VLJIM, Institute for Theoretical Physics, University of Amsterdam, Science Park 904, 1090 GL Amsterdam, The Netherlands, MARTIN GANAHL, Perimeter Institute for Theoretical Physics, 31 Caroline Street North, ON N2L 2Y5, Canada, MICHAEL BROCKMANN, MASUD HAQUE, Max-Planck-Institut für Physik komplexer Systeme, Nthnitzer Strasse 38, 01187 Dresden, Germany, HANS-GERD EVERTZ, Institut für Theoretische Physik, Technische Universität Graz, Petersgasse 16, 8010 Graz, Austria, JEAN-SBASTIEN CAUX, Institute for Theoretical Physics, University of Amsterdam, Science Park 904, 1090 GL Amsterdam, The Netherlands — The quantum scattering of magnon bound states in the anisotropic Heisenberg spin chain is shown to display features similar to the scattering of solitons in classical exactly solvable models. Localized colliding Gaussian wave packets of bound magnons are constructed from string solutions of the Bethe equations and subsequently evolved in time, relying on an algebraic Bethe ansatz based framework for the computation of local expectation values in real space-time. The local magnetization profile shows the trajectories of colliding wave packets of bound magnons, which obtain a spatial displacement upon scattering. Analytic predictions on the displacements for various values of anisotropy and string lengths are derived from scattering theory and Bethe ansatz phase shifts, matching time evolution fits on the displacements. The TEBD algorithm allows for the study of scattering displacements from spin-block states, showing similar displacement scattering features.

**8:24AM X22.00003 Influence of spinons fluctuations near the spin liquid Mott transition**, TSUNG-HAN LEE, Florida State University and National High Magnetic Field Laboratory, SERGE FLORENS, Institut Neel, CNRS and Université Grenoble Alpes, VLADIMIR DOBROSLAVJEVIC, Florida State University and National High Magnetic Field Laboratory — We investigate the metal to Mott-insulator transition (MIT) in the Hubbard-Heisenberg model using the slave-rotor technique, which allows to combine for the first time the dynamical mean field theory (DMFT) with the Resonating Valence Bond (RVB) approach. In the spin-liquid phase at large Coulomb repulsion, the system shows a RVB transition from a trivial paramagnetic Mott insulator towards a low temperature insulating state with long lived spinons, as seen by the emergence of a linear specific heat. This quenching of the entropy in the spin liquid phase provides strong modifications in the shape of the standard DMFT phase diagram for the MIT occurring at intermediate values of the Coulomb repulsion. We find that the RVB transition happens concomitantly with the first order MIT lines at low temperature. This implies that the Mott insulator always accommodates a spinon Fermi surface, even in the coexistence regime of the MIT, and that the metallic state always stays a Fermi-liquid as it rejects the presence of free spinons, due to their strong scattering onto the holons.

**8:36AM X22.00004 Fractionalized Fermi liquids in a quantum dimer model**, JUNHYUN LEE, Harvard University, STEVEN WHITE, University of California, Irvine, SUBIR SACHDEV, Harvard University — We consider a quantum dimer model with bosonic and fermionic dimers, proposed to describe the pseudogap phase of cuprates. <sup>1</sup> By density matrix renormalization group calculations on a finite cylinder, we obtain the ground state density distribution of the fermionic dimers for a number of different total densities. From the Friedel oscillations at open boundaries, we deduce that the Fermi surface consists of small hole pockets near  $(\pi/2, \pi/2)$ , and this feature persists up to 1/8 doping. Our results support the existence of a “fractionalized Fermi liquid” in this model. We also discuss the form factors of the density modulations.

**8:48AM X22.00005 Infinite bandwidth of a Mott-Hubbard insulator**<sup>1</sup>, JAMES FREERICKS, JEFFREY COHN, Georgetown University, PETER VAN DONGEN, University of Mainz, HULIKAL KRISHNAMURTHY, Indian Institute of Science, Bangalore — The conventional viewpoint of the strongly correlated electron metal-insulator transition is that a single band splits into two upper and lower Hubbard bands at the metal-insulator transition. Much work has investigated whether this transition is continuous or discontinuous. Here we focus on another aspect and ask the question of whether there are additional upper and lower Hubbard bands, which stretch all the way out to infinity—leading to an infinite bandwidth for the Mott insulator. While we are not yet able to provide a rigorous proof of this result, we use exact diagonalization studies on small clusters to motivate the existence of these additional bands, and we discuss some different methods that might be utilized to provide a rigorous proof of this result. Even though the extra upper and lower Hubbard bands have very low total spectral weight, those states are expected to have extremely long lifetimes, leading to a nontrivial contribution to the transport density of states for dc transport and modifying the high temperature limit for the electrical resistivity.

**9:00AM X22.00006 Gaps, Pseudogaps, and the Nature of Charge in Holographic Fermion Models**, GARRETT VANACORE, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Building on prior holographic constructions of Fermi arcs and Mott physics, we investigate the landscape of gapped and gapless strongly-correlated phases resulting from bulk fermion interactions in gauge/gravity duality. We test a proposed connection between bulk chiral symmetry and gapless boundary states, and discuss implications for discrete symmetry breaking in pseudogapped systems like the cuprate superconductors. Numerical methods are used to treat gravitational backreaction of bulk fermions, allowing more rigorous investigation of the existence of holographic Fermi surfaces and their adherence to Luttinger’s rule. We use these techniques to study deviations from Luttinger’s rule in holography, testing a recent claim that momentum-deconfined charges are at the heart of the Mott state.

**9:12AM X22.00007 Dimensional decoupling at continuous Mott transitions**, LIUJUN ZOU, Department of Physics, Harvard University, T SENTHIL, Department of Physics, Massachusetts Institute of Technology — For continuous Mott metal-insulator transitions in layered two dimensional systems, we demonstrate the phenomenon of dimensional decoupling: the system behaves as a three-dimensional metal in the Fermi liquid side but as a stack of decoupled two-dimensional layers in the Mott insulator. We show that the dimensional decoupling happens at the Mott quantum critical point itself. We derive the temperature dependence of the interlayer electric conductivity in various crossover regimes near such a continuous Mott transition, and discuss experimental implications.

### 9:24AM X22.00008 Doping dependence of ordered phases in the Hubbard-Holstein model

, CHRISTIAN MENDEL, SLAC National Accelerator Laboratory and Stanford University, ELIZABETH NOWADNICK, Cornell University, YVONNE KUNG, BRIAN MORITZ, SLAC National Accelerator Laboratory and Stanford University, STEVEN JOHNSTON, University of Tennessee, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University — Complex phase diagrams of strongly correlated materials are often accessed by the addition or removal of carriers, for example the emergence of high-temperature superconductivity from a charge transfer insulating state in the cuprates, and the metal-insulator transition in the nickelates. In many cases, these doping-dependent transitions are closely linked to the competition between multiple phases of similar energy scales, e.g., charge-stripe and superconducting states in the cuprates. The Hubbard-Holstein model, which includes electron-electron and electron-phonon interactions, provides a framework to study competing phases. In this talk I will present determinant quantum Monte Carlo (DQMC) simulations of the Hubbard-Holstein model and use spin and charge susceptibilities and single-particle spectral functions to elucidate the doping evolution of the competition between spin and charge order.

### 9:36AM X22.00009 An electric field-driven MIT in strongly-correlated thin-film superlattices: an inhomogeneous dynamical mean-field theory study<sup>1</sup>

, PETAR BAKALOV, JEAN-PIERRE LOCQUET, Department of Solid-state physics, KU Leuven — Using an inhomogeneous dynamical mean-field theory (IDMFT) approach to the single-band Hubbard model we investigate the properties of thin-film superlattices made up of alternating strongly ( $U_1$ ) and weakly ( $U_2 < U_1$ ) correlated regions. In particular, we study the influence of temperature, doping, interaction strengths ( $U_1, U_2$ ), superlattice parameters ( $L_1, L_2$ ) and transverse electric field on the correlation driven Mott-Hubbard metal-to-insulator transition. We find that when the periodicity of the superlattice is such that the strongly correlated regions are below a certain thickness, the MIT is suppressed due to proximity effects.

<sup>1</sup>This work was partially funded by the Flemish Fund for Scientific Research (FWO - Vlaanderen) under FWO grant G.0520.10 and by the SITOGA FP7 project. Most of the calculations were performed on KU Leuven's ThinKing HPC cluster.

### 9:48AM X22.00010 Filament Formation and Electric-field-driven Resistive Switching in ordered Mott insulator

, JIAJUN LI, State Univ of NY - Buffalo, CAMILLE ARON, Princeton University, GABRIEL KOTLIAR, Rutgers University, JONG HAN, State Univ of NY - Buffalo — Formation of conductive filaments is widely observed in resistive switching experiments of strongly correlated materials. Although several theoretical scenarios have been suggested, the underlying mechanism is still far from completely understood within microscopic models. In this work, we study the spatial inhomogeneity during electric-field-driven AFI-to-PM transition in a dissipative Hubbard model<sup>1, 2</sup>. We focus on the non-equilibrium steady state, by means of space-dependent Hartree-Fock approximation. It is shown that external field induces a first order insulator-to-metal transition (IMT) even when equilibrium transition is continuous. Disorder turns out to be crucial for formation of filaments. When impurities are placed in lattice, Joule heating assists to create robust conductive paths. Insulator-to-metal transition is then stimulated by conductive paths, with critical field significantly reduced.

### 10:00AM X22.00011 A Functional Renormalization Group Study of Hubbard Models with Correlated Hopping interactions.

, NAHOM YIRGA, Boston University, ARIANNA MONTORSI, Politecnico di Torino, DAVID CAMPBELL, Boston University — Hubbard Models with correlated hopping interactions have recently been derived from the Floquet Hamiltonian for driven Hubbard models [1]. We consider these models generalized to include an extended Hubbard interaction ( $V$ ) and both with and without particle-hole symmetry. Using the Functional Renormalization Group method, we derive the phase diagram of this class of models in one and two dimensions. In one dimension we reproduce a spin transition to a bond-ordered phase previously seen in DMRG studies [2]. We extend these results to two dimensions. [1] M. Di Liberto, C. E. Creffield, G. I. Japaridze, C. Morais Smith, Phys. Rev. A **89**, 013624 (2014) [2] A.A. Aligia et al., Phys. Rev. Lett. **99**, 206401 (2007)

### 10:12AM X22.00012 Quantum Monte Carlo study of bilayer ionic Hubbard model<sup>1</sup>

, MI JIANG, Institute for Theoretical Physics, ETH Zurich, Switzerland and Swiss National Supercomputing Center, ETH Zurich, 6900 Lugano, Switzerland — The interaction-driven insulator-to-metal transition has been reported in the ionic Hubbard model (IHM) for intermediate interaction  $U$ , which poses fundamental interest in the correlated electronic systems. Here we use determinant quantum Monte Carlo to study the interplay of interlayer hybridization  $V$  and two types of intralayer staggered potentials: one with the same (in-phase) and the other with a  $\pi$ -phase shift (anti-phase) potential in two layers termed as “bilayer ionic Hubbard model”. We demonstrate that the interaction-driven Insulator-Metal transition extends to bilayer IHM with finite  $V$  for both types of staggered potentials. Besides, the system with in-phase potential is prone to metallic phase with turning on interlayer hybridization while that with anti-phase potential tends to insulators with stronger charge density order.

<sup>1</sup>The author thanks CSCS, Lugano, Switzerland for computing facilities.

### 10:24AM X22.00013 Percolative Metal-Insulator transition in the doped Hubbard-Holstein model with the Gutzwiller Approach

, JAMSHID MORADI KURDESTANY, SASHI SATPATHY, Department of Physics and Astronomy, University of Missouri, Columbia, MO 65211-7010, USA. — Motivated by the recent progress in understanding of Mott insulators away from half filling, observed in many perovskite oxides, we study the metal-insulator transition in the Hubbard-Holstein model, which contains both the Coulomb and the electron-lattice (Jahn Teller) interactions by using the Gutzwiller variational method. We find that strong electron-lattice interaction leads to phase separation, which however can be frustrated due to the long-range Coulomb interaction, resulting in a mixed phase consisting of puddles of metallic phases embedded in an insulating matrix. When the dopant concentration exceeds a threshold value  $x_c$ , the metallic part forms a percolating network leading to metallic conduction. Depending on the strength of the electron-lattice interaction,  $x_c$  can be of the order of 0.05 - 0.20 or so, which is the typical value observed in the perovskites.

### 10:36AM X22.00014 Doping evolution of low-energy quasiparticles in the Hubbard model

, BRIAN MORITZ, YAO WANG, CHUNJING JIA, YU HE, SLAC National Accelerator Laboratory and Stanford University, KRZYSZTOF WOHLFELD, University of Warsaw, CHENG-CHIEN CHEN, Argonne National Laboratory, THOMAS P. DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University — We investigate the single-particle spectra of the two-dimensional, single-band Hubbard model using cluster perturbation theory (CPT), paying considerable attention to low doping with a supercluster construction. At half-filling we find two distinct features: a spin polaron band due to strong coupling of a hole to magnons; and a second feature due to strongly renormalized, but effectively free, next-nearest neighbor hopping from additional delocalization pathways. With light hole-doping a third feature forms which disperses across the Fermi level, rapidly stealing spectral weight from the spin polaron. The doping evolution of this third feature is of particular importance as it constitutes the lowest energy degrees of freedom in the model. The three spectral features appear distinct, up to a relatively modest doping (12.5%) where the spectral weight effectively has been exhausted in the spin polaron. We comment on the similarities, differences, and implications for the spectrum in doped cuprates and on competing interpretations of the spectral properties in the Hubbard model.

# Friday, March 18, 2016 8:00AM - 11:00AM –

Session X23 DMP GERA FIAP: Thermoelectrics Theory II 322 - Heiner Linke, Lund University

**8:00AM X23.00001 Thermal and Electronic Transport in Inorganic and Organic Thermoelectric Materials**, ZHITING TIAN, Virginia Tech — In this talk, we will first talk about first-principles calculations of phonon and electron transport in inorganic thermoelectric materials. We will start with rocksalt PbTe and PbSe, and move on to wurtzite ZnO. We will emphasize the strategies to reduce the lattice thermal conductivity. Then we apply first-principles calculations to organic thermoelectric materials. The thermoelectric properties of doped polypyrrole (PPy) will be discussed. In addition, we will cover the chain confinement effects observed in amorphous polymer thin films using molecular dynamics simulations, which highlights the fundamental difference in heat conduction between crystalline polymers and amorphous polymers

**8:36AM X23.00002 Electron-phonon coupling and thermal transport in thermoelectric compound  $\text{Mo}_3\text{Sb}_{7-x}\text{Te}_x$** , DIPANSHU BANSAL, CHEN LI, Oak Ridge National Lab, AYMAN SAID, Argonne National Lab, DOUGLAS ABERNATHY, JIAQIANG YAN, OLIVIER DELAIRE, Oak Ridge National Lab — Complex interactions between solid-state excitations, such as phonon-phonon, phonon-electron, and phonon-magnon couplings are often responsible for unusual material properties. In this presentation, we report on our investigations of phonon propagation and thermal transport in thermoelectric  $\text{Mo}_3\text{Sb}_{7-x}\text{Te}_x$ . We have performed extensive inelastic neutron and x-ray scattering measurements of phonons in  $\text{Mo}_3\text{Sb}_{7-x}\text{Te}_x$ , mapping the phonon dispersions and density of states, as function of temperature and composition. Our first-principles density functional theory simulations, coupled with experimental measurements, reveal the importance of electron-phonon coupling, which dominates the scattering rates over alloy disorder scattering. Doping with Te shifts the Fermi surface near the top of the valence band, suppressing screening and causing phonons to stiffen markedly. Our measurements of acoustic dispersions and linewidths, coupled with DFT simulations and models of phonon scattering enable us to quantify the impact of the electron-phonon coupling on the thermal conductivity.

**8:48AM X23.00003 Vibrational Dynamics of Filled Skutterudites**, SUSMITA BASAK, CHRISTIAN CARBOGNO, MATTHIAS SCHEFFLER, Fritz Haber Institute of the Max Planck Society — Skutterudites are promising candidates for thermoelectric applications, since their cage like structure can be filled with guest atoms to tune the electronic and vibrational properties and so to optimize the thermoelectric transport coefficients. Various conflicting phenomenological models (e.g., incoherent rattling, coherent coupling [1]) have been proposed to explain the interaction between guest and host, but the exact mechanisms are still topic of debate. To clarify this question, we determine the temperature dependence of the geometric, electronic, and vibrational properties for a set of skutterudites ( $\text{CoSb}_3$ ,  $\text{CoAs}_3$ ) and guests (Ga, In, Sn, etc.) using density-functional theory in the quasi-harmonic approximation. We find different coupling mechanisms to be active depending on the guest, which leads to drastically different dynamics ranging from localized to coherent phonon modes. These modes, which are robust against doping and defy the common assumption that the guest's mass primarily determines the coupling, also largely influence the structural and electronic properties. Finally, we discuss the implications of our findings for the control and optimization of the thermoelectric efficiency. [1] M. M. Koza *et al.*, Nat. Mat. 7, 805, (2008).

**9:00AM X23.00004 Low-energy phonon dispersion in  $\text{LaFe}_4\text{Sb}_{12}$** , ANDREAS LEITHE-JASPER, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MARTIN BOEHM, HANNU MUTKA, MICHAEL M. KOZA, Institut Laue-Langevin, Grenoble, France — We studied the vibrational dynamics of a single crystal of  $\text{LaFe}_4\text{Sb}_{12}$  by three-axis inelastic neutron spectroscopy. The dispersion of phonons with wave vectors  $q$  along  $[xx0]$  and  $[xxx]$  directions in the energy range of eigenmodes with high amplitudes of lanthanum vibrations, i.e., at  $\hbar\omega < 12\text{ meV}$  is identified. Symmetry-avoided anticrossing dispersion of phonons is established in both monitored directions and distinct eigenstates at high-symmetry points and at the Brillouin-zone center are discriminated. The experimentally derived phonon dispersion and intensities are compared with and backed up by *ab initio* lattice dynamics calculations. results of the computer model match well with the experimental data.

**9:12AM X23.00005 First-principles investigations of phonon anharmonicity and electronic instability in thermoelectric  $\text{SnSe}^1$** , JIAWANG HONG, CHEN W. LI, A. F. MAY, D. BANSAL, S. CHI, T. HONG, G. EHLERS, OLIVIER DELAIRE, Oak Ridge National Laboratory — The promising thermoelectric material SnSe exhibits ultra-low and strongly anisotropic thermal conductivity. By combining first-principles calculations and inelastic neutron scattering measurements, we have investigated the phonon dispersions and phonon scattering mechanisms, and probed the origin of the large anharmonicity in SnSe.<sup>2</sup> We will discuss the connection between the phonon properties and the high-temperature structural phase transition, and how the electronic structure leads to large anharmonic phonon interactions in SnSe. The present results provide a microscopic picture connecting electronic structure and phonon anharmonicity in SnSe, which could help design materials with ultralow thermal conductivity.

<sup>1</sup>Computations were performed using the OLCF at ORNL. Modeling of neutron data was performed in CAMM, measurements were funded by the US DOE, BES, Materials Science and Engineering Division.

<sup>2</sup>C.W. Li\*, J. Hong\*, A.F. May, D. Bansal, S. Chi, T. Hong, G. Ehlers, and O. Delaire, Orbitaly driven giant phonon anharmonicity in SnSe, Nature Physics, (2015)

**9:24AM X23.00006 Phonons Near Lattice Instabilities in Thermoelectric SnSe, SnTe, and PbTe**, OLIVIER DELAIRE, Duke University, Oak Ridge National Laboratory, CHEN LI, JIAWANG HONG, JIE MA, ANDREW MAY, DIPANSHU BANSAL, GEORG EHLERS, SONGXUE CHI, TAO HONG, Oak Ridge National Laboratory — A number of high-performance thermoelectric materials are found in the vicinity of lattice instabilities, including PbTe, SnTe, SnSe, tetrahedrites,  $\text{Cu}_2\text{Se}$ , among others. The large phonon anharmonicity found in such compounds suppresses the lattice thermal conductivity, a key aspect of their thermoelectric efficiency. In this presentation, we will discuss results from our recent investigations of phonons in these materials using inelastic neutron scattering and first-principles simulations, focusing on anharmonic effects near lattice instabilities. Commonalities will be highlighted, including connections between strong anharmonicity and the electronic structure and bonding.

**9:36AM X23.00007 Pressure intrinsically induced thermoelectric enhancement in the SnSe crystal**, YONGSHENG ZHANG, Institute of Solid State Physics, Chinese Academy of Sciences, SHIQIANG HAO, Department of Materials Science and Engineering, Northwestern University, LI-DONG ZHAO, Beihang University, CHRISTOPHER WOLVERTON, Northwestern University, ZHI ZENG, Institute of Solid State Physics, Chinese Academy of Sciences — SnSe is an excellent thermoelectric material due to its high  $ZT$  value ( $\sim 2.6$  along the  $b$  direction) at high temperature  $\sim 923\text{ K}$ . However, in the temperature range of  $300\text{--}773\text{ K}$ , the  $ZT$  values are just  $0.1\text{--}0.9$ . To make this material more efficient, its thermoelectric properties should be large in the entire temperature range. Here, we use DFT calculations to show how pressure intrinsically enhances the thermoelectric properties below  $700\text{ K}$  along the three directions ( $a$ ,  $b$  and  $c$ ) of the crystal (the low- $T$  SnSe- $Pnma$  phase) due to a significant boost in electrical transport. The estimated  $ZT$  values of  $p$ -type along the  $b$  and  $c$  directions can reach as high as  $3.3$  and  $2.1$  at  $6\text{ GPa}$  and  $700\text{ K}$ , respectively. At  $6\text{ GPa}$ , the  $a$  direction shows  $n$ -type properties and its  $ZT$  value is  $1.9$  at  $600\text{ K}$ . It is significant that high-performance both  $n$ -type and  $p$ -type conductors could be available in SnSe just through applying pressure. Our work on SnSe under pressure sheds light on a new mechanism for screening high efficiency thermoelectric materials.

**9:48AM X23.00008 Broadband Phonon Scattering in PbTe-based Materials Driven Near the Peierls Phase Transition by Strain or Alloying<sup>1</sup>**, IVANA SAVIC, RONAN MURPHY, EAMONN MURRAY, STEPHEN FAHY, Tyndall National Institute, Cork, Ireland — Efficient thermoelectric energy conversion is highly desirable as 60% of the consumed energy is wasted as heat. Low lattice thermal conductivity is one of the key factors leading to high thermoelectric efficiency of a material [1]. However, the major obstacle in the design of such materials is the difficulty in efficiently scattering phonons across the frequency spectrum [2]. Using first principles calculations, we predict that driving PbTe materials close to a Peierls-like phase transition could be a powerful strategy to solve this problem. We illustrate this concept by applying tensile [001] strain to PbTe and its alloys with another rock-salt IV-VI material, PbSe; and by alloying PbTe with a IV-VI Peierls-distorted material, GeTe. This induces extremely soft optical modes, which increase acoustic-optical phonon coupling and decrease phonon lifetimes at all frequencies. We show that PbTe, Pb(Se,Te) and (Pb,Ge)Te alloys driven near the phase transition in the described manner could have the lattice thermal conductivity considerably lower than that of PbTe. The proposed concept may open new opportunities for the development of more efficient thermoelectric materials. [1] G. J. Snyder and E. S. Toberer, *Nature Mater.* 7, 105 (2008). [2] K. Biswas et al. *Nature* 489, 414 (2012).

**10:00AM X23.00009 Understanding of phonon anharmonicity in thermoelectric clathrates**, KATSUMI TANIGAKI, JIAZHEN WU, HIDEKAZU SHIMOTANI, KHUONG HUYNH, KAZUTO AKAGI, Tohoku University, AIMR COLLABORATION, DEPARTMENT OF PHYSICS, GRADUATE SCHOOL OF SCIENCE COLLABORATION — Anharmonicity in phonons, apart from the conventional Einstein- or Debye- mode harmonic phonons, is frequently observed for amorphous or glass-like materials. A frontier topic relating to anharmonic phonons revolves around the fact that they are also observed in a single crystal with a void of cage structure. Although the origin of the phonon anharmonicity has been the center of scientific debate for many years, a clear understanding has not yet been achieved. In the present study, we show that the anharmonic oscillations in thermoelectric clathrates can successfully be rationalized in terms of a single unified exponential line for a variety of clathrates by employing a new parameter associated with the freedom of space. The intrinsic nature of phonon anharmonicity is described based on the unified picture with a help of first principles calculations. Although the origin of the anharmonicity appearing in disordered materials is complex to understand due to the missing information on the real structure, the present unified picture gives important information applicable to other systems.

**10:12AM X23.00010 First-principles Study of Guest Impurities of Na and Ba on Lattice Thermal Conductivity of Type-I Si Clathrate**, YI XIA, University of California, Los Angeles, FEI ZHOU, Lawrence Livermore National Laboratory, VIDVUDS OZOLINS, University of California, Los Angeles — The type-I clathrate compounds, known as good thermoelectric materials, exhibit phonon-glass electron-crystal properties with their open cages filled with guest atoms. We present a first-principles study of the intrinsic impact of these rattlers on the lattice thermal conductivity in type-I Si clathrate compounds. We observe both coherent and incoherent coupling between guest and framework acoustic modes which could be ascribed to the difference in atomic radius, confirming the “avoided crossing” behavior. Our calculated lattice thermal conductivities for  $\text{Si}_{46}$  (37.64 W/(m K)),  $\text{Na}_8\text{Si}_{46}$  (2.75 W/(m K)) and  $\text{Ba}_8\text{Si}_{46}$  (1.37 W/(m K)) are in good agreement with experimental measurements and simulations at room temperature. Significant reductions in both phonon lifetime and group velocity due to guest atoms are responsible for the reduction in lattice thermal conductivity. The energy widths of acoustic modes of both empty and filled silicon clathrates are beyond the resolution limit of 0.2 meV of inelastic x-ray scattering and thus cannot be used to exclude the Umklapp scatterings as main cause of reduction in lattice thermal conductivity. In addition, the Umklapp scatterings of acoustic modes are directly mediated by the guest modes.

**10:24AM X23.00011 First-Principles Study of Guest-Host Bonding in the Type-II Clathrate Compounds  $\text{A}_x\text{Si}_{136}$  ( $\text{A} = \text{Na, K, Rb, Cs}$ ;  $0 \leq x \leq 24$ )**, CHARLES MYLES, DONG XUE, Texas Tech University — The Type II clathrate-based materials are interesting due to their potential thermoelectric applications. Recently, a synthesis and characterization of  $\text{Na}_x\text{Si}_{136}$  for various  $x$  has been reported [1]. Powdered X-Ray diffraction (XRD) data and density functional theory (DFT) studies of  $\text{Na}_x\text{Si}_{136}$  have found a lattice contraction as  $x$  increases for  $0 < x < 8$  and an expansion as  $x$  increases for  $x > 8$ . This is explained by XRD data showing that, as  $x$  increases, the 28-atom Si cages are filled first for  $x < 8$  and the 20-atom Si cages are then filled for  $x > 8$ . We report results of first-principles calculations focused on analyzing the underlying mechanisms relevant to guest-host interactions and to understanding the role of the guest atom to host atom size ratio in this material. We have also studied the compounds  $\text{A}_x\text{Si}_{136}$  ( $\text{A} = \text{Na, K, Rb, Cs}$ ;  $0 \leq x \leq 24$ ). Our LDA calculations for  $\text{K}_x\text{Si}_{136}$  ( $0 < x < 16$ ) predict that this material should exhibit a non-monotonic structural response similar to that in  $\text{Na}_x\text{Si}_{136}$ ; the lattice should contract and then expand as  $x$  increases. We find that the heavier guests (Rb, Cs) vibrate nearer to the center of the  $\text{Si}_{28}$  cages than do Na and K. Our results also show that Na and K are both strongly coupled to the Si framework in  $\text{A}_x\text{Si}_{136}$  ( $\text{A} = \text{Na, K}$ ;  $x = 4, 8$ ). [1] S. Stefanoski, C.D. Malliakas, M.G. Kanatzidis, G.S. Nolas, *Inorg. Chem.* 51, 8686 (2012).

**10:36AM X23.00012 Thermoelectric property of a new silicon crystal**, KISUNG CHAE, SEON-MYEONG CHOI, Korea Inst for Advanced Study, DUCK YOUNG KIM, Carnegie Institute of Washington, YOUNG-WOO SON, Korea Inst for Advanced Study — We present ab initio calculations on thermoelectric properties of a recently synthesised allotrope of silicon crystal [1]. A new silicon crystal with 24 Si atoms per unit cell has open channels along the specific crystallographic direction and shows a quasidirect energy gap of 1.3 eV. Using various first-principles calculation techniques for electrical and thermal conductivity as well as Seebeck coefficient, we find large suppression of thermal conductivity and relatively large Seebeck coefficient in the new silicon crystal, thus demonstrating a competitive thermoelectric figure of merit. [1] D. Y. Kim et al, *Nat. Mat.* 14, 169 (2015).

**10:48AM X23.00013 First Principles Study of the Properties of the Type II Clathrate Alloy  $\text{Si}_{136-x}\text{Ge}_x$  ( $x = 8, 32, 96$ )**, DONG XUE, CHARLES MYLES, Texas Tech University — The Type-II clathrate materials based on Si, Ge, and Sn have “open-framework” lattices consisting of large “cages” of atoms covalently bonded together. Due primarily to their potential thermoelectric applications, there has been considerable research on these materials with various guest atoms in the cages and with various substitutional atoms on the lattice framework. Also of interest are the pure Type II clathrates  $\text{M}_{136}$  ( $\text{M} = \text{Si, Ge, Sn}$ ) with neither framework substitution nor guest atoms in the cages. A fundamental understanding of the intrinsic properties of these “guest-free” clathrates is therefore also needed. Mixtures or “alloys” of two different Type II clathrate materials are also potentially interesting. For example, Moriguchi *et al.* [1] have reported the successful synthesis of Type II clathrates with mixtures of Si and Ge on the framework lattice. Motivated by these experiments, we have carried out a computational and theoretical study the properties of the Type II clathrate “alloy”  $\text{Si}_{136-x}\text{Ge}_x$ . We report the results of DFT-based first-principles calculations of the structural, electronic, vibrational, and thermal properties of  $\text{Si}_{136-x}\text{Ge}_x$  for  $x = 8, 32, 96$ . Our calculations have assumed that the ideal lattice symmetry is unaffected by the mixing of Si and Ge. Among other results, we predict that  $\text{Si}_{136-x}\text{Ge}_x$  should have a direct band gap ranging from 1.2 to 2.0 eV. [1]. K. Moriguchi, S. Munetoh, A. Shintani, *Phys. Rev. B* 62, 7138 (2000).

**8:36AM X24.00002 First-principles Equations of State and Shock Hugoniot of First- and Second-Row Plasmas**<sup>1</sup> , KEVIN DRIVER, FRANCOIS SOUBIRAN, SHUAI ZHANG, BURKHARD MILITZER, University of California, Berkeley — A first-principles methodology for studying high energy density physics and warm dense matter is important for the stewardship of plasma science and guiding inertial confinement fusion experiments. In order to address this challenge, we have been developing the capability of path integral Monte Carlo (PIMC) for studying dense plasmas comprised of increasingly heavy elements, including nitrogen, oxygen (J. Chem. Phys., 164507 (2015)), and neon (Phys. Rev. B, 91, 045103 (2015)). In recent work, we have extended PIMC methodology beyond the free-particle node approximation by implementing localized nodal surfaces capable of describing bound plasma states in second-row elements, such as silicon (Phys. Rev. Lett. 115, 176403 (2015)). We combine results from PIMC with results from density functional theory molecular dynamics (DFT-MD) calculations to produce a coherent equation of state that bridges the entire WDM regime. Analysis of pair-correlation functions and the electronic density of states reveals an evolving plasma structure and ionization process that is driven by temperature and pressure. We also compute shock Hugoniot curves for a wide range of initial densities, which generally reveal an increase in compression as the second and first shells are ionized.

**8:48AM X24.00003 X-Ray Thomson Scattering Without the Chihara Decomposition** , RUDOLPH MAGYAR, ANDREW BACZEWSKI, LUKE SHULENBURGER, STEPHANIE B. HANSEN, MICHAEL P. DESJARLAIS, Sandia National Laboratories, SANDIA NATIONAL LABORATORIES COLLABORATION — X-Ray Thomson Scattering is an important experimental technique used in dynamic compression experiments to measure the properties of warm dense matter. The fundamental property probed in these experiments is the electronic dynamic structure factor that is typically modeled using an empirical three-term decomposition (Chihara, J. Phys. F, 1987). One of the crucial assumptions of this decomposition is that the system's electrons can be either classified as bound to ions or free. This decomposition may not be accurate for materials in the warm dense regime. We present unambiguous first principles calculations of the dynamic structure factor independent of the Chihara decomposition that can be used to benchmark these assumptions. Results are generated using a finite-temperature real-time time-dependent density functional theory applied for the first time in these conditions. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Security Administration under contract DE-AC04-94AL85000.

**9:00AM X24.00004 Comminution of Ceramic Materials Under High-Shear Dynamic Compaction**<sup>1</sup> , MICHAEL HOMEL, Lawrence Livermore Natl Lab, JASON LOISEAU, ANDREW HIGGINS, Dept of Mechanical Engineering, McGill University, ERIC HERBOLD, Lawrence Livermore Natl Lab, JAMIE HOGAN, Dept of Mechanical Engineering, University of Alberta — The post-failure “granular flow” response of high-strength lightweight ceramics has important implications on the materials' effectiveness for ballistic protection. We study the dynamic compaction and shear flow of ceramic fragments and powders using computational and experimental analysis of a collapsing thick-walled cylinder geometry. Using newly developed tools for mesoscale simulation of brittle materials, we study the effect of fracture, comminution, shear-enhanced dilatation, and frictional contact on the continuum compaction response. Simulations are directly validated through particle Doppler velocimetry measurements at the inner surface of the cylindrical powder bed. We characterize the size distribution and morphologies of the initial and compacted material fragments to both validate the computational model and to elucidate the dominant failure processes.

<sup>1</sup>A portion of this work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344. Lawrence Livermore National Security, LLC. LLNL-ABS-678862.

**9:12AM X24.00005 Real-time dynamics of high-velocity micro-particle impact** , DAVID VEYSSET, Massachusetts Inst of Tech-MIT, ALEX HSIEH, U.S. Army Research Laboratory, STEVE KOOL, ALEX A. MAZNEV, SHENGCHANG TANG, BRADLEY D. OLSEN, KEITH A. NELSON, Massachusetts Inst of Tech-MIT — High-velocity micro-particle impact is important for many areas of science and technology, from space exploration to the development of novel drug delivery platforms. We present real-time observations of supersonic micro-particle impacts using multi-frame imaging. In an all optical laser-induced projectile impact test, a monolayer of micro-particles is placed on a transparent substrate coated with a laser absorbing polymer layer. Ablation of a laser-irradiated polymer region accelerates the micro-particles into free space with speeds up to 1.0 km/s. The particles are monitored during the impact on the target with an ultrahigh-speed multi-frame camera that can record up to 16 images with time resolution as short as 3 ns. In particular, we investigated the high-velocity impact deformation response of poly(urethane urea) (PUU) elastomers to further the fundamental understanding of the molecular influence on dynamical behaviors of PUUs. We show the dynamic-stiffening response of the PUUs and demonstrate the significance of segmental dynamics in the response. We also present movies capturing individual particle impact and penetration in gels, and discuss the observed dynamics. The results will provide an impetus for modeling high-velocity microscale impact responses and high strain rate deformation in polymers, gels, and other materials.

**9:24AM X24.00006 Sensitivity Characterization of Pressed Energetic Materials using Flyer Plate Mesoscale Simulations.** , NIRMAL RAI, H.S. UDAYKUMAR, Univ of Iowa — Heterogeneous energetic materials like pressed explosives have complicated microstructure and contain various forms of heterogeneities such as pores, micro-cracks, energetic crystals etc. It is widely accepted that the presence of these heterogeneities can affect the sensitivity of these materials under shock load. The interaction of shock load with the microstructural heterogeneities may lead to the formation of local heated regions known as “hot spots”. Chemical reaction may trigger at the hot spot regions depending on the hot spot temperature and the duration over which the temperature can be maintained before phenomenon like heat conduction, rarefaction waves withdraws energy from it. There are different mechanisms which can lead to the formation of hot spots including void collapse. The current work is focused towards the sensitivity characterization of two HMX based pressed energetic materials using flyer plate mesoscale simulations. The aim of the current work is to develop mesoscale numerical framework which can perform simulations by replicating the laboratory based flyer plate experiments. The current numerical framework uses an image processing approach to represent the microstructural heterogeneities incorporated in a massively parallel Eulerian code SCIMITAR3D. The chemical decomposition of HMX is modeled using Henson-Smilowitz reaction mechanism. The sensitivity characterization is aimed towards obtaining James initiation threshold curve and comparing it with the experimental results.

**9:36AM X24.00007 Blow Up Exponents and Deviations from Ideal Taylor Cone Shapes in Ultrathin Liquid Metal Films**, THEODORE G. ALBERTSON<sup>1</sup>, SANDRA TROIAN, California Institute of Technology, 1200 E. California Blvd., MC 128-95, Pasadena, CA — We employ a finite element, moving mesh model to investigate the axisymmetric flow of an ultrathin liquid metal film overlay by a thin vacuum layer confined between two circular disks held at a constant potential difference close to field evaporation values. Within nanoseconds, a small Gaussian protrusion centered about the origin evolves into a sharpened cusp elongated by Maxwell stresses and rounded by capillary stresses. Previous analytic studies<sup>2</sup> and numerical simulations based on marker and cell techniques<sup>3,4</sup> have uncovered a self-similar regime in time where the opposing stresses and kinetic energy exhibit blow up behavior with a characteristic exponent of  $-2/3$ , and cusp shapes that deviate from the ideal Taylor cone angle. Our simulations consistently yield exponents in the range  $-3/4$  to  $-4/5$ , with values that depend sensitively on the choice of blowup time. We also find that deviations from the ideal Taylor cone angle become significant all along the film interface as the Gaussian amplitude increases beyond fractions of a micron.

**9:48AM X24.00008 A Study of the Multiferroic State Under High Pressure for Co doped MnWO<sub>4</sub>**, MELISSA GOOCH, NARAYAN POUDEL, BERND LORENZ, K. C. LIANG, Texas Center for Superconductivity at the University of Houston, Y. Q. WANG, Y. Y. SUN, Retired, JINCHEN WANG, FENG YE, JAIME FERNANDEZ-BACA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, CHING-WU CHU, Texas Center for Superconductivity at the University of Houston — Multiferroic materials are well understood to be sensitive to small perturbations induced through chemical substitution, magnetic and electric fields, or external pressure. These sensitivities can result in rich and complex phase diagrams to explore; one such system is Co doped MnWO<sub>4</sub>. To gain further insight into this system, high pressure measurements were conducted up to 18 kbars. Results thus far suggest that, in a Co doping range near 13

**10:00AM X24.00009 High Pressure Seebeck Coefficient Measurements Using Paris-Edinburgh Cell**, JASON BAKER, RAVHI KUMAR, HIPSEC and Department of Physics, University of Nevada, Las Vegas, CHANGYONG PARK, CURTIS KENNEY-BENSON, HPCAT, Geophysical Laboratory, Carnegie Institution of Washington, NENAD VELISAVLJEVIC, Shock and Detonation Physics Group, Los Alamos National Laboratory, HIPSEC AND DEPARTMENT OF PHYSICS, UNIVERSITY OF NEVADA, LAS VEGAS COLLABORATION, HPCAT, GEOPHYSICAL LABORATORY, CARNEGIE INSTITUTION OF WASHINGTON COLLABORATION, SHOCK AND DETONATION PHYSICS GROUP, LOS ALAMOS NATIONAL LABORATORY COLLABORATION — We have developed a new type of sample cell assembly for the Paris-Edinburgh (PE) type large volume press for simultaneous x-ray diffraction, electrical resistance, and thermal measurements at high pressures. We demonstrate the feasibility of performing in situ measurements of the Seebeck coefficient over a broad range of pressure-temperature conditions by observing the well-known solid-solid and solid-melt transitions of bismuth (Bi) up to 3GPa and 450 K. We observed a gradual increase in the Seebeck coefficient which becomes positive during transition to the Bi - II phase. Also, we have performed successful Seebeck coefficient measurements on the thermoelectric material PbTe. This new capability enables us to directly correlate pressure-induced structural phase transitions to electrical and thermal properties.

**10:12AM X24.00010 Mechanical Model for Dynamic Behavior of Concrete Under Impact Loading<sup>1</sup>**, YUANXIANG SUN, State Key Laboratory of Explosion Science and Technology, Beijing Institute of Technology, China — Concrete is a geo-material which is used substantively in the civil building and military safeguard. One coupled model of damage and plasticity to describe the complex behavior of concrete subjected to impact loading is proposed in this research work. The concrete is assumed as homogeneous continuum with pre-existing micro-cracks and micro-voids. Damage to concrete is caused due to micro-crack nucleation, growth and coalescence, and defined as the probability of fracture at a given crack density. It induces a decrease of strength and stiffness of concrete. Compaction of concrete is physically a collapse of the material voids. It produces the plastic strain in the concrete and, at the same time, an increase of the bulk modulus. In terms of crack growth model, micro-cracks are activated, and begin to propagate gradually. When crack density reaches a critical value, concrete takes place the smashing destroy. The model parameters for mortar are determined using plate impact experiment with uni-axial strain state. Comparison with the test results shows that the proposed model can give consistent prediction of the impact behavior of concrete. The proposed model may be used to design and analysis of concrete structures under impact and shock loading.

**10:24AM X24.00011 Jetting mechanisms of particles under shock wave acceleration: the role of force chains**, KUN XUE, Beijing Institute of Technology — The particle jetting phenomenon is widely observed in many problems associated with blast/shock dispersal of granular materials, although its origin is still unidentified. We carried out discrete element simulations of the shock dispersal of two-dimensional particle rings in order to extract the particle-scale evolution of the shocked rings in terms of the velocity profile and the force-chain networks. Initially the force chains distribute uniformly along the circumference, but after several dozens of microseconds, they disseminate into a handful of blobs which mainly consist of long linear or branched chains align with the radial direction. These blobs are separated by zones featuring relatively sparse force chains which take forms of short chains or small compact polygons. The radial-like force chains in blobs serves as the channels transferring the momentum from the inner layers to outer layers, resulting in fast moving blocks without appreciable velocity differences. By contrast, the shock energy in the zones with short force chains is largely dissipated among the particle collision. Thus particles in these zones lag behind those bound by strong force chains. The resultant heterogeneous velocity profile acts as the precursor of the ensuing particle jetting.

**8:00AM X25.00001 ABSTRACT WITHDRAWN —**

**8:12AM X25.00002 Spin order, charge order, and spin liquid in spin-fermion model of cuprates.**, KYUNGMIN LEE, Cornell University, OINAM NGAMBA MEETEL, American Express, STEVEN WHITE, University of California, Irvine, EUN-AH KIM, Cornell University — Recent experimental observations that intra-unit-cell structures play crucial role in the detection of charge order motivates numerical studies that can include strong correlation effects as well as multi-site until cells. However, this costs precious Hilbert space. In this talk I will present our results using a minimal model for cuprates that can access intra-unit-cell information: multi-band spin-fermion model with spins on the copper sites and holes on oxygen sites. For this we used exact diagonalization as well as density matrix renormalization group. In addition to charge and spin order tendencies we test for evidence of the so-called FL\* state.

**8:24AM X25.00003 Interplay of pair density wave and charge density wave order in the cuprate pseudogap phase**, DANIEL AGTERBERG, ADIL AMIN, University of Wisconsin - Milwaukee — Recent x-ray measurements in the cuprate YBCO suggest that the charge density wave (CDW) order seen at high-field has a different c-axis structure than that seen at zero-field and further suggests that CDW order breaks the c-axis mirror plane symmetry of the  $\text{CuO}_2$  layers. We examine pair density wave order that induces CDW order consistent with these observations.

**8:36AM X25.00004 Hybridization of Higgs modes in a bond-density-wave state in cuprates**, ZACHARY RAINES, VALENTIN STANEV, VICTOR GALITSKI, Univ of Maryland-College Park — Recently, several groups have reported observations of collective modes of the charge order present in underdoped cuprates. Motivated by these experiments, we study theoretically the oscillations of the order parameters, both in the case of pure charge order, and for charge order coexisting with superconductivity. We find in the coexistence regime two Higgs modes arising from hybridization of the amplitude oscillations of the different order parameters, one of which has a minimum frequency that is within the single particle energy gap and which is a non-monotonic function of temperature. Additionally, we explore an unusual low-energy damping channel for the collective modes, which relies on the band reconstruction caused by the coexistence of the two orders.

**8:48AM X25.00005 Thermodynamic properties of underdoped  $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$  cuprates for doping values  $x \in (0.5, 0.9)^1$** , P. SALAS, M. A. SOLIS, M. FORTES, Instituto de Física, UNAM, Mexico — We extend the Boson-Fermion superconductivity model to include layered systems, such as underdoped cuprate superconductors  $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$ , with  $x \in (0.5, 0.9)$  ranging from underdoped to optimally doped. We model cuprates as a boson-fermion quantum gas mixture immersed in a layered structure, generated via a Dirac comb potential applied in one direction while the particles move freely in the other two directions. The optimum parameters of the system, which are the impenetrability of the planes and the paired fermion fraction, are obtained by minimizing the Helmholtz free energy and setting the experimental critical temperature  $T_c$ . Using this optimized scheme, we are able to predict the following thermodynamic properties of cuprates as a function of temperature: the entropy; the Helmholtz free energy; the electronic specific heat and the total specific heat for different doping values. Furthermore, we determine the behavior of the jump height in the electronic specific heat, the normal electronic specific heat coefficient  $\gamma(T_c)$ , the quadratic  $\alpha$  and cubic  $\beta$  terms of the specific heat for low temperatures, the ground state energy and the mass anisotropy as a function of doping. Comparison to experimental values reported is analyzed.

**9:00AM X25.00006 The roles of antiferromagnetic and nematic fluctuations in cuprate superconductors: a sign-free quantum Monte-Carlo study**, ZIXIANG LI, HONG YAO, Institute for Advanced Study, Tsinghua University, FA WANG, International Center for Quantum Materials, School of Physics, Peking University, DUNG-HAI LEE, Department of Physics, University of California at Berkeley — Superconductivity is an emergent phenomena in the sense that the energy scale at which Cooper pairs form is generically much lower than the bare energy scale, namely the electron kinetic energy bandwidth. Addressing the mechanism of Cooper pairing amounts to finding out the effective interaction (or the renormalized interaction) that operates at the low energies. Finding such interaction from the bare microscopic Hamiltonian has not been possible for strong correlated superconductors such as the copper-oxide high temperature superconductor. In fact even one is given the effective interaction, determining its implied electronic instabilities without making any approximation has been a formidable task. Here, we perform sign-free quantum Monte-Carlo simulations to study the antiferromagnetic, superconducting, and the charge density wave instabilities which are ubiquitous in both electron and hole doped cuprates. Our result suggests only after including both the nematic and antiferromagnetic fluctuation, are the observed properties associated with these instabilities reproduced by the theory.

**9:12AM X25.00007 Strong-coupling approach to nematicity in the cuprates**, PETER PHILIPP ORTH, University of Minnesota, BHILAHARI JEEVANESAN, JOERG SCHMALIAN, Karlsruhe Institute of Technology (KIT), RAFAEL FERNANDES, University of Minnesota — The underdoped cuprate superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  is known to exhibit an electronic nematic phase in proximity to antiferromagnetism. While nematicity sets in at large temperatures of  $T \approx 150$  K, static spin density wave order only emerges at much lower temperatures. The magnetic response shows a strong in-plane anisotropy, displaying incommensurate Bragg peaks along one of the crystalline directions and a commensurate peak along the other one. Such an anisotropy persists even in the absence of long-range magnetic order at higher temperatures, marking the onset of nematic order. Here we theoretically investigate this situation using a strong-coupling method that takes into account both the localized Cu spins and the holes doped into the oxygen orbitals. We derive an effective spin Hamiltonian and show that charge fluctuations promote an enhancement of the nematic susceptibility near the antiferromagnetic transition temperature.

**9:24AM X25.00008 Interplay between pair density waves and random field disorders in the pseudogap regime of cuprate superconductors**, CHEUNG CHAN, Institute for Advanced Study, Tsinghua University — To capture various experimental results in the pseudogap regime, we propose a four-component pair density wave (PDW) state in which all components compete with each other. Without random field disorders (RFD), globally the PDW components are phase separated and only one of the component survives locally. If the RFD is included, this state becomes a phase separated state with short range PDW stripes, and induces charge density waves (CDW) and loop current order as secondary composite orders. We call this phase-separated pair nematic (PSPN) state. This state could capture a number of important experimental features in the pseudogap, in particular, the predominantly  $d$ -wave CDW with spatial dependent charge smecticity, the unusual ARPES quasiparticle spectrum, and the time reversal symmetry breaking order in polarized neutron diffraction and polar Kerr rotation. We also discuss how the various temperature scales arisen in the pseudogap can be understood in terms of the interplay with the RFD and fluctuating orders.

**9:36AM X25.00009 Breakup of superconducting order parameter into 2 subbands of Cooper pairs increases temperature range of fluctuations in the pseudogap phase**, FU-CHUN ZHANG, Department of Physics, Zhejiang University, Hangzhou 310027, China, YE-HUA LIU, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, ROBERT KONIK, Condensed Matter Physics and Material Science Department, Brookhaven National Laboratory, Upton, NY 11973, THOMAS MAURICE RICE, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland — The opening of the pseudogap in underdoped cuprates breaks up the Fermi surface, into 4 disconnected arcs centered on the nodal directions. In the superconducting phase, the  $d$ -wave order parameter breaks up into 2 subbands of Cooper pairs along  $(1,1)$  and  $(1,-1)$ , with strong intra-subband and weak inter-subband couplings. This multiple-band superconductivity allows a low-energy Leggett mode to emerge due to phase fluctuations between the subbands. We propose that the overdamped Leggett mode is responsible for the highly unusual wide temperature range of superconducting fluctuations observed in the c-axis infrared conductivity in the pseudogap phase.

**9:48AM X25.00010 Giant phonon anomaly associated with strong superconducting fluctuations in the pseudogap phase of underdoped cuprates**, YE-HUA LIU, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, ROBERT KONIK, Condensed Matter Physics and Material Science Department, Brookhaven National Laboratory, Upton, NY 11973, THOMAS MAURICE RICE, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, FU-CHUN ZHANG, Department of Physics, Zhejiang University, Hangzhou 310027, China — Phonons with wavevectors connecting Fermi-arc ends are strongly damped in the pseudogap phase as  $T \rightarrow T_c$  from above. Below  $T_c$  the anomaly abruptly switches to a dip in the phonon dispersions at the same wavevectors. Based on our proposed 2-subband model of superconductivity, we analyze the coupling between these phonons and the Leggett mode. We consider the phonon self energy arising from a forward scattering of the phonon accompanied by Cooper-pair transfers between the subbands. The intermediate state of this process involves 2 Leggett modes and a forward scattered phonon. Above  $T_c$ , the Leggett mode is overdamped giving rise to the giant phonon damping, while below  $T_c$ , the Leggett mode develops a finite energy turning the phonon anomaly into a dip in the energy dispersion.

**10:00AM X25.00011 Pairing in the presence of a pseudogap<sup>1</sup>**, DOUGLAS SCALAPINO, Univ of California - Santa Barbara, THOMAS MAIER, ORNL, PETER STAAR, IBM Research (Zurich), VIVEK MISHRA, ORNL — After 30 years, the quest to experimentally identify the mechanism responsible for pairing in the high  $T_c$  superconductors continues. Here we discuss an approach in which angle resolved photoemission (ARPES) data for BSCCO 2212 ( $T_c=89K$ ) is used to extract the single particle spectral weight  $A(k,w)$ . This spectral weight is then used to calculate the BCS kernel and estimate the RPA spin-fluctuation d-wave pairing strength. Previously  $A(k,w)$  results at  $T=140K$ , extrapolated to lower temperatures, found that the BSCCO pseudo gap suppressed the logarithmic singularity of the BCS kernel and the spin-fluctuation interaction was too weak to produce superconductivity [V.Mishra et al., Nat. Phys. 10, 357]. Here using results for  $A(k,w)$  at  $T=40K$  for this same system, we find that while the BCS kernel is suppressed, there is a significant increase in the d-wave pairing strength for the spin-fluctuation interaction when the temperature drops from  $T=140K$  and  $40K$ . These results are shown to be consistent with DCA calculations for a 2D Hubbard model of a BSCCO like system which has a pseudo gap. We conclude that in spite of the suppression of the usual BCS logarithmic instability by the pseudo gap, the increase in strength of the spin-fluctuation interaction is sufficient to lead to superconductivity.

**10:12AM X25.00012 Effect of Extended Saddle Point Singularities in Cuprates and Evidences<sup>1</sup>**, GUANG-LIN ZHAO, Physics Department, Southern University and A & M College — First-principles calculations and angle-resolved photoemission spectroscopy measurements showed extended saddle point singularities in the electron structures of some cuprates such as  $YBa_2Cu_3O_7$  (YBCO). The extended saddle point singularities in the electronic structures of the materials can lead to anomalous physical properties. In this work, a new methodology is implemented by integrating first-principles calculations of electronic structures of the materials into the theory of many-body physics for superconductivity. The aim is to seek a unified methodology to calculate the electronic and superconducting properties of the materials. It is demonstrated from first-principles that the extended saddle point singularities in the materials such as YBCO strongly correlate to the anomalous isotope effect in the superconductors.

<sup>1</sup>The work was funded in part by NSF LASIGMA Project (Award EPS-1003897, NSF92010-15-RII-SUBR) and by ARO (Award W911NF-15-1-0483).

**10:24AM X25.00013 Theory of Berry Phases in the Cuprate Pseudogap Phase**, GEREMIA MASSARELLI, TAMAR PEREG-BARNEA, McGill University — The geometric Berry phase is part of the phase accumulated by a quantum system undergoing adiabatic evolution around a closed loop in parameter space <sup>1</sup>. Recently, data from quantum oscillations experiments, in which Berry's phase is accessible via its contribution to the phase offset, were used to determine Berry's phase in certain electron- and hole-doped cuprate superconductors in high-magnetic-field regimes <sup>2</sup>. The data reveal a trivial Berry phase of 0 in the hole-doped materials examined, while a phase of  $\sim 1.4\pi$  was found in the electron-doped material. These findings set new, significant constraints on the possible descriptions of the pseudogap phase of the cuprates. This is used as a test of validity for some proposed models of cuprate superconductors. Berry's phase is computed within the framework of these models in high-field regimes and compared to the experimental findings.

**10:36AM X25.00014 Interplay between uni-directional and bi-directional charge orders in underdoped cuprates**, YUXUAN WANG, University of Illinois at Urbana-Champaign, ANDREY CHUBUKOV, University of Minnesota — We analyze the interplay between charge-density-wave (CDW) orders with axial momenta  $(Q, 0)$  and  $(0, Q)$  ( $\Delta_x$  and  $\Delta_y$  respectively), detected in the underdoped cuprates. The CDW order in real space can be uni-directional (either  $\Delta_x$  or  $\Delta_y$  is non-zero) or bi-directional (both  $\Delta_x$  and  $\Delta_y$  are non-zero). To understand which of the two orders develop, we adopt the magnetic scenario, in which the CDW order appears due to spin-fluctuation exchange. We derive the Ginzburg-Landau action to the sixth order in  $\Delta_x$  and  $\Delta_y$  and argue that the CDW order is bi-directional at the onset but changes to uni-directional inside the CDW phase. This implies that, at a given temperature, CDW order is uni-directional at smaller dopings, but becomes bi-directional at larger dopings. These results are consistent with recent x-ray data on YBCO, which detected tendency towards bi-directional order at larger dopings. We also discuss for completeness the effect of yet unobserved intertwined pair-density-wave (PDW) order, which may appear along with CDW.

**10:48AM X25.00015 Dipolon Theory of High Temperature Superconductors— Prediction of the Existence of New Very Low Energy Excitations to be Observed in Photoemission Experiments**, RAM R SHARMA, University of Illinois at Chicago — The dipolon theory [1,2] first discovered [3,4] two high energy kinks in electron energy [5]. It [1-2] has also predicted two superconducting states, symmetric ("s") and anti-symmetric ("as"). Here we report the prediction of very low energy excitations due to transition from "as" state to "s" state ("ass") (or vice versa) which creates (annihilates) the quantum ("asson") of energy  $\hbar\omega_a(\vec{q}_a) = E^s(\vec{k}^i) - E^{as}(\vec{k}^f)$ ; "a" is for "asson" and  $E^s(\vec{k}^i)$  and  $E^{as}(\vec{k}^f)$  are electron energies in "s" and "as" states, respectively ( $E^i(\vec{k}) = \bar{E}_r^i(\vec{k})$  [1-4]). Our theory [1-4] finds in BISCCO at M point on Fermi level at  $T=13$  K asson energy about  $14 \pm 8$  meV. We predict that these assons create a new kink in electron energy at this energy. Also, a single pair transitions are possible which involve two assons. (1) R. R. Sharma, Phys. Rev. B **63**, 054506 (2001). (2) R. R. Sharma, Physica C **439**, 47 (2006). (3) R. R. **Friday, March 18, 2016 8:00AM - 11:00AM —**

Session X27 DCMP: New Methods for Strongly Correlated Systems 326 - Gia-Wei Chern, University of Virginia

**8:00AM X27.00001 Non-equilibrium DMFT - Polaritonics** , ANDREAS LUBATSCH, Georg-Simon-Ohm Technical University of Applied Sciences, REGINE FRANK, Serin Physics Laboratory, E273 Department of Physics and Astronomy Rutgers University 136 Frelinghuysen Road Piscataway, NJ 08854-8019, USA — Non-equilibrium physics recently really becomes important with the progress of ultrafast laser sciences. However in our understanding there is still a gap between equilibrium physics and the non-equilibrium, even though numerical methods have been advanced in recent years. We compare in this talk novel results at hand with equilibrium physics. The comparison will show that especially theoretical efforts are needed to explain many - so far - unresolved problems and to predict novel research on the basis of ab initio computing. We specifically discuss several non-equilibrium extensions of DMFT, numerical methods as well as semi-analytical solvers.

**8:12AM X27.00002 Strange metals from quantum geometric fluctuations of interfaces** , JIAN-HUANG SHE, Cornell University, ALAN BISHOP, ALEXANDER BALATSKY, Los Alamos National Lab — The emerging picture of strongly correlated electron systems is that they possess a multiplicity of nearly degenerate ground states. A general theoretical framework for such systems is lacking. Here we explore a new approach based on the observation that different ground states can coexist and fluctuate in real space. Specifying to systems near the Mott metal-insulator transition, we propose a real space picture as itinerant electrons functioning in the fluctuating geometries bounded by interfaces between metallic and insulating regions. The interface fluctuations give rise to non-Fermi liquid behavior for the itinerant electrons, and furthermore mediate Cooper pairing.

**8:24AM X27.00003 A real-time impurity solver for DMFT** , HYUNGWON KIM, Rutgers University, CAMILLE ARON, Laboratoire de Physique Théorique, École Normale Supérieure, CNRS, Paris, France, JONG E. HAN, State University of New York at Buffalo, GABRIEL KOTLIAR, Rutgers University — Dynamical mean-field theory (DMFT) offers a non-perturbative approach to problems with strongly correlated electrons. The method heavily relies on the ability to numerically solve an auxiliary Anderson-type impurity problem. While powerful Matsubara-frequency solvers have been developed over the past two decades to tackle equilibrium situations, the status of real-time impurity solvers that could compete with Matsubara-frequency solvers and be readily generalizable to non-equilibrium situations is still premature. We present a real-time solver which is based on a quantum Master equation description of the dissipative dynamics of the impurity and its exact diagonalization. As a benchmark, we illustrate the strengths of our solver in the context of the equilibrium Mott-insulator transition of the one-band Hubbard model and compare it with iterative perturbation theory (IPT) method. Finally, we discuss its direct application to a nonequilibrium situation.

**8:36AM X27.00004 Constrained Path Monte Carlo with Matrix Product State trial wavefunctions** , CHIA-MIN CHUNG, University California Irvine, MATTHEW FISHMAN, California Institute of Technology, STEVEN WHITE, University California Irvine, SHIWEI ZHANG, College of William and Mary — Constrained path Monte Carlo (CPMC) is a powerful method for simulating strongly correlated systems. By constraining the path with a trial wavefunction, CPMC circumvents the minus sign problem, but at the cost of introducing a bias. The Density Matrix Renormalization Group (DMRG) is an alternative simulation technique, which is immune to the minus sign problem, but which has an analogous "dimensionality problem" for two and three dimensions. Here we present a combination of these techniques, where we use a DMRG matrix product state as a trial wavefunction for CPMC. We demonstrate our method in two-dimensional Hubbard model, and show the comparison to DMRG alone and to CPMC with single-determinant trial functions.

**8:48AM X27.00005 Efficient implementation of the parquet equations - role of the reducible vertex function and its kernel approximation<sup>1</sup>** , GANG LI, NILS WENTZELL, PETRA PUDLEINER, PATRIK THUNSTRÖM, KARSTEN HELD, Vienna University of Technology — We present an efficient implementation of the parquet formalism which respects the asymptotic structure of the vertex functions at both single- and two-particle levels in momentum- and frequency-space. We identify the two-particle reducible vertex as the core function which is essential for the construction of the other vertex functions. This observation stimulates us to consider a two-level parameter-reduction for this function to simplify the solution of the parquet equations. The resulting functions, which depend on fewer arguments, are coined "kernel functions". With the use of the "kernel functions", the open boundary of various vertex functions in the Matsubara-frequency space can be faithfully satisfied. We justify our implementation by accurately reproducing the dynamical mean-field theory results from momentum-independent parquet calculations. The high-frequency asymptotics of the single-particle self-energy and the two-particle vertex are correctly reproduced, which turns out to be essential for the self-consistent determination of the parquet solutions. The current implementation is also feasible for the dynamical vertex approximation.

**9:00AM X27.00006 Exact Real-time Dynamics with non-equilibrium QMC** , QIAOYUAN DONG, ANDREY ANTIPOV, EMANUEL GULL, University of Michigan — We present an overview of recent methodological progress for non-equilibrium hybridization expansion diagrammatic Monte Carlo impurity solver and we examine the real-time dynamics of a correlated quantum dot in the mixed valence regime. We perform numerically exact calculations of currents and magnetic susceptibilities after a quantum quench from equilibrium by rapidly applying a bias voltage in a wide range of initial temperatures. We observe Kondo signatures both in transient regimes and in the steady state.

**9:12AM X27.00007 Dynamical simulations of strongly correlated electron materials** , JOEL KRESS, KIPTON BARROS, CRISTIAN BATISTA, Los Alamos National Laboratory, GIA-WEI CHERN, University of Virginia, GABRIEL KOTLIAR, Rutgers University — We present a formulation of quantum molecular dynamics that includes electron correlation effects via the Gutzwiller method. Our new scheme enables the study of the dynamical behavior of atoms and molecules with strong electron interactions. The Gutzwiller approach goes beyond the conventional mean-field treatment of the intra-atomic electron repulsion and captures crucial correlation effects such as band narrowing and electron localization. We use Gutzwiller quantum molecular dynamics to investigate the Mott transition in the liquid phase of a single-band metal and uncover intriguing structural and transport properties of the atoms.

**9:24AM X27.00008 Ab Initio Dynamical Correlations from Auxiliary-field quantum Monte Carlo: applications in the Hubbard model<sup>1</sup>** , ETTORE VITALI, HAO SHI, MINGPU QIN, SHIWEI ZHANG, William and Mary College — The possibility of calculating dynamical correlation functions from first principles provides a unique opportunity to explore the manifold of the excited states of a quantum many-body system. Such calculations allow us to predict interesting physical properties like spectral functions, excitation spectra and charge and spin gaps, which are more difficult to access from usual equilibrium calculations. We address the ab-initio calculation of dynamical Green functions and two-body correlation functions in the Auxiliary-field Quantum Monte Carlo method, using the two-dimensional Hubbard model as an example. When the sign problem is not present, an unbiased estimation of imaginary time correlation functions is obtained. We discuss in detail the complexity and the stability of the calculations. Moreover, we propose a new approach which is expected to be very useful when dealing with dilute systems, e.g. for cold gases, allowing calculations with a very favorable complexity in the system size.

<sup>1</sup>Supported by NSF, DOE SciDAC, and Simons Foundation

**9:36AM X27.00009 Bond Order Correlations in the 2D Hubbard Model<sup>1</sup>** , CONRAD MOORE, SAMEER ABU ASAL, SHUXIANG YANG, JUANA MORENO, MARK JARRELL, Louisiana State Univ - Baton Rouge — We use the dynamical cluster approximation to study the bond correlations in the Hubbard model with next nearest neighbor (nnn) hopping to explore the region of the phase diagram where the Fermi liquid phase is separated from the pseudogap phase by the Lifshitz line at zero temperature. We implement the Hirsch-Fye cluster solver that has the advantage of providing direct access to the computation of the bond operators via the decoupling field. In the pseudogap phase, the parallel bond order susceptibility is shown to persist at zero temperature while it vanishes for the Fermi liquid phase which allows the shape of the Lifshitz line to be mapped as a function of filling and nnn hopping. Our cluster solver implements NVIDIA's CUDA language to accelerate the linear algebra of the Quantum Monte Carlo to help alleviate the sign problem by allowing for more Monte Carlo updates to be performed in a reasonable amount of computation time.

**9:48AM X27.00010 Entanglement Entropy of U(1) Quantum Spin Liquids** , MICHAEL PRETKO, T SENTHIL, Massachusetts Institute of Technology — We investigate the entanglement structure of the ground state of a (3+1)-dimensional U(1) quantum spin liquid, described by the deconfined phase of a compact U(1) gauge theory. The excitations of the system are a gapless photon and gapped electric/magnetic charges. The elements of the entanglement spectrum can be grouped according to the electric flux between the two regions, leading to an interpretation in terms of particles living on the boundary. The entanglement spectrum is given additional structure due to the presence of the gapless photon. Making use of the Bisognano-Wichmann theorem and a local thermal approximation, these two contributions are recast in terms of boundary and bulk contributions, respectively. Both pieces give rise to universal subleading logarithms in the entanglement entropy, as opposed to the subleading constant in gapped topologically ordered systems. The photon term arises from the low-energy conformal field theory and is essentially local in character. The particle term arises due to the constraint of closed electric loops and is shown to be the natural generalization of topological entanglement entropy to the U(1) spin liquid. This contribution to the entanglement entropy can be isolated by means of a special geometric construction.

**10:00AM X27.00011 Optical Conductivity in Holography with Hyperscaling Violation and Massive Gravity** , BRANDON LANGLEY, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — One of the long-standing enigmas in the field of strongly-interacting electron systems is the mid-frequency power law form of the optical conductivity in the cuprates,  $|\sigma| \sim \omega^{-\alpha}$ . Many efforts have been put forth to obtain this power law using the AdS/CFT correspondence while maintaining the experimentally observed Drude form of the conductivity at low frequency. Some models have obtained the power law form over a very narrow range but none have matched the robust form lasting over decades as in experimental observations. We expand on previous constructions by introducing the dynamical exponent  $z$  and hyperscaling parameter  $\theta$  in a theory that breaks translational invariance using massive gravity. We seek a form of the optical conductivity that reproduces the functional form of the cuprates over all frequency regimes.

**10:12AM X27.00012 Probing Critical Surfaces in Momentum Space Using Real-Space Entanglement Entropy: Bose versus Fermi<sup>1</sup>** , KUN YANG, Department of Physics and National High Magnetic Field Laboratory, Florida State University, HSIN-HUA LAI, Department of Physics and Astronomy, Rice University — A co-dimension one critical surface in the momentum space can be either a familiar Fermi surface, which separates occupied states from empty ones in the non-interacting fermion case, or a novel Bose surface, where gapless bosonic excitations are anchored. Their presence gives rise to logarithmic violation of entanglement entropy area law. When they are *convex*, we show that the shape of these critical surfaces can be determined by inspecting the leading logarithmic term of real space entanglement entropy. The fundamental difference between a Fermi surface and a Bose surface is revealed by the fact that the logarithmic terms in entanglement entropies differ by a factor of two:  $S_{log}^{Bose} = 2S_{log}^{Fermi}$ , even when they have identical geometry. Our method has remarkable similarity with determining Fermi surface shape using quantum oscillation. We also discuss possible probes of *concave* critical surfaces in momentum space.

**10:24AM X27.00013 Entanglement spectrum and entangled modes of highly excited states in random XX spin chains** , MOHAMMAD POURANVARI, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University, Tallahassee, Florida 32306, USA — We examine the newly developed real space renormalization group method of finding excited eigenstate (RSRG-X) of the XX spin-1/2 chain, from entanglement perspectives. Eigenmodes of the entanglement Hamiltonian, especially the maximally entangled mode (that contributes the most to the entanglement entropy) and corresponding entanglement energies are studied and compared with predictions of RSRG-X. Our numerical results demonstrate the accuracy of the RSRG-X method in the strong disorder limit, and quantify its error when applied to weak disorder regime. Overall, our results validate the RSRG-X method qualitatively, but as in the case of real space renormalization group method for the ground state (RSRG) there are quantitative errors for weaker randomness, and also such error grows with increasing temperature/excitation energy density.

**10:36AM X27.00014 Two-component Structure in the Entanglement Spectrum of Highly Excited States** , ZHI-CHENG YANG, CLAUDIO CHAMON, Boston University, ALIOSCIA HAMMA, Tsinghua University, EDUARDO MUCCILOLO, University of Central Florida — We study the entanglement spectrum of highly excited eigenstates of two known models which exhibit a many-body localization transition, namely the one-dimensional random-field Heisenberg model and the quantum random energy model. Our results indicate that the entanglement spectrum shows a “two-component” structure: a universal part that is associated to Random Matrix Theory, and a non-universal part that is model dependent. The non-universal part manifests the deviation of the highly excited eigenstate from a true random state even in the thermalized phase where the Eigenstate Thermalization Hypothesis holds. The fraction of the spectrum containing the universal part decreases continuously as one approaches the critical point and vanishes in the localized phase in the thermodynamic limit. We use the universal part fraction to construct a new order parameter for the many-body delocalized-to-localized transition. Two toy models based on Rokhsar-Kivelson type wavefunctions are constructed and their entanglement spectra are shown to exhibit the same structure.

**10:48AM X27.00015 Matrix-product-state method with local basis optimization for nonequilibrium electron-phonon systems<sup>1</sup>** , FABIAN HEIDRICH-MEISNER, LMU Munich, Germany, CHRISTOPH BROCKT, University of Hanover, Germany, FLORIAN DORFNER, LMU Munich, Germany, LEV VIDMAR, Penn State University, USA, ERIC JECKELMANN, University of Hanover, Germany — We present a method for simulating the time evolution of quasi-one-dimensional correlated systems with strongly fluctuating bosonic degrees of freedom (e.g., phonons) using matrix product states [1]. For this purpose we combine the time-evolving block decimation (TEBD) algorithm with a local basis optimization (LBO) approach. We discuss the performance of our approach in comparison to TEBD with a bare boson basis, exact diagonalization, and diagonalization in a limited functional space. TEBD with LBO can reduce the computational cost by orders of magnitude when boson fluctuations are large and thus it allows one to investigate problems that are out of reach of other approaches. First, we test our method on the non-equilibrium dynamics of a Holstein polaron [2] and show that it allows us to study the regime of strong electron-phonon coupling. Second, the method is applied to the scattering of an electronic wave packet off a region with electron-phonon coupling. Our study reveals a rich physics including transient self-trapping and dissipation.

**8:00AM X28.00001 Weyl Phases in a Three Dimensional Network Model<sup>1</sup>** , HAILONG WANG, YIDONG CHONG, Division of Physics and Applied Physics, Nanyang Technological University, THEORETICAL PHOTONICS TEAM — We study the topological properties of 3D “Floquet” band structures, defined using unitary evolution matrices rather than Hamiltonians. Such band structures can be realized in coherent-wave networks or lattices subjected to time-periodic drives. Previously, 2D Floquet band structures have been shown to exhibit unusual topological behaviors such as topologically-nontrivial zero-Chern-number phases. Here, we analyze the Floquet band structure of a 3D network model, which exhibits an Floquet analogue of a Weyl phase. The surface states exhibit topologically-protected “Fermi” arcs, similar to the recently-discovered Weyl semi-metals; however, the Weyl points in different quasi-energy gaps are related by a particle-hole symmetry which is unique to the Floquet system. By tuning the coupling parameters of the network, we can drive a transition between conventional insulator, weak topological insulator, and Weyl phases. Finally, we discuss the possibility of realizing this model using custom-designed electromagnetic networks.

**8:12AM X28.00002 Magnetic response in three-dimensional nodal semimetals** , MIKITO KOSHINO, INTAN FATIMAH HIZBULLAH, Tohoku University — We study the magnetic response in various three-dimensional gapless systems, including Dirac and Weyl semimetals and a line-node semimetal. We show that the susceptibility is decomposed into the orbital term, the spin term and also the spin-orbit cross term which is caused by the spin-orbit interaction. We show that the orbital susceptibility logarithmically diverges at the band touching energy in the point-node case, while it exhibits a stronger delta-function singularity in the line node case. The spin-orbit cross term is shown to be paramagnetic in the electron side while diamagnetic in the hole side, in contrast with other two terms which are both even functions in Fermi energy. The spin-orbit cross term in the nodal semimetal is found to be directly related to the chiral surface current induced by the topological surface modes.

**8:24AM X28.00003 Quasi-Topological Electromagnetic Response of Line-node Semimetals<sup>1</sup>** , SRINIDHI RAMAMURTHY, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — Topological semimetals are gapless states of matter which have robust surface states and interesting electromagnetic responses. We consider the electromagnetic response of gapless phases in 3 + 1-dimensions with line nodes. We show through a layering approach that an intrinsic 2-form  $\mathcal{B}_{\mu\nu}$  emerges in the effective response field theory that is determined by the geometry and energy-embedding of the nodal lines. This 2-form is shown to be simply related to the charge polarization and orbital magnetization of the sample. We conclude by discussing the relevance for recently proposed materials and heterostructures with line-node fermi-surfaces.

**8:36AM X28.00004 Multipolar orders and quantum criticality of a three-dimensional parabolic semimetal** , BITAN ROY, PALLAB GOSWAMI, University of Maryland — Motivated by the observation of multipolar ordering in many heavy fermion compounds and 227 pyrochlore iridates, we investigate the phase diagram of an interacting, three dimensional parabolic semimetal as a paradigmatic toy model for studying the interplay among electronic correlations, topology and quantum critical phenomena. The generic forms of the local order parameters and quartic interactions are constructed according to the irreducible representations of octahedral point group symmetry. Through a renormalization group analysis, we elucidate the competition between time-reversal symmetric quadrupolar and time-reversal symmetry breaking octopolar ordered phases for sufficiently strong interactions. We show that the quadrupolar ordering can give rise to a correlated topological insulator phase, while the octopolar order generically leads to a Weyl semimetal phase. The quantum phase transitions between the semimetal and the broken symmetry phases are controlled by non-Gaussian, itinerant quantum critical points.

**8:48AM X28.00005 Topological ‘Luttinger’ invariants protected by crystal symmetry in semimetals<sup>1</sup>** , S.A. PARAMESWARAN, University of California, Irvine — Luttinger’s theorem is a fundamental result in the theory of interacting Fermi systems: it states that the volume inside the Fermi surface is left invariant by interactions, if the number of particles is held fixed. Although this is traditionally justified using perturbation theory, it can be viewed as arising from a momentum balance argument that examines the response of the ground state to the insertion of a single flux quantum [M. Oshikawa, *Phys. Rev. Lett.* **84**, 3370 (2000)]. This reveals that the Fermi sea volume is a topologically protected quantity. Extending this approach, I show that spinless or spin-rotation-preserving fermionic systems in non-symmorphic crystals possess generalized topological ‘Luttinger invariants’ that can be nonzero even in cases where the Fermi sea volume vanishes. A nonzero Luttinger invariant then forces energy bands to touch, leading to semimetals whose gaplessness is rooted in topology; opening a gap without symmetry breaking automatically triggers fractionalization. The existence of these invariants is linked to the inability of non-symmorphic crystals to host band insulating ground states except at special fillings. I exemplify the use of these new invariants by showing that they distinguish various classes of semimetals.

**9:00AM X28.00006 Ferromagnetic interactions between transition-metal impurities in topological and 3D Dirac semimetals**, TOMASZ DIETL, Inst Phys, Polish Acad of Sci; Inst Theor Phys, Univ Warsaw; WPI-AIMR Tohoku Univ — The magnitude of ferromagnetic coupling driven by inter-band (Bloembergen-Rowland - BR) and intra-band (Ruderman-Kittel-Kasuya-Yoshida - RKKY) spin polarization is evaluated within  $k$ - $p$  theory for topological semimetals  $\text{Hg}_{1-x}\text{Mn}_x\text{Te}$  and  $\text{Hg}_{1-x}\text{Mn}_x\text{Se}$  as well as for 3D Dirac semimetal  $(\text{Cd}_{1-x}\text{Mn}_x)_3\text{As}_2$ . In these systems  $\text{Mn}^{2+}$  ions do not introduce any carriers. Since, however, both conduction and valence bands are built from anion  $p$ -type wave functions, hybridization of Mn  $d$  levels with neighboring anion  $p$  states leads to spin-dependent  $p-d$  coupling of both electrons and holes to localized Mn spins, resulting in sizable inter-band spin polarization and, thus in large BR interactions. We demonstrate that this ferromagnetic coupling, together with antiferromagnetic superexchange, elucidate a specific dependence of spin-glass freezing temperature on  $x$ , determined experimentally for these systems. Furthermore, by employing a multi-orbital tight-binding method, we find that superexchange becomes ferromagnetic when Mn is replaced by Cr or V. Since Cr should act as an isoelectronic impurity in HgTe, this opens a road for realization of ferromagnetic topological insulators based on (Hg,Cr)Te.

**9:12AM X28.00007 Gyrotropic magnetic effect in Weyl semimetals**, SHUDAN ZHONG, JOEL MOORE, Univ of California - Berkeley, IVO SOUZA, Universidad del País Vasco — The transport current  $\mathbf{J}$  induced in a clean metal by a magnetic field  $\mathbf{B}$  is shown to be equivalent to the low-frequency limit of natural optical activity (optical gyrotropy). For a generic multiband Hamiltonian, there is a simple expression for  $\alpha_{ij} = J_i/B_j$  in terms of the intrinsic magnetic moment (orbital plus spin) of the Bloch electrons on the Fermi surface. This “gyrotropic magnetic effect” (GME) is fundamentally different from the chiral magnetic effect (CME) driven by the chiral anomaly, which is only nonzero away from equilibrium and is governed by the Berry curvature. The two effects are compared for a minimal model of a Weyl semimetal. We discuss a simple semiclassical picture of the GME and its possible experimental observation by measuring the rotary power of low-symmetry materials like  $\text{SrSi}_2$ .

**9:24AM X28.00008 Optical conductivity of disordered Weyl semimetals in collisionless regime at zero temperature**, VLADIMIR JURICIC, Nordita, Center for Quantum Materials, KTH Royal Institute of Technology, and Stockholm University, Roslagstullsbacken 23, S-106 91 Stockholm, BITAN ROY, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD 20742, USA — Weyl semimetals have recently attracted considerable attention as prime examples of topologically nontrivial gapless states of quantum matter. They have been experimentally found and the chiral anomaly, which represents their hallmark feature, has been measured. In this work, we study transport in the disordered Weyl semimetals using the Kubo formalism. We consider point-like impurity potentials, which are irrelevant in the renormalization-group sense, and compute the corresponding leading correction to the collisionless conductivity at zero temperature. As a result, we find that all eight possible types of the point-like disorder potentials give rise to a correction to the real part of the optical conductivity in the clean limit, which is universal up to a sign. Consequently, the dielectric constant of a Weyl material receives a disorder correction which is linear in frequency. Finally, we discuss some experimental consequences of our findings.

**9:36AM X28.00009 Current at a distance and resonant transparency in Weyl semimetals**, ADY STERN, YUVAL BAUM, EREZ BERG, Weizmann Institute of Science, SIDDHARTH PARAMESWARAN, UC Irvine — Surface Fermi arcs are the most prominent manifestation of the topological nature of Weyl semimetals. In the presence of a static magnetic field oriented perpendicular to the sample surface, their existence leads to unique inter-surface cyclotron orbits. We propose two experiments which directly probe the Fermi arcs: a magnetic field dependent non-local DC voltage and sharp resonances in the transmission of electromagnetic waves at frequencies controlled by the field. We show that these experiments are insensitive to small momentum scattering and do not rely on quantum mechanical phase coherence, which renders them far more robust and experimentally accessible than quantum effects. We also comment on the applicability of these ideas to Dirac semimetals.

**9:48AM X28.00010 Self-consistent theory of electronic states in topological broken-gap quantum wells<sup>1</sup>**, R. WINKLER, Northern Illinois University — Recently broken-gap quantum wells made of  $\text{InAs}/\text{GaSb}/\text{AlSb}$  have raised great interest as they may show a gate-tunable phase transition from a trivial phase to a topologically protected quantum spin Hall phase. We present a quantitative self-consistent theory of electronic states in such systems taking into account the charge transfer between different layers which can substantially modify the level structure including the phase boundary between the inverted and non-inverted regime. We also discuss spin effects and the unusual Landau fans in a quantizing magnetic field.

<sup>1</sup>Work supported by the NSF grant DMR-1310199.

**10:00AM X28.00011 Topological edge states in ultra thin Bi(110) puckered crystal lattice**, BAKKAI WANG, Northeastern University, CHUANGHAN HSU, GUOQING CHANG, HSIN LIN, National University of Singapore, ARUN BANSIL, Northeastern University — We discuss the electronic structure of a 2-ML  $\text{Bi}(110)$  film with a crystal structure similar to that of black phosphorene. In the absence of Spin-Orbit coupling (SOC), the film is found to be a semimetal with two kinds of Dirac cones, which are classified by their locations in the Brillouin zone. All Dirac nodes are protected by crystal symmetry and carry non-zero winding numbers. When considering ribbons, along specific directions, projections of Dirac nodes serve as starting or ending points of edge bands depending on the sign of their carried winding number. After the inclusion of the SOC, all Dirac nodes are gapped out. Correspondingly, the edge states connecting Dirac nodes split and cross each other, and thus form a Dirac node at the boundary of the 1D Brillouin zone, which suggests that the system is a Quantum Spin Hall insulator. The nontrivial Quantum Spin Hall phase is also confirmed by counting the product of parities of the occupied bands at time-reversal invariant points.

**10:12AM X28.00012 Detecting 2D symmetry-protected topological phases with the tensor-network method**, CHING-YU HUANG, TZU-CHIEH WEI, C. N. Yang Institute for Theoretical Physics and Department of Physics and Astronomy, State University of New York at Stony Brook — Symmetry-protected topological (SPT) phases exhibit nontrivial order if symmetry is respected but are adiabatically connected to the trivial product phase if symmetry is not respected. However, unlike the symmetry breaking phase, there is no local order parameter for SPT phases. Here we employ a tensor-network method to compute the topological invariants characterized by the simulated modular  $S$  and  $T$  matrices proposed by Hung and Wen [PRB 89,075121 (2014)] to study a transition in a one-parameter family of wavefunctions which are  $\mathbb{Z}_2$  symmetric. The studied wavefunctions are in some sense the SPT analog of  $\mathbb{Z}_2$  topological states under a string tension. The numerically obtained  $S$  and  $T$  matrices are able to characterize the two different phases and identify the transition point.

**10:24AM X28.00013 Analytical characterization of bulk-boundary separation for non-interacting fermionic Hamiltonians**, EMILIO COBANERA, ABHIJEET ALASE, Dartmouth Coll, GERARDO ORTIZ, Indiana University, LORENZA VIOLA, Dartmouth Coll — In topological quantum matter the notions of bulk and boundary are closely intertwined by the Hamiltonian. For non-interacting systems, the bulk-boundary correspondence relates this phenomenon to topological properties of the single-particle Hamiltonian defined in momentum space, but, so far, no analytic, systematic approach has been put forward to investigate the edge modes themselves. We show how Schrodinger's equation for a confined system of independent fermions may be separated into a bulk and a boundary equation in a manner that depends critically on the nature of the Hamiltonian. The bulk equation may be solved in closed or near closed form, and the Brillouin zone associated to the infinitely extended system emerges naturally embedded in the full complex plane or higher dimensional analogue. The bulk equation determines uniquely all possible zero modes of the system, whereas the boundary equation selects those, if any, compatible with the prescribed boundary.

**10:36AM X28.00014 Prediction of two-dimensional topological insulator by forming surface alloy on Au/Si(111) substrate**, ZHI-QUAN HUANG, FENG-CHUAN CHUANG, CHIA-HSIU HSU, HSIN-LEI CHOU, CHRISTIAN CRISOS-TOMO, SHIH-YU WU, CHIEN-CHENG KUO, Natl. Sun Yat-sen U., WANG-CHI YEH, Natl. Dong Hwa U., HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — Two-dimensional (2D) topological insulators (TIs), which can be integrated into the modern silicon industry, are highly desirable for spintronics applications. Here, using first-principles electronic structure calculations, we show that the Au/Si(111)-root3 substrate can provide a new platform for hosting 2D-TIs obtained through the formation of surface alloys with a honeycomb pattern of adsorbed atoms. We systematically examined elements from groups III to VI of the periodic table at 2/3 monolayer coverage on Au/Si(111)-root3, and found that In, Tl, Ge, and Sn adsorbates result in topologically non-trivial phases with band gaps varying from zero to 72 meV. Our scanning tunneling microscopy and low-energy electron diffraction experiments confirm the presence of the honeycomb pattern when Bi atoms are deposited on Au/Si(111)-root3 in accord with our theoretical predictions. Our findings pave the way for using surface alloys as a potential new route for obtaining viable 2D-TI platforms.

**8:00AM X29.00001 Hidden landscapes in thin film topological insulators: between order and disorder, 2D and 3D, normal and topological phases<sup>1</sup>**, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers, The State University of New Jersey — Topological insulator (TI) is one of the rare systems in the history of condensed matter physics that is initiated by theories and followed by experiments. Although this theory-driven advance helped move the field quite fast despite its short history, apparently there exist significant gaps between theories and experiments. Many of these discrepancies originate from the very fact that the worlds readily accessible to theories are often far from the real worlds that are available in experiments. For example, the very paradigm of topological protection of the surface states on Z2 TIs such as Bi<sub>2</sub>Se<sub>3</sub>, Bi<sub>2</sub>Te<sub>3</sub>, Sb<sub>2</sub>Te<sub>3</sub>, etc, is in fact valid only if the sample size is infinite and the crystal momentum is well-defined in all three dimensions. On the other hand, many widely studied forms of TIs such as thin films and nano-wires have significant confinement in one or more of the dimensions with varying level of disorders. In other words, many of the real world topological systems have some important parameters that are not readily captured by theories, and thus it is often questionable how far the topological theories are valid to real systems. Interestingly, it turns out that this very uncertainty of the theories provides additional control knobs that allow us to explore hidden topological territories. In this talk, I will discuss how these additional knobs in thin film topological insulators reveal surprising, at times beautiful, landscapes at the boundaries between order and disorder, 2D and 3D, normal and topological phases.

**8:36AM X29.00002 Finite-size driven topological and metal-insulator transition in (Bi<sub>1-x</sub>In<sub>x</sub>)<sub>2</sub>Se<sub>3</sub> thin films**, MARYAM SALEHI, Rutgers University, HASSAN SHAPOURIAN, University of Illinois at Urbana-Champaign, NIKESH KOIRALA, Rutgers University, MATTHEW BRAHLEK, Pennsylvania State University, JISOO MOON, SEONGSHIK OH, Rutgers University — In a topological insulator (TI), if one of its heavy elements is replaced by a light one, the spin-orbit coupling (SOC) strength decreases and eventually the TI transforms into a normal insulator beyond a critical level of substitution. This is the standard description of the topological phase transition (TPT). However, this notion of TPT, driven solely by the SOC (or something equivalent), is not complete for finite size samples considering that the thickness of the topological surface states diverges at the critical point. Here, on specially-engineered (Bi<sub>x</sub>In<sub>1-x</sub>)<sub>2</sub>Se<sub>3</sub> thin films, using systematic transport measurements we show that not only the SOC but also the finite sample size can induce TPT. This study sheds light on the role of spatial confinement as an extra tuning parameter controlling the topological critical point.

**8:48AM X29.00003 Quantum transport of two-species Dirac fermions in dual-gated three-dimensional topological insulators<sup>1</sup>**, YANG XU, IRENEUSZ MIOTKOWSKI, YONG P. CHEN, Department of Physics and Astronomy, Purdue University — Topological insulators (TI) are a novel class of quantum matter with a gapped insulating bulk yet gapless spin helical Dirac fermion conducting surface states. Here, we report local and non-local electrical and magneto transport measurements in dual-gated BiSbTeSe<sub>2</sub> thin film TI devices, with conduction dominated by the spatially separated top and bottom surfaces, each hosting a single species of Dirac fermions with independent gate control over the carrier type and density. We observe many intriguing quantum transport phenomena in such a fully-tunable two-species topological Dirac gas, including a zero-magnetic-field minimum conductivity of  $4e^2/h$  at the double Dirac point, a series of ambipolar two-component "half-integer" Dirac quantum Hall states and an electron-hole total filling factor  $\nu=0$  state (with a zero-Hall plateau), exhibiting dissipationless (chiral) and dissipative (non-chiral) edge conduction respectively. Such a system paves the way to explore rich physics ranging from topological magnetoelectric effects to exciton condensation.

<sup>1</sup>DARPA MESO program

**9:00AM X29.00004 Separation of quantum oscillations from bulk and topological surface states in metallic Bi<sub>2</sub>Se<sub>2.1</sub>Te<sub>0.9</sub><sup>1</sup>**, BERND LORENZ, TCSUH and Dept. of Physics, University of Houston, KESHAV SHRESTHA, TCSUH, University of Houston, DAVID E. GRAF, NHMFL, Florida State University, VERA MARINOVA, Institute of Optical Materials and Technology, Bulgarian Academy of Sciences, PAUL C. W. CHU, TCSUH and Dept. of Physics, University of Houston — Shubnikov-de Haas (SdH) oscillations in metallic Bi<sub>2</sub>Se<sub>2.1</sub>Te<sub>0.9</sub> are studied in magnetic fields up to 35 Tesla. It is demonstrated that two characteristic frequencies determine the quantum oscillations of the conductivity. Angle dependent measurements and calculations of the Berry phase show that the two frequencies  $F_1$  and  $F_2$  describe oscillations from surface and bulk carriers, respectively. At low magnetic fields, only SdH oscillation from topological surface states can be detected whereas at high magnetic field the bulk oscillations dominate. The origin of the separation of bulk and surface SdH oscillations into different magnetic field ranges is revealed in the difference of the cyclotron masses  $m_c$ . The bulk  $m_c$  is nearly three times larger than the surface cyclotron mass resulting in a stronger attenuation of the bulk oscillation amplitude upon decreasing magnetic field. This makes it possible to detect and characterize the surface SdH oscillations in the low-field range.

**9:12AM X29.00005 Record surface state mobility and quantum Hall effect in topological insulator thin films via interface engineering**, NIKESH KOIRALA, MATTHEW BRAHLEK, MARYAM SALEHI, Rutgers U., LIANG WU, JHU, JIXIA DAI, Rutgers Univ, JUSTIN WAUGH, THOMAS NUMMY, U. of Colorado, MYUNG-GEUN HAN, BNL, JISOO MOON, Rutgers U., YIMEI ZHU, BNL, DANIEL DESSAU, U. of Colorado, WEIDA WU, Rutgers U., N. PETER ARMITAGE, JHU, SEONGSHIK OH, Rutgers U. — Thin films of topological insulators (TIs) with conduction dominated by high mobility topological surface state (TSS) channel have been difficult to achieve due to increased material defects, thus making it difficult to probe TIs in quantum regime. Here by utilizing a structurally matched buffer layer based on In<sub>2</sub>Se<sub>3</sub>, we have achieved Bi<sub>2</sub>Se<sub>3</sub> films with low defect density resulting in 'order of magnitude' improvement in mobilities and carrier densities. This has led to TSS dominated transport and first observation of quantum Hall effect in Bi<sub>2</sub>Se<sub>3</sub>.

## 9:24AM X29.00006 Differentiation of surface and bulk conductivities in topological insulator via four-probe spectroscopy<sup>1</sup>

AN-PING LI, CORENTIN DURAND, SABAN HUS, XIAOGUANG ZHANG, MICHAEL MCGUIRE, Oak Ridge National Laboratory, YONG CHEN, Purdue University — The direct measurement of the topological surface states (TSS) conductivity is often hard to achieve due to the pronounced contribution from the bulk conduction channel. Here, we show a new method to differentiate conductivities from the surface states and the coexisting bulk states in topological insulators (TI) using a four-probe transport spectroscopy in a multi-probe scanning tunneling microscopy system. In contrast to conventional models that assume two resistors in parallel to count for both the TSS and bulk conductance channels, we derive a scaling relation of measured resistance with respect to varying inter-probe spacing for two interconnected conduction channels, which allows quantitative determination of conductivities from both channels. Using this method, we demonstrate the separation of 2D and 3D conduction in TI by comparing the conductance scaling of Bi<sub>2</sub>Se<sub>3</sub>, Bi<sub>2</sub>Te<sub>2</sub>Se, and Sb-doped Bi<sub>2</sub>Se<sub>3</sub> with that of a pure 2D conductance of graphene on SiC substrate. We also quantitatively show the effect of surface doping carriers on the 2D conductance enhancement in TI. The method offers an approach to understanding not just the topological insulators but also the 2D to 3D crossover of conductance in other complex systems.

## 9:36AM X29.00007 High magnetic field Shubnikov-de Haas oscillations in BiTeCl<sup>1</sup>

CATALIN MARTIN, Ramapo College of New Jersey, Mahwah, NJ, 07430, L. E. WINTER, R. G. MCDONALD, V. ZAPF, A. V. SUSLOV, National High Magnetic Field Laboratory, Los Alamos, NM, 87545, USA, PHILIPPE BUGNON, ARNAUD MAGREZ, H. BERGER, Crystal Growth Facility, Ecole Polytechnique Federale de Lausanne, Switzerland, D. B. TANNER, University of Florida, Gainesville, Florida, 32611, USA — We report high magnetic field Shubnikov-de Haas oscillations on single crystals of the bulk Rashba compound BiTeCl. Effective mass and scattering rate extracted from temperature and magnetic field dependence of the oscillations amplitude are in good agreement with our previous optical measurements. The present work will focus on the angular dependence study. First, we notice that oscillations were detected for all our measured angles between the magnetic field and the crystallographic z-axis,  $0 \leq \theta \leq 120^\circ$ . This is consistent with a 3D Fermi surface and, in good agreement with optical data, confirms that oscillations originate from bulk carriers. Second, the frequency has unusual angular dependence around  $\theta = 90^\circ$ . We will show that this behavior is consistent with a torus shaped Fermi surface, providing direct evidence for a Rashba spin-split bulk conduction band. Moreover, we extract reliably the bulk Rashba parameters and the anisotropy of BiTeCl.

## 9:48AM X29.00008 Quantized steps and topological nature of universal conductance fluctuation in Bi<sub>2</sub>Te<sub>2</sub>Se

FENGQI SONG, Nanjing Univ — Here we report the experimental observation of universal conductance fluctuations (UCF) in Bi<sub>2</sub>Te<sub>2</sub>Se. Four aspects were addressed to support the UCF's topological nature of the electronic state. i) The irregular fluctuations are repeatable in different temperature and reversal magnetic fields. ii) All the UCF features coincide after the field is normalized to the perpendicular direction. This points to a two-dimensional electronic state. iii) A parallel field is applied to suppress the bulk coherent paths, while the UCF features stays similar. This excludes a quasi-2D bulk state. iv). The intrinsic UCF magnitude is extracted, which is close to the predicted values of a topological surface state. v). Quantized steps of the UCF magnitudes are observed when the magnetic field is modulated. (*Sci.Rep.* 2012, 2,595; *Appl. Phys. Expre.* 2014,7,065202; arxiv 2015)

## 10:00AM X29.00009 Edge states and integer quantum Hall effect in topological insulator thin films

SONG-BO ZHANG, Department of Physics, The University of Hong Kong, HAI-ZHOU LU, Department of Physics, South University of Science and Technology of China, SHUN-QING SHEN, Department of Physics, The University of Hong Kong — The integer quantum Hall effect is a topological state of quantum matter in two dimensions, and has recently been observed in three-dimensional topological insulator thin films. In this report, I will talk about the Landau levels and edge states of surface Dirac fermions in topological insulators under a strong magnetic field. We examine the formation of the quantum plateaux of the Hall conductance and find two different patterns, in one pattern the filling number covers all integers while only odd integers in the other. We focus on the quantum plateau closest to zero energy and demonstrate the breakdown of the quantum spin Hall effect as a result of the interplay of magnetic field and structure inversion asymmetry. We also reveal that the edge states exist only for the integer Hall conductance while no edge-state solution can be found for the "half-integer" Hall conductance. The addition of top and bottom surface Dirac fermions always form well-defined edge states, and gives an integer quantum Hall effect. This work establishes an intuitive picture of the edge states to understand the integer quantum Hall effect for Dirac electrons in topological insulator thin films.

## 10:12AM X29.00010 Duo gating on a 3D topological insulator - independent tuning of both topological surface states

CHUAN LI, BOB DE RONDE, MARIEKE SNELDER, MARTIN STEHNO, Twente Tech Univ, YINGKAI HUANG, MARK GOLDEN, University of Amsterdam, ALEXANDER BRINKMAN, Twente Tech Univ, ICE TEAM, IOP COLLABORATION — ABSTRACT: Topological insulators are associated with a trove of exciting physics, such as the ability to host robust anyons, Majorana Bound States, which can be used for quantum computation. For future Majorana devices<sup>1</sup> it is desirable to have the Fermi energy tuned as close as possible to the Dirac point of the topological surface state. Based on previous work on gating BSTS<sup>2,3</sup>, we report the experimental progress towards gate-tuning of the top and bottom topological surface states of BiSbTeSe<sub>2</sub> crystal flakes. When the Fermi level is moved across the Dirac point conduction is shown to change from electron dominated transport to hole dominated transport independently for either surface. In the high magnetic field, one can tune the system precisely between the different Landau levels of both surfaces, thus a full gating map of the possible Landau levels combination is established. In addition, we provide a simple capacitance model to explain the general hysteresis behaviors in topological insulator systems.

## 10:24AM X29.00011 Weak antilocalization in Bi<sub>2-x</sub>In<sub>x</sub>Te<sub>3</sub> single crystals

HANG CHI, QIANG LI, Brookhaven Natl Lab, CTIRAD UHER, University of Michigan — Bi<sub>2</sub>Te<sub>3</sub> has recently been identified as one of the most promising systems with which to realize a three-dimensional topological insulator. However, the bulk, stoichiometric Bi<sub>2</sub>Te<sub>3</sub> single crystals often exhibit *p*-type metallic electrical conduction due to the Bi<sub>Te</sub>-type antisite defects, which overshadows the contribution of surface states. We have established that, upon group III (indium and/or thallium) doping, the Fermi level of Bi<sub>2</sub>Te<sub>3</sub> can be lifted from the valence band into the band gap, and eventually shifted into the conduction band. Such doping progressively changes the electrical conduction of Bi<sub>2-x</sub>A<sub>x</sub>Te<sub>3</sub> (A = In, Tl, and  $x = 0 - 0.30$ ) single crystals from *p*-type to *n*-type. This is observed via measurements of both the Hall effect and the Seebeck coefficient performed in the (0001) basal plane in the temperature range of 2 - 300 K. At low levels, the temperature dependent in-plane electrical resistivity maintains its metallic character as the density of holes decreases. Heavier doping content,  $x = 0.20$  (0.10) for In (Tl), drives the electrical resistivity into a prominent non-metallic regime displaying the weak anti-localization type of magnetoresistance at the lowest temperatures for Bi<sub>1.80</sub>In<sub>0.20</sub>Te<sub>3</sub>. At the highest concentration, the samples revert back into the metallic state with electron dominated conduction. Thermal conductivity measurements of Bi<sub>2-x</sub>A<sub>x</sub>Te<sub>3</sub> single crystals, as examined by the Debye-Callaway phonon conductivity model, reveal a generally stronger point defect scattering of phonons upon doping.

**10:36AM X29.00012 Induced Superconductivity In Bi<sub>2</sub>Se<sub>3</sub> Nanostructures By Anneal Doping Of Palladium<sup>1</sup>**, JEROME T. MLACK, ATIKUR RAHMAN, NATALIA DRICHKO, NINA MARKOVIC, Johns Hopkins University — Utilizing thermal annealing at temperatures in excess of 100 Celsius we induce superconductivity in Bi<sub>2</sub>Se<sub>3</sub> by palladium doping. Changes in the material structure are analyzed using a combination of AFM, optical microscopy and Raman spectroscopy. The absorption of Pd results in superconductivity in the material with a transition temperature below 1K. The differential conductance as a function of temperature and magnetic field reveals multiple transitions in the material at several applied currents.

**10:48AM X29.00013 Chromium Doping of the Topological Insulator Bi<sub>1.5</sub>Sb<sub>0.5</sub>Te<sub>1.7</sub>Se<sub>1.3</sub>**, DANIEL DOUGHERTY, ANDREW HEWITT, Department of Physics North Carolina State University, RAJ KUMAR, Department of Materials Science and Engineering North Carolina State University, JONATHAN BOLTERSDORF, PAUL MAGGARD, Department of Chemistry North Carolina State University, FRANK HUNTE, Department of Materials Science and Engineering North Carolina State University — A major materials science challenge is to minimize bulk conductivity in topological insulators so that topological surface state physics can be cleanly accessed. One solution to this problem has been the development of quaternary bismuth chalcogenides Bi<sub>2-x</sub>Sb<sub>x</sub>Te<sub>3-y</sub>Se<sub>y</sub> (BSTS) which can be tuned to place the mid-gap Fermi level near the Dirac point associated with the topological surface state. This is ideal for accessing interesting topological physics including the exotic magnetoelectric effects associated with breaking time reversal symmetry. With this goal in mind, we have grown Cr-doped crystals of Bi<sub>1.5</sub>Sb<sub>0.5</sub>Te<sub>1.7</sub>Se<sub>1.3</sub> to assess the impact of magnetic dopants on the electronic and magnetic properties of this material. For 4 percent Cr doping we find electronic structure modifications measured by angle-resolved ultraviolet photoelectron spectroscopy and observe magnetic ordering below 50 K in bulk magnetometry. Higher doping levels show evidence of phase segregation.

**Session X30 DMP: Structural and Functional Imaging of Oxide Interfaces** 329 - Ying-Hao Chu, National Chiao Tung University

**8:00AM X30.00001 A Fresh Twist on The Electron Microscope: Probing Broken Symmetries at a New Level**, JUAN CARLOS IDROBO, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — The introduction of aberration-correction in scanning transmission electron microscopy (STEM) has allowed the realization of Richard Feynmans long sought dream, atom-by-atom structural and elemental identification of materials by simply looking at the thing. Until now, the goal of aberration-correction in STEM has been to produce the smallest possible electron probes, which essentially corresponds to a near constant phase across the probe. Phases increase the size of electron probes and result in images and spectra with a lower spatial resolution. In this talk, calculations will be presented showing that aberrations in lenses are intrinsic generators of angular momentum, and that phases introduced in atomic-size electron probes can actually be beneficial when studying the symmetry of materials. In particular, examples of mapping magnetic ordering of materials with atomic size electron probes will be shown. Magnetic dichroism is one of the new frontiers where aberration-correction STEM can have a significant impact, and reveal information that is physically out of reach in X-ray and neutron synchrotrons. Current and future limitations in the experiments and requirements to reveal the magnetic moment (orbital and spin), charge ordering, crystal field splitting, spin-orbit-coupling, optical dichroism, and other physical phenomena associated with broken symmetries will be discussed. This research was supported by the Center for Nanophase Materials Sciences (CNMS), which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy. Collaborators: J. Rusz, J. Spiegelberg, M.A. McGuire, C.T. Symons, R.R. Vatsavai, C. Cantoni and A.R. Lupini.

**8:36AM X30.00002 Atomic Structure Refinement of *Pbnm*-type Perovskite Oxide Films**, AMBER CHOQUETTE, COLE SMITH, STEVE MAY, Drexel Univ — Complex ABO<sub>3</sub> oxide heterostructures are of interest due to their wide variety of electronic, optical, and magnetic properties. One of the controlling factors to these functionalities is the distortions and rotations of the corner-connected BO<sub>6</sub> octahedral network. This BO<sub>6</sub> octahedra network directly couples to the electronic bandwidth of these materials, but the inability to determine the full atomic structure in thin films has inhibited quantitative understanding of how factors such as epitaxial strain alter the octahedral rotations in this broad class of materials. Earlier work of has demonstrate that half-order diffraction peaks can be used to quantify octahedral rotations in thin strained films. Here, we build on this approach to solve for both the oxygen and A-site positions in films of the commonly occurring *Pbnm* structure type. We present on epitaxial RFeO<sub>3</sub> heterostructures, where *R* is a rare earth element, to demonstrate the feasibility of quantifying oxygen and A-site displacements in films using synchrotron diffraction. This work is supported by the National Science Foundation (DMR-1151649).

**8:48AM X30.00003 Direct measurement of oxygen octahedral rotations in improper ferroelectric superlattices by STEM<sup>1</sup>**, JASON LAPANO, RYAN HAISLMAIER, GREGORY STONE, VENKAT GOPALAN, ROMAN ENGEL-HERBERT, Penn State University — Complex ABO<sub>3</sub> perovskites are an intensely studied class of materials due to their numerous magnetic and electronic functionalities. Using strain and A-site cation, can induce new high temperature functionality known as improper ferroelectricity<sup>1</sup>. Visualizing the interplay between strain, cation ordering and octahedral rotations in improper ferroelectrics is crucial to understand how this property manifests itself in thin films<sup>2</sup>. A series of CaTiO<sub>3</sub><sub>n</sub>/SrTiO<sub>3</sub><sub>n</sub> with periodicities n=2-10 were grown on (La,Sr)(Al,Ta)O<sub>3</sub> by hybrid molecular beam epitaxy. I will discuss how strain and layering affects the cation and oxygen sublattices, and how these distortions propagate through the layers, with direct imaging of the oxygen cations by annular bright field (ABF) STEM. I will then relate these back to understanding how improper ferroelectricity evolves in these films. 1. Rondinelli, J. M. & Fennie, C. J. Octahedral Rotation-Induced Ferroelectricity in Cation Ordered Perovskites. Adv. Mater. 24, 1961–1968 (2012). 2. Biegalski, M. D. et al. Impact of symmetry on the ferroelectric properties of CaTiO<sub>3</sub> thin films. Appl. Phys. Lett. 106, 162904 (2015).

**9:00AM X30.00004 Effects of local sample bending on atom positions and polarization mapping in HAADF-STEM images**, ZHEN WANG, HANGWEN GUO, LINA CHEN, E.W. PLUMMER, JIANDI ZHANG, Louisiana State Univ - Baton Rouge, JING TAO, LIJUN WU, YIMEI ZHU, Brookhaven National Laboratory — Characterization of the structural distortion/reconstruction in the transition-metal oxide heterostructures play an important role in understanding their novel properties. In recent years, high-angle annular dark field (HAADF) in scanning transmission electron microscopy (STEM) has become a powerful technique to determine local atomic arrangements, particularly near interfaces and boundaries. However, sample bending, especially near the edge of a thin specimen, is often introduced during the TEM sample preparation process. Our recent studies reveal that small sample bending can affect significantly the measurement of atom positions in HAADF-STEM image as a result of channeling effect of the incident electron beam. Here we take SrTiO<sub>3</sub> (STO) as an example to show how to remove sample bending induced artifact from its intrinsic structural distortions. A polar-related artifact in STO at different bending angles were revealed both in our experiments and imaging simulation. This artifact can be removed successfully by quantitative comparing experimental with simulated HAADF-STEM images under the same imaging condition. The bending angle and thickness of the sample can be determined using convergent beam electron diffraction. Our study provide a useful guidance for removing the sample bending-induced artifact in STEM images for the studies of local lattice structures, polarization and distortion of complex materials.

**9:12AM X30.00005 Quantifying the electronic reconstruction in  $\text{LaTiO}_3/\text{LaNiO}_3/(\text{LaAlO}_3)_3$  heterostructures using RIXS<sup>1</sup>**, GILBERTO FABBRIS, Brookhaven Natl Lab, ANKIT S. DISA, SOHAB ISMAIL-BEIGI, FREDERICK J. WALKER, CHARLES H. AHN, Yale University, JONATHAN PELLICIARI, YAobo HUANG, THORSTEN SCHMITT, Swiss Light Source, PSI, LEI XU, LIVIU HOZOI, JEROEN VAN DEN BRINK, IFW Dresden, MARK DEAN, Brookhaven Natl Lab — A novel approach for manipulating the 3d state in transition metal oxide heterostructures has emerged with the growth of trilayer nickelate  $\text{LaTiO}_3/\text{LaNiO}_3/(\text{LaAlO}_3)_3$  (LTNAO) (Disa et al., PRL 114 026801 (2015)). This heterostructure induces a striking reconstruction of the  $\text{LaNiO}_3$  electronic structure, which is due to a combination of charge transfer from Ti's 3d state and octahedral elongation along the *c* axis. We use resonant inelastic x-ray scattering (RIXS) experiments at Ni  $L_{2,3}$  and O K edges to spectroscopically resolve the LTNAO electronic structure. Surprisingly, our results show that the octahedral elongation generates minor changes in crystal fields at Ni's 3d state compared to bulk  $\text{LaNiO}_3$ . Instead, heterostructuring creates an anisotropic reconstruction of the Ni 3d - O 2p hybridization. The  $x^2-y^2$  orbital is significantly more hybridized with O p, leading to a  $3z^2-r^2/x^2-y^2$  hole ratio of  $\sim 0.55$  and large orbital polarization as measured by x-ray absorption spectroscopy. This work establishes RIXS as an ultra-sensitive probe of complex oxide heterostructures.

<sup>1</sup>Work at BNL was supported by the US Department of Energy under Award no DEAC02-98CH10886 and under Early Career Award no 20878.

**9:24AM X30.00006 Electronic Structure near the Interface of Complex Oxide Heterostructure  $\text{SmTiO}_3/\text{SrTiO}_3$** , RYO MORI, University of California, Berkeley and Lawrence Berkeley National Laboratory, BRANDON ISAAC, PATRICK MARSHALL, University of California, Santa Barbara, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, SUSANNE STEMMER, University of California, Santa Barbara, ALESSANDRA LANZARA, University of California, Berkeley and Lawrence Berkeley National Laboratory — Quantum wells created from oxide heterostructures induce quantum confinement systems at the heterostructure interface, which show unique properties, such as strong electron correlation, two-dimensional superconductivity, high carrier densities and mobility, and/or magnetism. The rare earth titanate,  $\text{SmTiO}_3$ , and the transition metal oxide,  $\text{SrTiO}_3$ , create such confined electron systems at their interface, which has a controllable quantum well length by changing the number of SrO layers in  $\text{SrTiO}_3$ . By Varying the number of SrO layers, we will present the layer-dependent electronic structure of the  $\text{SmTiO}_3/\text{SrTiO}_3$  interface system from angle-resolved photoemission spectroscopy (ARPES) measurements and discuss these results in terms of strong correlations.

**9:36AM X30.00007 Probing Momentum-Resolved Orbital Polarization at the Oxide Interfaces with SW-ARPES**, ARIAN ARAB, Department of Physics, Temple University, SLAVOMIR NEMSAK, Peter-Grunberg-Institut PGI-6, Forschungszentrum Julich, GIUSEPPINA CONTI, Department of Physics, UC Davis; Materials Sciences Division, LBNL, VLADIMIR STROCOV, Swiss Light Source, PSI, MARK HUIJBEN, University of Twente, JAN MINAR, Department Chemie, Universitat Munchen; University of West Bohemia, CHARLES FADLEY, Department of Physics, UC Davis; Materials Sciences Division, LBNL, ALEXANDER GRAY, Department of Physics, Temple University — Interface electronic structure is critical to the functional properties of strongly-correlated multilayer systems such as the  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$  heterostructure, a promising candidate for a magnetic tunnel junction. Recently it was demonstrated that for periodic superlattice samples controllable depth selectivity in angle-resolved photoemission spectroscopy (ARPES) can be accomplished by setting up an x-ray standing-wave (SW) field in the sample and translating it vertically along the surface normal by varying x-ray incidence angle. Here, by varying polarization of the incident x-rays we add orbital sensitivity to SW-ARPES, thus allowing us to distinguish momentum-resolved electronic dispersions for the electronic states of different symmetries (e.g.  $x^2-y^2$  and  $3z^2-r^2$ ). Distinctly different momentum-resolved orbital polarization maps are obtained for the bulk-like and interface-like Mn 3d electronic states. The results are compared to state-of-the-art first-principles calculations. Future directions and applications are discussed.

**9:48AM X30.00008 Interface properties of  $\text{LaCrO}_3/\text{SrTiO}_3$  superlattices studied by standing-wave excited photoemission spectroscopy**, CHENG-TAI KUO, SHIH CHIEH LIN, Univ of California - Davis, RYAN COMES, Pacific Northwest National Laboratory, JULIEN RAULT, SOLEIL, PETER SUSHKO, Pacific Northwest National Laboratory, AMINA TALEB-IBRAHIMI, SOLEIL, SCOTT CHAMBERS, Pacific Northwest National Laboratory, CHUCK FADLEY, Univ of California - Davis, CHUCK FADLEY TEAM, SCOTT CHAMBERS TEAM, AMINA TALEB-IBRAHIMI TEAM — The interface between  $\text{LaCrO}_3$  (LCO) and  $\text{SrTiO}_3$  (STO) is of interest due to a polar discontinuity, built-in potential [1] and recent evidence of polarization in STO-LCO superlattices (SLs). However, an unambiguous depth profiling of the polarization-induced electronic structure has not been attempted. We here present the quantitative determination of the depth profiles of composition, charge state, potential and momentum-resolved electronic structure for LCO/STO SLs using resonant-excitation x-ray standing wave (SW) photoemission spectroscopy. By varying the incident angle and photon energy around the Bragg condition, the standing wave was moved vertically through the interfaces, giving us the ability to focus on either surface, interface or bulk electronic properties. We are thus able to decompose the valence band spectra into layer-specific contributions for both STO and LCO. We also present momentum-resolved electronic structure using resonant SW angle-resolved photoemission spectroscopy (SW-ARPES) [2] and compare these results to DFT theory for the band dispersions of each layer of the SL. [1] S. Chambers et al. PRL, 107, 206802 (2011) [2] A.X. Gray et al., EPL 104, 17004 (2013)

**10:00AM X30.00009 Built-in electric field and polarization in  $\text{LaCrO}_3\text{-SrTiO}_3$  superlattices**, PETER SUSHKO, RYAN COMES, STEVEN SPURGEON, PHUONG-VU ONG, Pacific Northwest National Laboratory, STEVE HEALD, Argonne National Laboratory, SHIH-CHIEH LIN, CHENG-TAI KUO, CHUCK FADLEY, UC Davis, SCOTT CHAMBERS, Pacific Northwest National Laboratory — Superlattices combining ferroelectric and non-polar materials exhibit an intriguing induced polarization in the non-ferroelectric phase, such as  $\text{SrTiO}_3$  (STO). However, there has been no report of a superlattice where two non-ferroelectric materials combine to produce bulk polarization. We present studies of STO- $\text{LaCrO}_3$  (LCO) superlattices and show that by controlling interfacial termination between layers we can induce a ferroelectric-type polarization in STO. Density functional theory (DFT) predictions show that by alternating terminations between positively charged  $\text{TiO}_2\text{-LaO}$  and negative  $\text{CrO}_2\text{-SrO}$  interfaces a polarization is induced in each material. Using molecular beam epitaxy, we have synthesized superlattices with such interfaces and a built-in electric field is observed using x-ray photoelectron spectroscopy. X-ray absorption spectroscopy and electron microscopy confirmed these results and were used to estimate the polarization within the STO layers. Our results agree well with the DFT predictions for the cation displacements and induced polarization. We also present models of the band dispersion to quantify the electronic structure in each of the STO and LCO layers.

**10:12AM X30.00010 XPS characterization scheme for phase-pure epitaxial  $\text{NbO}_2$** , TOBIAS HADAMEK, AGHAM POSADAS, ALEX DEMKOV, University of Texas at Austin —  $\text{NbO}_2$  shows a semiconductor-to-metal transition with an associated structural transition of Peierls type.  $\text{NbO}_2$  and  $\text{Nb}_2\text{O}_5$  or mixtures thereof have also shown electrically induced insulator-to-metal transitions. To shed light on the nature of the electrically induced insulator-to-metal transition it is important to grow high phase purity  $\text{NbO}_2$  and  $\text{Nb}_2\text{O}_5$  and compare electrical measurements with mixed niobium oxides and with different electrode materials. Processing  $\text{NbO}_2$  and avoiding surface oxidation requires ultra-high vacuum (UHV) conditions. Niobium oxide thin films where grown in UHV by molecular beam epitaxy on 111-oriented STO substrates and analyzed by X-ray photoelectron spectroscopy (XPS). It was shown that the  $\text{NbO}_2$  3d core level spectrum exhibits an asymmetric spin-orbit peak pair with more spectral weight on the high binding energy side. Based on the shape of the Nb 3d core levels, peak positions relative to the oxygen O 1s peak, and the valence band shape and height ratio of the niobium  $4d_{xy}$  split-off band to the oxygen 2p band, an identification scheme for  $\text{NbO}_2$  by XPS was devised. Complementary the  $\text{NbO}_2$  phase was confirmed by reflection high-energy electron and x-ray diffraction analysis.

**10:24AM X30.00011 Thickness-dependent structure variation and novel electronic properties of  $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  film on  $\text{SrTiO}_3$  (001) substrate<sup>1</sup>**, LINA CHEN, ZHEN WANG, JISUN KIM, GAOMIN WANG, HANGWEN GUO, MOHAMMAD SAGHAYEZHIANE, WARD PLUMMER, JIANDI ZHANG, Louisiana State University, JING TAO, YIMEI ZHU, Brookhaven National Laboratory — In principle,  $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  (LSMO) is a half metal, which exhibits colossal magnetoresistance. However, it has been observed that the transport properties of LSMO thin films depends on their thickness. By combining *in-situ* scanning tunneling spectroscopy (STS), X-ray photoelectron spectroscopy, and low energy electron diffraction, as well as *ex-situ* scanning transmission electron microscopy, we have studied the structure-property relationship of LSMO on  $\text{SrTiO}_3$ (001) as a function of film thickness and temperature. Studying the electronic properties by STS, we found that LSMO films have the novel zero current bias shifts at low temperature, further enhanced by photons, which can be related to the charging of dielectric layer near the interface and polar surface effect. To figure out it, STS thickness and temperature dependence were systematically studied. Furthermore, film thickness-dependent structure and stoichiometry variation were determined, and their effect to the zero current bias shifts will be discussed.

**10:36AM X30.00012 Aberration Corrected Scanning Transmission Electron Microscopy of  $(\text{Ca}, \text{Sr})\text{Fe}_2\text{O}_5$  Brownmillerite superlattices<sup>1</sup>**, DEBANGSHU MUKHERJEE, The Pennsylvania State University, GREG STONE, United States Army Armament Research, Development and Engineering Center, EUN JU MOON, JOSHUA YOUNG, Drexel University, VENKATRAMAN GOPALAN, The Pennsylvania State University, JAMES RONDINELLI, Northwestern University, STEVEN MAY, Drexel University, NASIM ALEM, The Pennsylvania State University — The brownmillerite phase  $\text{A}_2\text{B}_2\text{O}_5$  consists of ordered oxygen vacancies in alternate perovskite layers forming chiral tetrahedral chains. The handedness of these tetrahedral chains control the polarization of the structure. The current study focuses on 1-1 brownmillerite superlattices grown on a  $\text{SrTiO}_3$  substrates using molecular beam epitaxy. The B-site in this structure is iron throughout the superlattice film, while the A-site alternates between calcium and strontium in the superlattice layers. In this study, we use atomic resolution aberration corrected scanning transmission electron microscopy (STEM) to investigate the structure and chemistry of the film-substrate interface as well as the chemical structure of the superlattice. Atom positions are determined to measure displacement vectors of A-site cations in the superlattice structure.

**Session X31 DCP GSOFT: Nanoconfined and Interfacial Water** 331 - Nicolas Giovambattista, CUNY

**8:00AM X31.00001 TBA**, SHEKHAR GARDE, Rensselaer Polytechnic University — No abstract available.

**8:36AM X31.00002 Water in nanoconfined spaces: from superhydrophobicity to Janus interfaces to curved hydrophobes**, ALENKA LUZAR, Department of Chemistry, Virginia Commonwealth University — The talk will review our theoretical and molecular simulation works that predict and elucidate thermodynamic driving forces and kinetic factors pertinent to nanoconfined water. Retrieval of superhydrophobicity on nanostructured surfaces will be one example. We will discuss a new mechanism for water mediated (Laplace) attraction between solutes with contrasting polarities (Janus interfaces) that can play an important role by enabling adhesion between polar and nonpolar particles in both, biophysical systems and heterogeneous nanomaterials. Other examples will show how macroscopic thermodynamics remarkably works down to molecular lengthscales. We will elucidate why water-induced interaction between curved hydrocarbon surfaces can be repulsive.

**9:12AM X31.00003 Behavior of aqueous solutions in hydrophobic confinement studied using molecular simulations**, SUMIT SHARMA, Ohio University — Biological processes, such as formation of cell membranes, vesicles and folding of protein molecules, entail formation of a predominantly hydrophobic interior devoid of water. These processes occur in crowded aqueous environments comprising of amino acids, carbohydrates, ionic species, protein molecules, etc. Kinetics of these processes involve drying of hydrophobic pockets. Previous studies reveal that the kinetics of evaporation of water in hydrophobic confinement significantly slow down as the confinement gap increases. Presumably, the constituents of aqueous environment in biological systems modulate the kinetics of evaporation of confined water. In this work, we employ forward flux sampling in molecular dynamics simulations to study the role of solutes at different concentrations in modulating the kinetics and mechanism of evaporation of water under hydrophobic confinement. The results of these simulations will be useful for understanding optimum conditions for protein folding and other biological self-assembly processes.

**9:24AM X31.00004 Quasi-Elastic Neutron Scattering Study of Characteristic Features of Water Dynamics in Confined Geometries**, SOULEYMANE DIALLO, Oak Ridge National Laboratory Oak Ridge, TN, USA, NARESH OSTI, Oak Ridge National Laboratory, Oak Ridge, TN, USA, ALEXANDRA COTE, University of Miami, FL, USA, EUGENE MAMONTOV, ANIBAL RAMIREZ-CUESTA, DAVID WESOLOWSKI, Oak Ridge National Laboratory, Oak Ridge, TN, USA — Water trapped in restricted environments is ubiquitous in nature and known to influence many biochemical and geophysical processes. Understanding the structural and dynamical properties of nano-confined water (very different than those of the bulk phase) is thus of key fundamental interests. We present a survey of various quasi-elastic neutron (QENS) studies of nano-confined water, which we further analyzed in the context of a proposed universal scaling law. Using this predictive law, we specifically investigate how the diffusive behavior of water changes with changing hydration level, confinement size, or geometry. Finally, we present our recent QENS results of water in nanoporous media evaluated using this scaling law.

**9:36AM X31.00005 Salt Solutions in Carbon Nanotubes: The Role of Cation- $\pi$  Interactions<sup>1</sup>**, TUAN ANH PHAM, Lawrence Livermore Natl Lab, GOLAM MORTUZA, School of Mechanical and Materials Engineering, Washington State University, BRANDON WOOD, EDMOND LAU, TADASHI OGITSU, Lawrence Livermore Natl Lab, STEVEN BUCHSBAUM, ZUZANNA SIWY, Department of Physics and Astronomy, University of California, Irvine, FRANCESCO FORNASIERO, ERIC SCHWEGLER, Lawrence Livermore Natl Lab — Understanding the structure of aqueous electrolytes at interfaces is essential for predicting and optimizing device performances for a wide variety of emerging energy and environmental technologies. In this work, we investigate the structure of two common salt solutions, NaCl and KCl, at a hydrophobic interface within narrow carbon nanotubes (CNTs). Using a combination of first-principles and classical molecular dynamics simulations, we find that the solvation structure of the cations in the CNTs can deviate substantially from the conventional weakly interacting hydrophobic picture. Instead, interactions between solvated ions and the  $\pi$ -orbitals of the CNTs are found to play a critically important role, with the ion solvation structure ultimately determined by a subtle interplay between cation- $\pi$  interactions and the intrinsic flexibility of the solvation shell. In the case of  $\text{K}^+$ , these effects result in an unusually strong propensity to partially desolvate and reside closer to the carbon wall than either  $\text{Na}^+$  and  $\text{Cl}^-$ , in sharp contrast to the known ion ordering at the water-vapor interface.

**9:48AM X31.00006 Confined water between two graphene layers**, FRANCOIS PEETERS, MARIO SOBRINO FERNANDEZ, MEHDI NEEK-AMAL, University of Antwerp, Dept. of Physics, 2020 Antwerp, CONDENSED MATTER THEORY TEAM — Water confined between two layers with a separation of a few Angstrom forms a layered two-dimensional ice structure. Using large scale molecular dynamics simulations with the adoptable ReaxFF interatomic potential we found that monolayer ice with a rhombic-square structure nucleates between graphene layers which is non-polar and non-ferroelectric. We provide different energetic considerations and H-bonding results that explain the inter-layer and intra-layer properties of two-dimensional ice. The controversial AA-stacking found experimentally [G. Algara-Siller et al. Nature 519, 443445 (2015)] is consistent with our minimum energy crystal structure of bilayer ice. Furthermore, we predict that odd-number of layers of ice has the same lattice structure as monolayer ice, while even number of ice layers exhibit the square ice AA-stacking of bilayer ice. We predict that an inplane electric field polarizes the water molecules resulting in distinct-ferroelectricity. Electrical hysteresis in the response of the total dipole moment of monolayer ice is found

**10:00AM X31.00007 Structure, Spectroscopy and Thermodynamics at the Water – Graphene Interface**<sup>1</sup>, TOD PASCAL, The Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, CRAIG SCHWARTZ, Stanford Synchrotron Radiation Laboratory, Menlo Park, CA 94025, USA, KEITH LAWLER, Department of Chemistry, University of Nevada Las Vegas, Las Vegas, NV 89154, USA, DAVID PRENDERGAST<sup>2</sup>, The Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA — The recent discovery of an ordered two-dimensional phase of water with a square lattice between graphene sheets has led to tremendous interest in the structure of confined water, particularly under pressure.[1] Despite being recently discovered, this finding is fiercely being debated, with other researchers suggesting that the observed structures is due to the presence of NaCl, while various theoretical models predict the formation of water ice between graphene only under enormous external pressures.[1-3] Herein, by examining the EELS data, combined with simulated spectroscopy calculations and molecular dynamic simulations, we examine the thermodynamic properties of nano-encapsulated water, and demonstrate how charge transfer and chemical defects alters the phase diagram. **10:12AM X31.00008 ABSTRACT WITHDRAWN —**

**10:24AM X31.00009 Probing the water on chemically heterogeneous surface: interfacial-structural analysis for surface charge distribution**, SUCHEOL SHIN, ADAM WILLARD, Massachusetts Institute of Technology — We introduce the novel method for predicting the charge distribution of chemically heterogeneous surface, but reconstructed from the perspective of the interfacial water molecules. Our approach is to analyze the response of water to a disordered surface and infer from that response the heterogeneous distribution of surface charge. We accomplish this using a framework that is based on a probabilistic description of waters interfacial molecular structure and maximum likelihood estimation. This framework allows to deduce the apparent charge that is most congruently represented by the set of water configurations over the particular region of a surface. We demonstrate that the estimated charge distribution is consistent to the actual distribution for a static model substrate and hence that our method can be applied to investigate a dynamic fluctuating substrate such as the surface of a hydrated protein. This novel technique provides the useful information that can reflect the influence of fluctuations in the structure of biomolecule.

**10:36AM X31.00010 Enhanced configurational entropy in high-density nanoconfined bilayer ice**, FABIANO CORSETTI, Department of Materials and the Thomas Young Centre for Theory and Simulation of Materials, Imperial College London, London SW7 2AZ, United Kingdom, JON ZUBELTZU, EMILIO ARTACHO, CIC nanoGUNE, 20018 Donostia-San Sebastian, Spain — Understanding the structural tendencies of nanoconfined water is of great interest for nanoscience and biology, where nano/micro-sized objects may be separated by very few layers of water. We present a study of water confined to a 2D geometry by a featureless, chemically neutral potential, in order to characterize its intrinsic behaviour. We use molecular dynamics simulations with the TIP4P/2005 potential, combined with density-functional theory calculations with a non-local van der Waals density functional and an *ab initio* random structure search procedure. We propose a novel kind of crystal order in high-density nanoconfined bilayer ice. A first-order transition is observed between a low-temperature proton-ordered solid and a high-temperature proton-disordered solid. The latter is shown to possess crystalline order for the oxygen positions, arranged on a close-packed triangular lattice with AA stacking. Uniquely amongst the ice phases, the triangular bilayer is characterized by two levels of disorder (for the bonding network and for the protons) which results in a configurational entropy twice that of bulk ice.

**10:48AM X31.00011 Determination of interfacial properties using a PC-SAFT based classical density functional theory for fluid mixtures of industrial interest**, JIAN YANG, DIEGO CRISTANCHO, RAKESH SRIVASTAVA, The Dow Chemical Company — In this paper, a recent development of a PC-SAFT based classical density functional theory (DFT) is applied to the determination of interfacial properties of pure fluids and mixtures of industrial interest. Initially, the DFT formalism is described and the methodology for the property calculations explained. The consistency of this approach allows the determination of interfacial properties for fluids using the PC-SAFT equation of state parameters determined from bulk physical property data, such as vapor-liquid-equilibrium and densities. This methodology is an excellent alternative for the predictions of interfacial property of fluids and extrapolation to high pressure ranges where experimental measurements becomes challenging.

Session X32 DCP: Plasmonics and Beyond IV: Single particle dynamics 332 - Hrvje Petek, University of Pittsburgh

**8:00AM X32.00001 Plasmonic nano-focused four-wave mixing for femtosecond nano-imaging**, VASILY KRAVTSOV, RONALD ULBRICHT, University of Colorado at Boulder, JOANNA ATKIN, University of North Carolina at Chapel Hill, MARKUS RASCHKE, University of Colorado at Boulder — We experimentally demonstrate efficient and broadband nonlinear optical four-wave mixing (FWM) in a deep sub-wavelength volume using adiabatic nanofocusing of surface plasmon polaritons (SPPs). We couple few-femtosecond laser pulses into SPPs that propagate and experience nanofocusing on a sharp Au tip, and detect blue-shifted intra-pulse FWM response of the nanofocused plasmons. Due to the asymptotic mode volume compression and resulting steep increase in SPP field enhancement when approaching the tip apex, the nonlinear signal is highly localized in a nanoscopic volume at the apex. The simultaneous enhanced generation and further FWM field compression into the tip apex provides for a highly sensitive nano-probe for ultrafast near-field microscopy and spectroscopy. We demonstrate the use of the nano-localized nonlinear frequency conversion to spatially resolve few-femtosecond dynamics in ultrafast coherent spatio-temporal nano-imaging of the localized plasmonic modes of an inhomogeneous Au layer edge. Our results are supported by simulations and provide a perspective for an all-optical implementation of the novel multidimensional nano-spectroscopies.

**8:12AM X32.00002 Femtosecond Snapshots of quantum mechanics at work in plasmonic nano-structures.**<sup>1</sup>, FABRIZIO CARBONE, EPFL — Ultrafast Transmission Electron Microscopy enabled a new technique (Photon-Induced Near Field Electron Microscopy, PINEM), capable of controlling electromagnetic fields confined on the surface of nanostructures and image their properties with nm-resolution in direct space and fs resolution in time. In this presentation, we will show some recent results where the standing wave formed by the plasmonic field confined on the surface of one silver nano-wire was imaged together with its energy exchange with the imaging electrons. In these results, both the interference and the quantization of the plasmonic near field could be imaged simultaneously, revealing both a quantum and a classical aspect of the electromagnetic field in one snapshot. The implications of these results will be discussed, and we will also present new ideas and methodologies to go beyond such an experiment and image the interaction between single electrons and single plasmons. We will also show that shaping the electron density in a thin film via light pulses is possible by taking advantage of the plasmon-plasmon interference and the ability of light polarization to control the excitation of different plasmonic field geometries in ad hoc designed nanostructures. Movies of the propagation of plasmons will also be presented, providing insights into their speed, propagation losses and the effect of confinement.

**8:48AM X32.00003 Ultrafast Nonlinear Plasmonics of Single Nano-Objects**, NATALIA DEL FATTI, Institut Lumiere Matiere, CNRS - Universite Lyon 1 — Investigating, understanding and modeling the physical properties of nano-objects are intense fields of research. Of particular interest are metal-based nano-objects, where their morphology and environment dependent surface plasmon resonances (SPR) have been extensively exploited to design new optical systems. As a SPR is associated to electromagnetic local field enhancement in the nano-object, it also leads to enhancement of its optical nonlinearity, opening many possibilities for investigating fundamental processes at nanoscale [1]. Most of these studies were performed on large ensembles of nano-objects, providing mean information which impedes detailed comparison between experimental data and theoretical models. With the advance of single nanoparticle spectroscopy methods, the linear and nonlinear responses of a single nano-object can now be addressed, which, associated to determination of its morphology by electron microscopy, opens the way to their quantitative modeling [2]. In this context we discuss experimental and theoretical investigations of the ultrafast response of individual model nano-objects, either formed by a single particle (gold nanorod) or by two particles at a nanometric distance (gold-silver nano-dimer). Results obtained in gold nanorods are in excellent quantitative agreement with a model computing the change of the metal dielectric function due to ultrafast electron heating and relaxation. This shows that the nonlinear response of a metal nano-object can be fully described as that of the bulk metal enhanced by plasmonic effects. Extension of these studies to more complex nano-objects, as nano-dimers formed by two different materials, permits analysis of the impact of their interaction. We demonstrate here the existence of Fano effect in the absorption of a single Ag-Au dimer, experimentally proving previous theoretical predictions [3]. Furthermore, we show that ultrafast pump-probe nonlinear spectroscopy permits to selectively address at nanoscale only one of the components of a dimer, paving the way toward quantitative investigations of energy and charge exchanges in multi-material nano-objects. [1] F. Vallée and N. Del Fatti, in "Plasmonics: theory and applications", eds. T.Shahbazyan & M.Stockman, Springer, p. 167 (2013) [2] A. Crut, P. Maioli, N. Del Fatti and F. Vallée, Chem. Soc. Rev. **43**, 3921 (2014) [3] G. Bachelier, I. Russier-Antoine, E. Benichou, C. Jonin, N. Del Fatti, F. Vallée, P.F. Brevet, Phys. Rev. Lett. **101**, 197401 (2008).

**9:24AM X32.00004 Dirac single particle and plasmon excitations in topological insulators**, STEFANO LUPI, Department of Physics, Sapienza University of Rome — Topological Insulators (TIs), like Bi<sub>2</sub>Se<sub>3</sub> and Bi<sub>2</sub>Te<sub>3</sub>, are one of the most intriguing issues at focus in Condensed Matter Physics. TIs exhibit a band gap in the bulk like ordinary insulators, but have intrinsic 2D conducting states on their edge and surface. This means that the topology, associated with the electronic wavefunctions of the system, changes discontinuously when passing from the bulk to the surface. The edge states arise from a strong spin-orbit coupling, and they are backscattering protected, i.e. not sensitive to disorder (except that coming from magnetic impurities). Such as graphene, TIs surface charge transport is carried out by Dirac fermions, with a very high surface carrier density ( $n \geq 10^{13} \text{ cm}^{-2}$ ), compared to typical values on metal surfaces. Apart single particle excitations, Dirac fermions in TIs sustain exotic plasmons (collective) modes whose properties of tunability and temperature dependence can be used for photonics applications at the nanoscale. Moreover, unlike plasmons in metals, Dirac plasmons in TIs are expected to be strongly affected by an external magnetic field B due to fact that the cyclotron frequency is comparable to the plasmon frequency, in particular when plasmons are engineered in the terahertz region of the electromagnetic spectrum. In this talk, after a general review on the properties of Topological Insulators, I will discuss the terahertz linear response of Dirac plasmons in TIs and their behavior under a strong magnetic field up to 30 T. The appearance of strong non-linear optical effects, when the THz electric field reaches values on the order of 1 MV/cm, will be also discussed. In the second part of the talk, I will discuss the sub-ps dynamics of Dirac single-particle and collective excitations as measured by optical-pump THz-probe experiments. Both the steady state and time-resolved experiments provide a unifying picture of single particle and collective electronic excitations in Topological Insulators.

**10:00AM X32.00005 Quantum Plasmonics with Free Electrons**, JAVIER GARCIA DE ABAJO, ICFO - Institut de Ciències Fotoniques, Barcelona, Spain — Fast electrons offer the means to excite and probe plasmons with an unparalleled combination of space and energy resolutions. In particular, electron energy-loss and cathodoluminescence spectral microscopies are widely used to obtain snapshots of these excitations. Additionally, access to ultrafast plasmon dynamics is possible by recording photoelectrons excited with femtosecond light pulses, while recent experiments demonstrate optical pumping followed by electron-beam probing with similar temporal resolution. In this talk, we will review recent highlights of these techniques and present a unified theoretical description. We will further discuss some exciting phenomena enabled by the quantum nature of the electron-plasmon interaction, including quantum nonlinearities, electron-plasmon entanglement, and vacuum fluctuations. Emphasis will be placed on the potential application of these phenomena for improving and extending spectrally resolved electron microscopy, as well as for on-demand creating and probing of plasmons in integrated devices.

**10:36AM X32.00006 ABSTRACT MOVED TO M1.000376 —**

**Friday, March 18, 2016 8:00AM - 11:00AM —**

**Session X33 DPOLY FIAP: Organic Electronics and Photonics - Organic Electronic Devices**

336 - Lei Zhu, Case Western University

**8:00AM X33.00001 Charge Transport Properties in Polymer Brushes.** , MARK MOOG, FRANK TSUI, IAN VONWALD, WEI YOU, University of North Carolina at Chapel Hill — Electrical transport properties in poly(3-methyl)thiophene (P3MT) brushes have been studied. The P3MT brushes correspond to a new type of surface-tethered, vertically oriented conjugated molecular wires, sandwiched between two metallic electrodes to form the electrode-molecule-electrode (EME) devices. P3MT is a highly conjugated polymer, a "workhorse" material for organic electronics and photonics. The P3MT brushes were grown on ITO surfaces with controlled length (between 2 and 100 nm). The top electrodes were transfer-printed Au films with lateral dimensions between 200 nm and 50  $\mu\text{m}$ . I-V and differential conductance measurements were performed using conductive AFM and 4-terminal techniques. Tunneling and field-emission measurements in EME devices with molecular lengths < 5 nm show HOMO mediated direct hole tunneling with energy barriers of 0.3 and 0.5 eV at the respective interfaces with ITO and Au. The transport properties in longer brushes are indicative of the two quasi-Ohmic interfaces with a characteristic offset in the conductance minimum of 0.12 V biased toward the ITO. Temperature dependent parameters have been examined at various molecular lengths. The drift mobility and the interplay between intra- and intermolecular transport have been investigated.

**8:12AM X33.00002 Hall effect and band-like carrier transport in high mobility polymer transistors** , YU YAMASHITA, The University of Tokyo, FELIX HINKEL, TOMASZ MARZALEK, WOJCIECH ZAJACZKOWSKI, WOJCIECH PISULA, MARTIN BAUMGARTEN, Max Planck Institute for Polymer Research, HIROYUKI MATSUI, The University of Tokyo, KLAUS MLLEN, Max Planck Institute for Polymer Research, JUN TAKEYA, The University of Tokyo, PROF. TAKEYA GROUP TEAM, PROF. MLLEN GROUP TEAM — A microscopic understanding of charge carrier transport in polymeric semiconductors is essential to improve the state of the art of flexible or printed electronic devices. In particular, thin-film field-effect transistors based on donor-acceptor polymers are in the focus of current literature reaching high charge-carrier mobility. In this work, we demonstrate the Hall effect and the temperature dependence of the charge carrier mobility based on uniaxially ordered CDT-BTZ donor-acceptor copolymer films. Uniaxially ordered films of CDT-BTZ with hexadecyl (C16) and eicosyl (C20) sidechains showed mobility of 5.6  $\text{cm}^2/\text{Vs}$  and 11.4  $\text{cm}^2/\text{Vs}$  respectively. The activation energy of the mobility decreased with the increasing carrier density, and finally the negative temperature dependence of the mobility was observed. Both polymers showed Hall effect, which also indicates the presence of extended electronic states. The temperature and carrier density dependence will be further discussed in the presentation.

**8:24AM X33.00003 ABSTRACT WITHDRAWN —**

**8:36AM X33.00004 Growth and characterization of organic ferroelectric croconic acid thin films<sup>1</sup>** , XUANYUAN JIANG, HAIDONG LU, YUEWEI YIN, AXEL ENDERS, ALEXEI GRUVERMAN, XIAOSHAN XU, Univ of Nebraska - Lincoln — Using vapor phase evaporation, we have studied the growth of the croconic acid (CCA) thin films, at various conditions such as temperature, thickness, growth speed, and substrates. The morphology of thin film was measured by atomic force microscopy (AFM); the ferroelectric property was confirmed by piezoresponse force microscopy (PFM). A critical thickness of 40 nm and optimal temperature of -30 celsius were found for continuous films, while the substrate and growth speed are found to play a minimal role. According to the reflection high energy electron diffraction (RHEED), the CCA films are polycrystalline. For a 40 nm continuous film, the roughness is about 3 nm, while the coercive voltage for the ferroelectric domain switching is approximately 7V. This is the first molecule ferroelectric thin film. The successful growth of continuous CCA films enhances the applications potential of CCA, which is a molecular crystal of ferroelectricity.

**8:48AM X33.00005 Enhance the lifetime and bias stress reliability in organic vertical transistor by UV/Ozone treatment** , HUNG-CHENG LIN, MING-YU CHANG, HSIAO-WEN ZAN, HSIN-FEI MENG, National Chiao Tung University, Taiwan, YU-CHIANG CHAO, Chung-Yuan Christian University, Taiwan — In this paper, we use UV/Ozone treatment to improve the lifetime and bias stress reliability of organic transistor with vertical channel. Even if vertical organic transistor exhibits better bias stress reliability than organic field effect transistor (OFET) due to bulk conduction mechanism, poor lifetime performance is still a challenge. Adding octadecyltrichlorosilane (OTS) to treat the vertical channel can reduce the trapping state and hence improve the bias stress ability. However, off-current is much higher after 6 days and lifetime performance is degraded. On the other hand, after 4000-s on-state bias stress, stable output current and on/off current ratio are demonstrated by using UV/Ozone to treat vertical channels. Threshold voltage shift is only -0.02 V which is much smaller than OFET with the same organic semiconductor material. Furthermore, the output current is also an order enhanced. Nevertheless, unlike device with OTS treatment, no obvious degradation is observed for UV/Ozone treated devices even after 170 days. With UV/Ozone treatment, the output current, bias stress reliability and lifetime were all improved. It makes vertical transistor become a promising device for the further application in display technology and flexible electronics.

**9:00AM X33.00006 Gate-controlled energy barrier at a graphene/molecular semiconductor junction** , S. PARUI, L. PIETROBON, D. CIUDAD, S. VELEZ, X. SUN, P. STOLJAR, CIC nanoGUNE, 20018 Donostia-San Sebastian, Basque Country, Spain, F. CASANOVA, L. E. HUESO, CIC nanoGUNE, 20018 Donostia-San Sebastian, Basque Country, Spain; and IKERBASQUE, Basque Foundation for Science, 48011 Bilbao, Basque Country, Spain — The formation of an energy barrier at a metal/molecular semiconductor junction is both a ubiquitous phenomenon as well as the subject of intense research in order to improve the performance of molecular semiconductor-based electronic and optoelectronic devices. For these devices, a junction with a large energy barrier provides rectification, leading to a diode behavior, whereas a relatively small energy barrier provides nearly-ohmic behavior, resulting in efficient carrier injection (extraction) into the molecular semiconductor. Typically, a specific metal/molecular semiconductor combination leads to a fixed energy barrier; therefore, the possibility of a gate-controlled energy barrier is very appealing for advanced applications. Here [S. Parui *et al*, Adv. Fun. Mat. **25**, 2972 (2015)], we present a graphene/C<sub>60</sub> junction-based vertical field-effect transistor in which we demonstrate control of the interfacial energy-barrier such that the junction switches from a highly rectifying diode at negative gate voltages to a nearly-ohmic behavior at positive gate voltages and at room temperature. We extract an energy-barrier modulation of up to 660 meV, a transconductance of up to five orders of magnitude and a gate-modulated photocurrent.

**9:12AM X33.00007 Influence of Morphological Disorder on In- and Out-of-Plane Charge Transport in Conjugated Polymer Films** , BAN DONG, ANTON LI, PETER GREEN, University of Michigan — We report the unequal impacts of morphological disorder on in- and out-of-plane charge transport in thin films of poly(3-hexylthiophene) (P3HT) fabricated by both conventional spin-casting and the novel technique Matrix-Assisted Pulsed Laser Evaporation (MAPLE). MAPLE produces films with inhomogeneous globular subfeatures with dimensions on the order of 100 nm. Optical absorbance spectroscopy corroborates that MAPLE-deposited films are more energetically disordered, but possesses average conjugation lengths comparable to spin-cast P3HT. Both in- and out-of-plane carrier transport measurements of MAPLE-deposited films show characteristics that reflect a higher degree of energetic disorder and broadened density of states. Whereas in-plane carrier mobilities of MAPLE-deposited thin-film transistors are comparable to spin-cast analogues ( $8.3 \times 10^{-3} \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$  versus  $5.5 \times 10^{-3} \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ ), the out-of-plane mobilities of MAPLE-deposited samples are nearly an order of magnitude lower ( $4.1 \times 10^{-4} \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$  versus  $2.7 \times 10^{-3} \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ ). The unusual ensemble of properties and behaviors arising from the unique morphologies produced by MAPLE provide important perspectives on the extent to which disorder impacts different mechanisms of charge transport in conjugated polymers.

**9:24AM X33.00008 Polarization-induced transport in TIPS-pentacene field-effect transistors<sup>1</sup>**, AMRIT LAUDARI, SUCHI GUHA, University of Missouri, Columbia — The dielectric constant of polymer ferroelectric dielectrics can be tuned by changing the temperature, offering a platform for monitoring the changes in interfacial transport in organic field-effect transistors (FETs), as the polarization strength is tuned. Temperature dependent transport studies of FETs have been carried out from a solution-processed organic semiconductor, 6,13-bis(triisopropylsilyl)ethynylpentacene (TIPS-pentacene), using both ferroelectric and non-ferroelectric gate insulators. Non-polar dielectric based TIPS-pentacene FETs show a clear activated transport in contrast to the ferroelectric dielectric polymer, poly(vinylidene fluoride-trifluoroethylene) (PVDF-TrFE), where a negative temperature coefficient of the mobility is observed in the ferroelectric temperature range. We attribute the weak temperature-dependence of the charge carrier mobility to a polarization fluctuation driven transport resulting from a coupling of the charge carriers to the surface phonons of the polar dielectric. The negative coefficient of mobility ( $\frac{d\mu}{dT} < 0$ ) observed with ferroelectric dielectrics is not a signature of an extended-state conduction but rather denotes polarization fluctuation driven transport.

**9:36AM X33.00009 Radical Polymer Utilization for Interfacial Improvement of Organic Field-Effect Transistors**, SEUNG HYUN SUNG, NIKHIL BAJAJ, JEFFREY RHOADS, GEORGE CHIU, BRYAN BOUDOURIS, Purdue University — Metal-semiconductor interfacial contact is one of the crucial factors for high-performance organic electronic device applications. In particular, the performance of organic field-effect transistors (OFETs) is critically dependent on the engineering of the interface between the organic semiconductor and the source/drain electrodes. Here, we modulate the performance of pentacene-based OFETs through the inclusion of a specific radical polymer, poly(2,2,6,6-tetramethylpiperidine-1-oxyl methacrylate) (PTMA), at the pentacene-gold electrode interface. Using a simple and fast inkjet printing method, the OFET performance is highly enhanced by the systematic deposition of a thin PTMA layer. The insertion of the radical polymer has an impact on the highly-improved OFET performance due to its redox charge transport ability and the amorphous nature allowing the stable growth of the pentacene. The synergistic effect facilitates the charge injection at the interface of the metal and organic semiconductor, resulting in the highly improved OFET performance. As such, the fundamental insights associated with radical polymers can be widened and their utilization as a highly-improved, low-cost interfacial modifier in myriad organic electronic devices is of great promise.

**9:48AM X33.00010 Small Molecule Doping of Radical Polymers for Enhanced Electronic Performance**, ADITYA BARADWAJ, SI HUI WONG, BRYAN BOUDOURIS, Purdue University — Radical polymers have emerged as a class of conducting polymers that show immense potential for solid state electronic applications. However, very little has been done to explore the small molecule doping of these materials for increased electrical performance. Here, we present the characterization of the charge transport ability of a model radical polymer, poly(2,2,6,6-tetramethylpiperidinyloxy methacrylate) (PTMA), doped with varying levels of the small molecule, 4-Acetamido-2,2,6,6-tetramethyl-1-oxopiperidinium tetrafluoroborate (TEMPO<sup>+</sup>ium). We demonstrate that the addition of the TEMPO<sup>+</sup>ium to PTMA thin films creates a distinct relationship between doping level and electrical conductivity. At optimal doping levels, we find that the electrical conductivity of PTMA thin films increases by over an order of magnitude. Furthermore, we illustrate the competing effects of electrical and ionic conductivity that exists in this system by probing the dependence of current on time in these thin films. Finally, we show that the TEMPO<sup>+</sup>ium doping greatly enhances the film quality of these typically brittle PTMA thin films. We anticipate that these findings will encourage novel methods to enhance the electrical performance of these open shell systems in the solid state.

**10:00AM X33.00011 Understanding the growth of organic semiconductors on semiconducting surfaces**, MINA YOON, CHANGWON PARK, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, BING HUANG, Beijing Computational Science Research Center, SEAN R. WAGNER, PENG PENG ZHANG, Michigan State University — A selective mechanism for tuning the molecule-substrate interaction has been a long sought after goal towards tailored molecular growth. Using first-principles theory and scanning tunneling microscopy, we show that by controlling the strength of orbital hybridization between phthalocyanine molecules and the deactivated Si surface via the selective p-d orbital coupling, we can tune the molecular ordering and molecular orientation at the hetero-interface. This mechanism offers a novel approach to balance the critical interactions, leading to controlled long-ranged ordered molecular growth [1]. [1] S.R. Wagner, B. Huang, C. Park, J. Feng, M. Yoon, and P. Zhang, Phys. Rev. Lett. 115, 096101 (2015). This work was supported by the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy and partly supported by the Materials Sciences and Engineering Divisions, Office of Basic Energy Sciences, U.S. Department of Energy.

**10:12AM X33.00012 Stencil Nano Lithography Based on a Nanoscale Polymer Shadow Mask: Towards Organic Nanoelectronics<sup>1</sup>**, SANG WOOK LEE, HOYEOL YUN, HAKSEONG KIM, KIRSTIE MCALLISTER, DONG HOON SHIN, Konkuk University, JUN SUNG KIM, POSTECH, SEUNGMOON PYO, WI HYOUNG LEE, Konkuk University, ELEANOR CAMPBELL, University of Edinburgh, NENM TEAM — A stencil lithography technique has been developed to fabricate organic-material-based electronic devices with sub-micron resolution. Suspended polymethylmethacrylate (PMMA) membranes were used as shadow masks for defining organic channels and top electrodes. Arrays of pentacene field effect transistors (FETs) with various channel lengths from 50  $\mu\text{m}$  down to 500 nm were successfully produced from the same batch using this technique. Electrical transport measurements showed that the electrical contacts of all devices were stable and the normalized contact resistances were much lower than previously studied organic FETs. Scaling effects, originating from the bulk space charge current, were investigated by analyzing the channel-length-dependent mobility and hysteresis behaviors. This novel lithography method provides a reliable means for studying the fundamental transport properties of organic materials at the nanoscale as well as enabling potential applications requiring the fabrication of integrated organic nanoelectronic devices.

**10:24AM X33.00013 Ab initio studies of the optoelectronic properties of biphenyl derivatives in OLEDs<sup>1</sup>**, HOSSEIN HASHEMI, AVI BREGMAN, JAEHUN JUNG, MINSANG KWON, JINSANG KIM, JOHN KIEFFER, Univ of Michigan - Ann Arbor, KIEFFER GROUP TEAM, KIM GROUP TEAM — The influence of molecular conformation on electron relaxation and photophysical properties of a series of biphenyl derivatives have been investigated using density functional theory (DFT) and time-dependent DFT (TDDFT). The calculated absorption and emission properties of the series as well as phosphorescence quantum yield are in good agreement with the available experimental data. The spin orbit coupling values and the  $S \rightarrow T$  intersystem-crossing matrix elements and crossing rate constants are also explored as a function of the twist angle between the rings. The  $T \rightarrow S_0$  radiative and non-radiative transition rates are calculated and discussed for each member of the series. In addition, the  $T \rightarrow S_0$  radiative transition rate constant is calculated for twisted biphenyls and compared to those for planar molecules.

**10:36AM X33.00014 A Comparison Between Magnetic Field Effects in Excitonic and Exciplex Organic Light-Emitting Diodes**, KEYSER SAHIN TIRAS, YIFEI WANG, NICHOLAS J HARMON, MARKUS WOHLGENANN, MICHAEL E FLATTE, University of Iowa — In flat-panel displays and lighting applications, organic light emitting diodes (OLEDs) have been widely used because of their efficient light emission, low-cost manufacturing and flexibility. The electrons and holes injected from the anode and cathode, respectively, form a tightly bound exciton as they meet at a molecule in organic layer. Excitons occur as spin singlets or triplets and the ratio between singlet and triplet excitons formed is 1:3 based on spin degeneracy. The internal quantum efficiency (IQE) of fluorescent-based OLEDs is limited 25% because only singlet excitons contribute the light emission. To overcome this limitation, thermally activated delayed fluorescent (TADF) materials have been introduced in the field of OLEDs. The exchange splitting between the singlet and triplet states of two-component exciplex systems is comparable to the thermal energy in TADF materials, whereas it is usually much larger in excitons. Reverse intersystem crossing occurs from triplet to singlet exciplex state, and this improves the IQE. An applied small magnetic field can change the spin dynamics of recombination in TADF blends. In this study, magnetic field effects on both excitonic and exciplex OLEDs will be presented and comparison similarities and differences will be made.

**10:48AM X33.00015 Tunable white light emission in Parallel Tandem OLEDs made with silver metal as interlayer**, JORGE OLIVA, Centro de Investigaciones en Optica, ALEXIOS PAPADIMITRATOS, ANVAR ZAKHIDOV, University of Texas at Dallas, UT DALLAS TEAM — Parallel tandem organic light emitting diodes (OLEDs) which consisted in a top and bottom subunits, and joined with a thin layer of silver (interlayer) were fabricated. In this parallel tandem architecture the Ag metal is an active common anode, which permitted to inject holes into top and bottom subunits. Both subunits of the tandem can thus be connected functionally in a new geometry and addressed separately. Those Tandems had a yellow emitter (a mixture of MEH-PPV and TFB polymers) in the bottom subunit and a blue emitting molecule in the top subunit. The simultaneous combination of the emitted yellow and blue light when both subunits are operating produced white light. We could tune the white light from cool (CIE: 0.33, 0.25) to warm (CIE: 0.38, 0.39) by changing the intensity of the yellow light, that in turn depends on the ratio of MEH-PPV/TFB mixture used to make the emitting layer in the bottom subunit. We also compared the performance of the parallel tandem with these in series and we found additional advantages of the parallel architecture over the configuration for the series tandems such as: tunable chromaticity, lower turn on voltage (4V compared to 7V in the in-series tandem) and higher brightness. The best CIE coordinate we obtained for white light was (0.35, 0.35) which is near the ideal coordinate of (0.33,0.33).

**Friday, March 18, 2016 8:00AM - 11:00AM –**

**Session X34 GSOFD DPOLY: Emulsions, Foams, Gels, and Complex Fluids** 337 - Carlos Orellana, Emory University

**8:00AM X34.00001 Experimental measurement of the angle of repose of a pile of soft frictionless grains**, KLEBERT FEITOSA, DANIEL SHORTS, Dept. of Physics and Astronomy, James Madison University — It is well known that dry granular materials can flow like a liquid, but can also behave as a solid and sustain a finite angle of repose, partially as a result of inter-particle friction. Here we investigate the nature of piles formed with soft frictionless grains and measure its angle of repose. The pile is produced by a continuous bubbling of air into a soapy solution in a narrow container of rectangular cross section. We observe a gentle slope at the water-foam interface whose angle depends on the viscosity of the liquid. In contrast with sand piles, the fluidized region along the interface is several layers deep. We also find that, unlike sand piles, upon interruption of the gas flux, the slope relaxes back to zero as a result of bubble rearrangements and liquid drainage.

**8:12AM X34.00002 Rearrangements during slow compression of a jammed 2D emulsion**, XIN DU, CARLOS ORELLANA, XIA HONG, ERIC WEEKS, Department of Physics, Emory University — We experimentally study non-affine motion within an evaporating quasi two-dimensional emulsion system. Our samples are oil-in-water emulsions confined between two close-spaced parallel plates, so that the oil droplets are deformed into pancake shapes. In this system, water slowly evaporates from an open edge of the chamber and, as a consequence, the volume fraction of oil droplets gradually increases. By means of microscopy, we analyzed the motion of droplets and measure the deformation of the droplet's outlines. Based on this information, we calculate the force network and the Voronoi cell when the system approaching jamming state. Using a recently proposed method (J. Rieser et al., arXiv:1509.05496), we calculate the Voronoi cell anisotropy vectors which point from the center of each particle to the corresponding Voronoi cell centroid, and identify void spaces where droplets may be more likely to move toward according to the field of the vectors. These allow us to study the correlations between the force network, the Voronoi vector field, and the non-affine displacements of droplets in our evaporating system.

**8:24AM X34.00003 Self-Assembly of Emulsion Droplets into Polymer Chains**, DYLAN BARGTEIL, ANGUS MCMULLEN, JASNA BRUJIC, New York Univ NYU — We experimentally investigate 'beads-on-a-string' models of polymers using the spontaneous assembly of emulsion droplets into linear chains. Droplets functionalized with surface-mobile DNA allow for programmable 'monomers' through which we can influence the three-dimensional structure of the assembled 'polymer'. Such model polymers can be used to study conformational changes of polypeptides and the principles governing protein folding. In our system, we find that droplets bind via complementary DNA strands that are recruited into adhesion patches. Recruitment is driven by the DNA hybridization energy, and is limited by the energy cost of surface deformation and the entropy loss of the mobile linkers, yielding adhesion patches of a characteristic size with a given number of linkers. By tuning the initial surface coverage of linkers, we control valency between the droplets to create linear or branched polymer chains. We additionally control the flexibility of the model polymers by varying the salt concentration and study their dynamics between extended and collapsed states. This system opens the possibility of programming stable three-dimensional structures, such as those found within folded proteins.

**8:36AM X34.00004 Cellulose Nanocrystals as Water in Water Emulsion Stabilizers**, KARTHIK REDDY PEDDIREDDY, ISABELLE CAPRON, Institut National de la Recherche Agronomique, TACO NICOLAI, LAZHAR BENYAHIA, UMR CNRS Université du Maine — Cellulose is the most abundant polymer on the earth. Thus, it is very much desirable to find as many practical applications as possible for it. Cellulose, in its original form, contains both amorphous and crystalline parts. It is possible to separate both parts by dissolving the amorphous part in concentrated sulfuric acid. The remaining crystalline cellulose part exists in the form of rod-like particles. The dimensions of the particles depend on the source. We produce the particles from the acid hydrolysis of cotton cellulose fibers. It results in cellulose nanocrystals (CNCs) with dimensions of ~150 nm x 6 nm x 6 nm. It is well known that CNCs could very efficiently stabilize oil in water (O/W) emulsions by forming very dense monolayers of CNCs at O-W interfaces. However, it is not yet known whether they could also stabilize water in water (W/W) emulsions. The W/W emulsions can be produced by any two incompatible polymers. It is challenging to find effective stabilizers for W/W emulsions due to ultralow interfacial tension and large interfacial thickness. In this talk, I will show the efficiency and effectiveness of these one-dimensional rods as W/W emulsion stabilizers.

**8:48AM X34.00005 Single droplet-level understanding of flow-induced phase inversion of emulsions**, ANKIT KUMAR, Univ of Pennsylvania, SHIGENG LI, CHIEH-MIN CHENG, Xerox Corp., DAEYEON LEE, Univ of Pennsylvania — Phase inversion emulsification (PIE) is a process of generating emulsions by inverting the continuous and dispersed phases of a pre-existing emulsion. It is particularly useful when it is challenging to generate the target emulsions by conventional emulsification methods. Phase inversion of emulsions by flowing them through precisely engineered conduits is called flow-induced phase inversion emulsification (FIPIE). In this study a fundamental understanding of the underlying mechanism of FIPIE is developed. Phase inversion of monodisperse oil-in-water (O/W) emulsions into water-in-oil (W/O) emulsions is achieved by flowing them through specifically designed microfluidic channels. Based on in situ observation of single droplet-level events which lead to phase inversion, a mechanism of the process has been proposed. The outcome of the process is shown to depend on two dimensionless groups - Capillary number (relative importance of viscous and surface tension effects) and dimensionless droplet deformation ( $D/w$ , ratio of droplet size to channel width). It can be concluded from a state-plot between  $Ca$  and  $D/w$  that lower  $Ca$  and higher ( $D/w$ ) facilitate FIPIE.

**9:00AM X34.00006 Local Rearrangements of Droplets in a Dense Emulsion Under Shear Rearrangements**, VISHWAS VENKATESH, Georgetown University, SUDEEP DUTTA, University of Maryland, EMANUELA DEL GADO, DANIEL BLAIR, Georgetown University — Jammed suspensions can flow when subjected to shear deformation. The flow properties are complex, depend on shear rates and can be inhomogeneous through the material. The microscopic origin of such flow properties is still a subject of intense research. In this work, we present a study of jammed emulsions under shear deformation, using a combination of experiments and molecular dynamics simulations. In the steady state regime, we investigate the local rearrangement of jammed emulsion droplets at a wide range of shear rates and shear strains and characterise the local rearrangement of droplets in terms of mean square displacement (MSD), displacement maps and displacement correlation function. At small shear strains and high shear rates, we find localised flow events and super diffusive motion of droplets. But at low shear rates, we observe emerging shear localisation from plastic events in an elastic background and avalanches. The characterisation of local rearrangements is also done in the stress over-shoot regime as well in the regime approaching the steady state stress. We observe a transient shear banding that progressively disappears as the pressure reaches a steady state value.

**9:12AM X34.00007 Tuneable Rheological Properties of Fluorinated Pickering Emulsions**, LAURA ANDREINA CHACON ORELLANA, CNRS, Univ. Bordeaux, CRPP, UPR 8641, 33600 Pessac, France, BIRTE RIECHERS, Max Plank Institute for Dynamics and Self-organization, Am Fassberg 17, D-37077 Goettingen, Germany, OURIEL CAEN, Univ. Paris Sorbonne Cite, INSERM UMR-S775, 75270 Paris Cedex, France, JEAN-CHRISTOPHE BARET, CNRS, Univ. Bordeaux, CRPP, UPR 8641, 33600 Pessac, France — Pickering emulsions are an appealing approach to stabilize liquid-liquid dispersions without surfactants. Recently, amphiphilic silica nanoparticles have been proposed as an alternative to surfactants for droplet microfluidics applications, where aqueous drops are stabilized in fluorinated oils [1]. This system, proved to be effective in preventing the leakage of resorufin, a model dye that was known to leak in surfactant-stabilized drops [1][2]. The overall capabilities of droplet-based microfluidics technology is highly dependent on the dynamic properties of droplets, interfaces and emulsions [3]. Therefore, fluorinated pickering emulsions dynamic properties need to be characterized, understood and controlled to be used as a substitute of already broadly studied emulsions for droplet microfluidics applications. In this study, fluorinated pickering emulsions have been found to behave as a Herschel Bulkley fluid, representing a challenge for common microfluidic operations as re-injection and sorting of droplets. We found that this behavior is controlled by the interaction between the interfacial properties of the particle-laden interface and the bulk properties of the two phases. [1]M. Pan et al. ACS Appl. Mater 2014 [2]Y. Skhiri et al. Soft Matter 2012 [3]J.C. Baret, Lab Chip 2012

**9:24AM X34.00008 A Computational Study of the Rheology and Structure of Surfactant Covered Droplets**, JOAO MAIA, ARMAN BOROMAND, Case Western Reserve University — Using different types of surface-active agents are ubiquitous in different industrial applications ranging from cosmetic and food industries to polymeric nano-composite and blends. This allows to produce stable multiphase systems like foams and emulsions whose stability and shelf-life are directly determined by the efficiency and the type of the surfactant molecules. Moreover, presence and self-assembly of these species on an interface will display complex dynamics and structural evolution under different processing conditions. Analogous to bulk rheology of complex systems, surfactant covered interfaces will response to an external mechanical forces or deformation differently depends on the molecular configuration and topology of the system constituents. Although the effect of molecular configuration of the surface-active molecules on the planar interfaces has been studied both experimentally and computationally, it remains challenging from both experimental and computational aspects to track efficiency and effectiveness of different surfactant molecules with different molecular geometries on curved interfaces. Using Dissipative Particle Dynamics, we have studied effectiveness and efficiency of different surfactant molecules on a curved interface in equilibrium and far from equilibrium. Interfacial tension is calculated for linear and branched surfactant with different hydrophobic and hydrophilic tail and head groups with different branching densities. Deformation parameter and Taylor plots are obtained for individual surfactant molecules under shear flow.

**9:36AM X34.00009 The origin of power-law rheology in foams**, HYUN JOO HWANG, ROBERT RIGGLEMAN, JOHN CROCKER, University of Pennsylvania — Soft glassy matter (SGM) such as foams, emulsions, and colloids, exhibit interesting rheological properties that have long defied explanation. In particular, the shear modulus of these materials displays weak power law frequency dependence. To understand the origin of this property in more depth, we have built a three-dimensional, modified Bubble Dynamics model. The bubbles interact with a purely repulsive harmonic potential and ripen according to diffusion-based governing equations. Notably, the bubble motion has a Levy flight character, in addition to being spatially correlated in the form of avalanches. Microrheology studies reveal that the power-law shear modulus is the result of constraint release driven by the bubbles' super-diffusive motion combined with simple yield of the resulting stress. The super-diffusive motion of the bubbles, in turn, is the result of the system taking a fractal path in configuration space. We shall discuss the origins of this fractal scaling.

**9:48AM X34.00010 Creep dynamics in soft matter**, RAFFAELA CABRIOLU, Universite' Joseph Fourier — Detecting any precursors of failure in Soft Matter Systems (SMS) is an inter-disciplinary topic with important applications (e.g. prediction of failure in engineering processes). Further, it provides an ideal benchmark to understand how mechanical stress and failure impacts the flow properties of amorphous condensed matter. Furthermore, some SMS are viscoelastic, flowing like viscous liquids or deforming like a solid according to applied forces. Often SMS are fragile and local rearrangements trigger catastrophic macroscopic failure. Despite the importance of the topic little is known on the local creep dynamics [1,2] before the occurrence of such catastrophic events [3,4]. To study creep and failure at an atomic/molecular level and at time scales that are not easily accessible by experiments we chose to carry out microscopic simulations. In this work we present the response of a colloidal system to uniaxial tensile stress applied and we compare our results to experimental works [8]. References: [1] Schurtenberger et al., J. Phys. Chem. 95, 4173 (1991). [2] Bauer et al., Phys. Rev. Lett. 97, 258303 (2006) [3] Chaudhuri P. et al., Phys. Rev. E 88, 040301 (2013). [4] Zausch J. et al., J. Phys. Condens. Matter 20, 404210 (2008).

**10:00AM X34.00011 Modeling Discontinuous Phase Transitions in Gel Membranes: Focus on Hysteresis and Feedback Mechanisms**, OLGA KUKSENOK, Clemson Univ — Feedback mechanisms are vital in a number of processes in biological systems. For example, feedback loops play an essential role during a limb development in mammals and are responsible for the asymmetric cell division to constrain the growth in plants to the specific regions. An integration of well-controlled feedback loops into the fully synthetic materials is an important step in designing a range of biomimetic functionalities. Herein, we focus on hydrogels functionalized with light-sensitive trisodium salt of copper chlorophyllin and study discontinuous phase transitions in these systems. Prior experimental studies had shown that illumination of these functionalized gels results in their heating and in discontinuous, first order phase transition upon the variation in temperature. Herein, we develop the first computational model for these gels; the framework of the model is based on the gel Lattice Spring Model, in this work we account for the gel heating under the illumination. The results of our simulations are in a good agreement with prior experimental studies. We focus on pattern development during the volume phase transitions in membranes of various thicknesses and show that one can effectively utilize light intensity to remotely control feedback loops in these systems.

**10:12AM X34.00012 X-ray speckle measurements of concentrated nanoemulsions under shear**, SAMY ABIDIB, MICHAEL ROGERS, University of Ottawa, ROBERT LEHENY, KUI CHEN, Johns Hopkins University, THOMAS MASON, UCLA, JAMES HARDEN, University of Ottawa — We present in situ X-ray Photon Correlation Spectroscopy (XPCS) measurements of a set of concentrated nanoemulsions subjected to oscillatory shear. The nanoemulsion set contained samples with varying packing fractions of oil droplets ( $r \approx 20\text{nm}$ ) above the jamming transition. In order to study their elasticity, yielding, and flow at various shear amplitudes, we employed stroboscopic coherent X-ray scattering measurements triggered at the maximums of the shear cycle. The degree of correlation between speckle in images taken a full period apart is a direct measurement of particle rearrangements during cycling. A comparison of such XPCS echo measurements with rheological measurements shows an onset of irreversible particle motion at shear strains below the crossover of the storage and loss moduli, which is typically used to indicate the transition to viscoplastic flow. Moreover, the XPCS echo measurements indicate that particle irreversibility increases rapidly with shear amplitude, in contrast to the comparably smooth transition to yielding shown in bulk rheology measurements. However, the macroscopic yield strain observed in rheology and the microscopic yield strain identified from XPCS, which were strong functions of droplet packing fraction, tracked each other closely.

**10:24AM X34.00013 Dynamics of a DNA Gel**, RAMESH ADHIKARI, ANIKET BHATTACHARYA, ARISTIDE DOGARIU, University of Central Florida — We study *in silico* the properties of a gel consisting of DNA strands (modeled as semi-flexible chains) and linkers of varying flexibility, length, and topology. These linkers are envisioned and modeled as active components with additional attributes so as to mimic properties of a synthetic DNA gel containing motor proteins. We use Brownian dynamics to directly obtain frequency dependent complex shear moduli of the gel. We further carry out force spectroscopy on these computer generated gels and study the relaxation properties as a function of the important parameters of the model, e.g., densities and relative ratios of the DNAs and the linkers, the average life time of a link, etc. Our studies are relevant for designing synthetic bio-materials for both materials and medical applications.

**10:36AM X34.00014 Supramolecular Structural Forces in Stratifying Foam Films and Micelle Aggregation Number**, SUBINUER YILIXIATI, YIRAN ZHANG, EWELINA WOJCIK, RABEES RAFIQ, VIVEK SHARMA, Univ of Illinois - Chicago — Understanding and controlling the drainage kinetics of thin films is an important problem that underlies the stability, lifetime and rheology of foams and emulsions. Foam films containing micelles, colloidal particles or polyelectrolyte-surfactant mixtures exhibit step-wise thinning or stratification, due to the influence of non-DLVO forces, including supramolecular oscillatory structural forces. In this study, we use experiments and theory to investigate the drainage and stratification in vertical and horizontal thin foam films ( $<100\text{ nm}$ ) formed by aqueous sodium dodecyl sulfate (SDS) solutions. We determine how the concentration of surfactants and added salt influences the stepwise thinning process for micellar solutions, and how step size can be used for estimating micelle size and interactions. The concentration-dependent aggregation number extracted from our experiments match-up reasonably well with values obtained by other techniques including scattering and fluorescence.

**10:48AM X34.00015 Microrheology using a custom-made AFM<sup>1</sup>**, SEBASTIEN KOSGODAGAN ACHARIGE, UMR CNRS 5672 Laboratoire de Physique de l'Ecole Normale Supérieure de Lyon, 46 Allée d'Italie, 69364 Lyon cedex 07, France, MICHAEL BENZAQUEN<sup>2</sup>, UMR CNRS 7083 Gulliver, ESPCI ParisTech, 10 Rue Vauquelin 75005 Paris, France, AUDREY STEINBERGER, UMR CNRS 5672 Laboratoire de Physique de l'Ecole Normale Supérieure de Lyon, 46 Allée d'Italie, 69364 Lyon cedex 07, France — In the past few years, a new method was developed to measure local properties of liquids (X. Xiong *et al.*, Phys. Rev. E 80, 2009). This method consists of gluing a micron-sized glass fiber at the tip of an AFM cantilever and probing the liquid with it. In ENS Lyon, this method was perfected (C. Devailly *et al.*, EPL, 106 5, 2014) with the help of an interferometer developed in the same laboratory (L. Bellon *et al.*, Opt. Commun. 207 49, 2002 and P. Paolino *et al.*, Rev. Sci. Instrum. 84, 2013), which background noise can reach  $10^{-14}\text{ m}/\sqrt{\text{Hz}}$ . This method allows us to measure a wide range of viscosities ( $1\text{ mPa}\cdot\text{s}$  to  $500\text{ mPa}\cdot\text{s}$ ) of transparent and opaque fluids using a small sample volume ( $\sim 5\text{ mL}$ ). In this presentation, I will briefly describe the interferometer developed in ENS Lyon, then explain precisely the microrheology measurements and then compare the experimental results to a model developed by M. Benzaquen.

## Friday, March 18, 2016 8:00AM - 11:00AM – Session X35 DBIO GSNP: Critical Transitions in Biological Systems 338 - Chen Zeng, GWU

**8:00AM X35.00001 Detecting early-warning signals of critical transitions for complex systems<sup>1</sup>**, LUONAN CHEN, Shanghai Institutes for Life Sciences, Chinese Academy of Sciences — Considerable evidence suggests that during the progression of complex diseases, the deteriorations are not necessarily smooth but are abrupt, and may cause a critical transition from one state to another at a tipping point. Here, we develop a model-free method to detect early-warning signals of such critical transitions, even with only a small number of samples. Specifically, we theoretically derive an index based on a dynamical network biomarker (DNB) for biological systems or dynamical network marker (DNM) for general systems that serves as a general early-warning signal indicating an imminent bifurcation or sudden deterioration before the critical transition occurs. Based on theoretical analyses, we show that predicting a sudden transition from small samples is achievable provided that there are a large number of measurements for each sample, e.g., high-throughput data. We employ microarray data of three diseases to demonstrate the effectiveness of our method for detecting "un-occurred" disease state. The relevance of DNBs with the diseases was also validated by related experimental data and functional analysis.

<sup>1</sup>Detecting early-warning signals of critical transitions for complex systems

**8:36AM X35.00002 The evolution of lossy compression**, SARAH MARZEN, University of California, Berkeley, SIMON DEDEO, Indiana University, Bloomington — In complex environments, there are costs to both ignorance and perception. An organism needs to track fitness-relevant information about its world, but the more information it tracks, the more resources it must devote to memory and processing. As a first step towards an understanding of this tradeoff, we use rate-distortion theory to study large, unstructured environments with fixed, randomly-drawn penalties for stimuli confusion ("distortions"). We find that two different environments will have nearly identical rate-distortion functions (but very different codebooks) when distortions are drawn from the same distribution, suggesting an interesting weak universality. We further identify two distinct regimes for organisms in these structured environments: a high-fidelity regime where perceptual costs grow linearly with environmental complexity, and a low-fidelity regime where perceptual costs are, remarkably, independent of the number of environmental states. This last result suggests that evolution will drive organisms to the threshold between the high- and low-fidelity regimes. In dynamic environments of rapidly-increasing complexity, well-adapted organisms will find themselves able to make, just barely, the most subtle distinctions in their environment.

**8:48AM X35.00003 Dynamics of neuroendocrine stress response: bistability, timing, and control of hypocortisolism** , MARIA D'ORSOGNA, California State University at Northridge, TOM CHOU, LAE KIM , UCLA — The hypothalamic-pituitary-adrenal (HPA) axis is a neuroendocrine system that regulates numerous physiological processes. Disruptions in its activity are correlated with stress-related diseases such as post-traumatic stress disorder (PTSD) and major depressive disorder. We characterize “normal” and “diseased” states of the HPA axis as basins of attraction of a dynamical system describing the inhibition of peptide hormones, corticotropin-releasing hormone (CRH) and adrenocorticotrophic hormone (ACTH), by circulating glucocorticoids such as cortisol (CORT). Our model includes ultradian oscillations, CRH self-upregulation of CRH release, and distinguishes two components of negative feedback by cortisol on circulating CRH levels: a slow direct suppression of CRH synthesis and a fast indirect effect on CRH release. The slow regulation mechanism mediates external stress-driven transitions between the stable states in novel, intensity, duration, and timing-dependent ways. We find that the *timing* of traumatic events may be an important factor in determining if and how the hallmarks of depressive disorders will manifest. Our model also suggests a mechanism whereby exposure therapy of stress disorders may act to normalize downstream dysregulation of the HPA axis.

**9:00AM X35.00004 Dynamics of blood flow in a microfluidic ladder network** , JEEVAN MADDALA, JEVGENIA ZILBERMAN-RUDENKO , OWEN MCCARTY, Oregon Health and Science University — The dynamics of a complex mixture of cells and proteins, such as blood, in perturbed shear flow remains ill-defined. Microfluidics is a promising technology for improving the understanding of blood flow under complex conditions of shear; as found in stent implants and in tortuous blood vessels. We model the fluid dynamics of blood flow in a microfluidic ladder network with dimensions mimicking venules. Interaction of blood cells was modeled using multiagent framework, where cells of different diameters were treated as spheres. This model served as the basis for predicting transition regions, collision pathways, re-circulation zones and residence times of cells dependent on their diameters and device architecture. Based on these insights from the model, we were able to predict the clot formation configurations at various locations in the device. These predictions were supported by the experiments using whole blood. To facilitate platelet aggregation, the devices were coated with fibrillar collagen and tissue factor. Blood was perfused through the microfluidic device for 9 min at a physiologically relevant venous shear rate of  $600 \text{ s}^{-1}$ . Using fluorescent microscopy, we observed flow transitions near the channel intersections and at the areas of blood flow obstruction, which promoted larger thrombus formation. This study of integrating model predictions with experimental design, aids in defining the dynamics of blood flow in microvasculature and in development of novel biomedical devices.

**9:12AM X35.00005 Identifying driving gene clusters in complex diseases through critical transition theory** , NATHANIEL WOLANYK, The Department of Physics University of Alabama at Birmingham, XUJING WANG, NHLBI, NIH, MARTIN HESSNER, Medical College of Wisconsin, SHOUGUO GAO, YE CHEN, NHLBI, NIH, SHUANG JIA, Medical College of Wisconsin — A novel approach of looking at the human body using critical transition theory has yielded positive results: clusters of genes that act in tandem to drive complex disease progression. This cluster of genes can be thought of as the first part of a large genetic force that pushes the body from a curable, but sick, point to an incurable diseased point through a catastrophic bifurcation. The data analyzed is time course microarray blood assay data of 7 high risk individuals for Type 1 Diabetes who progressed into a clinical onset, with an additional larger study requested to be presented at the conference. The normalized data is 25,000 genes strong, which were narrowed down based on statistical metrics, and finally a machine learning algorithm using critical transition metrics found the driving network. This approach was created to be repeatable across multiple complex diseases with only progression time course data needed so that it would be applicable to identifying when an individual is at risk of developing a complex disease. Thusly, preventative measures can be enacted, and in the longer term, offers a possible solution to prevent all Type 1 Diabetes.

**9:24AM X35.00006 Finding the role of time-delays in complex systems<sup>1</sup>** , WEI LIN, School of Mathematical Sciences and Centre Computational Systems Biology, Fudan University — Time delays are omnipresently observed in many nature and artificial systems including physical, biological, and chemical systems. Naturally, two kinds of questions arise: How to identify the time delays when a certain amount of datasets are obtained from the experiments or real world systems whenever the theoretical model is known or unknown? and How to characterize the intrinsic roles of time delays that are played in the critical transition of coupled network systems In this talk, we introduce recent works that address the previous two questions, and show the significance of time delays in dealing with various biological systems.

<sup>1</sup>The work is supported by NNSF of China [Grant No. 11322111 and 61273014] and SCMS.

**9:36AM X35.00007 Detecting critical state before phase transition of complex systems by hidden Markov model** , RUI LIU, PEI CHEN, YONGJUN LI, South China University of Technology, LUONAN CHEN, Shanghai Institutes for Biological Sciences — Identifying the critical state or pre-transition state just before the occurrence of a phase transition is a challenging task, because the state of the system may show little apparent change before this critical transition during the gradual parameter variations. Such dynamics of phase transition is generally composed of three stages, i.e., before-transition state, pre-transition state, and after-transition state, which can be considered as three different Markov processes. Thus, based on this dynamical feature, we present a novel computational method, i.e., hidden Markov model (HMM), to detect the switching point of the two Markov processes from the before-transition state (a stationary Markov process) to the pre-transition state (a time-varying Markov process), thereby identifying the pre-transition state or early-warning signals of the phase transition. To validate the effectiveness, we apply this method to detect the signals of the imminent phase transitions of complex systems based on the simulated datasets, and further identify the pre-transition states as well as their critical modules for three real datasets, i.e., the acute lung injury triggered by phosgene inhalation, MCF-7 human breast cancer caused by heregulin, and HCV-induced dysplasia and hepatocellular carcinoma.

**9:48AM X35.00008 Identification of driving network of cellular differentiation from single sample time course gene expression data.** , YE CHEN, The National Heart, Lung, and Blood Institute (NHLBI), NATHANIEL WOLANYK, University of Alabama at Birmingham, TUNC ILKER, SHOUGUO GAO, XUJING WANG, The National Heart, Lung, and Blood Institute (NHLBI) — Methods developed based on bifurcation theory have demonstrated their potential in driving network identification for complex human diseases, including the work by Chen, et al. Recently bifurcation theory has been successfully applied to model cellular differentiation. However, there one often faces a technical challenge in driving network prediction: time course cellular differentiation study often only contains one sample at each time point, while driving network prediction typically require multiple samples at each time point to infer the variation and interaction structures of candidate genes for the driving network. In this study, we investigate several methods to identify both the critical time point and the driving network through examination of how each time point affects the autocorrelation and phase locking. We apply these methods to a high-throughput sequencing (RNA-Seq) dataset of 42 subsets of thymocytes and mature peripheral T cells at multiple time points during their differentiation (GSE48138 from GEO). We compare the predicted driving genes with known transcription regulators of cellular differentiation. We will discuss the advantages and limitations of our proposed methods, as well as potential further improvements of our methods.

**10:00AM X35.00009 Experimental and theoretical description of higher order periods in cardiac tissue action potential duration** , CONNER HERNDON, FLAVIO FENTON, ILIJA UZELAC, Georgia Tech — Much theoretical, experimental, and clinical research has been devoted to investigating the initiation of cardiac arrhythmias by alternans, the first period doubling bifurcation in the duration of cardiac action potentials. Although period doubling above alternans has been shown to exist in many mammalian hearts, little is understood about their emergence or behavior. There currently exists no physiologically correct theory or model that adequately describes and predicts their emergence in stimulated tissue. In this talk we present experimental data of period 2, 4, and 8 dynamics and a mathematical model that describes these bifurcations. This model extends current cell models through the addition of memory and includes spatiotemporal nonlinearities arising from cellular coupling by tissue heterogeneity.

**10:12AM X35.00010 Theory of advection-driven long range biotic transport** , OLEG KOGAN, KEVIN O'KEEFFE, Cornell University, DAVID SCHNEIDER, United States Department of Agriculture; Cornell University, CHRISTOPHER MYERS, Cornell University — We consider a new reaction-transport framework, and apply it to the problem of advection-driven biotic transport. The are two compartments - the growth layer, coupled to a separate, advective layer. Density fronts propagate in both layers. Crucially, the downwind front speed goes to a finite value as the coupling goes to zero. We next include diffusion in the growth layer, and study the competition between the advective and diffusive transport mechanisms. Advection wins for small diffusion and cannot be ignored, no matter how weak is the coupling. When coupling is not small, both mechanisms work cooperatively, without a clear winner. A further surprise is the existence of a critical diffusion constant at which the front speed is independent of the interlayer coupling.

**10:24AM X35.00011 Geometric phase transition in the cellular network of the pancreatic islets may underlie the onset of type 1 diabetes.** , XUJING WANG, NHLBI, NIH — Living systems are characterized by complexity in structure and emergent dynamic orders. In many aspects the onset of a chronic disease resembles phase transition in a dynamic system: quantitative changes accumulate largely unnoticed until a critical threshold is reached, which causes abrupt qualitative changes of the system. In this study we investigate this idea in a real example, the insulin-producing pancreatic islet  $\beta$ -cells and the onset of type 1 diabetes. Within each islet, the  $\beta$ -cells are electrically coupled to each other, and function as a network with synchronized actions. Using percolation theory we show how normal islet function is intrinsically linked to network connectivity, and the critical point where the islet cellular network loses site percolation, is consistent with laboratory and clinical observations of the threshold  $\beta$ -cell loss that causes islet functional failure. Numerical simulations confirm that the islet cellular network needs to be percolated for  $\beta$ -cells to synchronize. Furthermore, the interplay between site percolation and bond strength predicts the existence of a transient phase of islet functional recovery after disease onset and introduction of treatment, potentially explaining a long time mystery in the clinical study of type 1 diabetes: the honeymoon phenomenon. Based on these results, we hypothesized that the onset of T1D may be the result of a phase transition of the islet  $\beta$ -cell network. We further discuss the potential applications in identifying disease-driving factors, and the critical parameters that are predictive of disease onset.

## Friday, March 18, 2016 8:00AM - 10:24AM —

Session X36 GSOF: Metallic Glasses and Quasicrystals 339 - Fei Wang, Missouri State University

**8:00AM X36.00001 Local growth rules and kinetics for ordered icosahedral quasicrystals** , JOSHUA SOCOLAR, Duke University, CONNOR HANN, Duke University, PAUL STEINHARDT, Princeton University — Icosahedral quasicrystals (IQCs) with extremely high degrees of translational order have been produced in the lab and found in naturally occurring minerals. While the existence of IQCs is well established, questions remain about how IQCs form. We address the question of whether it is possible in principle for nucleation and growth dominated by local growth rules and kinetics to produce a *perfectly* ordered IQC. We find that it is possible to produce an IQC with a vanishing density of defects through a local growth algorithm for sequential, face-to-face addition of tiles of two different shapes to a growing cluster. The choice of how to add a tile at any selected vertex on the surface is based only on short-range information about tiles that share the vertex. The process is analogous to the Onoda growth rule for 2D Penrose tilings [Onoda et al., PRL 60, 2653 (1988)], but new subtleties emerge in three dimensions. The geometric features underlying this algorithm can inform analyses of experimental systems and numerical models that generate highly ordered quasicrystals.

**8:12AM X36.00002 Low participation ratio vibrational modes in a limit-periodic structure<sup>1</sup>** , CATHERINE MARCOUX, JOSHUA E. S. SOCOLAR, Duke University — Motivated by the demonstration that patterned colloidal particles may form a limit-periodic phase<sup>2</sup>, we study the nature of vibrational modes in a toy model based on the Taylor-Socolar tiling. We consider a triangular lattice of identical point masses with nearest neighbors connected by springs of two different strengths, where the pattern of spring constants reflects the limit-periodic structure of the tiling. Using calculations of the phonon spectra for crystalline approximants to the limit-periodic structure, we identify several hierarchies of modes shared by the full limit-periodic system that have arbitrarily low participation ratios. We present a heuristic explanation of the existence of such modes, which are robust in the presence of vacancies and small amounts of disorder in the spring constants.

**8:24AM X36.00003 Magnetism in the i-R-Cd ( $R = Y, Gd-Tm$ ) binary quasicrystals<sup>1</sup>** , ALAN GOLDMAN, TAI KONG, ANDREAS KREYSSIG, Ames Laboratory, U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, TSUNETOMO YAMADA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, Sendai, Miyagi 980-9870, Japan, HIROYUKI TAKAKURA, Division of Applied Physics, Faculty of Engineering, Hokkaido University, Sapporo, Hokkaido, 060-8628, Japan, SERGEY BUD'KO, PINAKI DAS, WAGEESHA JAYASEKARA, PAUL CANFIELD, Ames Laboratory, U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA, MARC DE BOISSIEU, SIMAP, Grenoble-INP, UJF, CNRS, Saint Martin d'Heres Cedex, 38402, France — Progress in our understanding of the consequences of aperiodicity for physical phenomena such as the electronic, magnetic, and optical properties has recently seen a surge of activity and new results. A new family of i-R-Cd binary magnetic quasicrystals, exhibiting spin-glass-like behavior, and the closely related  $RCd_6$  crystalline approximants, which manifest long-range magnetic order at low temperature, offer new opportunities for studies of the impact of aperiodicity on magnetic interactions in compounds that have similar local structures. I will discuss their magnetic behavior, as well as recent x-ray diffraction and elastic magnetic neutron scattering investigations that provide some insight into their structural and magnetic properties.

<sup>1</sup>The research was supported by the Office of the Basic Energy Sciences, Materials Sciences Division, US Department of Energy (DOE).

**8:36AM X36.00004 Crystal electric field excitations in quasicrystal approximant TbCd<sub>6</sub> studied by inelastic neutron scattering**<sup>1</sup>, PINAKI DAS, R. FLINT, T. KONG, P.C. CANFIELD, A. KREYSSIG, A.I. GOLDMAN, Ames Laboratory, Iowa State Univ., USA, M. DE BOISSIEU, P.- F. LORY, G. BEUTIER, SIMap, Grenoble-INP, France, T. HIROTO, Tokyo Univ. of Science, Japan — All of the known quasicrystals with local moments exhibit frustration and spin glass-like behavior at low temperature. The onset of the spin freezing temperature is believed to be affected by the crystal electric field (CEF) splitting of the local moments. The quasicrystal approximant TbCd<sub>6</sub> and its related icosahedral quasicrystal phase, i-Tb-Cd, form a set of model systems to explore how magnetism evolves from a conventional lattice (approximant phase) to an aperiodic quasicrystal. Though TbCd<sub>6</sub> shows long-range antiferromagnetic ordering ( $T_N = 24$  K), only spin glass like behavior is observed in i-Tb-Cd with a spin freezing temperature of  $T_F = 6$  K. To investigate further, we have performed inelastic neutron scattering measurements on powder samples of TbCd<sub>6</sub> and observed two distinct CEF excitations at low energies which points to a high degeneracy of the CEF levels related to the Tb surrounding with almost icosahedral symmetry.

**8:48AM X36.00005 Magnetoresistance in i-R-Cd icosahedral quasicrystals (R=Y, Gd)**<sup>1</sup>, GARIMA SARASWAT, DRAGANA POPOVIĆ, Natl. High Magnetic Field Lab., Florida State Univ., TAI KONG, SERGEY L. BUD'KO, PAUL C. CANFIELD, Ames Laboratory / Iowa State Univ. — We use magnetoresistance (MR) to probe the electronic properties of the recently discovered binary quasicrystals (QCs) i-Gd-Cd and i-Y-Cd, with and without local magnetic moments, respectively. DC magnetization has revealed spin-glass freezing in i-Gd-Cd at a temperature  $T_f = 4.6$  K. MR was measured at  $1.6 \leq T(K) \leq 300$  and in magnetic fields  $H$  up to 12 T. The most interesting behavior is observed in i-Gd-Cd, in which the MR exhibits thermo-magnetic history dependence at low  $T$ . In particular, there is a clear difference between the ZFC and FC values of the low-field positive MR. In contrast, the i-Y-Cd MR does not depend on magnetic history. The onset of the history dependent MR at  $T \sim 20$  K  $> T_f$ , when the QC with local magnetic moments is cooled in a high field of 12 T, may be related to the formation of magnetic clusters above  $T_f$ , as inferred from the magnetization and specific heat studies. Possible mechanisms responsible for the striking coupling between charge transport and local magnetic environment observed in the MR will be discussed.

**9:00AM X36.00006 Predicting Novel Bulk Metallic Glasses via High- Throughput Calculations**<sup>1</sup>, E. PERIM, Duke University, D. LEE, Harvard University, Y. LIU, Yale University, C. TOHER, Duke University, P. GONG, Y. LI, Yale University, W. N. SIMMONS, O. LEVY, Duke University, J. VLASSAK, Harvard University, J. SCHROERS, Yale University, S. CURTAROLO, Duke University — Bulk metallic glasses (BMGs) are materials which may combine key properties from crystalline metals, such as high hardness, with others typically presented by plastics, such as easy processability[1]. However, the cost of the known BMGs poses a significant obstacle for the development of applications, which has lead to a long search for novel, economically viable, BMGs[2,3]. The emergence of high-throughput DFT calculations, such as the library provided by the AFLOWLIB consortium[4], has provided new tools for materials discovery. We have used this data to develop a new glass forming descriptor combining structural factors with thermodynamics in order to quickly screen through a large number of alloy systems in the AFLOWLIB database, identifying the most promising systems and the optimal compositions for glass formation. **9:12AM X36.00007 Stretched Exponential relaxation in pure Se glass.**<sup>1</sup>, S DASH, S RAVINDREN, P BOOLCHAND, University of Cincinnati — A universal feature of glasses is the stretched exponential relaxation,  $f(t) = \exp[-t/\tau]^\beta$ . The model of diffusion of excitations to randomly distributed traps in a glass by Phillips<sup>1</sup> yields the stretched exponent  $\beta = d/[d+2]$  where  $d$ , the effective dimensionality. We have measured the enthalpy of relaxation  $\Delta H_{nr}(t_w)$  at  $T_g$  of Se glass in modulated DSC experiments as glasses age at 300K and find  $\beta = 0.43(2)$  for  $t_w$  in the  $0 < t_w < 8$  months range. The observed  $\beta$  is in harmony with the trap model. The result is consistent with the growth of interchain structural correlations mediated by both long range (van der Waals forces) and short-range (covalent) interactions. A striking consequence of this relaxation is a narrowing of the glass transition width from 7.1C to 1.4C, and the  $\Delta H_{nr}$  term increasing from 0.21 cal/gm to 0.92 cal/gm. In bulk  $Ge_xSe_{100-x}$  glasses as  $x$  increases to 20%, the length of the polymeric  $Se_n$  chains between the Ge-crosslinks decreases to  $n = 2$ . and the striking relaxation effects nearly vanish.

**9:24AM X36.00008 Low-temperature internal friction in quenched amorphous selenium films**<sup>1</sup>, THOMAS METCALF, XIAO LIU, Naval Research Laboratory, MATTHEW ABERNATHY, NRC Postdoc, RICHARD STEPHENS, University of Pennsylvania — Using ultra-high-quality-factor silicon mechanical resonators, we have measured the internal friction and shear modulus of amorphous selenium (a-Se) films at liquid helium temperatures. The glass transition temperature of selenium lies at a conveniently accessible  $40 - 50^\circ\text{C}$ , facilitating a series of in- and ex-situ annealing and quench cycles. The a-Se films exhibit the low-temperature internal friction plateau ( $10^{-4} \leq Q^{-1} \leq 10^{-3}$ ) found in almost all amorphous solids, which is a result of (and direct measure of) a broad distribution of two-level tunneling systems (TLS), whose origin is still unknown. We find a clear correlation between the post-anneal quench rate and the value of this plateau. The implications of these observations for understanding the microscopic origin of TLS will be discussed. Principally, the observed changes in the internal friction plateau could show the way in which the density of TLS could be manipulated or suppressed in other amorphous systems.

### 9:36AM X36.00009 Non-Gaussian resistance noise in misfit layer compounds: Bi-Se-Cr , LINTAO

PENG, Electrical Engineering and Computer Science & Applied Physics, Northwestern University, Evanston, IL 60208, USA, ALEX FREEDMAN, Electrical Engineering and Computer Science, Northwestern University, Evanston, IL 60208, USA, SAMANTHA CLARKE, DANNA FREEDMAN, Department of Chemistry, Northwestern University, Evanston, IL 60208, USA, M GRAYSON, Electrical Engineering and Computer Science & Applied Physics, Northwestern University, Evanston, IL 60208, USA — Misfit layer ternary compounds Bi-Se-Cr have been synthesized and structurally and magnetically characterized [1]. However, the nature of the magnetic ordering below the transition temperature remains debatable between ferromagnetic and spin-glass. These misfit layer compounds consist of two alternating chalcogenide layers of CrSe<sub>2</sub> and BiSe along the c-axis. Whereas the a-axis is lattice matched, the lattice mismatch along the b-axis introduces non-periodic modulation of atomic position leading to quasi-crystalline order along the b-axis alone. We explore unconventional electrical transport properties in the noise spectrum of these compounds. After thinning down the compounds to nanoscale, Van der Pauw devices are fabricated with standard electron beam lithography process. Large resistance noise was observed at temperature below the Curie temperature. The magnitude of resistance noise is much greater than trivial intrinsic noises like thermal Johnson noise and increases as temperature decreases. The probability density function of the relative noise shows 2-4 peaks among different observations which indicate strong non-Gaussian statistic property suggesting glassy behaviors in this material. ### 9:48AM X36.00010 Synthesis, optical and thermal characterization of NaPO<sub>3</sub> glass.<sup>1</sup> , C MOHANTY,

R CHBEIR, A WELTON, P BOOLCHAND, Univ of Cincinnati — We have synthesized the stoichiometric bulk glass by reacting equimolar amounts of Na<sub>2</sub>CO<sub>3</sub> and P<sub>2</sub>O<sub>5</sub>, and handling the anhydrous starting materials and reacted product in a dry ambient environment. The bulk glass displays a T<sub>g</sub> of 306(2)C and an enthalpy of relaxation of 0.26 cal/gm using MDSC. In a previous report a T<sub>g</sub> = 287C was obtained<sup>1</sup> using DSC. The glass was crystallized and characterized by XRD and revealed a powder pattern that is in excellent agreement with the known structure (CSD 174021). Raman scattering of the glass revealed prominent modes of symmetric vibration of the PO<sub>4</sub> tetrahedra bearing P-O<sub>br</sub> and P-O<sub>ter</sub> bonds near 684 cm<sup>-1</sup> and 1162 cm<sup>-1</sup> respectively. The integrated intensity ratio R of the 1162 cm<sup>-1</sup>/684 cm<sup>-1</sup> modes is close to 1.0(1) in the crystal but increases to 1.4(1) in the glass reflecting the finite length of the P-O-P chains in the latter. The highest frequency mode is a weak feature near 1268 cm<sup>-1</sup>, which coincides with the TO response in IR reflectivity of the glass, suggesting that it represents the TO mode of the NaPO<sub>3</sub> glass.

### 10:00AM X36.00011 Raman scattering and Medium Range Structure of (BaO)<sub>x</sub>(B<sub>2</sub>O<sub>3</sub>)<sub>100-x</sub>-

glasses.<sup>1</sup> , CHAD HOLBROOK, Air Force Research Labs, RALPH CHBEIR, ANDREW CZAJA, PUNIT BOOLCHAND, University of Cincinnati — In Raman scattering of titled glasses we observe a triad of modes (770 cm<sup>-1</sup>, 750 cm<sup>-1</sup>, 705 cm<sup>-1</sup>) on the low frequency side of the famous Boroxyl-Ring (BR) mode (808 cm<sup>-1</sup>) as the BaO content x increases in the 0 < x < 40% range. Raman polarization experiments reveal that the triad of modes show a rather low depolarization ratio ( $\rho < 0.25$ ) suggesting that each mode results from a symmetric stretch of O atoms in mixed-3-member-rings, analogous to the BR-mode. In the 0 < x < 15% range, the conspicuous absence of these mixed-ring modes is consistent with the composition range representing the immiscibility range. At x > 15%, the 770 cm<sup>-1</sup> mode scattering strength grows precipitously to show a maximum near x<sub>c</sub> = 20%, consistent with presence of Ba-tetraborate structural grouping (SG). At x > 15%, we also observe scattering strength of the 750 cm<sup>-1</sup> mode to increase with x and show a maximum near x<sub>c</sub> = 33%, consistent with formation of Ba-diborate SG. Finally, a mode near 705 cm<sup>-1</sup>, whose scattering strength increases linearly with x in the 15% < x < 40% range, we identify with Ba-metaborate SG. FTIR measurements permit a measurement of the B<sub>4</sub>/B<sub>3</sub> fraction and also the LO-TO splittings.

<sup>1</sup>NSF grant DMR-08-53957

### 10:12AM X36.00012 The effect of spherical inclusions in metallic glass nanowires under tensile test and its relation to atomic structure<sup>1</sup> , MATIAS SEPULVEDA, GONZALO GUTIERREZ, NICOLAS AMIGO, Departamento de

Física, Facultad de Ciencias, Universidad de Chile — The plastic behavior of crystalline metals is well understood. It is known that this regime is mainly mediated by nucleation and propagation of dislocations as well as by grain boundary sliding. In metallic glasses (MGs) the plastic behavior is quite different from their crystalline counterparts and a relationship between atomic-micro structure and properties remains one of the barriers that has hampered the progress to wide applications of MGs. In particular it would be desirable to have studies which directly relate the evolution of the shear bands (SBs) and glass matrix structure to each step of the applied strain, which would allow us to easily connect the evolution of the atomic structure to the stress-strain curve. Here we present a computational tensile test which shows the evolution of the atomic structure according to the strain is applied for a Cu<sub>50</sub>Zr<sub>50</sub> metallic glass nanowire at 300 K with a Cu-Zr b2 inclusion in the center of the system with three different radius from 20 to 60 Å. The system consists of a million atoms and the local structure is analyzed by means of the Voronoi polyhedral technique and the nucleation and propagation of SBs by monitoring the local atomic shear strain.

Session X37 GSOF: Liquid Crystals: Defects, Theory and Simulations 340 - Chenhui Zhu, Lawrence Berkeley Laboratory

### 8:00AM X37.00001 Topological defects in liquid crystals as templates for molecular self-assembly. , XIAO GUANG WANG, DANIEL MILLER, EMRE BUKUSOGLU, University of Wisconsin-Madison, JUAN DE PABLO, University of Chicago,

NICHOLAS ABBOTT, University of Wisconsin-Madison — Topological defects in liquid crystals (LCs) have been widely used to organize colloidal dispersions and template polymerizations, leading to a range of elastomers and gels with complex mechanical and optical properties. However, little is understood about molecular-level assembly processes within defects. This presentation will describe an experimental study that reveals that nanoscopic environments defined by LC defects can selectively trigger processes of molecular self-assembly. By using fluorescence microscopy, cryogenic transmission electron microscopy and super-resolution optical microscopy, key signatures of molecular self-assembly of amphiphilic molecules in topological defects are observed - including cooperativity, reversibility, and controlled growth of the molecular assemblies. By using polymerizable amphiphiles, we also demonstrate preservation of molecular assemblies templated by defects, including nanoscopic o-rings synthesized from Saturn-ring disclinations. Our results reveal that topological defects in LCs are a versatile class of three-dimensional, dynamic and reconfigurable templates can direct processes of molecular self-assembly in a manner that is strongly analogous to other classes of macromolecular templates.

**8:12AM X37.00002 Molecular nature of liquid crystal defects**, MOHAMMAD RAHIMI, Institute for Molecular Engineering, University of Chicago, NICHOLAS L. ABBOTT, Department of Chemical Engineering, University of Wisconsin - Madison, JUAN J DE PABLO, Institute for Molecular Engineering, University of Chicago, RUI ZHANG, University of Chicago — Distortion of liquid crystal (LC) director creates defects which can be easily observed and controlled experimentally. Liquid crystal defects, which are a consequence of symmetry breaking, have significant influence on the macroscopic properties of liquid crystals, and many of the features that make LCs particularly exciting for new applications can be traced back to the existence of liquid crystal defects. However, the molecular nature of liquid crystal defects remains largely unknown. In this work, we perform large-scale atomistic simulations of 5CB/8CB mixture with a cylinder with strong homeotropic anchoring. The presence of the cylinder distorts the nematic field around the cylinder surface and creates two line defects. The local order parameter and biaxiality are calculated to characterize these defects. The results of this study indicate that, the density and the order parameter are correlated, and at the defect both parameters are low.

**8:24AM X37.00003 Topological defects and self-assembly of cuboidal colloidal particles with sharp edges in a nematic liquid crystal.**, JUAN J. DE PABLO, MONIRO SADAT, JULIO C. ARMAS-PEREZ, The University of Chicago, Institute for Molecular Engineering, VISHAL SONI, WILLIAM T. M. IRVINE, The University of Chicago, James Franck Institute — The geometry of colloidal particles defines the topology and self-assembly of colloidal superstructures in nematic liquid crystals. Past research has largely focused on the defects that arise around spherical colloids, and the defect-induced aggregation between them. In this work, we examine experimentally and theoretically, the effect of edge curvature of colloidal particles on their defect configurations and self-assembly in a nematic liquid crystal (5CB). The polarized images of the particles with homeotropic surface anchoring in 5CB show that the presence of sharp edges can reshape completely the defect ring. The defect makes sharp turns and follows the edge of the cube particles, which significantly affects the interaction between particles and their eventual self-assembly. In agreement with our experimental results, our computational studies indicate that the gradual increase of the edges sharpness that occurs as we transition from spheres to cubes, changes the defect structure from a Saturn ring to a twisted ring, which is pinned to the edges of the cube particle. The wide variety of topological defects achievable by changing the curvature could provide new tools to tune colloidal self-assembly.

**8:36AM X37.00004 Nematic liquid crystal bridges**, SUSANNAH DOSS, PERRY ELLIS, Georgia Institute of Technology, JAYALAKSHMI VALLAMKONDU, National Institute of Technology, Warangal (India), EDWARD DANEMILLER, MARK VERNON, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — We study the effects of confining a nematic liquid crystal between two parallel glass plates with homeotropic boundary conditions for the director at all bounding surfaces. We find that the free surface of the nematic bridge is a surface of constant mean curvature. In addition, by changing the distance between the plates and the contact angle with the glass plates, we transition between loops and hedgehogs that can be either radial or hyperbolic.

**8:48AM X37.00005 Fine structure of the topological defect core: Disclination in lyotropic chromonic liquid crystal<sup>1</sup>**, SHUANG ZHOU, SERGIY SHYANOVSKI, HEUNG-SHIK PARK, YOUNG-KI KIM<sup>2</sup>, Liquid crystal institute, Kent State University, Kent, Ohio 44242, USA, TRISTAN HEARN, LOTHAR REICHEL, Department of Mathematical Science, Kent State University, Kent, Ohio 44242, USA, OLEG LAVRENTOVICH, Liquid crystal institute, Kent State University, Kent, Ohio 44242, USA — Topological defects represent an important concept in many branches of modern physics ranging from cosmology and optics to hard and soft matter. One of the most difficult problems is the fine structure of the so-called core region of defects, where the deformations of the order parameter are so strong that the phenomenological description valid in the far field becomes invalid. Experimental exploration of the fine core structure is usually hindered by the small size (atomic/molecular level) of the core, where optical or even electron microscopy techniques are invalid. In this work, we take advantage of the peculiar nature of the so-called lyotropic chromonic liquid crystals (LCLC) of a nematic type that carry disclinations with a core extending over macroscopic distances (tens of micrometers), large enough to explore their spatial variation by optical and electron microscopy. We demonstrate that the director and the scalar order parameter (associated with the degree of orientational order) show a profound change in the core region. In particular, as one approaches the center of the defect, the azimuthal dependency of the director field changes dramatically and the scalar order parameter shows a strong dependence on the strength of splay and bend deformations.

**9:00AM X37.00006 Lassoing the Saddle-Splay: Harnessing  $K_{24}$  Distortions to Line Up Disclinations**, LISA TRAN, MAXIM LAVRENTOVICH, Department of Physics, University of Pennsylvania, DANIEL BELLER, School of Engineering and Applied Sciences, Harvard University, NINGWEI LI, KATHLEEN STEBE, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, RANDALL KAMIEN, Department of Physics, University of Pennsylvania — Systems with holes, such as colloidal handlebodies and toroidal droplets, have been studied in the nematic liquid crystal (NLC) 4-cyano-4-pentylbiphenyl (5CB). It was found that point or ring topological defects occur within each hole and around the system, such that the overall topological charge of the system is conserved. However, what has not been fully appreciated is the ability of the hole geometry with homeotropic (perpendicular) anchoring conditions to induce a saddle-like deformation in the NLC bulk. We exploit this by creating an array of many holes suspended in an NLC cell with oriented planar (parallel) anchoring at the cell boundaries. Through simulations and experiments, we study how the bulk saddle deformations of each hole interact to create novel defect structures, including an array of  $\frac{1}{2}$  disclination lines, reminiscent of those that occur in LC blue phases. The locations of these disclination lines are tunable via the geometry of the cell and hole array, which has potential for controlled, three-dimensional self-assembly in NLCs.

**9:12AM X37.00007 The weirdest martensite: Smectic liquid crystal microstructure and Weyl-Poincaré invariance**, DANILO LIARTE, MATTHEW BIERBAUM, Cornell University, RICARDO MOSNA, Universidade Estadual de Campinas, RANDALL KAMIEN, University of Pennsylvania, JAMES SETHNA, Cornell University — We propose a generalization of the mathematical theory of martensites to describe the complex assembly of focal conics in smectic liquid crystals. Smectics are remarkable, beautiful examples of materials microstructure, with ordered patterns of geometrically perfect ellipses and hyperbolas. The solution of the complex problem of filling three-dimensional space with domains of focal conics under constraining boundary conditions yields a set of strict rules, which are similar to the compatibility conditions in a martensitic crystal. Here we present the rules giving compatible conditions for the concentric circle domains found at two-dimensional smectic interfaces with planar boundary conditions. Using configurations generated by numerical simulations, we develop a clustering algorithm to decompose the planar boundaries into domains. The interfaces between different domains agree well with the smectic compatibility conditions. We also discuss generalizations of our approach to describe the full three-dimensional smectic domains, where the variant symmetry group is the restricted Weyl-Poincaré group of Lorentz boosts, translations, rotations, and dilatations.

**9:24AM X37.00008 4 x 4 Matrix Method Simulations of Swinging Nematic Liquid Crystals**, IGHODALO IDEHENRE, Univ of Dayton, DEAN EVANS, Air Force Research Laboratory, PARTHA BANERJEE, Univ of Dayton, TIMOTHY BUNNING, Air Force Research Laboratory — We present the results of numerical simulations of swinging nematic liquid crystal (SNLC) systems using the 4 x 4 Berreman matrix method. SNLCs are a special class of cholesteric liquid crystals that periodically change handedness when propagating along the helical axis. Unlike standard cholesterics which can only reflect one circular polarization state allowing the other to pass, SNLCs are able to reflect both simultaneously. Our simulations explore the advantages and disadvantages of various periodic functions (sinusoidal, square wave, triangular, etc...), the influence of pitch and optical birefringence on the reflection central wavelength and bandwidth, as well as the overall impact incidence angle has on the reflection spectra.

**9:36AM X37.00009 Phase transitions and order parameters of complex liquid crystalline ordered systems** , KE LIU, JAAKKO NISSINEN, ROBERT-JAN SLAGER, Instituut-Lorentz for Theoretical Physics, Universiteit Leiden, KAI WU, Stanford Institute for Materials and Energy Sciences, Stanford University, JAN ZAAENEN, Instituut-Lorentz for Theoretical Physics, Universiteit Leiden — Liquid crystalline states of matter possess rich phase diagrams, exotic topological defects and unique responses to external fields. Traditionally the focus has been on liquid crystal phases with uniaxial  $D_{\infty h}$  symmetry and biaxial  $D_{2h}$  symmetry. However, in full generality liquid crystalline orders are associated with breaking the  $O(3)$  rotational symmetry to any point group symmetry  $G \subset O(3)$ . We present a general theory for arbitrary three dimensional point group symmetries that allows to derive order parameters and investigate phase transitions of liquid crystalline states. The theory is constructed on symmetry grounds, and adapts to the description of both thermal and quantum liquid crystal systems. The realization of the model in experimental systems are also discussed.

**9:48AM X37.00010 Coarsening Dynamics of Inclusions and Thermocapillary Phenomena in Smectic Liquid Crystal Bubbles** , CHEOL PARK, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK, University of Colorado, TORSTEN TRITTEL, ALEXEY EREMIN, RALF STANNARIUS, University of Magdeburg, PADETHA TIN, NANCY HALL, NASA Glenn Research Center — The Observation and Analysis of Smectic Islands in Space (OASIS) project comprises a series of experiments that probe interfacial and hydrodynamic behavior of thin spherical-bubbles of smectic liquid crystal in microgravity. Smectic films are the thinnest known stable condensed phase structures, making them ideal for studies of two-dimensional (2D) coarsening dynamics and thermocapillary phenomena in microgravity. The OASIS flight hardware was launched on SpaceX-6 in April 2015 and experiments were carried out on the International Space Station using four different smectic A and C liquid crystal materials in separate sample chambers. We will describe the behavior of collective island dynamics on the bubbles, including temperature gradient-induced thermomigration, and the diffusion and coalescence-driven coarsening dynamics of island emulsions in microgravity. This work was supported by NASA Grant No. NNX-13AQ81G, and NSF MRSEC Grants No. DMR-0820579 and DMR-1420736.

**10:00AM X37.00011 Competition of lattice and basis for alignment of nematic liquid crystals** , ANDREW DEBENEDICTIS, Department of Physics and Astronomy, Tufts University, CANDY ANQUETIL-DECK, DOUGLAS J. CLEAVER, Materials and Engineering Research Institute, Sheffield Hallam University, DAVID B. EMERSON, MATHEW WOLAK, JAMES H. ADLER, Department of Mathematics, Tufts University, TIMOTHY J. ATHERTON, Department of Physics and Astronomy, Tufts University — Due to elastic anisotropy, two-dimensional patterning of substrates can promote weak azimuthal alignment of adjacent nematic liquid crystals. We consider a periodic square lattice of elliptical motifs to examine ways in which the lattice and motif can combine to favor differing orientations. Using semi-analytic elastic continuum theory and Monte Carlo simulations, we find, for circular motifs, that the coverage fraction controls both the polar anchoring angle and a transition in the azimuthal orientation. If the circles are generalized to ellipses, arbitrary control of the effective easy axis and effective anchoring potential becomes achievable by appropriate tuning of the orientation of the ellipse motif relative to the lattice vectors. To determine the behavior of liquid crystals near the domain boundaries, we additionally formulate and solve the full 3D Euler-Lagrange equations directly. We additionally comment on the role of weak anchoring and saddle-splay elasticity.

**10:12AM X37.00012 ABSTRACT MOVED TO P36.013 —**

**10:24AM X37.00013 Particles and curvatures in nematic liquid crystals.** , FRANCESCA SERRA, YIMIN LUO, SHU YANG, RANDALL D. KAMIEN, KATHLEEN J. STEBE, University of Pennsylvania — Elastic interactions in anisotropic fluids can be harnessed to direct particle interactions. A strategy to smoothly manipulate the director field in nematic liquid crystals is to vary the topography of the bounding surfaces. A rugged landscape with peaks and valleys create local deformations of the director field which can interact with particles in solution. We study this complex interaction in two different settings. The first consists of an array of shallow pores in a poly-dimethyl-siloxane (PDMS) membrane, whose curvature can be tuned either by swelling the PDMS membrane or by mechanical stretching. The second is a set of grooves with wavy walls, fabricated by photolithography, with various parameters of curvature and shapes. In this contexts we study how the motion of colloidal particles in nematic liquid crystals can be influenced by their interaction with the peaks and valleys of the bottom substrate or of the side walls. Particles with different associated topological defects (hedgehogs or Saturn rings) behave differently as they interact with the topographical features, favoring the docking on peaks or valleys. These experimental systems are also ideal to study the “lock and key” mechanism of particles in holes and to investigate a possible route for particle sorting.

**10:36AM X37.00014 Effect of an applied electric field on a weakly anchored non-planar Nematic Liquid Crystal (NLC) layer<sup>1</sup>** , ENSELA MEMA, LINDA J. CUMMINGS, LOU KONDIC, New Jersey Institute of Technology — We consider a mathematical model that consists of a NLC layer sandwiched between two parallel bounding plates, across which an external field is applied. We investigate its effect on the director orientation by considering the dielectric and flexoelectric contributions and varying parameters that represent the anchoring conditions and the electric field strength. In particular, we investigate possible director configurations that occur in weakly anchored and non-planar systems. We observe that non-planar anchoring angles destroy any hysteresis seen in a planar system by eliminating the fully vertical director configuration and the “saturation threshold” seen in weakly anchored planar Freedericksz cells.

**Friday, March 18, 2016 8:00AM - 10:48AM —**

**Session X38 DPOLY: Block Copolymer Thin Films: Directed Assembly** 341 - Ryan Hayward, U Mass Amherst

**8:00AM X38.00001 Out-of-plane Block Copolymer Microdomains in High Aspect-Ratio Templates** , KARIM GADELRAH, WUBIN BAI, ALFREDO ALEXANDER-KATZ, CAROLINE ROSS, Massachusetts Inst of Tech-MIT — The use of directed self-assembly DSA of block copolymers BCP proved to be a power approach for nanoscale fabrication. It combines the ability of BCPs to self-assemble into nanoscale features with the use of lithographic tools to create controlled long range order. In addition, BCP with highly incompatible blocks (high Flory-Huggins interaction parameter ( $\chi$ )) offer improvement in resolution, and line edge fluctuations of the self-assembled patterns. Unfortunately, high- $\chi$  BCPs usually exhibit large differences in surface affinity between the two blocks, leading to the formation of a surface layer of the lower surface energy block and favoring in-plane orientation of lamellae or cylindrical microdomains. Here, we explore the conditions under which a high  $\chi$  BCP creates an out-of-plane lamellar structure using functionalized high aspect ratio trenches with preferential walls. We employ the free energy analysis of self-consistent field theory SCFT to identify whether an in-plane or out-of-plane structure is stable for a particular trench width. In addition, we employ the single mode expansion of Ginzburg-Landau free energy expression in the weak segregation limit to analytically construct a phase diagram of the in-plane and out-of-plane lamellae as a function of aspect ratio and surface attraction strength. It is found that achieving an out of plane lamellar structure necessitates a coupling between aspect ratio and surface functionality. In particular, strong side wall attraction results in out-of-plane lamellae when the trench aspect ratio is greater than unity. The results are validated for a lamellar forming polystyrene-block-polydimethylsiloxane (PS-b-PDMS) within trenches made using interference lithography.

**8:12AM X38.00002 Characterizing the interfaces of block copolymers with high  $\chi$** , DANIEL SUNDAY, NIST - Natl Inst of Stds & Tech, MICHAEL MAHER, Department of Chemistry, University of Texas, GREGORY BLACHUT, YUSUKE ASANO, SUMMER TEIN, Department of Chemical Engineering, University of Texas, C. GRANT WILLSON, Department of Chemistry/Chemical Engineering, University of Texas, CHRISTOPHER ELLISON, Department of Chemical Engineering, University of Texas, R. JOSEPH KLINE, NIST - Natl Inst of Stds & Tech — In order for block copolymer (BCP) directed self-assembly (DSA) to be able to pattern features below 10 nm there must be materials which can spontaneously assemble at the required length scales. For the smallest features this will require phase separation where the total chain lengths are under 50 monomer units, demanding very large interaction parameters ( $\chi$ ) to have an order-disorder transition. One of the key parameters for DSA will be the interfacial width between the blocks, which is expected to be correlated to the interaction parameter and will help determine the line edge roughness (LER). We have used resonant soft X-ray reflectivity to investigate a series of high  $\chi$  BCPs with different compositions and molecular weights to determine the interfacial width and degree of phase separation. We use these results to estimate the value of  $\chi$  and determine relationships between  $\chi$  and the interfacial mixing.

**8:24AM X38.00003 Reducing Line Edge Roughness of PS-*b*-PMMA pattern by inducing hydrogen bonding at the interface of the block copolymer microdomains**, KYU SEONG LEE, SUNG HYUN HAN, SANGSHIN JANG, JICHEOL PARK, JONGHEON KWAK, JIN KON KIM, POSTECH — Sharp interface between two blocks in block copolymer nano pattern is one of the important issues in industrial applications to nano-patterning. We utilized hydrogen bonding between N-(4-aminomethyl-benzyl)-4-hydroxymethyl-bezamide (BA) and urea (U) at the interface of polystyrene-*block*-poly(methyl methacrylate) copolymer (PS-PMMA). For this purpose, we first synthesized PS by ATRP, then the end group was converted to amino group. Next, it was reacted with BA, followed by reaction with 4-pentynoic acid, resulting in alkyne-terminated group (PS-U-BA-alkyne). Also, azide-terminated PMMA was prepared by anionic polymerization followed by end functionalization. Finally, by the azide-alkyne click reaction between PS-U-BA-alkyne and PMMA-azide, PS-U-BA-PMMA was synthesized. We prepared vertical oriented lamellar nanopatterns on pre-patterned wafers and investigated line edge roughness (LER) after removing PMMA block by dry etching process. We found that LER was reduced compared with PS-PMMA without hydrogen bonding.

**8:36AM X38.00004 Photothermal assembly of block copolymers**, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory — This talk will discuss recent work on the use of photothermal methods to control the ordering of block copolymer thin films. Photothermal methods can be used to generate temperature gradients and shear fields, which have a strong influence on block copolymer assembly. For example, assembly can be accelerated, and morphology can be aligned. These methods also highlight the non-equilibrium, pathway-dependence of self-assembly. We present examples of exploiting these effects to control alignment, and to iteratively construct arbitrary lattice symmetries.

**9:12AM X38.00005 Numerical Simulations of Directed Self-Assembly in Diblock Copolymer Films using Zone Annealing and Templating Techniques**, JOSEPH HILL, PAUL MILLETT, Univ of Arkansas-Fayetteville — Bulk fabrication of surface patterns with sub-20 nm feature sizes is tremendously desirable for many existing and emerging technologies. Directed self-assembly (DSA) of block copolymers (BCPs) has been a recently demonstrated approach to achieve such feature resolution over large-scale areas with minimal defect populations. Much work however remains to understand and optimize DSA methods in order to move this field forward. This talk will present results from large-scale numerical simulations of zone annealing and topological template processing of BCP films to achieve long-range orientational order. The simulations utilize a Time-Dependent Ginzburg-Landau model and parallel processing to elucidate relationships between thermal gradient velocities and domain orientations as well as defect densities. Additional simulations have been conducted to study to what degree orientational order can be further enhanced with both zone annealing and topological templating techniques. It is found that these two DSA methods do synergistically enhance long-range order with a particular relationship between thermal gradient velocity and topological template spacing.

**9:24AM X38.00006 Rapid microwave annealing for perpendicular oriented cylinders in PS-*b*-PMMA thin films**, ZHE QIANG, KEVIN CAVICCHI, BRYAN VOGT, University of Akron, UNIVERSITY OF AKRON TEAM — Self-assembly of block copolymer (BCP) has been extensively studied for decades due to their wide range of potential applications such as lithography. Direct microwave annealing provides rapid ordering kinetics. However, the knowledge regarding the structural and orientation evolution of morphology during microwave annealing without solvents remains sparse. Herein, we report on how microwave-annealing conditions impact the morphology developed in cylinder forming PS-*b*-PMMA films on unmodified silicon wafers. The fraction of perpendicular cylinders developed during microwave annealing is primarily determined by temperature ramp from microwave heating itself. The heating of the substrate during microwave annealing is varied from 0.5 C/s to 2.8 C/s by two factors: (1) the microwave output energy and (2) the local heating position of BCP film in the microwave reaction vessel. A maximum in the fraction of perpendicular cylinders (97 %) occurs at 1.83 C/s and appears independent of the microwave power used. This work demonstrates the importance of controlling conditions of microwave annealing in the morphology developed.

**9:36AM X38.00007 Directed Self-assembly of Block Copolymer with Sub-15 nm Domain Spacing Using Nanoimprinted Photoresist Templates**, ZHIWEI SUN, Univ of Mass - Amherst, ZHENBIN CHEN, Lanzhou University of Technology, WENXU ZHANG, E. BRYAN COUGHLIN, Univ of Mass - Amherst, SHUAIGANG XIAO, Seagate Technology, THOMAS RUSSELL, Univ of Mass - Amherst — There has been increasing interest in preparing block copolymer thin films with ultra-small domain spacings for use as etching masks for ultra-high resolution nanolithography. One method to prepare block copolymer materials with small feature sizes is salt doping, increasing the Flory-Huggins interaction and allowing microphase separation to be maintained at lower molecular weights. Lamellae-forming P2VP-*b*-PS-*b*-P2VP block copolymer with various molecular weight was synthesized using RAFT polymerization with a dual functional chain transfer agent. Copper (II) Chloride or Gold (III) chloride was found to be selectively associated with P2VP block and increase the unfavorable interactions between PS and P2VP blocks, driving the disordered block copolymer into the ordered state. A 14 nm lamellar spacing of P2VP-*b*-PS-*b*-P2VP thin film was prepared using copper (II) Chloride doping after acetone vapor annealing on neutral brushes. Metallic nano-wire arrays were prepared after selective infiltration of platinum salt into the P2VP domain and oxygen plasma treatment. The directed self-assembly of salt doped P2VP-*b*-PS-*b*-P2VP triblock copolymer having long-range lateral order on nanoimprinted photoresist templates with shallow trenches was also studied.

**9:48AM X38.00008 Exploring the Use of Additives to Optimize the Directed Self-Assembly of Block Copolymers via Self-Consistent Field Theory Simulations**, ADAM HANNON, DANIEL SUNDAY, R. JOSEPH KLINE, National Institute of Standards and Technology — The directed self-assembly (DSA) of block copolymers (BCPs) is being investigated for the fabrication of next generation memory and integrated circuit technologies. Much progress has been made showing how these materials can be processed to produce a variety of transferable patterned morphologies that meet the requirements for fabricating integrated circuit geometries. One lingering issue in using these materials to produce sub-10 nm structures is finding new BCPs with a high enough  $\chi$  Flory-Huggins interaction parameter to create small resolution features with low interfacial widths that are also easily processable. An alternative approach to synthesizing new materials is to instead blend the BCP with additives that strongly interact with one of the blocks. Here we present findings on how the addition of a hydrogen bonding homopolymer affects the overall effective  $\chi$ , the periodicity, and the morphology of the BCP. Self-consistent field theory simulations are used to explore how the relative  $\chi$  values and degrees of polymerization between the BCP and homopolymer affect these parameters and suggest optimal blending conditions. Results are compared with experimental X-ray and neutron scattering studies of a polystyrene-*b*-poly(methyl methacrylate)/poly(vinyl phenol) blend.

**10:00AM X38.00009 Controlled Ordering of Long-range Perpendicular Lamellae by Block Copolymer Self-assembly**, DU YEOL RYU, KYUNGINN KIM, SUNGMIN PARK, YEONGSIK KIM, Yonsei Univ, YONSEI UNIV TEAM — We introduce a simple approach to fabricating highly stable, perpendicularly oriented lamellae through the self-assembly of high-molecular-weight polystyrene-*b*-poly(methyl methacrylate) (PS-*b*-PMMA). The desired morphology was achieved over a narrow annealing period (5–10 min) under solvent vapor, since the SVA process need to terminate immediately before the saturated BCP films begin to dewet the substrate. This narrow processing period impeded practical applications to continuous industrial processes. A controlled SVA process at a selected temperature gap was found to show the excellent long-term stability, at which highly ordered line-arrays of perpendicularly oriented lamellae were confined to topographic line patterns.

**10:12AM X38.00010 Using chemically patterned substrates to suppress thermal placement errors in the directed self-assembly of block copolymer multi-cylinder linear arrays**, CORINNE CARPENTER, KRIS DELANEY, GLENN FREDRICKSON, Univ of California - Santa Barbara — Directed self assembly (DSA) of block copolymers is a promising alternative approach for ~10nm microelectronics patterning, both for feature-size reduction and rectification. One prototypical application of DSA is the use of vertical interconnect access (VIA) cylinders for fabricating conducting channels between circuit layers. Typically a compromise exists between the fidelity and low defect density obtained by using a small number of cylinders per pre-pattern guide and the objective to further increase feature density. In particular for 1D linear arrays of multiple VIAs in a single prepattern, prior experimental and theoretical work has demonstrated that thermal fluctuations in larger arrays cause cylinder placement to vary widely around the equilibrium positions in a manner analogous to the collective excitations in a simple 1D coupled oscillator model (Landau-Peierls instability). In the present work, we assess the efficacy of using chemically patterned substrates to suppress the thermal placement errors using both a phenomenological oscillator model and full field theoretic simulations.

**10:24AM X38.00011 Minimal Topographic Patterns for Guiding Hexagonal Arrays of Cylindrical Microdomains in Block Copolymer Thin Films**, JAEWON CHOI, YINYONG LI, University of Massachusetts Amherst, ILJA GUNKEL, Lawrence Berkeley National Laboratory, ZHIWEI SUN, University of Massachusetts Amherst, FENG LIU, Lawrence Berkeley National Laboratory, KENNETH CARTER, THOMAS RUSSELL, University of Massachusetts Amherst — Topographically patterned substrates have been widely studied to control the lateral order of block copolymer (BCP) microdomains in thin films. However, most studies have been focused on deep topographic patterns, where a confinement depth is comparable to or larger than domain spacing of BCP, limiting the grain size of BCP due to the confinement width. Also, the investigation of BCP microdomains using grazing incidence small angle X-ray scattering (GISAXS) is limited because the scattering peaks from BCP are generally hidden by the strong scattering peaks from the deep topographic pattern. Here, we present the use of minimal topographic patterns for guiding hexagonal arrays of cylindrical microdomains of poly(styrene-*b*-ethylene oxide) (PS-*b*-PEO) thin films. Since the confinement depth of the minimal pattern is much smaller than domain spacing of BCP, this enables cylindrical microdomains to overcome the confined width, generating macroscopic ordered hexagonal arrays. In the GISAXS experiment, we confirmed that the (10) plane of hexagonal arrays was parallel to the direction of the trench by rotating the sample stage and changing the incident angle of X-ray.

**10:36AM X38.00012 Polarized Resonant Critical Dimension Small Angle X-Ray Scattering for the Characterization of Polymer Patterns**, CHRISTOPHER LIMAN, DANIEL SUNDAY, HYUN WOOK RO, LEE RICHTER, ADAM HANNON, R. JOSEPH KLINE, National Institute of Standards and Technology — Critical dimension small angle X-ray scattering (CDSAXS) is a recently developed technique that enables the characterization of the three-dimensional shape of periodic patterns, such as directed self-assembled (DSA) block copolymer (BCP) lamellae thin films. Information about the polymer patterns is extracted by fitting simulated scattering patterns to the experimental ones using an inverse iterative algorithm. Conducting CDSAXS at resonant energies near the carbon or nitrogen edge can enhance the strength of the scattering, but also causes the scattering to be influenced by any anisotropic orientation of the polymer chains. In this work, to assess the degree to which the scattering may be influenced by orientation, we simulate polarized resonant CDSAXS patterns for BCP lamellae with varying degrees of orientation, as well as orientation as a function of location within the lamellae, for different polarizations of the incident X-rays. Also, to assess the influence of a higher degree of orientation, we use capillary force lithography to pattern nanogratings of two semiconducting homopolymers which are known to orient strongly. We characterize these nanogratings, which have similar length scales to DSA BCP lamellae, with polarized resonant CDSAXS and spectroscopic ellipsometry. Finally, we fit simulated CDSAXS and ellipsometric data to the experimental data to obtain information about the shape and the orientation of the nanogratings.

**Session X39 DBIO: Method in Molecular Biophysics: DBIO Doctoral Thesis Award** 342 - Henrik Flyvbjerg, Danish Technical University

**8:00AM X39.00001 How to determine local stretching and tension in a flow-stretched DNA molecule**, JONAS N. PEDERSEN, RODOLPHE MARIE, ANDERS KRISTENSEN, HENRIK FLYVBJERG, Tech Univ of Denmark — We determine the nonuniform stretching of and tension in a Mbp-long fragment of DNA that is flow-stretched in a nanofluidic chip. We use no markers, do not know the contour length of the DNA, and do not have the full DNA molecule inside our field-of-view. Instead we analyze the transverse thermal motion of the DNA. Tension at the center of the DNA adds up to 16 pN, giving almost fully stretched DNA. Fitted parameters agree well with simplified expressions, where the DNA is modeled as a cylinder in a parallel flow.

**8:12AM X39.00002 Magnetic Actuation of Self-Assembled DNA Hinges**, S. LAUBACK, K. MATTIOLI, M. ARMSTRONG, C. MILLER, C. PEASE, C. CASTRO, R. SOORYAKUMAR, The Ohio State University — DNA nanotechnology offers a broad range of applications spanning from the creation of nanoscale devices, motors and nanoparticle templates to the development of precise drug delivery systems. Central to advancing this technology is the ability to actuate or reconfigure structures in real time, which is currently achieved primarily by DNA strand displacement yielding slow actuation times (about 1-10min). Here we exploit superparamagnetic beads to magnetically actuate DNA structures which also provides a system to measure forces associated with molecular interactions. DNA nanodevices are folded using DNA origami, whereby a long single-stranded DNA is folded into a precise compact geometry using hundreds of short oligonucleotides. Our DNA nanodevice is a nanohinge from which rod shaped DNA nanostructures are polymerized into micron-scale filaments forming handles for actuation. By functionalizing one arm of the hinge and the filament ends, the hinge can be attached to a surface while still allowing an arm to rotate and the filaments can be labeled with magnetic beads enabling the hinge to be actuated almost instantaneously by external magnetic fields. These results lay the groundwork to establish real-time manipulation and direct force application of DNA constructs.

**8:24AM X39.00003 Nanopore DNA sequencing using kinetic proofreading<sup>1</sup>**, XINSHENG LING, Southeast University (Nanjing China) and Brown University — We propose a method of DNA sequencing by combining the physical method of nanopore electrical measurements and Southern's sequencing-by-hybridization. The new key ingredient, essential to both lowering the costs and increasing the precision, is an asymmetric nanopore sandwich device capable of measuring the DNA hybridization probe twice separated by a designed waiting time. Those incorrect probes appearing only once in nanopore ionic current traces are discriminated from the correct ones that appear twice. This method of discrimination is similar to the principle of kinetic proofreading proposed by Hopfield and Ninio in gene transcription and translation processes. An error analysis of this nanopore kinetic proofreading (nKP) technique for DNA sequencing is carried out in comparison with the most precise 3' dideoxy termination method developed by Sanger.

<sup>1</sup>Nanopore DNA sequencing using kinetic proofreading

**8:36AM X39.00004 Genetic Assessment of the Space Environment using MEMS Technologies**<sup>f1</sup>, DILIP JANA, DILEON SAINT JEAN, SIYOVUSH ABDURAKHIMOV, VARUN KOPPARTHY, GERGAN NESTOROVA, NABAMITA PAL, NAM NGUYEN, PEDRO DEROSA, LEE SAWYER, NIEL CREWS, MARK DECOSTER, Louisiana Tech University, LOUISIANA TECH UNIVERSITY TEAM — *h-abstract-* For decades, researchers have studied the damage to DNA by high-energy radiation. Radiation induced damage include DNA strand breaks, base damage and base substitution. Currently, though, scientists are discovering that it is, in fact, the non-irradiated cells adjacent to the irradiated cells are the primary source of carcinogenesis. To address these "bystander effects", we developed a radiation detector using multi-clad scintillating fibers and silicon pixel arrays to study the effect of radiation on gene expression changes using Microelectromechanical systems (MEMS) technology. The efficiency of proton energy deposition on each of the different layers of the radiation tracking detector has been simulated using GEANT4 toolkit and tested experimentally using the detector. The position of the proton beam was determined from the intensity of the output signal from orthogonal planes of the tracking detector. We have developed and tested an instrument that automates the extraction and quantification of RNA from living cells that automates the collection, purification, and reverse transcription (RT) of RNA from a precisely-defined area of the biological sample. *-pard-/abstract-*

<sup>1</sup>NASA EPSCOR GRANT 13-EPSCoR-0027

**8:48AM X39.00005 Fabrication and characterization of nanopore sandwich devices for DNA kinetic proofreading studies**, ZHISHAN YUAN, JIAJIA YE, HONGWEN WU, XIAO XIE, Southeast University (Nanjing China), QIANJIN WANG, Nanjing University (Nanjing China), JINGJIE SHA, YUNFEI CHEN, ZHONGHUA NI, Southeast University (Nanjing China), XINSHENG LING, Southeast University and Brown University — It has been proposed [1] that solid-state nanopores can be used as a kinetic proofreading mechanism for oligonucleotide hybridization on ssDNA molecules. We describe the first generation of nanopore sandwich structures consisted of two nanopores of different thicknesses of Si<sub>3</sub>N<sub>4</sub> separated by a SiO<sub>2</sub> cavity. We will discuss the results of helium ion-beam and Ga FIB drilling and TEM characterization of the nanopore sandwiches devices. This work was supported by the National 1000-People Plan of China and Jiangsu-985 Fund, and NSFC grant no.51302037. [1] X.S. Ling, "Methods of sequencing nucleic acids using nanopores and active kinetic proofreading", WO/2013/119784, International Application No.: PCT/US2013/025106.

**9:00AM X39.00006 Confinement-induced Molecular Templating and Controlled Ligation**, DANIEL BERARD, MARJAN SHAYEGAN, FRANCOIS MICHAUD, GIL HENKIN, SHANE SCOTT, JASON LEITH, SABRINA LESLIE, McGill University, LESLIE LAB TEAM — Loading and manipulating long DNA molecules within sub-50 nm cross-section nanostructures for genomic and biochemical analyses, while retaining their structural integrity, present key technological challenges to the biotechnology sector, such as device clogging and molecular breakage. We overcome these challenges by using Convex Lens-induced Confinement (CLiC) technology to gently load DNA into nanogrooves from above. Here, we demonstrate single-fluorophore visualization of custom DNA barcodes as well as efficient top-loading of DNA into sub-50 nm nanogrooves of variable topographies. We study confinement-enhanced self-ligation of polymers loaded in circular nanogrooves. Further, we use concentric, circular nanogrooves to eliminate confinement gradient-induced drift of stretched DNA.

**9:12AM X39.00007 Computational and Experimental Characterization of Ribosomal DNA and RNA G-Quadruplexes**, SAMUEL CHO, Wake Forest University — DNA G-quadruplexes in human telomeres and gene promoters are being extensively studied for their role in controlling the growth of cancer cells. Recent studies strongly suggest that guanine (G)-rich genes encoding pre-ribosomal RNA (pre-rRNA) are a potential anticancer target through the inhibition of RNA polymerase I (Pol I) in ribosome biogenesis. However, the structures of ribosomal G-quadruplexes at atomic resolution are unknown, and very little biophysical characterization has been performed on them to date. Here, we have modeled two putative rDNA G-quadruplex structures, NUC 19P and NUC 23P, which we observe via circular dichroism (CD) spectroscopy to adopt a predominantly parallel topology, and their counterpart rRNA. To validate and refine the putative ribosomal G-quadruplex structures, we performed all-atom molecular dynamics (MD) simulations using the CHARMM36 force field in the presence and absence of stabilizing K<sup>+</sup> or Na<sup>+</sup> ions. We optimized the CHARMM36 force field K<sup>+</sup> parameters to be more consistent with quantum mechanical calculations (and the polarizable Drude model force field) so that the K<sup>+</sup> ion is predominantly in the G-quadruplex channel. Our MD simulations show that the rDNA G-quadruplex have more well-defined, predominantly parallel-topology structures than rRNA and NUC 19P is more structured than NUC 23P, which features extended loops. Our study demonstrates that they are both potential targets for the design of novel chemotherapeutics.

**9:24AM X39.00008 Observation of an angular change in the structure of an RNA complex using Fluorescence Resonance Energy Transfer<sup>1</sup>**, SHEEMA RAHMANSERESHT, PEKER MILAS, LOUIS PARROT, LORI S. GOLDNER, University of Massachusetts, Amherst, Physics Department — Single-molecular-pair FRET is often used to study distance fluctuations of single molecules. It is harder to capture angular changes using FRET, because rotational motion of the dyes tends to wash out the angular sensitivity. Using a dye labeling scheme that minimizes the rotational motion of the dyes with respect to the RNA, we use spFRET to measure an angular change in structure of an RNA kissing complex upon protein binding. The model system studied here, R1inv-R2inv, is derived from the RNAI-RNAII complex in *E.coli*. RNA II is a primer for replication of the ColE1 plasmid; its function is modulated by interaction with RNA I, Rop protein is known to stabilize the bent R1inv-R2inv kissing complex against dissociation. The effect, if any, of Rop protein on the conformation of the kissing complex is not known. The eight minimized-energy NMR structures reported for R1inv-R2inv show a small difference in end-to-end distances and much larger differences in twist and bend angles. We compare a first-principles model with spFRET data to determine if the observed change in FRET is consistent with an angular change in structure, as suggested by the model.

**9:36AM X39.00009 Two-color spectroscopy of UV excited ssDNA complex with a single-wall nanotube (SWNT) probe: Fast nucleobase autoionization mechanism<sup>1</sup>**, SLAVA V ROTKIN, Lehigh University, TETYANA IGNATOVA, UC Irvine, ALEXANDER BALAEFF, University of Central Florida, MING ZHENG, National Institute of Standards and Technology, MICHAEL BLADES, Lehigh University, PETER STOECKL, University of Rochester — DNA autoionization is a fundamental process wherein UV-photoexcited nucleobases dissipate energy to the environment without undergoing chemical damage. SWNT is shown to serve as a photoluminescent reporter for studying the mechanism and rates of DNA autoionization. Two-color photoluminescence (PL) spectroscopy revealed a strong SWNT PL quenching when the UV pump is resonant with the DNA absorption [Nano Research, 2015]. Semiempirical calculations of the DNA-SWNT electronic structure, combined with a Green's function theory for charge transfer, show a 20 fs autoionization rate, dominated by the hole transfer. Rate-equation analysis of the spectroscopy data confirms that the quenching rate is limited by the thermalization of the free charge carriers transferred to the nanotube reservoir. The developed approach has a great potential for monitoring DNA excitation, autoionization, and chemical damage both *in vivo* and *in vitro*.

**9:48AM X39.00010 Mapping DNA methylation by transverse current sequencing: Reduction of noise from neighboring nucleotides**, JOSE ALVAREZ, Department of Physics, University of Puerto Rico, San Juan, PR 00931-3344, USA, STEVEN MASSEY, Department of Biology, University of Puerto Rico, San Juan, PR 00631-3360, USA, ALAN KALITSOV, JULIAN VELEV, Department of Physics, University of Puerto Rico, San Juan, PR 00931-3344, USA — Nanopore sequencing via transverse current has emerged as a competitive candidate for mapping DNA methylation without needed bisulfite-treatment, fluorescent tag, or PCR amplification. By eliminating the error producing amplification step, long read lengths become feasible, which greatly simplifies the assembly process and reduces the time and the cost inherent in current technologies. However, due to the large error rates of nanopore sequencing, single base resolution has not been reached. A very important source of noise is the intrinsic structural noise in the electric signature of the nucleotide arising from the influence of neighboring nucleotides. In this work we perform calculations of the tunneling current through DNA molecules in nanopores using the non-equilibrium electron transport method within an effective multi-orbital tight-binding model derived from first-principles calculations. We develop a base-calling algorithm accounting for the correlations of the current through neighboring bases, which in principle can reduce the error rate below any desired precision. Using this method we show that we can clearly distinguish DNA methylation and other base modifications based on the reading of the tunneling current.

**10:00AM X39.00011 Amylin Detection with a Miniature Optical-Fiber Based Sensor**, ZHAOWEN LIU, MATSKO ANN, ADAM HUGHES, MARK REEVES, George Washington University — We present results of a biosensor based on shifts in the localized surface plasmon resonance of gold nanoparticles self-assembled on the end of an optical fiber. This system allows for detection of protein expression in low sensing volumes and for scanning in cell cultures and tissue samples. Positive and negative controls were done using biotin/avidin and the BSA/Anti-BSA system. These demonstrate that detection is specific and sensitive to nanomolar levels. Sensing of amylin, an important protein for pancreatic function, was performed with polyclonal and monoclonal antibodies. The measured data demonstrates the difference in sensitivity to the two types of antibodies, and titration experiments establish the sensitivity of the sensor. Further experiments demonstrate that the sensor can be regenerated and then reused.

**10:12AM X39.00012 A Nanocoaxial-Based Electrochemical Sensor for the Detection of Cholera Toxin<sup>1</sup>**, MICHELLE ARCHIBALD, BINOD RIZAL, TIMOTHY CONNOLLY, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, THOMAS C. CHILES, Boston College, BIOLOGY AND PHYSICS COLLABORATION — We report a nanocoax-based electrochemical sensor for the detection of bacterial toxins using an electrochemical enzyme-linked immunosorbent assay (ELISA) and differential pulse voltammetry (DPV). The device architecture is composed of vertically-oriented, nanoscale coaxial electrodes, with coax cores and shields serving as integrated working and counter electrodes, respectively. Proof-of-concept was demonstrated for the detection of cholera toxin (CT), with a linear dynamic range of detection was 10 ng/ml - 1 g/ml, and a limit of detection (LOD) of 2 ng/ml. This level of sensitivity is comparable to the standard optical ELISA used widely in clinical applications. The nanocoax array thus matches the detection profile of the standard ELISA while providing a simple electrochemical readout and a miniaturized platform with multiplexing capabilities, toward point-of-care (POC) implementation. In addition, next generation nanocoax devices with extended cores are currently under development, which would provide a POC platform amenable for biofunctionalization of ELISA receptor proteins directly onto the device.

**8:00AM X40.00001 Chaotic dynamics of a candle oscillator**, MARY ELIZABETH LEE, Georgia Inst of Tech, GREG BYRNE, FDA, FLAVIO FENTON, Georgia Inst of Tech — The candle oscillator is a simple, fun experiment dating to the late nineteenth century. It consists of a candle with a rod that is transverse to its long axis, around which it is allowed to pivot. When both ends of the candle are lit, an oscillatory motion will initiate due to different mass loss as a function of the flame angle. Stable oscillations can develop due to damping when the system has friction between the rod and the base where the rod rests. However, when friction is minimized, it is possible for chaos to develop. In this talk we will show periodic orbits found in the system as well as calculated, maximal Lyapunov exponents. We show that the system can be described by three ordinary differential equations (one each for angle, angular velocity and mass loss) that can reproduce the experimental data and the transition from stable oscillations to chaotic dynamics as a function of damping.

**8:12AM X40.00002 Spike Bursts from an Excitable Optical System<sup>1</sup>**, JOSE R RIOS LEITE, EDISON J ROSERO, WENDSON A S BARBOSA, Depto. Física- Univ. Fed. de Pernambuco-Recife, JORGE R TREDICCE, INLN-Univ de Nice-Sophie Antipolis -France — Diode Lasers with double optical feedback are shown to present power drop spikes with statistical distribution controllable by the ratio of the two feedback times. The average time between spikes and the variance within long time series are studied. The system is shown to be excitable and present bursting of spikes created with specific feedback time ratios and strength. A rate equation model, extending the Lang-Kobayashi single feedback for semiconductor lasers proves to match the experimental observations. Potential applications to construct network to mimic neural systems having controlled bursting properties in each unit will be discussed.

**8:24AM X40.00003 Singular probability distribution of a parametric oscillator driven by Poisson noise** , PAVEL M. POLUNIN, Michigan State University, PANPAN ZHOU, Hong Kong University of Science and Technology, STEVEN W. SHAW, Michigan State University, HO BUN CHAN, Hong Kong University of Science and Technology, MARK I. DYKMAN, Michigan State University — We provide the results of the theoretical and experimental studies of the probability distribution of a parametric oscillator, which is additionally driven by a Poisson-like noise. The noise consists of pulses at the vibration frequency with duration small compared to the oscillator relaxation time but long compared to the vibration period. We find that the stationary probability distribution of an oscillator quadrature can display a self-similar structure of sharp peaks, almost symmetrical with respect to the maximum, or can have a strongly asymmetric two-peak structure. The form of the distribution depends on the oscillator dynamics in the rotating frame and the rate of the noise pulses. In particular, the self-similar multi-peak structure emerges if the oscillator dynamics in the rotating frame is underdamped. The peaks have a singular power-law shape. We show that the singularity is smeared by thermal noise, which makes the peaks Gaussian near the maxima. We also discuss the frequently encountered situation where the Poisson noise describes fluctuations of the oscillator eigenfrequency. The theoretical and experimental results are in excellent agreement.

**8:36AM X40.00004 Quantum Boltzmann Machine** , BOHDAN KULCHYTSKYI, Univ of Waterloo, EVGENY ANDRIYASH, MOHAMMED AMIN, D-Wave Systems Inc, ROGER MELKO, Univ of Waterloo, Perimeter Institute — The field of machine learning has been revolutionized by the recent improvements in the training of deep networks. Their architecture is based on a set of stacked layers of simpler modules. One of the most successful building blocks, known as a restricted Boltzmann machine, is an energetic model based on the classical Ising Hamiltonian. In our work, we investigate the benefits of quantum effects on the learning capacity of Boltzmann machines by extending its underlying Hamiltonian with a transverse field. For this purpose, we employ exact and stochastic training procedures on data sets with physical origins.

**8:48AM X40.00005 Quantum Feynman Ratchet** , KETAN GOYAL, RYOICHI KAWAI, Univ of Alabama - Birmingham — As nanotechnology advances, understanding of the thermodynamic properties of small systems becomes increasingly important. Such systems are found throughout physics, biology, and chemistry manifesting striking properties that are a direct result of their small dimensions where fluctuations become predominant. The standard theory of thermodynamics for macroscopic systems is powerless for such ever fluctuating systems. Furthermore, as small systems are inherently quantum mechanical, influence of quantum effects such as discreteness and quantum entanglement on their thermodynamic properties is of great interest. In particular, the quantum fluctuations due to quantum uncertainty principles may play a significant role. In this talk, we investigate thermodynamic properties of an autonomous quantum heat engine, resembling a quantum version of the Feynman Ratchet, in non-equilibrium condition based on the theory of open quantum systems. The heat engine consists of multiple subsystems individually contacted to different thermal environments.

**9:00AM X40.00006 Reversibility in Quantum Models of Stochastic Processes** , DAVID GIER, University of Kansas, JAMES CRUTCHFIELD, JOHN MAHONEY, RYAN JAMES, University of California at Davis — Natural phenomena such as time series of neural firing, orientation of layers in crystal stacking and successive measurements in spin-systems are inherently probabilistic. The provably minimal classical models of such stochastic processes are  $\varepsilon$ -machines, which consist of internal states, transition probabilities between states and output values. The topological properties of the  $\varepsilon$ -machine for a given process characterize the structure, memory and patterns of that process. However  $\varepsilon$ -machines are often not ideal because their statistical complexity ( $C_\mu$ ) is demonstrably greater than the excess entropy ( $E$ ) of the processes they represent. Quantum models (q-machines) of the same processes can do better in that their statistical complexity ( $C_q$ ) obeys the relation  $C_\mu \geq C_q \geq E$ . q-machines can be constructed to consider longer lengths of strings, resulting in greater compression. With code-words of sufficiently long length, the statistical complexity becomes time-symmetric — a feature apparently novel to this quantum representation. This result has ramifications for compression of classical information in quantum computing and quantum communication technology.

**9:12AM X40.00007 Finding stability domains and escape rates in kicked Hamiltonians** , ARCHISHMAN RAJU, SAYAN CHOUDHURY, DAVID RUBIN, JAMES SETHNA, Cornell University — We use an effective Hamiltonian to characterize particle dynamics and find escape rates in a one dimensional system with a periodically kicked Hamiltonian. We study a model of particles in storage rings which is given by a symplectic map where the chaos is described by the KAM theorem. Ignoring the resonances, the dynamics typically has a finite region in phase space where it is stable. Photon noise in the system leads to particle loss from this stable region. Determining this 'aperture' and finding escape rates is therefore an important physical problem. We characterize the stable region in phase space using a perturbation theory developed in the context of quantum mechanics. We then derive analytical expressions for the escape rate in the small damping regime and compare them with numerical simulations. We discuss the possibility of extending the procedure to include higher dimensions and more complicated noise terms.

**9:24AM X40.00008 The canonical ensemble revisited: a projection operator approach** , WIM MAGNUS, Universiteit Antwerpen / Imec, FONS BROSENS, Universiteit Antwerpen, CONDENSED MATTER THEORY TEAM, THEORY OF QUANTUM SYSTEMS AND COMPLEX SYSTEMS TEAM — Constraining the particle number  $N$  in the canonical ensemble hampers the systematic calculation of the partition function  $Z_N$  for non-interacting fermions and bosons, unlike in the case of the grand-canonical ensemble. Recently, we have shown that this task can be accomplished by invoking a projection operator that automatically imposes the particle number constraint in the many-particle Hilbert space. As a result, an integral representation is obtained for  $Z_N$ , as well as for the two-point and four-point correlation functions. As an illustration, the Helmholtz free energy and the chemical potential are calculated for a two-dimensional electron gas typically residing in the inversion layer of a field-effect transistor.

**9:36AM X40.00009 Novel dynamics and thermodynamics of a new Hamiltonian mean field model<sup>1</sup>** , SERGIO CURILEF, BORIS ATENAS, Universidad Catlica del Norte — Statistical systems are idealized by the hypothesis that the particles do not interact among them, or the range of interactions is short enough, reaching very fast the statistical state that we know as equilibrium. However, systems with long-range interactions are common in nature because of they are observed from the atomic scale to the astronomical scale, exhibiting some anomalies as inequivalence of ensembles, negative heat capacity, ergodicity breaking, non equilibrium phase transitions, quasi-stationarity, anomalous diffusion, etc. We present in this contribution a new Hamiltonian mean field model whose potential is inspired in the dipole-dipole interactions. The equilibrium is analytically studied in the canonical ensemble and coincides with the one obtained from molecular dynamics simulations (microcanonical ensemble). We notice, this model presents a kind of inequivalence of ensembles in long-standing states before arriving at equilibrium. However, the novelty, compared to other models presented in recent literature, is that two quasi-stationary states appear in the behavior of this system. The first quasi-stationary state decays to a second one, which is different to the first, before going to the equilibrium. We characterize them by its dynamics and thermodynamics.

**9:48AM X40.00010 Optimization of finite-size errors in finite-temperature calculations of unordered phases** , DEEPAK IYER, Bucknell University, MARK SREDNICKI, University of California Santa Barbara, MARCOS RIGOL, Pennsylvania State University — It is common knowledge that the microcanonical, canonical, and grand canonical ensembles are equivalent in thermodynamically large systems. Here, we study finite-size effects in the latter two ensembles. We show that contrary to naive expectations, finite-size errors are exponentially small in grand canonical ensemble calculations of translationally invariant systems in unordered phases at finite temperature. Open boundary conditions and canonical ensemble calculations suffer from finite-size errors that are only polynomially small in the system size. We further show that finite-size effects are generally smallest in numerical linked cluster expansions. Our conclusions are supported by analytical and numerical analyses of classical and quantum systems.

**10:00AM X40.00011 Complex Pole Approach in Thermodynamic Description of Fluid Mixtures with Small Number of Molecules**, TIMUR ASLYAMOV, OLEG DINARIEV, Schlumberger Moscow Research — Physically consistent description of equilibrium small molecular systems requires the extension of thermodynamics. The reason is the absence of thermodynamic limit, which is mandatory for the applicability of classical thermodynamics. New theoretical method of complex pole decomposition for the statistical description of small multicomponent molecular systems is implemented. Similar approach has been previously developed and applied in nuclear physics for finite systems of nucleons. We have significantly transformed and extended the original formulation to make it work for multicomponent molecular mixtures in small systems. The aim of this research is to provide new comprehensive description of small equilibrium molecular systems with numerous scientific and industrial applications for artificial and natural materials with nanopores. Several cases for molecular systems in small cavities are studied. In particular size-dependent additional pressure for small systems is evaluated analytically and numerically. The obtained results are in correspondence to published experimental data and molecular dynamics simulations.

**10:12AM X40.00012 Exact  $\Phi^4$  Critical Exponents via the Limit of Finite Periodic Systems**, ANTHONY HEGG, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — We formulate an RG procedure to nonperturbatively calculate the critical exponents of  $\Phi^4$  theory in arbitrary dimension. Our method first calculates the exact RG equations for a finite but arbitrarily large system with periodic boundary. We then take the limit as that boundary diverges to simplify the equations and recover a true critical point of the system. In particular this provides the 3d critical Ising exponents to high precision. This method is not specific to  $\Phi^4$  theory and thus should apply to many other systems.

**10:24AM X40.00013 The three-dimensional  $O(n \rightarrow \infty)$   $\phi^4$  model on a strip with free boundary conditions: exact results for a nontrivial dimensional crossover**, HANS WERNER DIEHL, SERGEI RUTKEVICH, Univ Duisburg-Essen — The  $O(2)$   $\phi^4$  model on a 3D film of thickness  $L$  with free boundaries is relevant for the explanation of the thinning of wetting layers of  $^4\text{He}$  caused by critical Casimir forces near and below the  $\lambda$ -transition. Just as its  $O(n)$  analog, the model has long-range order below the bulk critical temperature  $T_c$  if  $L = \infty$ , but remains disordered for all  $T > 0$  when  $L < \infty$ . A proper analysis of its scaling behavior near  $T_c$  is challenging: it involves a nontrivial dimensional crossover in addition to bulk, boundary, and finite-size critical behaviors. The  $n \rightarrow \infty$  limit of the model can be solved exactly in terms of the eigenvalues and eigenfunctions of a self-consistent Schrödinger equation whose potential  $v(z)$  becomes singular at the boundary planes. Complementing recent numerically exact results, we derive various exact analytical results for series expansion coefficients of  $v(z)$ , its  $L = \infty$  scattering data for all values  $m_0$  of the temperature scaling field, and the low-temperature asymptotic behavior of the residual free energy and the Casimir force using a combination of boundary-operator and short-distance expansions, proper extensions of inverse scattering theory, new trace formulae, and semi-classical expansions.

**10:36AM X40.00014 A Molecular Model for Chiral Symmetry Breaking**, FOLARIN LATINWO, FRANK STILLINGER, PABLO DEBENEDETTI, Princeton University — In this work, we present a new class of molecular models for chiral phenomena in condensed matter systems. A key feature of these models is the ability of the four-site (tetramer) “molecules” to inter-convert between two distinct chiral forms (enantiomers). Given this feature, we use analytical theory and computer simulations to investigate the emergent chiral properties (including symmetry breaking) over a range of conditions. In particular, we consider the single-molecule level and condensed-phase behavior of our model system. Interestingly, we find that our liquid-phase predictions are in excellent agreement with recent experimental reports on chiral self-sorting in isotropic liquids. From this perspective, our model demonstrates accurate predictive capabilities, as well as a platform for understanding the microscopic origins of a variety of chiral phenomena. In a broader context, we anticipate that this class of models will be relevant to chirality-dominated areas such as the pharmaceutical industry and pre-biotic geochemistry.

**10:48AM X40.00015 Thermal diffusion and colored energy dissipation in hydrogen bonded liquids.**, RICCARDO DETTORI, Department of Physics - University of Cagliari (I), CLAUDIO MELIS, Department of Physics - University of Cagliari, MICHELE CEROTTI, Ecole Polytechnique Federale de Lausanne (CH), DAVIDE DONADIO, Department of Chemistry - UC Davis (USA), LUCIANO COLOMBO, Department of Physics - University of Cagliari (I) — H-bonded liquids show a manifold energy dissipation dynamics due to: strong directionality of H-bonds and complexity of their network. This affects both thermal diffusion and energy dissipation mechanisms in pump-probe spectroscopy experiments. By nonequilibrium molecular dynamics (MD) simulations we investigate such phenomena in liquid methanol. While heat transport is studied by approach-to-equilibrium MD, energy dissipation is investigated by making use of a novel Generalized Langevin Equation (GLE) colored noise thermostat, which can generate a non-equilibrium frequency-resolved dynamics by using a correlated noise. The colored thermostat can thermally excite a narrow range of vibrational modes, typically the stretching mode of the OH involved in H-bonding, leaving the other degrees of freedom at the equilibrium temperature. The energy dissipation is then observed as a function of time, by probing the excitation decay and the energy transfer to other modes. In particular, by monitoring in time the different contributions to the potential energy of the system, we evaluate how energy is transferred from the excited mode to other modes of the nearby molecules and provide understanding on the dynamics of H-bonded liquids, as resulting from current experimental investigations

**Friday, March 18, 2016 8:00AM - 11:00AM –**

**Session X41 DBIO DPOLY DCOMP: Physics of Proteins: Structure and Dynamics II** 344 - Yi Cao, Nanjing University

**8:00AM X41.00001 Dual-resolution modeling demonstrates greater conformational heterogeneity of CENP-A/H4 dimer than that of H3/H4**, HAIQING ZHAO, University of Maryland — Centromere protein A (CENP-A) is a centromere-specific H3 histone variant and shares only about 50% amino acid sequence identity with the canonical H3 protein. CENP-A is required for packaging the centromere and for the proper separation of chromosomes during mitosis. Despite their discrete functions, previously reported crystal structures of the CENP-A/H4 and H3/H4 dimers reveal surprising similarity. In this work, we characterize the structure and dynamics of CENP-A/H4 and H3/H4 dimers with a dual-resolution approach, using both all-atom and coarse-grained (CG) molecular dynamics (MD) simulations. Interestingly, the histone dimer containing CENP-A is more structurally variable than the canonical H3 dimer. Furthermore, our calculations revealed significant conformational distinctions between the interface profiles of CENP-A/H4 and H3/H4. In addition, the presence of the CENP-A-specific chaperone HJURP dramatically reduced the conformational heterogeneity of CENP-A/H4. Overall, these results are in general agreement with the available experimental data and provide new dynamic insights into the mechanisms underpinning the chaperone-mediated assembly of CENP-A nucleosomes *in vivo*.

**8:12AM X41.00002 Aggregation of alpha-synuclein by a coarse-grained Monte Carlo simulation**, BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — Alpha-synuclein, an intrinsic protein abundant in neurons, is believed to be a major cause of neurodegenerative diseases (e.g. Alzheimer, Parkinson's disease). Abnormal aggregation of ASN leads to Lewy bodies with specific morphologies. We investigate the self-organizing structures in a crowded environment of ASN proteins by a coarse-grained Monte Carlo simulation. ASN is a chain of 140 residues. Structure detail of residues is neglected but its specificity is captured via unique knowledge-based residue-residue interactions. Large-scale simulations are performed to analyze a number local and global physical quantities (e.g. mobility profile, contact map, radius of gyration, structure factor) as a function of temperature and protein concentration. Trend in multi-scale structural variations of the protein in a crowded environment is compared with that of a free protein chain.

**8:24AM X41.00003 Network Analysis Reveals the Recognition Mechanism for Mannose-binding Lectins**, YUNJIE ZHAO, YIREN JIAN, CHEN ZENG, Department of Physics, The George Washington University, COMPUTATIONAL BIOPHYSICS LAB TEAM — The specific carbohydrate binding of mannose-binding lectin (MBL) protein in plants makes it a very useful molecular tool for cancer cell detection and other applications. The biological states of most MBL proteins are dimeric. Using dynamics network analysis on molecular dynamics (MD) simulations on the model protein of MBL, we elucidate the short- and long-range driving forces behind the dimer formation. The results are further supported by sequence coevolution analysis. We propose a general framework for deciphering the recognition mechanism underlying protein-protein interactions that may have potential applications in signaling pathways.

**8:36AM X41.00004 Unliganded EphA3 dimerization promoted by the SAM domain**, KALINA HRISTOVA, DEO SINGH, CHRISTOPHER KING, FOZIA AHMED, Johns Hopkins University, ELENA PASQUALE, Sanford-Burnham Medical Research Institute — The EphA3 receptor tyrosine kinase regulates morphogenesis during development, and is overexpressed and mutated in a variety of cancers. EphA3 activation is believed to follow a “seeding mechanism” model, in which ligand binding to the monomeric receptor acts as a trigger for signal-productive receptor clustering. We use a novel approach to study EphA3 lateral interactions on the surface of live cells, and we demonstrate that EphA3 forms dimers in the absence of ligand binding. We further show that these dimers are stabilized by interactions involving the EphA3 SAM domain. The discovery of unliganded EphA3 dimers challenges the current understanding of the chain of EphA3 activation events, and suggests that EphA3 may follow the “pre-formed dimer” model of activation known to be relevant for other receptor tyrosine kinases. This work also establishes a new role for the SAM domain in promoting Eph receptor lateral interactions and signaling on the cell surface.

**8:48AM X41.00005 Dissecting the active site of a photoreceptor protein**, WOUTER HOFF, MIWA HARA, JIE REN, FARZANEH MOGHADAM, AIHUA XIE, MASATO KUMAUCHI, Oklahoma State University — While enzymes are quite large molecules, functionally important chemical events are often limited to a small region of the protein: the active site. The physical and chemical properties of residues at such active sites are often strongly altered compared to the same groups dissolved in water. Understanding such effects is important for unraveling the mechanisms underlying protein function and for protein engineering, but has proven challenging. Here we report on our ongoing efforts on using photoactive yellow protein (PYP), a bacterial photoreceptor, as a model system for such effects. We will report on the following questions: How many residues affect active site properties? Are these residues in direct physical contact with the active site? Can functionally important residues be recognized in the crystal structure of a protein? What structural resolution is needed to understand active sites? What spectroscopic techniques are most informative? Which weak interactions dominate active site properties?

**9:00AM X41.00006 Statistical mechanics of hydrophobic amino acids in aqueous solution: A joint experimental scattering and computational study**, LINGSHUANG SONG, Case Western Reserve University, LIN YANG, Brookhaven National Laboratory, WEI HUANG, Case Western Reserve University, JIE MENG, Peking University, SICHUN YANG, Case Western Reserve University — How hydrophobic amino acids interact with each other is still a fundamental question in understanding protein dynamics and folding. Here, we describe an integrative experimental-computational approach of combining x-ray solution scattering and atomistic molecular simulations to determine the molecular properties of a hydrophobic leucine amino acid in an aqueous solution. First, scattering data were acquired at a series of amino acid and salt concentrations and these scattering profiles were further used to calibrate atomistic molecular simulations via a single parameter for solute-solvent interaction. Second, these accurate data of atomistic leucine simulations were used to quantify the effective interacting potentials via a structural simplification of one-bead-per-residue and two-bead-per-residue representations. Third, comparative energetic analyses between the one-bead and two-bead representations were performed to reach a simple picture of residue-residue interactions with an accurate energy function. Taken together, this joint experimental-computational study provides critical insights into microscopic interactions of hydrophobic amino acids in solution with a profound application for studying molecular dynamics of, e.g., intrinsically disordered proteins and their folding.

**9:12AM X41.00007 Mapping the temperature-dependent conformational landscapes of the dynamic enzymes cyclophilin A and urease<sup>1</sup>**, ROBERT THORNE, Cornell University, DANIEL KEEDY, University of California, San Francisco, MATTHEW WARKENTIN, Cornell University, JAMES FRASER, University of California, San Francisco, DAVID MOREAU, HAKAN ATAKISI, PETER RAU, Cornell University — Proteins populate complex, temperature-dependent ensembles of conformations that enable their function. Yet in X-ray crystallographic studies, roughly 98% of structures have been determined at 100 K, and most refined to only a single conformation. A combination of experimental methods enabled by studies of ice formation and computational methods for mining low-density features in electron density maps have been applied to determine the evolution of the conformational landscapes of the enzymes cyclophilin A and urease between 300 K and 100 K. Minority conformations of most side chains depopulate on cooling from 300 to ~200 K, below which subsequent conformational evolution is quenched. The characteristic temperatures for this depopulation are highly heterogeneous throughout each enzyme. The temperature-dependent ensemble of the active site flap in urease has also been mapped. These all-atom, site-resolved measurements and analyses rule out one interpretation of the protein-solvent glass transition, and give an alternative interpretation of a dynamical transition identified in site-averaged experiments. They demonstrate a powerful approach to structural characterization of the dynamic underpinnings of protein function.

**9:24AM X41.00008 Computational modeling of the side chain dihedral angle distributions of methionine using hard-sphere repulsive and short-range attractive interactions<sup>1</sup>**, ALEJANDRO VIRRUETA, COREY O'HERN, LYNNE REGAN, Yale University — Methionine (Met) is a versatile amino acid found frequently both in protein cores and at protein-protein interfaces. Thus, a complete description of the structure of Met is tantamount to a fundamental understanding of protein structure and design. In previous work, we showed that our hard-sphere dipeptide model is able to recapitulate the side chain dihedral angle distributions observed in high-resolution protein crystal structures for the 8 amino acids we have studied to date: Val, Thr, Ser, Leu, Ile, Cys, Tyr, and Phe. Using the same approach, we can predict the observed Met side chain dihedral angle distributions  $P(\chi_1)$  and  $P(\chi_2)$ , but not  $P(\chi_3)$ . In this manuscript, we investigate the possible origins of the discrepancy and identify the minimal additions to the hard-sphere dipeptide model necessary to quantitatively predict  $P(\chi_3)$  of Met. We find that applying a Lennard-Jones potential with weak attraction between hydrogen atoms is sufficient to achieve predictions that match the observed  $\chi_3$  side chain dihedral angle probability distributions for Met, Nle, and Mse without negatively affecting our results for the 8 previously studied amino acids.

**9:36AM X41.00009 Model comparison in X-ray crystallography**, DAVID SIVAK, NATHAN BABCOCK, Dept. of Physics, Simon Fraser University, DANIEL KEEDY, JAMES FRASER, Dept. of Bioengineering and Therapeutic Sciences, University of California, San Francisco — X-ray crystallographers conventionally infer a single best-fit structure from experimental data. Recently, attention has turned to inference of multiple structures and more generally to more complex model types that improve quality of fit—yet potentially increase overfitting to experimental noise. Significant research effort has been focused on inferring the best-fit parameters within a given model type, yet comparatively little attention has been given to selection between model types. Using metrics from the statistics community, we develop a model comparison framework for statistically-rigorous inference of protein conformational heterogeneity. We compare these information criteria to conventional model comparison criteria, and we assess their utility for judging different model types on their balance between quality of fit and model parsimony.

## 9:48AM X41.00010 Small-Angle Neutron Scattering study of the NIST mAb reference material

, MARIA MONICA CASTELLANOS, NIST Center for Neutron Research, IBBR, YUN LIU, NIST Center for Neutron Research, Univ. Delaware, SUSAN KRUEGER, JOSEPH CURTIS, NIST Center for Neutron Research — Monoclonal antibodies (mAbs) are of great interest to the biopharmaceutical industry because they can be engineered to target specific antigens. Due to their importance, the biomanufacturing initiative at NIST is developing an IgG1 mAb reference material 'NIST mAb', which can be used by industry, academia, and regulatory authorities. As part of this collaborative effort, we aim at characterizing the reference material using neutron scattering techniques. We have studied the small-angle scattering profile of the NIST mAb in a histidine buffer at 0 and 150 mM NaCl. Using Monte Carlo simulations, we generate an ensemble of structures and calculate their theoretical scattering profile, which can be directly compared with experimental data. Moreover, we analyze the structure factor to understand the effect of solution conditions on the protein-protein interactions. Finally, we have measured the solution scattering of the NIST mAb, while simultaneously performing freeze/thaw cycles, in order to investigate if the solution structure was affected upon freezing. The results from neutron scattering not only support the development of the reference material, but also provide insights on its stability and guide efforts for its development under different formulations.

**10:00AM X41.00011 Replica-exchange Wang-Landau simulations of the HOP lattice protein model<sup>1</sup>**, GUANGJIE SHI, Center for Simulation Physics, The University of Georgia, THOMAS WÜST, ID Scientific IT Services, ETH Zürich, Switzerland, YING WAI LI, National Center for Computational Sciences, Oak Ridge National Laboratory, DAVID P. LANDAU, Center for Simulation Physics, The University of Georgia — The hydrophobic-polar (HP) lattice protein model has been the subject of intensive investigation in an effort to aid our understanding of protein folding. However, the high ground state degeneracies caused by its simplification stands in contrast to the generally unique native states of natural proteins. Here we proposed a simple modification, by introducing a new type of "neutral" monomer, 0, i.e. neither hydrophobic nor polar, thus rendering the model more realistic without increasing the difficulties of sampling significantly<sup>2</sup>. With the replica exchange Wang-Landau (REWL) scheme<sup>3</sup> we investigated several widely studied HP proteins and their HOP counterparts. Dramatic differences in both ground state and thermodynamic properties have been found. For example, the HOP version of Crambin shows more clear two-step folding and 3 order of magnitudes less ground state degeneracy than its HP counterpart.

## 10:12AM X41.00012 Experimental and Computational Study of Beta-Galactosidase Inhibition

, ANTHONY COOPER, LUCA LARINI, Rutgers University-Camden — In this study, we combine experiments and simulations to design novel inhibitors of enzymes. We aim to characterize the inhibition mechanism which we show to be dependent on the aggregation of inhibitor peptides. As a model system we chose to use  $\beta$ -galactosidase. We selected four peptides out of 10,000 initially screened using microarrays and that show the greatest Michaelis-Menten constant and highest solubility. Molecular dynamics simulations were performed to identify the exact mechanism of action of these peptides. We show that the positive residues, like arginine and lysine, are crucial for inhibiting enzyme activity. According to simulations, these residues are also responsible for the conformations adopted by the peptide in solution. Dynamic light scattering study revealed that the aggregation of peptides with the enzyme takes place and is responsible for inhibiting enzyme activity.

## 10:24AM X41.00013 ABSTRACT MOVED TO M1.392 —

## 10:36AM X41.00014 Dynamic switching mechanisms of a CC chemokine, CCL5 (RANTES).

**A simulation study.**, EMANUEL PETER, IGOR PIVKIN, University of Lugano — CCL5 (RANTES) belongs to the class of pro-inflammatory chemokines which are part of the human immune-response. It is known to activate leukocytes through its associated chemokine receptor 5 (CCR5) and plays a key role in several malignancies, including HIV-1 infections and cancer. In this talk, we present our results from enhanced sampling simulations of the CCL5 (RANTES) monomer. We find that this protein can adopt 2 different conformations: a globular form, with an orthogonal alignment of the N-terminal part, and a 'cis' form, in which the N-terminus is aligned parallel to the  $\beta$ -strand interface. A detailed analysis of the structure reveals that each of these states is stabilized by salt-bridges along the sequence, and corresponds to a defined dihedral-geometry of the 2 disulfide bridges Cys10-34 and Cys11-50. We derive a uniform distribution of transitions from the globular form of CCL5 (RANTES), and find that each of the main conformers adopts different electrostatic patterns.

## 10:48AM X41.00015 Using Excel To Study The Relation Between Protein Dihedral Angle Omega And Backbone Length<sup>1</sup>

, CHRISTOPHER SHEW, SAMARI EVANS, XIUPING TAO, Winston-Salem State University — How to involve the uninitiated undergraduate students in computational biophysics research? We made use of Microsoft Excel to carry out calculations of bond lengths, bond angles and dihedral angles of proteins. Specifically, we studied protein backbone dihedral angle omega by examining how its distribution varies with the length of the backbone length. It turns out Excel is a respectable tool for this task. An ordinary current-day desktop or laptop can handle the calculations for midsized proteins in just seconds. Care has to be taken to enter the formulas for the spreadsheet column after column to minimize the computing load.

## Friday, March 18, 2016 8:00AM - 11:00AM —

Session X42 DPOLY: Semicrystalline Polymers 345 - Ahmed Ismail, University of West Virginia

## 8:00AM X42.00001 Crystallization of atactic polystyrene.

, YU CHAI, JAMES FORREST, Univ of Waterloo — Atactic polystyrene is often used as an archetypical example of a material that has no crystalline ground state due to the lack of order in the arrangement of phenyl groups along the backbone. However, even in polymers with perfect Bernoullian (random) statistics, there is a probability that a given molecule will have larger blocks of a given stereoregularity. These blocks, in turn, could allow the formation of nanocrystalline domains. As a model system to investigate whether such blocks could lead to nanoscale crystallinity, we consider PS with Mw less than 1000 where there is a reasonable probability of a molecule having all meso or racemo diads. For the case of Mw 600, there are clear indications of crystal growth with two characteristic temperatures below which two different crystal species can nucleate and grow. Similar crystal growth and melting behavior is observed for Mw 1000.

## 8:12AM X42.00002 Bisoxalamide Clarifiers to Improve Optical Performance of Polyethylene

**Resins<sup>1</sup>**, LIN WANG, MARTIN HILL, NESTOR SANTOS JR, ANDREW BANKS, JESSICA HUANG, ELLEN KEENE, RICH KEATON, Dow chemical — The use of special nucleating agents, often referred to as clarifying agents, to improve optical performance of polyethylene is not widely used in the industry. A series of bisoxalamide compounds were synthesized and mixed with linear low density polyethylene (LLDPE) to test clarification effects. In this talk, we will discuss structure/property relationship of these molecules on optical and thermal properties of LLDPE.

<sup>1</sup>Bisoxalamide clarifiers to improve optical performance of polyethylene resins

**8:24AM X42.00003 Coincident Crystallization of PEO-*b*-PCL Copolymers with Similar Block Molecular Weights**, RYAN VAN HORN, NATASHA BRIGHAM, CHRISTOPHER NARDI, Allegheny College — Poly(ethylene oxide)-*block*-poly(epsilon-caprolactone) (PEO-*b*-PCL) copolymers have garnered much attention for their use in the biomedical field due to their biocompatibility and the degradation of PCL. The applications of this polymer are heavily dependent on the polymer's physical properties, including crystalline content. One complicating factor is the relatively similar transition temperatures for PEO and PCL. We have studied the coincident crystallization behavior of 5k-5k and 10k-10k g/mol samples using FTIR. Both samples were isothermally crystallized at varying temperatures to track the development of crystallinity over time. Experiments showed that the crystallization of both blocks occurred nearly simultaneously over all temperatures. Each block's crystallization behavior was affected by the other block's crystallization.

**8:36AM X42.00004 Self Nucleation and Crystallization of Poly(vinyl alcohol)<sup>1</sup>**, DAVID THOMAS, PEGGY CEBE, Tufts Univ — Polyvinyl alcohol (PVA) is a hydrophilic, biodegradable, semi-crystalline polymer with uses ranging from textiles to medicine. Film samples of PVA were investigated to assess crystallization and melting behavior during self-nucleation experiments, and thermal degradation, using differential scanning calorimetry (DSC) and thermogravimetric (TG) analysis, respectively. TG results show that degradation occurred at temperatures close to the observed peak melting temperature of 223 C. Using conventional DSC, PVA was heated at a rate of 10 C/min to various self-nucleation temperatures,  $T_s$ , within its melting range, briefly annealed, cooled and reheated. Three distinct crystallization regimes were observed upon cooling, depending upon self nucleation temperature. At low values of  $T_s$ , below 227 C, PVA only partially melts; residual crystal anneals while new, less perfect crystals form during cooling. Between 228 C and 234 C, PVA was found to crystallize exclusively by self-nucleation. For  $T_s$  above 235 C the PVA melts completely. Fast scanning chip-based calorimetry was used to heat and cool at 2000 K/s, to prevent degradation. Results of self nucleation experiments using fast scanning and conventional DSC will be compared.

<sup>1</sup>NSF DMR-1206010

**8:48AM X42.00005 Folding of Polymer Chains in Early Stage of Crystallization<sup>1</sup>**, SHICHEN YUAN, TOSHIKAZU MIYOSHI, Univ of Akron — Understanding the structural formation of long polymer chains in the early stage of crystallization is one of the long-standing problems in polymer science. Using solid state NMR, we investigated chain trajectory of *isotactic* polypropylene in the mesomorphic nano-domains formed via rapid and deep quenching. Comparison of experimental and simulated <sup>13</sup>C-<sup>13</sup>C Double Quantum (DQ) buildup curves demonstrated that instead of random re-entry models and solidification models, individual chains in the mesomorphic form *i*PP adopt adjacent reentry sequences with an average folding number of  $\langle n \rangle = 3-4$  (assuming an adjacent re-entry fraction of  $\langle F \rangle$  of 100%) during mesomorphic formation process via nucleation and growth in the early stage.

**9:00AM X42.00006 Flow-Induced Crystallization of Poly(ether ether ketone).**, BEHZAD NAZARI, ALICYN RHOADES, RALPH COLBY, Pennsylvania State University — The effects of an interval of shear above the melting temperature  $T_m$  on subsequent isothermal crystallization below  $T_m$  is reported for the premier engineering thermoplastic, poly(ether ether ketone) (PEEK). The effect of shear on the crystallization rate of PEEK is investigated by means of rheological techniques and differential scanning calorimetry (DSC) under a protocol of imposing shear in a rotational cone and plate rheometer and monitoring crystallization after quenching. The rate of crystallization at 320 C was not affected by shear for shear rates  $< 7 \text{ s}^{-1}$  at 350 C, whereas intervals of adequate shear at higher shear rates prior to the quench to 320 C accelerated crystallization significantly. As the duration of the interval of shear above  $7 \text{ s}^{-1}$  is increased, the crystallization time decreases but at each shear rate eventually saturates once the applied specific work exceeds  $\sim 120 \text{ MPa}$ . The annealing of the flow-induced precursors was also investigated. The nuclei were fairly persistent at temperatures close to 350 C, however very unstable at temperatures above 375 C. This suggests that the nanostructures formed under shear might be akin to crystalline lamellae of greater thickness, compared to quiescently crystallized lamellae.

**9:12AM X42.00007 Fluoropolymer Microstructure and Dynamics: Influence of Molecular Orientation Induced by Uniaxial Drawing<sup>1</sup>**, DANIEL MIRANDA, CHAOQING YIN, JAMES RUNT, Pennsylvania State Univ — Fluorinated semi-crystalline polymer films are attractive for dielectric film applications due to their chemical inertness, heat resistance, and high thermal stability. In the present investigation we explore the influence of orientation induced by uniaxial drawing on the crystalline microstructure and relaxation processes of poly(ethylene-tetrafluoroethylene) (ETFE), in order to ascertain how morphological control can benefit polymer dielectric design. When drawn below or near the  $T_g$ , the crystallinity of the drawn films is unchanged, and oriented amorphous structures and crystalline microfibrils form at high draw ratios. This orientation slows segmental relaxation, reflected by an increase in the dynamic  $T_g$ , and also delays the transition to the high temperature crystalline form of ETFE. When drawing above the  $T_g$ , the films undergo strain-induced crystallization at high draw ratios. For these films an increase in the dynamic  $T_g$  is also observed, in addition to a second segmental relaxation process, appearing as a shoulder on the primary process. We propose that this represents a contribution from a rigid amorphous fraction, having slowed chain dynamics.

**9:24AM X42.00008 Structure of Poly(3-(2'-ethyl)hexylthiophene) (P3EHT) Containing Diblock Copolymers Controlled via Thermal Processing**, EMILY DAVIDSON, UC Berkeley, RACHEL SEGALMAN, UC Santa Barbara — Poly(3-alkylthiophene)s with modified alkyl side chains crystallize confined within block copolymer microphases, serving as a good model system for the confined crystallization of semiflexible polymers. We hypothesize that the diblock structure may impose an equilibrium degree of crystalline conjugated chain folding which here is only accessible for small degrees of undercooling. Crystallization of these P3ATs in soft confinement drives microdomain expansion; here, we show that this expansion is minimized for crystallization at small degrees of undercooling. Upon heating, domains return to their melt structure over three distinct regimes. These regimes directly correspond to thermal features we assign to the relaxation of a rigid-amorphous fraction at the diblock interface, melt-recrystallization which reorganizes the degree of chain folding, and a final complete melting transition.

**9:36AM X42.00009 Annealing effects on the crystalline structures of syndiotactic polystyrene after the crystalline  $\beta$  to  $\alpha$  form structural transition induced by mechanical strain.**, FUYUAKI ENDO, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The thermal effects on the polymorphic behavior of syndiotactic polystyrene (sPS) after the crystalline structural transition from  $\beta$  to  $\alpha$  were investigated. Our group has previously reported that  $\beta$  form crystals of sPS could transform into  $\alpha$  form crystals by mechanical strain at about 200C. In this study, we investigated possible crystalline structural transitions of pre-stretched sPS by thermal treatments. More specifically, the samples containing  $\beta$  form crystals were stretched at temperatures above the glass transition temperature ( $T_g$ ) before annealing. The crystalline structures in the sPS samples were characterized by Fourier-transform infrared spectroscopy and X-ray diffraction analyses. Before the annealing treatment, the samples stretched at near  $T_g$  possessed mesomorphic  $\alpha$  form crystals, whereas the samples stretched at higher temperatures had more perfect  $\alpha$  form crystals. It was also found that the mesomorphic  $\alpha$  form crystals, produced by the mechanical strain at lower temperatures, could transform into perfect  $\alpha$  form crystals by annealing, and that the amount of  $\alpha$  form crystals slightly increased with the increase in the annealing temperature.

**9:48AM X42.00010 Investigating the Equilibrium Melting Temperature of Polyethylene Using the Non-Linear Hoffman-Weeks Analysis: Effect of Molecular Weight**, HADI MOHAMMADI, HERVE MARAND, Virginia Tech, Department of Chemistry — The limiting equilibrium melting temperature for infinite molar mass linear polyethylene,  $T_m^o$ , has been a point of controversy for about five decades. On one hand, Broadhurst and Flory-Vrij extrapolated melting data for short alkanes to a value of ca. 145°C. On the other hand, Wunderlich proposed a value of 141°C from melting studies of extended-chain PE crystals formed under high pressure. While a difference in  $T_m^o$  by 4°C might seem superfluous, it has significant implication for the analysis of the temperature and chain length dependences of crystal growth kinetic data. In this work we estimate the equilibrium melting temperatures,  $T_m$  for three linear narrow molecular weight distribution polyethylenes using the non-linear Hoffman-Weeks treatment. The resulting  $T_m$  values thus obtained are significantly lower than these predicted by the Flory-Vrij treatment and are within experimental uncertainty indistinguishable from those reported by Wunderlich and Hikosaka et al. Our results also suggest that the constant  $C_2$  in the expression for the undercooling dependence of the initial lamellar thickness ( $l_g^* = C_1/\Delta T + C_2$ ) increases linearly with chain length.

**10:00AM X42.00011 Free surfaces overcome superheating in simulated melting of isotactic polypropylene<sup>1</sup>**, QIN CHEN, Department of Chemical Engineering, The Pennsylvania State University, ERIC B. SIROTA, ExxonMobil Research and Engineering, MIN ZHANG, T.C. MIKE CHUNG, Department of Materials Science and Engineering, The Pennsylvania State University, SCOTT T. MILNER, Department of Chemical Engineering, The Pennsylvania State University — The equilibrium melting point ( $T_m$ ) is a challenging experimental benchmark for molecular dynamics simulation of polymer melting and crystallization.  $T_m$  obtained from melting simulation of  $\alpha$  phase isotactic polypropylene (iPP) can exhibit superheating of over 100°C. Superheating has been attributed to the use of periodic boundary conditions and ultrafast simulated heating rates, both of which inhibit melting. We have developed a simple method to overcome superheating; we replace the periodic crystal structure with a periodic array of finite thickness slabs, separated by vacuum gaps. Thermal disorder at the slab surface promotes nucleation of the melt phase. Above  $T_m$ , we observe that the melting front advances into the crystal with a velocity proportional to  $T - T_m$ . This correspond to a quadratic rise in the system energy versus temperature, at constant heating rate. We obtain  $T_m$  as the onset of this quadratic rise in energy, which give values consistent with experimental melting points for iPP oligomers. The same simulations allow reasonable estimates of the crystal-vacuum interfacial free energy, from the energy difference between crystalline slabs and periodic crystals.

**10:12AM X42.00012 Yield Stress Enhancement in Glassy-Polyethylene Block Copolymers.**, WILLIAM MULHEARN, RICHARD REGISTER, Princeton University — Polyethylene (PE) has the highest annual production volume of all synthetic polymers worldwide, and is valuable across many applications due to its low cost, toughness, processability, and chemical resistance. However, PE is not well suited to certain applications due to its modest yield stress and Young's modulus (approximately 30 MPa and 1 GPa, respectively for linear, high-density PE). Irreversible deformation of PE results from dislocation of crystal stems and eventual crystal fragmentation under applied stress. The liquid-like amorphous fraction provides no useful mechanical support to the crystal fold surface in a PE homopolymer, so the only method to enhance the force required for crystal slip, and hence the yield stress, is crystal thickening via thermal treatment. An alternative route towards modifying the mechanical properties of PE involves copolymerization of a minority high-glass transition temperature block into a majority-PE block copolymer. In this work, we investigate a system of glassy/linear-PE block copolymers prepared via ring-opening metathesis polymerization of cyclopentene and substituted norbornene monomers followed by hydrogenation. We demonstrate that a large change in mechanical properties can be achieved with the addition of a short glassy block (e.g. a doubling of the yield stress and Young's modulus versus PE homopolymer with the addition of 25 percent glassy block). Furthermore, owing to the low interaction energy between PE and the substituted polynorbornene blocks employed, these high-yield PE block copolymers can exhibit single-phase melts for ease of processability.

**10:24AM X42.00013 On the structure and morphology of poly (vinylidene fluoride) nanoscrolls**, GABRIEL BURKS, SARAH GLEESON, SHAN MEI, HAO QI, CHRISTOPHER LI, Drexel University — Beyond its widely popular piezoelectric effect and  $\beta$ -phase molecular conformation, poly (vinylidene fluoride) PVDF also offers great intrigue as it relates to understanding its intrinsic crystallization behavior and morphological preference. It has been suggested that the  $\gamma$ -phase of PVDF adopts a highly regular scrolling lamellar habit which can be attributed to small differences in the folding volume of atomic level hydrogen and fluorine atoms resulting in the evolution of highly curved polymer lamellae. To date this scrolled morphology of  $\gamma$ -phase PVDF has been witnessed via high temperature melt crystallization of crystalline thin films and via severe chemical etching of PVDF bulk films. Here we show the first growth of free-standing  $\gamma$ -phase PVDF scrolls via the solution crystallization technique. Differential scanning calorimetry (DSC), X-Ray Diffraction (XRD), Fourier Transformed-Infrared Spectroscopy (FT-IR), and Atomic Force Microscopy (AFM) have been used to both characterize and to further understand the fundamental preferred crystalline habit of the  $\gamma$ -phase of poly (vinylidene fluoride).

**10:36AM X42.00014 Structure and Properties of Tactic Hydrogenated Polynorbornenes**, ADAM B. BURNS, RICHARD A. REGISTER, Princeton University — Tacticity is one of the most important structural parameters for determining the physical properties of a polymer. A high degree of stereoregularity typically promotes crystallization, with different tacticities giving rise to differences in crystal structure, melting point, and degree of crystallinity. In polynorbornene (PN) made by ring-opening metathesis polymerization (ROMP), tacticity is determined by the relative configuration of the nonplanar cyclopentylene rings enchain in the backbone. Traditional ROMP initiators yield *atactic* polymers (*aPN*); however, recent advances in catalyst design have produced both *isotactic* and *syndiotactic* PN. Newly reported *cis, isotactic*- and *cis, syndiotactic*-PNs were catalytically hydrogenated (abbreviated *ihPN* and *shPN*, respectively) without altering the tacticity. The thermal and structural characteristics of *ihPN* and *shPN* were studied by differential scanning calorimetry (DSC) and wide-angle x-ray scattering (WAXS) and compared to that of *ahPN*. Remarkably, all three polymers are semicrystalline, each with a distinct crystal structure. *ihPN* has a nominal melting point of 165 C, more than 20 C above that of *ahPN*. WAXS patterns of melt-drawn fibers of *ihPN* show few strong reflections indicative of either a highly symmetric unit cell or poor long-range order. *ihPN* fibers also exhibit a crystal-crystal transition near 130 C, which is not fully reversible on subsequent cooling. On the other hand, *shPN* has a nominal melting point some 15 C below that of *ahPN*, and *shPN* fibers show no evidence of polymorphism.

**10:48AM X42.00015 Crystallization and recrystallization behavior study on biopolymer composites with polymer grafted halloysite nanotubes<sup>1</sup>**, YA-TING HSIEH, KEN KOJIO, ATSUSHI TAKAHARA, Institute for Materials Chemistry and Engineering, Kyushu University — We study the crystallization and recrystallization behavior of poly(lactic acid) (PLA) in PLA/halloysite composites. Specifically, we are interested in finding the additional effect of interface properties variation in composites except for enhancing filler dispersion. Halloysite nanotubes are grafted with polymer to create different surface properties at their surface. These polymer grafted halloysite nanotubes are then spread into PLA via solvent mixing. Using differential scanning calorimeter, we track and analyze the influence of halloysite surface properties on the crystallization and recrystallization behavior of PLA composites under several conditions. We also present investigations of polarizing optical microscopy, in-situ Fourier transform infrared spectroscopy, and in-situ synchrotron X-ray diffraction measurements. The investigations provide insight into interface effect on PLA composites.

Session X43 GSNP: Statistical Mechanics of Social Systems 346 - Eli Ben Naim, Los Alamos National Laboratory

**8:00AM X43.00001 Microscopic to Macroscopic Dynamical Models of Sociality<sup>1</sup>**, CITLALI SOLIS SALAS, THOMAS WOOLLEY, Mathematical Institute, University of Oxford, EILUNED PEARCE, ROBIN DUNBAR, Department of Experimental Psychology, University of Oxford, PHILIP MAINI, Mathematical Institute, University of Oxford, SOCIAL AND EVOLUTIONARY NEUROSCIENCE RESEARCH GROUP (SENRG) COLLABORATION — To help them survive, social animals, such as humans, need to share knowledge and responsibilities with other members of the species. The larger their social network, the bigger the pool of knowledge available to them. Since time is a limited resource, a way of optimising its use is meeting amongst individuals whilst fulfilling other necessities. In this sense it is useful to know how many, and how often, early humans could meet during a given period of time whilst performing other necessary tasks, such as food gathering. Using a simplified model of these dynamics, which comprehend encounter and memory, we aim at producing a lower-bound to the number of meetings hunter-gatherers could have during a year. We compare the stochastic agent-based model to its mean-field approximation and explore some of the features necessary for the difference between low population dynamics and its continuum limit. We observe an emergent property that could have an inference in the layered structure seen in each person's social organisation. This could give some insight into hunter-gatherer's lives and the development of the social layered structure we have today.

**8:12AM X43.00002 Impact of Bursty Communication Patterns on Naming Game Competitions.<sup>1</sup>**, CASEY DOYLE, GYORGY KORNISS, BOLESŁAW SZYMANSKI, Rensselaer Polytech Inst — The currently dominant model of opinion spread dynamics chooses speakers randomly, giving rise to an exponentially distributed wait time between speaking events. Many studies, however, suggest that a more appropriate distribution would be a power law since it captures the bursty nature of communication<sup>2,3,4,5,6</sup>. Here we study how adjusting the wait times for agents to speak to fit various distributions affects the dynamics of the naming game. Specifically, we show that by creating a system with competition between two groups (each with a different wait time distribution but the same mean), the symmetry of the system is broken and in the infinite system the 'burstier' community always wins. In contrast, when this burstiness is studied in the voter model, the symmetry breaking does not occur. Lastly, we show that burstiness in the naming game with committed agents shifts downwards the critical population required for consensus.

**8:24AM X43.00003 Comparison of human mobility patterns in different settings<sup>1</sup>**, XIANGWEN WANG, MICHEL PLEIMLING, Virginia Tech — The development of location tracking technologies and big-data analysis capacities makes it possible to understand human mobility patterns at the global level through the analysis of huge datasets made available by open-data communities. Working with millions of empirical world-wide GPS trajectories, we examine users' mobility patterns in urban, rural and intermediate scenarios. Similar scaling properties are found in the analysis of several quantities, including end-to-end distance, radius of gyration, mean-squared displacement, and fixed-interval step-length. The impact of cities is elucidated by comparing mobility patterns in major cities worldwide.

**8:36AM X43.00004 Effects of long-range interactions in the one-dimensional Sznajd model**, JOSEPH GARCIA, University of Maine, THOMAS STONE, Husson University, SUSAN MCKAY, University of Maine — The Sznajd model is a one-dimensional, binary, voter-like model used to study consensus in systems where information flows outward from like-minded agent pairs. Here, we introduce long-range interactions to the Sznajd model, quantified by the parameter  $p$  in analogy with the dynamic and static small-world rewiring parameter ( $p \rightarrow 1$  is the mean-field limit,  $p \rightarrow 0$  is the 1-D limit). We use Monte Carlo simulations and finite-size scaling analyses to characterize the exit probability for  $p \neq 0$ , finding a step function that depends on two  $p$ -dependent exponents. By examining the  $p \rightarrow 0$  limit of these exponents, we comment on the functional form of the exit probability in one dimension, which has been an open question. We complement this limiting approach (letting  $p \rightarrow 0$ , which offers considerable computational speedup over the pure  $p=0$  case) by also simulating the  $p=0$  case via a parallel algorithm. This investigation also probes the dependence of consensus time and system magnetization on  $p$ .

**8:48AM X43.00005 Selection Strategies for Social Influence in the Threshold Model<sup>1</sup>**, PANAGIOTIS KARAMPOURNIOTIS, BOLESŁAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytech Inst — The ubiquity of online social networks makes the study of social influence extremely significant for its applications to marketing, politics and security. Maximizing the spread of influence by strategically selecting nodes as initiators of a new opinion or trend is a challenging problem. We study the performance of various strategies for selection of large fractions of initiators on a classical social influence model, the Threshold model (TM). Under the TM, a node adopts a new opinion only when the fraction of its first neighbors possessing that opinion exceeds a pre-assigned threshold. The strategies we study are of two kinds: strategies based solely on the initial network structure (Degree-rank, Dominating Sets, PageRank etc.) and strategies that take into account the change of the states of the nodes during the evolution of the cascade, e.g. the greedy algorithm. We find that the performance of these strategies depends largely on both the network structure properties, e.g. the assortativity, and the distribution of the thresholds assigned to the nodes<sup>2</sup>. We conclude that the optimal strategy needs to combine the network specifics and the model specific parameters to identify the most influential spreaders.

**9:00AM X43.00006 Pattern Selection and Super-Patterns in Opinion Dynamics** , ELI BEN-NAIM, Los Alamos National Laboratory, ARND SCHEEL, University of Minnesota — We study pattern formation in the bounded confidence model of opinion dynamics. In this random process, opinion is quantified by a single variable. Two agents may interact and reach a fair compromise, but only if their difference of opinion falls below a fixed threshold. Starting from a uniform distribution of opinions with compact support, a traveling wave forms and it propagates from the domain boundary into the unstable uniform state. Consequently, the system reaches a steady state with isolated clusters that are separated by distance larger than the interaction range. These clusters form a quasi-periodic pattern where the sizes of the clusters and the separations between them are nearly constant. We obtain analytically the average separation between clusters  $L$ . Interestingly, there are also very small quasi-periodic modulations in the size of the clusters. The spatial periods of these modulations are a series of integers that follow from the continued-fraction representation of the irrational average separation  $L$ .

**9:12AM X43.00007 Spatially clustered zealots in a two-dimensional voter model** , THOMAS STONE, Husson University, MATTHEW LUDDEN, SUSAN MCKAY, University of Maine — The voter model, solvable in all dimensions in its standard form, has been extensively used to study behavior dynamics by using the tools of statistical mechanics. Recently, much work has been focused on determining the effects of zealots in the voter model, where a zealot is an agent that maintains its opinion (akin to an Ising spin variable) no matter the local environment. Here we investigate the effects of spatially clustered zealots in the standard voter model on a two-dimensional square lattice. The clustering of zealots is quantified by the conditional probability that a zealot of the  $+1$  state appears on an adjacent site to a randomly chosen zealot. (All zealots are of the  $+1$  state.) We determine the functional forms of the system consensus time with respect to system size, clustering, and zealot density, and compare these findings to previous results that do not include clustering. We also discuss an interesting random walk problem that arises when one attempts to calculate how clustering affects the consensus time for fixed zealot density and system size.

**9:24AM X43.00008 Highlighting impact: Do editors' selections identify influential papers?** , MANOLIS ANTONOYIANNAKIS, (1) Columbia University (2) American Physical Society — A recent trend in scientific publishing is that journal editors highlight each week a select set among the papers published (usually) in their respective journals. The highlighted papers are deemed of higher quality, importance, or interest than the 'average' paper and feature prominently in the publishers' websites. We perform a citation analysis of the highlighted papers for a number of journals from various publishers in physics. By comparing the performance of highlighted papers relative to (a) typical papers and (b) highly cited papers in their source journals and in other journals in the field, we explore whether, and to what extent, the selection process at the time of publication identifies papers that will turn out to be influential. We discuss the broader implications for research assessment.

**9:36AM X43.00009 Measuring diversity and coherence using hierarchical APS-PACS classification of sub fields of physics and their impact on citations.** , SHIVAKUMAR JOLAD, MURALI KRISHNA ENDURI, I. VINOD REDDY, IIT Gandhinagar — American Physical Society introduced Physics and Astronomy Classification Scheme (PACS) in 1975 to classify different subfields of physics in a hierarchical tree structure. Since 1985, almost all the physical review articles include the PACS code to refer different subfields it belongs to. In this work, we define the notion of diversity of articles and authors based on the PACS codes they are associated with, using Weitzmann diversity index, from 1985-2012. We find that the fraction of authors with high diversity is increasing with time, whereas the fraction of least diversity are decreasing, and moderate diversity authors have higher tendency to switch over to other diversity groups. By measuring the interconnectedness among the PACS codes, we define measures of coherence of papers and authors. The diversity and coherence captures the dimensions of Interdisciplinarity. Based on which we study the correlation between Interdisciplinarity (within sub fields of physics) and citations. We find that the diversity index of articles is correlated with the citations they received in a given time period from their publication year. Articles with lower and higher end of diversity index receive lesser citations than the moderate diversity papers.

**9:48AM X43.00010 Untangling Performance from Success<sup>1</sup>** , BURCU YUCESoy, ALBERT-LASZLO BARABASI, Northeastern University — Fame, popularity and celebrity status, frequently used tokens of success, are often loosely related to, or even divorced from professional performance. This dichotomy is partly rooted in the difficulty to distinguish performance, an individual measure that captures the actions of a performer, from success, a collective measure that captures a community's reactions to these actions. Yet, finding the relationship between the two measures is essential for all areas that aim to objectively reward excellence, from science to business. Here we quantify the relationship between performance and success by focusing on tennis, an individual sport where the two quantities can be independently measured. We show that a predictive model, relying only on a tennis player's performance in tournaments, can accurately predict an athlete's popularity, both during a player's active years and after retirement. Hence the model establishes a direct link between performance and momentary popularity. The agreement between the performance-driven and observed popularity suggests that in most areas of human achievement exceptional visibility may be rooted in detectable performance measures.

**10:00AM X43.00011 A simple model for research interest evolution patterns** , TAO JIA, Southwest University, China, DASHUN WANG, Pennsylvania State University, BOLESŁAW SZYMANSKI, Rensselaer Polytechnic Institute — Sir Isaac Newton supposedly remarked that in his scientific career he was like "... a boy playing on the sea-shore ... finding a smoother pebble or a prettier shell than ordinary". His remarkable modesty and famous understatement motivate us to seek regularities in how scientists shift their research focus as the career develops. Indeed, despite intensive investigations on how microscopic factors, such as incentives and risks, would influence a scientist's choice of research agenda, little is known on the macroscopic patterns in the research interest change undertaken by individual scientists throughout their careers. Here we make use of over 14,000 authors' publication records in physics. By quantifying statistical characteristics in the interest evolution, we model scientific research as a random walk, which reproduces patterns in individuals careers observed empirically. Despite myriad of factors that shape and influence individual choices of research subjects, we identified regularities in this dynamical process that are well captured by a simple statistical model. The results advance our understanding of scientists' behaviors during their careers and open up avenues for future studies in the science of science.

**10:12AM X43.00012 Development of kink jams in traffic flow** , DOUGLAS KURTZE, Saint Joseph's Univ — Near the threshold of absolute stability of uniform, steady traffic flow, car-following models can often be reduced to a modified Korteweg-deVries (mKdV) equation plus small corrections. The mKdV equation has a continuous family of hyperbolic-kink solutions describing boundaries between regions of different traffic densities, i.e. the edges of traffic jams. A solvability calculation picks out the one member of this family which is consistent with the correction terms; this is usually labelled the "selected" kink. This identification is problematic, however, since it must be the downstream boundary condition that determines which kink solution is realized. We display a two-parameter family of mKdV solutions which has the kink solutions as one limit and uniform flow as another, and show how the correction terms can lead to kinks developing from initially near-uniform traffic. We then clarify the meaning of the usual solvability calculation and of the "selected" kink.

**10:24AM X43.00013 A Langevin model for low density pedestrian dynamics**, ALESSANDRO CORBETTA, Eindhoven University of Technology, CHUNG-MIN LEE, California State University Long Beach, ROBERTO BENZI, University of Rome Tor Vergata, ADRIAN MUNTEAN, Karlstad University, Sweden, FEDERICO TOSCHI, Eindhoven University of Technology — The dynamics of pedestrian crowds shares deep connections with statistical physics and fluid dynamics. Reaching a quantitative understanding, not only of the average behaviours but also of the statistics of (rare) fluctuations would have major impact, for instance, on the design and safety of civil infrastructures. A key feature of pedestrian dynamics is its strong intrinsic variability, that we can already observe at the single individual level. In this work we aim at a quantitative characterisation of this statistical variability by studying individual fluctuations. We consider experimental observations of low-density pedestrian flows in a corridor within a building at Eindhoven University of Technology. Few hundreds of thousands of pedestrian trajectories with high space and time resolutions have been collected via a Microsoft Kinect 3D-range sensor and automatic head tracking techniques. From these observations we model pedestrians as active Brownian particles by means of a generalised Langevin equation. With this model we can quantitatively reproduce the observed dynamics including the statistics of ordinary pedestrian fluctuations and of rarer U-turn events. Low density, pair-wise interactions between pedestrians are also discussed.

**10:36AM X43.00014 A Hierarchy of Multi-Lane Driven Diffusive Systems with Unfair Resource Availability**<sup>1</sup>, AYSE YESIL, CEMAL YALABIK, Bilkent University — We present a model system for objects which have the ability to move along columns with the availability of a low entropy resource which is provided abundantly to a first column. The unused part of this resource is available to objects in neighbouring consecutive columns. This forms a hierarchy of multi-lane driven diffusive systems, which displays interesting dynamics. We present results from Monte Carlo simulations of the system.

**10:48AM X43.00015 Kinetic model for dilute traffic flow**, ASHKAN BALOUCHI, DANA A. BROWNE, Louisiana State University, Department of Physics and Astronomy — The flow of traffic represents a many-particle non-equilibrium problem with important practical consequences. Traffic behavior has been studied using a variety of approaches, including fluid dynamics models, Boltzmann equation, and recently cellular automata (CA). The CA model for traffic flow that Nagel and Schreckenberg (NS) introduced can successfully mimic many of the known features of the traffic flow. We show that in the dilute limit of the NS model, where vehicles exhibit free flow, cars show significant nearest neighbor correlation primarily via a short-range repulsion. introduce an approximate analytic model to describe this dilute limit. We show that the distribution of the distance between consecutive vehicles obeys a drift-diffusion equation. We compared this model with direct simulations. The steady state solution and relaxation of this model agrees well with direct simulations. We explore how this model breaks down as the transition to jams occurs.

**8:00AM X44.00001 Consecutive Measurements in Quantum Mechanics**<sup>1</sup>, JENNIFER R. GLICK, CHRISTOPH ADAMI, Michigan State University — The physics of quantum measurement still continues to puzzle with no resolution in sight between competing interpretations, in particular because no interpretation has so far produced predictions that would be falsifiable via experiment. Here we present an analysis of consecutive projective measurements performed on a quantum state using quantum information theory, where the entanglement between the quantum system and a measuring device is explicitly taken into account, and where the consecutive measurements increase the joint Hilbert space while the wavefunction of the joint system never collapses. Using this relative-state formalism we rederive well-known results for the pairwise correlation between any two measurement devices, but show that considering the joint as well as conditional entropy of three devices reveals a difference between the collapse and no-collapse pictures of quantum measurement that is experimentally testable.

**8:12AM X44.00002 Hidden Variables Theorems with Fewer Measurements**, JAY LAWRENCE, Dartmouth College and University of Chicago — A Greenberger-Horne-Zeilinger (GHZ) contradiction may be thought of as a sequence of measurements on a system of  $N$  particles, for which each may be duplicated by local hidden variables up to, but not including the last of an irreducible set. Each measurement consists of  $N$  spatially separated local measurements on individual particles. Existing contradictions require more such measurements than there are particles, the minimum number being  $N + 1$ . By allowing successive measurements to impose incremental local constraints on the hidden variables (as opposed to global constraints associated with products of hidden variables), we derive contradictions that require fewer measurements. We have found protocols for which the number of measurements,  $N_m$ , grows more slowly than linearly with the number of particles: Asymptotically,  $N_m \sim \sqrt{2N}$  for large  $N$  if the particles are qubits, and a similar relation holds for particles of higher spins.

**8:24AM X44.00003 Statistical and optimal behaviours of weak continuous quantum measurement using stochastic path integral formalism**, AREEYA CHANTASRI, University of Rochester, ANDREW JORDAN, University of Rochester, Chapman University — We study stochastic behaviour and optimal dynamics of quantum systems under weak continuous measurement. Using the stochastic path integral formalism and action principle introduced in [Phys. Rev. A 88, 042110 (2013) and Phys. Rev. A 92, 032125 (2015)], the optimal evolution, such as the most likely paths, can be obtained by extremizing the action of the stochastic path integral. We also show that any statistical information, such as multi-time correlation functions for quantum state variables, can be derived by applying functional methods and a perturbative approach to the stochastic path integral. Examples are given in one-qubit and two-qubit case. Moreover, we consider an example of qubit measurement with feedback control, using the action principle to investigate the global dynamics of its most likely paths, and finding that qubit state stabilization at any desired pure state is possible with linear feedback.

**8:36AM X44.00004 Localizing and observing Kochen-Specker quantum contextuality using weak measurements.**<sup>1</sup>, MORDECAI WAEGELL, JEFF TOLLAKSEN, Institute for Quantum Studies, Chapman University, YUJI HASEGAWA, STEPHAN SPONAR, TOBIAS DENKMAYR, HERMANN GEPPERT, Atominstitut, TU-Wien, INSTITUTE FOR QUANTUM STUDIES COLLABORATION, RESEARCH GROUP OF DR. YUJI HASEGAWA COLLABORATION — Experimental tests of the Kochen-Specker (KS) theorem conventionally require a set of different measurement settings, and the test can furthermore be applied to an arbitrary prepared state. These experiments show that nature is contextual, but they do not indicate which specific observables must behave nonclassically. We show that, using pre- and post-selected states from within a set of projectors that prove the KS theorem, it is possible to identify another specific projector in the set that behaves nonclassically, in this case because it has an anomalous weak value. We explore specific KS sets that gives rise to the Quantum Pigeonhole Effect (QPE), and use weak measurements on a large ensemble of identically pre- and post-selected neutrons to verify the QPE, and also to measure the anomalous weak value of the nonclassical projector. We construct a new contextuality inequality based on the recent result of Pusey showing that any projector with a negative weak value is a proof of contextuality, and show that our measured weak value is many standard deviations below zero.

**8:48AM X44.00005 Direct Characterization of Quantum Dynamics with Noisy Ancilla**<sup>1</sup>, EUGENE DUMITRESCU, TRAVIS HUMBLE, Oak Ridge National Laboratory, University of Tennessee — We present methods for the direct characterization of quantum dynamics (DCQD) in which both the principal and ancilla systems undergo noisy processes. Using a concatenated error detection code, we discriminate between located and unlocated errors on the principal system in what amounts to filtering of ancilla noise. The example of composite noise involving amplitude damping and depolarizing channels is used to demonstrate the method, while we find the rate of noise filtering is more generally dependent on code distance. Our results indicate the accuracy of quantum process characterization can be greatly improved while remaining within reach of current experimental capabilities.

<sup>1</sup>We acknowledge support from the IC postdoctoral research program.

**9:00AM X44.00006 Realizing quantum advantage without entanglement in single-photon states**, ALEJANDRA MALDONADO-TRAPP, PABLO SOLANO, Joint Quantum Institute, ANZI HU, American University, CHARLES W. CLARK, Joint Quantum Institute — Correlations allow us to measure, and quantitatively study, the properties of physical systems, their evolution and their interactions. Quantum discord expresses quantum correlations beyond those associated with entanglement.<sup>1</sup> However, discord has not yet been adopted as a standard subject of study by the experimental community. Here we propose a feasible optical setup to generate symmetric two-qubit  $X$ -states with controllable coherences, where the two qubits correspond to the spin and path of a photon. With these states we show how a classical random variable  $K$  can be encoded by Alice and decoded by Bob. Using our previous results<sup>2</sup> we study the correlations between the spin and path qubits and its relation with the information about  $K$  that can be decoded by Bob using local measurements with or without two-qubit gate operations.<sup>3</sup> Discord is the mutual information contained in the coherences of the system, and it is possible to exploit it for quantum advantage even in the absence of entanglement.

**9:12AM X44.00007 A novel computational approach towards the certification of large-scale boson sampling**<sup>1</sup>, JOONSUK HUH, Pohang University of Science and Technology — Recent proposals of boson sampling and the corresponding experiments exhibit the possible disproof of extended Church-Turning Thesis. Furthermore, the application of boson sampling to molecular computation has been suggested theoretically [1]. Till now, however, only small-scale experiments with a few photons have been successfully performed. The boson sampling experiments of 20-30 photons are expected to reveal the computational superiority of the quantum device. A novel theoretical proposal for the large-scale boson sampling using microwave photons is highly promising due to the deterministic photon sources and the scalability [2]. Therefore, the certification protocol of large-scale boson sampling experiments should be presented to complete the exciting story. We propose, in this presentation, a computational protocol towards the certification of large-scale boson sampling. The correlations of paired photon modes and the time-dependent characteristic functional with its Fourier component can show the fingerprint of large-scale boson sampling. [1] J. Huh, G. G. Guerreschi, B. Peropadre, J. R. McClean, and A. Aspuru-Guzik. *Nature Photon.* 9 (2015): pp 615-620. [2] B. Peropadre, G. G. Guerreschi, J. Huh, and A. Aspuru-Guzik. Preprint: arXiv:1510.08064.

**9:24AM X44.00008 Occupation number entanglement in mesoscopic conductors**, DAVID DASENBROOK, University of Geneva, Switzerland, CHRISTIAN FLINDT, Aalto University, Finland — The controlled entanglement of electrons in mesoscopic conductors has been theoretically investigated before using the spin- and orbital degrees of freedom. By contrast, entanglement of two spatially separated electronic channels using the fermionic occupation number has mostly been considered inaccessible due to the charge superselection rule. However, using non-local measurements or combining several copies of occupation number entangled states, the superselection rules can be lifted and the entanglement can be detected using current and noise measurements. We present the theory for an interferometric setup to detect entanglement in the electron-hole degree of freedom of electronic excitations [1] as well as a mesoscopic setup that demonstrates entanglement and non-locality of a single electron. ### 9:36AM X44.00009 Neutron interferometry for precise characterization of quantum systems<sup>1</sup>

, DUSAN SARENAC, Institute for Quantum Computing, CHANDRA SHAHI, Tulane University, TAI SIYA MINEEVA, CHRISTOPHER J. WOOD, Institute for Quantum Computing, MICHAEL G. HUBER, MUHAMMAD ARIF, National Institute of Standards and Technology, CHARLES W. CLARK, Joint Quantum Institute, DAVID G. CORY, DMITRY A. PUSHIN, Institute for Quantum Computing — Neutron interferometry (NI) is among the most precise techniques used to test the postulates of quantum mechanics. It has demonstrated coherent spinor rotation and superposition, gravitationally induced quantum interference, the Aharonov-Casher effect, violation of a Bell-like inequality, and generation of a single-neutron entangled state. As massive, penetrating and neutral particles neutrons now provide unique capabilities in classical imaging applications that we seek to extend to the quantum domain. We present recent results on NI measurements of quantum discord in a bipartite quantum system<sup>2</sup> and neutron orbital angular momentum multiplexing,<sup>3</sup> and review progress on our commissioning of a decoherence-free-subspace NI user facility at the NIST Center for Neutron Research.<sup>4</sup>

### 9:48AM X44.00010 Recovering the ideal results of a perturbed quantum emulator , MICHAEL

MARTHALER, Karlsruhe Institute of Technology, LIN TIAN, University of California, Merced, IRIS SCHWENK, Karlsruhe Institute of Technology — We consider a quantum emulator which is a model of an ideal Hamiltonian of interest  $H_S$ . However, inevitably the system is perturbed by coupling to additional degrees of freedom. We study the case where we are interested in extracted a correlator from the emulated system in equilibrium. We show that it is possible to extract the ideal correlator from a perturbed system under certain conditions. The ideal correlator can be reconstructed if any n-time correlator of the ideal system can be written as a product of two-time correlators.

### 10:00AM X44.00011 Experimental observation of melting of the effective Minkowski

spacetime<sup>1</sup> , IGOR SMOLYANINOV, University of Maryland, VERA SMOLYANINOVA, Towson University — Cobalt nanoparticle-based ferrofluid in the presence of an external magnetic field forms a self-assembled hyperbolic metamaterial, which may be described as an effective 3D Minkowski spacetime for extraordinary photons. Moreover, such extraordinary photons perceive thermal gradients in the ferrofluid as an effective gravitational field, which obeys the Newton law. If the magnetic field is not strong enough, the effective Minkowski spacetime gradually melts under the influence of thermal fluctuations. On the other hand, it may restore itself if the magnetic field is increased back to its original value. Here we present direct microscopic visualization of such a Minkowski spacetime melting/crystallization, which is somewhat similar to hypothesized formation of the Minkowski spacetime in loop quantum cosmology [1]. ### 8:00AM X47.00001 Oxidic copper on the Au(111) surface:A theoretical surface science ap-

proach , TAEHUN LEE, Yonsei University, YONGHYUK LEE, KISUNG KANG, ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University — Recently, via reactive Cu deposition in an oxygen ambience, high quality gold-supported cuprous oxide ( $\text{Cu}_2\text{O}$ ) ultrathin nanofilms [1] have been prepared as a model system to further such catalytic studies. Nonetheless, an accurate atomic picture of these ultrathin  $\text{Cu}_2\text{O}$  nanofilms, which largely depends on its immediate oxygen environment, is currently lacking. In this work, we perform density-functional theory (DFT) calculations using the Vienna ab initio Simulation Package in combination with *ab initio* atomistic thermodynamics [2] to investigate stability of  $\text{Cu}_2\text{O}$  thin films on Au(111) as a function of oxygen chemical potential. Our results indeed show that some of the surface structures suggested in Ref. [1] are energetically more stable than the traditional copper oxide thin film structures on copper substrate, and elucidated the electronic structure of these ultrathin copper oxide films on gold, in comparison with available experimental data. ### 8:12AM X47.00002 Interaction of Molecular Oxygen with Au (001) Surface<sup>1</sup> , MICHAEL PIERCE,

ANDREW LOHEAC<sup>2</sup>, Rochester Institute of Technology, ANDI BARBOUR, Brookhaven National Laboratory, VLADIMIR KOMANICKY, Safarik University, ANTHONY RUFFINO, Rochester Institute of Technology, HOYDOO YOU, Argonne National Laboratory — Kinetics of dioxygen - Au (001) surface interaction has been studied at high temperature and near atmospheric pressures with in situ x-ray scattering measurements. We find that the hexagonal reconstruction (hex) of Au (001) surface lifts to (11) in the presence of dioxygen. The measured lifting rate constant vs. temperature shows a ‘volcano’-type behavior indicating that oxygen adsorption limits at high temperature while activation barrier of the lifting limits at low temperature. The pressure–temperature (PT) phase diagram obtained in our study shows three regions: hex at low P and T, (11) at high P and T, and coexistence of the hex and the (11) at the intermediate P and T.

### 8:24AM X47.00003 Stabilization of the O p2x2 phase on Cu(001) sheltered by wrinkled BN

over-layer<sup>1</sup> , YONG-SUNG KIM, Korea Research Institute of Standards and Science, Yuseong, Daejeon 305-340, Korea, CHUANXU MA, AN-PING LI, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — The  $2\sqrt{3}\times\sqrt{3}R45^\circ$  phase of oxygen (O) on the Cu(001) surface has been observed in scanning tunneling microscopy (STM) measurements. Although the p2x2 phase of O on the Cu(001) surface has been proposed theoretically to be the most stable in O-lean conditions, it has not been observed in experiments for a long time. Recently, the O p2x2 phase has been found in STM on the Cu(001) surface with an overlying BN monolayer. In this theoretical study, we investigate what the role of BN over-layer is to stabilize the O p2x2 phase on the Cu(001) surface. The BN over-layer is lattice-matched with the Cu(001) surface and the BN mono-layer sheet is periodically wrinkled along the BN arm-chair direction and along the [100] or [010] direction on the Cu(001) surface. The interlayer space between the Cu(001) surface and the bulge of the wrinkled BN sheet is found to play as a preferential shelter for O to be adsorbed, and the boundary of the BN inner wall along the [010] or [100] direction makes the p2x2 phase more favorable against the  $45^\circ$ -tilted  $2\sqrt{3}\times\sqrt{3}R45^\circ$  phase of O on the Cu(001) surface.

**8:36AM X47.00004 Multiscale Investigations of the Early Stage Oxidation on Cu Surfaces**, QING ZHU, University of Pittsburgh, PENGHAO XIAO, XIN LIAN, SHEN-CHE YANG, GRAME HENKELMAN, University of Texas at Austin, WISSAM SAIDI, JUDITH YANG, University of Pittsburgh, UNIVERSITY OF PITTSBURGH TEAM, UNIVERSITY OF TEXAS AT AUSTIN TEAM — Previous *in situ* TEM experiments have shown that the oxidation of the three low index Cu surfaces (100), (110) and (111) exhibit different oxide nucleation rates, and the resulting oxides have 3-dimensional (3D) island shapes or 2D rafts under different conditions. In order to better understand these results, we have investigated the early stages of Cu oxidation using a multiscale computational approach that employs density functional theory (DFT), reactive force field (ReaxFF), and kinetic Monte Carlo (KMC). With DFT calculation, we have compared O<sub>2</sub> dissociation barriers on Cu (100), (110) and (111) surfaces at high oxygen coverage to evaluate the kinetic barrier of sublayer oxidation. We found that O<sub>2</sub> dissociation barriers on Cu(111) surface are all lower than those on (110) and (100) surfaces. This trend agrees with experimental observations that (111) surface is easier to oxidize. These DFT calculated energy barriers are then incorporated into KMC simulations. The large scale ReaxFF molecular dynamics and KMC simulations detail the oxidation dynamics of the different Cu surfaces, and show the formation of various oxide morphologies that are consistent with experimental observations.

**8:48AM X47.00005 Inducing electric polarization in ultrathin insulating layers**, JOSE MARTINEZ-CASTRO, London Center for Nanotechnology, London, MARTEN PIANTEK, Instituto de Nanociencia de Aragn and Laboratorio de Microscopias Avanzadas, Universidad de Zaragoza, MATS PERSSON, SSRC, University of Liverpool, Liverpool, DAVID SERRATE, Instituto de Nanociencia de Aragn and Laboratorio de Microscopias Avanzadas, Universidad de Zaragoza, CYRUS F. HIRJIBEHDIN, London Center for Nanotechnology, London — Studies of ultrathin polar oxide films have attracted the interest of researchers for a long time due to their different properties compared to bulk materials. However they present several challenges such as the difficulty in the stabilization of the polar surfaces and the limited success in tailoring their properties. Moreover, recently developed Van der Waals materials have shown that the stacking of 2D-layers trigger new collective states thanks to the interaction between layers. Similarly, interface phenomena emerge in polar oxides, like induced ferroelectricity. This represents a promising way for the creation of new materials with customized properties that differ from those of the isolated layers. Here we present a new approach for the fabrication and study of atomically thin insulating films. We show that the properties of insulating polar layers of sodium chloride (NaCl) can be engineered when they are placed on top of a charge modulated template of copper nitride (Cu<sub>2</sub>N). STM studies carried out in ultra-high vacuum and at low temperatures over NaCl/Cu<sub>2</sub>N/Cu(001) show that we are able to build up and stabilize interfaces of polar surface at the limit of one atomic layer showing new properties not present before at the atomic scale.

**9:00AM X47.00006 Role of oxygen diffusion at Ni/Cr<sub>2</sub>O<sub>3</sub> interface in intergranular oxidation of Ni-Cr alloy<sup>1</sup>**, BHARAT MEDASANI, MARIA SUSHKO, DANIEL SCHREIBER, KEVIN ROSSO, STEPHEN BRUEMMER, PACIFIC NORTHWEST NATIONAL LAB — Certain Ni-Cr alloys used in nuclear systems experience intergranular oxidation and stress corrosion cracking when exposed to high-temperature water leading to their degradation and unexpected failure. To develop a mechanistic understanding of grain boundary oxidation processes, we proposed a mesoscale metal alloy oxidation model that combines quantum Density Functional Theory (DFT) with mesoscopic Poisson-Nernst-Planck/classical DFT. This framework encompasses the chemical specificity of elementary diffusion processes and mesoscale reactive dynamics, and allows modeling oxidation processes on experimentally relevant length scales from first principles. As a proof of concept, a preliminary model was previously employed that limited oxygen diffusion pathways to those through the oxide phase and did not allow oxygen diffusion in the alloy or across oxide/alloy interfaces. In this work, we expand the model to include oxygen diffusion pathways along Ni/Cr<sub>2</sub>O<sub>3</sub> interfaces and demonstrate the increasing importance of such pathways for intergranular oxidation of Ni-Cr alloys with high Cr content.

**9:12AM X47.00007 Theoretical Investigation of Supported Ultra-Thin Cobalt/Nickel/Iron/Manganese Oxides**, MICHAL BAJDICH, MAX GARCA MELCHOR, ALEXANDRA VOJVODIC, SLAC National Accelerator Laboratory — In the last decade, a number of experiments have shown that ultra-thin layers of transition metal oxides (TMOs) can be stabilized when interfaced with precious metal supports such as Au(111) and Pt(111) or Ir(100). Moreover, gold supported Co/Ni/Mn-based catalysts have been experimentally proven to exhibit higher oxygen evolution reaction (OER) activities than other metal supported oxide catalysts. However, the synergistic effect of contact with gold support is yet to be fully understood. In this talk, I will report on our recent investigation of thermodynamic stability and and high water reactivity of ultra-thin cobalt oxide nanoislands supported on Au(111). Furthermore, the stability trends, scaling of the metal-support interaction and charge transfer of several Mn/Fe/Co/Ni supported oxides on all FCC(111) metals will be analyzed. The type and role of different edge sites for the OER activity of these nanoislands will be discussed.

**9:24AM X47.00008 A DFT study of metastable *h*-WO<sub>3</sub> surfaces**, YONGHYUK LEE, TAEHUN LEE, WOOSUN JANG, ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University — Polycrystalline WO<sub>3</sub> has gained considerable interest as an efficient oxide material for photoreactions [1], and its surface-dependent catalytic properties have been exploited by shape-control crystal engineering of this oxide for photochemistry reactions e.g. water-splitting. Recently, hexagonal single crystal WO<sub>3</sub> nanorods with dominant (0001) and (11 $\bar{2}$ 0) facets were synthesized and these nanorods are found to be highly effective photoanode [2] However, the precise local atomic structures and surface orientations of this metastable *h*-WO<sub>3</sub>, which are important for understanding surface-dependent photoreactions, are not well studied. In this work, using first-principles density-functional theory (DFT), we consider the various orientations and terminations of *h*-WO<sub>3</sub> surfaces and address the predicted nanomorphologies under corresponding experimental conditions based on the DFT-derived Gibbs-Wulff polyhedrons. We provide a microscopic perspective for its potential applications in photoreactions by studying the surface energetics and electronic structure. [1] Y. Ping and G. Galli, *J. Phys. Chem. C* **118**, 6019 (2014); [2] P. M. Rao *et al.*, *Nano Lett.* **14**, 1099 (2014)

**9:36AM X47.00009 Structural and electrical characterization of NbO<sub>2</sub> vertical devices grown on TiN coated SiO<sub>2</sub>/Si substrate<sup>1</sup>**, TOYANATH JOSHI, PAVEL BORISOV, West Virginia University, Morgantown, WV, DAVID LEDERMAN, West Virginia University, Morgantown, WV, University of California, Santa Cruz, CA — Due to its relatively high MIT temperature (1081 K) and current-controlled negative differential resistance, NbO<sub>2</sub> is a robust candidate for memory devices and electrical switching applications. In this work, we present in-depth analysis of NbO<sub>2</sub> thin film vertical devices grown on TiN coated SiO<sub>2</sub>/Si substrates using pulsed laser deposition (PLD). Two of the films grown in 1 mTorr and 10 mTorr O<sub>2</sub>/Ar (~7% O<sub>2</sub>) mixed growth pressures were studied. The formation of NbO<sub>2</sub> phase was confirmed by Grazing Incidence X-ray Diffractometry (GIXRD), X-ray Photoelectron Spectroscopy (XPS) and current vs. voltage measurements. A probe station tip (tip size ~2  $\mu$ m) or conductive AFM tip was used as a top and TiN bottom layer was used as a bottom contact. Device conductivity showed film thickness and contact size dependence. Current pulse measurements, performed in response to applied triangular voltage pulses, showed a non-linear threshold switching behavior for voltage pulse durations of ~100 ns and above. Self-sustained current oscillations were analyzed in terms of defect density presented in the film.

<sup>1</sup>Supported by FAME (sponsored by MARCO and DARPA, Contract 2013-MA-2382), WV Higher Education Policy Commission grant (HEPC.dsr.12.29), and WVU SRF. We also thank S. Kramer from Micron for providing the TiN-coated Si substrates.

**9:48AM X47.00010 Multiferroic fluoride BaCoF<sub>4</sub> Thin Films Grown Via Molecular Beam Epitaxy<sup>1</sup>**, PAVEL BORISOV, TRENT JOHNSON, West Virginia University, CAMILO GARCA-CASTRO, Universite de Liege, Belgium, AMIT KC, DUSTIN SCHRECONGOST, CHENG CEN, ALDO ROMERO, West Virginia University, DAVID LEDERMAN, West Virginia University; University of California, Santa Cruz — Multiferroic materials exhibit exciting physics related to the simultaneous presence of multiple long-range orders, in many cases consisting of antiferromagnetic (AF) and ferroelectric (FE) orderings. In order to provide a new, promising route for fluoride-based multiferroic material engineering, we grew multiferroic fluoride BaCoF<sub>4</sub> in thin film form on Al<sub>2</sub>O<sub>3</sub> (0001) substrates by molecular beam epitaxy. The films grow with the orthorhombic b-axis out-of-plane and with three in-plane structural twin domains along the polar c-axis directions. The FE ordering in thin films was verified by FE remanent hysteresis loops measurements at T = 14 K and by room temperature piezoresponse force microscopy (PFM). An AF behavior was found below Neel temperature T<sub>N</sub> ~ 80 K, which is in agreement with the bulk properties. At lower temperatures two additional magnetic phase transitions at 19 K and 41 K were found. First-principles calculations demonstrated that the growth strain applied to the bulk BaCoF<sub>4</sub> indeed favors two canted spin orders, along the b- and a-axes, respectively, in addition to the main AF spin order along the c-axis.

<sup>1</sup>supported by FAME (Contract 2013-MA-2382), WV Research Challenge Grant (HEPC.dsr.12.29), and DMREF-NSF 1434897

**10:00AM X47.00011 Transport Physics in Thin-Film Oxides: From Capacitors to Memristors<sup>1</sup>**, BRIAN TIERNEY, HAROLD HJALMARSON, MICHAEL MCLAIN, DAVID HUGHART, MATTHEW MARINELLA, DENIS MAMALUY, XUJIAO GAO, Sandia Natl Labs — A physics-based model of transport mechanisms in metal-insulator-metal (M-I-M) systems is developed to explain transport through the metal-oxide interfaces and in the bulk of the insulating oxide. Interface tunneling, such as that between the metal to the conduction band or bound defect states, is accounted for by a WKB model. Our model also incorporates the evolution of the associated oxide defect chemistry. Continuum calculations are performed for both Ta<sub>2</sub>O<sub>5</sub> M-I-M capacitors and TaO<sub>x</sub>-Based M-I-M memristors, as both devices are structurally similar and can be characterized by a common set of transport mechanisms. However, due to the electroforming process for which memristors are subjected, different transport mechanisms dominate for each type of device. Also, the effects of pulsed ionizing radiation from an external source are included in the model. It is shown that such radiation can be used to probe whether the M-I-M system is in a capacitive or memristive state. <sup>1</sup>Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:12AM X47.00012 The effect of Si impurities on the effective work function at TiN/tetragonal-HfO<sub>2</sub> interface.**, GEUN-MYEONG KIM, YOUNG JUN OH, KEE JOO CHANG, Department of Physics, KAIST — The TiN/monoclinic-HfO<sub>2</sub> (TiN/m-HfO<sub>2</sub>) interface structure is widely used in high-k/metal gate stacks of metal-oxide-semiconductor field-effect transistors. As the device size is continuously reduced, high-k dielectric materials are required to reduce the gate leakage current. The tetragonal HfO<sub>2</sub> (t-HfO<sub>2</sub>) is beneficial in high-k/metal gate stacks because its dielectric constant is much higher than that of m-HfO<sub>2</sub>. It is known that Si doping can reduce the crystalline temperature of t-HfO<sub>2</sub>. However, there is a lack of studies for the effect of Si impurities at TiN/t-HfO<sub>2</sub> interface. Here we perform first-principles density functional calculations to investigate the effect of Si impurities on the work function at TiN/t-HfO<sub>2</sub> interface. It is energetically favorable for Si atoms to substitute for interface N atoms. The change of interface bonds by the Si atoms enhances the effective work function(EWF). On the other hand, when the Si atoms replace the N atoms in bulk region, the EWF is almost unchanged. Our results indicate that the Si impurities incorporated in the interface region mostly affect the work function at TiN/t-HfO<sub>2</sub> interface.

**10:24AM X47.00013 Absolute surface energy calculations of Wurtzite (0001)/(000-1): a study of ZnO and GaN<sup>1</sup>**, JINGZHAO ZHANG, YIOU ZHANG, KINFAT TSE, BEI DENG, Chinese Univ of Hong Kong, HU XU, South University of Science and Technology of China, JUNYI ZHU, Chinese Univ of Hong Kong — The accurate absolute surface energies of (0001)/(000-1) surfaces of wurtzite structures are crucial in determining the thin film growth mode of important energy materials. However, the surface energies still remain to be solved due to the intrinsic difficulty of calculating dangling bond energy of asymmetrically bonded surface atoms. We used a pseudo-hydrogen passivation method to estimate the dangling bond energy and calculate the polar surfaces of ZnO and GaN. The calculations were based on the pseudo chemical potentials obtained from a set of tetrahedral clusters or simple pseudo-molecules, using density functional theory approaches, for both GGA and HSE. And the surface energies of (0001)/(000-1) surfaces of wurtzite ZnO and GaN we obtained showed relatively high self-consistencies. A wedge structure calculation with a new bottom surface passivation scheme of group I and group VII elements was also proposed and performed to show converged absolute surface energy of wurtzite ZnO polar surfaces.

**10:36AM X47.00014 The Effect of Gate -Bias Stress and Light illumination on the performance of ZnO Thin-Film Field Effect Transistors<sup>1</sup>**, PRAKASH GAJUREL, Department of Physics and Astronomy, West Virginia University, MICHAEL ALDRIDGE, Department of Biology, West Virginia University, YURI GLINKA, PAVEL BORISOV, Department of Physics and Astronomy, West Virginia University, KEVIN DALY, Department of Biology, West Virginia University, DAVID LEDERMAN, Department of Physics and Astronomy, West Virginia University, Department of Physics, University of California, Santa Cruz, 95064 — We have investigated the stability of ZnO thin film field effect transistors (TFETs) grown on Si/SiO<sub>2</sub> under the application of positive gate bias stress and light illumination at room temperature. A gate voltage applied over a few seconds in ZnO TFET devices is known to induce a positive shift in the threshold voltage as a consequence of charge trapping at or near the conducting channel / insulator interface. This bias stress remains unchanged even if a negative gate voltage stress is applied. A negative shift of the transfer curve for stressed devices was achieved while exposing the transistor to light in the presence of a small source voltage. The negative shift in threshold voltage depended on the photon energy and exposure time. Our experimental results indicate that the traps responsible for the stress are approximately 2.1 eV below the bottom of the ZnO conduction band with an energy distribution width of 3.40 eV. Stressed devices recovered their original characteristics with the photon energy of UV light (365 nm, 3.6 mW/cm<sup>2</sup>) at room temperature within 1818s. This approach could be used to reset stressed TFETs using light sources.

**10:48AM X47.00015 Tuning electrical transport in rare-earth delta-doped SrTiO<sub>3</sub> epitaxially grown on Si (001)**, KAMYAR AHMADI MAJLAN, MOHAMMADREZA JAHANGIR MOGHADAM, University of Texas at Arlington, XUAN SHEN, Brookhaven National Laboratory, RICKY HENSLEY, PATRICK CONLIN, ZHENG HUI LIM, University of Texas at Arlington, DONG SU, Brookhaven National Laboratory, JOSEPH H. NGAI, University of Texas at Arlington — The monolithic integration of crystalline oxides on semiconductors provides a pathway to integrate new functionalities into semiconductor devices. In particular, strongly correlated oxides that exhibit metal-insulator transitions are technologically important due to their potential use in a variety of applications. Here we present transport characteristics of strongly correlated, ultra-thin layers of Re<sub>x</sub>Sr<sub>1-x</sub>TiO<sub>3</sub> (Re = rare earth) that have been epitaxially imbedded, or “delta-doped”, into SrTiO<sub>3</sub> grown on Si(100). We will discuss how the interplay of dimensionality, rare-earth composition, and strain affects the transport characteristics and metal-insulator behavior of such correlated oxides.

**11:00AM X47.00016 Sand effects on thermal barrier coatings for gas turbine engines.**<sup>1</sup>, MICHAEL WALOCK, BLAKE BARNETT, ANINDYA GHOSHAL, MUTHUVEL MURUGAN, JEFFREY SWAB, MARC PEPI, DAVID HOPKINS, GEORGE GAZONAS, US Army Rsch Lab - Aberdeen, KEVIN KERNER, US Army Aviation and Missile Research Development and Engineering Center — Accumulation and infiltration of molten/ semi-molten sand and subsequent formation of calcia-magnesia-alumina-silicate (CMAS) deposits in gas turbine engines continues to be a significant problem for aviation assets. This complex problem is compounded by the large variations in the composition, size, and topology of natural sands, gas generator turbine temperatures, thermal barrier coating properties, and the incoming particulate's momentum. In order to simplify the materials testing process, significant time and resources have been spent in the development of synthetic sand mixtures. However, there is debate whether these mixtures accurately mimic the damage observed in field-returned engines. With this study, we provide a direct comparison of CMAS deposits from both natural and synthetic sands. Using spray deposition techniques, 7% yttria-stabilized zirconia coatings are deposited onto bond-coated, Ni-superalloy discs. Each sample is coated with a sand slurry, either natural or synthetic, and exposed to a high temperature flame for 1 hour. Test samples are characterized before and after flame exposure. In addition, the test samples will be compared to field-returned equipment.

**Friday, March 18, 2016 8:00AM - 11:00AM –**  
**Session X48 GQI: Scalable Hardware for Superconducting Qubits** 349 - William Oliver, Massachusetts Institute of Technology, Lincoln Laboratory

**8:00AM X48.00001 High-Q 3D coaxial resonators for cavity QED**, TAEKWAN YOON, JOHN C OWENS, RAVI NAIK, AMAN LACHAPPELLE, RUICHAO MA, JONATHAN SIMON, DAVID I SCHUSTER, Univ of Chicago — Three-dimensional microwave resonators provide an alternative approach to transmission-line resonators used in most current circuit QED experiments [1]. Their large mode volume greatly reduces the surface dielectric losses that limits the coherence of superconducting circuits, and the well-isolated and controlled cavity modes further suppress coupling to the environment. In this work, we focus on unibody 3D coaxial cavities which are only evanescently coupled and free from losses due to metal-metal interfaces, allowing us to reach extremely high quality-factors. We achieve quality-factor of up to 170 million using 4N6 Aluminum at superconducting temperatures, corresponding to an energy ringdown time of ~4ms. We extend our methods to other materials including Niobium, NbTi, and copper coated with Tin-Lead solder. These cavities can be further explored to study their properties under magnetic field or upon coupling to superconducting Josephson junction qubits, e.g. 3D transmon qubits. Such 3D cavity QED system can be used for quantum information applications, or quantum simulation in coupled cavity arrays. References: [1] Matthew Reagor et al., A quantum memory with near-millisecond coherence in circuit QED. arXiv: 1508.05882 (2015)

**8:12AM X48.00002 Three-Dimensional Architecture at Chip Level for Large-Scale-Integration of Superconducting Quantum Electronic Devices**, MARTIN GÖPPL, Sensirion AG, PHILIPP KURPIERS, ANDREAS WALL-RAFF, ETH Zurich — We propose a novel way to realize three-dimensional circuit QED systems at chip level. System components such as qubits, transmission lines, capacitors, inductors or cross-overs can be implemented as suspended, electromagnetically shielded and optionally, as hermetically sealed structures. Compared to known state-of-the-art devices, volumes of dielectrics penetrated by electromagnetic fields can be drastically reduced. Our intention is to harness process technologies for very-large-scale-integration, reliably applied and improved over decades in micro-sensor- and semiconductor industry, for the realization of highly integrated circuit QED systems. Process capabilities are demonstrated by fabricating first exploratory devices using the back-end-of-line part of a commercial 180 nm CMOS foundry process in conjunction with HF vapor phase release etching.

**8:24AM X48.00003 3D Integration for Superconducting Qubits**, DANNA ROSENBERG, DONNA-RUTH YOST, RABINDRA DAS, DAVID HOVER, LIVIA RACZ, STEVEN WEBER, JONILYN YODER, ANDREW KERMAN, MIT Lincoln Laboratory, WILLIAM OLIVER, MIT Lincoln Laboratory; Research Laboratory of Electronics, MIT — As the field of superconducting quantum computing advances from the few-qubit stage to large-scale fault-tolerant devices, scalability requirements will necessitate the use of standard 3D packaging and integration processes. While the field of 3D integration is well-developed, relatively little work has been performed to determine the compatibility of the associated processes with superconducting qubits. Qubit coherence time could potentially be affected by required process steps or by the proximity of an interposer that could introduce extra sources of charge or flux noise. As a first step towards a large-scale quantum information processor, we have used a flip-chip process to bond a chip with flux qubits to an interposer containing structures for qubit readout and control. We will present data on the effect of the presence of the interposer on qubit coherence time for various qubit-chip-interposer spacings and discuss the implications for integrated multi-qubit devices. This research was funded by the ODNI and IARPA under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

**8:36AM X48.00004 Extensible circuit QED processor architecture with vertical I/O**<sup>1</sup>, ALESSANDRO BRUNO, STEFANO POLETTTO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, NADIA HAIDER, QuTech, Delft University of Technology, and Netherlands Organisation for Applied Scientific Research (TNO), Delft, The Netherlands, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands — Achieving quantum fault tolerance in an extensible architecture is an outstanding challenge across experimental quantum computing platforms today. Traditionally, circuit QED processors have millimeter dimensions and lateral coupling for all input/output (I/O) signals, precluding the increase in qubit numbers beyond ~10. We present a scalable footprint for circuit QED processors with vertically coupled I/O. Our demonstration using centimeter scale chips can accommodate the ~50 qubits needed in next-generation processors targeting the experimental demonstration of quantum fault tolerance.

**8:48AM X48.00005 The Quantum Socket: Wiring for Superconducting Qubits - Part 1**, T.G. MCCONKEY, J.H. BEJANIN, J.R. RINEHART, J.D. BATEMAN, C.T. EARNEST, C.H. MCRAE, Y. ROHANIZADEGAN, D. SHIRI, M. MARIANTONI, University of Waterloo, B. PENAVA, P. BREUL, S. ROYAK, M. ZAPATKA, Ingun, A.G. FOWLER, Google Inc. — Quantum systems with ten superconducting quantum bits (qubits) have been realized, making it possible to show basic quantum error correction (QEC) algorithms. However, a truly scalable architecture has not been developed yet. QEC requires a two-dimensional array of qubits, restricting any interconnection to external classical systems to the third axis. In this talk, we introduce an interconnect solution for solid-state qubits: The quantum socket. The quantum socket employs three-dimensional wires and makes it possible to connect classical electronics with quantum circuits more densely and accurately than methods based on wire bonding. The three-dimensional wires are based on spring-loaded pins engineered to insure compatibility with quantum computing applications. Extensive design work and machining was required, with focus on material quality to prevent magnetic impurities. Microwave simulations were undertaken to optimize the design, focusing on the interface between the micro-connector and an on-chip coplanar waveguide pad. Simulations revealed good performance from DC to 10 GHz and were later confirmed against experimental measurements.

**9:00AM X48.00006 The Quantum Socket: Wiring for Superconducting Qubits - Part 2** , J.H. BEJANIN, T.G. MCCONKEY, J.R. RINEHART, J.D. BATEMAN, C.T. EARNEST, C.H. MCRAE, Y. ROHANIZADEGAN, D. SHIRI, M. MARIANTONI, University of Waterloo, B. PENAVA, P. BREUL, S. ROYAK, M. ZAPATKA, Ingun, A.G. FOWLER, Google Inc. — Quantum computing research has reached a level of maturity where quantum error correction (QEC) codes can be executed on linear arrays of superconducting quantum bits (qubits). A truly scalable quantum computing architecture, however, based on practical QEC algorithms, requires nearest neighbor interaction between qubits on a two-dimensional array. Such an arrangement is not possible with techniques that rely on wire bonding. To address this issue, we have developed the quantum socket, a device based on three-dimensional wires that enables the control of superconducting qubits on a two-dimensional grid. In this talk, we present experimental results characterizing this type of wiring. We will show that the quantum socket performs exceptionally well for the transmission and reflection of microwave signals up to 10 GHz, while minimizing crosstalk between adjacent wires. Under realistic conditions, we measured an  $S_{21}$  of -5 dB at 6 GHz and an average crosstalk of -60 dB. We also describe time domain reflectometry results and arbitrary pulse transmission tests, showing that the quantum socket can be used to control superconducting qubits.

**9:12AM X48.00007 The Quantum Socket: Wiring for Superconducting Qubits - Part 3** , M. MARIANTONI, J.H. BEJANIN, T.G. MCCONKEY, J.R. RINEHART, J.D. BATEMAN, C.T. EARNEST, C.H. MCRAE, Y. ROHANIZADEGAN, D. SHIRI, University of Waterloo, B. PENAVA, P. BREUL, S. ROYAK, M. ZAPATKA, Ingun, A.G. FOWLER, Google Inc. — The implementation of a quantum computer requires quantum error correction codes, which allow to correct errors occurring on physical quantum bits (qubits). Ensemble of physical qubits will be grouped to form a logical qubit with a lower error rate. Reaching low error rates will necessitate a large number of physical qubits. Thus, a scalable qubit architecture must be developed. Superconducting qubits have been used to realize error correction. However, a truly scalable qubit architecture has yet to be demonstrated. A critical step towards scalability is the realization of a wiring method that allows to address qubits densely and accurately. A quantum socket that serves this purpose has been designed and tested at microwave frequencies. In this talk, we show results where the socket is used at millikelvin temperatures to measure an on-chip superconducting resonator. The control electronics is another fundamental element for scalability. We will present a proposal based on the quantum socket to interconnect a classical control hardware to a superconducting qubit hardware, where both are operated at millikelvin temperatures.

**9:24AM X48.00008 Development of superconducting bonding for multilayer microwave integrated quantum circuits** , TERESA BRECHT, CHRISTOPHER AXLINE, YIWEN CHU, WOLFGANG PFAFF, LUIGI FRUNZIO, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University — Future quantum computers are likely to take the shape of multilayer microwave integrated quantum circuits.[1] The proposed physical architecture retains the superb coherence of 3D structures while achieving superior scalability and compatibility with planar circuitry and integrated readout electronics. This hardware platform utilizes known techniques of bulk etching in silicon wafers and requires metallic bonding of superconducting materials. Superconducting wafer bonding is a crucial tool in need of development. Whether micromachined in wafers or traditionally machined in bulk metal, 3D cavities typically possess a seam where two parts meet. Ideally, this seam consists of a perfect superconducting bond. Pursuing this goal, we have developed a new understanding of seams as a loss mechanism that is applicable to 3D cavities in general.[2] We present quality factor measurements of both 3D cavities and 2D stripline resonators to study the losses of superconducting bonds. **9:36AM X48.00009 High speed on-chip current measurement using a low-Q tunable LC resonator** , BROOKS CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, C. NEILL, P.J.J. O'MALLEY, C. QUINTANA, A. VAINSENER, J. WENNER, UC Santa Barbara, R. BARENDTS, Y. CHEN, A. FOWLER, E. JEFFREY, J. KELLY, E. LUCERO, A. MEGRANT, J. MUTUS, M. NEELEY, P. ROUSHAN, D. SANK, Google, Santa Barbara, T.C. WHITE, JOHN M. MARTINIS, UC Santa Barbara and Google, Santa Barbara — Superconducting quantum computing technology requires precise high frequency analog waveforms to perform single and multi-qubit gates. Due to signal path irregularities, gates are tuned-up by perturbing the drive signal until qubit state populations indicate the desired gate function. A more direct approach is to measure the effect of circuit imperfections by sampling control waveforms directly, as seen by the qubits. We proceed by measuring the resonant frequency shift of a capacitively shunted SQUID and converting the control waveform to DC flux applied to the SQUID. By measuring the reflected phase of a CW tone applied to this resonant circuit while applying the resonance-shifting flux pulse, we are able to reconstruct the current waveform of the input pulse at the SQUID loop. This device's geometry is the same as the z-control lines used in qubit experiments to control the qubit frequency. I will present this method of on-chip waveform sampling for superconducting circuits in addition to proof of concept data. This technique opens the door for improved gate bring up and a deeper understanding of qubit control as well as the circuit parasitics that deform these waveforms.

**9:48AM X48.00010 Maintaining Qubit Coherence in the face of Increased Superconducting Circuit Complexity** , DAVID HOVER, STEVE WEBER, DANNA ROSENBERG, GABRIEL SAMACH, ADAM SEARS, JEFFREY BIRENBAUM, WAYNE WOODS, JONILYN YODER, LIVIA RACZ, JAMIE KERMAN, MIT Lincoln Laboratory, WILLIAM D. OLIVER, MIT Lincoln Laboratory; Research Laboratory of Electronics, Massachusetts Institute of Technology — Maintaining qubit coherence in the face of increased superconducting circuit complexity is a challenge when designing an extensible quantum computing architecture. We consider this challenge in the context of inductively coupled, long-lived, capacitively-shunted flux qubits. Specifically, we discuss our efforts to mitigate the effects of radiation loss, parasitic chip-modes, cross-coupling, and Purcell decay. Our approach employs numerical modeling of the ideal Hamiltonian and electromagnetic analysis of the circuit, both of which are independently shown to be consistent with experimental results. This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

**10:00AM X48.00011 Time Reversal Symmetry Breaking Microwave Resonators** , JOHN C OWENS, AMAN LACHAPPELLE, TAEKWAN YOON, RUICHAO MA, DAVID SCHUSTER, JONATHAN SIMON, University of Chicago — In this talk we present our work towards realizing high Q, superconducting circulators to be employed in topological circuit QED lattices. These circulators generate gauge fields that produce protected edge states. We couple magnon excitations in spheres of the ferrite Yttrium Iron Garnet (YIG) to microwave cavity fields in order to break the degeneracy between modes that precess with different handedness. The YIG sphere only couples strongly (1 GHz) to cavity modes that precess with the same handedness. We tune the YIG sphere into resonance with degenerate cavity modes to shift only the frequency of the modes with the same handedness, leaving the uncoupled mode at its original frequency. Since this mode is dark to the YIG excitation, its quality factor is dependent only on the characteristics of the cavity. We make the cavities out of the Type II superconductor Niobium Titanium so that we achieve high quality factors while also tolerating the large magnetic fields acting on the YIG spheres within the cavities. These cavities can be evanescently coupled to create topologically nontrivial lattices. Photon-photon interactions can then be added via couplings to qubits to create fractional quantum hall states for microwave photons.

**10:12AM X48.00012 On Chip Josephson Junction Microwave Switch** , OFER NAAMAN, MOHAMED ABU-TALEB, CHRIS KIRBY, MICHAEL RENNIE, Northrop Grumman Systems Corp. — We report on the design and measurement of a reflective single-pole single-throw microwave switch based on a superconducting circuit containing a single Josephson junction. The device has no internal power dissipation, minimal insertion loss, and is controlled by  $\Phi_0$ -level base-band signals. The data demonstrates the device operation with 2 GHz instantaneous bandwidth centered at 10 GHz and better than 20 dB on/off ratio for input powers up to -100 dBm.

**10:24AM X48.00013 Realization of an on-chip superconducting microwave switch**, MAREK PECHAL, SIMONE GASPARINETTI, MINTU MONDAL, MARKUS OPPLIGER, ANDREAS WALLRAFF, ETH Zurich — As state-of-the-art superconducting quantum devices get increasingly complex, they require a growing number of control and detection channels. On-chip routing and multiplexing of signals presents a way to realize these without requiring an unrealistically large number of microwave lines. The ability to route signals on a chip will also be a useful tool for fast in-situ characterization of superconducting devices. Here, we describe and experimentally demonstrate a superconducting on-chip microwave switch which can be integrated with current superconducting quantum circuits. The device is based on interference effects and is in principle lossless, making it well-suited for operation in dilution cryostats and for routing of signals at the single quantum level with near-unity efficiency. The first proof-of-principle device has a bandwidth of 150 MHz, a 1 dB compression point of  $-80$  dBm and turn-on/off times on the order of 5 ns. On/off power ratios reach values of approximately 30 dB. We expect that our device will find use in (de)multiplexing of control and readout in superconducting circuits and routing of microwave fields in quantum optical experiments and quantum communication applications.

**10:36AM X48.00014 Coherent control of a linear microwave cavity via single flux quantum pulses**, SHAOJIANG ZHU, GUILHEM RIBEILL, TED THORBECK, EDWARD LEONARD, MAXIM VAVILOV, Department of Physics, University of Wisconsin Madison, BRITTON PLOURDE, Department of Physics, Syracuse University, ROBERT MCDERMOTT, Department of Physics, University of Wisconsin Madison — Classical Josephson digital logic based on single flux quantum (SFQ) pulses offers a path to robust, low-latency control of a large-scale quantum processor. Here we describe the coherent control of a linear superconducting cavity by direct excitation via SFQ pulses. Resonant trains of SFQ pulses are capacitively coupled to a thin-film coplanar waveguide cavity. We examine the resulting cavity states as a function of subharmonic drive and temperature. In addition, we describe first steps toward the coherent control of a superconducting qubit with SFQ pulses.

**10:48AM X48.00015 Development of Integrated Single Flux Quantum - Superconducting Qubit Circuits**, EDWARD LEONARD JR., TED THORBECK, SHAOJIANG ZHU, Univ of Wisconsin, Madison, CALEB HOWINGTON, MATTHEW HUTCHINGS, JJ NELSON, BRITTON PLOURDE, Syracuse University, ROBERT MCDERMOTT, Univ of Wisconsin, Madison — Significant theoretical and experimental progress has been made in recent years towards a scalable superconducting quantum circuit architecture. Here we present a first attempt to integrate classical control elements from the single flux quantum (SFQ) digital logic family with a superconducting transmon qubit on a single chip. The SFQ driving circuit is fabricated in a six-layer high- $J_c$  Nb/Al-AIOx/Nb junction process while the transmon qubit is subsequently formed using submicron Al-AIOx-Al junctions grown by double-angle evaporation. We investigate sources of decoherence associated with the more complex fabrication process and describe first attempts to perform coherent qubit manipulations using resonant trains of SFQ pulses.

## Friday, March 18, 2016 8:00AM - 11:00AM –

**Session X50 DAMOP GQI: Quantum Information with Cold Atoms and Ions** Hilton Baltimore Holiday Ballroom 1 - Zhexuan Gong, Joint Quantum Institute, University of Maryland

**8:00AM X50.00001 Entanglement area law for long-range interacting systems**, ZHEXUAN GONG, MICHAEL FOSS-FEIG, Joint Quantum Institute, FERNANDO G.S.L. BRANDAO, Microsoft Research, ALEXEY V. GORSHKOV, Joint Quantum Institute — Area laws for entanglement provide crucial insight into the low-energy behavior of many-body systems and are intimately connected to the efficiency of classical computational methods. For 1D systems, an area law was rigorously proven for ground states of gapped Hamiltonians with local interactions and for states with exponentially decaying correlations. In the presence of long-range interactions, the proof of an area law for gapped ground states becomes much more challenging because long-range interactions can change the effective dimensionality of the system and introduce correlations decaying slower than an exponential. Based on recent theoretical advances that reveal strong remnants of locality in quenched systems with power-law decaying interactions, we prove an area law for a large class of gapped Hamiltonians with long-range interactions. As an intermediate step, we prove tight bounds on the decay of ground-state correlations.

**8:12AM X50.00002 A System For High Flexibility Entangling Gates With Trapped Ions**, ALISTAIR MILNE, CLAIRE EDMUNDS, SANDEEP MAVADIA, TODD GREEN, MICHAEL BIERCUK, Univ of Sydney — Trapped ion qubits may be entangled via coupling to shared modes of motion using spin-dependent forces generated by optical fields. Residual qubit-motional coupling at the conclusion of the entangling operation is the dominant source of infidelity in this type of gate. For synchronously entangling increasing numbers of ions, longer gate times are required to minimise this residual coupling. We present a scheme that enables the state of each qubit to be simultaneously decoupled from all motional modes in an arbitrarily chosen gate time, increasing the gate fidelity and scalability. This is achieved by implementing discrete phase shifts in the optical field moderating the entangling operation. We describe an experimental system based on trapped ytterbium ions and demonstrate this scheme for two-qubit entangling gates on ytterbium ion pairs.

**8:24AM X50.00003 Phase-modulated spin-motional decoupling with trapped ions**, CLAIRE EDMUNDS, ALISTAIR MILNE, SANDEEP MAVADIA, TODD GREEN, MICHAEL BIERCUK, Univ of Sydney — We present a technique to minimize residual spin-motional entanglement after a phonon-mediated entangling gate in trapped  $^{171}\text{Yb}^+$  ion qubits. Phonon-mediated gates, such as the Mølmer-Sørensen gate, engineer spin-spin entanglement by coupling the qubits to their collective modes of motion. Consequently, a major experimental limitation is residual motional entanglement at the conclusion of the gate, resulting in a degradation of the final spin state purity. Our work utilizes phase-modulated pulse sequences to decouple the qubits from multiple motional modes simultaneously at a variable gate time. In addition, we extend this technique to the suppression of time-dependent noise using concatenated gate sequences, which allows for the recovery of a higher purity spin state. Using a single, experimentally controllable modulation parameter we are able to achieve more optimal quantum control in these gate sequences.

**8:36AM X50.00004 The effect of electrode surface roughness on the motional heating rate of electromagnetic trapped ions**, KUANG-YU LIN, GUANG HAO LOW, ISAAC CHUANG, Massachusetts Inst of Tech-MIT — Electric field noise is a major source of motional heating in trapped ion quantum computation. While it is well known that this noise is influenced by trap electrode geometry in patch potential and surface adsorbate models, this has only been analyzed for smooth surfaces. We investigate the dependence of electric field noise on the roughness of surface electrodes by deriving a Greens function describing this roughness, and evaluating its effects on adsorbate-surface binding energies. At cryogenic temperature, surface roughness is found to exponentially enhance or suppress heating rate, depending on the density distribution of surface adsorbates. Our result suggests that heating rates can be tuned over orders of magnitude by careful engineering of electrode surface profiles.

**8:48AM X50.00005 Universal critical phenomena of the cloud  $\rightarrow$  crystal phase transition in the Paul trap: Powerlaws**, DANIEL WEISS, YUNSEONG NAM, REINHOLD BLMEL, Wesleyan University —  $N$  charged particles, simultaneously stored in a radio-frequency (rf) Paul trap, exhibit deterministic heating. Depending on the damping ( $\gamma$ ) imparted to the system, these particles can exist in multiple phases, the most commonly found being the cloud and crystal phases. With a small  $\gamma$ , the particles exhibit gas-like behavior, where the heating and cooling equilibrate and a stable cloud results. For larger  $\gamma$ , the damping overcomes the heating and the particles are forced into the crystalline state. We explore the cloud  $\rightarrow$  crystal transition as a critical phenomenon. We find that the transition occurs at a critical value  $\gamma_c$  of the damping constant  $\gamma$ . We find that as a function of  $N$ ,  $\gamma_c$  scales approximately like an iterated log law. We also present a universal power law,  $\bar{\tau}_m \sim (\gamma - \gamma_c)^{-\beta}$ ,  $\gamma > \gamma_c$ ,  $\beta > 0$ , independent of both  $N$  and the Paul trap parameter  $a$ , depending only on the Paul trap parameter  $q$ , that describes the number of cycles necessary for the system to crystallize as a function of  $\gamma - \gamma_c$ .

**9:00AM X50.00006 Ion-crystal metamorphoses in the Paul trap**, VARUN URSEKAR, YUN SEONG NAM, REINHOLD BLMEL, Wesleyan Univ — We construct a generalized time-independent pseudo potential to describe the crystal morphologies and transitions between them for a three-ion Coulomb-interacting system in a Paul trap. The derivation of this pseudo potential extends a similar method that was already successfully constructed for the two-ion case to the case of three ions. Our method is based on keeping second-order micro-motion terms in the derivation of the pseudo potential. The resulting improved pseudo potential predicts ion-crystal morphologies that are corroborated by numerical simulations but are not captured by the standard pseudo potential. We provide a general method for extending this improved pseudo potential to a system of  $N$  Coulomb-interacting ions in a Paul trap.

**9:12AM X50.00007 Storage of multiple single-photon pulses emitted from a quantum dot in a solid-state quantum memory.**, JIAN-SHUN TANG, ZONG-QUAN ZHOU, YI-TAO WANG, CHUAN-FENG LI, GUANG-CAN GUO, University of Science and Technology of China — Quantum repeaters are critical components for distributing entanglement over long distances in presence of unavoidable optical losses during transmission. Stimulated by Duan-Lukin-Cirac-Zoller protocol, many improved quantum-repeater protocols based on quantum memories have been proposed, which commonly focus on the entanglement-distribution rate. Among these protocols, the elimination of multi-photons (multi-photon-pairs) and the use of multimode quantum memory are demonstrated to have the ability to greatly improve the entanglement-distribution rate. Here, we demonstrate the storage of deterministic single photons emitted from a quantum dot in a polarization-maintaining solid-state quantum memory; in addition, multi-temporal-mode memory with 1, 20 and 100 narrow single-photon pulses is also demonstrated. Multi-photons are eliminated, and only one photon at most is contained in each pulse. Moreover, the solid-state properties of both sub-systems make this configuration more stable and easier to be scalable. Our work will be helpful in the construction of efficient quantum repeaters based on all-solid-state devices.

**9:24AM X50.00008 Towards the coupling of single photons from dye molecules to a photonic waveguide.**, CLAUDIO POLISSENI, KIANG WEI KHO, KYLE MAJOR, SAMUELE GRANDI, SEBASTIEN BOISSER, JAESUK HWANG, ALEX CLARK, EDWARD HINDS, Imperial College London — Single photons are very attractive for quantum information processing given their long coherence time and their ability to carry information in many degrees of freedom. A current challenge is the efficient generation of single photons in a photonic chip in order to scale up the complexity of quantum operations. We have proposed that a dibenzoterrylene (DBT) molecule inside an anthracene (AC) crystal could couple lifetime-limited indistinguishable single photons into a photonic waveguide if deposited in its vicinity. In this talk I describe the recent progress towards the realization of this proposal. A new method has been developed for evaporating AC and DBT to produce crystals that are wide and thin. The crystals are typically several microns across and have remarkably uniform thickness, which we control between 20 and 150 nm. The crystal growth is carried out in a glove bag in order to exclude oxygen, which improves the photostability of the DBT molecules by orders of magnitude. We image the fluorescence of single DBT molecules using confocal microscopy and analyse the polarization of this light to determine the alignment of the molecules. I will report on our efforts to control the alignment of the molecules by aligning the host matrix with the substrate.

**9:36AM X50.00009 Ultra-Low Power Cross-Phase Shifts using Metastable Xenon in a High-Finesse Cavity**<sup>1</sup>, GARRETT HICKMAN, TODD PITTMAN, JAMES FRANSON, University of Maryland, Baltimore County — Many important applications in quantum information and quantum communications make use of weak single-photon nonlinearities. These nonlinearities have been produced using a number of methods, but they generally require a complicated experimental setup. We demonstrate a relatively simple system for producing ultra-low power cross-phase modulation, by using metastable xenon as the nonlinear medium within an optical cavity. Using metastable xenon prevents the degradation of optical surfaces which typically occurs with the use of alkali vapors such as rubidium. We produce phase shifts of up to 10 mrad using 4.5-fJ control pulses. We discuss the performance of this system and outline the planned improvements that will allow the cavity to produce single-photon phase shifts on the order of 1 mrad.

**9:48AM X50.00010 Electric-Field Noise above a Thin Dielectric Layer on Metal Electrodes**, MUIR KUMPH, IBM, CARSTEN HENKEL, Universitaet Potsdam, PETER RABL, TU Wien, MICHAEL BROWNNUTT, The University of Hong Kong, RAINER BLATT, University of Innsbruck — The electric-field noise above a layered structure composed of a planar metal electrode covered by a thin dielectric is evaluated and it is found that the dielectric film considerably increases the noise level, in proportion to its thickness. Importantly, even a thin (mono) layer of a low-loss dielectric can enhance the noise level by several orders of magnitude compared to the noise above a bare metal. Close to this layered surface, the power spectral density of the electric field varies with the inverse fourth power of the distance to the surface, rather than with the inverse square, as it would above a bare metal surface. Furthermore, compared to a clean metal, where the noise spectrum does not vary with frequency (in the radio-wave and microwave bands), the dielectric layer can generate electric-field noise which scales in inverse proportion to the frequency. For various realistic scenarios, the noise levels predicted from this model are comparable to those observed in trapped-ion experiments. Thus, these findings are of particular importance for the understanding and mitigation of unwanted heating and decoherence in miniaturized ion traps.

**10:00AM X50.00011 Carving complex many-atom entangled states by single-photon detection**, JIAZHONG HU, WENLAN CHEN, YIHENG DUAN, BORIS BRAVERMAN, HAO ZHANG, VLADAN VULETIC, Massachusetts Inst of Tech-MIT — We propose a versatile and efficient method to generate a broad class of complex entangled states of many atoms via the detection of a single photon. For an atomic ensemble contained in a strongly coupled optical cavity illuminated by weak single- or multi-frequency light, the atom-light interaction entangles the frequency spectrum of a transmitted photon with the collective spin of the atomic ensemble. Simple time-resolved detection of the transmitted photon then projects the atomic ensemble into a desired pure entangled state. This method can be implemented with existing technology, yields high success probability per trials, and can generate complex entangled states such as multicomponent Schrödinger cat states with high fidelity.

### 10:12AM X50.00012 Exponentially small dependence of the Q-function on quantum coherence<sup>1</sup>

, R. A. BREWSTER, J. D. FRANSON, University of Maryland Baltimore County — We show that the Huisimi Q-function has an exponentially small dependence on the relative phase of a Schrodinger cat state, as might be expected from its definition. This raises the question as to whether or not the Q-function provides a complete description of the coherence of quantum states. We calculate the Q-function for a cat state and then invert it by first calculating the Glauber-Sudarshan P-function using a Fourier transform, which can then be used to calculate the state itself. This process is shown to multiply the small phase-dependent terms in the Q-function by an exponentially large factor as needed in order to obtain the original state once again. This exponential factor is strongly degraded by decoherence, such as by amplification of the original state.

### 10:24AM X50.00013 Generation and multi-pass propagation of a squeezed vacuum field in hot Rb vapor<sup>1</sup>

, MI ZHANG, College of William and Mary, R. NICHOLAS LANNING, ZHIHAO XIAO, JONATHAN P. DOWLING, Louisiana State University, IRINA NOVIKOVA, EUGENIY E. MIKHAILOV, College of William and Mary — We study a squeezed vacuum field (with reduced quantum noise level) generated in hot Rb vapor via the polarization self-rotation effect. By propagating the strong laser beam through a vapor cell once, we were able to achieve a noise suppression of 1.5-2 dB below shot noise. Our previous experiments showed that the amount of observed squeezing may be limited by the contamination of the squeezed vacuum output with higher-order spatial modes, also generated inside the cell. Here, we investigate whether or not the squeezing can be improved by making the light interact several times with a less dense atomic ensemble. We carry out a comparison of various conditions, e.g. injection power, atomic density, passing numbers etc., and studied their effect on squeezing level and the spatial structure of the output squeezed vacuum field. We believe(or show) optimization of the conditions can lead to higher achievable squeezing which would be very useful for precision metrology and quantum memory applications.

### 10:36AM X50.00014 Bright Single Photon Emitter in Silicon Carbide

, BENJAMIN LIENHARD, TIM SCHROEDER, SARA MOURADIAN, FLORIAN DOLDE, Massachusetts Inst of Tech-MIT, TOAN TRONG TRAN, IGOR AHARONOVICH, University of Technology Sydney, Australia, DIRK ENGLUND, Massachusetts Inst of Tech-MIT — Efficient, on-demand, and robust single photon emitters are of central importance to many areas of quantum information processing. Over the past 10 years, color centers in solids have emerged as excellent single photon emitters. Color centers in diamond are among the most intensively studied single photon emitters, but recently silicon carbide (SiC) has also been demonstrated to be an excellent host material. In contrast to diamond, SiC is a technologically important material that is widely used in optoelectronics, high power electronics, and microelectromechanical systems. It is commercially available in sizes up to 6 inches and processes for device engineering are well developed. We report on a visible-spectrum single photon emitter in 4H-SiC. The emitter is photostable at both room and low temperatures, and it enables 2 million photons/second from unpatterned bulk SiC. We observe two classes of orthogonally polarized emitters, each of which has parallel absorption and emission dipole orientations. Low temperature measurements reveal a narrow zero phonon line with linewidth  $< 0.1$  nm that accounts for more than 30% of the total photoluminescence spectrum. To our knowledge, this SiC color emitter is the brightest stable room-temperature single photon emitter ever observed.

### 10:48AM X50.00015 Ring-shaped Wigner crystals of trapped ions at the microscale

, HAOKUN LI, ERIK URBAN, CRYSTAL NOEL, ALEXANDER CHUANG, YANG XIA, BORGE HEMMERLING, YUAN WANG, XIANG ZHANG, HARTMUT HAEFFNER, University of California, Berkeley — Trapped ion crystals are ideal platforms to study many-body physics and quantum information processing, with both the internal electronic states and external motional degree-of-freedom controllable at the single quantum level. In contrast to conventional, finite, linear chains of ions, a ring topology exhibiting periodic boundary conditions and rotational symmetry opens up a new directions to diverse topics. However, previous implementations of ion rings result in small aspect ratios ( $< 0.07$ ) of ion-electrode distance to ring diameter, making the rotational symmetry of the ion crystals prone to stray electric fields from imperfections of the trap electrodes, particularly evident at low temperatures. Here, using a new trap design with a 60-fold improvement of this aspect ratio, we demonstrate crystallization of  $^{40}\text{Ca}^+$  ions in a ring with rotational energy barriers comparable to the thermal energy of Doppler laser cooled ion crystals. When further reducing the rotational energy barriers, we observe delocalization of the ion rings. With this result, we enter a regime where quantum topological effects can be studied and novel quantum computation and simulation experiments can be implemented.

### 8:00AM X51.00001 Surface Acoustic Wave Study of Exciton Condensation in Bilayer Quantum Hall Systems<sup>1</sup>

, J. POLLANEN, J.P. EISENSTEIN, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA, L.N. PFEIFFER, K.W. WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA — In bilayer two-dimensional electron systems (2DES) in GaAs a strongly correlated many-electron state forms at low temperature and high magnetic field when the total electron density  $n_T$  becomes equal to the degeneracy of a single spin split Landau level. This state corresponds to a total filling factor  $\nu_T = 1$  and can be described in terms of pseudospin ferromagnetism, or equivalently, Bose condensation of bilayer excitons. We have simultaneously measured magneto-transport and the propagation of pulsed surface acoustic waves (SAWs) at a frequency of 747 MHz to explore the phase transition between two independent layers at  $\nu_T = 1/2 + 1/2$  and the correlated state at  $\nu_T = 1$  in a high quality double quantum well device. We tune through this transition by varying the total electron density in our device with front and backside electrostatic gates.

### 8:12AM X51.00002 Vibrational modes in the quantum Hall system<sup>1</sup>

, RACHEL WOOTEN, BIN YAN, Purdue University, KEVIN DAILY, Wolfram Research, CHRIS H. GREENE, Purdue University — The hyperspherical adiabatic technique is more familiar to atomic and nuclear few-body systems, but can also be applied with high accuracy to the many-body quantum Hall problem<sup>2</sup>. This technique reformulates the Schrödinger equation for  $N$  electrons into hyperspherical coordinates, which, after extracting the trivial center of mass, describes the system in terms of a single global size coordinate known as the hyperradius  $R$ , and  $2N - 3$  remaining internal angular coordinates. The solutions are approximately separable in the hyperradial coordinate, and solutions in the system are found by treating the hyperradius as an adiabatic coordinate. The approximate separability of the wave functions in this coordinate suggests the presence of hyperradial vibrational modes which are not described in conventional theories. The vibrationally excited states share the internal geometry of their quantum Hall ground states, and their excitation frequencies may vary with the number of participating particles or the strength of the confinement. We plan to discuss the features of these vibrational modes and their possible detection in quantum Hall systems.

**8:24AM X51.00003 Surface acoustic waves as a probe of the Wigner crystal in n-GaAs/AlGaAs in vicinity of  $\nu = 1/5, 1$ , and  $2^1$** , A.V. SUSLOV, NHMFL, Tallahassee, FL 32310, USA, I.L. DRICHKO, I.YU. SMIRNOV, A. F. Ioffe PTI of RAS, 194021 St.-Petersburg, Russia, L.N. PFEIFFER, K.W. WEST, Princeton University, Princeton, NJ 08544, USA, Y.M. GALPERIN, University of Oslo, 0316 Oslo, Norway — Both attenuation of a surface acoustic wave (SAW) and variation of its speed due to interaction with 2D electrons in n-GaAs/GaAlAs structures are measured versus perpendicular magnetic field of up to 18 T in the frequency range of (28.5 – 306) MHz and at temperatures (40 – 380) mK. The study is performed on  $\delta$ -doped from both sides 65 nm wide GaAs quantum well with the carrier density of  $n = 5 \cdot 10^{10} \text{ cm}^{-2}$  and their mobility of  $\mu = 8 \cdot 10^6 \text{ cm}^2/\text{Vs}$ . The complex AC conductance,  $\sigma$  is calculated. Analysis of  $\sigma$  shows that at low temperatures and at the filling factor of 2, 1, and 1/5 the electron system resides in the integer and fractional quantum Hall states, respectively. However, in vicinities to these values, namely at  $\nu = 1.9$ , (1.1 and 0.9), (0.21 and 0.19), the electron states can be interpreted as so-called pinning modes of Wigner crystal (WC). Temperature dependences of  $\sigma$  indicates a crossover between the localized modes (at  $\nu = 1$  and 2) and a pinned WC. When the temperature (or the SAW intensity) increases the behavior of the complex conductance can be understood as manifestation of WC melting.

**8:36AM X51.00004 Examining the Influence of Alloy Disorder on the  $\nu = 7/3$  Fractional Quantum Hall State**, ETHAN KLEINBAUM, NIANPEI DENG, GEOFFREY GARDNER, MICHAEL MANFRA, GABOR CSATHY, Purdue University — The fractional quantum Hall states of the second Landau level elicit interest from their potential to realize novel many-body ground states. In addition to the notable even denominator FQHS, the odd denominator states in this region are worthy of considerable attention. Specifically, the nature of the most prominent odd denominator state,  $\nu = 7/3$ , remains unknown – admitting both the conventional Laughlin-Jain state and more exotic candidate states. We examine the  $\nu = 7/3$  state in a series of samples with alloy disorder intentionally added during MBE growth. In these samples, we measure the energy gap at  $\nu = 7/3$  to explore the influence of disorder on the  $\nu = 7/3$  FQHS. A comparison of these data to the energy gap measurements of the even denominator  $\nu = 5/2$ . This work was supported by DOE DE-SC000671.

**8:48AM X51.00005 Diagnosis of phase transitions in disordered fractional quantum Hall liquids using quantum entanglement<sup>1</sup>**, ZHAO LIU, Dahlem Center for Complex Quantum Systems and Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany, R. N. BHATT, Department of Electrical Engineering, Princeton University, Princeton, NJ 08540 — The conventional method to study phase transitions from fractional quantum Hall (FQH) liquids to a localized phase induced by disorder has relied on the collapse of the mobility gap and Hall conductance [1,2]. Here, we scrutinize this issue from the perspective of quantum entanglement. We consider electrons in the disordered lowest Landau level at Laughlin filling fractions  $\nu = 1/m$  with either Haldane's pseudopotentials or Coulomb interaction. We find that the derivative of the orbital-cut von-Neumann entropy with respect to the disorder strength has a sharp peak, which diverges with system size, providing a clear fingerprint of the transition from FQH liquids to a localized phase. Further, the fluctuation of the entropy with different cut boundaries is utilized to examine whether the ground states are localized in some region. We also investigate the level statistics of the entanglement spectrum, as well as the low-lying spectrum of the Hamiltonian to extract more information about the phase transition. Our method can be applied to study many-body localization in other topological systems. [1] D. N. Sheng *et al.*, Physical Review Letters **90**, 256802 (2003). **9:00AM X51.00006 Excitation spectra of unconventional FQHE states in the SLL from Light Scattering Experiments<sup>1</sup>**, URSULA WURSTBAUER, Walter Schottky Institut TU München, ANTONIO LEVY, ARON PINCZUK, Columbia University, JOHN WATSON, GEOFF GARDNER, MICHAEL MANFRA, Purdue University, KEN WEST, LOREN PFEIFFER, Princeton University — The fascinating interaction physics in the second Landau level (SLL) supports the emergence of exotic quantum phases and unconventional possibly FQHE states such as e.g. at  $\nu = 5/2$  and  $2+1/3$  and the weaker state at  $\nu = 2+3/8$  and  $2+2/5$ . We observe clear signatures for gapped collective excitations in inelastic light scattering experiments just for these 'magic' filling factors and only for low temperatures substantiating access to the physics of the incompressible quantum fluids [1]. The lowest excitation feature in the spectrum at  $2+1/3$  occurs at around 70  $\mu\text{eV}$ . The analysis of spectral lineshapes suggests magnetoroton features that are characteristic of 2D neutral excitations in a perpendicular magnetic field. The striking polarization dependence observable in light scattering experiments in the SLL are consistent with nematic FQHE states. [1] U. Wurstbauer *et al.*, arXiv:1507.04939v2 (2015).

**9:12AM X51.00007 High Pressure Studies of the Second Landau Level Region of a Two-Dimensional Electron System<sup>1</sup>**, KATHERINE SCHREIBER, Purdue University Dept. of Physics, NODAR SAMKHARADZE, Delft University of Technology, GEOFFREY GARDNER, Purdue University Birck Nanotechnology Center, EDUARDO FRADKIN, University of Illinois Urbana-Champaign Dept. of Physics, MICHAEL MANFRA, GABOR CSATHY, Purdue University Dept. of Physics — Hydrostatic pressure has become a prevalent tool in condensed matter systems because the application of pressure to crystalline structures results in the shrinking of the lattice constant. This allows one to tune the Bloch wavefunction of the electrons and therefore all band parameters such as effective carrier mass, carrier density, and effective g-factor. In this manner, pressure acts as a probe into various strongly interacting electronic states. Motivated in particular by the capability to discern the spin polarization of quantum Hall states, we apply hydrostatic pressure up to 10 kbar to a two dimensional electron system (2DES) in a high-mobility GaAs/AlGaAs quantum well. This 2DES is subjected to milliKelvin temperatures and strong magnetic fields to observe the effect of pressure on fractional quantum Hall states, especially those in higher Landau levels, a regime not previously studied under pressure. We report our findings, focusing on the observation of a pressure-driven transition from a fractional quantum Hall state to the quantum Hall nematic phase in the second Landau level.

**9:24AM X51.00008 Spatially resolved breakdown in reentrant quantum Hall states**, OLEKSANDR ROSSOKHATY, JOSHUA FOLK, University of British Columbia, YUVAL BAUM, ADY STERN, Weizmann Institute of Science, JOHN WATSON, GEOFFREY GARDNER, MICHAEL MANFRA, Purdue University — Electrons in a two dimensional electron gas in the fractional quantum Hall regime may rearrange into a quasi-crystalline structure that gives rise to a reentrant Integer Quantum Hall (RIQH) effect in transport. As bias current increases, longitudinal and Hall resistivities measured for these states show multiple sharp breakdown transitions, a signature that is unique to RIQH states and has previously been ascribed to pinning-depinning transitions or to the development of bias-induced anisotropy. We present an alternate interpretation of the characteristic features of RIQH breakdown at high bias, based on spatially-resolved measurements that indicate a phase boundary between broken-down and unbroken regions propagating chirally from source and drain contacts as a function of bias current. As the phase boundary passes various contacts, its spreading generates multi-stage breakdown signatures like those reported elsewhere. Confirming numerical simulations, the chiral sense of the spreading is set not by the chirality of the edge state itself, but instead depends on electron- or hole-like character of the RIQH state.

### 9:36AM X51.00009 Observation of an Even-odd Anisotropic Transport in High Landau Levels<sup>1</sup>

, GUANGTONG LIU, CHANGLI YANG, QIN WANG, YUYING ZHU, YUAN PANG, JIE FAN, XIUNIAN JING, ZHONGQING JI, LI LU, Institute of Physics, Chinese Academy of Sciences, RUI-RUI DU, International Center for Quantum Materials, Peking University, Beijing 100871, China, LOREN PFEIFFER, KEN WEST, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, INSITITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM, INTERNATIONAL CENTER FOR QUANTUM MATERIALS, PEKING UNIVERSITY, BEIJING 100871, CHINA COLLABORATION — Magnetotransport experiments (including tilt fields) were performed on ultrahigh mobility L-shaped Hall-bar samples of GaAs/AlGaAs quantum wells. The low-temperature longitudinal resistance  $R_{xx}$  data demonstrate that a striking even-odd anisotropic transport exists only along the [110] direction at half filling in  $N \geq 2$  high Landau levels. Although the origin for the peculiar even-odd anisotropy remains unclear, we propose that the coupling strength between electrons within the same Landau level and between the neighboring two Landau levels should be considered in future studies. The tilt field data show that the in-plane field can suppress the formation of both bubble and stripe phases.

### 9:48AM X51.00010 ABSTRACT MOVED TO L51.012 —

### 10:00AM X51.00011 New Method for Studying Localization effects in Quantum Hall Systems

, R. N. BHATT, SCOTT GERAEDTS, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544 — Disorder is central to the study of the fractional quantum Hall effect. It is responsible for the finite width of the quantum Hall plateaus, and it is of course present in experiment. Numerical studies of the disordered fractional quantum Hall effect are nonetheless very difficult, because the lack of symmetry present in clean systems limits the size of systems that can be studied [1,2]. We introduce a new method for studying the integer and fractional quantum Hall effect in the presence of disorder that allows larger system sizes to be studied. The method relies on truncating the single particle Hilbert space, which leads to an exponential reduction in the Hilbert space of the many-particle system while preserving the essential topological nature of the state. We apply the model to the study of disorder transitions in the quantum Hall effect, both for the ground state and excited states. This work was supported by the US Department of Energy, Office of Basic Energy Sciences, through Grant DE-SC0002140. [1] D. N. Sheng, Xin Wan, E. H. Rezayi, Kun Yang, R. N. Bhatt and F. D. M. ### 10:12AM X51.00012 Reorientation of the anisotropic phase of a 2D electron system using a very small density modulation

, MD SHAFAYAT HOSSAIN, M A MUEED, HAO DENG, MANSOUR SHAYEGAN, LOREN PFEIFFER, K.W. WEST, KIRK BALDWIN, Princeton University — A high-quality two-dimensional electron system (2DES) confined to a GaAs quantum well typically exhibits isotropic transport coefficients when the Fermi level resides in the first excited ( $N = 1$ ) Landau level. Adding an in-plane magnetic field ( $B_{||}$ ) leads to an anisotropic (stripe) phase with the stripes oriented perpendicular to the  $B_{||}$  direction. We study how a periodic density modulation of the 2DES, induced by a surface strain grating from lines of negative electron-beam resist, affects the orientation of the  $\nu = 7/2$  stripe phase. Our results reveal that the external potential modulation competes against the  $B_{||}$ -induced orientational order of the stripe phase. Even a minute ( $\sim 0.5\%$ ) density modulation is sufficient to reorient the stripes at  $\nu = 7/2$  along the direction of the surface grating.

### 10:24AM X51.00013 Edge mode velocities in the quantum Hall effect from a dc measurement<sup>1</sup>

, PHILIP ZUCKER, D. E. FELDMAN, Brown University — Because of the bulk gap, low energy physics in the quantum Hall effect is confined to the edges of the 2D electron liquid. The velocities of edge modes are key parameters of edge physics. They were determined in several quantum Hall systems from time-resolved measurements and high-frequency ac transport. We propose a way to extract edge velocities from dc transport in a point contact geometry defined by narrow gates. The width of the gates assumes two different sizes at small and large distances from the point contact. The Coulomb interaction across the gates depends on the gate width and affects the conductance of the contact. The conductance exhibits two different temperature dependencies at high and low temperatures. The transition between the two regimes is determined by the edge velocity. An interesting feature of the low-temperature  $I - V$  curve is current oscillations as a function of the voltage. The oscillations emerge due to charge reflection from the interface of the regions defined by the narrow and wide sections of the gates. This work is available at arXiv:1510.01725

### 10:36AM X51.00014 Composite Fermion States near 3/2 Hosted by a High-Mobility 2D Hole System<sup>1</sup>

, PO ZHANG, Peking Univ, RUIYUAN LIU, Rice University, JIANLI WANG, CHI ZHANG, Peking Univ, CHANGLI YANG, LI LU, IOP, Chinese Academy of Sciences, LOREN PFEIFFER, KEN WEST, Princeton University, RUI-RUI DU, Rice University — Magnetotransport experiments of Carbon-doped GaAs/AlGaAs 2D hole gas (2DHG) have revealed a variety of interesting phenomena previous not seen in the 2DEG counterpart. For example, it was found that the effective  $g$ -factor of 2DHG is large enough to cause Landau level crossing even at  $\sim 1$  T, and the product of  $gm^*$  (where  $m^*$  is the hole effective mass) increases with total magnetic field (Yuan et al, Appl. Phys. Lett. 94, 052103 (2009)). Such level crossings could have profound influences on the fractional quantum Hall states in the relevant magnetic fields. We systematically investigate the composite fermion states near 3/2 in C-doped high-mobility 2DHG by tilted-magnetic field experiments, and map out the Landau levels and composite fermion spectra as a function of hole density and tilt angles. Preliminary results and brief discussions will be presented.

### 10:48AM X51.00015 Quantum Hall plateau-plateau transition probed by magnon quantum Hall insulator

, BAOLONG XU, School of Physics, Peking University, TOMI OHTSUKI, Department of Physics, Sophia University, RUIYCHI SHINDOU, School of Physics, Peking University — Based on a generalization of quantum Hall physics to quasi-particle boson system, we introduce a magnetic superlattice structure in the dipolar regime whose lowest gapped magnon bands mimic magnon quantum Hall insulator in strong out-of-plane magnetic fields. By calculating two-terminal conductance and localization length, we characterize the critical nature of the localization-delocalization transition in the magnon quantum Hall insulator. Especially, we show that the calculated conductance distribution at the 'plateau-plateau' transition in our system exhibits essentially the same distribution as that in the critical point of the Chalker-Corrington network model, demonstrating the 'universality' of the conductance distribution at the quantum Hall critical point beyond Fermion system.

**8:00AM X52.00001 Comparison between two models of time-dependent absorption of matter waves<sup>1</sup>**, MAXIMILIEN BARBIER, Northumbria University, UK, MATHIEU BEAU, University of Massachusetts Boston, USA, and Dublin Institute for Advanced Studies, Ireland, ARSENI GOUSSEV, Northumbria University, UK — The interaction between an atom and a laser might give rise to transitions between two, or more, internal states of the atom. Such processes can be efficiently described within the framework of matter wave absorption, in which the laser beam is mimicked by an absorbing barrier. In this talk we present a quantitative comparison between two models describing the interaction between a non-relativistic quantum particle and a thin time-dependent absorbing barrier. The first model represents the barrier by time-dependent discontinuous matching conditions imposed on both the wave function of the particle and its spatial derivative. The second model treats the particle as a spinor submitted to a time-dependent off-diagonal  $\delta$ -potential. We show the two models to be in excellent agreement in a semiclassical regime. **8:12AM X52.00002 Bell Experiment with Classical Optical Fields<sup>1</sup>**, BETHANY LITTLE, XIAO-FENG QIAN, JOHN HOWELL, J. H. EBERLY, University of Rochester — We theoretically and experimentally explore the implications of entanglement in statistically classical optical fields<sup>2</sup>. The description of these fields in terms of polarization and amplitude degrees of freedom can take a non-separable form which employs a mathematical description of entanglement often associated with quantum phenomena. By subjecting these optical fields to a Bell analysis, we examine the role of entanglement in marking the quantum-classical boundary. We report a value of the Bell parameter greater than  $B = 2.54$ , many standard deviations outside the limit  $B = 2$  established by the Clauser-Horne-Shimony-Holt Bell inequality<sup>3</sup>. This suggests that Bell violation has less to do with quantum theory than previously thought, but everything to do with entanglement.

**8:24AM X52.00003 Non-equilibrium Transport of Light**, CHIAO-HSUAN WANG, JQI/UMD/QuICS, JACOB TAYLOR, JQI/NIST/QuICS — Non-equilibrium Transport of Light The thermalization of light under conditions of parametric coupling to a bath provides a robust chemical potential for light [1]. We study non-equilibrium transport of light using non-equilibrium Green's function approach under the parametric coupling scheme, and explore a potential photonic analogue to the Landauer transport equation. Our results provide understandings of many-body states of photonic matter with chemical potential imbalances. The transport theory of light paves the way for quantum simulation and even practical applications of diode-like circuits using quantum photonic sources in the microwave and optical domain.

**8:36AM X52.00004 Determination of Zak phase by reflection phase in 1D photonic crystals**, WENSHENG GAO, HKUST, MENG XIAO COLLABORATION, CHETING CHAN COLLABORATION, WINGYIM TAM TEAM — For a one-dimensional (1D) periodic system with inherent mirror symmetry, the value of the geometric “Zak” phase in a bulk band is related to the sign of reflection phase for wavelengths inside the bandgaps sandwiching the bulk band. We designed an interference setup which allows us to measure the reflection phase of 1D photonic crystal fabricated for the optical range, and this in turn enabled us to determine the Zak phases of the bands. We then found interface states whose existence can be traced to the topological properties of the bandgaps and the geometric phases of the bulk bands. (accepted by optics letters)

**8:48AM X52.00005 Experimental Apparatus for the Observation of the Topological Change Associated with Dynamical Monodromy**, DANIEL SALMON, M. PERRY NEREM, SETH AUBIN, JOHN DELOS, William & Mary Coll — Monodromy means once around a path, therefore systems that have non-trivial monodromy are systems such that, when taken around a closed circuit in some space, the system has changed state in some way. Classical systems that exhibit non-trivial Hamiltonian monodromy have action and angle variables that are multivalued functions. A family, or loop, of trajectories of this system has a topological change upon traversing a monodromy circuit. We present an experimental apparatus for observing this topological change. A family of particles moving in a cylindrically symmetric champagne-bottle potential exhibits non-trivial Hamiltonian monodromy. At the center of this system is a classically forbidden region. By following a monodromy circuit, a loop of initial conditions on one side of the forbidden region can be made to evolve continuously into a loop that surrounds the forbidden region. We realize this system using a spherical pendulum, having at its end a permanent magnet. Magnetic fields generated by coils can then be used to create the champagne-bottle potential, as well as drive the pendulum through the monodromy circuit.

**9:00AM X52.00006 Topological Charge Screening in Disordered Aharonov-Bohm Wavefunctions**, ALEXANDER HOUSTON, JOHN HANNAY, ALEXANDER TAYLOR, MARK DENNIS, University of Bristol — Free electrical charges are typically subject to screening relations. For example, in ionic fluids and Coulomb gases there is screening (both global and local) of the electrical charges, described by the first and second Stillinger-Lovett sum rules [1]. A topological analogy governs the statistical behaviour of the nodal points in Gaussian random superpositions of plane waves. These nodal points are integer topological charges, i.e. vortices and antivortices of the complex wavefunction, whose sign is that of the phase circulation. Such superpositions are known to model high energy eigenfunctions in the presence of wave chaos [2], and display topological charge screening in the bulk [3]. We investigate how these screening relations are affected by the introduction of a magnetic flux line [4], which may be fractional in strength. We find that the global screening relation is broken, with the average total topological charge of the vortices given by the flux strength, and that the local screening of the flux itself shows unexpected features. [1] F. H. Stillinger and R. Lovett, *J. Chem. Phys.* **49**, 1991-94 (1968) [2] M. V. Berry, *J. Phys. A* **10**, 2083-91 (1977) [3] M. V. Berry and M. R. Dennis, *Proc. R. Soc. A* **456**, 2059-79 (2000) [4] Y. Aharonov and D. Bohm, *Phys. Rev.* **115**, 485-91 (1959)

**9:12AM X52.00007 Synthetic gauge flux and Weyl points in acoustic systems.<sup>1</sup>**, MENG XIAO, stanford university, WEN-JIE CHEN, WEN-YU HE, C. T. CHAN, the Hong Kong University of Science and Technology — We consider acoustic systems comprising a honeycomb lattice in the xy plane and periodic along the z direction. As  $k_z$  is a good quantum number here, for each fixed  $k_z$ , this system can be treated as a reduced two-dimensional system. By engineering the interlayer coupling in the z-direction, we show that we can realize effective inversion symmetry breaking and synthetic staggered gauge flux in the reduced two-dimensional system. The realizations of chiral edge states for fixed values of  $k_z$  are direct consequences of the staggered gauge flux. And we then show that the synthetic gauge flux is closely related to the Weyl points in the three-dimensional band structure.

**9:24AM X52.00008 Atomic collisions, inelastic indeed.** , HERVE BERCEGOL, GWENAEL FERRANDO, ROLAND LEHOUCQ, CEA — At the turn of the twentieth century, a hot controversy raged about the ability of Boltzmann's framework to take care of irreversibility. The so-called Loschmidt's paradox progressively faded with time during the last hundred years, due to the predictive efficiency of statistical mechanics. However, one detail at the origin of the controversy – the elasticity of atomic collisions – was not completely challenged. A semi-classical treatment of two atoms interacting with the vacuum zero-point field permits to predict a friction force acting against the rotation of the pair of atoms [Bercegol H. & Lehoucq R., *Phys. Rev. Lett.* **115**, 090402 (2015)]. By its form and its level, the calculated torque is a candidate as a physical cause for diffusion of energy and angular momentum, and consequently for entropy growth. It opens the way to a revision of the standard vision of irreversibility. This presentation will focus on two points. First we will discuss the recent result in a broader context of electromagnetic interactions during microscopic collisions. The predicted friction phenomenon can be compared to and distinguished from Collision-Induced Emission and other types of inelastic collisions. Second we will investigate the consequences of the friction torque on calculated trajectories of colliding atoms, quantifying the generation of dimers linked by dispersion forces.

**9:36AM X52.00009 Hydrogen Dissociation in Generalized Hartree-Fock Theory: Breaking the diatomic bond<sup>1</sup>** , JONATHAN JERKE, Texas Southern University, SAMINA MASOOD, University of Houston Clear Lake, CJ TYMCZAK, Texas Southern University — Generalized Hartree Fock theory predicts molecular Hydrogen dissociation without correlation. A variational Gaussian-Sinc linear superposition is the basis of 50 calculations with 3-4 significant digits of quality. The spin singlet covalent bond spontaneously breaks into a pair of uncorrelated doublets at atomic separation of 1.22 Angstroms. Quantum spin numbers and energetic comparison with Configuration Interaction theory—correlation—point to a first order phase transition in the molecular Hydrogen bond without correlation.

**9:48AM X52.00010 Stretching of Picosecond Laser Pulses with Uniform Reflecting Volume Bragg Gratings.** , SERGIY MOKHOV, CREOL - the College of Optics and Photonics, Univ. of Central Florida — It is shown that a uniform reflecting volume Bragg grating (VBG) can be used as a compact monolithic stretcher of high-power picosecond laser pulses in cases when chirped Bragg gratings with an appropriate chirp rate are difficult to fabricate. A chirp-free reflected stretched pulse is generated of almost rectangular shape when incident short pulse propagates along a grating and experiences local Bragg diffraction. The increase in duration of the reflected pulse is approximately equal to twice the propagation times along the grating. We derived the analytic expression for diffraction efficiency, which incorporates incident pulse duration, grating thickness, and amplitude of refractive index modulation, enabling an optimum selection of the grating for pulse stretching. The typical expected theoretical value of diffraction efficiency is about 10% after taking into account the spectral narrowing of the reflected emission. We believe that the relatively low energy efficiency of the proposed method is more than offset by a number of advantages, which are chirp-free spectrum of a stretched pulse, compactness, robustness, preservation of setup alignment and beam quality, and tolerance to high power. Obtained pulses of several tens of picoseconds can be amplified by standard methods which are not requiring special measures to avoid undesirable non-linear effects. We propose a simple and reliable method to control the temporal parameters of the high-power picosecond pulses using the same laser source and the VBG of variable thickness that can significantly simplify the experiments requiring different pulse durations.

**10:00AM X52.00011 Ablation-cooled material removal with ultrafast bursts of pulses** , F. MER ILDAY, Department of Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, C. KERSE, H. KALAYCIOGLU, P. ELAHI, Department of Physics, Bilkent University, Turkey, S. YAVAS, FiberLAST, Inc., Ankara, Turkey, D. KESIM, . AKAALAN, Department of EEE, Bilkent University, Turkey, B. ETIN, Department of Mechanical Engineering, Bilkent University, Turkey, B. KTEM, Department of Physics, Bilkent University, Turkey, M. ASIK, Nanotechnology and Nanomedicine Department, Hacettepe University, Turkey, H. HOOGLAND, R. HOLZWARTH, Department of Physics, University of Erlangen-Nuremberg, Germany — Use of femtosecond pulses allows precise and thermal-damage-free material removal with broad applications. However, its potential is limited by low material removal speeds and complexity of the required lasers. The laser complexity arises from the high pulse energy threshold for ablation. Physics of the laser-material interaction precludes a straightforward scaling up of the removal rate by using more powerful lasers due to shielding and collateral damage from heat accumulation. Here, we exploit ablation cooling, a technique used in aerospace engineering since 1950s, to circumvent this limitation. We apply rapid successions of pulses from specially developed lasers to ablate the target material before the residual heat deposited by previous pulses diffuse away from the interaction region. This constitutes a new physical regime of laser-material interactions, where heat removal due to ablation is comparable to conduction. Proof-of-principle experiments demonstrate reduction of required pulse energies by 1000x, while simultaneously increasing efficiency and speed by 10x.

**10:12AM X52.00012 Formation of ultrashort pulses from monochromatic XUV radiation via interaction with a medium of IR-dressed He atoms.** , TIMUR AKHMEDZHANOV, Texas A&M University and Institute for Quantum Studies and Engineering, College Station, TX, VLADIMIR ANTONOV, Institute of Applied Physics of the Russian Academy of Sciences, Nizhny Novgorod, Russia, OLGA KOCHAROVSKAYA, Texas A&M University and Institute for Quantum Studies and Engineering, College Station, TX — Trains of high intensity ultrashort XUV pulses could find a lot of applications. Recently, a mechanism of high efficiency formation of a train of XUV pulses from quasi-monochromatic XUV field was suggested [Opt. Lett. **36**, 2296 (2011)]. XUV field propagates through the medium of atoms, which are space-time modulated by IR field. The field scattered by modulated atoms contains sidebands of incident XUV field frequency and, for properly chosen parameters, train of ultrashort pulses is formed at the output of the medium. In this contribution, we study formation of ultrashort pulses in the medium of He atoms. Contrary to our recent work [Phys. Rev. A **91**, 023830 (2015)], IR field is chosen to be weak enough, so that pulses are formed due to modulation of excited atomic levels, rather than tunnel ionization. The suggested method allows to form train of pulses with high efficiency and can be scaled to He-like ions in order to get even shorter pulses.

**10:24AM X52.00013 Chiral Molecular Optical Response to Nano-Shaped Light<sup>1</sup>** , PRASOON SAURABH, Univ of California - Irvine, VLADIMIR CHERNYAK, Wayne State University, JEREMY ROUXEL, SHAUL MUKAMEL, Univ of California - Irvine — Chiral linear optical signals are an important spectroscopic tool for biomolecules and chemical sensing applications. Exact expressions are derived which express these signals as a convolution of a non-local linear susceptibility of matter with a non-local intrinsic property of the electric field. The chiral response can be enhanced and optimized using nano-optical fields with strong spatial variation. The approach is based on a gauge invariant calculation using the minimal coupling Hamiltonian. The multipolar expansion is avoided and all multipoles are naturally incorporated. We apply these expression to achiral (planar) and chiral (dihedral angle of 45°) bi-phenyl as a physically intuitive illustration.

**10:36AM X52.00014 Study of Rydberg blockade mediated optical non-linearity in thermal vapor<sup>1</sup>** , ARUP BHOWMICK, Senior Research Fellow, ASHOK MOHAPATRA, Reader-F — We demonstrate Rydberg blockade by coupling to Rydberg state via two-photon excitation in rubidium thermal vapor. The probe beam coupling to the  $D2$  transition was blue detuned by 1.3 GHz and a coupling beam was scanned to excite the atoms to Rydberg state via two-photon transition ( $5s_{1/2} \rightarrow ns_{1/2}$ ). The dispersion of the probe beam is modified due to the 2-photon excitation and is measured using an optical heterodyne detection technique in the experiment. We have observed that the dispersion of the probe beam depends linearly on atomic vapor density while coupling to a Rydberg state with principal quantum number,  $n = 30$ . However, density dependent suppression of the dispersion is observed while coupling to the Rydberg state with  $n = 60$ . Since the dispersion of the probe beam due to 2-photon excitation depends on the Rydberg population, the density dependent suppression is explained by introducing the concept of blockade. The blockade radius is measured to be about  $2.2 \mu\text{m}$  which is consistent with the scaling due to Doppler width of the 2-photon resonance in thermal vapor. Our result promises the realization of single photon source and strong single photon non-linearity based on Rydberg blockade in thermal vapor.

**10:48AM X52.00015 'Relativistic' corrections to the mass of a plucked guitar string** , MICHAEL KOLODRUBETZ, Univ of California - Berkeley, ANATOLI POLKOVNIKOV, Boston University — Quantum systems respond non-adiabatically when parameters controlling them are ramped at a finite rate. If the parameters themselves are dynamical for instance the position of a box that defines the boundary of a quantum field the feedback of these excitations gives rise to effective Newtonian equations of motion for the parameter. For the age old problem of photons in a box, this correction gives rise to a mass proportional to the energy of the photons. We show that a similar correction arises for a classical guitar string plucked with energy  $E$ ; moving clamps at the ends of the string requires inertial mass  $m = 2E/c_s^2$ , where  $c_s$  is the speed of sound. This quasi-relativistic effect should be observable in freshman physics level experiments. We then comment on how these simple methods have been readily extended to treat problems such as ramps and quenches of strongly-interacting superconductors and dynamical trapping near a quantum critical point.

**Session X53 FIAP: Electricity and Hydrogen Production, Storage and Delivery** Hilton Baltimore Holiday Ballroom 4 - Ernesto Marinero, Purdue University

**8:00AM X53.00001 Generation of Electric Energy and Desalinating Water from Solar Energy and the Oceans Hydropower** , NIAZI ELFIKKY<sup>1</sup>, Saudi Electricity Company — Brief. All warnings and fears about the environment in our Earth planet due to the serious effects of the industrial revolution were certainly predicted early. But the eager contest and the powerful desire for more profits beside the human interest for welfare and development closed all minds about the expected severe destructive impacts on our earth planet. Also, we have to remember that the majority of the African, Asian and Latin American countries are still in the first stage of their development and if they will be left to generate all their demand of energy by the conventional machine e.g (Fossil Fuel, Biofuel and Nuclear Fuel), then our Earth planet will confront an endless and ceaseless severe destructive impacts due to the encroachment of the released hot Carbon Dioxide and hot vapours of Acids which will never forgive any fruitful aspect in our Earth Planet from destruction. 1. Importance of the New Project. Building the Extra cheap, clean Power plants with safe and smooth Operation in addition to the long life time in service for generating enough and plentiful electric energy the sustainable renewable resources will invigorate the foresaking of all Nuclear, Fossil and Biofuel power plants to avoid the nuclear hazards and stop releasing the hot carbon dioxide, hot acids for the recovery of our ill environment. Also, the main sustainable, renewable, and cheap resources for generating the bulky capacity of the electric energy in our project are the Sun and the Oceans in addition to all Seas Surrounding all Continents in our Earth planet. Therefore, our recourses are so much enormous plentiful, clean, and renewable. 2. Generation of Electricity from Solar Energy by Photovoltaic Cells (PVCs) or Concentrated Solar Power (CSP). Characteristics of Photovoltaic Cells (PVCs). It is working only by Sun's Light (Light photons) and its efficiency will decrease as the Solar Thermal Radiation will increase, i.e. as the temperature of the Solar Voltiac will increase, its output will decrease or when the Solar thermal radiation of the Sun will increase, the efficiency of the Solar Voltiac Cells will nearly fully degrade at the ambient temperature  $55^\circ\text{C}$  ( $131^\circ\text{Fahrenheit}$ ). As known, in the African countries near the Atlantic Ocean like Mauritania, Senegal, South Africa and Guinea .etc, also the middle east countries like Morocco, Tuniz, Lybia, Algeria, Egypt, Sudan, Saudi Arabia, Kuwait, United Arab Emirates and Iraqetc. the range of the ambient temperature in the Summer seasons especially in the Desert near the Atlantic Ocean, the Mediterranean Sea, Red Sea and the Persian Gulf is around  $(60-70)^\circ\text{C}$  or  $(140^\circ\text{F}-158^\circ\text{F})$ . Similarly the majority of the Latin American countries with India and China. So, all the environments of the antecedent countries are not the suitable environment for generating electric energy from the Solar Voltiac cells in all seasons along the year. Characteristics of the Concentrated Solar Power (CSP). It uses half cylindrical mirrors to reflect with concentration the Solar thermal Radiation around a pipe to heat a special liquid. When the liquid will be heated it will pass through a water tank to exchange its heat in water tank to evaporate the water and create a steam to drive the Power Turbine for generating electricity. Also the capacity of the electric power generated by such technique is so much limited with respect to the wide area (3000 acres, about five miles end to end) occupied by the Concentrated Solar Power Plant. 3. The New Project Profile. Employing the water from the Oceans, Mediterranean Sea, Red Sea and Chinese sea to generate the bulky Hydraulic power capacity which will be delivered directly to the electric power Grid without any inverters. The Salt water will be drawn for desalination after driving A Steam Power Turbine for generating additional electric power.

**8:36AM X53.00002 Suppressing diborane production during the hydrogen release in metal borohydrides: The example of doped  $\text{Al}(\text{BH}_4)_3$ <sup>1</sup>** , DAVID HARRISON, TIMO THONHAUSER, Wake Forest University — Aluminum borohydride ( $\text{Al}(\text{BH}_4)_3$ ) is an example of a promising hydrogen storage material with exceptional hydrogen densities by weight and volume and a low hydrogen desorption temperature. But, unfortunately its production of diborane ( $\text{B}_2\text{H}_6$ ) gases upon heating restricts its practical use. To elucidate this issue, we investigate the properties of a number of metal borohydrides with the same problem and find that the electronegativity of the metal cation is not the best descriptor of diborane production. We show that, instead, the closely related formation enthalpy is a much better descriptor and we find that diborane production is an exponential function thereof. We conclude that diborane production is sufficiently suppressed for formation enthalpies of  $-80 \text{ kJ/mol BH}_4$  or lower, providing specific design guidelines to tune existing metal borohydrides or synthesize new ones. We then use first-principles methods to study the stabilizing effects of Sc alloying in  $\text{Al}(\text{BH}_4)_3$ , predicting that with sufficient alloying diborane can be fully suppressed. We conclude that stabilizing  $\text{Al}(\text{BH}_4)_3$  and similar borohydrides via alloying or other means is a promising route to suppress diborane production and thus develop viable hydrogen storage materials.

<sup>1</sup>Supported by NSF DMR-1145968

**8:48AM X53.00003 Improving ammonia borane as a hydrogen storage material with B-group substitutions<sup>1</sup>**, E. WELCHMAN, T. THONHAUSER, Wake Forest Univ — We present *ab initio* results for substitutions intended to lower the hydrogen desorption temperature of  $\text{NH}_3\text{BH}_3$  (ammonia borane or AB), already a promising hydrogen storage material. Substitutions in the  $\text{NH}_3$  group have previously been investigated with success; we propose a different route, instead performing substitutions in the  $\text{BH}_3$  group. To keep gravimetric density high, we focus on the second period elements C, N, O, and F, all with higher electronegativities than H. We also investigate Cu and S as possible substituents. Results include hydrogen binding energies and kinetic barriers for the hydrogen release in the gas phase as well as the solid. Of the substituents studied, we identify Cu as the most promising substituent, which lowers the reaction barrier for the hydrogen release by 38% compared to pure AB and we estimate a new hydrogen desorption temperature between  $-10^\circ\text{C}$  and  $40^\circ\text{C}$ .

<sup>1</sup>This work was supported in full by NSF Grant No. DMR-1145968

**9:00AM X53.00004 Stability of alkali-metal hydrides: effects of n-type doping<sup>1</sup>**, MONICA ARACELI OLEA AMEZCUA, OMAR DE LA PEÑA SEAMAN, JUAN FRANCISCO RIVAS SILVA, Institute of Physics, Benemérita Universidad Autónoma de Puebla (IFUAP-BUAP), ROLF HEID, KLAUS-PETER BOHNEN, Institute of Solid State Physics, Karlsruhe Institute of Technology (IFP-KIT) — Metal hydrides could be considered ideal solid-state hydrogen storage systems, they have light weight and high hydrogen volumetric densities, but the hydrogen desorption process requires excessively high temperatures due to their high stability. Efforts have been performed to improve their dehydrogenation properties, based on the introduction of defects, impurities and doping. We present a systematic study of the n-type (electronic) doping effects on the stability of two alkali-metal hydrides:  $\text{Na}_{1-x}\text{Mg}_x\text{H}$  and  $\text{Li}_{1-x}\text{Be}_x\text{H}$ . These systems have been studied within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method and the self-consistent version of the virtual crystal approximation to model the doping. The full-phonon dispersions are analyzed for several doping content, paying special attention to the crystal stability. It is found a doping content threshold for each system, where they are close to dynamical instabilities, which are related to charge redistribution in interstitial zones. Applying the quasiharmonic approximation, the vibrational free energy, the linear thermal expansion and heat capacities are obtained for both hydrides systems and are analyzed as a function of the doping content.

<sup>1</sup>This work is partially supported by the VIEP-BUAP 2016 and CONACYT-México (No.221807) projects

**9:12AM X53.00005 Transition metal dichalcogenides as a catalyst for hydrogen-evolution reaction**, JUN-HO LEE, YOUNG-WOO SON, Korea Inst for Advanced Study, JINBONG SEOK, HEEJUN YANG, Department of Energy Science and IBS Center for Integrated Nanostructure Physics, Institute for Basic Science, Sungkyunkwan University — Hydrogen evolution using electrochemical reaction of water with specific catalysts has been considered as next-generation energy resources. The best-known and most productive electrochemical catalyst is platinum. However, there has been a continuous struggle to replace the precious Pt-based catalysts by inexpensive and earth-abundant materials such as transition metal dichalcogenides (TMDs). We investigated catalytic performances of various TMDs for hydrogen-evolution reaction (HER) by using first-principles density functional theory calculation. We calculate Gibbs free energy, most widely used descriptor of catalytic activity, of hydrogen atom on TMDs and analyze an origin of significant performance of HER.

**9:24AM X53.00006 Computational study on the hydrogen storage in 2-dimensional potential well using K-intercalated graphite oxide**, JAEHYUN BAE, JISOON IHM, Seoul National University, SEOUL NATIONAL UNIVERSITY TEAM — Here, we present a new hydrogen storage strategy based on a diffusive equilibrium of gas molecules under the external potential we show that density of a gas inside the potential well increases exponentially relative to the ambient gas by the corresponding Boltzmann factor. In this mechanism, hydrogen molecules reside in the delocalized gas form in the potential well, in contrast to the conventional storage localized to specific binding sites. As a realization of the potential well, we choose K-intercalated graphite oxide (KGO) as a scaffold material and show that a relatively uniform potential well arises in between KGO layers. The average potential well depth is much enhanced due to the induced dipole interaction by the electric field generated by K ions and functional groups. The grand canonical Monte-Carlo calculation is employed to obtain the equilibrium hydrogen molecule density in the room temperature and the simulation results are explained by the density enhancement due to the attractive potential inside the KGO layers.

**9:36AM X53.00007 ABSTRACT WITHDRAWN —**

**9:48AM X53.00008 Hydrogen production by thermal water splitting using ferroelectric  $\text{PbTiO}_3$** , ARVIN KAKEKHANI, SOHRAB ISMAIL-BEIGI, Yale University — The increasing demand for renewable energy sources is a prominent challenge facing humanity in 21st century. In this regard, hydrogen production by splitting water has received great attention. Here, we theoretically propose a catalytic cycle that by leveraging the pyroelectric properties of ferroelectric  $\text{PbTiO}_3$ , and using a controlled temperature modulation around Curie temperature as a switch for surface chemical properties, can thermally split  $\text{H}_2\text{O}$  into  $\text{O}_2$  and  $\text{H}_2$ . Since the Curie temperature of  $\text{PbZr}_{1-x}\text{Ti}_x\text{O}_3$  class of materials is tunable and usually in the range of 250-450 degree Celsius; the energy needed to drive this catalytic cycle can be provided by low/intermediate grade heat, for instance: geothermal, industrial waste heat or concentrated solar power. Since no precious metal is needed in this scheme, and all the elements are earth abundant, this can potentially become an economically viable method for hydrogen production.

**10:00AM X53.00009 Engineering and characterization of high surface area graphitic carbon nitrides for hydrogen sorption**, DAVID STALLA, FLORIAN SEYDEL, ANDREW GILLESPIE, THOMAS LAM, MARK SWEANY, MARK LEE, PETER PFEIFER, University of Missouri, Columbia — Theoretical calculations predict graphitic carbon nitride to produce a binding energy to hydrogen ( $6.4\text{ kJ/mol}$ ) which is greater than that of pure graphene, making it attractive as a storage medium. However, the prohibitively small surface areas characteristic of g-CN materials dramatically limit  $\text{H}_2$  uptake. We discuss efforts to increase surface areas through physical/chemical exfoliation and templating.  $\text{N}_2$  sorption directly determines improvements to surface area, EF/TEM maps the thickness of aggregated planes, powder XRD indicates a novel, 2-phase structure, and XPS quantifies in-plane chemistry largely independent of the literature, which fails in a consensus regarding binding energy assignments.

**10:12AM X53.00010 Hydrogen Storage Studies of Palladium-Cobalt alloy nanoparticles dispersed Nitrogen Doped Graphene**, ASHOK PULLAMSETTY, Research scholar, RAMAPRABHU SUNDARA, Professor — Solid state hydrogen storage has significant importance in the present scenario of depleting conventional energy sources. Recent studies reveal that nanomaterials can play a significant role in the performance enhancement of energy conversion and storage device. Carbon based nanomaterials are considered as suitable candidates for hydrogen storage due to their high porosity, large surface area and high chemical stability. The two dimensional graphene, which has been discovered recently, consists of a single layer of atoms arranged in a honeycomb lattice, exhibits surface area. In the present work, we have been studied the hydrogen storage properties of Palladium-Cobalt alloy nanoparticles dispersed nitrogen doped graphene ( $\text{Pd}_3\text{Co}/\text{NG}$ ). Graphitic oxide was prepared by Hummers method and mixed with Palladium Cobalt and melamine precursors. The compound was reduced in hydrogen atmosphere at  $500^\circ\text{C}$  for 5 h. Structural and micro-structural characterization of these samples has been carried out by X-ray diffraction pattern (XRD), Raman spectroscopy, scanning electron microscope (SEM), transmission electron microscopy (TEM) and X-ray photo electro spectroscopy (XPS). The hydrogen adsorption measurements were carried out for NG as well as  $\text{Pd}_3\text{Co}/\text{NG}$  at different temperatures ( $25\text{--}100^\circ\text{C}$ ) and pressures ( $5\text{--}40\text{ bar}$ ) using a high pressure Sieverts apparatus. The material  $\text{Pd}_3\text{Co}/\text{NG}$  exhibits high storage capacity compared to NG due to spillover mechanism and the results have been discussed.

**10:24AM X53.00011 Direct Measurement of the Adsorbed Film Volume for Estimating Heats of Adsorption**, ANDREW GILLESPIE, ELMAR DOHNKE, TYLER RASH, DAVID STALLA, ERNEST KNIGHT, FLORIAN SEYDEL, MARK SWEANY, PETER PFEIFER, Univ of Missouri - Columbia — Compressed hydrogen and methane require extremely high pressures or low temperatures in order to compete with the energy density of conventional fossil fuels. Adsorbent materials provide a means to increase the energy density of these gasses up to 6 times that of compressed gas at the same temperature and pressure. One major concern in engineering adsorbed gas systems is thermal management during charging and discharging. Adsorption is an exothermic process, releasing heat during charging and absorbing heat during discharging. To estimate the heat of adsorption, it is common to analyze excess adsorption isotherms by converting to absolute adsorption and employ the Clausius Clapeyron relation. However, this method requires an assumed volume of the adsorbed state. It is common for researchers to assume that the adsorbed film occupies the entire pore volume of the adsorbent material. However, the adsorbed film only occupies a fraction of the total pore volume. This yields heats of adsorption that are underestimated by as much as 10kJ/mol at high coverage. In this talk, we present a method to directly measure the adsorbed film volume as a function of temperature and present the resulting heats of adsorption for both methane and hydrogen.

**10:36AM X53.00012 Anticipated detection of favorable periods for wind energy production by means of information theory**, EUGENIO VOGEL, GONZALO SARAVIA, Universidad de La Frontera, Temuco, Chile, SIGISMUND KOBE, ROLF SCHUMANN, Technische Universität Dresden, Dresden, Germany, ROLF SCHUSTER, Driedorf, Germany — Managing the electric power produced by different sources requires mixing the different response times they present. Thus, for instance, coal burning presents large time lags until operational conditions are reached while hydroelectric generation can react in a matter of some seconds or few minutes to reach the desired productivity. Wind energy production (WEP) can be instantaneously fed to the network to save fuels with low thermal inertia (gas burning for instance), but this source presents sudden variations within few hours. We report here for the first time a method based on information theory to handle WEP. This method has been successful in detecting dynamical changes in magnetic transitions [J. Mag. Mag. Mater. 372 (2014) 173] and variations of stock markets [Eur. Phys. J. B 87 (2014) 177]. An algorithm called wzip based on information recognition is used to recognize the information content of a time series. We make use of publically available energy data in Germany to simulate real applications. After a calibration process the system can recognize directly on the WEP data the onset of favorable periods of a desired strength. Optimization can lead to a few hours of anticipation which is enough to control the mixture of WEP with other energy sources, thus saving fuels.

**10:48AM X53.00013 Quasi-Elastic Neutron Scattering (QENS) Studies of Hydrogen Dynamics for Nano-Confined NaAlH<sub>4</sub>**<sup>1</sup>, TABBETHA DOBBINS, Rowan University, Dept. of Physics, SHATHABISH NARASEGOWDA<sup>2</sup>, Louisiana Tech University, CRAIG BROWN, MADHUSUDAN TYAGI, TIMOTHY JENKINS<sup>3</sup>, National Institute for Standards and Technology, Center for Neutron Research — The hydrogen dynamics of nano-confined sodium alanate (NaAlH<sub>4</sub>) has been studied using quasi-elastic neutron scattering (QENS). Results indicate thermodynamic destabilization is responsible for reduced desorption temperatures of NaAlH<sub>4</sub> upon confinement within the nanopores of a metal organic framework (MOF). Both the bulk (microscale) NaAlH<sub>4</sub> and the nanoconfined NaAlH<sub>4</sub> data were fitted to re-orientation models which yielded corresponding percent mobile hydrogen and jump lengths. The jump lengths calculated from the nano-NaAlH<sub>4</sub> were  $\approx 2.5$  Å, and in conformity with those jump lengths determined for bulk NaAlH<sub>4</sub> of  $\approx 2.3$  Å. As much as 18 % of the hydrogen atoms were estimated to be mobile in the nano-NaAlH<sub>4</sub> sample even at relatively low temperatures of 350 K. In contrast, bulk NaAlH<sub>4</sub> shows less than 7 % mobile H-atoms even at higher temperatures of  $\approx 450$  K. The activation energy for the long range is 3.1meV.

Session X55 DBIO GSNP: Principles of Cell to Cell Communication Hilton Baltimore Holiday Ballroom

6 - Ned S. Wingreen, Princeton University

**8:00AM X55.00001 Optimal census by quorum sensing**, THIBAUD TAILLEFUMIER, Princeton University — Bacteria regulate their gene expression in response to changes in local cell density in a process called quorum sensing. To synchronize their gene-expression programs, these bacteria need to glean as much information as possible about local density. Our study is the first to physically model the flow of information in a quorum-sensing microbial community, wherein the internal regulator of the individuals response tracks the external cell density via an endogenously generated shared signal. Combining information theory and Lagrangian optimization, we find that quorum-sensing systems can improve their information capabilities by tuning circuit feedbacks. At the population level, external feedback adjusts the dynamic range of the shared input to individuals detection channels. At the individual level, internal feedback adjusts the regulators response time to dynamically balance output noise reduction and signal tracking ability. Our analysis suggests that achieving information benefit via feedback requires dedicated systems to control gene expression noise, such as sRNA-based regulation.

**8:36AM X55.00002 Using memory to enforce stereotyped behavior in a bacterial community**, RICHARD LOSICK, Harvard University — Bacteria communicate with each other by the exchange of chemical cues. I will describe a simple system in which bacteria form a one-dimensional community in which behavior in the community is enforced by trans-generational memory inherited from a founder cell rather than by intercellular signaling. The bacterium *B. subtilis* held under constant conditions of exponential phase growth switches between a unicellular, motile state and a sessile state in which individual cells are held together in a chain. I will show that cells enter the chaining state spontaneously by a stochastic competition mechanism involving tight binding between two proteins and remain in that state for a stereotyped number of generations due to the action of a third protein that is responsible for memory. The motile state, in contrast, is memoryless. Reconstruction of the principal features of the two states in an unrelated bacterium, *E. coli*, provides evidence that the three proteins are necessary and sufficient to account for the alternative behaviors. Thus, *B. subtilis* is capable of cell-cell communication by an epigenetic information is transmitted to progeny cells for a characteristic number of cell divisions.

**9:12AM X55.00003 Design principles of paradoxical signaling in the immune system**, YUVAL HART, Physics department, School of Engineering and Applied Sciences, Harvard University — A widespread feature of cell-cell signaling systems is paradoxical pleiotropy: the same secreted signaling molecule can induce opposite effects in the responding cells. For example, the cytokine IL-2 can promote proliferation and death of T-cells. The role of such paradoxical signaling remains unclear. We suggest that this mechanism provides homeostatic concentration of cells, independent of initial conditions. The crux of the paradoxical mechanism is the combination of a positive and a negative feedback loops creating two stable states - an OFF state and an ON state. Experimentally, we found that CD4+ cells grown in culture with a 30-fold difference in initial concentrations reached a homeostatic concentration nearly independent of initial cell levels (ON-state). Below an initial threshold, cell density decayed to extinction (OFF-state). Mathematical modeling explained the observed cell and cytokine dynamics and predicted conditions that shifted cell fate from homeostasis to the OFF-state. We suggest that paradoxical signaling provides cell circuits with specific dynamical features that are robust to environmental perturbations.

**9:48AM X55.00004 The BMP Pathway is a Programmable Multi-Ligand Signal Processing System**, YARON ANTEBI, Caltech — The BMP signaling pathway comprises multiple ligands and receptors that interact promiscuously and appear in combinations. This feature is often understood in the context of redundancy and tissue specificity, but it has remained unclear whether it enables specific signal processing capabilities. Here, we show that the BMP pathway performs a specific set of computations, including sums, ratios, and balance and imbalance detection, across the multi-dimensional space of ligand concentrations. These computations can arise directly from receptor-ligand interactions without requiring transcriptional regulation. Furthermore, cells can re-program the type of computation performed on specific ligands through changes in receptor expression, allowing different cell types to perceive distinct signals in the same ligand environment. Together, these results may help explain the prevalence of promiscuous ligand-receptor architectures across pathways and enable predictive understanding and control of BMP signaling.

**10:24AM X55.00005 A positional code and anisotropic forces control tissue remodeling in Drosophila**, JENNIFER ZALLEN, Sloan Kettering Institute — A major challenge in developmental biology is to understand how tissue-scale changes in organism structure arise from events that occur on a cellular and molecular level. We are using cell biological, biophysical, and quantitative live-embryo imaging approaches to understand how genes encode the forces that shape tissues, and to identify the mechanisms that modulate cell behavior in response to local forces. In many animals, the elongated head-to-tail body axis is achieved by rapid and coordinated movements of hundreds of cells. We found that in the fruit fly, these cell movements are regulated by subcellular asymmetries in the localization of proteins that generate contractile and adhesive forces between cells. Asymmetries in the force-generating machinery are in turn controlled by a positional code of spatial information provided by an ancient family of Toll-related receptors that are widely used for pathogen recognition by the innate immune system. I will describe how this spatial system systematically orients local cell movements and collective rosette-like clusters in the Drosophila embryo. Rosettes have now also been shown to shape the body axis in chicks, frogs, and mice, demonstrating that rosette behaviors are a general mechanism linking cellular asymmetry to tissue reorganization.

**Friday, March 18, 2016 11:15AM - 2:15PM –**  
**Session Y1 DCMP DAMOP: Orbital Angular Momentum of Light and Matter** Ballroom I - Charles Clark, NIST

**11:15AM Y1.00001 Ghost imaging with entangled photons and orbital angular momentum**, MILES PADGETT, University of Glasgow — We utilise the position and orbital angular momentum (OAM) correlations between the signal and idler photons generated in the down-conversion process to obtain ghost images of a phase object. By using an OAM phase filter, which is non-local with respect to the object, the ghost images exhibit isotropic edge-enhancement. The strong spatial correlations between the signal and idler photons generated by spontaneous parametric downconversion have been widely utilised in many different imaging systems. The use of a scanning single element detector to recover the spatial information in the signal and idler beams fundamentally limits the detection efficiency of the imaging system to a maximum of  $1/N$  where  $N$  is the number of pixels in the image. Our approach overcomes this limitation by replacing the scanning detector by an intensified CCD camera, therefore detecting all photons irrespective of their position within the image. Using a camera in this way, coupled with the OAM edge-enhancement and image reconstruction techniques allows us to obtain images of phase objects with an average of fewer than one photon per image pixel.

**11:51AM Y1.00002 Twisting Neutron Waves<sup>1</sup>**, DMITRY PUSHIN, IQC, University of Waterloo — Most waves encountered in nature can be given a “twist”, so that their phase winds around an axis parallel to the direction of wave propagation. Such waves are said to possess orbital angular momentum (OAM). For quantum particles such as photons, atoms, and electrons, this corresponds to the particle wavefunction having angular momentum of  $L\hbar$  along its propagation axis. Controlled generation and detection of OAM states of photons began in the 1990s, sparking considerable interest in applications of OAM in light and matter waves<sup>2</sup>. OAM states of photons have found diverse applications such as broadband data multiplexing, massive quantum entanglement, optical trapping, microscopy, quantum state determination and teleportation, and interferometry. OAM states of electron beams have been used to rotate nanoparticles, determine the chirality of crystals and for magnetic microscopy. Here I discuss the first demonstration of OAM control of neutrons<sup>3</sup>. Using neutron interferometry with a spatially incoherent input beam, we show the addition and conservation of quantum angular momenta, entanglement between quantum path and OAM degrees of freedom. Neutron-based quantum information science heretofore limited to spin, path, and energy degrees of freedom, now has access to another quantized variable, and OAM modalities of light, x-ray, and electron beams are extended to a massive, penetrating neutral particle. The methods of neutron phase imprinting demonstrated here expand the toolbox available for development of phase-sensitive techniques of neutron imaging.

**1:03PM Y1.00004 Creating High-Harmonic Beams with Controlled Orbital Angular Momentum**, ROBERT W. BOYD, University of Ottawa — A beam of light with an angle-dependent phase  $\Phi = \ell\phi$ , where  $\phi$  is the azimuthal coordinate, about the beam axis carries an orbital angular momentum (OAM) of  $\ell\hbar$  per photon. Such beams have been exploited to provide superresolution in visible-light microscopy. The ability to create extreme ultraviolet or soft-x-ray beams with controllable OAM would be a critical step towards extending superresolution methods to extremely small feature size. Here we show that OAM is conserved during the process of high-harmonic generation (HHG). Experimentally, we use a fundamental beam with  $\ell = 1$  and interferometrically determine that the  $q$ -th harmonic has an OAM quantum number  $\ell$  equal to its harmonic order  $q$ . We also show theoretically how to couple an arbitrary low value of the OAM quantum number  $\ell$  to any harmonic order  $q$  in a controlled manner. Our results open a route to microscopy on the molecular, or even submolecular, scale.

**1:39PM Y1.00005 Unveiling orbital angular momentum and acceleration of light beams and electron beams<sup>1</sup>**, ADY ARIE, Tel-Aviv University — Special beams, such as the vortex beams that carry orbital angular momentum (OAM) and the Airy beam that preserves its shape while propagating along parabolic trajectory, have drawn significant attention recently both in light optics and in electron optics experiments. In order to utilize these beams, simple methods are needed that enable to easily quantify their defining properties, namely the OAM for the vortex beams and the nodal trajectory acceleration coefficient for the Airy beam. Here we demonstrate a straightforward method to determine these quantities by astigmatic Fourier transform of the beam. For electron beams in a transmission electron microscope, this transformation is easily realized using the condenser and objective stigmators, whereas for light beam this can be achieved using a cylindrical lens. In the case of Laguerre-Gauss vortex beams, it is already well known that applying the astigmatic Fourier transformation converts them to Hermite-Gauss beams. The topological charge (and hence the OAM) can be determined by simply counting the number of dark stripes of the Hermite-Gauss beam. We generated a series of electron vortex beams and managed to determine the topological charge up to a value of 10. The same concept of astigmatic transformation was then used to unveil the acceleration of an electron Airy beam. The shape of astigmatic-transformed depends only on the astigmatic measure and on the acceleration coefficient. This method was experimentally verified by generating electron Airy beams with different known acceleration parameters, enabling direct comparison to the deduced values from the astigmatic transformation measurements. The method can be extended to other types of waves. Specifically, we have recently used it to determine the acceleration of an optical Airy beams and the topological charge of so-called Airy-vortex light beam, i.e. an Airy light beam with an embedded vortex.

**Session Y2 DCMF DMP GMAG: Spin and Valley Pseudo-Spin Transport in Strongly Spin-Orbit Coupled Systems** Ballroom II - Kin Fai Mak, Pennsylvania State University

**11:15AM Y2.00001 Transport measurements of MoS<sub>2</sub> using a van der Waals heterostructure device platform**, JAMES HONE, Columbia University — No abstract available.

**11:51AM Y2.00002 Theory of classical and quantum transport in monolayers of MoS<sub>2</sub><sup>1</sup>**, SHAFFIQUE ADAM, Yale-NUS College, 16 College Avenue West, Singapore 138527, Singapore — From the family of new van der Waals materials, the class of layered transition metal dichalcogenides has emerged as a particularly interesting system due to the inherent spin and valley degrees of freedom. In this talk we focus on the interplay between these degrees of freedom and the different types of disorder in monolayers of molybdenum disulphide. Within the semiclassical Drude-Boltzmann formalism, treating the screening of impurities with the random phase approximation, we demonstrate that different scattering mechanisms such as charged impurity scattering, intervalley scattering, and phonons provide different signatures in electronic transport. This allows us to conclude, for example, that in CVD-grown monolayers of MoS<sub>2</sub>, intervalley scattering dominates over other mechanisms at low temperatures [1]. Interestingly, charged impurities generate spatial inhomogeneity in the carrier density that results in a classical disorder-induced magnetoresistance that can be observed at room temperature [2]. However, at lower temperatures, in this regime of strong intervalley scattering, we predict that the quantum phase-coherent corrections to the conductivity results in a one-parameter crossover from weak localization to weak anti-localization as a function of magnetic field, where this crossover is determined only by the spin lifetime. By comparing with available experimental data [3], we show that this combined framework allows for a novel way to measure the spin-relaxation in monolayers of MoS<sub>2</sub>. We find that the spin scattering arises from the Dyakonov-Perel spin-orbit scattering mechanism with a conduction band spin-splitting of about 4 meV, consistent with calculations using density functional theory. **12:27PM Y2.00003 Optical imaging of the valley Hall effect in MoS<sub>2</sub> transistors**, JIEUN LEE, Penn State University — The newly emerged two-dimensional (2D) transition metal dichalcogenides (TMDs) with nonequivalent K and K' valleys have provided an ideal laboratory for exploring the valley degree of freedom of electrons, as well as their potential applications for information processing. Valley Hall effect (VHE), in which a transverse valley current is formed under a longitudinal electrical bias in the absence of a magnetic field, has been predicted in 2D TMDs with broken inversion symmetry. The effect has recently been demonstrated in monolayer MoS<sub>2</sub> through a photo-induced anomalous Hall effect, which uses circularly polarized light to preferentially excite electrons into a specific valley. In this talk, we will present our recent results on the development of Kerr rotation microscopy to image the VHE. The valley polarizations of opposite sign accumulated on two opposing edges of MoS<sub>2</sub> transistors from the VHE are measured directly. We will also discuss the possibility of electrical control of the VHE in bilayer MoS<sub>2</sub>, which possesses inversion symmetry. An application of a vertical electric field breaks the inversion symmetry and consequently yields the VHE.

**1:03PM Y2.00004 Breaking time reversal symmetry, quantum anomalous Hall state and dissipationless chiral conduction in topological insulators<sup>1</sup>** , JAGADEESH MOODERA<sup>2</sup>, MIT — Breaking time reversal symmetry (TRS) in a topological insulator (TI) with ferromagnetic perturbation can lead to many exotic quantum phenomena exhibited by Dirac surface states including the quantum anomalous Hall (QAH) effect and dissipationless quantized Hall transport. The realization of the QAH effect in realistic materials requires ferromagnetic insulating materials and topologically non-trivial electronic band structures. In a TI, the ferromagnetic order and TRS breaking is achievable by conventional way, through doping with a magnetic element, or by ferromagnetic proximity coupling. Our experimental studies by both approaches will be discussed. In doped TI van Vleck ferromagnetism was observed. The proximity induced magnetism at the interface was stable, beyond the expected temperature range. We shall describe in a hard ferromagnetic TI system a robust QAH state and dissipationless edge current flow is achieved,<sup>1,2</sup> a major step towards dissipationless electronic applications with no external fields, making such devices more amenable for metrology and spintronics applications. Our study of the gate and temperature dependences of local and nonlocal magnetoresistance, may elucidate the causes of the dissipative edge channels and the need for very low temperature to observe QAH. Session Y3 DCMP GMAG: Skyrmions in Chiral Magnets Ballroom III - Nandini Trivedi, Ohio State University

### 11:15AM Y3.00001 INVITED ABSTRACT WITHDRAWN –

**11:51AM Y3.00002 Experimental Studies of Berry Phase Effects and Collective Excitations in Skyrmion Materials** , CHRISTIAN PFLEIDERER, Physik-Department, Technische Universität München, D-85748 Garching, Germany — The emergence, stability and decay of skyrmions in chiral magnets and the associated emergent electrodynamics are reviewed. The non-zero topological winding, which corresponds to precisely one quantum of emergent magnetic flux, mediates an extremely efficient coupling between the conduction electrons and the magnetic properties. This emergent flux leads to a topological Hall signal, spin transfer torques at ultra-low current densities and emergent electric fields. Additionally skyrmions are characterised by an exceptional stability, which cannot be simply suppressed under large hydrostatic pressures or doping. In fact, measurements of the Hall effect suggest the survival of non-trivial topological winding akin that of the skyrmion lattice in a non-Fermi liquid regime at high pressures, where neutrons scattering suggests the absence of long-range magnetic order. The topological unwinding of skyrmions, which involves emergent magnetic monopoles, may be at the heart of the loss of long-range order.

**12:27PM Y3.00003 Skyrmions in chiral magnets with Rashba and Dresselhaus Spin-Orbit Coupling<sup>1</sup>** , MOHIT RANDERIA, The Ohio State University — Studies of skyrmions in chiral magnets have focused largely on systems with broken bulk inversion and a Dzyaloshinskii-Moriya interaction (DMI) of the Dresselhaus form. The skyrmion crystal is then stable only in a small regime with easy-axis anisotropy. I will show how skyrmion crystal phases can be stabilized over a much larger region of field and anisotropy down to zero temperature in systems with a Rashba DMI that break surface inversion or mirror symmetry [1,2]. Increasing the ratio of Rashba to Dresselhaus DMI leads to a progressively larger domain of stability for skyrmions, especially in the easy-plane anisotropy regime. The spin texture and topological charge density then develop nontrivial spatial structures, different from conventional skyrmions, with a quantized topological charge given by a Chern number. Our theoretical results predict how tuning the Rashba spin orbit coupling and magnetic anisotropy can help stabilize skyrmion phases in thin films, surfaces, interfaces and bulk magnets with broken mirror symmetry. [1] J. Rowland, S. Banerjee, and M. Randeria, arXiv:1509.07508v2. [2] S. Banerjee, J. Rowland, O. Erten, and M. Randeria, PRX 4, 031045 (2014).

**1:03PM Y3.00004 Skyrmions in frustrated magnets<sup>1</sup>** , SHIZENG LIN, Los Alamos Natl Lab — A skyrmion in magnets or magnetic skyrmion is a stable spin texture with nontrivial topology and behaves like a particle at mesoscale. To stabilize a skyrmion, it is required to have a characteristic length scale, which can be introduced by competing interactions. Recently skyrmion lattice has been observed experimentally in chiral magnets without inversion symmetry, where the skyrmions are stabilized by the competition between the exchange and Dzyaloshinskii-Moriya interactions. The skyrmions in chiral magnets have been studied actively and have been demonstrated to be promising for applications. These skyrmions share qualitatively similar properties in metals, semiconductors and insulators and can be described by a simple universal Hamiltonian. Skyrmions can also be stabilized in frustrated magnets with inversion symmetry. In the talk, we will present a general Ginzburg-Landau theory for the skyrmions in the frustrated magnets. We will discuss their unusual properties in comparison to those in chiral magnets. Finally we will also discuss the conditions for the stabilization of skyrmions.

Session Y4 FIP: Physics and Physicists in Cuba Ballroom IV - Mria Spiropulu, California Institute of Technology

**11:15AM Y4.00001 The Role of Science Cooperation in World-Wide Social Progress** , DAVID GROSS, Univ of California - Santa Barbara — No abstract available.

**11:51AM Y4.00002 Physics & Physicists in Cuba** , FIDEL CASTRO DAZ-BALART, Vice-president of the Academy of Sciences of Cuba — No abstract available.

**12:27PM Y4.00003 Science and Technology Diplomacy with Cuba**, FRANCES COLON, US Department of State — President Obama's announcement of U. S. policy change toward Cuba and increased freedom of interaction with the Cuban people opens unprecedented and long-awaited opportunities for the scientific and engineering communities in the U. S. and in Cuba to establish and expand collaborative efforts that will greatly advance U.S. and Cuba science and technology agendas. New rules for export of donated-only items for scientific use will bring researchers closer to the level of their professional peers around the world. Increasing Cubans' access to information will result in greater interactions between scientific communities and enable the sharing of ideas and discoveries that can fuel entrepreneurship on the island. The scientific community has expressed an extraordinary level of interest in the wide range of scientific opportunities that the new policy presents, in collaborating with their Cuban counterparts, and in supporting the development of scientific capacity in Cuba. In response to numerous expressions of interest and inquiries from the scientific community, the Office of the Science and Technology Adviser to the Secretary of State (STAS) has engaged in public outreach to inform the U.S. science and technology community of the implications of the new policy for collaborative research, emerging scientific opportunities, and the standing limitations for engagement with the people of Cuba.

**Friday, March 18, 2016 11:15AM - 2:03PM** —

**Session Y5 GMAG DMP FIAP: Semiconductor Spin Qubits** 301 - Igor Zutic, University at Buffalo

**11:15AM Y5.00001 Microscopic origin of the prolonged coherence in 4H-SiC divacancy spin qubits<sup>1</sup>**, HOSUNG SEO, ABRAM FALK, PAUL KLIMOV, DAVID CHRISTLE, DAVID AWSCHALOM, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Long coherence times of quantum bits (qubits) is a key prerequisite for quantum computing and quantum metrology. Recently, electronic spin qubits localized to divacancies in 4H-SiC were found to have a long spin coherence time ( $T_2$ ) exceeding 1 ms, which is longer than that of the nitrogen-vacancy (NV) center in chemically but not isotopically purified diamond. In this talk, we discuss the microscopic origin behind the prolonged divacancy coherence. By using optically detected magnetic resonance (ODMR), we show that the divacancy  $T_2$  rapidly increases as a function of magnetic field, saturating at 1.3 ms at  $T = 20$  K. We used a quantum-bath model combined with a cluster correlation expansion technique to calculate the divacancy coherence function and found an excellent agreement between theory and experiment. We show that an effective decoupling of the  $^{29}\text{Si}$  and  $^{13}\text{C}$  nuclear spins due to their gyromagnetic ratio difference is one of the key reasons responsible for suppressing the decoherence of the divacancy qubits in SiC under magnetic fields larger than 100G.

<sup>1</sup>We gratefully acknowledge financial support from the National Science Foundation through the University of Chicago MRSEC under award number DMR-1420709.

**11:27AM Y5.00002 Coherent population trapping of a nitrogen vacancy center induced by optical and surface acoustic waves**, THEIN OO, ANDREW GOLTER, HAILIN WANG, University of Oregon — We report experimental demonstration of coherent population trapping (CPT) driven by resonant optical and mechanical coupling in a nitrogen vacancy (NV) center in diamond. A surface acoustic wave (SAW) is generated with an inter-digital transducer fabricated on a ZnO layer sputtered on diamond surface. The SAW couples resonantly to a transition between two excited states of the NV center, while a laser field couples to a corresponding resonant optical transition. The combined optical and mechanical coupling to the lambda- or ladder- type three-level system leads to CPT of the NV center. These studies open the door to exploiting strong excited-state electron-phonon coupling for applications such as laser cooling of a mechanical resonator and mechanically-mediated spin entanglement.

**11:39AM Y5.00003 Quantum Control of a Nitrogen-Vacancy Center using Surface Acoustic Waves in the Resolved Sideband Limit**, DAVID GOLTER, THEIN OO, MAIRA AMEZCUA, HAILIN WANG, University of Oregon — Micro-electromechanical systems research is producing increasingly sophisticated tools for nanophononic applications. Such technology is well-suited for achieving chip-based, integrated acoustic control of solid-state quantum systems. We demonstrate such acoustic control in an important solid-state qubit, the diamond nitrogen-vacancy (NV) center. Using an interdigitated transducer to generate a surface acoustic wave (SAW) field in a bulk diamond, we observe phonon-assisted sidebands in the optical excitation spectrum of a single NV center. This exploits the strong strain sensitivity of the NV excited states. The mechanical frequencies far exceed the relevant optical linewidths, reaching the resolved-sideband regime. This enables us to use the SAW field for driving Rabi oscillations on the phonon-assisted optical transition. These results stimulate the further integration of SAW-based technologies with the NV center system.

**11:51AM Y5.00004 Development of single-crystal diamond scanning probes with nitrogen-vacancy centers for cryogenic magnetometry with nanoscale spatial resolution**, ALEC JENKINS, MATTHEW PELLICIONE, PREETI OVARTCHAIYAPONG, CHRISTOPHER REETZ, ANIA BLESZYNSKI JAYICH, University of California, Santa Barbara — Scanning probes based on the nitrogen-vacancy (NV) defect center in diamond are powerful tools for imaging magnetic phenomena at the nanoscale. In particular, extending the operation of these probes to cryogenic temperatures opens up a wide range of condensed matter systems that can be studied. In this talk, we demonstrate a variable temperature NV scanning magnetometer consisting of an atomic-force microscope housed in a closed-cycle cryostat integrated with custom confocal optics. With this microscope we have observed 6-nm spatial resolution and  $3 \mu\text{T}/\sqrt{\text{Hz}}$  sensitivity at  $T = 6$  K. The single-crystal diamond scanning probes that contain shallow and coherent NV centers are critical to the performance of the microscope. The probes are designed with the aim of reducing the NV-sample separation and increasing collection of NV fluorescence, both while maintaining the spin coherence properties of the defects. We describe the fabrication of these probes as well as ongoing efforts to improve their sensitivity and spatial resolution.

**12:03PM Y5.00005 Scanned probe imaging of nanoscale magnetism at cryogenic temperatures with a single-spin quantum sensor**, MATTHEW PELLICIONE, ALEC JENKINS, PREETI OVARTCHAIYAPONG, CHRISTOPHER REETZ, University of California, Santa Barbara, EVE EMMANUELIDU, NI NI, University of California, Los Angeles, ANIA BLESZYNSKI JAYICH, University of California, Santa Barbara — The nitrogen vacancy (NV) defect in diamond has emerged as a promising candidate for high resolution magnetic imaging based on its atomic size and quantum-limited sensing capabilities afforded by long spin coherence times. Although the NV center has been successfully implemented as a nanoscale scanning magnetic probe at room temperature, it has remained an outstanding challenge to extend this capability to cryogenic temperatures, where many solid-state systems exhibit non-trivial magnetic order. In this talk, we present NV magnetic imaging at  $T = 6$  K, first benchmarking the technique with a magnetic hard disk sample, then utilizing the technique to image vortices in the iron pnictide superconductor  $\text{BaFe}_2(\text{As}_{0.7}\text{P}_{0.3})_2$  with  $T_c = 30$  K. In addition, we discuss other candidate solid-state systems that can benefit from the high spatial resolution and field sensitivity of the scanning NV magnetometer.

**12:15PM Y5.00006 Coupling a driven magnetic vortex to individual nitrogen-vacancy spins for fast, nanoscale addressability and coherent manipulation<sup>1</sup>**, MICHAEL WOLF, ROBERT BADEA, JESSE BEREZOVSKY, Case Western Reserve University — The core of a ferromagnetic (FM) vortex domain creates a strong, localized magnetic field which can be manipulated on nanosecond timescales using small magnetic fields, or electrical currents. These capabilities present opportunities for nanoscale spin-based devices. Here, we demonstrate how these FM vortex properties can be used in a room temperature, integrated device by coupling a FM vortex to nitrogen-vacancy (NV) center spins in diamond [1]. Measurements are carried out using a combined magneto-optical microscopy and optically-detected spin resonance technique. We show that the FM vortex can be driven into proximity with an NV, inducing significant NV spin splitting and sufficiently large magnetic field gradient to address spins separated by nanometer length scales. By applying a microwave-frequency magnetic field, we drive both the vortex and the NV spins, resulting in enhanced coherent rotation of the spin state. Finally we demonstrate that by driving the vortex on fast timescales, sequential addressing and coherent manipulation of spins is possible on 100 ns timescales, while driving on faster timescales results in non-trivial coherent dynamics of the coupled vortex/NV system. **12:27PM Y5.00007 Navigating the vortex pinning landscape for bistable coupling of a ferromagnetic vortex to individual nitrogen vacancy spins<sup>1</sup>**, JESSE BEREZOVSKY, MICHAEL WOLF, ROBERT BADEA, Case Western Reserve University — A ferromagnetic (FM) vortex coupled to nitrogen-vacancy (NV) spins in diamond provides an integrated platform for fast, nanoscale addressability of coherent spins [1]. The vortex moves in a complex effective potential landscape set by the geometry of the disk and the defects present in the material. As the vortex moves through this landscape, the coupling to a proximal NV varies. We use differential magneto-optical microscopy to extract the effective potential through which the vortex moves [2], and optically-detected magnetic resonance to study the coupling of the vortex to an adjacent NV spin. When multiple local minima are present in the vortex potential, the vortex/NV coupling displays bistability. We switch between these bistable states with short magnetic field pulses. This allows an NV spin transition to be switched between on-resonance and off-resonance with a driving field with the same set of external parameters, and also yields information about the mechanisms of vortex/NV coupling. [1] M.S. Wolf, R. Badea, J. Berezovsky, arXiv:1510.07073, 2015 [2] R. Badea, J. Berezovsky, arXiv:1510.07059, 2015.

**12:39PM Y5.00008 Phonon induced two-electron relaxation in two donor qubits in silicon**, YULING HSUEH, ARCHANA TANKASALA, YU WANG, GERHARD KLIMECK, Purdue University, MICHELLE SIMMONS, University of New South Wales, RAJIB RAHMAN, Purdue University — An atomistic method of calculating two-electron spin-lattice relaxation times ( $T_1$ ) is presented for two donor qubits in silicon. The singlet-triplet two-electron states are calculated from full-configuration interaction (FCI) method with one-electron basis states obtained from the tight-binding Hamiltonian including spin-orbit interaction. The FCI solution enables the investigation of various regimes of donor separations, including very closely separated donor pairs in which rearrangement of excited bonding and anti-bonding states change the wavefunction symmetries. Hyperfine mixing from the nuclear spins is included perturbatively into the two-electron states. To calculate the  $T_1$  times, the electron-phonon Hamiltonian is evaluated from the strain-dependent tight-binding Hamiltonian. The results show how the  $T_1$  times in donor qubits vary with magnetic field and donor separation for each of the three triplets. Moreover, the variation of  $T_1$  with the electric field controlled exchange coupling is also investigated.

**12:51PM Y5.00009 Pauli spin blockade in CMOS silicon double dots probed by dual gate reflectometry<sup>1</sup>**, DHARMRAJ KOTEKAR PATIL, CEA-INAC and Universit Grenoble Alpes, 17 Rue des Martyrs, F-38000 Grenoble, France, ALESSANDRO CRIPPA, Laboratorio MDM, CNR-IMM, ROMAIN MAURAND, ANDREA CORNA, CEA-INAC and Universit Grenoble Alpes, ROMAIN LAVIEVILLE, LOUIS HUTIN, SYLVAIN BARRAUD, CEA, LETI, MINATEC Campus, ALEXEI ORLOV, University of Notre Dame, Notre Dame, SILVANO DE FRANCESCHI, MARC SANQUER, XAVIER JEHL, CEA-INAC and Universit Grenoble Alpes, TEAM TEAM, COLLABORATION COLLABORATION, COLLABORATION COLLABORATION, TEAM TEAM, COLLABORATION COLLABORATION — Silicon quantum dots are attractive candidates for the development of scalable spin-based qubits. The Pauli spin blockade effect in double quantum dots can provide an efficient, temperature-independent mechanism for qubit readout. Here we report the observation of Pauli blockade in silicon double quantum dots defined in double-gate nanowire transistors fabricated using silicon-on-insulator CMOS technology. Each of the two gates is connected to an LC resonator to perform radio-frequency reflectometry. This powerful technique allows high-sensitivity detection of charge transitions in the double quantum dot down to the few-electron regime. We find evidence of Pauli spin blockade and study the magnetic-field dependence of the underlying singlet-triplet states.

**1:03PM Y5.00010 Direct observation of long-distance coherent superexchange spin coupling in a quantum dot array**  
**Spin Exchange oscillations between distant quantum dots**, TAKAFUMI FUJITA, TIM BAART, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zurich, LIEVEN VANDERSYPEN, Delft University of Technology — Interactions mediated by long-range quantum coherence lie at the heart of important phenomena in many different fields. Charge transfer during oxidative stress in DNA [1], reactions in photosynthetic molecules [2], and behaviour of cuprate superconductors [3] are all described by tunnelling via virtual hopping. Such mechanism may also provide new ways of using quantum dots for fault tolerant quantum information processing [4]. In the presence of long-range tunnel coupling mediated by virtual occupation of intermediate levels, superexchange interactions can induce coherent oscillations between two distant electron spins. We implement this scheme in a linear array of three quantum dots with one electron on each of the outer dots. We observe coherent exchange oscillations between the two spins, and the oscillation frequency is controlled by the detuning of the electrochemical potential of the dot in between. Spin exchange at a distance may provide a new route for scaling up electron spin qubits using quantum dots. [1] B. Giese, et al, Nature 412, 318-320 (2001). [2] X.F. Wang, et al, Phys. Rev. Lett. 97,106602 (2006). [3] C. Kim, et al, Phys. Rev. Lett. 80, 4245 (1998). [4] F. Braakman, et al, Nature Nano. 8, 432-437 (2013).

**1:15PM Y5.00011 Decoherence of an electron spin qubit in an optically active quantum dot**, FUXIANG LI, Theoretical Division and CNLS, LANL, ALEXANDER BECHTOLD, DOMINIK RAUCH, TOBIAS SIMMET, PER-LENNART ARDELT, ARMIN REGLER, KAI MULLER, Walter Schottky Institut, Technische Universitat Munchen, 85748 Garching, Germany, NIKOLAI SINITSYN, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, JONATHAN FINLEY, Walter Schottky Institut, Technische Universitat Munchen, 85748 Garching, Germany — Understanding the spin dynamics in quantum dot, especially its detailed decoherence and relaxation is not only of theoretical interests, but also a crucial problem towards the application of quantum dot as a solid-state quantum qubit. From the phenomenological models of decoherence developed more than a decade ago, it has been now fairly accepted that the spin dynamics undergoes two stages, first a fast ensemble dephasing due to the coherent precession of spin qubit around nearly static but randomly distributed hyperfine fields ( $\sim 2$  ns) and then a much slower relaxation process ( $> 1\mu$  s) due to dynamics of the nuclear spin bath induced by complex many-body interaction effects. However, this characteristics has never been verified in the experiment, until the recent experiment breakthrough I'm going to talk about. What's more interesting is that, the experiment unambiguously shows a more complex picture, in which two dips rather than one, develops, which can be attributed to the effect of the comparatively strong quadruple field.

**1:27PM Y5.00012 Coherent control of single spins in a silicon carbide pn junction device at room temperature**, SANG-YUN LEE, MATTHIAS WIDMANN, 3rd Institute of Physics, University of Stuttgart, IAN BOOKER, Department of Physics, Chemistry and Biology, Linköping University, MATTHIAS NIETHAMMER, 3rd Institute of Physics, University of Stuttgart, TAKESHI OHSHIMA, Japan Atomic Energy Agency, ADAM GALL, Wigner Research Centre for Physics, Hungarian Academy of Sciences, NGUYEN T. SON, ERIK JANZÉN, Department of Physics, Chemistry and Biology, Linköping University, JOERG WRACHTRUP, 3rd Institute of Physics, University of Stuttgart — Spins in single defects have been studied for quantum information science and quantum metrology. It has been proven that spins of the single nitrogen-vacancy (NV) centers in diamond can be used as a quantum bit, and a single spin sensor operating at ambient conditions. Recently, there has been a growing interest in a new material in which color centers similar to NV centers can be created and whose electrical properties can also be well controlled, thus existing electronic devices can easily be adapted as a platform for quantum applications. We recently reported that single spins of negatively charged silicon vacancies in SiC can be coherently controlled and long-lived at room temperature<sup>1</sup>. As a next step, we isolated single silicon vacancies in a SiC pn junction device and investigated how the change in Fermi level, induced by applying bias, alters the charge state of silicon vacancies, thus affects the spin state control. This study will allow us to envision quantum applications based on single defects incorporated in modern electronic devices.

**1:39PM Y5.00013 Optical and Spin Signatures of Transition Metal Impurities in Silicon Carbide**<sup>1</sup>, WILLIAM KOEHL, SAMUEL J. WHITELY, BERK DILER, ALEXANDRE BOURASSA, DAVID D. AWSCHALOM, Institute for Molecular Engineering, University of Chicago, NGUYEN TIEN SON, Department of Physics, Chemistry and Biology, Linköping University, Sweden — Point defects and impurities are increasingly viewed as an important resource for solid-state implementations of quantum information technologies. Electronic spins bound to point defects like the nitrogen vacancy center in diamond and divacancy in silicon carbide are especially attractive because they function as long-lived qubit states that can be controlled optically at the single-site level. These capabilities have generated a growing interest in identifying other classes of point defect with similar properties, since discovery of such systems might allow for new ranges of functionality in solid-state quantum device design. Transition metal ions are a promising area for exploration, since they often introduce isolated electronic levels within the bandgaps of semiconductors and possess a wide variety of magnetic and optical properties. Here we describe recent experimental studies of the optical and spin properties of transition metal impurities in silicon carbide. Using ensemble spectroscopies, we evaluate their potential for use as optically-controllable spin states within this industrially-important, wide-bandgap, optoelectronic material.

**1:51PM Y5.00014 Measurement of Spin Coherence Times in Proton Irradiated 4H-SiC**, JACOB EMBLEY, JOHN COLTON, Brigham Young University, SAM CARTER, Naval Research Lab, KYLE MILLER, Brigham Young University, MARGARET MORRIS, Brandeis University — Silicon vacancy defects in silicon carbide (SiC) have potential for use in spintronic devices. We used optically detected magnetic resonance and a spin echo technique to measure  $T_2$  spin coherence times for electrons in 4H-SiC. These experiments were performed at a magnetic field strength of 0.371 T and a resonant microwave frequency of 10.5 GHz. Each sample contained silicon vacancy defects that were formed through irradiation with 2 MeV protons at unique fluences ( $10^{13}$  and  $10^{14}$  cm<sup>-2</sup>). Measurements for each sample were made across a range of temperatures, from 8 K to room temperature. While we generally observed a decrease in spin coherence time with temperature, we also observed a range of temperatures (from 60 K to 160 K) for which the overall trend was reversed.

**Session Y6 GMAG DMP: Magnetic Complex Oxides II** 302 - Antia Botana, Argonne National Laboratory

**11:15AM Y6.00001 The extreme quantum limit in lightly-doped SrTiO<sub>3</sub>**<sup>1</sup>, ANAND BHATTACHARYA, Materials Science Division and Nanoscience and Technology Division, Argonne National Laboratory, Lemont IL, BRIAN SKINNER, Materials Science Division, Argonne National Laboratory, Lemont IL, GURU KHALSA, CNST, National Institute of Standards and Technology, Gaithersburg MD, ALEXEY SUSLOV, National High Magnetic Field Laboratory, Tallahassee FL — When a three dimensional electron gas is placed in a sufficiently strong magnetic field, it is said to be in the quantum limit when the cyclotron energy  $\hbar\omega_c > \epsilon_F \gg kT$ , and all of the electrons occupy the lowest Landau level. Achieving this limit in a material requires a small Fermi energy relative to the applied magnetic field, and a weak disorder potential such that magnetic freeze-out is avoided. We present an experimental study of lightly-doped single crystals of SrTiO<sub>3</sub>, which remain good bulk conductors in temperatures down to 25 mK and magnetic fields up to 45 T. Our measurements probe deep into the quantum limit, where  $\hbar\omega_c \gg \epsilon_F$  and theory has long predicted that electron-electron interactions can drive the system into a charge density wave or Wigner crystal like state. A number of interesting features arise in electrical transport in this regime, including a striking re-entrant nonlinearity in the current-voltage characteristics. We discuss these features in the context of possible correlated electron states, and present a picture based on magnetic field induced puddling of electrons in a disorder potential landscape.

**11:27AM Y6.00002 Phonon-induced ultrafast band gap control in LaTiO<sub>3</sub>**<sup>1</sup>, MINGQIANG GU, JAMES M. RONDINELLI, Northwestern University — We propose a route for ultrafast band gap engineering in correlated transition metal oxides by using optically driven phonons. We show that the  $\Gamma$ -point electron band energies can be deterministically tuned in the nonequilibrium state. Taking the Mott insulator LaTiO<sub>3</sub> as an example, we show that such phonon-assisted processes dynamically induce an indirect-to-direct band gap transition or even a metal-to-insulator transition, depending on the electron correlation strength. We explain the origin of the dynamical band structure control and also establish its generality by examining related oxides. Lastly, we describe experimental routes to realize the band structure control with impulsive stimulated Raman scattering.

**11:39AM Y6.00003 Tuning the magnetic ordering in EuTiO<sub>3</sub> through doping**, ZHIGANG GUI, ANDERSON JANOTTI, Univ of Delaware — EuTiO<sub>3</sub> (ETO) is a complex oxide that displays strong spin-lattice coupling, large magnetoelectric effects, and undergoes a series of structural and magnetic phase transitions when subjected to pressure or epitaxial strain. ETO adopts a cubic structure and is paramagnetic at high temperatures, while at very low temperatures it transforms to an antiferrodistortive tetragonal structure with a G-type antiferromagnetic (AFM) ordering. Several approaches have been presented to tune the magnetic ordering from the G-type antiferromagnetism to the F-type ferromagnetism, often relying on external pressure or epitaxial strain. Doping through substitution of trivalent species on the europium sites or creation of oxygen vacancies have also been proposed to lead to ferromagnetism. However, the fundamental mechanism by which excess electrons from impurities or defects lead to ferromagnetic ordering is unclear. In this study, we explore the effects of doping on the magnetic ordering in EuTiO<sub>3</sub> through first-principles calculations. We show how itinerant carriers in the Ti-*d*-derived conduction-band states interact with europium *f* states, inducing an alignment of the large moments on the europium ions. The effects of doping of different types of magnetic ordering are considered, a

**11:51AM Y6.00004 Point defects, impurities, and small hole polarons in  $\text{GdTiO}_3$** , LARS BJAALIE, University of California, Santa Barbara, ANDERSON JANOTTI, University of Delaware, KARTHIK KRISHNASWAMY, CHRIS G. VAN DE WALLE, University of California, Santa Barbara —  $\text{GdTiO}_3(\text{GTO})$  has become the focus of great interest because of its use in complex-oxide heterostructures that display two-dimensional electron gases with unprecedented high densities. GTO is a Mott insulator, with a band gap arising within the partially filled Ti 3d band due to strong electron-electron interactions. GTO often displays hole conductivity, likely attributed to defects or impurities, yet the cause of this unintentional conductivity has not yet been explored. We therefore used density functional theory with a hybrid functional to study their electronic structure. Among native defects, the cation vacancies have the lowest formation energies in oxygen-rich conditions, and oxygen vacancies have the lowest formation energy in oxygen-poor conditions. Among the impurities,  $\text{r}_{\text{Gd}}$ ,  $\text{H}_i$  and  $\text{C}_\text{O}$  have the lowest formation energies. The defects and impurities are intrinsically stable only in a single “natural” charge state, to which various numbers of hole polarons can be bound, which explains the frequent observation of *p*-type hopping conductivity in the rare-earth titanates. These small hole polarons also lead to optical absorption and act as electron traps in devices. Work supported by NSF and by the LEAST Center.

**12:03PM Y6.00005 Low-energy dispersion of dynamic charge stripes in  $\text{La}_{1.75}\text{Sr}_{0.25}\text{NiO}_4$  observed with inelastic neutron scattering**<sup>1</sup>, RUIDAN ZHONG, JOHN TRANQUADA, GENDA GU, Brookhaven Natl Lab, DMITRY REZNIK, University of Colorado, BARRY WINN, Oak Ridge Natl Lab — The dynamic stripe correlations have been the subject of intense research, owing to the possible links with high- $T_c$  superconductivity. In light of a recently published, direct observation of charge-stripe fluctuations in  $\text{La}_{2-x}\text{Sr}_x\text{NiO}_4$  using inelastic neutron scattering<sup>2</sup>, we did a follow-up neutron experiment on a  $x=0.25$  sample to characterize the low-energy dispersion of these dynamic charge stripes using the HYSPEC instrument at the Spallation Neutron Source. The scattering signals are collected in the vicinity of a charge-order peak with a large wave vector (4.4, 3, 0), where dynamic spin-stripe correlations are negligible. Mapping the low-energy charge-stripe fluctuations in a wide temperature range, we observe a finite dispersion along the stripe-modulation direction at  $T \geq 160\text{K}$  where the charge stripes become disordered, while the steep dispersion in the orthogonal direction is not resolved.

**12:15PM Y6.00006 Ultrafast Dynamics of the Symmetry Breaking in Charge-ordered  $\text{La}_{1.75}\text{Sr}_{0.25}\text{NiO}_4$  Single Crystals.**<sup>1</sup>, GIACOMO COSLOVICH, Lawrence Berkeley National Lab, SLAC National Accelerator Lab, ALEXANDER F. KEMPER, Lawrence Berkeley National Lab, North Carolina State University, SASCHA BEHL, BERNHARD HUBER, Lawrence Berkeley National Lab, HANS A. BECHTEL, Advanced Light Source, Lawrence Berkeley National Lab, TAKAO SASAGAWA, Tokyo Institute of Technology, MICHAEL C. MARTIN, Advanced Light Source, Lawrence Berkeley National Lab, ROBERT A. KAINDL, Lawrence Berkeley National Lab — We report equilibrium and ultrafast optical pump-THz probe spectroscopy of the stripe-phase rare-earth nickelate compound  $\text{La}_{1.75}\text{Sr}_{0.25}\text{NiO}_4$ , unveiling the ultrafast dynamics of the crystal symmetry breaking and of local electronic arrangements. At low temperatures the folding of finite momenta vibrations due to symmetry breaking lead to the appearance of new IR-active resonances, particularly around the phonon bending mode frequency ( $\approx 11\text{ THz}$ ). Ultrafast experiments in the multi-THz spectral range show sharp THz reflectivity modulations associated with the phonon zone-folding dynamics, while the background conductivity is reminiscent of the opening of the mid-IR pseudogap. We combine experimental data with DFT calculations of the phonon dispersion to reveal the distinct dynamics of the LO and TO phonon modes at finite momenta. This work provides new insight in the role of polar electron-phonon coupling and symmetry breaking in charge-ordered systems.

**12:27PM Y6.00007 Single crystal preparation and long-range charge fluctuations in the square-planar nickelate  $\text{La}_4\text{Ni}_3\text{O}_8$ .**<sup>1</sup>, JUNJIE ZHANG, Argonne National Laboratory, YU-SHENG CHEN, Argonne National Laboratory/The University of Chicago, HONG ZHENG, DANIEL PHELAN, JOHN MITCHELL, Argonne National Laboratory — Since the discovery of high- $T_c$  superconductivity in cuprates, intensive effort has been focused on a search for superconductivity in related materials, with particular attention on nickelates. Bulk nickelates containing square-planar coordinated  $\text{Ni}^{2+}$  are of interest because  $\text{Ni}^{1+}$  is isoelectronic with  $\text{Cu}^{2+}$ , the building block of high- $T_c$  cuprates. Here we report the first single crystal synthesis of  $\text{La}_4\text{Ni}_3\text{O}_8$ , a layered nickelate containing square-planar coordinated  $\text{Ni}^{2+}$  with crystallographic and electronic structure related to that of cuprates. Magnetic susceptibility, resistivity, and heat capacity measurements confirm the reported phase transition at  $\sim 105\text{ K}$ [1]. Long-range charge fluctuations with  $q \sim (1/3, 1/3, L)$  was observed for the first time through synchrotron X-ray single crystal diffraction. Our results challenge the current understanding of the origin of the phase transition. Availability of bulk  $\text{La}_4\text{Ni}_3\text{O}_8$  single crystals is also of significant importance for unraveling its ambiguous ground-state magnetic structure, the spin state of the Ni ion, and potential for superconductivity in nickelates involving  $\text{Ni}^{2+}$  in a square-planar coordination. [1] Poltavets, V. V. et al. PRL 2010, 104, 206403.

**12:39PM Y6.00008 Cooperative phonon effects in the metal-insulator transitions of manganite and nickelate perovskites**, RICHARD T. BRIERLEY, Yale University, GIAN G. GUZMAN VERRI, Universidad de Costa Rica and Argonne National Laboratory, PETER B. LITTLEWOOD, Argonne National Laboratory and The University of Chicago — Metal-insulator transitions in manganite and nickelate perovskites depend on the competition between the electron kinetic energy, which favors the metallic phase, and the electron-phonon coupling and Coulomb interaction, which favor localization. The size of the A-site cation controls the relative rotation of the octahedral structural units of the perovskite in the range of  $0 - 15^\circ$ . This is accompanied by changes in the metal-insulator transition temperature from  $0 - 600\text{K}$ . This effect is commonly attributed to modification in the electron bandwidth from changes in orbital overlap. Although previous theoretical studies of these materials include the electron-phonon interaction, they typically do not consider cooperative phonon effects. Using a phenomenological model of the perovskite structure, we show that the long-range anisotropic forces arising from inter-site phonon interactions are modulated by changes in the octahedral rotation. We demonstrate using statistical mechanical calculations that these changes in the strain interaction can capture the variation in transition temperature with tolerance factor observed in both the manganites and nickelates.

**12:51PM Y6.00009 Direct proof of static charge stripe correlations in  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$** <sup>1</sup>, X M CHEN, V THAMPY, C MAZZOLI, A BARBOUR, G GU, J P HILL, J M TRANQUADA, M P M DEAN, S B WILKINS, Brookhaven National Laboratory — The nature of charge stripe order in the cuprates, and in particular whether the stripes are static or dynamic, is a key issue in understanding the relationship between stripes and superconductivity. In  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$  (LBCO) a low temperature structural distortion is widely believed to pin stripes into fixed, static domains, but such an assertion has never been directly verified. We performed resonant soft x-ray photon correlation spectroscopy (XPCS) to probe the charge order Bragg peak of 1/8 doped LBCO. At low temperatures, we observe time-independent x-ray speckle patterns persisting for more than three hours, proving the static nature of the stripes and we go on to discuss how stripe order melts with increasing temperature. Our results demonstrate that the combination of XPCS with diffraction limited light sources such as the National Synchrotron Light Source II can probe the dynamics of even subtle order parameters such as stripes in the cuprates.

<sup>1</sup>Work performed at Brookhaven National Laboratory was supported by the US Department of Energy, Division of Materials Science, under Contract No.DE-AC02-98CH10886. Use of the National Synchrotron Light Source II was supported under Contract No DE-SC0012704

**1:03PM Y6.00010 Quasi-static magnetoelectric quadrupoles as the order parameter for the pseudo-gap phase in cuprate superconductors**, MICHAEL FECHNER, MERLIN J. A. FIERZ, FLORIAN THÖLE, Materials Theory, ETH Zurich, Wolfgang-Pauli-Strasse 27, 8093 Zurich, URS STAUB, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, NICOLA A. SPALDIN, Materials Theory, ETH Zurich, Wolfgang-Pauli-Strasse 27, 8093 Zurich — A characteristic of ferroic materials is the emergence of a temporally static finite expectation value of an order parameter. Here, we introduce a new mechanism [1] for ferroic order, in which a non-zero quasi-static magnetoelectric quadrupolar order appears due to the coupling of fluctuating spin magnetic dipole moments and polar optical phonons. Using first-principles calculations within the LSDA+*U* method of density functional theory, we calculate the magnitude of the effect for the prototypical cuprate superconductor,  $\text{HgBa}_2\text{CuO}_{4+\delta}$ . We show that our proposed mechanism is consistent, to our knowledge, with many experimental observations for the onset of the pseudo-gap phase and therefore propose the quasi-static magnetoelectric quadrupole as a possible pseudo-gap order parameter. Finally, we show that our mechanism embraces some key aspects of previous theoretical models, in particular the description of the pseudo-gap phase in terms of orbital currents. [1] M. Fechner, M. J. A. Fierz, F. Thöle, U. Staub, and N. A. Spaldin, arXiv 1510.04844, (2015).

**1:15PM Y6.00011 Quantum oscillations in a bilayer with broken mirror symmetry: a minimal model for  $\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}$** <sup>1</sup>, AKASH MAHARAJ, YI ZHANG, Stanford University, BRAD RAMSHAW, National High Magnetic Field Laboratory, Los Alamos National Laboratory,, STEVEN KIVELSON, Stanford University — Using an exact numerical solution and semiclassical analysis, we investigate quantum oscillations (QOs) in a model of a bilayer system with an anisotropic (elliptical) electron pocket in each plane. Key features of QO experiments in the high temperature superconducting cuprate YBCO can be reproduced by such a model, in particular the pattern of oscillation frequencies (which reflect “magnetic breakdown” between the two pockets) and the polar and azimuthal angular dependence of the oscillation amplitudes. However, the requisite magnetic breakdown is possible only under the assumption that the horizontal mirror plane symmetry is spontaneously broken and that the bilayer tunneling,  $t_{\perp}$ , is substantially renormalized from its ‘bare’ value. Under the assumption that  $t_{\perp} = \tilde{Z}t_{\perp}^{(0)}$ , where  $\tilde{Z}$  is a measure of the quasiparticle weight, this suggests that  $\tilde{Z} \sim 1/20$ . Detailed comparisons with new  $\text{YBa}_2\text{Cu}_3\text{O}_{6.58}$  QO data, taken over a very broad range of magnetic field, confirm specific predictions made by the breakdown scenario.

<sup>1</sup>Supported in part by the US DOE, Office of Basic Energy Sciences under contract DE-AC02-76SF00515 (A.V.M.), the US DOE Office of Basic Energy Sciences “Science at 100 T,” (B.J.R.) and the National Science Foundation Grant No. DMR 1265593 (S.A.K., YZ)

**1:27PM Y6.00012 Controlling Spin Ordering in Rare-Earth Perovskite Vanadates**, NICHOLAS WAGNER, JAMES RONDINELLI, Northwestern University — We investigate the role and influence of local structure distortions on the antiferromagnetic spin ordering temperatures for large *A*-site radii *RVO3* perovskites (*R*=Yb-La) using a combination of data analytics (DA) and density functional theory (DFT). First, mode crystallography is used to parameterize the structural phase space. Next, we identify the important local structural features that correlate strongly with the Néel temperatures ( $T_N$ ) using Pearson correlation coefficients. From this data, we then formulate a regression model using gradient boosted decision trees (GBDT) that returns the relative importance of each feature in predicting  $T_N$ . Our analysis indicates that the amplitude of the subtle Jahn-Teller active mode, which leads to variations in the V-O bond lengths and angles, could be used as an effective structural control parameter to modify the spin ordering temperature. We then validate this data-driven structure-property relationship in artificial vanadate structures using  $T_N$  based on both our GBDT model and a model Hamiltonian using DFT energies. This combined approach allows us to gauge the accuracy of existing physical models for the antiferromagnetic ordering in vanadates and opens possible strategies to design materials with targeted  $T_N$ .

**1:39PM Y6.00013 Giant Magnetocaloric Effect in the Double-perovskite  $\text{Gd}_2\text{NiMnO}_6$** <sup>1</sup>, JAE YOUNG MOON, MI KYUNG KIM, DONG KUN OH, SANG HYUP OH, NARA LEE, YOUNG JAI CHOI, Yonsei Univ — We have synthesized single crystal of  $\text{Gd}_2\text{NiMnO}_6$  (GNMO) by the Bi-flux method and investigated magnetocaloric effect in them by magnetic measurements. Magnetic susceptibility of GNMO increases smoothly as temperature decrease and ferromagnetic order occurs below 135 K, and additional anomaly show at low temperature, indicative of the onset of  $\text{Gd}^{3+}$  spin arrangement. At the temperature, magnetic entropy change,  $-\Delta S_M$ , with the field changes of 0-9 T, calculated from isothermal *M*(*H*) data using Maxwell relation, exhibits sharp peak. This peak is gigantic and cryogenic, these make GNMO promising cryogenic magnetic refrigerant materials.

<sup>1</sup>Giant Magnetocaloric Effect in the Double-perovskite  $\text{Gd}_2\text{NiMnO}_6$

**1:51PM Y6.00014 ABSTRACT WITHDRAWN —**

**Friday, March 18, 2016 11:15AM - 1:51PM —**

**Session Y7 DCMP: Superconductivity: Devices, Vortex Dynamics, and Conductors** 303 - Lei Wang, University of South Carolina

**11:15AM Y7.00001 Silicon superconducting quantum interference device**, ANAS FRANCHETEAU, JEAN-EUDES DUVAUCHELLE, CHRISTOPHE MARCENAT, CEA Grenoble, FRANCESCA CHIODI, DOMINIQUE DBARRE, IEF Orsay, KLAUS HASSELBACH, Institut Néel CNRS Grenoble, J.R. KIRTLEY, Stanford University California, FRANOIS LEFLOCH, CEA Grenoble — We have studied a Superconducting Quantum Interference SQUID device made from a single layer thin film of superconducting silicon. The superconducting layer is obtained by heavily doping a silicon wafer with boron atoms using the Gas Immersion Laser Doping (GILD) technique. The SQUID device is composed of two nano-bridges (Dayem bridges) in a loop and shows magnetic flux modulation at low temperature and low magnetic field. The overall behavior shows very good agreement with numerical simulations based on the Ginzburg-Landau equations.

**11:27AM Y7.00002 Waveguide-integrated NbTiN superconducting nanowire single-photon detector with ultralow jitter**, RISHENG CHENG, XIAOSONG MA, Department of Electrical Engineering, Yale University, PRASANA RAVINDRAN, JOSEPH BARDIN, Department of Electrical and Computer Engineering, University of Massachusetts Amherst, HONG TANG, Department of Electrical Engineering, Yale University — We demonstrate NbTiN superconducting nanowire single-photon detectors (SNSPDs) integrated with Si<sub>3</sub>N<sub>4</sub> waveguides for counting visible and infrared photons. The nanowires with different width (30-90 nm) and length (40-80  $\mu$ m) are patterned into U-shapes on 200nm-thick Si<sub>3</sub>N<sub>4</sub> waveguides, and the photons travelling along the waveguides could be efficiently absorbed by the nanowires via evanescent coupling. With the use of high-speed SiGe cryogenic amplifier, which operates together with the detector chip at the temperature of 1.7K, the jitter of the detection system is measured to be only 19 ps due to the improved signal-to-noise ratio (SNR), compared to 48 ps measured with room-temperature amplifiers. By investigating the background noise level and the pulse shape of the output signal from the detector, we determine the contribution of the noise to the final system jitter is less than 3ps, indicating that our results are very close to the intrinsic jitter of the detector.

**11:39AM Y7.00003 A Superconducting Ion Detection Scheme for Atom Probe Tomography**, JOSEPH SUTTLE, University of Wisconsin–Madison, THOMAS KELLY, Cameca Instruments Inc., ROBERT MCDERMOTT, University of Wisconsin–Madison — Superconducting detectors are a promising avenue for improving the performance of Atom Probe Microscopes. Many types of superconducting detectors have been developed within the past several decades, each with its own strengths and weaknesses. Many of these detectors are inherently slow, bulky, require complex multiplexing schemes to attain position sensitivity, or require complex read-out electronics. In response to the rigorous demands of atom probe technology, and with the goal of developing an elegant, simple to use solution, we have developed a novel superconducting delay line detector. The principal of detection is to use the kinetic energy of incoming ions to generate excess quasiparticles in a superconducting stripline. These quasiparticles generate a measurable signal which propagates along the delay line. By measuring the timing of the output signals from this delay line, we are able to measure the time of flight for the ion and the position of its impact on the detector. We will be presenting on the performance of this detector as measured in a Field Ion Microscope.

**11:51AM Y7.00004 Highly flexible, mechanically robust superconducting wire consisting of NbN-carbon-nanotube nanofibril composites**, JEONG-GYUN KIM, CINAP, IBS, DOES, Sungkyunkwan Univ, HAEYONG KANG, DOES, Sungkyunkwan Univ, JOONGGYU KIM, YOUNG HEE LEE, DONGSEOK SUH, CINAP, IBS, DOES, Sungkyunkwan Univ — A flexible superconducting fiber is prepared by twisting carbon nanotube (CNT) sheets coated with sputter-deposited niobium nitride (NbN) layer to form the shape of yarn. Twisted CNT yarn, which has been extensively studied due to its high flexibility as well as excellent mechanical properties, and NbN, which is a superconducting material with high transition temperature ( $T_c$ ) and critical magnetic field ( $H_c$ ), are combined together by the deposition of NbN layer on free-standing CNT-sheet substrate followed by the biscrolling process. We tried many experimental conditions to investigate the superconducting properties of NbN-CNT yarn as a function of NbN thickness and number of CNT-sheet layers, and found out that the superconducting property of NbN on CNT-sheet can be comparable to that of NbN thin film on the normal solid substrate. In addition, the superconducting property survived even under the condition of severe mechanical deformation such as knotting. These results show the potential application of this technology as a large-scale fabrication method of flexible, mechanically robust, high performance superconducting wire. This work is supported by the Institute for Basic Science (IBS-R011-D1), and by the National Research Foundation (BSR-2013R1A1A1076063) funded by the Ministry of Science, ICT & Future Planning, Republic of Korea.

**12:03PM Y7.00005 Development of semi-rigid cables for low temperature superconducting detectors**, AKIHIRO KUSHINO, Kurume University, SOICHI KASAI, COAX CO., LTD. — We are developing semi-rigid cables for accurate readout of superconducting radiation/particle detectors and other low temperature experiments. The center conductor with a diameter of 0.86 mm is separated with seamless metal outer conductor by dielectric material, polytetrafluoroethylene. We used various metal materials with low thermal conductivity for the electrical conductors such as stainless-steel, cupro-nickel, brass, beryllium-copper, phosphor-bronze, niobium-titanium, and niobium. In addition to the conventional semi-rigid cables, low-pass-filter type cables were manufactured and evaluated to cut the high frequency noise into superconducting detectors. We measured their low thermal conductance and attenuation property up to 10 GHz below the liquid helium temperature.

**12:15PM Y7.00006 Understanding and eliminating the fast creep problem in Fe-based superconductors**, LEONARDO CIVALE, SERENA ELEY, BORIS MAIOROV, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos, USA, MASASHI MIURA, Graduate School of Science & Technology, Seikei University, Tokyo, Japan — One surprising characteristic of Fe-based superconductors is that they exhibit flux creep rates ( $S$ ) as large as, or larger than, those found in oxide high temperature superconductors (HTS). This very fast vortex dynamics appears to be inconsistent with the estimate of the influence of the thermal fluctuations as quantified by the Ginzburg number ( $Gi$ ), which measures the ratio of the thermal energy to the condensation energy in an elemental superconducting volume. In particular, compounds of the  $AFe_2As_2$  family ("122") have  $Gi \sim 10^{-5}$  to  $10^{-4}$ , so  $S$  could be expected to lie between that of low  $T_c$  materials (where typically  $Gi \sim 10^{-8}$ ) and HTS such as  $YBa_2Cu_3O_7$  ( $Gi \sim 10^{-2}$ ), as indeed occurs in other superconductors with intermediate fluctuations, such as  $MgB_2$  ( $Gi \sim 10^{-6}$  to  $10^{-4}$ ). We have found the solution to this puzzle: the fast creep rates in 122 compounds are due to non-optimized pinning landscapes. Initial evidence comes from our previous studies showing that the introduction of additional disorder by irradiation decreases creep significantly in 122 single crystals, although still remaining well above the ideal limit. We now have new evidence from 122 thin films demonstrating that  $S$  can be reduced to the lower limit set by  $Gi$  by appropriate engineering of the pinning landscape.

**12:27PM Y7.00007 Tuning Vortex Creep in Irradiated  $YBa_2Cu_3O_{7-\delta}$  Coated Conductors**, SERENA ELEY, Los Alamos National Laboratory, KAREN KIHLLSTROM, SIGRID HOLLEIS, MAXIME LEROUX, Argonne National Laboratory, MARTIN RUPICH, American Superconductor Corporation, DEAN MILLER, Argonne National Laboratory, ASGHAR KAYANI, Western Michigan University, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory, LEONARDO CIVALE, Los Alamos National Laboratory —  $YBa_2Cu_3O_{7-\delta}$  coated conductors (CCs) show non-monotonic changes in the temperature-dependent creep rate,  $S(T)$ , due to mixed pinning landscapes comprised of twin boundaries, planar defects, point defects, and nanoparticle precipitates. Notably, in low fields, there is a conspicuous dip in  $S$  as  $T$  increases from  $\sim 20$ K to  $\sim 65$ K. The source of this dip is poorly understood. Moreover, pinning landscapes that are favorable for high critical currents,  $J_c$ , are not necessarily optimal for low  $S$ . We have found that, though oxygen irradiation introduces few-nm-sized defects that result in significant increases in  $J_c$ , it is detrimental to creep, increasing  $S$  (reducing the dip depth) for  $T > 20$ K. Understanding the source of this dip is crucial to engineering pinning landscapes that concurrently promote high  $J_c$  and low  $S$ . To this end, we study changes in  $S(T)$  as we tune the ratio of smaller (point to few-nm-sized) defects to larger nanoparticles in an oxygen-irradiated CC by annealing in  $O_2$  at 250C to 600C. We observe a steady decrease in  $S(T > 20$ K) with increasing annealing temperature. This suggests that pre-existing nanoparticle precipitates are likely responsible for the dip in  $S(T)$ , and underlines the fact that the effects of defects are not additive, but rather can be competitive.

**12:39PM Y7.00008 Enhancement of critical current through compound defect with proton irradiation and heavy ion irradiation in YBCO coated conductors and  $\text{FeSe}_x\text{Te}_{1-x}$  crystals<sup>1</sup>**, KAREN KIHLMSTROM, Argonne National Lab and University of Illinois at Chicago, MAXIME LEROUX, Argonne National Lab, SIGRID HOLLEIS, Atominstut TU Wien, DANIELLE HARRIS, Grand Valley State University, ULRICH WELP, HELMUT CLAUS, Argonne National Lab, ASGHAR KAYANI, Western Michigan University, GENDA GU, Brookhaven National Lab, MARTY RUPCH, SRIVATSAN SATHYAMURTHY, STEVEN FLESHLER, American Superconductor Corp, FRANCESCO LAVIANO, LAURA GOZZELINO, ROBERTO GERBALDO, GIANLUCA GHIGO, Politecnico di Torino, WAI-KWONG KWOK, Argonne National Lab — We investigate the enhancement of vortex pinning by both point and columnar defects and compare the results in 2G YBCO coated conductors (CC), with  $T_c$  90K, and in  $\text{FeSe}_x\text{Te}_{1-x}$  single crystals with  $T_c$  14K. Both samples were irradiated with 250 MeV Au ions to a dose-matching field of 1T. The samples were then irradiated with 4 MeV protons to a dose of  $4 \times 10^{16}$  p/cm<sup>2</sup> and  $8 \times 10^{16}$  p/cm<sup>2</sup> in the CC and single crystal, respectively. The major effect of compound particle irradiation in both samples resulted in a synergetic enhancement of the critical current across a wide field range, beyond the enhancement from either individual irradiation type.

**12:51PM Y7.00009 Critical Current by Design Through Large-scale Simulations<sup>1</sup>**, ANDREAS GLATZ, ALEX KOSHELEV, IVAN SADOVSKYY, GEORGE CRABTREE, Argonne National Laboratory — Understanding the dynamic behavior of vortex matter in complicated pinning landscapes is a major challenge for both fundamental science and energy applications. In particular, optimizing type, size and density of pinning centers can significantly enhance the critical current. Based on the time-dependent Ginzburg-Landau equation, we developed a numerical approach towards finding these optimal pinning configurations. I will give an overview of this new paradigm, called Critical Current by Design.

**1:03PM Y7.00010 Simulation of the vortex dynamics in a real pinning landscape of  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  coated conductors<sup>1</sup>**, IVAN SADOVSKYY, ALEXEI KOSHELEV, ANDREAS GLATZ, Argonne Natl Lab, VOLKAN ORTALAN, Purdue University, MARTIN RUPICH, American Superconductor, MAXIME LEROUX, Argonne Natl Lab — We present a critical current analysis of a real high-temperature superconducting (HTS) sample in a magnetic field by combining state-of-the-art large-scale Ginzburg-Landau simulations with reconstructive three-dimensional scanning transmission electron microscopy tomography of the pinning landscape in Dy-doped  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$ . This methodology provides a unique look at the vortex dynamics in the presence of a complex pinning landscape, responsible for the high current-carrying capacity characteristic of commercial HTS wires. Our method demonstrates very good functional and quantitative agreement of the critical current between simulation and experiment, providing a new predictive tool for HTS wires design.

**1:15PM Y7.00011 Rapid Doubling of the Critical Current of  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  Coated Conductors.**, U. WELP, M. LEROUX, K. J. KIHLMSTROM, Argonne National Laboratory, S. HOLLEIS, Technische Universitaet Wien, Austria, M. W. RUPICH, S. SATHYAMURTHY, S. FLESHLER, American Superconductor Corp., H. P. SHENG, D. J. MILLER, Argonne National Laboratory, S. ELEY, L. CIVALE, Los Alamos National Laboratory, P. M. NIRLAULA, A. KAYANI, Western Michigan University, W. K. KWOK, Argonne National Laboratory — We demonstrate the doubling of the critical current density of production-line REBCO coated conductors (CCs) in fields of 6 T ||c at 27 K by irradiation with a 3.5-MeV oxygen ion beam. This doubling of  $J_c$  is achieved within one second or less opening an industrially viable approach to address a persisting challenge, namely the greatly reduced performance of CCs in even modest applied magnetic fields. TEM images reveal that the enhanced critical current is due to finely dispersed small clusters approximately 5 nm in diameter. The major effect of the irradiation-induced defects is the reduction of the field-dependence of  $J_c$ , which we attribute to the mixed pinning landscape composed of strong pre-existing pin sites and the finely dispersed irradiation-induced defects. Patterning and microstructural characterization were performed at the Center for Nanoscale Materials, an Office of Science user facility, supported by the Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

**1:27PM Y7.00012 Numerical optimization methods for critical currents in superconductors<sup>1</sup>**, GREGORY KIMMEL, IVAN SADOVSKYY, ALEX KOSHELEV, ANDREAS GLATZ, Argonne National Laboratory — In this work, I present optimization methods for maximizing the critical current in high-temperature superconductors for energy applications. The critical current in the presence of an external magnetic field is mostly defined by the pinning landscape (pinscape) within the superconductor, which prevents magnetic vortices from moving and, therefore, increases its critical current. Our approach is to generate different pinscapes and obtain the resulting critical current by large-scale time-dependent Ginzburg-Landau equations [J. Comp. Phys. **294**, 639 (2015)]. Pinning centers could be any combination of defects, including spherical and columnar defects. The parameters controlling the pinscape are adaptively adjusted in order to find the optimal parameter set, which maximizes the critical current. Here, we compare different optimization methods and discuss their performance.

**1:39PM Y7.00013 Probing Topological Matter with Sound<sup>1</sup>**, DAVID SCHMELTZER, City College of New York — We introduce a microscopic formulation to identify the stress in a quantum fluid to compute the stress viscosity with sound waves. The viscosity stress tensor is used to determine, e.g. the ultrasound attenuation in superconductors. When an Abrikosov lattice is formed on the surface of a Topological Insulator in a external magnetic field, Majorana modes form dispersive bands. We show that the ultrasound attenuation is modified by the Majorana modes offering a novel method to identify Topological Superconductors. Moreover we compute the stress tunneling which uses Majorana modes and represent the sound analogue of the Andreev crossed reflection. We check the violation of the sound momentum conservation of systems which only exists on the boundary of a higher dimensional system, e.g. a 1D chiral fermion which can exist at the boundary of a 2D Quantum Hall system.

**Session Y11 DCMP DMP: Tunneling in Superconductors: Spectroscopy, Andreev Reflection, and Nanowires** 307 - Igor Fridman, Quasar, Inc.

**11:15AM Y11.00001 Pulsed tunneling spectroscopy of strongly correlated phases in 2D electronic systems** , JOONHO JANG, BENJAMIN HUNT, Massachusetts Institute of Technology, LOREN PFEIFFER, KENNETH WEST, Princeton University, RAYMOND ASHOORI, Massachusetts Institute of Technology — We used the pulsed tunneling spectroscopy to reveal the well-defined magnophonon modes of the magnetic-field-induced Wigner crystalline phase in a GaAs 2D QW. The strong evidence of the distinctive characteristics of the phonon mode such as the power laws and mass-independence is demonstrated. In the later part of the talk, I will also present the newly-developed momentum resolved tunneling spectroscopy, which utilizes the in-plane magnetic fields to tune the momentum of tunneling electrons. Using this technique, we successfully measured the energy-momentum dispersion curve of electrons embed in a 2D heterostructure.

**11:27AM Y11.00002 Fingerprints of the superconducting pairing glue via inelastic tunneling spectroscopy** , PATRIK HLOBIL, JRG SCHMALIAN, JASMIN JANDKE, WULF WULFHEKEL, Karlsruhe Institute of Technology — In the past, tunneling spectroscopy has been interpreted as a direct probe of the fermionic density of states in superconductors. However, in this talk we discuss the impact of inelastic tunneling on tunnel spectra and show that depending on the actual system these interpretations have to be revisited. We show how such inelastic tunneling processes can occur in bulk systems and how they affect the analysis of the experimental data. Considering the spin-gap for spin excitations in the high- $T_c$  superconductors we can trace back the peak-dip-hump features observed in many unconventional superconductors to the shift of the spin spectral weight to higher energies below the critical temperature  $T_c$ .

**11:39AM Y11.00003 Planar junction tunneling study of single-crystal eutectic phases of  $\text{Sr}_2\text{RuO}_4/\text{Sr}_3\text{Ru}_2\text{O}_7$**  , XINXIN CAI, BRIAN ZAKRZEWSKI, Pennsylvania State University, H. WANG, Zhejiang University, C. ANDREOU, Pennsylvania State University, D. SCHLOM, Cornell University, Z.-Q. MAO, Tulane University, R. J. CAVA, Princeton University, YING LIU, Pennsylvania State University, Shanghai Jiao Tong University — Despite of intensive study of many years, the precise value of the superconducting energy gap of the odd-parity superconductor  $\text{Sr}_2\text{RuO}_4$  has not been fully settled. Many complications exist. The band dependence of superconductivity makes the results from a bulk measurement of the gap difficult to interpret quantitatively. Surface based measurements such as scanning tunneling spectroscopy have to deal with the suppression of the superconducting energy gap on the cleaved *ab* surface due to surface reconstruction. We performed quasi-particle tunneling measurements of the superconducting energy gap in planar junctions prepared on naturally cleaved edges of a  $\text{Sr}_2\text{RuO}_4$  crystal found in the eutectic phase of  $\text{Sr}_2\text{RuO}_4/\text{Sr}_3\text{Ru}_2\text{O}_7$ . Cleaving of such eutectic crystals exposes thin  $\text{Sr}_2\text{RuO}_4$  plates inserted in a  $\text{Sr}_3\text{Ru}_2\text{O}_7$  bulk crystal with the *c* axis along that of the  $\text{Sr}_3\text{Ru}_2\text{O}_7$  bulk, as shown by X-ray diffraction data. Results obtained on  $\text{Au-Sr}_2\text{RuO}_4/\text{Sr}_3\text{Ru}_2\text{O}_7$  tunnel junctions suggest that superconductivity survives on the surface of the plates, showing a gap value of 0.2 meV, close to the BCS value for weak-coupling superconductors. Experiments on tunnel junctions made on cleaved crystals of a mesoscopic size are underway.

**11:51AM Y11.00004 Tunneling in Al/ $\text{Al}_2\text{O}_3$ /Al junctions and its direct link with energy gap and tunneling time across the barrier.** , EDGAR PATINO , NEELIMA KELKAR, Universidad de los Andes — Quantum tunneling has been widely used in order to investigate the density of states of the materials across the barrier and magnetoresistance in magnetic tunnel junctions (MTJs). In spite of the possible applications there is no clear understanding of the barrier parameters as a function of temperature. Measurements of current-voltage (*I-V*) characteristics of a high quality Al/ $\text{Al}_2\text{O}_3$ /Al junction at temperatures ranging from 3.5 K to 300 K have been used to extract the barrier properties. Fitting results using Simmons model led to a constant value of barrier width  $s \sim 20.8$  Å and a continuous increase in the barrier height with decreasing temperature. The latter is used to determine the energy band gap temperature dependence and average phonon frequency  $\omega = 2.05 \times 10^{13} \text{ sec}^{-1}$  in  $\text{Al}_2\text{O}_3$ . Finally from the experimentally extracted barrier height and width parameters we calculate the tunneling time for a solid state tunnel junction. The order of magnitude of this time corresponds to the one obtained in sophisticated experiments. The barrier parameters are used to extract the temperature dependent dwell times in tunneling ( $\tau_D = 3.6 \times 10^{-16} \text{ sec}$  at mid-barrier energies) and locate resonances above the barrier.

**12:03PM Y11.00005 Low temperature tunneling transport in van der Waals contacted superconductor/semiconductor Schottky barriers<sup>1</sup>** , ANG LI, ARTHUR HEBARD, University of Florida — We present a comparative study over a large temperature range (2.5-300K) of Schottky barriers formed either by evaporation of normal metals (Au, Al) or by van der Waals contact of mechanically exfoliated under-doped high- $T_c$  Bi-2212 flakes onto moderately doped n-type GaAs and p-type Si semiconductor substrates. Our modified barrier-inhomogeneity model applied to the thermionic emission equation [1] gives a good description of the temperature evolution of barrier parameters, such as the zero-bias Schottky barrier height  $\Phi_{SB}^0(T)$ , the ideality factor  $\eta(T)$  and the flat band barrier height, as the temperature is lowered from high temperatures where thermionic emission dominates to lower temperatures where thermal field emission and field emission (direct tunneling) dominate. At low temperatures for all barriers studied, both  $\Phi_{SB}^0(T)$  and  $\eta^{-1}(T)$  are linear in temperature with zero intercepts. Direct tunneling is verified in the Bi-2212/n-GaAs barriers by the appearance of superconducting density of states curves along with an energy gap  $2\Delta = 65 \text{ meV}$  in good agreement with ARPES and scanning tunneling microscope results by other investigators.

**12:15PM Y11.00006 Current-phase relations in epitaxial Al/InAs nanowire Josephson junctions** , ERIC SPANTON, Stanford Institute for Materials and Energy Sciences, MINGTANG DENG, PETER KROGSTROP, THOMAS JESPERSEN, JESPER NYGRD, CHARLES MARCUS, University of Copenhagen, KATHRYN MOLTER, Stanford Institute for Materials and Energy Sciences — Current-phase relations (CPRs) are a fundamental property of Josephson junctions, and in superconductor-normal-superconductor (SNS) junctions they can deviate from sinusoidal behavior at low temperatures. For short junctions, the shape and amplitude of the CPR is directly related to the properties of the Andreev bound states in the junction. Understanding the proximity effect, which is mediated by Andreev reflections, is particularly important in high spin-orbit and topological materials, where proximity-induced topological superconductivity is highly sought after. We used scanning superconducting quantum interference device microscopy to measure the CPR in many epitaxial Al/InAs nanowire junctions. We found CPRs that were very forward-skewed at low temperatures, indicating highly transmitting junctions. We will discuss the temperature, low magnetic field, and gate dependence of the CPRs, and the applicability of the short-junction theory to our junctions.

**12:27PM Y11.00007 Enhanced crossed Andreev reflection in a superconducting ladder<sup>1</sup>**, ABHIRAM SOORI, International Centre for Theoretical Sciences, TIFR, Bengaluru, SUBROTO MUKERJEE, Indian Institute of Science, Bangalore — Andreev reflection is a process that happens at the junction of a normal metal (NM) and a superconductor(SC), where the Cooper-pair current in the superconductor gets equal contributions from the electron and hole channels of the normal metal. Crossed Andreev reflection (cAr) is a related process that happens in a system of two NM's independently connected to a SC when the current in the electron channel of the first NM and the current in the hole channel of the second NM together contribute to the Cooper-pair current in the SC. A typical experimental set-up to investigate cAr consists of two ferromagnetic metal leads connected to an s-wave superconductor. We propose an alternative mesoscopic set-up that enhances cAr which contains no ferromagnetic parts. Instead, our set-up consists of two NM's coupled to a superconducting ladder. We calculate the currents in the different channels and demonstrate enhanced cAr.

**12:39PM Y11.00008 Spin polarization measurements of ferromagnetic atomic chains on a superconductor: Part I<sup>1</sup>**, YONGLONG XIE, SANGJUN JEON, ILYA DROZDOV, JIAN LI, ANDREI BERNEVIG, ALI YAZDANI, Princeton Univ — Introduction of magnetic defects in superconductors gives rise to spin polarized in-gap Shiba states. Recently chains of magnetic atoms, which give rise to a band of Shiba states, have been proposed as a platform for topological superconductivity. Spectroscopic evidence for in-gap Shiba states and Majorana end mode has been reported in previous studies of self-assembled chains of ferromagnetic Fe atoms on the surface of Pb[1]. In this talk, we introduce the technique of spin-polarized scanning tunneling microscopy and spectroscopy (SP-STM) and discuss how we prepare tips that can show spin contrast at zero magnetic field, without disrupting superconductivity on the Pb surface. We use this technique, combined with the use of a vector magnet to orient the tip magnetization to probe the spin polarization of the Shiba states induced by the Fe atomic chains onto the Pb surface. A key to interpreting such experiments with spin-polarized STM tip is to understand the role of spin-polarization in the setpoint effect, which will be discussed in the next talk. [1] S. Nadj-Perge, I.K. Drozdov, J. Li, H. Chen, S. Jeon, J. Seo, A.H. MacDonald, B.A. Bernevig, A. Yazdani, Science **346**,602 (2014)

**12:51PM Y11.00009 Spin Polarization Measurements of Ferromagnetic Atomic Chains on a Superconductor: Part II<sup>1</sup>**, SANGJUN JEON, YONGLONG XIE, ILYA K. DROZDOV, JIAN LI, B. ANDREI BERNEVIG, ALI YAZDANI, Princeton University — A key property of the Majorana fermions edge mode when realized at the edge of a topological superconductor is their spin. Unlike other low energy excitation in a conventional superconductor, which are made up of time-reverse partners of up and down spin, Majorana is expected to have a definite spin orientation. We utilize the technique of spin-polarized STM as described in the last talk to probe the nature of Majorana excitations in chains of Fe atoms on the surface of Pb. Previous effort on this system has detected signature of Majorana as a zero bias peak at end of such chains [1]. While this previous study shows evidence of ferromagnetism and spin-orbit coupling in such atomic chains on Pb, they did not probe the spin properties of the end mode specifically. We describe energy-resolved spin-polarized STM experiments designed to probe whether the previously reported zero energy end modes are spin-polarized or not. [1] Stevan Nadj-Perge, Ilya K. **1:03PM Y11.00010 Conductance and shot noise in ferromagnet-superconductor epitaxial tunnel junctions**, FARKHAD ALIEV, ISIDORO MARTINEZ, JUAN PEDRO CASCALES, Universidad Autonoma de Madrid, Spain, CORIOLAN TIUSAN, Technical University of Cluj-Napoca, Romania, MICHEL HEHN, Universit de Lorraine, Nancy, France — Recently ferromagnet/superconductor hybrids have attracted attention due to the possibility of inducing p-wave superconductivity and of creating novel superconducting-spintronic devices. Most of these devices have a lateral configuration and are non-epitaxial, so they could not provide coherent electron tunneling over the interfaces. Here we investigate the conductance and shot noise in fully epitaxial Fe/MgO/V/MgO/Fe, Fe/MgO/Fe/MgO/V and Fe/MgO/V tunnel junctions with 40 nm thick Vanadium and 2nm thick MgO as a function of the applied bias, temperature (down to 0.3K) and magnetic state. All junctions show presence of finite subgap conductance indicating coherent two-electron transport over the barrier. Moreover, we observe conductance anomalies above the gap suppressed at temperature exceeding critical temperature, which may imply quasiparticle interference effects. High crystalline quality of the MgO barriers is confirmed by the fact that the above gap shot noise is Poissonian (direct tunneling with single barrier) or sub-Poissonian (sequential tunneling over two barriers) and is magnetic state dependent in the last case. The subgap Fano factor shows strong increase supporting multiple Andreev reflections as a possible source of excess subgap conductance.

**1:15PM Y11.00011 Supercurrents and Andreev bound states in a superconducting/strained/superconducting silicene junction**, HAI LI, Univ of Houston, CHIN-SEN TING, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas 77004, USA — Based on the Dirac-Bogoliubov-de Gennes equation, we investigated strain effects on the supercurrent and Andreev bound states (ABSs) in a superconducting/strained/superconducting silicene junction. Owing to the novel buckled structure of silicene, the supercurrent and ABS configurations can be effectively controlled by a perpendicular electric field. It was found that the supercurrent strongly depends on the direction of the strain, and the supercurrent exhibits a on/off effect under certain strains. It was demonstrated that the spin-valley symmetry of silicene can induce a spin-valley polarized supercurrent, even though the strength of the supercurrent is strongly modulated by the strain. These findings would potentially provide some intriguing insights into the correlation transport in strained silicene-based superconducting hybrid structures.

**1:27PM Y11.00012 Over-bias Light Emission due to Higher Order Quantum Noise of a Tunnel Junction**, WOLFGANG BELZIG, University of Konstanz, FEI XU, University of Konstanz, Konstanz, Germany, CECILIA HOLMQVIST, Norwegian University of Science and Technology, Trondheim, Norway — Understanding tunneling from an atomically sharp tip to a metallic surface requires to account for interactions on a nanoscopic scale. Inelastic tunneling of electrons generates emission of photons, whose energies intuitively should be limited by the applied bias voltage. However, experiments [Phys. Rev. Lett. 102, 057401 (2009)] indicate that more complex processes involving the interaction of electrons with plasmon polaritons lead to photon emission characterized by over-bias energies. We propose a model of this observation in analogy to the dynamical Coulomb blockade, originally developed for treating the electronic environment in mesoscopic circuits. We explain the experimental finding quantitatively by the correlated tunneling of two electrons interacting with an LRC circuit modeling the local plasmon-polariton mode. To explain the over-bias emission, the non-Gaussian statistics of the tunneling dynamics of the electrons is essential. Reference: F. Xu, C. Holmqvist, and W. Belzig Phys. Rev. Lett. 113, 066801 (2014)

### 1:39PM Y11.00013 Enhanced superconductivity at the interface of W/Sr<sub>2</sub>RuO<sub>4</sub> point contact<sup>1</sup>

JIAN WEI, HE WANG, WEIJIAN LOU, JIAWEI LUO, Peking Univ, YING LIU, Pennsylvania State University, J.E. ORTMANN, Z.Q. MAO, Tulane University — Differential resistance measurements are conducted for point contacts (PCs) between the Sr<sub>2</sub>RuO<sub>4</sub> (SRO) single crystal and the tungsten tip. Since the tungsten tip is hard enough to penetrate through the surface layer, consistent superconducting features are observed. Firstly, with the tip pushed towards the crystal, the zero bias conductance peak (ZBCP) due to Andreev reflection at the normal-superconducting interface increases from 3% to more than 20%, much larger than previously reported, and extends to temperature higher than the bulk transition temperature. Reproducible ZBCP within 0.2 mV may also help determine the gap value of SRO, on which no consensus has been reached. Secondly, the logarithmic background can be fitted with the Altshuler-Aronov theory of electron-electron interaction for tunneling into quasi two dimensional electron system. Feasibility of such fitting confirms that spectroscopic information like density of states is probed, and electronic temperature retrieved from such fitting can be important to analyse the PC spectra. Third, at bias much higher than 0.2 mV there are conductance dips due to the critical current effect and these dips persist up to 6.2 K. For more details see Phys. Rev. B 91, 184514 (2015).

### 1:51PM Y11.00014 Point contact spectroscopy on materials with high spin-orbit coupling

GOUTAM SHEET, Indian Institute of Science Education and Research — We will discuss the results of our point-contact spectroscopy experiments on a number of systems with high spin-orbit coupling, including topological insulators and Dirac semimetals. Such materials sometimes give rise to exotic phases of matter like unconventional superconductivity under normal metallic point contacts. On the other hand, the special spin properties of the surface of such materials can be probed using point contacts with superconducting tips. The role of special symmetry-protected properties of the surface states of such systems on Andreev reflection can also be probed. We will also discuss that point contact spectroscopy can be used as an extremely powerful tool for investigating topological systems.

### 2:03PM Y11.00015 Fabrication and measurement of multi-terminal mesoscopic Josephson junctions.<sup>1</sup>

NATALYA SOLOVYEVA, Univ of Maryland-College Park, MISHIMA TETSUYA, MICHAEL SANTOS, Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, 440 West Brooks, Norman, Oklahoma 73019-3151, JAVAD SHABANI, Physics Department, City College of New York, New York, 10031, VLADIMIR MANUCHARYAN, Univ of Maryland-College Park — We present fabrication and characterization of 3- and 4-terminal mesoscopic Josephson junctions involving InAs quantum well heterostructures [1] and superconducting Al contacts. A cross-shaped nanowire junction region with dimensions of order a few 100 nm is dry-etched in the 2DEG, followed by deposition of superconducting contacts and gating electrodes. These novel 0D devices have been recently predicted to have topological features in their Andreev spectra and finite-bias transport [2]; they may also be useful in efforts towards observation and braiding of Majorana fermions in the solid state [3]. // References: [1] J. ### Session Y12 GSNP: Inference in Complex Networks 308 - Adilson Motter, Northwestern University

#### 11:15AM Y12.00001 Physics of Inference<sup>1</sup>, ZOLTAN TOROCZKAI<sup>2</sup>, Department of Physics, University of Notre Dame, USA

— Jaynes maximum entropy method provides a family of principled models that allow the prediction of a systems properties as constrained by empirical data (observables). However, their use is often hindered by the degeneracy problem characterized by spontaneous symmetry breaking, where predictions fail. Here we show that degeneracy appears when the corresponding density of states function is not log-concave, which is typically the consequence of nonlinear relationships between the constraining observables. We illustrate this phenomenon on several examples, including from complex networks, combinatorics and classical spin systems (e.g., Blume-Emery-Griffiths lattice-spin models). Exploiting these nonlinear relationships we then propose a solution to the degeneracy problem for a large class of systems via transformations that render the density of states function log-concave. The effectiveness of the method is demonstrated on real-world network data. Finally, we discuss the implications of these findings on the relationship between the geometrical properties of the density of states function and phase transitions in spin systems.

#### 11:51AM Y12.00002 Nonparametric inference of network structure and dynamics, TIAGO P.

PEIXOTO, University of Bremen — The network structure of complex systems determine their function and serve as evidence for the evolutionary mechanisms that lie behind them. Despite considerable effort in recent years, it remains an open challenge to formulate general descriptions of the large-scale structure of network systems, and how to reliably extract such information from data. Although many approaches have been proposed, few methods attempt to gauge the statistical significance of the uncovered structures, and hence the majority cannot reliably separate actual structure from stochastic fluctuations. Due to the sheer size and high-dimensionality of many networks, this represents a major limitation that prevents meaningful interpretations of the results obtained with such nonstatistical methods. In this talk, I will show how these issues can be tackled in a principled and efficient fashion by formulating appropriate generative models of network structure that can have their parameters inferred from data. By employing a Bayesian description of such models, the inference can be performed in a nonparametric fashion, that does not require any *a priori* knowledge or *ad hoc* assumptions about the data. I will show how this approach can be used to perform model comparison, and how hierarchical models yield the most appropriate trade-off between model complexity and quality of fit based on the statistical evidence present in the data. I will also show how this general approach can be elegantly extended to networks with edge attributes, that are embedded in latent spaces, and that change in time. The latter is obtained via a fully dynamic generative network model, based on arbitrary-order Markov chains, that can also be inferred in a nonparametric fashion. Throughout the talk I will illustrate the application of the methods with many empirical networks such as the internet at the autonomous systems level, the global airport network, the network of actors and films, social networks, citations among websites, voting correlations among politicians, co-occurrence of disease-causing genes and others.

#### 12:27PM Y12.00003 Identification of dynamical models of chemical reaction networks<sup>1</sup>, ALEK-

SANDAR HABER, Northwestern University — Current first-principles models of complex chemistry, such as combustion reaction networks, often give inaccurate predictions of the time variation of chemical species. Moreover, the high complexity and dimensionality of these models render them impractical for real-time prediction and control of chemical network processes. These limitations have motivated us to search for an alternative paradigm that is able to both identify the correct model from the observed dynamical data and reduce complexity while preserving the underlying network structure. In this talk, I will present one such modeling paradigm under the scenarios of complete and incomplete observability of the dynamics. The proposed approach is applicable to combustion chemistry and a range of other chemical reaction networks.

**1:03PM Y12.00004 Infering Networks From Collective Dynamics<sup>1</sup>** , MARC TIMME, Network Dynamics, Max Planck Society — How can we infer direct physical interactions between pairs of units from only knowing the units' time series? Here we present a dynamical systems' view on collective network dynamics, and propose the concept of a *dynamics' space* to reveal interaction networks from time series. We present two examples: one, where the time series stem from standard ordinary differential equations, and a second, more abstract, where the time series exhibits only partial information about the units' states. We apply the latter to neural circuit dynamics where the observables are spike timing data, i.e. only a discrete, state-dependent outputs of the neurons. These results may help revealing network structure for systems where direct access to dynamics is simpler than to connectivity, cf. [1,2,3].

**1:39PM Y12.00005 Clustering means geometry in networks** , DMITRI KRIOUKOV, Northeastern University — Using maximum-likelihood estimation techniques, any real network data can be fit to essentially any network model, inferring the most likely values of the model parameters for the network. However there is one caveat. The results of such fitting are not spurious but meaningful and predictive, only if the network is a typical network in the unbiased ensemble of random graphs with the inferred values of model parameters. Therefore, given a particular combination of a real network and a model, the first question one has to answer is what structural properties of the network ensure that this network is a typical element in the ensemble of random graphs defined by the model. This question is usually highly intractable, explaining why it is almost never answered before the fitting/inference task is performed. Inspired by recent observations that random geometric graphs reproduce many structural and dynamical properties of a variety of real networks, we find the network structural properties that guarantee that networks that have these properties are in fact geometric, meaning that latent space network models are their true models. Specifically we prove that peculiar organization of clustering observed in real networks is one of the main such properties. In other words, maximum-entropy random graphs with specific clustering properties, which are quite different from the clustering properties of random graphs in the Strauss model, are actually soft random geometric graphs with a specific form of the connection probability function. Using this function we can then infer the coordinates of nodes in a latent space for any given network, and reliably check if the network is a typical network in the resulting ensemble of soft random geometric graphs. If it is, then the inferred coordinates are meaningful and real, and can be used for prediction tasks with proved guarantees that the results of such predictions are reliable and not just transient artifacts.

Session Y13 DBIO: Beyond Darwin: Evolution in Single Cells 309 - Robert Austin, Princeton University

**11:15AM Y13.00001 Mutation Hotspots in Single Cells** , SUSAN ROSENBERG, Baylor College of Medicine — No abstract available.

**11:51AM Y13.00002 Unraveling the genetic driving forces enabling antibiotic resistance at the single cell level.** , JULIA BOS, Princeton University — Bacteria are champions at finding ways to quickly respond and adapt to environments like the human gut, known as the epicentre of antibiotic resistance. How do they do it? Combining molecular biology tools to microfluidic and fluorescence microscopy technologies, we monitor the behavior of bacteria at the single cell level in the presence of non-toxic doses of antibiotics. By tracking the chromosome dynamics of *Escherichia coli* cells upon antibiotic treatment, we examine the changes in the number, localization and content of the chromosome copies within one cell compartment or between adjacent cells. I will discuss how our work pictures the bacterial genomic plasticity as a driving force in evolution and how it provides access to the mechanisms controlling the subtle balance between genetic diversity and stability in the development of antibiotic resistance.

**12:27PM Y13.00003 Collective Functionality through Bacterial Individuality** , MARTIN ACKERMANN, ETH Zurich and Eawag — According to the conventional view, the properties of an organism are a product of nature and nurture - of its genes and the environment it lives in. Recent experiments with unicellular organisms have challenged this view: several molecular mechanisms generate phenotypic variation independently of environmental signals, leading to variation in clonal groups. My presentation will focus on the causes and consequences of this microbial individuality. Using examples from bacterial genetic model systems, I will first discuss different molecular and cellular mechanisms that give rise to bacterial individuality. Then, I will discuss the consequences of individuality, and focus on how phenotypic variation in clonal populations of bacteria can promote interactions between individuals, lead to the division of labor, and allow clonal groups of bacteria to cope with environmental uncertainty. Variation between individuals thus provides clonal groups with collective functionality.

**1:03PM Y13.00004 Longitudinal expression of the genome of a single cell** , NADER POURMAND, University of California Santa Cruz — No abstract available.

**1:39PM Y13.00005 Single Cell Oncogenesis.** , XIN LU, University of Texas MD Anderson Cancer Center — Cancer originates from a single cell that has gone through generations of evolution of genetic and epigenetic changes that drive the cell to become malignant. In some cancers such as various types of leukemia, cancer is clonal. Yet in other cancers like glioblastoma (GBM), that is likely to be caused by simultaneous evolution of multiple subclones within the same tissue. It is obvious that a single cell can evolve into a clonal tumor upon genetic alterations, at molecular and cellular levels, holds the key to the real appreciation of cancer biology and therapeutics. Surprisingly very little is known about the process of spontaneous tumorigenesis from single cells in human. The main reason is the lack of technology to track the natural process of single cell changes from a homeostatic state to a malignant state. We developed a patented compound, photoactivatable ("caged") tamoxifen analogue 4-OHC and associated techniques (photo-switch), which we believe opens the opportunity to address this urgent biological as well as clinical question about cancer. We are using genetically engineered mouse models of head and neck squamous cell carcinoma and high grade astrocytoma (in which the tumor cells, when transformed through acute loss of tumor suppressor genes PTEN and TP53 and gain of oncogenic KRAS, can drive tumorigenesis) and molecular heterogeneity in these tissues.

Single Cells” 3/18/2016 11:15 AM.

**Friday, March 18, 2016 11:15AM - 2:15PM –**

**Session Y14 DCOMP: Progress Towards a Solution of the Hubbard Model** 310 - Emanuel Gull, University of Michigan

**11:15AM Y14.00001 Tensor network studies of the two-dimensional t-J and Hubbard models**, PHILIPPE CORBOZ, Institute for Theoretical Physics, University of Amsterdam — Tensor networks are a class of variational wave functions enabling an efficient representation of quantum many-body states, where the accuracy can be systematically controlled by the bond dimension of the tensors. A well-known example are matrix product states, the underlying ansatz of the density matrix renormalization group (DMRG) method, which has become the state-of-the-art tool to study (quasi-) 1D systems. Progress in quantum information theory, in particular a better understanding of entanglement in quantum many-body systems, has led to the development of 2D tensor networks, including projected entangled-pair states (PEPS) or the 2D multi-scale entanglement renormalization ansatz (MERA). These methods provide one of the most promising routes for the simulation of strongly correlated systems in 2D, in particular models where Quantum Monte Carlo fails due to the negative sign problem. In this talk I report on recent progress in simulating the 2D t-J and Hubbard models with infinite PEPS (iPEPS) which is a tensor network ansatz for a 2D wave function in the thermodynamic limit. Our results reveal an extremely close competition between a uniform d-wave superconducting state and different types of stripe states, where iPEPS yields better variational energies than other state-of-the-art variational methods for large 2D systems.<sup>1</sup> The stripes are site-centered with coexisting charge-, spin-, and superconducting order, where stripes with in-phase d-wave order have an equal or only slightly lower energy than stripes with anti-phase d-wave order. Finally, a nematic anisotropy reduces the pairing amplitude and the energies of stripe states are lowered relative to the uniform state with increasing nematicity.

<sup>1</sup>P. Corboz, T. M. Rice, and M. Troyer, Phys. Rev. Lett. 113, 046402 (2014); P. Corboz, arXiv:1508.04003.

**11:51AM Y14.00002 Solutions of the Two Dimensional Hubbard Model: Benchmarks and Results from a Wide Range of Numerical Algorithms**, JAMES LEBLANC, Univ of Michigan - Ann Arbor — In this talk we present numerical results for ground state and excited state properties (energies, double occupancies, and Matsubara-axis self energies) of the single-orbital Hubbard model on a two-dimensional square lattice. In order to provide an assessment of our ability to compute accurate results in the thermodynamic limit we employ numerous methods including auxiliary field quantum Monte Carlo, bare and bold-line diagrammatic Monte Carlo, method of dual fermions, density matrix embedding theory, density matrix renormalization group, dynamical cluster approximation, diffusion Monte Carlo within a fixed node approximation, unrestricted coupled cluster theory, and multireference projected Hartree-Fock. We illustrate cases where agreement between different methods is obtained in order to establish benchmark results that should be useful in the validation of future results.

**12:27PM Y14.00003 Mott physics and spin fluctuations: A unified framework**, OLIVIER PARCOLLET, Institute of Theoretical Physics, IPHT, CEA-Saclay, France — I will present the "TRILEX" formalism for strongly correlated electron systems and its application to the Hubbard model. TRILEX is designed to unify Dynamical Mean Field Theory (DMFT) and spin fluctuation approaches close to the Mott transition in a minimal way. It is based on a local approximation of the dynamical three-leg interaction vertex and solved using a self-consistent local quantum impurity model. It allows to address simultaneously the Mott physics à la DMFT and the effect of long range antiferromagnetic fluctuations. While its computational cost is comparable to a single site Extended-DMFT computation, the self-energy is momentum-dependent. Moreover TRILEX is the starting point of a systematic and controlled method based on clusters. I will discuss the application of TRILEX to the Hubbard model on a two-dimensional square lattice. As interactions are increased towards the Mott insulating state, the local vertex acquires a strong frequency dependence, driving the system to a Mott transition, while at low enough temperatures the momentum dependence of the self-energy is enhanced due to large spin fluctuations. Upon doping, a Fermi arc is found in the one-particle spectral function, which is one signature of the pseudogap state.

**1:03PM Y14.00004 Dynamical Vertex Approximation for the Hubbard Model**, ALESSANDRO TOSCHI, Institute of Solid State Physics, TU Wien, Vienna (Austria) — A full understanding of correlated electron systems in the physically relevant situations of three and two dimensions represents a challenge for the contemporary condensed matter theory. However, in the last years considerable progress has been achieved by means of increasingly more powerful quantum many-body algorithms, applied to the basic model for correlated electrons, the Hubbard Hamiltonian. Here, I will review the physics emerging from studies performed with the dynamical vertex approximation [1], which includes diagrammatic corrections to the local description of the dynamical mean field theory (DMFT). In particular, I will first discuss [2] the phase diagram in three dimensions with a special focus on the commensurate and incommensurate magnetic phases, their (quantum) critical properties, and the impact of fluctuations on electronic lifetimes and spectral functions. In two dimensions, the effects of non-local fluctuations beyond DMFT grow enormously, determining the appearance of a low-temperature insulating behavior for all values of the interaction in the unfrustrated model [3]: Here the prototypical features of the Mott-Hubbard metal-insulator transition, as well as the existence of magnetically ordered phases, are completely overwhelmed by antiferromagnetic fluctuations of exponentially large extension, in accordance with the Mermin-Wagner theorem. Eventually, by a fluctuation diagnostics [4] analysis of cluster DMFT self-energies, the same magnetic fluctuations are identified as responsible for the pseudogap regime in the hole-doped frustrated case, with important implications for the theoretical modeling of the cuprate physics.

**1:39PM Y14.00005 Density matrix embedding theory studies of the two-dimensional Hubbard model<sup>1</sup>**, BO-XIAO ZHENG, Princeton University — Density matrix embedding theory (DMET) provides a quantum embedding framework to compute the electronic structure in strongly correlated lattice systems. It has been applied to various model Hamiltonians and *ab initio* systems. In this talk, I will review the results obtained in the two-dimensional one-band Hubbard model using DMET. Over the last years, we mapped a calibrated ground-state phase diagram of the two-dimensional Hubbard model, concerning magnetic, superconducting and various inhomogeneous phases. Based on the results from this work, as well as the consistent data from other numerical methods, we are able to conclude that many parts of the Hubbard phase diagram is already settled up to an accurate energy scale of 0.001t. Recently, by using large-scale auxiliary-field quantum Monte Carlo (AFQMC) in the impurity problem, we are able to treat much larger embedded clusters at half-filling (and with the constrained path approximation at non-half-filling), which provides a deeper understanding on the finite-size effects of energy and observables in both quantum embedding and finite cluster numerical methods. Finally, we systematically investigated the putative inhomogeneous phases in the underdoped, strong coupling Hubbard model, proposing new inhomogeneous patterns as strong candidates for the ground state. **Session Y15 DMP: 2D Materials: Superconductivity and Correlations III** 314 - Walter Lambrecht, Case Western Reserve University

**11:15AM Y15.00001 Superconductivity in monolayer FeSe and quantum Griffiths singularity in 2D superconductors<sup>1</sup>**, JIAN WANG, Peking University — By direct transport and magnetic measurements, we provide first direct evidence for high temperature superconductivity in monolayer FeSe films on insulating SrTiO<sub>3</sub> (STO) substrates with the onset T<sub>c</sub> and critical current density much higher than those for bulk FeSe [1]. Besides, the thickness dependent superconductivity in ultrathin FeSe films on STO has been investigated [2,3]. By both in situ scanning tunneling microscopy/spectroscopy and ex situ transport and magnetization measurements, we find that the two-atomic-layer Ga film with graphene-like structure on wide band-gap semiconductor GaN is superconducting with T<sub>c</sub> up to 5.4 K [4]. Furthermore, in three-atomic-layer Ga films, we observe for the first time the quantum Griffiths singularity of superconductor-metal transition in two dimensional (2D) superconductors [5]. **11:51AM Y15.00002 High-T<sub>c</sub> superconductivity at 40 K emerged in ultrathin FeSe electric-double-layer transistors**, SHIOGAI JUNICHI, YUKIHIRO ITO, TOSHIKI MITSUHASHI, TSUTOMU NOJIMA, ATSUSHI TSUKAZAKI, Institute for Materials Research, Tohoku University — A few unit-cell (UC) FeSe films on SrTiO<sub>3</sub> substrates have recently attracted much attentions owing to emergence of high temperature superconductivity (high-T<sub>c</sub>) about 65 K compared to the bulk value of 8 K. Modulation of electronic structure, charge transfer from SrTiO<sub>3</sub>, and electron-phonon coupling between the film and substrate are proposed as possible origins for high-T<sub>c</sub>. Although the in-situ scanning tunneling and photoemission spectroscopies have been intensively studied [1], systematic thickness, carrier density and substrate material dependences of electrical measurements have been limited so far. Here we report on high-T<sub>c</sub> in FeSe films on SrTiO<sub>3</sub> and MgO in electric-double-layer transistor (EDLT) [2]. Both the film thickness and electric field can be tuned by electrochemical etching and electrostatic doping in EDLT. The systematic thickness dependences reveal that the onset T<sub>c</sub> of 40 K appears from around 10 nm to 1 UC under the electric field while the initial 18-nm-thick FeSe shows no high-T<sub>c</sub>. Our results point out the importance of electron accumulation or electronic band modulation for high-T<sub>c</sub> in FeSe rather than electron-phonon coupling. [1] Q. Y. Wang et al., Chin. Phys. Lett. 29, 037402 (2012). [2] J. Shiogai et al., Nature Physics (2015).

**12:03PM Y15.00003 Ferromagnetism and d+id superconductivity in 1/2 doped correlated systems on triangular lattice**, BING YE, ANDREJ MESAROS, YING RAN, Boston Coll — We investigate the quantum phase diagrams of t-J model on triangular lattice at 1/2 doping with various lattice sizes by using a combination of density matrix renormalization group (DMRG), variational Monte Carlo and quantum field theories. To sharply distinguish different phases, we calculated the symmetry quantum numbers of the ground state wave functions, and the results are further confirmed by looking into correlation functions. Our results show there is a first order phase transition from ferromagnetism to d+id superconductor, with the transition taking place at  $J/t = 0.4 \pm 0.2$ .

**12:15PM Y15.00004 Topological superconductivity in magnetic adatom chains on a superconductor- multiple topological phases and disorder**, TEEMU OJANEN, KIM PYHNEN, ALEX WESTSTRM, Department of applied physics, School of Science, Aalto University — Recent experimental efforts to realize topological superconductors and Majorana bound states in magnetic chains on top of a superconductor has stimulated lots of associated theory work. In this talk I will present recent results on topological superconductivity in dilute ferromagnetic chains on a superconducting surface with a Rashba spin-orbit coupling. We develop a theoretical framework that allows us to study the properties of magnetic chains at arbitrary subgap energies. Our analysis reveals that the system can support at least five distinct topological phases within realistic parameter regime. Our findings also show that the isolated bound-state energies do not need to be fine-tuned close to the gap centre and that the topological phases may be surprisingly robust towards various sources of disorder.

**12:27PM Y15.00005 Iron-Based Superconductors as topological matter**, JIANGPING HU, purdue univeristy & Institute of physics, cas — We show the existence of non-trivial topological properties in Iron-based superconductors. Several examples are provided, including (1) the single layer FeSe grown on SrTiO<sub>3</sub> substrate, in which an topological insulator phase exists due to the band inversion at M point; (2) CaFeAs<sub>2</sub>, a staggered intercalation compound that integrates both quantum spin hall and superconductivity in which the nontrivial topology stems from the chain-like As layers away from FeAs layers; (3) the Fe(Te,Se) thin films in which the nontrivial Z<sub>2</sub> topological invariance originates from the parity exchange at  $\Gamma$  point that is controlled by the Te(Se) height; (4) nontrivial topology that is driven by the nematic order in FeSe. These results lay ground for integrating high T<sub>c</sub> superconductivity with topological properties to realize new emergent phenomena, such as majorana particles, in iron-based high temperature superconductors Reference: (1) NingNing Hao and Jiangping Hu, Topological phases in the Single Layer FeSe"; Phys. Rev. X 4, 031053 (2014). (2) X Wu, C Le, Y Liang, S Qin, H Fan and J. P. Hu Effect of As-chain layers in CaFeAs<sub>2</sub>" Phys. Rev. B 89 205102 (2014) (3) X. Wu, S. Qin, Y. Liang, C. Le, H. Fan, and J. Hu, CaFeAs<sub>2</sub>: a Staggered Intercalation of Quantum Spin Hall and High Temperature Superconductivity," Physics. Rev. **1:03PM Y15.00006 Supercurrent in the quantum Hall regime: part I**, CHUNG-TING KE, Duke University, FRANCOIS AMET, Appalachian state university, IVAN BORZENETS, University of Tokyo, JIYINGMEI WANG, Duke University, KEJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, RUSSELL DEACON, Center for Emergent Matter Science, RIKEN, MICHIIHISA YAMAMOTO, University of Tokyo, YURIY BOMZE, Duke University, SEIGO TARUCHA, University of Tokyo, GLEB FINKELSTEIN, Duke University — The remarkable electronic quality of graphene/boron nitride heterostructures makes them an ideal medium to study induced superconductivity. Our Josephson junctions are made of encapsulated graphene demonstrate ballistic superconducting transport at the micron scale. In the hole-doped regime, a Fabry-Perot resonator is formed by PN junctions close to superconducting contacts, which causes quantum interference of the critical current. We study variations of the Fraunhofer pattern (I.C vs. B) thought the gate voltage range. At higher magnetic fields, superconducting transport across the junctions becomes profoundly non-periodic. Despite demonstrating strong fluctuations as a function of density and magnetic field, we find that supercurrent persists in a wide range of parameters.

**1:15PM Y15.00007 Supercurrent in the quantum Hall regime, part II**, FRANCOIS AMET, Appalachian State University, CHUNG TING KE, Duke University, IVAN BORZENETS, University of Tokyo, JIYINGMEI WANG, Duke University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, RUSSEL DEACON, Center for Emergent Matter Science, RIKEN, MICHIIHISA YAMAMOTO, University of Tokyo, YURIY BOMZE, Duke University, SEIGO TARUCHA, University of Tokyo, GLEB FINKELSTEIN, Duke University — A novel promising route for creating topological states and excitations is to combine superconductivity and the quantum Hall effect. Despite this potential, signatures of superconductivity in the quantum Hall regime remain scarce, and a superconducting current through a Landau-quantized two-dimensional electron gas has so far eluded experimental observation. High-mobility graphene/BN heterostructures exhibit the quantum Hall effect at relatively low field and are therefore particularly suitable to study the fate of the Josephson effect in that regime. Here, we report the observation of a superconducting current through graphene at fields as high as 2 Tesla. In that regime, the normal-state resistance is quantized but pockets of superconductivity still persist at small current bias. We will describe their bias and temperature dependence. Magnetic field interference patterns in the supercurrent inform on possible mechanisms mediating this supercurrent.

**1:27PM Y15.00008 Complex Stoichiometry reordering of PTCDA on Ag(111) upon K Inter-calation**, G.P. BRIVIO, A. BABY, Univ. Milano-Bicocca (Italy), C. ZWICK, M. GRUENEWALD, R. FORKER, T. FRITZ, Univ. Jena (Germany), G. FRATESI, Univ. Milano (Italy), O.T. HOFMANN, E. ZOJER, Graz Univ. Technology (Austria) — Alkali metal atoms are a simple yet efficient n-type dopant of organic semiconductors. However, the molecular crystal structures need be controlled and well understood in order to optimize the electronic properties (charge carrier density and mobility) of the target material. Here, we report that potassium intercalation into PTCDA monolayer domains on a Ag(111) substrate induces distinct stoichiometry-dependent structural reordering processes, resulting in highly ordered and large K<sub>x</sub>PTCDA domains. The emerging structures are analyzed by low temperature scanning tunneling microscopy (STM), scanning tunneling hydrogen microscopy (STHM), and low-energy electron diffraction (LEED) as a function of the stoichiometry and by density functional theory (DFT) calculations. Large stable monolayer domains are found for x=2,4. The epitaxy types for all intercalated stages are determined as point-on-line. The K atoms adsorb in the vicinity of the oxygen atoms of the PTCDA molecules, and their positions are determined with sub-Angstrom precision. This is a crucial prerequisite for the prospective assessment of the electronic properties of such composite films, as they depend on the mutual alignment between donor atoms and acceptor molecules.

**1:39PM Y15.00009 Uncovering fermionic zero-energy modes through a boundary-matrix approach**, ABHIJEET ALASE, Graduate Student, EMILIO COBANERA, Postdoctoral researcher, GERARDO ORTIZ, LORENZA VIOLA, Professor — Given a non-interacting fermionic lattice system with arbitrary boundary conditions, we show how the problem of diagonalizing the single-particle Hamiltonian can be split into suitably defined bulk and boundary problems. Following this exact separation, a boundary matrix may be constructed, which contains complete information about the emergence and nature of zero-energy modes, even in the thermodynamic limit. Our approach is applicable to model Hamiltonians in arbitrary space dimensions of relevance to topological quantum matter. As a concrete illustration, we show how to correctly describe the zero-energy Majorana modes of a time-reversal-invariant two-band s-wave topological superconductor in a Josephson ring configuration, and also provide physical insight into the predicted unconventional Josephson effect.

**1:51PM Y15.00010 Interaction-driven strong topology on the boundary of a weak topological superconductor**, DANIEL MENDLER, Inst. für theo. Festkörperphysik, Inst. of Nanotechnology, Karlsruhe Inst. of Technology, PANAGIOTIS KOTETES, Center for Quantum Devices, Niels Bohr Inst., U. of Copenhagen/Inst. für theo. Festkörperphysik, Karlsruhe Inst. of Technology, GERD SCHÖN, Inst. für theo. Festkörperphysik, Inst. of Nanotechnology, Karlsruhe Inst. of Technology — We focus on a class of topological superconductors (TSCs) which exhibit a bulk energy gap and support Majorana flat bands (MFBs) on the surface. In contrast to previous proposals relying on strong TSCs with nodal bandstructure, here MFBs are solely protected by a weak topological invariant reflecting a global or local strong anisotropy. In the present case interactions play a dual role, on one hand driving the spontaneous symmetry breaking to an anisotropic superconducting phase and on the other, gapping out the arising MFBs yielding a strong topological phase on the boundary. The prototype system showing this kind of behavior is the nematic *p<sub>z</sub>*-superconductor, which supports surface MFBs. While the interactions stabilize the *p<sub>z</sub>*-SC phase in the bulk and induce the MFBs, suppressed bulk p-wave pairing terms occur on the surface, thus lifting the MFB-degeneracy. A similar situation can take place if the nematic features are only local, a scenario which is realizable in a heterostructure consisting of a conventional superconductor in proximity to a topological insulator surface with intrinsic magnetic order.

**Friday, March 18, 2016 11:15AM - 2:15PM –**

**Session Y16 DMP: Silicene, Germanene, and Beyond** 315 - Sufe Shi, Rensselaer Polytechnic Institute

**11:15AM Y16.00001 Graphene challengers: silicene, germanene and stanene, group IV elemental synthetic electronic materials.**, GUY LE LAY, Retired — Silicene, germanene and stanene, graphene's group IV elemental cousins, have attracted considerable interest since the birth of silicene in 2012 [1]. These novel synthetic two-dimensional (2D) Si, Ge and Sn allotropes are artificially created in situ under ultra high vacuum, since, at variance with graphene, which descends from graphite, they have no parent crystal in nature. They are considered as promising candidates for ultimate scaling of nanoelectronic devices [2,3]. Indeed, the recent fabrication of the first silicene field effect transistors with ambipolar characteristics operating at room temperature demonstrates their potential as emerging 2D electronic materials [4]. In this invited talk, I will present the archetype 3x3 silicene phase formed on a silver (111) substrate [1], its sister phases and the growth of multilayer silicene, which hosts Dirac fermions and which is stable in ambient air, protected by its ultra-thin native oxide [5]. The recent synthesis of single layer germanene [6,7] and stanene [8], near room temperature 2D topological insulators will be also presented, while multilayer germanene will be further addressed. Challenging graphene, silicene, germanene and stanene, which are directly compatible with the current semiconductor industry, could lead to the development of a new class of low energy consumption nanoelectronic devices. 1. **11:51AM Y16.00002 Prediction of a quantum anomalous Hall state in Co-decorated silicene.**, THANESHWOR KALONI, GEORG SCHRECKENBACH, University of Manitoba, MICHAEL FREUND, FTI — Based on first-principles calculations, we demonstrate that Co-decorated silicene can host a quantum anomalous Hall state. The exchange field induced by the Co atoms combined with the strong spin-orbit coupling of the silicene opens a nontrivial band gap at the K point. As compared to other transition metals, Co-decorated silicene is unique in this respect, since usually hybridization and spin-polarization induced in the silicene suppress a quantum anomalous Hall state.

**12:03PM Y16.00003 Ordered structure upon deposition of Ge on the monolayer silicene on Ag(111)**, HAN-DE CHEN, DENG SUNG LIN, Department of Physics, National Tsing Hua University — The growth of monolayer silicene on Ag (111) has been a hot research in recent years. The akin structure of the same group IV element: Germanene, has also been grown successfully on different metal substrates. In this investigation, Ge has been deposited by molecular beam epitaxy on the monolayer-thick silicene grown on Ag(111). Low-temperature scanning tunneling microscopy (LT-STM) has been employed to observe the surface morphology and atomic structure. On the  $(3 \times 3)$ Si phase, only one Ge adatom is found on each  $(3 \times 3)$ Si unit cell on two different sites, A and B. The deposited Ge adatoms prefer to settle around a unit cell that has already incorporated one Ge adatom, thereby forming two domains  $(3 \times 3)$ A and  $(3 \times 3)$ B. Results on  $(7 \times 7)$ Si superstructure showing local ordering will also be presented.

**12:15PM Y16.00004 Germanene-like defects in Reverse Monte Carlo model of amorphous germanium revealed through new visualization method**, AL RAHEMTULLA, Univ of Guelph, BRUNO TOMBERLI, Capilano University, EDWARD KIM, University of Guelph, SJOERD ROORDA, Université de Montreal, STEFAN KYCIA, University of Guelph — High Resolution x-ray diffraction experiments of amorphous germanium (a-Ge) revealed structural differences that cannot be reconciled with accepted theoretical models. An intuitive computational technique has been developed to construct 3D statistical density maps to directly resolve local atomic structure of a-Ge. A reverse monte carlo routine is used to compare the continuous random network model to the experimental model of a-Ge. Undercoordination in the refined model is shown to exist bimodally, as a 4-coordinated tetrahedron and a buckled 3-coordinated structure similar to germanene. These structures account for 95.7% of the total atoms in an approximate 5:2 ratio respectively.

**12:27PM Y16.00005 Room Temperature Silicene Field-Effect Transistors<sup>1</sup>**, DEJI AKINWANDE, The University of Texas - Austin — Silicene, a buckled Si analogue of graphene, holds significant promise for future electronics beyond traditional CMOS. In our predefined experiments via encapsulated delamination with native electrodes approach, silicene devices exhibit an ambipolar charge transport behavior, corroborating theories on Dirac band in Ag-free silicene. Monolayer silicene device has extracted field-effect mobility within the theoretical expectation and ON/OFF ratio greater than monolayer graphene, while multilayer silicene devices show decreased mobility and gate modulation. Air-stability of silicene devices depends on the number of layers of silicene and intrinsic material structure determined by growth temperature. Few or multi-layer silicene devices maintain their ambipolar behavior for days in contrast to minutes time scale for monolayer counterparts under similar conditions. Multilayer silicene grown at different temperatures below 300°C possess different intrinsic structures and yield different electrical property and air-stability. This work suggests a practical prospect to enable more air-stable silicene devices with layer and growth condition control, which can be leveraged for other air-sensitive 2D materials. In addition, we describe quantum and classical transistor device concepts based on silicene and related buckled materials that exploit the 2D topological insulating phenomenon. The transistor device physics offer the potential for ballistic transport that is robust against scattering and can be employed for both charge and spin transport.

**1:03PM Y16.00006 Nearest Neighbor Hopping conduction observed with ionic liquid induced silicon surface states<sup>1</sup>**, JJ NELSON, K. V. REICH, M. SAMMON, B. I. SHKLOVSKII, A. M. GOLDMAN, University of Minnesota — A two-dimensional hole gas can be created on the surface of a bulk Si wafer by using an ionic liquid in an electric double layer transistor configuration (EDLT). EDLTs are useful in observing metal to insulator and superconductor to insulator transitions due to record high carrier densities of  $10^{15} \text{ cm}^{-2}$  that can be achieved. In some cases the high carrier densities are due in part to oxidation of the sample surface. With an EDLT configuration we have observed a 2D insulator-to-metal transition with low mobility Si at the highest reported critical carrier density. [J. Nelson and A. M. Goldman Phys. Rev. B 91, 241304(R) (2015)] The experiment reported here is designed to promote electrostatic carrier induction over electrochemical reactions and is focused on carrier densities near  $10^{11} \text{ cm}^{-2}$ . At such a low densities we observe nearest neighbor hopping conduction on the surface of Si.[J. Nelson et al., Phys. Rev. B 92, 085424 (2015)] This observation suggests that the ionic liquid covering the surface should be treated as a series of discrete charges that can act as a platform to better understand EDLT physics at higher carrier densities.

**1:15PM Y16.00007 Gapped Dirac cone in silicene and germanene on  $\text{Al}_2\text{O}_3(0001)$** , MINGXING CHEN, MICHAEL WEINERT, Univ of Wisconsin, Milwaukee — Developing guidelines to find promising substrates that can stabilize the monolayer honeycomb structures of silicene and germanene while simultaneously preserving the Dirac-electron-driven properties is of practical importance for applications. From first-principles calculations, we find that silicene on Al-terminated  $\text{Al}_2\text{O}_3(0001)$  retains the main structural profile of the ideal low-buckled silicene with a binding energy comparable to that of silicene on Ag(111). Unfolded  $k$ -projected bands reveal that a gapped Dirac cone is formed at the K point. The underlying mechanism is that the substrate has a large energy gap and the workfunctions are such that there is little direct bonding of between the silicene Dirac states and the substrate, which further guides us to find gapped Dirac states in germanene on  $\text{Al}_2\text{O}_3(0001)$ .

**1:27PM Y16.00008 Single and Few Layer Silicene: Structural, Electronic and Transport Properties<sup>1</sup>**, J DAVID CAREY, NATHANAEEL ROOME, University of Surrey — Single layer silicene has weaker  $\pi$  bonding that graphene resulting in buckling of the Si atoms in different sub-lattices. Despite the loss of planarity, a linear bandstructure emerges where we find a Fermi velocity of about  $5.3 \times 10^5 \text{ m/s}$ . Determination of the phonon dispersion characteristics reveals a  $\Gamma$  point optical phonon with an energy of 69 meV and a K point optical phonon with an energy of 62 meV. In graphene these phonons play important role in scattering electrons, and in Raman spectroscopy, but have larger energies of 194 and 166 meV, respectively. The lower phonon energies in silicene, arising from the higher atomic masses, would be expected to scatter carriers efficiently and limit carrier mobility. We have calculated, however, that the electron-optical phonon coupling matrix elements are about a factor of 25 times smaller than in graphene and this important result will help with the further development of silicene based devices due to reduced phonon scattering. The two stable stacking configurations of bilayer silicene, AA and AB, now have to account of the position of the atomic buckling in the two layers, leading to four possible atomic configurations with the buckling between the layers being in- or out-of-phase with each other. We find that in contrast to graphene, the two stable configurations are based on AA type stacking being about 70 meV per atom more stable than AB stacking. The potential for elemental layered materials beyond graphene for device applications will also be discussed.

<sup>1</sup>Single and Few Layer Silicene: Structural, Electronic and Transport Properties

**1:39PM Y16.00009 Two-dimensional group-IV monochalcogenides: structural, electronic and optical properties.**<sup>1</sup>, LIDIA GOMES, ALEXANDRA CARVALHO, A. H. CASTRO NETO, National University of Singapore — Two-dimensional materials have attracted a massive attention of the scientific and industrial communities due to their unusual and interesting properties. The layered group-IV monochalcogenides-SnS, SnSe, GeS and GeSe- has gained attention as a promising group with potentially useful applications in diverse fields. The bulk SnS, a naturally occurring mineral, has been considered as an alternative to be used in film PV cells, due to its electronic and optical properties. We use first principles calculations to explore structural, electronic and optical properties of this group, with focus in their two-dimensional forms. We show that all those binary compounds are semiconducting, with bandgap energies covering most of the visible range. They have multiple valleys in the valence and conduction bands, with spin-orbit splitting of the order of 19-86 meV. An enhanced static dielectric permittivity is found for the monolayers. Structural analysis shows that the 2D form of these materials presents very high piezoelectric constants, exceeding values recently observed for other 2D-systems. The existence of a negative Poisson ratio is predicted for the GeS compound.

**1:51PM Y16.00010 Scattering mechanisms in shallow undoped Si/SiGe quantum wells**, DOMINIQUE LAROCHE, Sandia Natl Labs, SHIH-HSIEN HUANG, National Taiwan University and National Nano Device Laboratories, ERIK NIELSEN, Sandia Natl Labs, YEN CHUANG, JIUN-YUN LI, CHIH-WEN LIU, National Taiwan University and National Nano Device Laboratories, TZU-MING LU, Sandia Natl Labs — We report the magneto-transport and scattering mechanism analysis of a series of increasingly shallow Si/SiGe quantum wells with the shallowest 2DEG located only  $\sim 10$  nm away from the surface. The peak mobility increases with increasing depth, suggesting that charge centers near the oxide/semiconductor interface is the main source of disorder. The power-law exponent of the mobility versus density curve,  $\mu \propto n^\alpha$ , is extracted as a function of the depth. At intermediate densities, the power-law dependence is characterized by  $\alpha \sim 2.3$  while at the highest achievable densities for devices with intermediate depth, an exponent  $\alpha \sim 5$  is observed. We propose, and show by simulations, that this increase in  $\alpha$  is explained by a non-equilibrium model where electrons migrating to the surface smooth out the potential landscape seen by the 2DEG. This work has been supported by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy (DOE). Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL

**2:03PM Y16.00011 Silicene-type Surface Reconstruction on C40 Hexagonal Silicides**, CAMERON VOLDERS, PETRA REINKE, Univ of Virginia — Silicene has emerged as the next two-dimensional material possessing a Dirac type electronic structure making it a prime candidate for integration in electronic devices. The study of silicene is relatively new and many aspects have yet to be fully understood. Here we present a scanning tunneling microscopy (STM) study of a Silicene-type surface reconstruction observed on nanometer scale hexagonal-MoSi<sub>2</sub> crystallites. This surface reconstruction is specific to the C40 structure of h-MoSi<sub>2</sub> and can initially be defined as a geometric silicene while the coupling between the silicene surface and the silicide bulk is under investigation. The lateral dimensions correspond to a superstructure where the silicene hexagons are slightly buckled and two of the six Si atoms are visible in the STM images creating a honeycomb pattern. The local electronic structure of the silicene is currently being studied with ST spectroscopy and the impact of confinement will be addressed. These results open an alternative route to Silicene growth by using surface reconstructions on metallic and semiconducting C40 silicide structures, which is promising for direct device integration on Si-platforms.

**11:15AM Y17.00001 Engineering excitonic properties and valley polarization in transition metal dichalcogenide monolayers**<sup>1</sup>, BERNHARD URBASZEK, CNRS-Toulouse University — Binary Transition metal dichalcogenide (TMDC) monolayer (ML) materials MoS<sub>2</sub>, MoSe<sub>2</sub>, WSe<sub>2</sub>, WS<sub>2</sub> and MoTe<sub>2</sub> share common properties such as a direct optical bandgap, Spin-Orbit splittings of hundreds of meV and coupled spin-valley states. Optical absorption and emission are dominated by robust excitons, whose resonances also strongly influence Raman scattering amplitudes [1] and second harmonic generation efficiency [2]. Important differences in opto-electronic properties between these materials depend on whether the exciton ground state is optically bright or dark. This order will depend on the conduction band Spin-Orbit splitting and the electron-hole Coulomb interaction and will have strong influence on the light emission yield of the TMDC MLs. In this talk we discuss Spin-Orbit engineering in Mo(1-x)W(x)Se<sub>2</sub> alloy monolayers [3]. We probe the impact of the tuning of the conduction band Spin-Orbit spin splitting on the bright versus dark exciton population. For MoSe<sub>2</sub> monolayers the PL intensity decreases as a function of temperature by an order of magnitude (T=4-300 K), whereas for WSe<sub>2</sub> we measure surprisingly an order of magnitude increase. The ternary material shows a trend between these two extreme behaviors. In addition we show a non-linear increase of the optically generated valley polarization as a function of tungsten (W) concentration. Tuning the optical properties in applied external fields will be discussed. [1] G. Wang et al, PRL 115, 117401 (2015) [2] G. Wang et al, 2D Mater. 2, 045005 (2015) [3] G. Wang et al, Nature Comms. (in press, arxiv 1506.08114)

**11:51AM Y17.00002 Hybrid interlayer excitons with tunable dispersion relation**, BRIAN SKINNER, Massachusetts Institute of Technology — When two semiconducting materials are layered on top of each other, interlayer excitons can be formed by the Coulomb attraction of an electron in one layer to a hole in the opposite layer. The resulting exciton is a composite boson with a dispersion relation that is a hybrid between the dispersion relations of the electron and the hole separately. In this talk I show how such hybridization is particularly interesting when one layer has a Mexican hat-shaped dispersion relation and the other has a conventional parabolic dispersion. In this case the interlayer exciton can have a range of qualitatively different dispersion relations, which can be continuously altered by an external field. This tunability in principle allows one to continuously tune a collection of interlayer excitons between different quantum many-body phases, including Bose-Einstein condensate, Wigner crystal, and fermion-like moat band phases.

**12:03PM Y17.00003 Electric Field Dependent Photoluminescence in Atomically Thin Transition Metal Dichalcogenides van der Waals Heterostructures.**, LUIS A. JAUREGUI, ALEX A. HIGH, ALAN DIBOS, ANDREW JOE, ELGIN GULPINAR, HONGKUN PARK, PHILIP KIM, Harvard University, Department of Physics — Jauregui, Alex A. High, Alan Dibos, Andrew Joe, Elgin Gulpinar, Hongkun Park, Philip Kim Harvard University, Physics Department -abstract- Single layer transition metal dichalcogenides (TMDC) are 2-dimensional (2D) semiconductors characterized by a direct optical bandgap and large exciton binding energies ( $>100$  meV). We fabricate CQW heterostructures made of 2D TMDCs with hexagonal Boron nitride (BN) as atomically thin barrier and gate dielectric, with top and bottom gate electrodes. We study the evolution of photoluminescence (PL) spectrum with varying BN barrier thickness, electric field, temperature and polarization. Our measured low-temperature (T = 3K) PL peaks show full width at half maxima on the order of  $\sim 3$ meV. We identify the photoluminescence peaks, corresponding to the charged exciton emission, which red shifts and its brightness increases while the neutral exciton emission becomes darker for increasing electric field.

**12:15PM Y17.00004 Giant and tunable valley degeneracy splitting in  $\text{MoTe}_2$**  , XIAO LI, The University of Texas at Austin, JINGSHAN QI, Jiangsu Normal University, QIAN NIU, The University of Texas at Austin, JI FENG, Peking University — Valleys in monolayer transition-metal dichalcogenides seamlessly connect two basic carriers of quantum information, namely, the electron spin and photon helicity. Lifting the valley degeneracy is an attractive route to achieve further optoelectronic manipulations. However, the magnetic field only creates a very small valley splitting. We propose a strategy to create giant valley splitting by the proximity-induced Zeeman effect. Our first principles calculations of monolayer  $\text{MoTe}_2$  on a  $\text{EuO}$  substrate show that valley splitting over 300 meV can be generated. Interband transition energies become valley dependent, leading to selective spin-photon coupling by optical frequency tuning. The valley splitting is also continuously tunable by rotating the substrate magnetization. The giant and tunable valley splitting adds a different dimension to the exploration of unique optoelectronic devices based on magneto-optical coupling and magnetoelectric coupling.

**12:27PM Y17.00005 Tunable optical second-harmonic generation from bilayer  $\text{MoS}_2$  by controlled inversion symmetry breaking** , CLAUDIA RUPPERT, TU Dortmund/Columbia Univ., YILEI LI, Stanford Univ./Columbia Univ., LEI WANG, Cornell Univ./Columbia Univ., EN-MIN SHIH, JAMES HONE, Columbia Univ., TONY HEINZ, Stanford Univ./Columbia Univ. — Due to the presence of a center of inversion, optical second-harmonic generation (SHG) from an unperturbed bilayer  $2\text{H-MoS}_2$  crystal is strongly suppressed compared to the non-centrosymmetric monolayer. In this paper, we show that SHG from bilayer  $\text{MoS}_2$  is enhanced when it is supported on a fused silica substrate. This enhancement originates from lifting of inversion-symmetry induced by substrate interactions. Further, by applying an out-of-plane electrostatic field in a back-gating geometry, we demonstrate highly tunable SH radiation from supported  $\text{MoS}_2$  bilayers. Complementing recent work on bilayer  $\text{WSe}_2$  [1], where the sample is primarily studied in the hole-doped regime, the bilayer  $\text{MoS}_2$  samples in our study are shown to be in the electron-doped regime. Through a comparison of the field-induced change in the second-order nonlinear susceptibilities of monolayer and bilayer  $\text{MoS}_2$ , we identify the importance of interlayer coupling in the tunable SHG from bilayer  $\text{MoS}_2$ . [1] Huakang Yu, Deep Talukdar, Weigao Xu, Jacob B. Khurgin, and Qihua Xiong, Nano Lett. 15 5653 (2015)

**12:39PM Y17.00006 Strain-induced topological quantum phase transition in phosphorene oxide** , SEOUNG-HUN KANG, JEJUNE PARK, Kyung Hee University, SUNGJONG WOO, Korea Institute for Advanced Study, YOUNG-KYUN KWON, Kyung Hee University — Using *ab initio* density functional theory, we investigate the structural stability and electronic properties of phosphorene oxides ( $\text{PO}_x$ ) with different oxygen compositions  $x$ . A variety of configurations are modeled and optimized geometrically to search for the equilibrium structure for each  $x$  value. Our electronic structure calculations on the equilibrium configuration obtained for each  $x$  reveal that the band gap tends to increase with the oxygen composition of  $x \downarrow 0.5$ , and then to decrease with  $x \downarrow 0.5$ . We further explore the strain effect on the electronic structure of the fully oxidized phosphorene,  $\text{PO}$ , with  $x = 1$ . At a particular strain without spin-orbit coupling (SOC) is observed a band gap closure near the  $\Gamma$  point in the  $k$  space. We further find the strain in tandem with SOC induces an interesting band inversion with a reopened very small band gap ( $\sim 5$  meV), and thus gives rise to a topological quantum phase transition from a normal insulator to a topological insulator. Such a topological phase transition is confirmed by the wave function analysis and the band topology identified by the  $Z_2$  invariant calculation.

**12:51PM Y17.00007 Electronic and structural phase transitions induced by uniaxial strains in monolayer  $\text{SnSe}$**  , YABEI WU, Shanghai University; University at Buffalo, SUNY, WEIWEI GAO, University at Buffalo, SUNY, PEIHONG ZHANG, Shanghai University; University at Buffalo, SUNY, WEI REN, Shanghai University — Two dimensional (2D) materials have attracted unprecedented research interest owing to their unique properties that are suitable for various applications. Recent research has started to explore 2D materials beyond graphene; examples include transition metal dichalcogenides and black phosphorus. Bulk  $\text{SnSe}$  is a layered semiconductor which exists in two phases. The low temperature  $\text{Pnma}$  phase has an indirect band gap of 0.89 eV and a direct band gap of 1.3 eV, while the high temperature  $\text{Cmcm}$  phase is stabilized at  $T > 800$  K. In this talk, we will present first-principles investigations of the effects of strains on the electronic and structural properties of  $\text{SnSe}$ . We find that uniaxial strains are an effective means to tune the properties single layer  $\text{SnSe}$ , and may also induce phase transitions in this system.

**1:03PM Y17.00008 Strain Engineering of Transition Metal Dichalcogenides** , ALI DADGAR, ABHAY PASUPATHY, IRVING HERMAN, DENNIS WANG, Columbia University, KYUNGNAM KANG, EUI-HYEOK YANG, Stevens Institute of Technology — The application of strain to materials can cause changes to bandwidth, effective masses, degeneracies and even structural phases. In the case of the transition metal dichalcogenide (TMD) semiconductors, small strain (around 1 percent) is expected to change band gaps and mobilities, while larger strains are expected to cause phase changes from the triangular  $2\text{H}$  phase to orthorhombic  $1\text{T}'$  phases. We will describe experimental techniques to apply small and large (around 10 percent) strains to one or few layer samples of the TMD semiconductors, and describe the effect of the strain using optical (Raman, photoluminescence) and cryogenic transport techniques.

**1:15PM Y17.00009 Simultaneous tunability of electronic and phononic gap in  $\text{SnS}_2$  under normal compressive strain** , BABU RAM<sup>1</sup>, AADITYA MANJANATH<sup>2</sup>, Ph.D student , ABHISHEK KUMAR SINGH<sup>3</sup>, Assistant Professor — Ever since the discovery of graphene, 2D materials have emerged as an attractive field of research. Here, using density functional theory based calculations, we show tunability in the electronic structure of mono to multilayered  $\text{SnS}_2$  under biaxial tensile (BT), biaxial compressive (BC), and normal compressive (NC) strains. We obtain a reversible semiconductor to metal (S-M) transition in mono to multilayered  $\text{SnS}_2$  without changing the nature of the band gap (i.e. indirect). For the stability analysis with applied strain, we use bilayer (2L-)  $\text{SnS}_2$  as our prototype system. Surprisingly, under a high NC strain, 2L- $\text{SnS}_2$  does not exhibit unstable modes. The phonon spectra of 2L- $\text{SnS}_2$  shows a gap in the optical region, which, most interestingly, increases with applied NC strain. Such a simultaneous tunability of the electronic as well as phononic properties of  $\text{SnS}_2$  under applied strain can be exploited in many applications such as pressure sensors, micromechanical resonators, frequency filters, and in many other multi-physics devices.

**1:27PM Y17.00010 Using dispersive medium to control excitons in 2D materials.** , ANDREY KLOTS, Vanderbilt University, KIRILL I. BOLOTIN, Vanderbilt University; Freie University — Excitons in 2D materials (2DMs) are known to be sensitive to the surrounding environment. This makes it possible to modify 2D excitons by depositing materials with controlled dielectric constant on top of 2DMs. This possibility becomes especially interesting if we consider materials with dielectric permittivity  $\epsilon$  that depends both on wavevector  $k$  (this happens if the medium is spatially non-uniform) and frequency  $\omega$ . Here, we develop platforms to control  $\epsilon(k, \omega)$  and explore resulting changes in light-matter interactions of 2DMs. To examine the effect of wavevector-dependent permittivity of the medium, we study absorption/photoluminescence of graphene and  $\text{MoS}_2$  in the vicinity of highly non-uniform medium - an array of metal nanoparticles, 3-5 nm in diameter. In this case absorption of light can lead to creation of excitons with non-zero momentum. These dark states are not accessible via regular absorption spectroscopy. We study the case of frequency-dependent permittivity by surrounding  $\text{MoS}_2$  by a highly-dispersive media (e.g. dielectric liquids, graphene and  $\text{VO}_2$ ). We demonstrate non-trivial frequency-dependent renormalization of the quasiparticle bandgap and exciton binding energies.

**1:39PM Y17.00011 Functional polymers for electronic-structure modulation of MoS<sub>2</sub>** , ASHWIN RAMASUBRAMANIAM, Department of Mechanical and Industrial Engineering, University of Massachusetts Amherst, RYAN SELHORST, EGGLE PUODZIUKY-NAITE, JEFFREY DEWEY, Department of Polymer Science and Engineering, University of Massachusetts Amherst, PEIJIAN WANG, MICHAEL BARNES, Department of Chemistry, University of Massachusetts Amherst, TODD EMRICK, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Two-dimensional semiconductors based on the Mo and W family of transition metal dichalcogenides (TMDCs) are emerging as an important class of materials with unique optoelectronic properties. However, there remain challenges associated with precise control over carrier doping and work functions that need to be overcome for device applications. We report the synthesis of new tetrathiafulvalene (TTF)-based polymers that provide enhanced solution stabilization of MoS<sub>2</sub> nanosheets while simultaneously modulating their electronic structure through robust, non-covalent interactions. Kelvin probe force microscopy (KPFM) imaging of TTF-polymer functionalized 2H MoS<sub>2</sub> nanosheets confirms n-doping of the MoS<sub>2</sub> with an accompanying reduction in the work function. Density functional theory calculations provide insight into the TTF-MoS<sub>2</sub> interfacial interactions and provide a theoretical basis for modulation of electronic properties of MoS<sub>2</sub> via charge-transfer interactions. These combined results illustrate the potential for polymer doping of TMDCs as a viable and scalable approach for synthesis of new hybrid materials for optoelectronics.

**1:51PM Y17.00012 Electronic and magnetic engineering of transition metal dichalcogenides** , YOUJIAN TANG, VINCENT CRESPI, Penn State Univ. Physics Dept, VINCENT CRESPI GROUP TEAM — Transition metal dichalcogenides (TMDs) have moderate bandgaps and great potential in electronic and optoelectronic applications. We show that by intercalation and compensated doping of transition metal ions, we could generate a “half-semiconductor”, half-metal or doped magnetic semiconductor. We will also show that covalently connecting a single layer of WS<sub>2</sub> to a small aromatic molecule with appropriate electronegativity, it is possible to align the molecular energy levels with the WS<sub>2</sub> conduction band edge, yielding an electronic structure of potential interest for thermoelectric applications, and covalently connecting single-layer WS<sub>2</sub> to magnetic coordination compounds could introduce magnetization into the WS<sub>2</sub> layer.

**2:03PM Y17.00013 Electronic states at transition metal dichalcogenide lateral heterointerfaces<sup>1</sup>** , OSCAR AVALOS-OVANDO, Ohio University, DIEGO MASTROGIUSEPPE, Instituto de Física Rosario, SERGIO ULLOA, Ohio University — Materials with different band gaps are typically used to create heterostructures that enable band sculpting, depending on different shape and boundaries of the systems. These are used in diode lasers and high-speed transistors devices. Potential material candidates for such heterostructures at the monolayer level are the family of transition-metal dichalcogenides, MX<sub>2</sub> (with M=Mo,W and X=S,Se), especially interesting materials with strong spin-orbit coupling and valley degrees of freedom. We consider lateral interfaces between pairs of these materials, and study the effect of different boundary geometries, motivated by recent experimental reports of the growth of such interfaces with different geometries [2,3]. Using an effective 3-orbital tight-binding model [1], we focus our attention on monolayer ribbons and triangular flakes. We analyze the formation of edge/interface states for different gap nesting materials. We study the spatial distribution and orbital character of the wave functions throughout, as well as their dependence on interface termination. [1] G. B. Liu et al., PRB 88, 085433 (2013). [2] C. Session Y18 GMAG DMP: Frustrated Magnetism: Pyrochlore and Kagome Lattices 317 - Lucile Savary, MIT

**11:15AM Y18.00001 Quantum spin ices and magnetic states from dipolar-octupolar doublets on the pyrochlore lattice** , GANG CHEN<sup>1</sup>, Fudan Univ, Perimeter Institute for Theoretical Physics — We consider a class of electron systems in which dipolar-octupolar Kramers doublets arise on the pyrochlore lattice. In the localized limit, the Kramers doublets are described by the effective spin1/2 pseudospins. The most general nearest-neighbor exchange model between these pseudospins is the XYZ model. In addition to dipolar ordered and octupolar ordered magnetic states, we show that this XYZ model exhibits two distinct quantum spin ice (QSI) phases, that we dub dipolar QSI and octupolar QSI. These two QSIs are distinct symmetry enriched U(1) quantum spin liquids, enriched by the lattice symmetry. Moreover, the XYZ model is absent from the notorious sign problem for a quantum Monte Carlo simulation in a large parameterspace. We discuss the potential relevance to real material systems such as Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>, Nd<sub>2</sub>Zr<sub>2</sub>O<sub>7</sub>, Nd<sub>2</sub>Hf<sub>2</sub>O<sub>7</sub>, Nd<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub>, Nd<sub>2</sub>Sn<sub>2</sub>O<sub>7</sub> and Ce<sub>2</sub>Sn<sub>2</sub>O<sub>7</sub>.

**11:51AM Y18.00002 Layered kagome spin ice** , JAMES HAMP, SIAN DUTTON, University of Cambridge, MARTIN MOURIGAL, Georgia Tech, PAROMITA MUKHERJEE, University of Cambridge, JOSEPH PADDISON, Georgia Tech, HARAPAN ONG, CLAUDIO CASTELNOVO, University of Cambridge — Spin ice materials provide a rare instance of emergent gauge symmetry and fractionalisation in three dimensions: the effective degrees of freedom of the system are emergent magnetic monopoles, and the extensively many ‘ice rule’ ground states are those devoid of monopole excitations. Two-dimensional (kagome) analogues of spin ice have also been shown to display a similarly rich behaviour. In kagome ice however the ground-state ‘ice rule’ condition implies the presence everywhere of magnetic charges. As temperature is lowered, an Ising transition occurs to a charge-ordered state, which can be mapped to a dimer covering of the dual honeycomb lattice. A second transition, of Kosterlitz-Thouless or three-state Potts type, occurs to a spin-ordered state at yet lower temperatures, due to small residual energy differences between charge-ordered states. Inspired by recent experimental capabilities in growing spin ice samples with selective (layered) substitution of non-magnetic ions, in this work we investigate the fate of the two ordering transitions when individual kagome layers are brought together to form a three-dimensional pyrochlore structure coupled by long range dipolar interactions. We also consider the response to substitutional disorder and applied magnetic fields.

**12:03PM Y18.00003 Theory of quantum kagome ice<sup>1</sup>** , YI-PING HUANG, MICHAEL HERMELE, Department of Physics, University of Colorado Boulder — Some pyrochlore oxides realize novel dipolar-octupolar (DO) doublets on the sites of the pyrochlore lattice of corner-sharing tetrahedra. With magnetic field along the (111) direction, such systems can approximately be described as decoupled layers of a  $S = \frac{1}{2}$  XYZ model on Kagome planes, with perpendicular magnetic field. A recent quantum Monte Carlo study found a zero temperature disordered phase in this model, dubbed quantum kagome ice, and proposed that it is a type of  $Z_2$  quantum spin liquid (J. Carrasquilla, Z. Hao and R. G. Melko, *Nat. Comm.*, **6**, 7421). We will describe an effective theory for this putative  $Z_2$  spin liquid, and present results on its symmetry fractionalization and resulting properties that may be tested in future numerical simulations.

**12:15PM Y18.00004 Dynamics of quantum excitations in square ice<sup>1</sup>**, CLAUDIO CASTELNOVO, TCM group, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK, STEFANOS KOURTIS, Department of Physics, Princeton University, Princeton, NJ 08544, USA — The study of emergent excitations in classical spin ice has culminated in the discovery of a condensed-matter realization of magnetic monopoles. In spin-ice materials where quantum fluctuations play an important role, excitations acquire quantum properties that promote them to more complicated and exciting objects. To understand these quantum excitations better in a relatively simple context, we construct a toy model of excited square ice and solve it both exactly by tuning it to a Rokhsar-Kivelson point and numerically for small clusters. We furthermore numerically evaluate the dynamic spin structure factor and compare it to effective free-particle theories. Our results offer a useful point of comparison for further theoretical and experimental work.

**12:27PM Y18.00005 Magnetic monopoles in quantum spin ice**, OLGA PETROVA, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, SHIVAJI SONDHI, Princeton University — Typical spin ice materials can be modeled using classical Ising spins. The geometric frustration of the pyrochlore lattice causes the spins to satisfy ice rules, whereas a violation of the ice constraint constitutes an excitation. Flipping adjacent spins fractionalizes the excitation into two monopoles. Long range dipolar spin couplings result in Coulombic interactions between charges, while the leading effect of quantum fluctuations is to provide the monopoles with kinetic energy. We study the effect of adding quantum dynamics to spin ice, a well-known classical spin liquid, with a particular view of how to best detect its presence in experiment. For the weakly diluted quantum spin ice, we find a particularly crisp phenomenon, namely, the emergence of hydrogenic excited states in which a magnetic monopole is bound to a vacancy at various distances [1].

**12:39PM Y18.00006 Spinon walk in quantum spin ice**, YUAN WAN, JUAN CARRASQUILLA, ROGER MELKO, Perimeter Institute for Theoretical Physics — Quantum spin ice is a novel family of spin ice magnets that possess substantial quantum fluctuations. The fractional excitations are spinons, which are quantum analog of the monopoles in classical spin ice. The spinon propagates in quantum spin ice via quantum tunnelling. As opposed to a conventional quantum particle, the spinon moves in a background of disordered spins. The orientation of background spins controls the spinon motion, whereas the spinon motion in turn alters the spin background. One may naturally ask what a suitable framework for understanding the dynamics of spinon is in quantum spin ice, and furthermore, whether the spinon propagation is coherent. In this talk, we address these issues by investigating a minimal model that captures the essential features of single spinon dynamics in quantum spin ice. We demonstrate that the spinon motion can be thought of as a quantum walk with entropy-induced memory. Our numerical simulation shows that the simple quasi-particle behaviour emerges out of the intricate interplay between the spinon and the background spins.

**12:51PM Y18.00007 Neutron scattering in  $Er_{2-x}Y_xTi_2O_7$** , JONATHAN GAUDET, ALANNAH HALLAS, DALINI MAHARAJ, EDWIN KERMARREC, McMaster Univ, NICHOLAS P. BUTCH, NIST Center for Neutron Research, HANNA DABOWSKA, BRUCE GAULIN, McMaster Univ —  $Er_2Ti_2O_7$  (ETO) is a strong candidate for ground state selection via the order by disorder mechanism. A  $\psi_2$  magnetic ground state appears below  $T_N=1.2$  K, where  $\psi_2$  and  $\psi_3$  are the two basis states of the irreducible representation  $\Gamma_5$ . No sample dependence has been observed in the thermodynamics properties of ETO at low temperature, and in particular on its phase transition to long range magnetic order. ETO's ordered Neel state has been shown to be robust even to a relatively high level of magnetic dilution, as occurs with non-magnetic  $Y^{3+}$  substitution of  $Er^{3+}$ . However, recently two theoretical studies have predicted that ETO's  $\psi_2$  ground state should be unstable to formation of the  $\psi_3$  state, in the presence of such disorder. To explore this possibility, we grew single crystals of  $Er_{2-x}Y_xTi_2O_7$  (EYTO) with  $x = 0, 0.2$  and  $0.4$  and performed a systematic inelastic neutron scattering studies using the Disk Chopper time-of-flight spectrometer (DCS) at the National Institute of Standards and Technology (NIST). We will show elastic and inelastic neutron scattering at low temperatures and as a function of applied magnetic field for all three samples and discuss the role of such quenched disorder on the spin dynamics of EYTO.

**1:03PM Y18.00008 Semi-classical Theory of Quantum Spin Ice**, MICHAL KWASIGROCH, CLAUDIO CASTELNOVO, University of Cambridge — The low temperature properties of quantum spin ice compounds  $Yb_2Ti_2O_7$  and  $Pr_2Zr_2O_7$  are described by spin-1/2 degrees of freedom associated with magnetic Yb or Pr atoms residing on vertices of corner-sharing tetrahedra. Strong Ising exchange enforces the well-known 2-in-2-out rules for each tetrahedron at low temperatures. These describe the macroscopically degenerate spin ice configurations. Recently, it has been shown [Phys. Rev. B **69**, 064404 (2004)] that the addition of weak easy-plane exchange can lead to hybridisation of the classically allowed spin-ice configurations and the emergence of a gapless quantum spin liquid. We show that a semi-classical treatment of this U(1) liquid phase captures the QED-like physics and we derive quantitative estimates of the low-energy dispersion and the dynamic structure factor. These compare well with the existing Monte Carlo simulations.

**1:15PM Y18.00009 From pinch points to pinch lines: a new spin liquid on the pyrochlore lattice**, OWEN BENTON, LUDOVIC JAUBERT, HAN YAN, NIC SHANNON, Okinawa Inst of Sci & Tech — One of the most fascinating discoveries in the study of spin liquids has been the existence of emergent gauge fields arising out of a disordered magnetic ground state. The best known example is provided by the spin ice pyrochlores  $Ho_2Ti_2O_7$  and  $Dy_2Ti_2O_7$ , whose underlying gauge structure is revealed by the presence of pinch-point singularities in the neutron scattering response. Here we report the discovery of a new spin liquid on the pyrochlore lattice, the low temperature fluctuations of which are naturally described by the fluctuations of a tensor field with a continuous gauge freedom. This gauge structure underpins a novel form of spin correlations, giving rise to “pinch-line” singularities- line-like analogues of the pinch-point singularity extending along the  $\langle 111 \rangle$  directions of reciprocal space. Remarkably, our theory reproduces several otherwise unaccounted for features of neutron scattering experiments on  $Tb_2Ti_2O_7$ .

**1:27PM Y18.00010 Numerical evidence for a chiral spin liquid in the XXZ model on the kagome lattice in a magnetic field<sup>1</sup>**, HITESH CHANGLANI, KRISHNA KUMAR, BRYAN CLARK, EDUARDO FRADKIN, University of Illinois Urbana Champaign — Frustrated spin systems in two dimensions provide a fertile ground for discovering exotic states of matter, often with topologically non-trivial properties. In this work, we investigate the possible existence of a chiral spin liquid state in the spin 1/2 XXZ model on the frustrated kagome lattice in the presence of a magnetic field. This model is equivalent to a hard-core bosonic one with density-density interactions at finite filling fraction. Motivated by previous field theoretic predictions utilizing a Chern-Simons theory adapted for this lattice [1,2], we focus our attention to understanding the XY limit for the 2/3 magnetization plateau (equivalent to a system of hard-core bosons at 1/6 filling with weak nearest-neighbor repulsive interactions). Performing exact or accurate numerical computations, and based on energetics and construction of minimally entangled states and associated modular matrices, we provide evidence for such a spin liquid. We study the nature of this phase and examine its stability to additional interactions. [1] K. Kumar, K. Sun, and E. Fradkin, Phys. Rev. B **90**, 174409 (2014) [2] K. Kumar, K. Sun, and E. Fradkin, Phys. Rev. B **92**, 094433 (2015)

**1:39PM Y18.00011 Spin liquids on an anisotropic kagome lattice**, ROBERT SCHAFFER, KYUSUNG HWANG, YEJIN HUH, YONG BAEK KIM, Univ of Toronto — Much recent theoretical and experimental effort has been devoted to the search for quantum spin liquids, which arise in the presence of strong frustration of magnetic interactions. Motivated by recent experiments on the vanadium oxyfluoride material DQVOF, we examine possible spin liquid phases on an anisotropic kagome lattice of  $S = 1/2$  spins, in which the  $C_6$  symmetry is broken to  $C_3$ . Using the projective symmetry group analysis, we determine the possible phases for both bosonic and fermionic  $Z_2$  spin liquids on this lattice. Using VMC, we study the Heisenberg model on this lattice, and show that a  $Z_2$  spin liquid emerges as the ground state in the presence of this anisotropy.

**1:51PM Y18.00012 Classification of  $Z_2$  spin liquids in a hyperkagome lattice by projective symmetry groups**, BIAO HUANG, Ohio State Univ - Columbus, YONG BAEK KIM, University of Toronto; Korea Institute for Advanced Study, YUAN-MING LU, Ohio State Univ - Columbus — Being a rare candidate material supporting 3D spin liquid states,  $\text{Na}_4\text{Ir}_3\text{O}_8$  has attracted much theoretical and experimental interest in the past decade. Propelled by such developments, we give a complete classification of  $Z_2$  spin liquid states in the hyperkagome lattice formed by  $\text{Ir}^{4+}$  ions in the projective symmetry group approach. A list of mean field states with different fractional quasi-particle excitations are correspondingly given, and their excitation gaps are analyzed. The effects of spin-orbit coupling due to the 5d electrons in Ir are also discussed. This work paves the way for further variational Monte-Carlo study of the spin liquid physics in hyperkagome lattices.

**2:03PM Y18.00013  $Z_2$  gauge theory for valence bond solids on the kagome lattice**, KYUSUNG HWANG, YEJIN HUH, YONG BAEK KIM, Department of Physics and Centre for Quantum Materials, University of Toronto, Toronto, Ontario M5S 1A7, Canada — We present an effective  $Z_2$  gauge theory that captures various competing phases in spin-1/2 kagome lattice antiferromagnets: the topological  $Z_2$  spin liquid (SL) phase, and the 12-site and 36-site valence bond solid (VBS) phases. Our effective theory is a generalization of the recent  $Z_2$  gauge theory proposed for SL phases by Wan and Tchernyshyov. In particular, we investigate possible VBS phases that arise from vison condensations in the SL. In addition to the 12-site and 36-site VBS phases, there exists 6-site VBS that is closely related to the symmetry-breaking valence bond modulation patterns observed in the recent density matrix renormalization group simulations. We find that our results have remarkable consistency with a previous study using a different  $Z_2$  gauge theory. Motivated by the lattice geometry in the recently reported vanadium oxyfluoride kagome antiferromagnet, our gauge theory is extended to incorporate lowered symmetry by inequivalent up- and down-triangles. We investigate effects of this anisotropy on the 12-site, 36-site, and 6-site VBS phases. Particularly, interesting dimer melting effects are found in the 36-site VBS. We discuss the implications of our findings and also compare the results with a different type of  $Z_2$  gauge theory used in previous studies.

**11:15AM Y19.00001 Orbital Delocalization and Enhancement of Magnetic Interactions in Perovskite Oxyhydrides**, KAI LIU, YUSHENG HOU, XINGAO GONG, HONGJUN XIANG, Fudan University, CCMG TEAM — Recent experiments showed that some perovskite oxyhydrides have surprisingly high magnetic-transition temperature. In order to unveil the origin of this interesting phenomenon, we investigate the magnetism in  $\text{SrCrO}_2\text{H}$  and  $\text{SrVO}_2\text{H}$  on the basis of first-principles calculations and Monte Carlo simulations. Our work indicates that the Cr-O-Cr superexchange interaction in  $\text{SrCrO}_2\text{H}$  is unexpectedly strong. Different from the previous explanation in terms of the  $\text{H}^-$  ion substitution induced increase of the Cr-O-Cr bond angle, we reveal instead that this is mainly because the 3d orbitals in perovskite oxyhydrides becomes more delocalized since  $\text{H}^-$  ions have weaker electronegativity and less electrons than  $\text{O}^{2-}$  ions. The delocalized 3d orbitals result in stronger Cr-O interactions and enhance the magnetic-transition temperature. This novel mechanism is also applicable to the case of  $\text{SrVO}_2\text{H}$ . Furthermore, we predict that  $\text{SrFeO}_2\text{H}$  will have unprecedented high Neel temperature because of the extraordinarily strong Fe-H-Fe  $\sigma$ -type interactions. Our work suggests the anion substitution can be used to effectively manipulate the magnetic properties of perovskite compounds.

**11:27AM Y19.00002 Understanding the magnetoelastic behavior of pure and Co substituted  $\text{GdNi}^1$** , DURGA PAUDYAL, Y. MUDRYK, The Ames Laboratory, Iowa State University, Ames, IA 50011, V. K. PECHARSKY, K. A. GSCHNEIDNER, JR., The Ames Laboratory and Department of Materials Science and Engineering, Iowa State University, Ames, IA 50011 — Total-energy calculations employing local spin density approximation including Hubbard  $U$  (onsite electron correlation) parameter and temperature and magnetic field dependent x-ray diffraction experiments show large anisotropic shifts in lattice parameters and a giant linear magnetostriction without a structural transformation and a negligible volume magnetostriction in  $\text{GdNi}$ . In agreement with the magnetization and heat-capacity experiments, the total-energy and band splitting results confirm that the anisotropic shape changes in  $\text{GdNi}$  are associated with the second-order ferromagnetic to paramagnetic transformation. When the band splitting due to the ferromagnetic ordering of the 4f moments increases, the concomitant anisotropic changes in the lattice minimize the total free energy of the crystal indicating an unusual interplay between magnetism and crystal structure. The positive formation energy at 0K and the nature of the density of states at the Fermi level confirm an unstable equiatomic Gd compound when Ni is fully substituted by Co. However, the enhanced effective exchange interactions with small Co substitutions increase the Curie temperature without losing the chemical stability.

<sup>1</sup>The Ames Laboratory is operated for the US DOE by Iowa State. This work was supported by the DOE, Office of Basic Energy Sciences, Materials Sciences Division under contract No. DE-AC02-07CH11358.

**11:39AM Y19.00003 Direct observation of a helical magnetic order near the superconducting state of  $\text{MnP}$  under pressure**, YISHU WANG, California Institute of Technology, YEJUN FENG, Argonne National Lab, J.-G. CHENG, Chinese Academy of Sciences, T. F. ROSENBAUM, California Institute of Technology — A recent high-pressure electrical transport study of the 3d transition metal compound  $\text{MnP}$  manifested a complex pressure-temperature phase diagram of different types of magnetism and superconductivity. However, the nature of the high-pressure magnetic phase proximate to the superconducting state was not determined. We use non-resonant X-ray magnetic diffraction to probe the magnetic order in  $\text{MnP}$  under pressure. We discover incommensurate helical order in a confined region under high pressure, and ascertain the phase boundary through the pressure evolution of the lattice. Although the antiferromagnetic and superconducting phases are separated, there is no signature of a strong first-order phase transition between them. We discuss how our direct observation of a helimagnetic order in  $\text{MnP}$  helps to better understand aspects of magnetically-mediated superconductivity.

**11:51AM Y19.00004 Neutron scattering study on the magnetic and superconducting phases of MnP**, SHINICHIRO YANO, NSRRC, DIANE LANCON, HENRIK RONNOW, EPFL, THOMAS HANSEN, ILL, JASON GARDNER, NSRRC — We have performed series of neutron scattering experiments on MnP. MnP has been investigated for decades because of its rich magnetic phase diagram. The magnetic structure of MnP is ferromagnetic (FM) below  $T_C = 291$  K. It transforms into a helimagnetic structure at  $T_S = 47$  K with a propagation vector  $q = 0.117a^*$ . Superconductivity was found in MnP under pressures of 8 GPa with a  $T_{SC}$  around 1 K by J.-G. Cheng. Since Mn-based superconductors are rare, and the superconducting phase occurs in the vicinity of FM, new magnetic and helimagnetic phases, there is a need to understand how the magnetism evolves as one approach the superconducting state. MnP is believed to be a double helix magnetic structure at  $T_S = 47$  K. We observed new  $2\delta$  and  $3\delta$  satellite peaks whose intensity are  $200 \sim 1000$  times smaller than these of  $1\delta$  satellite peaks on the cold triple axis spectrometer SIKA under zero magnetic fields. We also found the periods of helimagnetic structure changes as a function of temperature. If time permits, we will discuss recent experiments under pressure. However, we have complete picture of magnetic structure of this system with and without applied pressure, revealing the interplay between the magnetic and superconducting phases.

**12:03PM Y19.00005 Unusual behavior of uranium dioxide at high magnetic fields. Part I<sup>1</sup>**, K. GOFRYK, Idaho National Laboratory, M. JAIME, V. ZAPF, N. HARRISON, Los Alamos National Laboratory, A. SAUL, Aix-Marseille University, France, G. RADTKE, University of Paris 06, CNRS, France, J. C. LASHLEY, Los Alamos National Laboratory, M. SALAMON, University of Texas, Dallas, A. D. ANDERSSON, C. STANEK, T. DURAKIEWICZ, J. L. SMITH, Los Alamos National Laboratory —  $UO_2$  is a Mott-Hubbard insulator with well-localized  $5f$ -electrons and its crystal structure is the face-centered-cubic fluorite. It experiences a first-order antiferromagnetic phase transition at 30.8 K to a non-collinear antiferromagnetic structure that remains a topic of debate. It is believed that the first order nature of the transition results from the competition between the exchange interaction and the Jahn-Teller distortion of oxygen atoms. Despite extensive experimental and theoretical efforts the nature of the competing degrees of freedom and their couplings (such as spin-phonon coupling) are still unclear. Here we present results of our extensive thermodynamic investigations, on well-characterized and oriented single crystals of  $UO_2$ , focusing on magnetization  $M(T,H)$  measurements in DC and pulsed magnetic fields to up 65 T at the NHMFL.

**12:15PM Y19.00006 Unusual behavior of uranium dioxide at high magnetic fields. Part II\***, M. JAIME, LANL, K. GOFRYK, INL, V. ZAPF, N. HARRISON, LANL, A. SAUL, Aix-Marseille Univ., G. RADTKE, Univ. Paris, J.C. LASHLEY, LANL, M. SALAMON, UT Dallas, A.D. ANDERSSON, C. STANEK, T. DURAKIEWICZ, J.L. SMITH, LANL — More than 65 years worth of unrelenting experimental and theoretical research on seemingly uncomplicated  $UO_2$ , a Mott-Hubbard insulator with well-localized  $5f$ -electrons and a fluorite  $fcc$  crystal structure, have not been able to elucidate some important questions such as the detailed nature of the low temperature AFM state, or the reasons behind unusual lattice properties that severely hinder the ability of this important nuclear material to transport heat. The high thermal conductivity shown by its non-magnetic counterpart,  $ThO_2$ , has hinted to the notion that unusual spin-lattice coupling is behind the crippled thermal behavior of  $UO_2$ . Here we present results of our thermodynamic investigations, on well-characterized and oriented single crystals, focusing on fiber Bragg grating magnetostriction measurements in pulsed magnetic fields to 90T at the NHMFL PFF. Our data support a multidomain non-collinear 3-k AFM order below 30.8K, coupled to an oxygen-cage trigonal distortion that breaks time reversal symmetry. \*Work supported by the US DOE BES, Mat. Sci., and Eng. Div. The NHMFL PFF is supported by the NSF, the U.S. DOE., and the State of Florida through NSF coop. grant DMR-1157490. Work at LANL was supported by the U.S. DOE BES project "Science at 100 Tesla".

**12:27PM Y19.00007 Modulated magnetism in the ferromagnet PrPtAl : clear experimental evidence of the 'order by disorder' theory.**, J.-PH. REID, Univ. of St. Andrews, CHRIS O'NEILL, Univ. of Edinburgh, ALEX WALKER, Univ. of St. Andrews, CALUM LITHGOW, GINO ABDUL-JABBAR, Univ. of Edinburgh, EDWARD YELLAND, Univ of St Andrews, DMITRY A. SOKOLOV, ANDREW D. HUXLEY, Univ. of Edinburgh — The ferromagnet PrPtAl is unlike any other. At the phase boundary between paramagnetism and ferromagnetism the fluctuations of the order parameter are so strong that energetically favourable phases of novel modulated magnetism emerge. In fact, its lack of order (the disorder) that is pivotal to promote a new order. This mechanism is referred to as order by disorder and is the centre of numerous theoretical studies [2,3]. In this seminar, following an introduction on the topic of ferromagnetic materials, I will show how we can use both electrical and thermal conductivities to learn everything about these phases of modulated magnetism and to validate the predictions of the order by disorder theory. **12:39PM Y19.00008 Unexpected magnetism, and transport properties in mixed lanthanide compound.**<sup>1</sup>, ARJUN PATHAK, KARL GSCHNEIDNER, JR, VITALIJ PECHARSKY, Ames Laboratory, US DOE, AMES LABORATORY TEAM — For intelligent materials design it is desirable to have compounds which have multiple functionalities such as a large magnetoresistance, ferromagnetic and ferimagnetic states, and field-induced first-order metamagnetic transitions. Here, we discuss one such example where we have combined two lanthanide elements Pr and Er in  $Pr_{0.6}Er_{0.4}Al_2$ . This compound exhibits multiple functionalities in magnetic fields between 1 and 40 kOe. It undergoes only a trivial ferrimagnetism to paramagnetism transition in a zero magnetic field, but  $Pr_{0.6}Er_{0.4}Al_2$  exhibits a large positive magnetoresistance (MR) for  $H \geq 40$  kOe, a small but non negligible negative MR for  $H \leq 30$  kOe, and a clear Griffiths-like phase behavior at  $< 1$  kOe. The compound also exhibits an asymmetry of hysteresis loop, or exchange bias (EB) effect after field cooling from the paramagnetic state. These phenomena are attributed to the competition between single-ion anisotropies of Pr and Er ions coupled with the opposite nearest-neighbor and next-nearest-neighbor exchange interactions.

**12:51PM Y19.00009 Magnetic and Metal-Insulator Transition in natural Transition Metal Sulfides**, RENXIONG WANG, TRISTIN METZ, I-LIN LIU, KEFENG WANG, XIANGFENG WANG, Department of Physics, University of Maryland College Park, J.R JEFFRIES, Lawrence Livermore National Laboratory, S.R. SAHA, R.L. GREENE, J. PAGLIONE, Department of Physics, University of Maryland College Park, C. C. SANTELLI, J. POST, Department of Mineral Sciences, Smithsonian Museum of Natural History — In collaboration with the Smithsonian Institution's National Museum of Natural History, we present detailed studies of a class of natural minerals with potential to harbor correlated behavior. Transition metal sulfide minerals, such as Bornite ( $Cu_5FeS_4$ ), are an important family of compounds known for their thermoelectric properties. We will present low temperature experimental studies of magnetic transitions and focus on a compound that exhibits a metal to insulator transition coincident with entrance to an antiferromagnetic ground state, suggesting a potentially interesting system with promise for realizing new correlated states of matter in a naturally occurring mineral.

**1:03PM Y19.00010 Emergent triangular structure in doped extended honeycomb Hubbard model**, LUCA F. TOCCHIO, Consiglio Nazionale delle Ricerche (CNR) and International School for Advanced Studies (SISSA), RYUI KANEKO, ROSER VALENTI, Goethe-Universität Frankfurt, FEDERICO BECCA, Consiglio Nazionale delle Ricerche (CNR) and International School for Advanced Studies (SISSA), CLAUDIUS GROS, Goethe-Universität Frankfurt — We investigate the extended honeycomb Hubbard model at  $3/4$  filling. By using the mean-field approximation, we find a transition from a normal metal to a ferromagnetic metal at large Coulomb interaction  $U$ , and a transition to a charge ordered metal at large nearest-neighbor Coulomb interaction  $V$ . In the presence of both  $U$  and  $V$ , we find a metal-insulator transition, where the insulating state possesses charge and magnetic orders. The charge rich sites are nearly fully occupied, while the charge poor sites form a triangular lattice at nearly half filling. We also apply the variational Monte Carlo method to take into account quantum fluctuations beyond the mean-field treatment, and find this charge ordered state to be stable at sufficiently large  $U$  and  $V$ .

**1:15PM Y19.00011 Mechanisms of finite-temperature magnetism in the three-dimensional Hubbard model**, DANIEL HIRSCHMEIER, Institut für Theoretische Physik, Universität Hamburg,, HARTMUT HAFERMANN, Mathematical and Algorithmic Sciences Lab, France Research Center, Huawei Technologies Co, EMANUEL GULL, Department of Physics, University of Michigan, ALEXANDER I. LICHTENSTEIN, Institut für Theoretische Physik, Universität Hamburg,, ANDREY E. ANTIPOV, Department of Physics, University of Michigan — We examine the nature of the transition to the antiferromagnetically ordered state in the half-filled three-dimensional Hubbard model using the dual-fermion multiscale approach. Consistent with analytics, in the weak-coupling regime we find that spin-flip excitations across the Fermi surface are important, and that the strong coupling regime is described by Heisenberg physics. In the intermediate interaction, strong correlation regime we find aspects of both local and non-local correlations. We analyze the critical exponents of the transition in the strong coupling regime and find them to be consistent with Heisenberg physics down to an interaction of  $U/t=10$ .

**1:27PM Y19.00012 Quantum Monte Carlo study of magnetism in the Lieb Lattice**, NATANIEL COSTA, TIAGO SANTOS<sup>1</sup>, THEREZA PAIVA, RAIMUNDO DOS SANTOS, Universidade Federal do Rio de Janeiro, RICHARD SCALETTAR, UC Davis — The Hubbard model on the 'Lieb lattice' provides an important example of how flat band systems may lead to ferromagnetism: at half filling Lieb proved that a ferrimagnetic ground state *can* be achieved. Since a rigorous proof that long range order does indeed emerge is still lacking, here we report Determinant Quantum Monte Carlo (DQMC) simulations for this model. We found that the spin correlation between nearest neighbors are always antiferromagnetic, and that for small  $U$  ferromagnetic long range order does set in in the ground state. However, spatial spin correlations weaken as  $U$  is increased, and we established that long range order is suppressed above  $U_c \approx 4.5$ . We obtain the dependence of the magnetization with the on-site repulsion  $U$ , and show that it displays a maximum at  $U \approx 3$ . The behavior of the compressibility and of the double occupancy across this transition is also discussed.

**1:39PM Y19.00013 Using dephasing to distinguish composite and elementary particles**, LEONID P. PRYADKO, University of California, Riverside, CLAUDIO CASTELNOVO, University of Cambridge, MARK I. DYKMAN, Michigan State University, RODERICH MOESSNER, Max-Planck-Institut für Physik komplexer Systeme, Dresden, VADIM N. SMELYANSKIY, Google — Many-body topological excitations like domain walls in 1D can be treated quantum mechanically as particles. We establish limits on such a description in the presence of weak dephasing. Specifically, we compare dynamics of a particle in a tight-binding model with weak on-site dephasing, and that of a kink separating two locally distinguishable domains. In the latter case, dephasing rate of the off-diagonal matrix elements  $\rho_{ab}$  of the density matrix is proportional to the distance  $|a - b|$  from the diagonal, compared to a constant dephasing rate of such matrix elements for a single particle. We show that in a transport setting (quantum diffusion), with small density gradients, the dynamics of these two systems is nearly identical. The difference can only be seen when far off-diagonal matrix elements are important, as in the formation of a bound state, or in a two-path interferometer. We analyze the spectroscopic signature of a bound state of a domain wall, and suggest possible experimental signatures in spin chains.

**1:51PM Y19.00014 Spontaneous symmetry breaking in correlated wave functions**, RYUI KANEKO, Goethe-Universität Frankfurt, LUCA F. TOCCHIO, Consiglio Nazionale delle Ricerche (CNR) and International School for Advanced Studies (SISSA), ROSER VALENTI, Goethe-Universität Frankfurt, FEDERICO BECCA, Consiglio Nazionale delle Ricerche (CNR) and International School for Advanced Studies (SISSA), CLAUDIUS GROS, Goethe-Universität Frankfurt — We show that Jastrow-Slater wave functions, in which a density-density Jastrow factor is applied onto an uncorrelated fermionic state, may possess long-range order even when all symmetries are preserved in the wave function. This fact is mainly related to the presence of a sufficiently strong Jastrow term (also including the case of full Gutzwiller projection, suitable for describing spin models). Selected examples are reported, including the spawning of Néel order and dimerization in spin systems, and the stabilization of density and orbital order in itinerant electronic systems. **2:03PM Y19.00015 On the magnetic structure and band gap of the double perovskite Ba<sub>2</sub>CuOsO<sub>6</sub>: Density functional analysis<sup>1</sup>**, CHANGHOON LEE, JISOOK HONG, JI HOON SHIM, Pohang University of Science and Technology, MYUNG-HWAN WHANGBO, North Carolina State University — The ordered double-perovskite Ba<sub>2</sub>CuOsO<sub>6</sub>, consisting of 3d and 5d transition-metal magnetic ions (Cu<sup>2+</sup> and Os<sup>6+</sup>, respectively), is a magnetic insulator. It obeys the Curie-Weiss law with  $\theta = -13.3$  K. We evaluated the spin exchange interactions of Ba<sub>2</sub>CuOsO<sub>6</sub> by performing energy-mapping analysis based on DFT+U calculations and determined the band gap of Ba<sub>2</sub>CuOsO<sub>6</sub> by DFT+U and DFT+U+SOC calculations. The antiferromagnetic ordering of Ba<sub>2</sub>CuOsO<sub>6</sub> is due largely to the spin exchange interactions between Cu<sup>2+</sup> ions, which are enhanced by the empty eg orbitals of the intervening Os<sup>6+</sup> ions. Both electron correlation and spin-orbit coupling are necessary to open a band gap for Ba<sub>2</sub>CuOsO<sub>6</sub>.

Session Y20 DMP: Correlations and Superconductivity in Fe-chalcogenides III 319 - Robert Moore, SLAC

**11:15AM Y20.00001 Unraveling the electron pairing mechanism of FeSe by MBE and STM<sup>1</sup>**, CANLI SONG, Tsinghua University — Studies of high-transition-temperature superconductivity usually suffer from various imperfections in materials. Here we apply the state-of-the-art molecular beam epitaxy (MBE) to prepare controllably high-quality FeSe films on various substrates, and explore their superconducting properties using cryogenic scanning tunneling microscope [1,2]. Single impurities, twin boundaries as well as strain are found in the MBE-grown FeSe films on graphene, and invariably suppress the superconductivity [1, 3, 4]. Meanwhile, electronic nematicity and signatures of a bosonic mode, whose energy also decreases with strain [4], were identified. More significantly, we observed two disconnected superconducting domes at alkali-metal potassium (K)-dosed FeSe surface, stepping towards the mechanistic understanding of superconductivity in FeSe-derived superconductors. Our results are clarifying the secret of high-T<sub>c</sub> superconductivity in FeSe-related superconductors, and by implications, in other unconventional superconductors, and guiding how to enhance T<sub>c</sub> by interface engineering. **11:51AM Y20.00002 In-plane Resistivity Anisotropy in Mechanically De- twinned Single Crystals FeSe**, ERIK TIMMONS, MAKARIY TANATAR, The Ames Laboratory and Iowa State University, ANNA BOHMER, The Ames Laboratory, GIL DRACHUCK, Iowa State University, VALENTIN TAUFOR, SERGEY BUD'KO, PAUL CANFIELD, RUSLAN PROZOROV, The Ames Laboratory and Iowa State University, MICHAEL SCHUETT, RAFAEL FERNANDES, University of Minnesota, RUSLAN PROZOROV GROUP TEAM, PAUL CANFIELD GROUP TEAM, RAFAEL FERNANDES GROUP TEAM — The in-plane resistivity anisotropy was studied in stress-detwinned vapor transport grown single crystals of FeSe, which exhibit the tetragonal-orthorhombic structural transition temperature at  $T_s \sim 90$  K in unstrained samples, but no long-range magnetic order. Direct transport and elastoresistivity measurements show a significant in-plane resistivity anisotropy above  $T_s$  induced by a very moderate mechanical stress. This anisotropy peaks slightly below  $T_s$  and decreases to nearly zero on cooling to base temperature, while the degree of orthorhombic distortion grows monotonically before saturating at low temperatures. We explain the non-monotonic temperature dependence of the resistivity anisotropy as a result of the inelastic scattering of electrons by anisotropic spin fluctuations. Experimental work was supported by the U.S. DOE/OS/MSED and was performed at the Ames Laboratory, Iowa State University under contract DE-AC02-07CH11358. M.S. acknowledges the support from the Humboldt Foundation. R.M.F. is supported by the U.S. DOE, Office of Science, Basic Energy Sciences, under Award No. DE-SC0012336.

**12:03PM Y20.00003 Nematic quantum criticality in FeSe<sub>1-x</sub>S<sub>x</sub> revealed by elastoresistance measurements**, SUGURU HOSOI, KOHEI MATSUURA, HAO WANG, KOUSUKE ISHIDA, YUTA MIZUKAMI, Department of Advanced Materials Science, University of Tokyo, Kashiwa, Chiba 277-8561, Japan, TATSUYA WATASHIGE, SHIGERU KASAHARA, YUJI MATSUDA, Department of Physics, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo, Kashiwa, Chiba 277-8561, Japan — Electronic nematicity and its connection to the high-temperature superconductivity is one of the central issues in iron-based superconductors. Among them, FeSe is unique in that it exhibits a tetragonal-to-orthorhombic structural transition but no antiferromagnetic order, which enables us to study the nematicity without the effect of magnetism. Here we report on elastoresistance measurements in FeSe<sub>1-x</sub>S<sub>x</sub> evidencing a nonmagnetic nematic quantum critical point near  $x \sim 0.2$ . When the Se site is substituted by the isovalent S, the structural transition temperature is reduced gradually and it vanishes above  $x \sim 0.2$ . From the changes in in-plane resistivity induced by anisotropic strain, we evaluate the nematic susceptibility which shows Curie-Weiss-like temperature dependence. We find that with increasing  $x$  the Weiss temperature changes its sign indicating a quantum critical point, while there is no sign of antiferromagnetism for all samples. The superconducting transition temperature does not show a significant change with S concentration, suggesting that the nonmagnetic nematic quantum criticality does not help to enhance superconductivity in this system.

**12:15PM Y20.00004 Nematic magnetoelastic effect contrasted between Ba(Fe<sub>1-x</sub>Co<sub>x</sub>)<sub>2</sub>As<sub>2</sub> and FeSe**, YUWEN HU<sup>1</sup>, XIAO REN, Peking University, China, RUI ZHANG, Rice University, USA, HUIQIAN LUO, Chinese Academy of Sciences, China, SHIGERU KASAHARA, TATSUYA WATASHIGE, Kyoto University, Japan, TAKASADA SHIBAUCHI, University of Tokyo, Japan, PENGCHENG DAI, Rice University, USA, YAN ZHANG, Peking University, China; Collaborative Innovation Center of Quantum Matter, China, YUJI MATSUDA, Kyoto University, Japan, YUAN LI, Peking University, China; Collaborative Innovation Center of Quantum Matter, China — Whether the nematic order ubiquitously found in Fe-based superconductors is driven by the spin or the charge or orbital degree of freedom is currently under heated debate. To elucidate its microscopic origin, we report a Raman scattering study of lattice dynamics, which quantify the extent of  $C_4$ -symmetry breaking, in BaFe<sub>2</sub>As<sub>2</sub> and FeSe. FeSe possesses a nematic ordering temperature  $T_s$  and orbital-related band-energy split below  $T_s$  that are similar to those in BaFe<sub>2</sub>As<sub>2</sub>, but unlike BaFe<sub>2</sub>As<sub>2</sub> it has no long-range magnetic order. We find that the  $E_g$  phonon-energy split in FeSe sets in only well below  $T_s$ , and its saturated value is substantially smaller than that in BaFe<sub>2</sub>As<sub>2</sub>. Together with reported results for the Ba(Fe<sub>1-x</sub>Co<sub>x</sub>)<sub>2</sub>As<sub>2</sub> family, the data suggest that magnetism exerts a major influence on the lattice.

<sup>1</sup>Present address: Princeton University, USA

**12:27PM Y20.00005 Berry's phase observed in the ordered state of Fe(Se,S)**, SHIGERU KASAHARA, T. YAMASHITA, Y. SHIMOYAMA, T. WATASHIGE, Y. MATSUDA, Kyoto University, J. BÉARD, M. NARDONE, W. KNAFO, LNCMI-Toulouse, M.D. WATSON, N.R. DAVIS, A.I. COLDEA, Univ. of Oxford, M. SUZUKI, R. ARITA, RIKEN, H. IKEDA, Ritsumeikan Univ., T. SHIBAUCHI, The Univ. of Tokyo — Among iron-based superconductors, FeSe offers a unique platform in that it exhibits a nematically ordered phase without long-range magnetic ordering. Several experiments have shown that the low-temperature Fermi surface of FeSe consists only of very small, shallow pockets [1-3]. Tuning the ground state via isoelectronic chemical substitution provides an ideal way to solve the puzzles regarding the nematic ordering in this material. Here, by using ultra-high magnetic fields up to  $\sim 90$  T, we report observations of Shubnikov-de Haas (SdH) oscillations in isoelectronically substituted Fe(Se,S). For the smallest pocket of  $\sim 0.2\%$  of the Brillouin-zone, we observe non-zero  $\pi$  Berry's phase shift in the SdH oscillations. Our results indicate presence of Dirac cone, which would be a key to understand the mechanism of the nematic ordering in this system.

### 12:39PM Y20.00006 Nematicity in FeSe single crystals probed by pump-probe spectroscopy<sup>1</sup>

, C. W. LUO, P. C. CHENG, K. H. WU, J. Y. JUANG, Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan, S.-H. WANG, J.-C. CHIANG, J.-Y. LIN, Institute of Physics, National Chiao Tung University, Hsinchu 300, Taiwan, D. A. CHAREEV, Institute of Experimental Mineralogy, Chernogolovka, Moscow Region, 142432, Russia, O. S. VOLKOVA, A. N. VASILIEV, Low Temperature Physics and Superconductivity Department, Moscow State University, 119991 Moscow, Russia — The anisotropic quasiparticle dynamics in FeSe single crystals have been studied by polarized pump-probe spectroscopy. Two distinguishable relaxation components were unambiguously observed in transient reflectivity changes ( $\Delta R/R$ ). The orientation-dependent fast component with the timescale of 0.1-1.5 ps associated with the electronic structure clearly shows two-fold symmetry, which further reveals the gap opening along  $k_y$  below the temperature of structure phase transition ( $T_s$ ) and the electronic nematicity can persist up to 200 K. For the slow component with the timescale of 8-25 ps, it is assigned to the energy relaxation through spin sub-system and also shows a two-fold symmetry below  $T_s$ . However, this two-fold symmetry is dramatically weakened above  $T_s$  and surprisingly persists up to at least 200 K. Consequently, the high-temperature nematic fluctuations in FeSe may be driven by the order parameters which associated with both charge (orbital) and spin sub-systems.

### 12:51PM Y20.00007 Nematic quantum paramagnet and possible application to FeSe , FA WANG,

Peking Univ, STEVEN A. KIVELSON, Stanford University, DUNG-HAI LEE, UC Berkeley — The nematic phases in iron pnictides are in close proximity to the stripe antiferromagnetic order, suggesting that magnetism is the driving force for the spontaneous 4-fold crystal rotation symmetry breaking. In contrast, bulk FeSe shows a nematic phase below 90K at ambient pressure, but has no magnetic long range order down to very low temperature. This prompts suggestions that the nematicity in FeSe is driven by some other mechanism. We argue that magnetic correlation can still drive nematic order in the absence of magnetic order. By field theoretical considerations and exact diagonalization results on finite size lattices, we conclude that the paramagnetic phase in frustrated spin-1  $J_1$ - $J_2$  models on square lattice is such a "nematic quantum paramagnet", which breaks only the crystal 4-fold rotation symmetry. The prototype wavefunctions of such quantum ground states are horizontal(vertical) aligned spin-1 AKLT chains. We suggest that the local spins in FeSe may form this phase due to strong frustration. One unique consequence of this proposal is that the nematic paramagnetic phase will be close to both stripe and Neel antiferromagnetic order, and will thus host low but finite energy spin fluctuations at both ordering wavevectors.

### 1:03PM Y20.00008 Sign-Reversing Orbital Polarization in FeSe Driven by the Nematic Symmetry Breaking Self-Energy , SEIICHIRO ONARI, Okayama University, YOUICHI YAMAKAWA, HIROSHI KONTANI, Nagoya University —

Novel  $k$ -dependence of the orbital polarization in the orthorhombic phase in FeSe has been observed by the ARPES measurement [1], where the sign-reversal of the orbital splitting appears between hole pockets and electron pockets. We analyze the multi-orbital Hubbard models in the orbital-ordered state by extending the orbital-spin fluctuation theory [2]. The present theory describes the spontaneous symmetry breaking with respect to the orbital polarization and spin susceptibility self-consistently. In the orbital-ordered state, we obtain the two Dirac cone Fermi pockets in addition to the sign-reversing orbital polarization, consistently with experiments. The orbital-order originates from the strong orbital-spin interplay due to the Aslamazov-Larkin processes. [1] Y. Suzuki *et al.*, arXiv:1504.00980. [2] S. Onari, Y. Yamakawa, and H. Kontani, arXiv:1509.01172.

### 1:15PM Y20.00009 Nematicity and magnetism in FeSe and other families of Fe-based superconductors , YOUICHI YAMAKAWA, Nagoya university, SEIICHIRO ONARI, Okayama university, HIROSHI KONTANI, Nagoya university —

We investigate the emergence of the nematic orbital order ( $n_{xz} \neq n_{yz}$ ) in various Fe-based superconductors based on the first-principles Hubbard models [1]. In Fe-based superconductors, spin-fluctuation-mediated large orbital-fluctuations appear because of the strong orbital-spin interplay due to the many-body effect. This effect is very significant in FeSe due to the small ratio between the Hund's and Coulomb interactions ( $J/\bar{U}$ ) and large  $d_{xz}$ ,  $d_{yz}$ -orbitals weight at the Fermi level. For this reason, in FeSe, orbital order is established by weak spin fluctuations, so the magnetism is absent. In contrast, in LaFeAsO, the magnetic order appears just below the structural transition temperature both experimentally and theoretically. Thus, the orbital-spin interplay is the key ingredient of the wide variety of the normal-state phase diagram in Fe-based superconductors. [1] Y. Yamakawa, S. Onari, and H. Kontani, arXiv:1509.01161.

### 1:27PM Y20.00010 Determinant Quantum Monte Carlo Study of a Multi-orbital Electronic Model: Application to Nematic and Superconducting Order in FeSe , PHILIPP DUMITRESCU, MAKSYM SERBYN,

University of California, Berkeley, RICHARD SCALETTAR, University of California, Davis, ASHVIN VISHWANATH, University of California, Berkeley — The iron chalcogenide FeSe has attracted much recent interest due to a high superconducting transition in monolayer samples. In bulk samples, nematic order is seen without the presence of magnetic order, hinting at the importance of nematic order in determining the monolayer properties. We study an effective two band model of the iron-pnictides with interactions that capture the nematic ordering arising from spontaneous symmetry breaking between the two orbitals. These models are sign-problem free and can be simulated in an unbiased fashion using Determinant Quantum Monte Carlo. We find a variety of unexpected orders and consider the effects of the nematic fluctuations on superconductivity.

### 1:39PM Y20.00011 Alternating-Sign S-Wave Superconductivity in Single-Layer FeSe from the Local Moment Limit<sup>1</sup> , JOSE RODRIGUEZ, California State University at Los Angeles —

We obtain the exact low-energy spectrum of two mobile electrons roaming over a 4 by 4 lattice of iron atoms governed by a t-J model for a monolayer of FeSe. Each iron atom contains the minimum  $d_{xz}$  and  $d_{yz}$  orbitals. The hopping parameters (t) account only for electron bands centered at wave vectors  $(\pi, 0)$  and  $(0, \pi)$ , while the Heisenberg exchange parameters (J) imply a quantum-critical point (QCP) at half-filling that separates a commensurate spin-density wave (cSDW) at strong Hund coupling from a hidden-order antiferromagnet at weak Hund coupling. The hidden-order antiferromagnet has ordering wavevector  $(\pi, \pi)$ . After tuning the Hund coupling near the QCP, we find an  $S^{+-}$  ground state and a  $D^{+-}$  excited state that are separated in energy from the edge of a quasi-particle continuum. Both bound states alternate in sign between electron pairs at cSDW momenta and electron pairs at emergent electronic structure with zero 2D momentum. Exact calculations for a single electron with the same t-J model parameters find that the emergent electronic structure at zero 2D momentum moves off the Fermi level as Hund coupling weakens below the QCP. We therefore suggest that the above  $S^{+-}$  groundstate describes Coopers pairs in a monolayer of FeSe.

### 1:51PM Y20.00012 Comparing the anomalous phonons in Fe(Te,Se) and (Fe,Ni)(Te,Se) via neutron scattering , JOHN SCHNEELOCH, Brookhaven National Laboratory, ZHIJUN XU, University of California, Berkeley, GENDA GU, IGOR ZALIZNYAK, Brookhaven National Laboratory, BARRY WINN, Oak Ridge National Laboratory, JOSE RODRIGUEZ-RIVERA, National Institute of Standards and Technology, ROBERT BIRGENEAU, University of California, Berkeley, GUANGYONG XU, JOHN TRANQUADA, Brookhaven National Laboratory —

We studied the anomalous acoustic-type phonons in the Fe(Te,Se) iron-based superconductor family that arise from the (100) Bragg peak, which is forbidden according to the reported crystal structure for these materials. Inelastic neutron scattering was performed on superconducting and non-superconducting crystals of various compositions. The (100) phonons were much weaker in a non-superconducting nickel-doped crystal than in a superconducting crystal with similar selenium fraction, but comparison with another non-superconducting crystal suggests the difference is not simply related to superconductivity. This composition dependence was observed for both transverse and longitudinal phonons. The temperature dependences of the (100) phonons resembled those of conventional phonons. We will discuss these results and possible explanations for the relation between composition and lattice dynamics in this system.

**2:03PM Y20.00013 Elucidating the magnetic and superconducting phases in  $\text{Rb}_x\text{Fe}_y\text{Se}_{2-z}\text{S}_z$ .** , MENG WANG, MING YI, University of California, Berkeley, WEI TIAN, Oak Ridge National Laboratory, EDITH BOURRET-COURCHESNE, Lawrence Berkeley National Laboratory, ROBERT BIRGENEAU, University of California, Berkeley — The complex interdigitated phases have greatly frustrated attempts to document the basic features of the superconductivity in the  $A_x\text{Fe}_y\text{Se}_{2-z}\text{S}_z$  ( $A$  = alkali metals) system. We have employed elastic neutron scattering, energy-dispersive x-ray spectroscopy, and resistivity measurements to elucidate the relations of these phases in  $\text{Rb}_x\text{Fe}_y\text{Se}_{2-z}\text{S}_z$ . We find: i) the iron content is the driving parameter in stabilizing the structural separated phases; ii) the existence of the 245 antiferromagnetic phase stabilizes the iron vacancy free phase; iii) the sulfur substitutions progressively tune the iron vacancy free phase from a superconductor in  $\text{Rb}_x\text{Fe}_2\text{Se}_2$  to a metallic phase in  $\text{Rb}_x\text{Fe}_2\text{S}_2$ . Several phase diagrams as functions of the iron content and the Se:S ratio will be provided.

**Session Y21 GSCCM DCOMP DMP: Materials in Extremes: Metals at High Strain Rates II**  
320 - Ramon Ravelo, University of Texas, El Paso

**11:15AM Y21.00001 The relaxation of shear stress in a metal alloys with a wide grain size distribution under shock loadings** , EVGENIYA G. SKRIPNYAK, VLADIMIR V. SKRIPNYAK, National Research Tomsk State University, NATALIYA V. SKRIPNYAK<sup>1</sup>, National Research Tomsk State University — The influence of a grain size distribution on the relaxation of shear stress in the metal alloys under shock wave loading was investigated by numerical simulation. The model takes into account the influence of a grain size distribution and a precipitation concentration on the kinetics of shear stress relaxation. The relaxation rate of shear stress in shock waves depends on the specific volume of nano- and ultra-fine grains in the FCC and HCP metal alloys. A wide distribution of grain size reduces the relaxation rate of elastic precursor in HCP alloys. The relaxation of the elastic precursor depends on size and volume concentration of precipitates in metal alloys. Results of simulation show that the rate of plastic deformation in the shock wave exceeds significantly that of the elastic precursor at the same value of shear stresses.

**11:27AM Y21.00002 Strain Functionals for Characterizing Atomistic Geometries** , EDWARD KOBER, SVEN RUDIN, Los Alamos National Laboratory — The development of a set of strain tensor functionals that are capable of characterizing arbitrarily ordered atomistic structures is described. This approach defines a Gaussian-weighted neighborhood around each atom and characterizes that local geometry in terms of  $n$ -th order strain tensors, which are equivalent to the moments of the neighborhood. Fourth order expansions can distinguish the cubic structures (and deformations thereof), but sixth order expansions are required to fully characterize hexagonal structures. Other methods used to characterize atomic structures, such as the Steinhardt parameters or the centrosymmetry metric, can be derived from this more general approach. These functions are continuous and smooth and much less sensitive to thermal fluctuations than other descriptors based on discrete neighborhoods. They allow material phases, deformations, and a large number of defect structures to be readily identified and classified. Applications to the analysis of shock-loaded samples of Cu, Ta and Ti will be presented. This strain functional basis can also then be used for developing interatomic potential functions, and an initial application to Cu will be presented.

**11:39AM Y21.00003 Dual Domain Material Point Method for Materials in Extreme<sup>1</sup>** , DUAN ZHANG, TILAK DHAKAL, Los Alamos National Laboratory — Dual domain material point method is the latest version of the material point method designed to overcome many numerical difficulties of the original material point method with an increased numerical accuracy. In this talk, after reviewing the numerical theory of the method, we apply this method to cases involving extreme material deformation, shock propagation, and pulverization based on continuum theories. We will compare this method to other similar particle methods, and then examine the applicability and needed modification of the continuum theory for cases involving strong thermodynamic non-equilibrium. The history of the material deformation is often important in such systems. We will explore the Lagrangian capability brought by the use of particles in the dual domain material point method and introduce a multiscale scheme taking advantages of the particle-mesh communications in the method to study history dependent thermodynamically non-equilibrium systems, caused by extreme material deformations, such as hypervelocity impact and shock loading. We will also discuss the history tracking capability, analyze numerical advantages and difficulties, and show the results obtained from this numerical scheme.

**11:51AM Y21.00004 Multiscale Modeling using Molecular Dynamics and Dual Domain Material Point Method<sup>1</sup>** , TILAK DHAKAL, DUAN ZHANG, Los Alamos National Laboratory — For problems with very large material deformation rate, the time scale of material deformation can be shorter than the time that the material takes to reach a thermodynamic equilibrium. In these situations constitutive relation for the material becomes difficult to obtain. Furthermore, for these non-equilibrium problems, the history dependency of the material becomes important. A numerical method capable of tracking material deformation history is needed in a numerical simulation effort. In this work we use the dual domain material point (DDMP) method, which uses Lagrangian material points to track the history of the material where as Eulerian grids are used to calculate the gradients in continuum level. Molecular dynamics (MD) calculations are performed in the material points to calculate the closure quantities such as stress bypassing the need for a constitutive relation. Since the material points do not need to directly communicate among each other, the MD calculations can be done in parallel. In this work, GPUs are used to accelerate MD calculations. Examples of shock wave propagation in monoatomic gas and in Cerium metal are presented.

**12:03PM Y21.00005 Study on the oblique perforation of thin steel plates by flat and ogival projectiles** , ZITAO GUO, School of Civil engineering & urban construction, Jiujiang University, WEI ZHANG, PENG REN, Hypervelocity Impact Research Center, Harbin Institute of Technology, HYPERVELOCITY IMPACT RESEARCH CENTER COLLABORATION — This paper presents a numerical study on the oblique perforation of thin steel plates. Numerical simulations of 1 mm single A3 steel plates impacted by flat and ogival projectiles at 0, 15, 30, 45 and 60 angles over a range of velocities from 50 to 250 m/s were performed using the finite element code ABAQUS, where a modified versions of the J-C constitutive relation and fracture criterion based on a series of quasi-static and dynamic tensile tests with smooth and notched axisymmetric specimens were adopted to approximate behaviors of target material. Corresponding oblique perforation experiments were also conducted in order to be compared and calibrated. Initial-residual velocity curves and ballistic limits of targets under different angle impact were determined and compared, and the effects of projectile nose shape and obliquity on the ballistic resistance and failure models of targets were investigated. Results show that the nose shape of the projectile and oblique angles severely affected both the energy absorption and the failure mode of the target plate during perforation. Good agreement is found between the numerical simulations and experimental results.

**12:15PM Y21.00006 Ductility of metal alloys with grain size distribution in a wide range of strain rates**, VLADIMIR V. SKRIPNYAK, NATALIYA V. SKRIPNYAK<sup>1</sup>, EVGENIYA G. SKRIPNYAK, National Research Tomsk State University — Ductility of ultrafine grained (UFG) metal alloys with a distribution of grain size was investigated in wide loading conditions by numerical simulation. The multiscale models with a unimodal and a bimodal grain size distributions were developed using the data of structure research of hexagonal close packed and face center cubic UFG alloys. Macroscopic fracture is considered as a result of the formation of percolation clusters of damage at the mesoscopic level. The critical fracture strain of UFG alloys on the mesoscale level depends on the relative volumes of coarse grains. The nucleation of damages at quasi-static and dynamic loading is associated with strain localization in UFG partial volumes with bimodal grain size distribution. The concentration of damages arise in the vicinity of the boundaries of coarse and ultrafine grains. The occurrence of a bimodal grain size distributions causes the increase of UFG alloys' ductility, but decrease of their tensile strength.

**12:27PM Y21.00007 Experimental analysis of quasi-static and dynamic fracture initiation toughness of gy4 armor steel material<sup>1</sup>**, PENG REN, Jiangsu University of Science and Technology, ZITAO GUO, Jiujiang University — Quasi-static and dynamic fracture initiation toughness of gy4 armour steel material are investigated using three point bend specimen. The modified split Hopkinson pressure bar (SHPB) apparatus with digital image correlation (DIC) system is applied to dynamic loading experiments. Full-field deformation measurements are obtained by using DIC to elucidate on the strain fields associated with the mechanical response. A series of experiments are conducted at different strain rate ranging from 10<sup>-3</sup> s<sup>-1</sup> to 10<sup>3</sup> s<sup>-1</sup>, and the loading rate on the fracture initiation toughness is investigated. Specially, the scanning electron microscope imaging technique is used to investigate the fracture failure micromechanism of fracture surfaces. The gy4 armour steel material fracture toughness is found to be sensitive to strain rate and higher for dynamic loading as compared to quasi-static loading.

**12:39PM Y21.00008 Lithium Melt Line Determined using the Z Method**, MARVIN ZOCHER, LEONID BURAKOVSKY, Los Alamos National Laboratory — The Z method is a numerical procedure that can be used for the construction of phase diagrams. In the present work the method is discussed and its use is demonstrated through a determination of the melt line for lithium.

**12:51PM Y21.00009 A fitting empirical potential for NiTi alloy and its application.**, GUOWU REN, TIEGANG TANG, Institute of Fluid Physics, Chinese Academy of Engineering Physics, Mianyang, 621999, HUSEYIN SEHITOGLU, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801 — Due to its superelastic behavior, NiTi shape memory alloy receives considerable attentions over a wide range of industrial and commercial applications. Limited to its complex structural transformation and multiple variants, semiempirical potentials for performing large-scale molecular dynamics simulations to investigate the atomistic mechanical process, are very few. In this work, we construct a new interatomic potential for the NiTi alloy by fitting to experimental or ab initio data. The fitting potential correctly predicts the lattice parameter, structural stability, equation of state for cubic B2(austenite) and monoclinic B19'(martensite) phases. In particular the elastic properties( three elastic constants for B2 and thirteen ones for B19') are in satisfactory agreement with the experiments or ab initio calculations. Furthermore, we apply this potential to conduct the molecular dynamics simulations of the mechanical behavior for NiTi alloy and the results capture its reversible transformation.

**1:03PM Y21.00010 Highly Accurate Calculations of the Phase Diagram of Cold Lithium**, LUKE SHULENBURGER<sup>1</sup>, ANDREW BACZEWSKI, Sandia National Laboratories — The phase diagram of lithium is particularly complicated, exhibiting many different solid phases under the modest application of pressure. Experimental efforts to identify these phases using diamond anvil cells have been complemented by ab initio theory, primarily using density functional theory (DFT). Due to the multiplicity of crystal structures whose enthalpy is nearly degenerate and the uncertainty introduced by density functional approximations, we apply the highly accurate many-body diffusion Monte Carlo (DMC) method to the study of the solid phases at low temperature. These calculations span many different phases, including several with low symmetry, demonstrating the viability of DMC as a method for calculating phase diagrams for complex solids. Our results can be used as a benchmark to test the accuracy of various density functionals. This can strengthen confidence in DFT based predictions of more complex phenomena such as the anomalous melting behavior predicted for lithium at high pressures.

**1:15PM Y21.00011 Cold melting of Li under pressure: Perspectives from first-principles molecular dynamics simulations<sup>1</sup>**, WEIYI XIA, WEIWEI GAO, Department of Physics, University at Buffalo, SUNY, Buffalo, NY 14260, USA, XIANG GAO, Beijing Computational Science Research Center, Beijing, China, 100084, PEIHONG ZHANG, Department of Physics, University at Buffalo, SUNY, Buffalo, NY 14260, USA — Despite much work (experiment and theory), the pressure-dependent melting temperature of Li is still under debate. In particular, there is still controversy and significant uncertainty in determining the melting temperature of Li at pressures around 50 GPa. An earlier report [1] suggests that Li melts at as low as 190 K between 40 and 64 GPa. Such a low melting temperature is not likely unless quantum effects of lattice vibration play a significant role. Later experiment [2], on the other hand, reports that Li melts above 300 K under pressured up to 64 GPa and does not seem to support the view that lattice quantum effects to play any important role. In this talk, we will present results from large-scale (large systems and long simulation times) first-principles molecular dynamics simulations and phonon free energy calculations, aiming at resolving some of the issues. **1:27PM Y21.00012 Nuclear quantum and electronic exchange-correlation effects on the high pressure phase diagram of lithium**, RAYMOND CLAY, Univ of Illinois - Urbana, MIGUEL MORALES, STANIMIR BONEV, Lawrence Livermore National Laboratory — Lithium at ambient conditions is the simplest alkali metal and exhibits textbook nearly-free electron character. However, increased core/valence electron overlap under compression leads to surprisingly complex behavior. Dense lithium is known to possess a maximum in the melting line, a metal to semiconductor phase transition around 80 GPa, reemergent metallicity around 120 GPa, and low coordination solid and liquid phases. In addition to its complex electronic structure at high pressure, the atomic mass of lithium is low enough that nuclear quantum effects could have a nontrivial impact on its phase diagram. Through a combination of density functional theory based path-integral and classical molecular dynamics simulations, we have investigated the impact of both nuclear quantum effects and anharmonicity on the melting line and solid phase boundaries. Additionally, we have determined the robustness of previously predicted tetrahedral clustering in the dense liquid to the inclusion of nuclear quantum effects and approximate treatment of electronic exchange-correlation effects.

**1:39PM Y21.00013 Nature of Pressure-induced Insulating States in Simple Metals**, IVAN NAUMOV, RUSSELL HEMLEY, Carnegie Institution of Washington — As experimentally established, all the alkali metals and heavy alkaline earth metals (Ca, Sr and Ba) become progressively less conductive on compression, at least up to some critical limit over a broad pressure range. Of these metals, Li and Na clearly undergo pressure-induced metal-insulator transitions, which may also be called reverse Mott transitions. Here, using group theory arguments and first-principles calculations, we show that such transitions can be understood in terms of band representations introduced by Zak. The valence bands in the insulating states are described by simple and composite band representations constructed from localized Wannier functions centered on points unoccupied by atoms [1]. The character of the Wannier functions is closely related to the degree of s-p(-d) hybridization and reflects multi-center chemical bonding in these insulating states. The conditions under which an insulating state is allowed for structures having an integer number of atoms per primitive unit cell as well as re-entrant (i.e., metal-insulator-metal) transition sequences are detailed, resulting in predictions of semimetallic phases with flat surface states. The general principles developed are tested and applied to the alkali and alkaline earth metals, including elements where high-pressure insulating phases have been identified or reported (e.g., Li, Na, and Ca). This research was supported by EFree, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DESC0001057. [1] I. I. Naumov and R. J. Hemley, PRL, **114**, 156403 (2015).

**1:51PM Y21.00014 Simulation texture development of polycrystalline aluminum under dynamic loading**, XIAOMIAN HU, HAO PAN, ZIHUI WU, Institute of Applied Physics and Computational Mathematics, Beijing — Effect of texture to dynamic response of polycrystalline metals under dynamic loading attracted much attention because of interesting phenomena and great challenges to experiment and simulation. This paper uses a crystal plasticity finite element method (CPFEM) with a dislocation based hardening law to model the texture development of polycrystalline aluminum under simple compression, uniaxial strain ramp loading and shock wave loading. Strain hardening under the three compression conditions is also compared. The simulation results show that the preferred orientation during of the polycrystalline aluminum under the three compression conditions has some different. It caused normalized stress-strain profiles of state of 1D stress and 1D strain are different when strain is over 5% and strain rate is same.

**2:03PM Y21.00015 Cooling rates dependence of medium range order development in metallic glasses**<sup>1</sup>, C. Z. WANG, Y. ZHANG, F. ZHANG, M. I. MENDELEV, M. J. KRAMER, K. M. HO, Ames Laboratory, Iowa State University — Rapid cooling from metallic liquids is a widely used approach to synthesize novel alloys with desirable properties because such rapid cooling drives phase selection away from equilibrium phases resulting in new metastable phases and morphologies. However, molecular dynamics simulation of such rapid solidifications faces a well-known time-scale challenge that the cooling rate is several orders of magnitude faster than experiments. We propose an efficient cooling strategy in which most of the computer time is spent on a prolonged isothermal process slightly below the glass-transition temperature  $T_g$ . Such a sub- $T_g$  annealing reduces the effective cooling rates in MD simulations to  $\sim 10^7$  K/s. The effects of lowering cooling rates on the evolution of short-range and medium-range orders are investigated. The glassy samples prepared in this way demonstrate significant energetic stability, slow dynamics, and well-developed short-range and medium-range orders.

**11:15AM Y22.00001 Quasi-local approximation of non-local exchange-correlation kernels in the adiabatic-connection fluctuation-dissipation theorem**<sup>1</sup>, DEYU LU, Brookhaven National Laboratory — The adiabatic-connection fluctuation-dissipation theorem (ACFDT) is a formal theoretical framework to treat van der Waals (vdW) dispersion interactions. Under the random phase approximation (RPA), it yields the correct asymptotic behavior at large distances, but the short-range correlation is overestimated. It has been demonstrated that non-local exchange-correlation kernels can systematically correct the errors of RPA for homogenous electron gas. However, direct extension of non-local kernels derived from the electron gas model to inhomogeneous systems raises several issues. In addition to the high computational expense, the non-local kernels worsen the rare gas dimer binding curve as compared to RPA. In this study, we propose a quasi-local approximation of the non-local kernel in order to address these issues.

**11:27AM Y22.00002 The Connection between Diagrams and Electrodynamics in the Long-Range Dispersion Energy**, RAHUL MAITRA, ROBERT DISTASIO, Cornell University — In this talk, we will discuss the different avenues that lead to the complete treatment of the long-range dispersion interaction energy between isolated fragments that are located outside the area of orbital (or electron density) overlap. By analyzing the higher-order terms in the perturbative expansion of the dispersion energy *via* a dipole response function formalism, we show that each of these terms can be expressed as physically meaningful quantities in classical electrodynamics. Based on this approach, we generalize the connection between the higher-order perturbative contributions to the dispersion energy, the different classes of diagrams (e.g. rings, ladders, etc.), and the aforementioned electrodynamic response functions.

**11:39AM Y22.00003 A fully consistent spin formalism for the nonempirical van der Waals density functional vdW-DF**<sup>1</sup>, T. THONHAUSER, S. ZULUAGA, C. ARTER, Wake Forest University, K. BERLAND, University of Oslo, E. SCHRÖDER, P. HYLDGAARD, Chalmers University of Technology — We present a proper nonempirical spin-density formalism for the van der Waals density functional (vdW-DF) method. We show that this generalization, termed svdW-DF, is firmly rooted in the single-particle nature of exchange and we test it on a range of spin systems. We investigate in detail the role of spin in the van der Waals driven adsorption of H<sub>2</sub> and CO<sub>2</sub> in the linear magnets Mn-MOF74, Fe-MOF74, Co-MOF74, and Ni-MOF74. In all cases, we find that spin plays a significant role during the adsorption process despite the general weakness of the molecular-magnetic responses. The case of CO<sub>2</sub> adsorption in Ni-MOF74 is particularly interesting, as the inclusion of spin effects results in an increased attraction, opposite to what the diamagnetic nature of CO<sub>2</sub> would suggest. We explain this counter-intuitive result, tracking the behavior to a coincidental hybridization of the O *p* states with the Ni *d* states in the down-spin channel. More generally, by providing insight on van der Waals interactions in concert with spin effects, our nonempirical svdW-DF method opens the door for a deeper understanding of weak nonlocal magnetic interactions.

**11:51AM Y22.00004 Dispersion Interactions in High-Density Molecular Crystals**, PETER CSERNICA, RAHUL MAITRA, ROBERT DISTASIO, Cornell University — Dispersion interactions are ubiquitous quantum mechanical phenomena arising from correlated electron density fluctuations in molecules and materials. As a key component of non-bonded interactions, dispersion forces play a critical role in determining the structure and stability of molecular crystals. Due to the relative intermolecular separation in high-density molecular crystals, an accurate description of these non-bonded interactions requires the inclusion of terms beyond the asymptotic induced-dipole–induced-dipole ( $C_6/R^6$ ) contribution. In this work, we have developed a first principles based approach within the framework of Density Functional Theory (i.e., that only depends on the charge density  $n(\mathbf{r})$ ) for capturing the higher-order induced multipolar contributions to the correlation energy. As a first application of this method, we have investigated the structure and stability of the high-density ice molecular crystal polymorphs at the ice VI—ice VII—ice VIII triple point (278K, 2.1GPa) using *ab-initio* molecular dynamics in the isobaric-isothermal ( $NpT$ ) ensemble.

**12:03PM Y22.00005 On the pseudopotential approximation in the van der Waals density functional calculations**, IKUTARO HAMADA, MARTIN CALLSEN, National Institute for Materials Science — The van der Waals density functional (vdW-DF)[1,2] is a density functional that is able to describe van der Waals and covalent interactions in a seamless fashion, and has been applied to a variety of systems. In practical calculations, the pseudopotential (PP) approximation has been employed, for which the PPs should be generated consistently for the chosen exchange correlation XC functional. However, usually PPs generated with a generalized gradient approximation (GGA) XC functional are used and the effect of the approximation to the XC functional applied in the PP generation is scarcely discussed. In this work, we discuss the appropriate XC functionals in the PP generation for the vdW-DF calculations. Furthermore, we compare the vdW-DF results for several systems using the PP's generated with appropriate XC and those with GGA XC[3].

**12:15PM Y22.00006 Van der Waals Interactions Between Subsystems with Overlapping Electron Density**, MICHELE PAVANELLO, Rutgers University — We claim that a subsystem formulation of Density-Functional Theory (DFT) can simplify both the theoretical framework and the computational effort for calculating the electronic structure of condensed phase systems. In addition, the naturally subsystem-like form of molecular aggregates makes subsystem DFT a better descriptor of the underlying physics than regular DFT of the supersystem. As an example, we present a novel van der Waals theory based on subsystem DFT which can treat seamlessly non-overlapping as well as overlapping subsystem electron densities. The theory is amenable to sensible approximations, such as RPA, and offers natural algorithms to fold in post-RPA corrections. Application of the theory to the computation of binding energies of dimers in the S22 set, and computation of selected potential energy surfaces is presented. **12:27PM Y22.00007 The Dipole Polarizability of a Water Molecule *in* Liquid Water**, ROBERT DISTASIO, RAHUL MAITRA, Cornell University — The dipole polarizability,  $\alpha$ , provides a measure of the tendency of a molecule or material to deform (or polarize) in the presence of an electric field. Within the framework of density functional theory (DFT), we present a hierarchy of first principles based approaches for computing  $\alpha$  of a molecule located in the condensed phase. This hierarchy includes a successive treatment of both short-range (hybridization, Pauli exchange-repulsion, etc.) and long-range (Coulomb) electrodynamic response screening in the computation of  $\alpha$ , while simultaneously accounting for the surrounding condensed-phase environment. Utilizing highly accurate liquid water configurations generated from van der Waals inclusive hybrid DFT based *ab initio* molecular dynamics, we computed  $\alpha$  for a given water molecule *in* liquid water as a first application of this approach. Our findings will be compared and contrasted with  $\alpha$  computed for an isolated gas-phase water molecule.

**12:39PM Y22.00008 Study of correlations from Ab-Initio Simulations of Liquid Water<sup>1</sup>**, ADRIAN SOTO, MARIVI FERNANDEZ-SERRA, Stony Brook University, DEYU LU, SHINJAE YOO, Brookhaven National Laboratory — An accurate understanding of the dynamics and the structure of H<sub>2</sub>O molecules in the liquid phase is of extreme importance both from a fundamental and from a practical standpoint. Despite the successes of Molecular Dynamics (MD) with Density Functional Theory (DFT), liquid water remains an extremely difficult material to simulate accurately and efficiently because of fine balance between the covalent O-H bond, the hydrogen bond and the attractive van der Waals forces. Small errors in those produce dramatic changes in the macroscopic properties of the liquid or in its structural properties. Different density functionals produce answers that differ by as much as 35% in ambient conditions, with none producing quantitative results in agreement with experiment at different mass densities [J. Chem Phys. **139**, 194502(2013)]. In order to understand these differences we perform an exhaustive scanning of the geometrical coordinates of MD simulations and study their statistical correlations with the simulation output quantities using advanced correlation analyses and machine learning techniques.

**12:51PM Y22.00009 The Role of Anharmonicity and Nuclear Quantum Effects in the Pyridine Molecular Crystal: An *ab initio* Molecular Dynamics Study<sup>1</sup>**, HSIN-YU KO, Princeton University, ROBERT A. DISTASIO JR., Cornell University, BISWAJIT SANTRA, ROBERTO CAR, Princeton University — Molecular crystal structure prediction has posed a substantial challenge to first-principles methods and requires sophisticated electronic structure methods to determine the stabilities of nearly degenerate polymorphs [1,2,3]. In this work, we demonstrate that the anharmonicity from van der Waals interactions is relevant to the finite-temperature structures of pyridine and pyridine-like molecular crystals. Using such an approach, we find that the equilibrium structures are well captured with classical *ab initio* molecular dynamics (AIMD), despite the presence of light atoms such as hydrogen. Employing path integral AIMD simulations, we demonstrate that the success of classical AIMD results from a separation of nuclear quantum effects between the intermolecular and intramolecular degrees of freedom. In this separation, the quasiclassical and anharmonic intermolecular degrees of freedom determine the equilibrium structure, while the quantum and harmonic intramolecular degrees of freedom are averaging to the correct intramolecular structure. **1:03PM Y22.00010 Phonon dispersion in acene molecular crystals using van der Waals density functionals**, FLORIAN BROWN-ALTVATER, University of California, Berkeley, TONATIUH RANGEL, Lawrence Berkeley National Laboratory, JEFFREY B. NEATON, University of California, Berkeley; Lawrence Berkeley National Laboratory — Much progress has been made of late in understanding the fundamental processes in optoelectronic materials. An ongoing challenge is the accurate inclusion of nuclear motion and to go beyond the Born-Oppenheimer approximation. Especially in materials like molecular crystals, where van der Waals (vdW) forces dominate the cohesive energy and the electronic structure is very sensitive to intermolecular geometry, phonons can be an important facilitator and dissipation mechanism. Thus there is a need to assess and understand the efficacy of existing approaches for phonon dispersions in vdW-bound solids. In this work we use a vdW density functional to calculate the phonon dispersion of members of the acene family. We establish the accuracy of the method using naphthalene, obtaining excellent agreement with experimental results, and in a further step, we explore the strength of the electron-phonon coupling across the Brillouin zone. Taken all together, our calculations illustrate the potential for quantitative prediction of vibrational properties of weakly-bound organic crystals over the entire Brillouin zone from first principles.

**1:15PM Y22.00011 Ligand control of magnetic ordering temperature in copper-pyrazine square lattice antiferromagnets<sup>1</sup>**, JOHN SINGLETON, National High Magnetic Field Laboratory, Los Alamos, P. GODDARD, Warwick University, UK, I. FRANKE, J. MOELLER, S. BLUNDELL, A. STEELE, C. TOPPING, University of Oxford, T. LANCASTER, Durham University, UK, C. BAINES, Paul Scherrer Institute, Switzerland, J. BENDIX, University of Copenhagen, R. MCDONALD, National High Magnetic Field Laboratory, Los Alamos, J. BRAMBLEBY, M. LEES, Warwick University, UK, S. LAPIDUS, P. STEPHENS, SUNY, Stony Brook, B. TRAMLEY, University of Idaho, K. FUNK, M. CONNER, J. CORBEY, H. TRAN, Eastern Washington University, J. SCHLUETER, Argonne National Laboratory, J. MANSON, Eastern Washington University — Using a mixed-ligand synthetic scheme, we create a family of quasi-two-dimensional (Q2D) antiferromagnets:  $[\text{Cu}(\text{HF}_2)(\text{pyz})_2]\text{ClO}_4$  [pyz = pyrazine],  $[\text{Cu}L_2(\text{pyz})_2](\text{ClO}_4)_2$  [ $L$  = pyO = pyridine-N-oxide and 4-phpyO = 4-phenylpyridine-N-oxide]. These possess equivalent 2D  $[\text{Cu}(\text{pyz})_2]^{2+}$  nearly square layers, but show interlayer spacings from 6.57 Å to 16.78 Å, dictated by the axial ligands. Structural and magnetic properties are derived from x-ray diffraction, ESR, pulsed-field magnetometry and muon-spin rotation, and compared to those of the prototypical 2D magnetic polymer  $\text{Cu}(\text{ClO}_4)_2(\text{pyz})_2$ . We find that the 2D exchange coupling remains largely unaffected by the axial ligand substitution, while the magnetic ordering temperature decreases slowly with increasing layer separation. Experimental data are compared to theory, including DFT.

**1:27PM Y22.00012 UNUSUALLY LARGE YOUNG'S MODULI OF AMINO ACID MOLECULAR CRYSTALS\***, IDO AZURI, ELENA MEIRZADEH, DAVID EHRE, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth, Israel, SIDNEY R. COHEN, Chemical Research Support, Weizmann Institute of Science, Rehovoth, Israel, ANDREW M. RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, PA, USA, MEIR LAHAV, IGOR LUBOMIRSKY, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovoth, Israel — Young's moduli of selected amino acid molecular crystals were studied both experimentally and computationally using nanoindentation and dispersion-corrected density functional theory. The Young modulus is found to be strongly facet-dependent, with some facets exhibiting exceptionally high values (as large as 44 GPa). The magnitude of Young's modulus is strongly correlated with the relative orientation between the underlying hydrogen-bonding network and the measured facet. Furthermore, we show computationally that the Young modulus can be as large as 70-90 GPa if facets perpendicular to the primary direction of the hydrogen-bonding network can be stabilized. This value is remarkably high for a molecular solid and suggests the design of hydrogen-bond networks as a route for rational design of ultra-stiff molecular solids. \*Angew. Chem. Int. Ed.. doi: 10.1002/anie.201505813

**11:15AM Y23.00001 Optimizing Thermoelectric Properties in Composites**, MICHAEL J. ADAMS, HYUNGYU JIN, JOSEPH P. HEREMANS, The Ohio State University — Here we consider semiconductor composites as a way to yield high thermoelectric figure of merit. Effective medium theory limits the figure of merit of a composite made from two non-interacting materials, A and B, to the larger of the two [1, 2]. In previous work, we describe a mechanism that can lift this limitation by treating charge and heat flux separately. Silica beads coated with a conducting shell are inserted into a thermoelectric host. Thermal conductivity decreases with insulating material added, but electrical conductivity is maintained via locally conducting surfaces. We apply the theory to p-type (Bi,Sb)2Te3 host material. Several permutations are possible: Te-coated beads in Sb-rich material, or Sb-coated beads in Te-rich material. First, we review data for varying bead coatings and heat treatments, followed by varying stoichiometry in the host. New data considers an additional parameter of varying bead diameter, as well as optimizing these parameters simultaneously to enhance thermoelectric performance. References: [1] David J. Bergman and Ohad Levy, J. Appl. Phys. 70 6821 (1991) [2] David J. Bergman and Leonid G. Fel, J. Appl. Phys. 85 8205 (1999)

**11:27AM Y23.00002 High thermoelectric figure-of-merit in Sb<sub>2</sub>Te<sub>3</sub>/Ag<sub>2</sub>Te bulk composites as Pb-free p-type thermoelectric materials**, MINHOO LEE, JONG-SOO RHYEE, Kyung Hee Univ - Suwon Campus, SU-DONG PARK, Korea Electrotechnology Research Institute — We investigated thermoelectric properties of the Sb<sub>2</sub>Te<sub>3</sub>/Ag<sub>2</sub>Te (ST/AT) composites with molar ratios of ST/AT = 1/1, 2/1, 4/1, 8/1, 16/1, and 32/1. The extrinsic composites, synthesized by wet ball milling of two separate powders of Sb<sub>2</sub>Te<sub>3</sub> and Ag<sub>2</sub>Te, are differentiated with intrinsic composites by high temperature phase separation in that it is low temperature synthesis process. The thermoelectric properties of the composites show systematic behaviour of decreased electrical and thermal conductivities with increasing Ag<sub>2</sub>Te dispersion concentration. The ST/AT = 1/1 composite exhibits extremely low lattice thermal conductivity with high power factor over a wide temperature range, resulting in high ZT value 1.5 at 700 K, which is the significantly enhanced value of ZT compared with other Pb-free p-type chalcogenide thermoelectric materials.

**11:39AM Y23.00003 Coupled improvement between thermoelectric and piezoelectric materials**, DAVID MONTGOMERY, COREY HEWITT, CHAOCHAO DUN, DAVID CARROLL, Wake Forest University — A novel coupling effect in a thermoelectric and piezoelectric meta-structure is discussed. Thermo-piezoelectric generators (TPEGs) exhibit a synergistic effect that amplifies output voltage, and has been observed to increase piezoelectric voltages over 500% of initial values a time dependent thermoelectric/pyroelectric effect. The resulting improvement in voltage has been observed in carbon nanotubes as well as inorganics such as two-dimensional Bismuth Selenide platelets and Telluride nanorods thin-film thermoelectrics. TPEGs are built by integrating insulating layers of polyvinylidene fluoride (PVDF) piezoelectric films between flexible thin film p-type and n-type thermoelectrics. The physical phenomena arising in the interaction between thermoelectric and piezoelectrics is discussed and a model is presented to quantify the expected coupling voltage as a function of stress, thermal gradient, and different thermoelectric materials. TPEG are ideal to capture waste heat and vibrational energy while creating larger voltages and minimizing space when compared with similar thermoelectric or piezoelectric generators.

**11:51AM Y23.00004 Thermomagnetic transport properties of ferromagnetic MnBi**, STEPHEN BOONA, JOSEPH HEREMANS, Ohio State University — Spin-dependent transport phenomena such as the spin Seebeck effect and magnon drag offer intriguing new possibilities for tuning the thermoelectric properties of magnetically ordered materials. One particularly interesting approach is to examine magnetic materials that are expected to display large intrinsic spin orbit coupling, such as MnBi. In spite of this material's popularity as a candidate for rare-earth free permanent magnets, no studies have been published so far concerning its Seebeck or Nernst coefficients. This talk will discuss our recent measurements of the thermomagnetic properties of high purity polycrystalline MnBi between 2K and 385K and in magnetic fields up to 7T. Our measurements reveal the existence of a substantial anomalous Nernst effect (ANE) from 382K down to the spin reorientation temperature of 90K, while the other transport phenomena show relatively weak magnetic field dependence at all temperatures. We also observe that the Seebeck and ANE coefficients display strikingly similar temperature dependence, with the former peaking at approximately  $-10 \mu\text{V/K}$  and the latter at approximately  $-2.5 \mu\text{V/K/T}$ , hinting at the important role of spin-dependent processes in determining the transport properties of this material.

**12:03PM Y23.00005 Integration of 2-Dimensional Materials for Thermoelectric Power Generation**, FADHEL ALSAFFAR, ABDULRAHMAN AL HUSSAIN, MOH. R. AMER, None, CENTER OF EXCELLENCE FOR GREEN NANOTECHNOLOGIES COLLABORATION, DEPARTMENT OF ELECTRICAL ENGINEERING (UCLA) COLLABORATION — Recent developments in nanomaterial research have significantly progressed the performance of thermoelectric devices. Theoretical investigations of the thermoelectric properties of 2-Dimensional monolayers demonstrate a high figure of merit (ZT) [1, 2]. Here, we investigate the integration of these 2-Dimensional materials for power generation applications using solar heat. We show that using black phosphorus monolayer (phosphorene) as the *p*-type material, and Molybdenum disulfide ( $\text{MoS}_2$ ) monolayers as the *n*-type material, we get an effective figure of merit (ZT) at least (1.5) with a conversion efficiency of 13% at 280°C. Our results suggest that the integration of various 2-Dimensional materials is a promising approach for commercial thermoelectric power generation applications. **References:** [1] W. Huang, X. Luo, C. K. Gan, S. Y. Quek, and G. Liang, "Theoretical study of thermoelectric properties of few-layer  $\text{MoS}_2$  and  $\text{WSe}_2$ ," *Physical Chemistry Chemical Physics*, vol. 16, pp. 10866-10874, 2014. [2] R. Fei, A. Faghaninia, R. Soklaski, J.-A. Yan, C. Lo, and L. Yang, "Enhanced thermoelectric efficiency via orthogonal electrical and thermal conductances in phosphorene," *Nano Letters*, vol. 14, pp. 6393-6399, 2014.

**12:15PM Y23.00006 First-Principles Study on Thermoelectric Performance of Phosphorene and Phosphorene Oxide**, SEUNGJUN LEE, JEJUNE PARK, SEOUNG-HUN KANG, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University, Seoul, 130-701, Korea — Using first-principles density functional theory, we studied thermoelectric properties of phosphorene and its oxidized structure called phosphorene oxide (PO). Using the identified stable configurations and electronic structures of phosphorene and PO, we solved the Boltzmann transport equation to evaluate their electrical conductivity, Seebeck coefficient, and thermal conductivity contributed from both electrons and phonons. In order to correctly estimate the thermoelectric figure of merit or ZT values, it is indispensable to determine the relaxation time, which can be estimated by applying the deformation potential theory. We observe that the electrical conductivity of phosphorene is higher along the armchair direction than along the zigzag direction, while the thermal conductivity shows an opposite behavior. Because of such an orthogonal relation between the electrical and thermal conductivities, phosphorene exhibits quite a large ZT value along the armchair direction. It is, on the other hand, calculated that PO has electrical conductivity similar to phosphorene, however its thermal conductivity is significantly smaller than phosphorene, resulting in larger ZT values. We expect that PO can be utilized for a high performance thermoelectric application.

**12:27PM Y23.00007 Understanding phonon transport in thermoelectric materials using *ab initio* approaches**, DAVID BROIDO, Boston College — Good thermoelectric materials have low phonon thermal conductivity,  $k_{ph}$  [1]. Accurate theories to describe  $k_{ph}$  are important components in developing predictive models of thermoelectric efficiency that can help guide synthesis and measurement efforts. We have developed *ab initio* approaches to calculate  $k_{ph}$ , in which phonon modes and phonon scattering rates are computed using interatomic force constants determined from density functional theory, and a full solution of the Boltzmann transport equation for phonons is implemented [2-5]. A recent approach to calculate interatomic force constants using *ab initio* molecular dynamics [6] has yielded a good description of the thermal properties of  $\text{Bi}_2\text{Te}_3$ . But, the complexity of new promising candidate thermoelectric materials introduces computational challenges in assessing their thermal properties. An example is germanane, a germanium based hydrogen-terminated layered semiconductor [7], which we will discuss in this talk. [1] H. J. Goldsmid, *Thermoelectric Refrigeration* (Plenum, New York, 1964); [2] D. A. Broido et al, *Appl. Phys. Lett.*, 91, 231922 (2007); [3] A. Kundu et al, *Phys. Rev. B*, 84, 125426 (2011); [4] W. Li et al, *Phys. Rev. B* 86, 174307 (2012); [5] Olle Hellman and I. A. Abrikosov, *Phys. Rev. B* 88, 144301 (2013); [6] O. Hellman and D. A. Broido, *Phys. Rev. B* 90, 134309 (2014); [7] E. Bianco, et al., *ACS Nano* 7, 4414 (2013).

**1:03PM Y23.00008 Ab initio theory of thermal properties of germanane**, MATTHEW HEINE, Boston College, LUCAS LINDSAY, Oak Ridge National Lab, JESÚS CARRETE, NATALIO MINGO, LITEN, CEA-Grenoble, OLLE HELLMAN, Linköping University, DAVID BROIDO, Boston College — Germanane(GeH) is a germanium based hydrogen-terminated multi-layered graphene analogue semiconductor, which may be a promising thermoelectric due to its high electron mobility and the capability to tune its transport properties [1]. We have performed first principles calculations of the thermal properties of germanane. Harmonic and anharmonic interatomic force constants are calculated within the framework of density functional theory, from which phonon dispersions, specific heat, thermal expansion are obtained. The phonon Boltzmann equation is solved to obtain the lattice thermal conductivity. The disparity in constituent masses in GeH gives phonon modes that are distinctly Ge or H in character and causes the specific heat not to saturate until much higher temperatures than in bulk Ge. Weak interlayer bonding and strong phonon-phonon scattering result in highly anisotropic and quite low intrinsic lattice thermal conductivity compared to Ge. [1] E. Bianco et. al., *ACS Nano* 7, 4414-4421 (2013).

**1:15PM Y23.00009 Thermal Conductance at the 2D  $\text{MoS}_2$ -hexagonal Boron Nitride Interface**, YI LIU, Natl Univ of Singapore, KEDAR HIPPALGAONKAR, Institute of Materials Research and Engineering, A\*STAR, ZHUN YONG ONG, Institute of High Performance Computing, A\*STAR, JOHN TL THONG, CHENGWEI QIU, Natl Univ of Singapore — In recent years, a number of 2D heterostructure devices have emerged, including graphene/hexagonal boron nitride (*h*-BN), graphene/ $\text{MoS}_2$  and  $\text{MoS}_2$ /*h*-BN. Among them,  $\text{MoS}_2$ /*h*-BN field-effect transistors with  $\text{MoS}_2$  channels and *h*-BN dielectric have been reported to have higher carrier mobility and reduced hysteresis compared to  $\text{MoS}_2$  on  $\text{SiO}_2$ . Despite relatively high in-plane thermal conductivity of  $\text{MoS}_2$  and *h*-BN, heat dissipation from these 2D devices is mainly limited by heat transfer in the vertical direction. Consequently, their operating temperatures are strongly influenced by the interface thermal conductance. In this work, we demonstrate the measurement of interface thermal conductance between  $\text{MoS}_2$  and *h*-BN. This is realized by electrically heating  $\text{MoS}_2$  and monitoring their temperatures through Raman spectroscopy. The obtained interface thermal conductance between  $\text{MoS}_2$  and *h*-BN is  $1.77 \text{ MW/m}^2\text{K}$ , smaller than the reported value for the graphene/*h*-BN interface, due to the weak coupling of phonon modes between  $\text{MoS}_2$  and *h*-BN based on our NEGF calculation. The low interface thermal conductance value suggests this interface is not favorable for heat dissipation, and should be considered carefully for the design of electronic and optoelectronic devices based on  $\text{MoS}_2$ /*h*-BN heterostructures.

**1:27PM Y23.00010 Maximizing the thermoelectric performance of topological insulator  $\text{Bi}_2\text{Te}_3$  films in the few-quintuple layer regime**, HUIJUN LIU, JINGHUA LIANG, LONG CHENG, JIE ZHANG, Wuhan University, ZHENYU ZHANG, University of Science and Technology of China — Using first-principles calculations and Boltzmann theory, we explore the feasibility to maximize the thermoelectric figure of merit ( $ZT$ ) of topological insulator  $\text{Bi}_2\text{Te}_3$  films in the few-quintuple layer regime. We discover that the delicate competitions between the surface and bulk contributions, coupled with the overall quantum size effects, lead to a novel and generic non-monotonous dependence of  $ZT$  on the film thickness. In particular, when the system crosses into the topologically non-trivial regime upon increasing the film thickness, the much longer surface relaxation time associated with the robust nature of the topological surface states results in a maximal  $ZT$  value, which can be further optimized to  $\sim 2.0$  under physically realistic conditions. We also reveal the appealing potential of bridging the long-standing  $ZT$  asymmetry of  $p$ - and  $n$ -type  $\text{Bi}_2\text{Te}_3$  systems. These findings help to establish intricate connections between the thermoelectric materials and topological insulators.

**1:39PM Y23.00011 Temperature sensing and real-time two-dimensional mapping at the micro-scale**, XIAOYE HUO, GANG LI, ZHENHAI WANG, XINYU MAO, SHENGYONG XU, Key Laboratory for Physics and Chemistry of Nanodevices, Department of Electronics, Peking University — To sense temperature at micro/nano scales and obtain its detailed distribution in space and in time remains a technical challenge in many cases. We observed an unexpected thermoelectric size effect, where the absolute Seebeck coefficient of metallic thin film stripes (e.g. Ni, Cr, Pd, W, Bi, Sc, etc.) decreased with the stripe width from  $100\mu\text{m}$  down to  $100\text{nm}$ . This phenomenon was utilized in micro/nano-stripe-based thin film temperature sensors. By using an array of such sensors, two-dimensional temperature distribution at the micro-scale could be precisely mapped. Small temperature sensors with a total width less than  $1\mu\text{m}$  and a sensitivity of  $0.5\text{--}2.2\mu\text{V/K}$  were fabricated, showing a potential for monitoring temperatures at submicro-scales. By using a special multiplexer and software, nearly real-time 2D temperature mapping was performed, demonstrating 2D thermal history of target surface with a delay of less than one minute. These thin film sensors were also fabricated on flexible Parylene-C substrates for application in flexible electronic devices, temperature monitoring of cell culturing, and heat transfer between Au nanoparticles and metallic stripes due to plasmonic excitation under laser radiation.

**1:51PM Y23.00012 Engineering Group-IV Monochalcogenides by Doping and Alloying**, HANSIKA SIRIKUMARA, TREVOR FITZPATRICK, THUSHARI JAYASEKERA, Southern IL Univ-Carbondale — Group-IV monochalcogenides,  $\text{MX}$  ( $\text{M}=\text{Sn, Ge}$  and  $\text{X}=\text{S, Se}$ ) have shown to be promising materials for thermoelectric and photovoltaic applications. These properties can be further engineered by substitutional doping and alloying. Using the results from *ab initio* Density Functional Theory calculations, we identified a series of new class of monochalcogenide alloys in the form  $\text{Ge}(1-x)\text{Sn}_x\text{S}$ ,  $\text{Ge}(1-x)\text{Sn}_x\text{Se}$ ,  $\text{GeS}_x\text{Se}(1-x)$ ,  $\text{SnS}_x\text{Se}(1-x)$ . Stability of their two-dimensional counterparts will also be discussed in this presentation.

**2:03PM Y23.00013 Thermal conductivity behavior of superatom molecular crystals**, WEE-LIAT ONG, Columbia University / Carnegie Mellon University, EVAN OBRIEN, Columbia University, PATRICK DOUGHERTY, JILLIAN EPSTEIN, C. FRED HIGGS, ALAN MCGAUGHEY, Carnegie Mellon University, XAVIER ROY, Columbia University, JONATHAN MALEN, Carnegie Mellon University — The room temperature thermal conductivity of several superatom molecular crystals (SMCs) are measured and found to be below  $0.3\text{ W/mK}$ . The trend of room temperature thermal conductivity of the different crystals agree well with their sound speeds obtained independently using nano-indentation. These crystals, however, can exhibit non-crystalline thermal conductivity behavior depending on their constituent elements. A superatom is a cluster of atoms that acts as a stable entity [e.g., fullerenes ( $\text{C}_{60}$ )]. By careful mixing and assembling these nano-sized superatoms, the resulting superatom-assembled materials hold promises for improving various technological devices. Organic-inorganic superatoms can assemble into unary SMCs or co-crystallized with  $\text{C}_{60}$  superatoms into binary SMCs. Thermal transport is of considerable interest with possible new physics in these hierarchically atomic precise crystals in the low temperature regime. The thermal conductivity of the SMCs are measured using the frequency domain thermoreflectance setup. Unary SMCs exhibit an almost invariant thermal conductivity down to a temperature of  $150\text{ K}$ . Binary SMCs, however, can either show a crystalline-like increase or an amorphous-like decrease with decreasing temperature.

Session Y25 DCMP: Superconductivity: Theory III 324 - Khadijah Najafi, Georgetown

**11:15AM Y25.00001 Valence Bond Theory of Correlated-Electron Superconductivity<sup>1</sup>**, TIRTHANKAR DUTTA, SUMIT MAZUMDAR, Univ of Arizona, TORSTEN CLAY, Mississippi State Univ — Whether or not the weakly doped Mott-Hubbard semiconductor is superconducting remains controversial. We present a new valence bond theory of correlated-electron superconductivity, that has overlap with the original RVB approach, and yet is substantively different. Superconductivity within the theory emerges from a correlated-electron state in which there is a strong tendency to spin-singlet formation, and where the bandwidth due to pair-tunneling is very large. We show that such a situation occurs far away from the  $1/2$ -filled band, at or near banfilling of  $1/4$ . In the presence of electron-phonon interactions the  $1/4$ -filled band can form a spin-paired CDW state that we have called a paired-electron crystal, and that is a Wigner crystal of pairs. In the presence of frustration the spin-paired bonds become mobile to give a paired-electron liquid, which is a precursor to superconductivity. The superconducting state here is reached from a co-operative effect between electron-electron and electron-phonon interactions, and the theory thus has overlap also with the bipolaron theory of superconductivity. We will present exact numerical calculations on a  $4\times 4$  lattice using the valence bond basis to substantiate our conjectures.

**11:27AM Y25.00002 Retarded VS instantaneous : not so conflicting views on the pairing dynamics of the extended Hubbard model<sup>1</sup>**, A. REYMBAUT, M. FELLOUS ASIANI, Université de Sherbrooke, L. FRATINO, Royal Holloway, U. London, M. CHARLEBOIS, S. VERRET, Université de Sherbrooke, G. SORDI, Royal Holloway, U. London, D.. SÉNÉCHAL, A.-M. S. TREMBLAY, Université de Sherbrooke — While most experimental and theoretical clues lean towards a magnetic origin for the pairing mechanism of high temperature superconductors, the question of its degree of retardation in the strong correlation regime remains highly controversial [1-5]. Part of the answer to this question lies in the frequency dependence of the anomalous spectral function of doped Mott insulators. That spectral function is associated with the Gorkov function and can be extracted at finite temperature using the MaxEntAux method for analytic continuation [6]. Using Cellular Dynamical Mean-Field Theory for the Hubbard model with nearest-neighbor repulsion, we show that the retarded contribution coming from the anomalous spectral function is accompanied by a contribution to the real part of the anomalous self-energy at infinite frequency. This contribution suggests the emergence of a "mixed" pairing mechanism, mostly retarded, slightly instantaneous. [1] P. W. Anderson, Science 316 (5832), 1705 (2007) [2] D. J. Scalapino, E-letter resp. to Science 316, 1705 (2007) [3] T. A. Maier, et al., PRL 100, 237001 (2008) [4] D. Sénéchal, et al., PRB 87, 075123 (2013) [5] E. Gull and A. **11:39AM Y25.00003 Crucial Role of Internal Collective Modes in Underdoped Cuprates<sup>1</sup>**, AABHAAS V. MALLIK, UMESH K. YADAV, Indian Institute of Science Bangalore, AMAL MEDHI, Indian Institute of Science Education and Research Thiruvananthapuram, H. R. KRISHNAMURTHY, VIJAY B. SHENOY, Indian Institute of Science Bangalore — The enigmatic cuprate superconductors have attracted resurgent interest with several recent reports and discussions of competing orders in the underdoped side. Motivated by this, here we address the natural question of frailty of the  $d$ -wave superconducting state in underdoped cuprates. Using a combination of theoretical approaches we study a  $t - J$  like model. We report an – as yet unexplored – instability that is brought about by an “internal” fluctuation (anti-symmetric mode) of the  $d$ -wave state. This new theoretical result helps in understanding recent ARPES and STM studies. We also suggest further experiments to uncover this physics.

<sup>1</sup>Work supported by CSIR, UGC, DST and DAE

**11:51AM Y25.00004 Competition between antiferromagnetism and superconductivity: a quantum Monte Carlo study**, TIANXING MA, 1, Department of Physics, Beijing Normal University, Beijing 100875, China 2, Department of Physics, University of California, San Diego, California, DA WANG, School of Physics, Nanjing University, Nanjing, 210093, China, CONJUN WU, Department of Physics, University of California, San Diego, California 92093, USA — Among correlated materials, the vicinity between various magnetic orders and superconductivity is one of the most notorious issues, which is present in high temperature superconductors like doped cuprates and ironpnictides, as well as in organic superconductors. In a multi-band Hubbard model, or, equivalently, a large-spin Hubbard model, it has been shown that the sign problem of quantum Monte Carlo simulations can be removed at arbitrary fillings in a wide parameter regime, which offers the unique opportunity to perform a detailed unbiased analysis of the competition between antiferromagnetism and superconductivity. Within this framework, we performed QMC simulations to investigate the phase diagram as doping and interaction strength, and our nonbiased numerical results reveal that the antiferromagnetic long-range order can be realized around doping  $0.06$ , and the maximal superconducting pairing correlation is brought by doping, which occurs around the optimal doping  $0.30$ , and then decreases in both the underdoped and overdoped regimes.

**12:03PM Y25.00005 Superconducting Fluctuations in the Normal State of the Two-Dimensional Hubbard Model**, XI CHEN, JAMES LEBLANC, EMANUEL GULL, University of Michigan — The dynamical mean field theory and its cluster extensions, such as the dynamical cluster approximation, are effective and accurate methods for solving the 2D Hubbard model. Progress is limited by exponential scaling, especially for quantities relevant to superconducting correlations. In this work, we demonstrate how the vertex contribution to the pairing susceptibility can be used as an indicator of the proximity to the superconducting transition temperature. This allows us to analyze a wider region of parameter space at a higher (numerically accessible) temperature in the normal state. The optimal interaction strength, doping and next-nearest hopping for  $d_{x^2-y^2}$  superconductivity are located. We conclude that optimal transition temperature occurs at intermediate coupling strength, electron-doped side. This approach is systematically extended to other superconducting symmetries as well. A change in sign of the vertex contribution to  $d_{xy}$  superconductivity from repulsive near half filling to attractive at large doping is discovered.

**12:15PM Y25.00006 Strongly enhanced superconductivity in coupled  $t$ - $J$  segments**, SAHINUR REJA, JEROEN VAN DEN BRINK, SATOSHI NISHIMOTO, IFW Dresden — The  $t$ - $J$  Hamiltonian is one of the cornerstones in the theoretical study of strongly correlated copper-oxide based materials. Using the density matrix renormalization group method we calculate the phase diagram of the one-dimensional (1D)  $t$ - $J$  chain in the presence of a periodic hopping modulation, as a prototype of coupled-segment models. While in the uniform 1D  $t$ - $J$  model near half-filling superconducting (SC) state dominates only at unphysically large values of the exchange coupling constant  $J/t > 3$ , we show that a small hopping and exchange modulation very strongly reduces the critical coupling to be as low as  $J/t \sim 1/3$  – well within the physical regime. The phase diagram as a function of the electron filling also exhibits metallic, insulating line phases and regions of phase separation. We suggest that a SC state is easily stabilized if  $t$ - $J$  segments creating local spin-singlet pairing are coupled to each other – another example is ladder system.

**12:27PM Y25.00007 Cluster dynamic mean-field study on the superconductivity in doped honeycomb lattice Hubbard model**, XIAO YAN XU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, HUNG T. DANG, STEFEN WESSEL, Institute for Theoretical Solid State Physics, JARA-FIT and JARA-HPC, RWTH Aachen University, 52056 Aachen, Germany, ZI YANG MENG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — The issue of superconductivities emerging from doped honeycomb lattice Mott insulator remains inconclusive. Existing proposals, such as  $p$ - $ip$  triplet pairing driven by ferromagnetic fluctuations,  $d$ - $id$  singlet pairing driven by antiferromagnetic fluctuations or van Hove singularities in the band structure, are not compatible. This is mainly due to the limitation of various approximated techniques employed in addressing such question with inherent strongly correlated nature. Trying to clarify the situation, we perform large-scale cluster dynamic mean-field simulations to explore the superconductivity instabilities in the doped honeycomb lattice Hubbard model, from medium to strong coupling. To benchmark, we make use of both interaction- and hybridization-expansion continuous time quantum Monte Carlo methods to exactly solve the quantum cluster embedded in self-consistently determined mean-field bath. Temperature dependence of various superconducting susceptibilities are calculated, hence, we provide the least biased results of the competition of the superconductivity in different channels in the phase diagram spanned by doping and electronic interaction.

**12:39PM Y25.00008 Charge dynamics in doped cuprates<sup>1</sup>**, MACIEJ MASKA, MARCIN MIERZEJEWSKI, University of Silesia, Poland, EVGENY KOCHETOV, Joint Institute for Nuclear Research, Russia, JANEZ BONCA, University of Ljubljana, Slovenia — It has recently been suggested that contrary to common belief, the quantum spin fluctuations of the antiferromagnetic background may not be crucial in explaining the dynamical properties of quasiparticles in strongly correlated systems near half-filling (see H. Ebrahimnejad, *et al.* Nature Physics **10**, 951 (2014)). In accordance with this suggestion, we demonstrate that the  $t$ - $J$  model even without the transverse spin components reproduces many of the ARPES results, provided that the three-site term, usually neglected in calculations, is properly taken into account. The dynamical properties of doped charges are calculated with the help of the Monte Carlo method combined with exact diagonalization. The validity of neglecting the spin-flip processes in the Ising version of the  $t$ - $J$  model is checked by a comparison with results of a fully quantum approach based on exact diagonalization in the limited functional space (EDLFS). Our method allows us to show how the spectral properties of doped holes change for a wide range of the doping level. We also demonstrate that the effective model reveals a tendency towards formation of charge density waves.

**12:51PM Y25.00009 Controllable electron interactions in quantum dots coupled to nanowires**, ALEXANDRE TACLA, Department of Physics and SUPA, University of Strathclyde, GUANGLEI CHENG, MICHELLE TOMCZYK, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, ANDREW DALEY, Department of Physics and SUPA, University of Strathclyde, DAVID PEKKER, Department of Physics and Astronomy, University of Pittsburgh — We theoretically study transport properties in quantum dot devices proximity coupled to superconducting nanowires. In particular, we investigate the controllable transition from resonant pair tunneling to Andreev bound states, which has been recently observed in nanodevices fabricated at the interface of the oxide heterostructure  $\text{LaAlO}_3/\text{SrTiO}_3$ . We show that such a transition in transport features can signify a Lifshitz transition, at which electron interactions change from attractive to repulsive. We also discuss an alternate description in terms of magnetic impurities.

**1:03PM Y25.00010 Spontaneously broken time-reversal symmetry in high-temperature cuprate superconductors.** , MIKAEL FOGELSTROM, MIKAEL HAKANSSON, TOMAS LOFWANDER, Chalmers — Conventional superconductors are strong diamagnets that through the Meissner effect expel magnetic fields. It would therefore be surprising if a superconducting ground state would support spontaneous magnetic fields. Such time-reversal symmetry broken states have been proposed for the high-temperature superconductors, but their identification remains experimentally controversial. Here we show a route to a low-temperature superconducting state with broken time-reversal symmetry that may accommodate currently conflicting experiments. This state is characterised by an unusual vortex pattern in the form of a necklace of fractional vortices around the perimeter of the material, where neighbouring vortices have opposite current circulation. This vortex pattern is a result of a spectral rearrangement of current carrying states near the edges. Ref. M. Håkansson, T. Löfwander, and M. Fogelström, Nature Phys.11 755, (2015)

**1:15PM Y25.00011 Searching for stripe order in the Hubbard model** , EDWIN HUANG, CHRISTIAN MENDEL, HONGCHEN JIANG, SHENXIU LIU, YVONNE KUNG, SLAC National Accelerator Laboratory and Stanford University, BRIAN MORITZ, SLAC National Accelerator Laboratory, STEVEN JOHNSTON, University of Tennessee, Knoxville, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory and Stanford University — The existence of stripe ordering in doped cuprates is well-established experimentally, but the microscopic mechanisms of their formation and their relation to superconductivity remain open questions. Previous density-matrix renormalization group (DMRG) studies on t-J and Hubbard ladders, in the parameter regimes relevant to cuprates, have suggested the presence of charge and spin stripes in the ground states of these microscopic models. To further investigate these tendencies towards stripe formation, we perform determinant quantum Monte Carlo (DQMC) and DMRG simulations for the single-band and three-band Hubbard models on identical rectangular lattice geometries. For both methods, upon hole doping, we find the spontaneous formation of domain walls in the spin correlation function, characterized by a  $\pi$ -phase shift of the antiferromagnetic ordering upon traversing a domain wall. We compare and contrast the results from the single-band and three-band Hubbard models using both techniques.

**1:27PM Y25.00012 Theory of dirty Rashba superconductivity in ultrathin Pb films<sup>1</sup>** , HUA CHEN, HYOUNGDO NAM, CHIH-KANG SHIH, ALLAN MACDONALD, The University of Texas at Austin — Pb is a typical s-wave superconductor and also has strong atomic spin-orbit coupling. In Pb thin films inversion symmetry breaking combined with the large atomic spin-orbit coupling will split the otherwise spin-degenerate bands of Pb, an effect which can be roughly accounted for by Rashba spin-orbit coupling. Motivated by a recent experiment, we used a 2D model involving Rashba spin-orbit coupling and s-wave pairing to study the influence of the former on the superfluid density, parallel critical field, and the resistive transition to the superconducting phase. We found that in both the clean and the dirty limits, Rashba spin-orbit coupling has little influence on the superfluid density and the Kosterlitz-Thouless transition temperature. However, in the dirty limit the Rashba spin-orbit coupling can significantly enhance the parallel critical field, making the Clogston-Chandrasekhar limit inapplicable. The strong suppression of the spin pair-breaking effect of a parallel magnetic field by the Rashba spin-orbit coupling and impurity scattering can make the orbital pair-breaking effect dominant again even in ultrathin films. Finally, we propose and examine a number of mechanisms that can lead to a smeared resistive transition under parallel magnetic fields.

**1:39PM Y25.00013 Directionality in photonic arrays via dissipation engineering** , A. METELMANN, H. E. TÜRECI, Princeton University — Achieving control over the direction of propagation of photons in one and higher dimensional structures is of high interest in a large number of research fields, e.g. in photonic crystals, metamaterials or superconducting circuit setups. Nonreciprocal devices can act as circulators and optical isolators, but they are hard to implement on chip because they require large magnetic fields. Several proposals have been made to overcome this limitation. A possible route to achieve directional properties in an optical device without utilizing the effect of Faraday rotation, is for example via the introduction of distinct phases via external driving or dynamical modulation of the refractive index. In this talk, we follow a different route by using dissipation engineering to obtain control over the propagation direction of photons in one and two dimensional structures. Moreover, we will discuss possible implementations within a superconducting circuit architecture.

**1:51PM Y25.00014 Current Correlations in a Majorana Beam Splitter** , EREZ BERG, ARBEL HAIM, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, 76100, Israel, FELIX VON OPPEN, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, YUVAL OREG, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, 76100, Israel — We study current correlations in a  $T$ -junction composed of a grounded topological superconductor and of two normal-metal leads which are biased at a voltage  $V$ . We show that the existence of an isolated Majorana zero mode in the junction dictates a universal behavior for the cross correlation of the currents through the two normal-metal leads of the junction. The cross correlation is negative and approaches zero at high bias voltages as  $-1/V$ . This behavior is robust in the presence of disorder and multiple transverse channels, and persists at finite temperatures. In contrast, an accidental low-energy Andreev bound state gives rise to non-universal behavior of the cross correlation. We employ numerical transport simulations to corroborate our conclusions.

**2:03PM Y25.00015 Odd-parity superconductors with two-component order parameters: nematic and chiral, gapped and nodal** , JRN W F VENDERBOS, VLADYSLAV KOZII, LIANG FU, Massachusetts Institute of Technology — Motivated by growing experimental evidence that superconductivity in the doped topological insulator  $\text{Cu}_x\text{Bi}_2\text{Se}_3$  has an odd-parity pairing with broken rotational symmetry, we study the general class of odd-parity superconductors with two-component order parameters. We address the energetics and physical properties of different superconducting phases, with special emphasis on the role of spin-orbit coupling, which is generally strong in topological insulator and related materials. We show that within the weak-coupling BCS theory, in the absence of spin-orbit coupling, isotropic superconductors are favored, which are analogs of the A- or B-phase of  $^3\text{He}$ . In the presence of spin-orbit coupling, however, we find that a nematic superconducting phase, which spontaneously breaks rotational symmetry are favored. We determine the superconducting gap structures and find, in addition to fully gapped odd-parity superconductors, nodal superconductors with Dirac and Weyl quasiparticles, which are markedly different from superfluid phases of  $^3\text{He}$ .

**11:15AM Y26.00001 Raman characterization of few-layered 1T'-MoTe<sub>2</sub><sup>1</sup>**, IRVING HERMAN, DENNIS WANG, ALI DADGAR, Columbia Univ, SANG-WOOK CHEONG, Rutgers, The State University of New Jersey, ABHAY PASUPATHY, Columbia Univ — Transition metal dichalcogenides (TMDs) exhibit a wealth of physical phenomena that have been studied via electronic transport and optical characterization because of their potential device applications in the 2-D limit. In particular, theory has predicted that a certain subset of TMDs, specifically those in the structurally distorted octahedral (1T') phase, are large-gap quantum spin Hall (QSH) insulators. Here we characterize the thickness of one such TMD, 1T'-MoTe<sub>2</sub>, down to the monolayer limit using Raman spectroscopy and compare our results to atomic force microscopy (AFM) measurements. Our goal is to determine how thinning it down via micromechanical exfoliation changes the intensities and frequencies of its Raman modes, thus enabling one to track layer dependence in a definitive yet minimally invasive manner in much the same way used for graphene and other layered materials.

## **11:27AM Y26.00002 ABSTRACT WITHDRAWN —**

**11:39AM Y26.00003 Resonant-Raman Intensities of N-layer Transition Metal Dichalcogenides from First Principles**, HENRIQUE MIRANDA, University of Luxembourg, GUILLAUME FROELICHER, ETTIENNE LORCHAT, FRANOIS FERNIQUE, IPCMS (CNRS - Universit de Strasbourg), ALEJANDRO MOLINA-SNCHEZ, University of Luxembourg, STPHANE BERCIAUD, IPCMS (CNRS - Universit de Strasbourg), LUDGER WIRTZ, University of Luxembourg — Transition metal dichalcogenides (TMDs) have interesting optical and electronic properties that make them good candidates for nano-engineering applications. Raman spectroscopy provides information about the vibrational modes and optical spectrum at the same time: when the laser energy is close to an electronic transition, the intensity is increased due to resonance. We investigate these effects combining different ab initio methods: we obtain ground-state and vibrational properties from density functional theory and the optical absorption spectrum using GW corrections and the Bethe-Salpeter equation to account for the excitonic effects which are known to play an important role in TMDs. Using a quasi-static finite differences approach [1], we calculate the dielectric susceptibility for different light polarizations and different phonon modes in order to determine the Raman tensor of TMDs, in particular of multi-layer and bulk MoTe<sub>2</sub>. We explain recent experimental results for the splitting of high-frequency modes [2] and deviations from the non-resonant Raman model. We also give a brief outlook on possible improvements of the methodology. [1] Y. Gillet et. al., Phys. Rev. B 88, 094305 (2013). [2] G. Froehlicher et. al., Nano Lett. 15, 6481 (2015).

**11:51AM Y26.00004 Raman investigation of molybdenum disulfide with different polytypes**, JAE-UNG LEE, KANGWON KIM, SONGHEE HAN, Sogang University, GYEONG HEE RYU, ZONGHOON LEE, UNIST, HYEONSIK CHEONG, Sogang University — The Raman spectra of molybdenum disulfide (MoS<sub>2</sub>) with different polytypes are investigated. Although 2H-MoS<sub>2</sub> is most common in nature, the 3R phase can exist due to a small difference in the formation energy. However, only a few studies are reported for the 3R phase, and most studies have focused on the 2H phase. We found the 2H, 3R and mixed phases of exfoliated few-layer MoS<sub>2</sub> from natural molybdenite crystals. The crystal structures of 2H- and 3R-MoS<sub>2</sub> are confirmed by the HR-TEM measurements. By using 3 different excitation energies, we compared the Raman spectra of different polytypes in detail. We show that the Raman spectroscopy can be used to identify not only the number of layers but also the polytypes of MoS<sub>2</sub>.

**12:03PM Y26.00005 Observation of anomalous Stokes versus anti-Stokes ratio in MoTe<sub>2</sub> atomic layers<sup>1</sup>**, THOMAS GOLDSTEIN, SHAO-YU CHEN, Department of Physics, University of Massachusetts Amherst, DI XIAO, Department of Physics, Carnegie Mellon University, ASHWIN RAMASUBRAMANIAM, Department of Mechanical & Industrial Engineering, University of Massachusetts Amherst, JUN YAN, Department of Physics, University of Massachusetts Amherst — We grow hexagonal molybdenum ditelluride (MoTe<sub>2</sub>), a prototypical transition metal dichalcogenide (TMDC) semiconductor, with chemical vapor transport methods and investigate its atomic layers with Stokes and anti-Stokes Raman scattering. We report observation of all six types of zone center optical phonons. Quite remarkably, the anti-Stokes Raman intensity of the low energy layer-breathing mode becomes more intense than the Stokes peak under certain experimental conditions, creating an illusion of 'negative temperature'. This effect is tunable, and can be switched from anti-Stokes enhancement to suppression by varying the excitation wavelength. We interpret this observation to be a result of resonance effects arising from the C excitons in the vicinity of the Brillouin zone center, which are robust even for multiple layers of MoTe<sub>2</sub>. The intense anti-Stokes Raman scattering provides a cooling channel for the crystal and opens up opportunities for laser cooling of atomically thin TMDC semiconductor devices.

## **12:15PM Y26.00006 ABSTRACT WITHDRAWN —**

**12:27PM Y26.00007 Magnetism and Raman Spectroscopy of Pristine and Hydrogenated TaSe<sub>2</sub> Monolayer tuned by Tensile and Pure Shear Strain**, SUGATA CHOWDHURY, The Catholic University of America, Washington DC & National Institute of Standards and Technology, MD, JEFFREY SIMPSON, Towson University, MD & National Institute of Standards and Technology, MD, T. L. EINSTEIN, Univ of Maryland-College Park, ANGELA R. HIGHT WALKER, National Institute of Standards and Technology, MD — 2D-materials with controllable optical, electronic and magnetic properties are desirable for novel nanodevices. Here we studied these properties for both pristine and hydrogenated TaSe<sub>2</sub> (TaSe<sub>2</sub>-H) monolayer (ML) in the framework of DFT using the PAW method. We considered uniaxial and biaxial tensile strain, as well as shear strain along the basal planes in the range between 1% and 16%. Previous theoretical works (e.g. APL 107, 032402 (2015)) considered only symmetrical biaxial tensile. Pristine ML is ferromagnetic for uniaxial tensile strain along  $\hat{x}$  or  $\hat{y}$ . For tensile strain in  $\hat{y}$ , the calculated magnetic moments of the Ta atoms are twice those for the same strain in  $\hat{x}$ . Under pure shear strain (expansion along  $\hat{y}$  and compression along  $\hat{x}$ ), a pristine ML is ferromagnetic, but becomes non-magnetic when the strain directions are interchanged. Due to carrier-mediated double-exchange, the pristine ML is ferromagnetic when the Se-Ta-Se bond angle is  $< 82^\circ$  and the ML thickness is  $< 3.25\text{\AA}$ . We find that all Raman-active phonon modes show obvious red-shifting due to bond elongation and the E<sub>2</sub> modes degeneracy is lifted as strain increases. For a TaSe<sub>2</sub>-H ML, the same trends were observed. Results show the ability to tune the properties of 2D-materials.

**12:39PM Y26.00008 Quantum plasmonic nano-imaging of few-layer MoS<sub>2</sub>**, DMITRI VORONINE, Texas AM University — Transition metal dichalcogenides such as MoS<sub>2</sub> are promising 2D materials with many applications. Their diffraction-limited optical characterization using Raman spectroscopy provides important structure-functional information. In this work, nanoscale tip-enhanced Raman scattering (TERS) signals of few-layer MoS<sub>2</sub> are presented and limits of signal enhancement are investigated by varying the tip-sample gap. Quantum plasmonic quenching of gold photoluminescence signals was observed for subnanometer gaps. Similar quantum plasmonic behavior was observed for more than 3 nm gaps between gold substrate and tip with few-layer MoS<sub>2</sub> junctions. These results may be used for designing new generation quantum optoelectronic devices.

**12:51PM Y26.00009 Nanoscale control of phonon excitations in graphene**, HYO WON KIM, WONHEE KO, JIYEON KU, Samsung Adv Inst of Tech, SEUNGHWA RYU, Korea Advanced Institute of Science and Technology, SUNG WOO HWANG, Samsung Adv Inst of Tech — Phonons, which are collective excitations in a lattice of atoms or molecules, play a major role in determining various physical properties of condensed matter, such as thermal and electrical conductivities. In particular, phonons in graphene interact strongly with electrons; however, unlike in usual metals, these interactions between phonons and massless Dirac fermions appear to mirror the rather complicated physics of those between light and relativistic electrons. Therefore, a fundamental understanding of the underlying physics through systematic studies of phonon interactions and excitations in graphene is crucial for realizing graphene-based devices. In this study, we demonstrate that the local phonon properties of graphene can be controlled at the nanoscale by tuning the interaction strength between graphene and an underlying Pt substrate. Using scanning probe methods, we determine that the reduced interaction due to embedded Ar atoms facilitates electron-phonon excitations, further influencing phonon-assisted inelastic electron tunneling.

**1:03PM Y26.00010 Observation of angle resolved bands of  $C_{60}$  by photoemission spectroscopy**, CLAUDIA OJEDA-ARISTIZABAL, Dept. of Physics and Astronomy California State University, DREW LATZKE, Dept. of Physics Univ. of California Berkeley, Lawrence Berkeley National Laboratory, JONATHAN DELINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, ALEX ZETTL, ALESSANDRA LANZARA, Dept. of Physics Univ. of California Berkeley, Lawrence Berkeley National Laboratory — The band structure of a  $C_{60}$  thick film deposited in-situ on a crystalline surface is studied by angle resolved photoemission spectroscopy (ARPES). We observe the presence of a well-defined low energy diffraction pattern (LEED) and dispersive HOMO bands, suggesting a crystalline arrangement of the  $C_{60}$  molecules. The momentum and photon energy dependence of these bands is presented.

**1:15PM Y26.00011 Optical properties of transition metal dichalcogenide monolayers**, BENEDIKT SCHARF, State Univ of NY - Buffalo, TOBIAS FRANK, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg, IGOR ZUTIC, State Univ of NY - Buffalo, VASIL PEREBEINOS, Skolkovo Institute of Science and Technology — In recent years, 2D materials, such as transition metal dichalcogenide (TMDCs) monolayers, have attracted a great deal of attention due to their excellent transport and optical properties. Using a tight-binding description and the Bethe-Salpeter equation, we theoretically investigate optical and excitonic properties of TMDC monolayers in different setups. Such 2D materials exhibit peculiar screening properties and excitons with large binding energies. This can also lead to important spin-based applications as the spin-orbit coupling in the valence band results in a splitting close to the K and K' points and yields spin-relaxation times orders of magnitude larger than in III-V semiconductors.

**1:27PM Y26.00012 Band Structure Studies of in situ Deposited  $C_{60}$  and the Effects of Doping**, DREW LATZKE, University of California, Berkeley and Lawrence Berkeley National Laboratory, CLAUDIA OJEDA-ARISTIZABAL, California State University Long Beach, Department of Physics and Astronomy, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, ALEX ZETTL, ALESSANDRA LANZARA, University of California, Berkeley and Lawrence Berkeley National Laboratory — We present electronic band structure studies of the unique system of in situ deposited thin film  $C_{60}$  on a bulk substrate through high-resolution angle-resolved photoemission spectroscopy (ARPES) measurements. We discuss the electronic band structure in relation to novel phenomena recently found in other low-dimensional samples. Finally, we investigate the doping dependence of the thin film  $C_{60}$  band structure as we deposit dopants on the surface in situ.

**1:39PM Y26.00013 ARPES studies of van der Waals heterostructure<sup>1</sup>**, ERYIN WANG, State Key Laboratory of Low Dimensional Quantum Physics and Department of Physics, Tsinghua University, Beijing, XIAOBO LU, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Science, Beijing, GUORUI CHEN, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai, ALEXEI V. FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, YUANBO ZHANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai, GUANGYU ZHANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Science, Beijing, SHUYUN ZHOU, State Key Laboratory of Low Dimensional Quantum Physics and Department of Physics, Tsinghua University, Beijing — Van der Waals heterostructures are a novel class of "materials by design" which are formed by stacking different two-dimensional crystals together via van der Waals interaction. The periodic potential by the Moiré superlattice can be used as a control knob for tuning the electronic properties of two dimensional materials and can induce various novel quantum phenomena. Here we report direct electronic structure studies of a model van der Waals heterostructure using angle-resolved photoemission spectroscopy (ARPES).

**1:51PM Y26.00014 Unified Description of the Optical Phonon Modes in  $N$ -Layer  $MoTe_2$** , GUILLAUME FROELICHER, ETIENNE LORCHAT, FRANÇOIS FERNIQUE, IPCMS (CNRS - Université de Strasbourg), CHAITANYA JOSHI, ALEJANDRO MOLINA-SÁNCHEZ, LUDGER WIRTZ, University of Luxembourg, STÉPHANE BERCIAUD, IPCMS (CNRS - Université de Strasbourg) —  $N$ -layer transition metal dichalcogenides (denoted  $MX_2$ ) provide a unique platform to investigate the evolution of the physical properties between the bulk (3D) and monolayer (quasi-2D) limits. Here, we present a unified analysis of the optical phonon modes in  $N$ -layer  $2H$ - $MX_2$  [1]. The  $2H$ -phase (or hexagonal phase) is the most common polytype for semiconducting  $MX_2$  (such as  $MoS_2$ ). Using Raman spectroscopy, we have measured the manifold of low-frequency (rigid layer), mid-frequency (involving intralayer displacement of the chalcogen atoms only), and high-frequency (involving intralayer displacements of all atoms) Raman-active modes in  $N = 1$  to 12 layer  $2H$ -molybdenum ditelluride ( $MoTe_2$ ). For each monolayer mode, the  $N$ -dependent phonon frequencies give rise to fan diagrams that are quantitatively fit to a force constant model. This analysis allows us to deduce the frequencies of *all* the bulk (including silent) optical phonon modes. [1] G. Froehlicher, E. Lorchat, F. Fernique, C. Joshi, A. Molina-Sánchez, L. Wirtz, and S. Berciaud, Unified Description of the Optical Phonon Modes in  $N$ -Layer  $MoTe_2$ , Nano Letters, **15** (10), pp 6481-6489 (2015)

**2:03PM Y26.00015 Mapping wavevector dependent electron-phonon coupling and nonequilibrium phonon dynamics in thin graphite with ultrafast electron diffuse scattering**, JEAN-PHILIPPE BOISVERT, ROBERT P. CHATELAIN, MARK J. STERN, MARK SUTTON, Department of Physics, Center for the Physics of Materials, McGill University, BRADLEY J. SIWICK, Departments of Physics and Chemistry, Center for the Physics of Materials, McGill University — Radio-frequency compressed ultrafast electron diffraction has been used to probe the coherent and incoherent coupling of impulsive electronic excitation at 1.55 eV (800 nm) to optical and acoustic phonon modes directly from the perspective of the lattice degrees of freedom. Recent improvements in source brightness for ultrafast diffraction experiments are now allowing for the study of diffuse scattering signals. Here, we show that ultrafast electron diffuse scattering (UEDS) can yield time and momentum-resolved phonon population data. Beyond the possibility of directly probing the dynamics of thermalization, this can also be used to determine the wavevector dependent electron-phonon coupling strength in materials. This new information provides significant insights into the electron relaxation pathways of graphitic materials. In particular, we present the first direct measurement of the  $K$ -point phonon population dynamics after impulsive electronic excitation and maps of the phonon population in momentum-space. Finally, we propose a simple mechanism for the thermalization of graphitic materials after impulsive electronic excitation which unifies all ultrafast measurements of this process to date.

**11:15AM Y27.00001 Electromagnetic response of time-reversal breaking metallic phases in two dimensions<sup>1</sup>**, VICTOR CHUA, WATHID ASSAWASUNTHONNET, EDUARDO FRADKIN, Univ of Illinois - Urbana — The electromagnetic response of models of nematic non Fermi-liquids previously proposed in Ref.[1] are re-examined using conventional many-body methods. Nematic phases of this model are described by two 2-component real vectors which express the isotropy breaking nematicity in two Fermi-surfaces. Of interest is the time-reversal symmetry breaking nematic phase with a non-vanishing unquantized spontaneous anomalous Hall effect at zero external magnetic fields, and has a geometrical description as a Berry phase. We compare and contrast our results with conventional response calculations with those predicted with the higher-dimensional bosonization method [2,3]. Finally we present preliminary results on an RG analysis of this system. [1] K Sun and E Fradkin, Phys. Rev. B 78, 245122 (2008). [2] HJ Kwon, A Houghton, and JB Marston, Phys. Rev. B 52, 8002 (1995) [3] MJ Lawler, DG Barci, V Fernandez, E Fradkin, L Oxman, Phys. Rev. B 73, 085101 (2006)

**11:27AM Y27.00002 Transport in a One-Dimensional Hyperconductor**, EUGENIU PLAMADEALA, Univ of California - Santa Barbara, MICHAEL MULLIGAN, Stanford University, CHETAN NAYAK, Univ of California - Santa Barbara, Microsoft Station Q — We define a ‘hyperconductor’ to be a material whose electrical and thermal DC conductivities are infinite at zero temperature. The low-temperature behavior of a hyperconductor is controlled by a quantum critical phase of interacting electrons that is stable to all potentially-gap-generating interactions and arbitrary potentially-localizing disorder. We compute the low-temperature DC and AC electrical and thermal conductivities in a one-dimensional hyperconductor, studied previously by the present authors, in the presence of both disorder and umklapp scattering. We identify the conditions under which the transport coefficients are finite, and exhibit examples of violations of the Wiedemann-Franz law. We show that the temperature dependence of the electrical conductivity is a power law,  $\sigma \propto 1/T^{1-2(2-\Delta_X)}$  for  $\Delta_X \geq 2$ , down to zero temperature when the Fermi surface is commensurate with the lattice. In the incommensurate case with weak disorder, such scaling is seen at high-temperatures, followed by an exponential increase of the conductivity  $\ln \sigma \sim 1/T$  at intermediate temperatures and, finally,  $\sigma \propto 1/T^{2-2(2-\Delta_X)}$  at the lowest temperatures. In both cases, the thermal conductivity diverges at low temperatures.

**11:39AM Y27.00003 Photon-dressed quasiparticle states in 1D and 2D materials: a many-body Floquet approach**, FRANCA MANGHI, MATTEO PUVIANI, University of Modena and Reggio Emilia — We study the interplay between electron-electron interactions and non-equilibrium conditions associated to time-dependent external fields. Exploring phases of quantum matter away from equilibrium may give access to regimes inaccessible under equilibrium conditions. What makes this field particularly interesting is the possibility to engineer new phases of matter by an external tunable control. We have developed a scheme that allows to treat photo-induced phenomena in the presence of electron-electron many body interactions, where both the nonlinear effects of the external field and the electron-electron correlation are treated simultaneously and in a non-perturbative way. The Floquet approach is used to include the effects of the external time periodic field, and the Cluster Perturbation Theory to describe interacting electrons in a lattice. They are merged in a Floquet-Green function method that allows to calculate photon dressed quasiparticle excitation. For 1D systems we show that an unconventional Mott insulator-to-metal transition occurs for given characteristics of the applied field (intensity and frequency). The method has also been applied to the 2D honeycomb lattice (graphene), where in the presence of realistic values of electron-electron interaction, we show that linearly polarized light may give rise to non-dissipative edge states associated to a non-trivial topological behavior.

**11:51AM Y27.00004 Composite fermions and the field-tuned superconductor-insulator transition**, SRINIVAS RAGHU, MICHAEL MULLIGAN, Stanford University — In several two-dimensional films that exhibit a magnetic field-tuned superconductor to insulator transition (SIT), stable metallic phases have been observed. Building on the ‘dirty boson’ description of the SIT, we suggest that the metallic region is analogous to the composite Fermi liquid observed about half-filled Landau levels of the two-dimensional electron gas. The composite fermions here are mobile vortices attached to one flux quantum of an emergent gauge field. The composite vortex liquid is a 2D non-Fermi liquid metal, which we argue is stable to weak quenched disorder. We describe several experimental consequences of the emergent composite vortex liquid.

**12:03PM Y27.00005 Mirror symmetry and the half-filled Landau level**, MICHAEL MULLIGAN, SHAMIT KACHRU, Stanford University, GONZALO TORROBA, Centro Atomico Bariloche and CONICET, HUAJIA WANG, University of Illinois at Champaign-Urbana — We study the dynamics of the half-filled zeroth Landau level of Dirac fermions using mirror symmetry, a supersymmetric duality between certain pairs of 2 + 1-dimensional theories. We show that the half-filled zeroth Landau level of a pair of Dirac fermions is dual to a pair of Fermi surfaces of electrically-neutral composite fermions, coupled to an emergent gauge field. Thus, we use supersymmetry to provide a derivation of flux attachment and the emergent Fermi liquid-like state for the lowest Landau level of Dirac fermions. We find that in the dual theory the Coulomb interaction induces a dynamical exponent  $z = 2$  for the emergent gauge field, making the interactions classically marginal. This enables us to map the problem of 2+1-dimensional Dirac fermions in a finite transverse magnetic field, interacting via a strong Coulomb interaction, into a perturbatively controlled model. We analyze the resulting low-energy theory using the renormalization group and determine the nature of the BCS interaction in the emergent composite Fermi liquid.

**12:15PM Y27.00006 Phase transitions induced by magnetic field in graphite**, BENOIT FAUQUE, LPEM (UPMC-CNRS), Ecole Supérieure de Physique et de Chimie Industrielles, 75005 Paris, France, DAVID LEBOEUF, Laboratoire National des Champs Magnétiques Intenses, UPR 3228, CNRS-UJF-UPS-INSA, 38042 Grenoble, France, WILLEM RISCHAU, LPEM (UPMC-CNRS), Ecole Supérieure de Physique et de Chimie Industrielles, 75005 Paris, France, WOJCIECH TABIS, BAPTISTE VIGNOLLE, CYRIL PROUST, Laboratoire National des Champs Magnétiques Intenses, CNRS, INSA, UJF, UPS, Toulouse 31400, France, KAMRAN BEHNIA, LPEM (UPMC-CNRS), Ecole Supérieure de Physique et de Chimie Industrielles, 75005 Paris, France — Graphite is compensated semi-metals characterized by a tiny three dimensional Fermi surface. A magnetic field of about 10T is large enough to confine electrons and holes to their lowest Landau levels. These are therefore ideal candidates to explore the nature of the electronic ground state of a three-dimensional electron gas pushed beyond the so-called quantum limit. Various instabilities have been predicted in this peculiar limit where electronic interactions are enhanced. We find that the magnetic field induces two successive phase transitions, made of two distinct ordered states, each restricted to a finite field window. In both states, the in-plane and out-of-plane conductivity behaves differently: not only the onset of the transition are different in both quantity but also an energy gap opens up in the out-of-plane conductivity and coexists with an unexpected in-plane metallicity for a fully gap bulk system. Such peculiar metallicity may arise as a consequence of edge-state transport expected to develop in the presence of a bulk gap.

**12:27PM Y27.00007 Exotic insulating states of  $(t_{2g})^4$  Hubbard model with spin-orbit coupling**, TOSHIHIRO SATO, RIKEN, TOMONORI SHIRAKAWA, RIKEN CEMS, SEIJI YUNOKI, RIKEN, RIKEN CEMS, RIKEN AICS — We numerically study electronic properties of a  $t_{2g}$ -orbital Hubbard model with a relativistic spin-orbit coupling (SOC) at four electrons per site. Our approach is a multi-orbital dynamical mean field theory with a continuous-time quantum Monte Carlo solver based on a strong coupling expansion. The main issue is the variation of electronic structure in the parameter space of the SOC and the Coulomb interactions at temperature fixed. For larger Coulomb interactions, a Van Vleck-type nonmagnetic insulating state with a total angular momentum  $J = 0$  is induced by the SOC. When the SOC decreases, the insulating state is magnetically ordered along with increasing the hybridization between a nonmagnetic  $J = 0$  state and an excited  $J = 1$  state. Moreover, for smaller Coulomb interactions, we demonstrate that an excitonic insulating state without magnetic order appears, in addition to metallic and band insulating states. The exciton condensation is formed by an electron-hole pairing between the local effective total angular momentum  $j = 1/2$  and  $j = 3/2$  based bands.

**12:39PM Y27.00008 Vison Condensation and Bond Density Wave Order in the Cuprates**, AAVISHKAR PATEL, ANDREA ALLAIS, DEBANJAN CHOWDHURY, SUBIR SACHDEV, Harvard Univ — We consider  $Z_2$  spin liquids on the square lattice. These can undergo a confinement transition to a valence bond solid (VBS) phase via the condensation of vortex excitations carrying  $Z_2$  magnetic flux (visons) [1]. The resulting condensed phase is described by a fully frustrated Ising model (FFIM) on the dual square lattice, with additional couplings allowed by symmetries. We argue that such a model can also apply to confinement transitions out of the fractionalized Fermi liquid (FL\*) states of doped antiferromagnets. We study the low energy states of such a model and discuss their implications for the incommensurate d-form factor bond density wave order observed in several recent experiments on the cuprate superconductors. [1] R. Jalabert and S. Sachdev, Phys. Rev. B 44, 686 (1991).

**12:51PM Y27.00009 Transition from the  $Z_2$  spin liquid to antiferromagnetic order: spectrum on the torus**, SETH WHITSITT, SUBIR SACHDEV, Harvard Univ — We study the finite-size spectrum of the quantum critical point between a  $Z_2$  spin liquid and a coplanar antiferromagnet on the torus. Due to the existence of nontrivial order on either side of this transition, this critical point cannot be described in a conventional Landau-Ginzburg framework. Instead it is described by a theory involving fractionalized degrees of freedom known as the  $O(4)^*$  model, whose spectrum is altered in a significant way by its proximity to a topologically ordered phase. We compute the spectrum by relating it to the spectrum of the  $O(4)$  Wilson-Fisher fixed point on the torus, along with a selection rule on the states, and with nontrivial boundary conditions corresponding to topological sectors in the spin liquid. The spectrum of the Wilson-Fisher fixed points is then calculated directly from the  $\epsilon$ - and large- $N$  expansions, which allows a reconstruction of the full spectrum of the  $O(4)^*$  model. This spectrum is a unique characteristic of a fractionalized quantum critical point as well as a universal signature of the existence of a proximate  $Z_2$  topological phase which can be compared with numerical computations.

**1:03PM Y27.00010 Long-range Coulomb interaction in nodal ring semi-metals**, YEJIN HUH, University of Toronto, EUN-GOOK MOON, KAIST, YONG BAEK KIM, University of Toronto — Recently there have been several proposals of materials predicted to be nodal ring semi-metals, where zero energy excitations are characterized by a nodal ring in the momentum space. This class of materials falls between the Dirac-like semi-metals and the more conventional Fermi-surface systems. As a step towards understanding this unconventional system, we explore the effects of the long-range Coulomb interaction. Due to the vanishing density of states at the Fermi level, Coulomb interaction is only partially screened and remains long-ranged. Through renormalization group and large- $N_f$  computations, we have identified a non-trivial interacting fixed point. The screened Coulomb interaction at the interacting fixed point is an irrelevant perturbation, allowing controlled perturbative evaluations of physical properties of quasiparticles. We discuss unique experimental consequences of such quasiparticles: acoustic wave propagation, anisotropic DC conductivity, and renormalized phonon dispersion as well as energy dependence of quasiparticle lifetime.

**1:15PM Y27.00011 Scaling of Greenwood Peierls conductance on a diluted square lattice**, WILLIAM SCHWALM, ALBERT SCHMITZ, Univ of North Dakota — The modified rectangle lattice of Dhar is a bond-diluted square lattice. The structure is self-similar and finitely ramified, like a fractal. Nevertheless certain discrete Schrödinger equation Green functions for the modified rectangle are known in closed form in the infinite lattice limit and the spectrum is continuous. By standard transfer matrix renormalization methods we present a study scaling properties of the Greenwood Peierls conductance distribution across the lattice with one dimensional lead wires attached as a function of lattice size and of additional disorder of several types.

**1:27PM Y27.00012 Phase coexistence in the  $O(N) \oplus O(M)$  nonlinear sigma model: a conformal bootstrap study**, CHRIS HOOLEY, SAM RIDGWAY, University of St Andrews, U.K. — The low-temperature physics of systems with competing orders is a ubiquitous topic in modern condensed matter physics. A commonly studied field theory of such systems is the  $O(N) \oplus O(M)$  nonlinear sigma model: an  $O(N+M)$  model with a mass term attached to  $N$  of the field components. Depending on the sign of the mass term, order in the  $O(N)$  sector or the  $O(M)$  sector is favored. However, the physics near the high-symmetry point is subtle, and in some cases (e.g.  $N=M=2$ ) it remains unclear whether there is a first-order spin-flop transition or a finite-width microscopic coexistence phase. In this talk, we present an analysis of the  $O(N) \oplus O(M)$  model based on the conformal bootstrap method. This allows us to classify the critical points of the models in question, and by extension determine whether a coexistence phase exists or not.

**1:39PM Y27.00013 Quantum Monte Carlo study of hard-core bosons in a pyrochlore lattice with six-site ring-exchange interactions**, CATHERINE TIEMAN, VALERY ROUSSEAU, College of Wooster — Highly frustrated quantum systems on lattices can exhibit a wide variety of phases. In addition to the usual Mott insulating and superfluid phases, these systems can also produce some so-called “exotic phases”, such as super-solid and valence-bond-solid phases. An example of particularly frustrated lattice is the pyrochlore structure, which is formed by corner-sharing tetrahedrons. Many real materials adopt this structure, for instance the crystal  $Cd_2Re_2O_7$ , which exhibits superconducting properties. However, the complex structure of these materials combined with the complexity of the dominant interactions that describe them makes their analytical study difficult. Also, approximate methods, such as mean-field theory, fail to give a correct description of these systems. In this work, we report on the first exact quantum Monte Carlo study of a model of hard-core bosons in a pyrochlore lattice with six-site ring-exchange interactions, using the Stochastic Green Function (SGF) algorithm. We analyze the superfluid density and the structure factor as functions of the filling and ring-exchange interaction strength, and we map out the ground state phase diagram.

**1:51PM Y27.00014 Phase Diagram of the  $Z_3$  Parafermionic Chain with Chiral Interactions**, YE ZHUANG, HITESH CHANGLANI, NORM TUBMAN, TAYLOR HUGHES, Univ of Illinois - Urbana — Majorana fermions and parafermions are exotic quasiparticles with non-Abelian fractional statistics that can be realized and stabilized in one-dimensional models. We study the simplest generalization of the Kitaev p-wave wire, i.e. the  $Z_3$  parafermionic chain [Phys. Rev. B 92, 035154 (2014)]. Using a Jordan-Wigner transform we focus on the equivalent three-state chiral clock model, and study its rich phase diagram using the density matrix renormalization group technique. We perform our analyses using quantum entanglement diagnostics which allow us to determine phase boundaries, and the nature of the phase transitions. In particular, we study the transition between the topological (ordered) and trivial phases (disordered), as well as to an intervening critical (incommensurate) phase which appears in a wide region of the phase diagram. The phase diagram is predicted to contain a Lifshitz type transition which we confirm using entanglement measures. We also attempt to locate and characterize a putative tricritical point in the phase diagram where the three above mentioned phases meet at a single point.

**2:03PM Y27.00015 Photon-induced phase transitions of individual electronic phase separated domains in manganites strips**, HANXUAN LIN, KAI ZHANG, HAO LIU, TIAN MIAO, YANG YU, LIFENG YIN<sup>1</sup>, JIAN SHEN<sup>2</sup>, Fudan University — Effective photosensors should be built on materials whose properties depend sensitively on light. Manganites are one of the candidates, where light can trigger resistivity change by several orders of magnitude. Such dramatic change is often associated with photoinduced phase transitions of electronic phase separated (EPS) domains in manganites. Previous studies of the light effect all use macroscopic manganite samples, which consist of large numbers of EPS domains smearing out the photon-induced phase transitions. Here, we observe the signature of individual domains' photoinduced phase transition by macroscopic transport measurement of spatially confined manganites strips. Pronounced photon-induced resistivity jumps emerge in the warming process, which reveals the dynamics of the phase transitions of individual EPS domains upon interaction with light. Magnetic force microscope (MFM) has been used to investigate the mechanism of those resistivity jumps.

**Session Y28 DMP DCMP: Weyl Semimetals: Theory and New Materials** 327 - Siddharth Parameswaran, University of California, Irvine

**11:15AM Y28.00001 Prediction of an arc-tunable Weyl Fermion metallic state in  $\text{Mo}_x\text{W}_{1-x}\text{Te}_2$** , TAY-RONG CHANG, Natl Tsing Hua U., SU-YANG XU, Princeton U., GUOQING CHANG, CHI-CHENG LEE, SHIN-MING HUANG, National University of Singapore, BAOKAI WANG, Northeastern U., GUANG BIAN, HAO ZHENG, DANIEL SANCHEZ, ILYA BELOPOLSKI, NASSER ALIDOUST, MADHAB NEUPANE, Princeton U., ARUN BANSIL, Northeastern U., HORNG-TAY JENG, Natl Tsing Hua U., HSIN LIN, National University of Singapore, M. ZAHID HASAN, Princeton U. — A Weyl semimetal is a new state of matter that hosts Weyl fermions as emergent quasiparticles. The Weyl fermions correspond to isolated points of bulk band degeneracy, Weyl nodes, which are connected only through the crystals boundary by an exotic Fermi arc surface state. The length of the Fermi arc gives a measure of the topological strength, because the only way to destroy the Weyl nodes is to annihilate them in pairs in k space. To date, Weyl semimetals are only realized in the TaAs class. Here, we propose a tunable Weyl metallic state in  $\text{Mo}_x\text{W}_{1-x}\text{Te}_2$  via our first-principles calculations, where the Fermi arc length can be continuously changed as a function of Mo concentration, thus tuning the topological strength of the system [1]. Our results provide an experimentally feasible route to realizing Weyl physics in the layered compound  $\text{Mo}_x\text{W}_{1-x}\text{Te}_2$  where non-saturating magneto-resistance and pressure driven superconductivity have been observed.

**11:27AM Y28.00002 Nonsymmorphic topological photonic crystal with a single surface Dirac cone**, LING LU, CHEN FANG, LIANG FU, STEVEN JOHNSON, JOHN JOANNOPOULOS, MARIN SOLJACIC, MIT, MIT COLLABORATION — We predict a realization of the nonsymmorphic topological crystalline phase: a three-dimensional (3D) photonic crystal with a single surface Dirac cone. A single Dirac cone on the surface is the hallmark of the 3D topological insulators, where the double degeneracy at the Dirac point is protected by time-reversal symmetry and the spin-splitting away from the point is provided by the spin-orbital coupling. In our 3D topological photonic crystal, the degeneracy at the Dirac point is protected by a nonsymmorphic glide reflection and the linear splitting away from it is enabled by breaking time-reversal symmetry. Such a gapless surface state is fully robust against random disorder of any type. This bosonic topological band structure is achieved by applying alternating magnetization to gap out the 3D "generalized Dirac points" discovered in the bulk of our crystal. The Z2 bulk invariant is characterized through the evolution of Wannier centers. Our proposal—readily realizable using ferrimagnetic materials at microwave frequencies—can also be regarded as the photonic analog of topological crystalline insulators, providing the first 3D bosonic symmetry-protected topological system.

**11:39AM Y28.00003 Topological semimetals with Riemann surface states<sup>1</sup>**, CHEN FANG, Institute of Physics, Chinese Academy of Sciences, LING LU, JUNWEI LIU, LIANG FU, Massachusetts Inst of Tech-MIT — Topological semimetals have robust bulk band crossings between the conduction and the valence bands. Among them, Weyl semimetals are so far the only class having topologically protected signatures on the surface known as the "Fermi arcs". Here we theoretically find new classes of topological semimetals protected by nonsymmorphic glide reflection symmetries. On a symmetric surface, there are multiple Fermi arcs protected by nontrivial  $Z_2$  spectral flows between two high-symmetry lines (or two segments of one line) in the surface Brillouin zone. We observe that so far topological semimetals with protected Fermi arcs have surface dispersions that can be mapped to noncompact Riemann surfaces representing simple holomorphic functions. We propose perovskite superlattice  $[(\text{SrIrO}_3)_{2m}, (\text{CaIrO}_3)_{2n}]$  as a nonsymmorphic Dirac semimetal.

**11:51AM Y28.00004 Type-II Weyl semimetals**, ALEXEY SOLUYANOV, DOMINIK GRESCH, ETH Zurich, ZHIJUN WANG, Princeton University, QUANSHENG WU, MATTHIAS TROYER, ETH Zurich, XI DAI, IOP, Chinese Academy of Sciences, ANDREI BERNEVIG, Princeton University — The Dirac equation of quantum field theory gives rise to massless Weyl fermions that respect Lorentz invariance. In condensed matter these fermions are realized as low energy excitations in Weyl semimetals. In these materials a topologically protected linear crossing of two bands, called a Weyl point, occurs at the Fermi level resulting in a point-like Fermi surface. Lorentz invariance, however, can be violated in condensed matter, and here we generalize the Dirac equation accordingly to obtain a fundamentally new kind of Weyl fermions. In particular, we report on a novel type of Weyl semimetal, with a new type of Weyl point that emerges at the boundary between electron and hole pockets. This node, although still a protected crossing, has an open, not point-like, Fermi surface, resulting in physical properties very different from that of standard Weyl points. We show that an established material,  $\text{WTe}_2$ , is an example of this novel type of topological semimetals.

**12:03PM Y28.00005 Topological Dirac line nodes in centrosymmetric semimetals**, YOUNGKUK KIM, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6323, USA, BENJAMIN WIEDER, CHARLES KANE, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6396, USA, ANDREW RAPPE, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6323, USA, TI SEED TEAM — Dirac line nodes (DLNs) are one-dimensional lines of Dirac band-touching points, characterized by linear dispersion in only a single direction in momentum space. In the presence of inversion symmetry and time-reversal symmetry, crystals with vanishing spin-orbit coupling can host topologically protected DLNs. Recently, we have proposed and characterized a novel Z2 class of DLN semimetals [1]. We present Z2 topological invariants, dictating the presence of DLNs, based on the parity eigenvalues at the time-reversal invariant crystal momenta. Our first-principles calculations show that DLNs can be realized in  $\text{Cu}_3\text{N}$  in an anti- $\text{ReO}_3$  structure via a metal-insulator electronic transition, driven by transition metal doping. We also discuss the resultant surface states and the effects of spin-orbit coupling.

**12:15PM Y28.00006 Symmetry-protected ideal Weyl semimetal in HgTe-class materials**, SHAO-KAI JIAN, Institute for Advanced Study, Tsinghua University, Beijing 100084, China, JIAWEI RUAN, National Laboratory of Solid State Microstructures, School of Physics, Nanjing University, Nanjing 210093, China, HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing 100084, China, HAIJUN ZHANG, National Laboratory of Solid State Microstructures, School of Physics, Nanjing University, Nanjing 210093, China, SHOU-CHENG ZHANG, Department of Physics, McCullough Building, Stanford University, Stanford, CA 94305-4045, USA, DINGYU XING, National Laboratory of Solid State Microstructures, School of Physics, Nanjing University, Nanjing 210093, China — Ideal Weyl semimetals with all Weyl nodes exactly at the Fermi level and no coexisting trivial Fermi surfaces in the bulk, similar to graphene, could feature deep and novel physics such as exotic transport phenomena induced by the chiral anomaly. Here, we show that HgTe and half-Heusler compounds, under a broad range of inplane compressive strain, could be the first materials in nature realizing ideal Weyl semimetals with four pairs of Weyl nodes and topological surface Fermi arcs. Generically, we find that the HgTe-class materials with nontrivial band inversion and noncentrosymmetry provide a promising arena to realize ideal Weyl semimetals. Such ideal Weyl semimetals could further provide a unique platform to study emergent phenomena such as the interplay between ideal Weyl fermions and superconductivity in the half-Heusler compound LaPtBi.

**12:27PM Y28.00007 Spin-Orbit Nodal Semimetals in the Layer Groups**, BENJAMIN WIEDER, Department of Physics and Astronomy, University of Pennsylvania, YOUNGKUK KIM, The Makineni Theoretical Laboratories, Department of Chemistry, University of Pennsylvania, CHARLES KANE, Department of Physics and Astronomy, University of Pennsylvania — Recent interest in point and line node semimetals has lead to the proposal and discovery of these phenomena in numerous systems. Frequently, though, these nodal systems are described in terms of individual properties reliant on specific space group intricacies or band-tuning conditions. Restricting ourselves to cases with strong spin-orbit interaction, we develop a more general framework which captures existing systems and predicts new examples of nodal materials. In many previously proposed systems, the three-dimensional nature of the space group has obscured key generalities. Therefore, we show how within our framework one can predict and characterize a diverse set of nodal phenomena even in two-dimensional systems constructed of three-dimensional sites, known as the “Layer Groups”. Introducing a set of simple models, we characterize the allowed semimetallic structures in the layer groups and draw connections to analogous three-dimensional systems.

**12:39PM Y28.00008 Scanning Tunneling Microscopy study and unusual transport properties of the topological semimetal  $\alpha$ -Sn.**, JIAWEI RUAN, Nanjing Univ — Weyl semimetals are new states of quantum matter with topological Weyl nodes near Fermi level in the bulk and Fermi arcs at the surface, which are paid a lot attention in recently years. Herewe report another topological semimetal  $\alpha$ -Sn., which is double Weyl semimetal in the magnetic field and Dirac semimetal in an appropriate in-plane strain. By combing Landau level spectroscopy and quasiparticle interference, we obtain the linear dispersion near the Dirac point within strain while quadratic band dispersion near  $\Gamma$  point without strain. We also observe the negative longitudinal magnetoresistance (LMR) in both two system, which is caused by chiral anomaly. However ,the LMR profiles of strained  $\alpha$ -Sn have a little rise and then descend while the unstrained one drop directly, which is due to the different type of Weyl semimetal and further confirm our prediction.

**12:51PM Y28.00009 Spinless Weyl semimetals and  $Z_2$  topological crystalline insulator with glide symmetry**, HEEJAE KIM, Tokyo Institute of Technology, SHUICHI MURAKAMI, TIES, Tokyo Institute of Technology — A topological crystalline insulator (TCI) is one of the kimmy protected topological phases protected by crystalline symmetries such as rotational symmetry, mirror symmetry etc. In recent works, a new class of three-dimensional (3D)  $Z_2$  TCI with a nonsymmorphic glide plane symmetry is theoretically predicted both for spinless and spinfull systems. Our study shows that a spinless Weyl semimetal (WSM) phase always emerges between a normal insulator (NI) and TCI phases transition in general glide symmetric spinless systems. In particular, we find how the  $Z_2$  topological invariant is changed by pair creations and pair annihilations of Weyl nodes in general phase transition. To confirm this scenario, we introduce a simple spinless tight-binding model on a 3D rectangular lattice with two sublattices and two orbitals with glide plane symmetry. Using this model, we show that the spinless WSM phase emerges between the NI and TCI phases, and the changing of  $Z_2$  topological invariant comes from the behavior of Weyl nodes. Our numerical calculation also shows that surface Fermi arcs in the spinless WSM phase evolve into a surface Dirac cone in the TCI phase.

**1:03PM Y28.00010 Interacting weak topological insulators and their transition to Dirac semimetal phases<sup>1</sup>**, GIORGIO SANGIOVANNI, WERNER HANKE, Universitat Wurzburg, GANG LI, Vienna University of Technology, BJOERN TRAUZETTEL, Universitat Wurzburg — Topological insulators in the presence of strong Coulomb interaction constitute novel phases of matter. Transitions between these phases can be driven by single-particle or many-body effects. On the basis of *ab-initio* calculations, we identify a concrete material, *i.e.*  $\text{Ca}_2\text{PtO}_4$ , that turns out to be a hole-doped weak topological insulator. Interestingly, the Pt-*d* orbitals in this material are relevant for the band inversion that gives rise to the topological phase. Therefore, Coulomb interaction should be of importance in  $\text{Ca}_2\text{PtO}_4$ . To study the influence of interactions on the weak topological insulating phase, we look at a toy model corresponding to a layer-stacked 3D version of the Bernevig-Hughes-Zhang model with local interactions. For small to intermediate interaction strength, we discover novel interaction-driven topological phase transitions between the weak topological insulator and two Dirac semimetal phases. The latter correspond to gapless topological phases. For strong interactions, the system eventually becomes a Mott insulator.

**1:15PM Y28.00011 Landau levels and longitudinal magnetoresistance in generalized Weyl semimetals**, XIAO LI, BITAN ROY, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland — The notion of axial anomaly is a venerable concept in quantum field theory that has received ample attention in condensed matter physics due to the discovery of Weyl materials (WSMs). In such systems Kramers non-degenerate bands touch at isolated points in the Brillouin zone that act as (anti)monopoles of Berry flux, and the monopole number ( $m$ ) defines the topological invariant of the system. Although so far only simple WSMs (with  $m = 1$ ) has been found in various inversion and/or time-reversal asymmetric systems, generalized Weyl semimetals with  $m > 1$  can also be found in nature, for example double-Weyl semimetals in  $\text{HgCr}_2\text{Se}_4$  and  $\text{SrSi}_2$  and triple-Weyl semimetals. In this work, we demonstrate the Landau level spectrum in generalized Weyl systems and its ramification on longitudinal magnetotransport measurements. We show that in the quantum limit generalized Weyl semimetals display negative longitudinal magnetoresistance due to the chiral anomaly. Moreover, the magnetoresistance has nontrivial dependence on the relative orientation of the external fields with the crystallographic axis, stemming from underlying anisotropic quasiparticle dispersion in the pristine system. Our theory can thus provide diagnostic tools to pin the quasiparticle properties in Weyl systems.

**1:27PM Y28.00012 Magnetotransport in a Weyl semimetal**, YUYA OMINATO, MIKITO KOSHINO, Tohoku University — We studied the magnetotransport in a Weyl semimetal having the surface boundary, to investigate the effect of the topological surface states on the chiral anomaly. We Found that the conductivity behavior becomes completely different from that of the in finite system, where the surface state plays a crucial role in the relaxation of the bulk carriers.

**1:39PM Y28.00013 Cohomological Insulators**, A. ALEXANDRADINATA, Yale University, ZHIJUN WANG, B. ANDREI BERNEVIG, Princeton University — We present a cohomological classification of insulators, in which we extend crystal symmetries by Wilson loops. Such an extended group describes generalized symmetries that combine space-time transformations with quasimomentum translations. Our extension generalizes the construction of nonsymmorphic space groups, which extend point groups by real-space translations. Here, we *further* extend nonsymmorphic groups by reciprocal translations, thus placing real and quasimomentum space on equal footing. From a broader perspective, cohomology specifies not just the symmetry group, but also the quasimomentum manifold in which the symmetry acts – both data are needed to specify the band topology. In this sense, cohomology underlies band topology.

**1:51PM Y28.00014 Hourglass Fermions**, ZHIJUN WANG, A. ALEXANDRADINATA, ROBERT J. CAVA, B. ANDREI BERNEVIG, Princeton University — Spatial symmetries in crystals are distinguished by whether they preserve the spatial origin. We show how this basic geometric property gives rise to a new topology in band insulators. We study spatial symmetries that translate the origin by a fraction of the lattice period, and find that these nonsymmorphic symmetries protect a novel surface fermion whose dispersion is shaped like an hourglass; surface bands connect one hourglass to the next in an unbreakable zigzag pattern. These exotic fermions are materialized in the large-gap insulators:  $\text{KHg}X$  ( $X=\text{As, Sb, Bi}$ ), which we propose as the first material class whose topology relies on nonsymmorphic symmetries. Beside the hourglass fermion, a different surface of  $\text{KHg}X$  manifests a 3D generalization of the quantum spin Hall effect. To describe the bulk topology of nonsymmorphic crystals, we propose a non-Abelian generalization of the geometric theory of polarization. Our nontrivial topology originates not from an inversion of the parity quantum numbers, but rather of the rotational quantum numbers, which we propose as a fruitful in the search for topological materials. Finally,  $\text{KHg}X$  uniquely exemplifies a cohomological insulator, a concept that we will introduce in a companion work.

**2:03PM Y28.00015 Hourglass Fermions and Cohomological Insulators**, B ANDREI BERNEVIG, Princeton university, ARIS ALEXANDRADINATA, Yale University, ZHIJUN WANG, ROBERT CAVA, Princeton university — We present a new fermion, the Hourglass fermions, which extends the currently known Dirac, Weyl and Majorana classification. We further present a set of materials which host this particle as a surface state. The materials already exist in nature and have a large gap. The topological index involves group cohomology, and, in our particular material example, a group-extension of an already non-symmorphic group.

## Friday, March 18, 2016 11:15AM - 2:15PM –

Session Y29 DCMP DMP: Topological Insulators: Theory II 328 - Jay Sau, University of Maryland

**11:15AM Y29.00001 Gauge-discontinuity contributions to the Chern-Simons orbital magnetoelectric coupling**, JIANPENG LIU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — We propose a new method for calculating the Chern-Simons orbital magnetoelectric coupling, conventionally parametrized in terms of a phase angle  $\theta$ . We propose to relax the periodicity condition in one direction ( $k_z$ ) so that a gauge discontinuity is introduced on a 2D  $\mathbf{k}$  plane normal to  $k_z$ . The total  $\theta$  response then has contributions from both the integral of the Chern-Simons 3-form over the 3D bulk BZ and the gauge discontinuity expressed as a 2D integral over the  $\mathbf{k}$  plane. Sometimes the boundary plane may be further divided into subregions by 1D “vortex loops” which make a third kind of contribution to the total  $\theta$ , expressed as a combination of Berry phases around the vortex loops. The total  $\theta$  thus consists of three terms which can be expressed as integrals over 3D, 2D and 1D manifolds. When time-reversal symmetry is present and the gauge in the bulk BZ is chosen to respect this symmetry, both the 3D and 2D integrals vanish; the entire contribution then comes from the vortex-loop integral, which is either 0 or  $\pi$  corresponding to the  $Z_2$  classification of 3D time-reversal invariant insulators. We demonstrate our method by applying it to the Fu-Kane-Mele model with an applied staggered Zeeman field.

**11:27AM Y29.00002 Bulk-boundary correspondence in (3+1)-dimensional topological phases**, APOORV TIWARI, XIAO CHEN, SHINSEI RYU, University of Illinois, Urbana Champaign — We discuss (2+1)-dimensional gapless surface theories of bulk (3+1)-dimensional topological phases, such as the BF theory at level K, and its generalization. In particular, we put these theories on a flat (2+1) dimensional torus  $T^3$  parameterized by its modular parameters, and compute the partition functions obeying various twisted boundary conditions. We show the partition functions are transformed into each other under  $SL(3, \mathbb{Z})$  modular transformations, and furthermore establish the bulk-boundary correspondence in (3+1) dimensions by matching the modular  $S$  and  $T$  matrices computed from the boundary field theories with those computed in the bulk. We also propose the three-loop braiding statistics can be studied by constructing the modular  $S$  and  $T$  matrices from an appropriate boundary field theory.

**11:39AM Y29.00003 Classification of interacting fermionic phases by dimensional reduction**, RAQUEL QUEIROZ, ESLAM KHALAF, Max Planck Institute for Solid State Physics, ADY STERN, Weizmann Institute of Science — Topological phases of noninteracting fermions are classified in each spatial dimension according to their symmetry class, in a periodic way [1]. When including interactions, however, this classification can be modified. It was first shown that in one-dimensional chains, the  $Z$  classification of the BDI symmetry class is reduced to  $Z_8$  [2]. That is, every group of 8 Majorana states at the edge of a BDI chain can be gapped out through a suitable interaction, despite preserving its fundamental symmetries. In this work, we present a dimensional reduction argument to derive the role of interactions in the classification of fermionic symmetry protected topological phases. For symmetry classes classified by a  $Z$  invariant in odd dimensions, we propose a general  $n$ -particle quartic interaction that renders the system topologically trivial. We argue that all phases characterized by a topological invariant smaller than  $n$  in the noninteracting limit remain topologically distinct once interactions are included, thereby reducing the noninteracting  $Z$  classification to  $Z_n$ . [1] Ryu, S., *et. al.*, NJP 12, 065010 (2010); [2] Fidkowski, L. and Kitaev, A., PRB 81, 134509 (2010).

**11:51AM Y29.00004 Dynamical Axion Field in a Magnetic Topological Insulator Superlattice<sup>1</sup>**, JING WANG, BIAO LIAN, SHOU-CHENG ZHANG, Department of Physics, Stanford University — We propose that the dynamical axion field can be realized in a magnetic topological insulator superlattice or a topological paramagnetic insulator. The magnetic fluctuations of these systems produce a pseudoscalar field which has an axionic coupling to the electromagnetic field, and thus it gives a condensed-matter realization of the axion electrodynamics. Compared to the previously proposed dynamical axion materials where a long range antiferromagnetic order is required, the systems proposed here have the advantage that only a uniform magnetization or a paramagnetic state is needed for the dynamic axion. We further propose several experiments to detect such a dynamical axion field.

**12:03PM Y29.00005 Surface theorem for the Chern-Simons magnetoelectric coupling**, THOMAS OLSEN, Department of Physics, Technical University of Denmark, IVO SOUZA, Centro de Física de Materiales, Universidad del País Vasco, MARYAM TAHERINEJAD, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — The magnetoelectric response  $\alpha_{ij} = \partial M_j / \partial \mathcal{E}_i$  of insulators has an isotropic geometric contribution,  $\alpha_{ij}^{\text{CS}} = (\theta e^2 / 2\pi h) \delta_{ij}$ . For crystals that respect neither inversion nor time-reversal symmetry the Chern-Simons (CS) axion coupling  $\theta$  can take arbitrary values, which however can only be determined modulo  $2\pi$  from bulk calculations. Once an insulating surface termination is specified it becomes possible to resolve the quantum of indeterminacy, as with the spontaneous electric polarization. We prove this "surface theorem" by considering the  $\theta$  coupling of a finite slab from the viewpoint of the hybrid Wannier representation. Each Wannier sheet carries a Chern number, and tiling up the periodic sheet structure close to the surface and counting the leftover Chern amount gives the excess quantized surface anomalous Hall conductivity (AHC). We illustrate these ideas for a tight-binding model consisting of Haldane-model layers with alternating Chern numbers. For appropriate choices of the interlayer couplings, this model realizes an adiabatic pump of CS axion coupling. Over a pumping cycle, one quantum of surface AHC gets transferred from the bottom to the top surface, changing  $\theta$  by  $2\pi$ .

**12:15PM Y29.00006 Effective hydrodynamic field theory and condensation picture of topological insulators**, ATMA CHAN, University of Illinois at Urbana-Champaign, THOMAS KVORNING, Stockholm University, SHINSEI RYU, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — While many features of topological band insulators are commonly discussed at the level of single-particle electron wave functions, such as the gapless Dirac spectrum at their boundary, it remains elusive to develop a hydrodynamic or collective description of fermionic topological band insulators in 3+1 dimensions. As the Chern-Simons theory for the 2+1-dimensional quantum Hall effect, such a hydrodynamic effective field theory provides a universal description of topological band insulators, even in the presence of interactions, and that of putative fractional topological insulators. In this paper, we undertake this task by using the functional bosonization. The effective field theory in the functional bosonization is written in terms of a two-form gauge field, which couples to a U(1) gauge field that arises by gauging the continuous symmetry of the target system (the U(1) particle number conservation). Integrating over the U(1) gauge field by using the electromagnetic duality, the resulting theory describes topological band insulators as a condensation phase of the U(1) gauge theory (or as a monopole condensation phase of the dual gauge field). The hydrodynamic description, and the implication of its duality, of the surface of topological insulators are also discussed.

**12:27PM Y29.00007 Emergence of a Chern-insulating state from a semi-Dirac dispersion**, HUAQING HUANG, Tsinghua University, ZHIRONG LIU, Peking University, HONGBIN ZHANG, Rutgers University, WENHUI DUAN, Tsinghua University, DAVID VANDERBILT, Rutgers University — By combining first-principles calculations with Wannier-based tight-binding modeling, we demonstrate that a  $\text{TiO}_2/\text{VO}_2$  heterostructure that was previously proposed as a prototypical semi-Dirac system becomes a Chern insulator (quantum anomalous Hall insulator) in the presence of spin-orbit coupling. We show that this occurs only when the semi-Dirac structure is of a special type that can be formed by the merging of three conventional Dirac points. Our results reveal how the nontrivial topology with nonzero Chern number emerges naturally from this kind of semi-Dirac structure, establishing a general scenario that provides a new route to the formation of Chern-insulating states in practical materials systems.

**12:39PM Y29.00008 Microscopic study of anomalous Hall effect edge states in topological insulator nanoribbons**, CARLO M. CANALI, ANNA PERTSOVA, Linnaeus University, ALLAN H. MACDONALD, The University of Texas at Austin — Thin films of a magnetic topological insulator (TI) support gapless chiral states on their lateral surfaces, which give rise to the quantum anomalous Hall effect (QAHE) [1,2]. Despite progress in the experimental realization of the QAHE there are many open issues which require an explanation, including remnant longitudinal resistance and relatively imprecise Hall quantization compared to the ordinary QHE in a strong perpendicular magnetic field. These features can be linked to the presence of non-chiral dissipative states on the side walls of the sample. We develop a microscopic theory of side-wall states in ribbons of a magnetic TI. We show the emergence of the chiral edge states as a function of exchange field strength and ribbon width. We demonstrate the existence of non-chiral edge states, whose number depends on the system dimensions. In contrast to previous work [3], we find that the non-chiral states are always gapped, a finding which is supported by recent experiments assessing the precision and temperature dependence of QAHE [4]. Finally, we investigate the role of chemical disorder in equilibrating edge channels and in Hall quantization accuracy. 1.Yu, Science 329, 61(2010); 2.Chang, Science 340, 167(2013); 3.Wang, PRL 111, 086803(2013); 4.Chang, PRL 115, 057206(2015).

**12:51PM Y29.00009 Universal framework for identifying topological materials and its numerical implementation in Z2Pack software package**, DOMINIK GRESCH, MATTHIAS TROYER, ALEXEY SOLUYANOV, ETH Zurich, GABRIEL AUTES, OLEG YAZYEV, EPFL, ANDREI BERNEVIG, Princeton University, DAVID VANDERBILT, Rutgers University — Band structure topology has drastic effects on many observable phenomena in solids, and thus is a fundamental characteristic of a material. We present general framework for identifying various topologies of band structures and introduce a public software package –Z2Pack – for computing the associated topological invariants. Z2Pack works with first-principles calculations, tight-binding and k.p models. It can be used to identify both topological insulators and semimetals.

**1:03PM Y29.00010 Geometric Effect on Quantum Anomalous Hall State in Magnetic Topological Insulator**, YANXIA XING, Department of Physics, Beijing Institute of Technology, Beijing 100081, China — An intriguing observation on the quantum anomalous Hall (QAH) effect in a magnetic topological insulator (MTI) is the dissipative edge states. With the aid of non-equilibrium Green's functions, the QAH effect in an MTI with a three dimensional effective tight-binding model is studied. We predict that due to geometric structure in the third dimension  $z$ , the unidirectional contact between terminal leads and central scattering region induces the backscattering in the central Hall bar, as the function of split gates. Such backscattering leads to a nonzero longitudinal resistance and quantized Hall resistance, which would explain the dissipative edge states in experiments. A further numerical simulation proves above prediction as well. These results are rewarding on future experimental observations and transport calculations based on first principle.

**1:15PM Y29.00011 Thermodynamic signatures of edge states in Topological Insulators**, ANTON QUELLE, EMILIO COBANERA, CRISTINA MORAIS SMITH, Univ of Utrecht — Topological insulators are states of matter distinguished by the presence of symmetry protected metallic boundary modes. These edge modes have been characterised in terms of transport and spectroscopic measurements, but a thermodynamic description has been lacking. The challenge arises because in conventional thermodynamics the potentials are required to scale linearly with extensive variables like volume, which does not allow for a general treatment of boundary effects. In this paper, we overcome this challenge with Hill thermodynamics. In this extension of the thermodynamic formalism, the grand potential is split into an extensive, conventional contribution, and the subdivision potential, which is the central construct of Hill's theory. For topologically non-trivial electronic matter, the subdivision potential captures measurable contributions to the density of states and the heat capacity: it is the thermodynamic manifestation of the topological edge structure. Furthermore, the subdivision potential reveals phase transitions of the edge even when they are not manifested in the bulk, thus opening a variety of new possibilities for investigating, manipulating, and characterizing topological quantum matter solely in terms of equilibrium boundary physics.

**1:27PM Y29.00012 Topological States of Heterostructures**, DEMET USANMAZ, PINKU NATH, JOSE J. PLATA, Department of Mechanical Engineering and Materials Science, Duke University, MARCO BUONGIORNO NARDELLI, Department of Physics and Department of Chemistry, University of North Texas, MARCO FORNARI, Department of Physics, Central Michigan University, STEFANO CURTAROLO, Materials Science, Electrical Engineering, Physics and Chemistry, Duke University — Topological insulators (TIs) have exotic properties, such as having insulating behavior in the bulk and metallic states at the surface<sup>[1]</sup>. Observations of metallic states rely on the spin-orbit induced band inversion in bulk materials and are protected by time-reversal symmetry or crystal symmetry<sup>[2]</sup>. These remarkable characteristics of TIs give rise to various applications from spintronics to quantum computers. In order to broaden the range of applications of TIs and make it more effective, an exploration of high quality heterostructures are required. Creating heterostructures of TIs has recently demonstrated to be advantageous for controlling electronic properties<sup>[3]</sup>. Inspired by these interesting properties, we have investigated the topological interface states of heterostructures. References [1] B. Yan, S-C. Zhang, *Rep. Prog. Phys.*, **75**, 096501 (2012). **1:39PM Y29.00013 Detecting band inversions by measuring the environment: fingerprints of electronic band topology in bulk phonon linewidths**, KUSH SAHA, University of California, Irvine, KATHERINE LEGARE, ION GARATE, University of Sherbrooke, Canada — The interplay between topological phases of matter and dissipative baths constitutes an emergent research topic with links to condensed matter, photonic crystals, cold atomic gases and quantum information. While recent studies suggest that dissipative baths can induce topological phases in intrinsically trivial quantum materials, the backaction of topological invariants on dissipative baths is overlooked. By exploring this back action for a centrosymmetric Dirac insulator coupled to phonons, we show that the linewidths of bulk optical phonons can reveal electronic band inversions. This result is the first known example where topological phases of an open quantum system may be detected by measuring the bulk properties of the surrounding environment.

**1:51PM Y29.00014 Spin Generation Via Bulk Spin Current in Three Dimensional Topological Insulators**, XINGYUE PENG, University of California, Davis - Physics Department — To date, charge transport and spin generation in three-dimensional topological insulators (3D TIs) are primarily modeled as a single-surface phenomenon. We propose a new mechanism of spin generation where the role of the insulating yet topologically non-trivial bulk becomes explicit: an external electric field creates a transverse pure spin current through the bulk of a 3D TI, which transports spins between the top and bottom surfaces and leads to spin accumulation on both. The surface spin density and charge current are then proportional to the spin relaxation time, which for a sufficiently high disorder level can be extended by nonmagnetic scattering analogous to the Dyakonov-Perel spin relaxation mechanism. This new spin generation mechanism suggests a distinct and practical strategy for the enhancement of surface spin polarization by increasing nonmagnetic impurity concentration. Numerical results obtained by coherent potential approximation (CPA) based on a 4-band lattice model confirm that this spin generation mechanism originates from the unique topological connection of the top and bottom surfaces and is absent in other two dimensional systems such as graphene, even though they possess a similar Dirac cone-type dispersion.

**2:03PM Y29.00015 Unconventional band structure for a periodically gated surface of a three dimensional Topological Insulator<sup>1</sup>**, SANKALPA GHOSH<sup>2</sup>, PUJA MONDAL<sup>3</sup>, Physics Department, IIT Delhi, New Delhi-110016, India — The surface states of the three dimensional (3D) Topological Insulators are described by two-dimensional (2D) massless Dirac equation. A gate voltage induced one dimensional potential barrier on such surface creates a discrete bound state in the forbidden region outside the Dirac cone. Even for a single barrier it is shown such bound state can create electrostatic analogue of Shubnikov de Haas oscillation which can be experimentally observed for relatively smaller size samples. However when these surface states are exposed to a periodic arrangement of such gate voltage induced potential barriers, the band structure of the same got nontrivially modified. This is expected to significantly alter the properties of macroscopic system. We also suggest that in suitable limit the system may offer ways to control electron spin electrostatically which may be practically useful

**11:15AM Y30.00001 Single atom electrochemical and atomic analytics<sup>1</sup>**, RAMA VASUDEVAN<sup>2</sup>, Oak Ridge National Laboratory — In the past decade, advances in electron and scanning-probe based microscopies have led to a wealth of imaging and spectroscopic data with atomic resolution, yielding substantial insight into local physics and chemistry in a diverse range of systems such as oxide catalysts, multiferroics, manganites, and 2D materials. However, typical analysis of atomically resolved images is limited, despite the fact that image intensities and distortions of the atoms from their idealized positions contain unique information on the physical and chemical properties inherent to the system. Here, we present approaches to data mine atomically resolved images in oxides, specifically in the hole-doped manganite  $\text{La}_{5/8}\text{Ca}_{3/8}\text{MnO}_3$ , on epitaxial films studied by in-situ scanning tunnelling microscopy (STM). Through application of bias to the STM tip, atomic-scale electrochemistry is demonstrated on the manganite surface. STM images are then further analyzed through a suite of algorithms including 2D autocorrelations, sliding window Fourier transforms, and others, and can be combined with basic thermodynamic modelling to reveal relevant physical and chemical descriptors including segregation energies, existence and strength of atomic-scale diffusion barriers, surface energies and sub-surface chemical species identification. These approaches promise to provide tremendous insights from atomically resolved functional imaging, can provide relevant thermodynamic parameters, and auger well for use with first-principles calculations to yield quantitative atomic-level chemical identification and structure-property relations.

**11:51AM Y30.00002 Transport Properties of Exfoliated BSCCO on LAO/STO Heterostructures<sup>1</sup>**, SYLVIA UJWARY, University of Pittsburgh, ERIN SUTTON, MASON GRAY, KENNETH BURCH, Boston College, JEREMY LEVY, University of Pittsburgh — We investigate the interaction between high-temperature superconductor  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$  (BSCCO) flakes deposited on the oxide heterostructure  $\text{LaAlO}_3/\text{SrTiO}_3$  (LAO/STO). Conductive-atomic force microscope (c-AFM) lithography will be used to create nanowires at the LAO/STO interface that couple to the BSCCO. Through coupling of these materials, we will be able to study phenomena such as the proximity effect and coulomb drag.

<sup>1</sup>We gratefully acknowledge support from the NASA PA Space Grant Consortium (SU), and the National Science Foundation (Grant No. DMR-1410846)

**12:03PM Y30.00003 Systematic investigation of chemical substitution in  $\text{BaSnO}_3$  using the combinatorial approach<sup>1</sup>**, ICHIRO TAKEUCHI, JONGMOON SHIN, SEUNGHUN LEE, XIAOHANG ZHANG, H. M. IFTEKHAR JAIM, Dept. of Materials Science and Engineering, University of Maryland, SE-YOUNG JEONG, Dept. of Cogno-Mechatronics Eng., Pusan National University —  $\text{BaSnO}_3$  has been regarded as a possible material for photo-catalysis, dielectric capacitors, and transparent conductors. We are systematically investigating the effect of chemical substitution for A and B sites in  $\text{BaSnO}_3$  using a high-throughput methodology. We have thus far investigated the effect of substituting La and Sr for the Ba-site and Pb and Bi for the Sn-site. The composition spread films were prepared on  $\text{MgO}$ ,  $\text{SrTiO}_3$  and  $\text{LaAlO}_3$  using combinatorial pulsed laser deposition. The lattice parameters and band-gap energies were found to continually change as a function of the concentration of each substitutional dopant. We find that the band gap can be tuned from 2.8 eV for  $\text{BaSn}_{0.05}\text{Pb}_{0.95}\text{O}_3$  to 4.5 eV for  $\text{Ba}_{0.05}\text{La}_{0.95}\text{SnO}_3$ . Especially for  $\text{Ba}_{1-x}\text{La}_x\text{SnO}_3$  with x in the range of  $0.05 < x < 0.5$ , we consistently observe resistivity as low as  $0.23 \text{ m}\Omega\text{cm}$  at room temperature while maintaining optical transparency with a typical bandgap of  $\sim 4 \text{ eV}$ . The effect of crystalline defects on electrical properties will also be discussed.

**12:15PM Y30.00004 Correlated Heterostructures for Efficient Solar Cells**, ELIAS ASSMANN, MARKUS AICHORN, TU Graz, Austria, GIORGIO SANGIOVANNI, University of Würzburg, Germany, SATOSHI OKAMOTO, Oak Ridge National Laboratory, PETER BLAHA, SUMANTA BHANDARY, KARSTEN HELD, TU Vienna, Austria — Polar/non-polar oxide heterostructures such as  $\text{LaAlO}_3/\text{SrTiO}_3$  have become well-known for the many intriguing phenomena occurring at the interface, especially the internal potential gradient and the resulting 2d electron gas. We propose to make use of these unique systems as absorbing materials for high-efficiency solar cells [1]. In particular,  $\text{LaVO}_3/\text{SrTiO}_3$  (i) has a direct band gap  $\sim 1.1 \text{ eV}$ , nearly optimal for a solar cell; (ii) the internal potential gradient serves to efficiently separate the photo-generated electron-hole pairs and reduce recombination losses; (iii) the conducting interface offers a natural contact for charge-carrier extraction. Furthermore, (iv) oxide heterostructures afford the flexibility to combine layers with different gaps, e.g.  $\text{LaVO}_3$  with  $\text{LaFeO}_3$ , in order to achieve even higher efficiencies with band-gap graded solar cells. We use density-functional theory and dynamical mean-field theory to study this strongly correlated heterostructure.

**12:27PM Y30.00005 Ferroelectricity and hysterically controlled photocurrent in  $\text{NaMnF}_3$  Thin Film<sup>1</sup>**, MING YANG, AMIT KC, PAVEL BORISOV, DAVID LEDERMAN, ALDO ROMERO, CHENG CEN, West Virginia Univ — Abstract: In recent year many fascinating electron correlation phenomena have been discussed, such as two dimensional electron gas, metal-insulator transitions and multiferroic interactions. While most of the researches concentrate on complex oxides, there are strong indications that complex fluorides may have analogous, or even enhanced properties.  $\text{NaMnF}_3$  is one such example. Theoretical work predicted that  $\text{NaMnF}_3$  has multiferroic characters and strong magneto-electric coupling. Thin films of  $\text{NaMnF}_3$  with 50 nm thickness were grown on  $\text{SrTiO}_3$  substrates via molecular beam epitaxy. By performing piezoelectric force microscopy, rewritable polarizations were manipulated and stable ferroelectric switching was obtained in  $\text{NaMnF}_3$  at room temperature. At low temperatures, persistent photocurrent was observed under the illumination of 400nm laser. Amplitude and direction of such photocurrent can be hysterically controlled by external biases. This phenomenon is due to the fact that photocarriers generated in  $\text{SrTiO}_3$  are driven by the controlled built-in electric field in  $\text{NaMnF}_3$  thin film. These findings indicate great potential of complex fluorides in applications such as ferroelectric switches, photovoltaic devices and memory storages. This work is supported by DMREF-NSF 1434897.

**12:39PM Y30.00006 Linear electro-optic effect in strained  $\text{BaTiO}_3$** , ALEX DEMKOV, KURT FREDREICKSON, The University of Texas — The nominal perovskite  $\text{ABO}_3$  structure is cubic and centro-symmetric. Therefore, by symmetry there should be no linear electro-optic (EO) effect. However, perovskites are known to experience various lattice distortions that result in reduced symmetry. The ferroelectric transition in  $\text{BaTiO}_3$  (BTO) is one obvious example. Below 393 K the cell becomes tetragonal and Ti shifts away from the center of inversion and produces a dipole moment and a robust linear EO or Pockels effect. In this talk I will discuss how the EO response in BTO can be enhanced by strain and show our recent results obtained with density functional theory. This work was supported by the Air Force Office of Scientific Research (Grant FA9550-12-1-0494)

**12:51PM Y30.00007 Build-in Electric Field Induced Mechanical Property Change**, TE-YU CHIEN, Univ of Wyoming, JIAN LIU, University of Tennessee, Knoxville, ANDREW J. YOST, University of Wyoming, JACQUES CHAKHALIAN, University of Arkansas, JOHN W. FREELAND, NATHAN P. GUISENGER, Argonne National Laboratory — Mechanical properties describe how materials respond to external stress. Microscopically, many intrinsic and extrinsic factors, such as bond length and strength (intrinsic) and grain boundaries (extrinsic), may affect the mechanical property of the materials. In this study, we observed a change of fracturing behavior of Nb-doped  $\text{SrTiO}_3$  in a Schottky barrier near the interfaces with metallic  $\text{LaNiO}_3$  films. Through cross-sectional scanning tunneling microscopy and spectroscopy (XSTM/S) experiments and theoretical analysis, the observed fractured topography could be explained by the change of the bond length caused alternation of mechanical property inside the Schottky barrier. Same model could also explain the widely observed dielectric dead layer for  $\text{SrTiO}_3$  in contact with metal electrodes.

**1:03PM Y30.00008 Ionic and electrochemical phenomena induced by structural and chemical defects in oxide thin films**, CARMELA ARUTA, National Research Council CNR-SPIN Rome, Italy — Interactions at the surfaces/interfaces between complex oxides and gaseous environment are fundamental for the efficiency of many environmental friendly systems and applications. Such interactions can be modified by the intricate interrelationship between microstructure and chemical substitution defects, being their role on functional properties, such as ionic conductivity and surface reaction rates, as particularly relevant as difficult to discriminate. New possibilities in thin film fabrication allow growth of oxide thin films with a more precise control of the structure and chemical stoichiometry, thus unveiling new perspectives in the study of electrochemical effects for physical functionalities, through nanoscale characterizations by complementary state-of-art techniques. As an example of interfacial structural defect effects, we will discuss the case of yttrium doped barium zirconate thin films, where the cation substitutions represent a viable mechanism, alternative to the formation of dislocations near the interface, to relieve the strain building up in the film growing on a highly mismatched substrate, thus providing fast transport pathways together with enhanced interface electrochemical reactivity. The effect of the chemical defects will be further presented in the case of samarium-doped ceria films with different doping concentration. We will explain the role of the trivalent doping on the conduction mechanism, i.e. proton or oxygen ion, which in turns may greatly influence the surface reactivity.

**1:39PM Y30.00009 First principles study of oxygen vacancies and iron impurities on electrical and optical properties of NiO<sup>1</sup>**, JOHN PETERSEN, TWAGIRAYEZU FIDELE, Texas State University, PABLO BORGES, Universidade Federal de Viosa, Brazil, LUISA SCOLFARO, WILHELMUS GEERTS, Texas State University — We are studying the properties of iron doped NiO by Density Functional Theory. NiO is being considered for use in RRAM, based on the reversible switching of a thin transition metal oxide (TMO) layer between a low and high resistance state using the mechanism of soft breakdown. RRAM's high integration density, its high endurance and good retention, its low energy use, and its high speed make it a potential candidate for replacing Flash memory. Switching between the high and low resistance state is inhomogeneous, and low resistance nano-filaments are formed. Fe impurities are introduced to optimize the switching properties. The effects of oxygen vacancies and iron on the electronic structure and optical properties of NiO are calculated and compared with experiment. Antiferromagnetic rhombohedral 108 atom cells with 1.85% Fe concentration are considered. Due to the highly-correlated nature of d orbitals in TMOs, a Hubbard U correction is applied to calculations in this work via the GGA + U method of DFT using VASP. Hybrid HSE06 calculations will also be considered. Localized energy levels from iron and from oxygen vacancies are identified, and their effects on dielectric permittivity are presented.

<sup>1</sup>Texas State University (Research Enhancement grant) and DOD (HBCU/MI grant W911NF-15-1-0394)

**1:51PM Y30.00010 Investigation on the Mechanism and Application of Nanoscale NiO Memristors**, ZHONG SUN, YONGGANG ZHAO, Tsinghua Univ, MIN HE, LIN GU, CHAO MA, KUIJUAN JIN, LINLIN WEI, JIANQI LI, IOP, CAS, NANNAN LUO, QINGHUA ZHANG, WENHUI DUAN, CEWEN NAN, Tsinghua Univ, DEPARTMENT OF PHYSICS TEAM, IOP, CAS COLLABORATION, SCHOOL OF MATERIALS SCIENCE AND ENGINEERING COLLABORATION — In contrast to the oxygen-vacancy-based model for the memristive *n*-type metal oxides, the coexistence of cation and anion vacancies had been suggested theoretically to be crucial to the bipolar memristive behavior of NiO. We have revealed the deterministic role of concentration surplus of cation vacancy over anion vacancy in bipolar memristive NiO, with C-AFM measuring the electrical properties, and STEM combined with EELS characterizing the ionic vacancies, giving an experimental support for the first time to the dual-defects-based model, which is of fundamental importance for the comprehensive understanding of memristor mechanisms. Furthermore, we have fabricated NiO nanodots with AAO templates, in which the intrinsically rectifying-resistive switching (IR-RS) has been observed. This is the first work studying the IR-RS in the scale of real devices, where the feasibility for selection device-free memory application has been demonstrated. The IR-RS in NiO nanodots has been ascribed exclusively to the built-in *p* – *n* homojunction, differing from previous cases dominated by the interfacial Schottky barriers.

**2:03PM Y30.00011 Nanoscale BaTiO<sub>3</sub> MOSCAP formation for ferroelectric field effect transistor application**, PATRICK PONATH, AGHAM POSADAS, Univ of Texas, Austin, MICHAEL SCHMIDT, PAUL HURLEY, RAY DUFFY, Tyndall National Institute, ALEX DEMKOV, Univ of Texas, Austin — Titanates are an important class of materials with many interesting functional properties and applications for non-volatile memory, i.e. BaTiO<sub>3</sub>, which is a promising candidate for the realization of a ferroelectric field-effect transistor. However, the difficulty of chemically etching titanates has hindered their commercial use in device manufacturing so far. Here, we report a technique to circumvent this problem. Using molecular beam epitaxy, we grew compressively strained ferroelectric BaTiO<sub>3</sub>, within photolithographically defined openings of a sacrificial SiO<sub>2</sub> layer on germanium (001) with Pt as a top electrode. Etching away the sacrificial SiO<sub>2</sub> can reveal isolated nanoscale gate stacks circumventing the need to etch the titanate thin film. Using X-ray diffraction we find that the BaTiO<sub>3</sub> film is tetragonal with the longer *c*-axis being out of plane, which is a requirement for the ferroelectric field effect transistor. The crystal quality of the BaTiO<sub>3</sub> films grown in the openings is confirmed using RHEED and cross-sectional transmission electron microscopy. Focused ion beam etching of the Pt layer is then used to electrically isolate a Pt/BaTiO<sub>3</sub>/SrTiO<sub>3</sub>/Ge stack to perform electrical measurements.

**11:15AM Y31.00001 Characterization of protein hydration by solution NMR spectroscopy**, JOSHUA WAND, Department of Biochemistry & Biophysics, University of Pennsylvania — A comprehensive understanding of the interactions between protein molecules and hydration water remains elusive. Solution nuclear magnetic resonance (NMR) spectroscopy has been proposed as a means to characterize these interactions but is plagued with artifacts when employed in bulk aqueous solution. Encapsulation of proteins in reverse micelles prepared in short chain alkane solvents can overcome these technical limitations. Application of this approach has revealed that the interaction of water with the surface of protein molecules is quite heterogeneous with some regions of the protein having long-lived interactions while other regions show relatively transient hydration. Results from several proteins will be presented including ubiquitin, staphylococcal nuclease, interleukin 1beta, hen egg white lysozyme (HEWL) and T4 lysozyme. Ubiquitin and interleukin 1beta are signaling proteins and interact with other proteins through formation of dry protein-protein interfaces. Interestingly, the protein surfaces of the free proteins show relatively slowed (restricted) motion at the surface, which is indicative of low residual entropy. Other regions of the protein surface have relatively high mobility water. These results are consistent with the idea that proteins have evolved to maximize the hydrophobic effect in optimization of binding with protein partners. As predicted by simulation and theory, we find that hydration of internal hydrophobic cavities of interleukin 1beta and T4 lysozyme is highly disfavored. In contrast, the hydrophilic polar cavity of HEWL is occupied by water. Initial structural correlations suggest that hydration of alpha helical structure is characterized by relatively mobile water while those of beta strands and loops are more ordered and slowed. These and other results from this set of proteins reveals that the dynamical and structural character of hydration of proteins is heterogeneous and complex. Supported by the National Science Foundation.

**11:51AM Y31.00002 Hydration Dynamics of Biomolecules from Co-solvents to Crowding**, KEVIN KUBARYCH, University of Michigan — Biomolecules self-assemble into complex functional structures with high fidelity largely due to interactions between the macromolecules and water. Once folded, the dynamics of water molecules in the vicinity of extended macromolecular interfaces can be altered relative to the bulk, leading to complex, heterogeneous and distance-dependent transport properties near these surfaces. Using a strategy based on transition metal carbonyl vibrational probes covalently conjugated to the protein surface, we have been able to use ultrafast two-dimensional infrared (2D-IR) spectroscopy to probe the dynamics from this most important perspective. In a series of studies, we have found these probes to be primarily sensitive to the orientational dynamics of the hydrating water molecules, and have studied both protein/water and membrane/water interfaces. Several key findings have emerged, including a modest 2-3-fold slowdown of hydration water's reorientational dynamics relative to the bulk, and a dynamical transition that occurs due to collective hydration induced by macromolecular crowding. We will summarize our progress to-date, as well as present our newest results on the effects of ions and the dynamical signatures of preferential solvation.

## **12:27PM Y31.00003 Observation of Water-Protein Interaction Dynamics with Broadband Two-Dimensional Infrared Spectroscopy**

**LUIGI DE MARCO, ANDREW HAKY, ANDREI TOKMAKOFF**, The University of Chicago — Two-dimensional infrared (2D IR) spectroscopy has proven itself an indispensable tool for studying molecular dynamics and intermolecular interactions on ultrafast timescales. Using a novel source of broadband mid-IR pulses, we have collected 2D IR spectra of protein films at varying levels of hydration. With 2D IR, we can directly observe coupling between water's motions and the protein's. Protein films provide us with the ability to discriminate hydration waters from bulk water and thus give us access to studying water dynamics along the protein backbone, fluctuations in the protein structure, and the interplay between the molecular dynamics of the two. We present two representative protein films: poly-L-proline (PLP) and hen egg-white lysozyme (HEWL). Having no N-H groups, PLP allows us to look at water dynamics without interference from resonant energy transfer between the protein N-H stretch and the water O-H stretch. We conclude that at low hydration levels water-protein interactions dominate, and the water's dynamics are tied to those of the protein. In HEWL films, we take advantage of the robust secondary structure to partially deuterate the film, allowing us to spectrally distinguish the protein core from the exterior. From this, we show that resonant energy transfer to water provides an effective means of dissipating excess energy within the protein, while maintaining the structure. These methods are general and can easily be extended to studying specific protein-water interactions.

## **12:39PM Y31.00004 Fluctuating Thermodynamics for Biological Processes<sup>1</sup>**

**SIHYUN HAM**, Sookmyung Women's University — Because biomolecular processes are largely under thermodynamic control, dynamic extension of thermodynamics is necessary to uncover the mechanisms and driving factors of fluctuating processes. The fluctuating thermodynamics technology presented in this talk offers a practical means for the thermodynamic characterization of conformational dynamics in biomolecules. The use of fluctuating thermodynamics has the potential to provide a comprehensive picture of fluctuating phenomena in diverse biological processes. Through the application of fluctuating thermodynamics, we provide a thermodynamic perspective on the misfolding and aggregation of the various proteins associated with human diseases. In this talk, I will present the detailed concepts and applications of the fluctuating thermodynamics technology for elucidating biological processes.

## **1:15PM Y31.00005 Thermodynamic properties of water solvating biomolecular surfaces<sup>1</sup>**

**MATTHIAS HEYDEN**, Ruhr-University Bochum — Changes in the potential energy and entropy of water molecules hydrating biomolecular interfaces play a significant role for biomolecular solubility and association. Free energy perturbation and thermodynamic integration methods allow calculations of free energy differences between two states from simulations. However, these methods are computationally demanding and do not provide insights into individual thermodynamic contributions, i.e. changes in the solvent energy or entropy. Here, we employ methods to spatially resolve distributions of hydration water thermodynamic properties in the vicinity of biomolecular surfaces. This allows direct insights into thermodynamic signatures of the hydration of hydrophobic and hydrophilic solvent accessible sites of proteins and small molecules and comparisons to ideal model surfaces. We correlate dynamic properties of hydration water molecules, i.e. translational and rotational mobility, to their thermodynamics. The latter can be used as a guide to extract thermodynamic information from experimental measurements of site-resolved water dynamics. Further, we study energy-entropy compensations of water at different hydration sites of biomolecular surfaces.

## **Friday, March 18, 2016 11:15AM - 2:15PM –**

**Session Y32 DCP: Chemical Physics of Extreme Environments III** 332 - Marsha Lester, University of Pennsylvania

## **11:15AM Y32.00001 Complexities in Pressure Dependent Kinetics Across a Wide-Range of Temperatures and Pressures**

**STEPHEN KLIPPENSTEIN**, Argonne Natl Lab — Sample ab initio transition state theory based master equation calculations will be used to illustrate interesting features of the kinetics for a variety of reactions of importance in astrochemistry, atmospheric, and combustion chemistry. The calculations will explore the role of long-range interactions, angular momentum conservation, tunneling, radiative emission, roaming processes, torsional motions, and prompt dissociation of incipient molecules. Comparisons with experiment will be presented to illustrate the current accuracy of such calculations.

## **11:51AM Y32.00002 Forming a Two-Ring Polycyclic Aromatic Hydrocarbon without a Benzene Intermediate: the Reaction of Propargyl with Acetylene**

**DAVID OSBORN**, Sandia National Laboratories, **JOHN SAVEE**, Los Gatos Research, **TALITHA SELBY**, University of Wisconsin, Washington County, **OLIVER WELZ**, BASF SE, **CRAIG TAATJES**, Sandia National Laboratories — The reaction of acetylene (HCCH) with a resonance-stabilized free radical is a commonly invoked mechanism for the generation of polycyclic aromatic hydrocarbons (PAH), which are likely precursors of soot particles in combustion. In this work, we examine the sequential addition of acetylene to the propargyl radical (H<sub>2</sub>CCCH) at temperatures of 800 and 1000 K. Using time-resolved multiplexed photoionization mass spectrometry with tunable ionizing radiation, we identified the isomeric forms of the C<sub>5</sub>H<sub>5</sub> and C<sub>7</sub>H<sub>7</sub> intermediates in this reaction sequence, and confirmed that the final C<sub>9</sub>H<sub>8</sub> product is the two-ring aromatic compound indene. We identified two different resonance-stabilized C<sub>5</sub>H<sub>5</sub> intermediates, with different temperature dependencies. Furthermore, the C<sub>7</sub>H<sub>7</sub> intermediate is the tropylium radical (c-C<sub>7</sub>H<sub>7</sub>), not the benzyl radical (C<sub>6</sub>H<sub>5</sub>CH<sub>2</sub>), as is usually assumed in combustion environments. These experimental results are in general agreement with the latest electronic structure / master equation results of da Silva et al. This work shows a pathway for PAH formation that bypasses benzene / benzyl intermediates.

**12:03PM Y32.00003 TBA**, **JOHN STANTON**, Univ of Texas, Austin — No abstract available.

## **12:39PM Y32.00004 Threshold collision induced dissociation experiment for azobenzene and its derivatives.**

**MOHAMMADREZA REZAEI**, Physics Department, University of Tennessee, Knoxville; The Department of Physics and Astronomy; **TEXAS AM UNIVERSITY**, **ROBERT COMPTON**, Physics Department, University of Tennessee, Knoxville; Chemistry Department, University of Tennessee, Knoxville — In this study we investigated protonated azobenzene cation and properties of trans 2,2',6,6'-tetrafluoroazobenzene anion using the collision induced dissociation method and the results are compared with the results from ab initio electronic structure calculations. We measured the bond dissociation energies experimentally and found which theoretical quantum chemistry methods yield best results. Several high accuracy multi-level calculations such as CBS-QB3, G3 and G4 had been carried out to obtain reliable thermochemical information for azobenzene and several of its derivatives and their anion or cation. We also performed other experiments such as Raman spectroscopy to study these light sensitive molecules with promising applications such as photo-switching.

**12:51PM Y32.00005 TBA**, **JUDIT ZADOR**, CRF-Sandia National Lab — No abstract available.

**1:27PM Y32.00006 A Compressed Sensing Approach to Select Optimal Atom-Centered Basis Functions for DFT and Beyond**, CHENCHEN WANG, Fritz Haber Institute, NIKLAS MENZEL, TU Berlin, LUCA M. GHIRINGHELLI, Fritz Haber Institute, GITTA KUTYNIOK, TU Berlin, MATTHIAS SCHEFFLER, Fritz Haber Institute — The choice of the basis sets is one of the most important factors in quantum chemical calculations. It is particularly challenging for functionals that treat electron correlations. Commonly used basis sets for advanced exchange-correlation functionals are not sufficiently accurate. This leads to extended basis set, such as the most famous correlation-consistent basis sets by Dunning. However, such basis sets have been so far widely used mainly for light atoms and their molecules, since they are too expensive for transition metals. We have developed a new approach to select basis functions based on compressed sensing (CS), a recently developed signal processing technique. CS provides a simple and efficient framework for basis selection based on  $l_1$  norm regularization techniques. As introductory example, we select via our CS-based approach Gaussian basis functions (GTO) from a large pool of various GTOs, in order to fit to the reference atomic orbitals. We calculate the total energy for atoms from H to O, and then extend to molecules, e.g.,  $H_2$ ,  $N_2$ , and  $O_2$ . For H, He, and Li, our total-energy results are within 0.05% compared with STO-6G energies. Starting from Be, CS selected basis set provide significantly better results than STO-6G, even when only 5 GTOs are considered. Our new approach enables us to determine optimal basis sets for heavier atoms and molecules.

**1:39PM Y32.00007 Accurately Predicting Complex Reaction Kinetics from First Principles**, WILLIAM GREEN, Massachusetts Institute of Technology — Many important systems contain a multitude of reactive chemical species, some of which react on a timescale faster than collisional thermalization, i.e. they never achieve a Boltzmann energy distribution. Usually it is impossible to fully elucidate the processes by experiments alone. Here we report recent progress toward predicting the time-evolving composition of these systems a priori: how unexpected reactions can be discovered on the computer, how reaction rates are computed from first principles, and how the many individual reactions are efficiently combined into a predictive simulation for the whole system. Some experimental tests of the a priori predictions are also presented.

**Session Y33 FIAP: Organic Electronics and Photonics - Spin Transport and Photophysics** 336  
- Bryan Boudouris, Purdue University

**11:15AM Y33.00001 Engineering of spin injection and spin transport in organic spin valves using  $\pi$ -conjugated polymer brushes.**<sup>1</sup>, RUGANG GENG, ANANDI ROY, RAM SUBEDI, JASON LOCKLIN, THO NGUYEN, University of Georgia, WENBO ZHAO, XIAOGUANG LI, University of Science and Technology of China — Charge transport in amorphous organic semiconductors is governed by carriers hopping between localized states with small spin diffusion length. Furthermore, the spin interfacial resistance of organic spin valves (OSVs) is poorly controlled resulting in controversial reports of the magnetoresistance response. Here, we used surface initiated Kumada transfer polycondensation to covalently graft  $\pi$ -conjugated poly(3-methylthiophene) brushes from the  $La_{0.67}Sr_{0.33}MnO_3$  (LSMO) bottom electrode. The covalent attachment along with the brush morphology allows for more control over the LSMO/brush interfacial resistance and large spacer mobility. Remarkably, with 15 nm brush spacer layer, we observed an optimum magnetoresistance (MR) effect of 70% at cryogenic temperatures and a MR of 2.7% at 280K. The temperature dependence of the MR is nearly an order of magnitude weaker than that found in control OSVs made from spin-coated poly(3-hexylthiophene). Using a variety of different brush layer thicknesses, the thickness dependent MR at 20K was investigated. A spin diffusion length of 20 nm at 5 mV junction voltage rapidly increases to 55 nm at -280 mV.

<sup>1</sup>We acknowledge NSF (CHE 1412714 and DMR 0953112) (J.L.), the UGA start-up funds and Faculty Research Grant (T.N.), NSFC and NBRPC (2012CB922003 and 2015CB921201, X.G.L.) for funding this work.

**11:27AM Y33.00002 Intrinsic spin and momentum relaxation in organic single-crystalline semiconductors probed by ESR and Hall measurements**<sup>1</sup>, JUNTO TSURUMI, ROGER HUSERMANN, SHUN WATANABE, CHIKAHIKO MITSUI, TOSHIHIRO OKAMOTO, HIROYUKI MATSUI, JUN TAKEYA, Univ of Tokyo — Spin and charge momentum relaxation mechanism has been argued among organic semiconductors with various methods, devices, and materials. However, little is known in organic single-crystalline semiconductors because it has been hard to obtain an ideal organic crystal with an excellent crystallinity and controllability required for accurate measurements. By using more than 1-inch sized single crystals which are fabricated via contentious edge-casting method developed by our group, we have successfully demonstrated a simultaneous determination of spin and momentum relaxation time for gate-induced charges of 3,11-didecyldinaphtho[2,3-*d*:2',3'-*d'*]benzo[1,2-*b*:4,5-*b'*]dithiophene, by combining electron spin resonance (ESR) and Hall effect measurements. The obtained temperature dependences of spin and momentum relaxation times are in good agreement in terms of power law with a factor of approximately -2. It is concluded that Elliott-Yafet spin relaxation mechanism can be dominant at room temperature regime (200 – 300 K). Probing characteristic time scales such as spin-lattice, spin-spin, and momentum relaxation times, demonstrated in the present work, would be a powerful tool to elucidate fundamental spin and charge transport mechanisms.

<sup>1</sup>We acknowledge the New Energy and Industrial Technology Developing Organization (NEDO) for financial support.

**11:39AM Y33.00003 Vast Hole- and Electron-Polaron Spatial Extent in Oligomeric  $\pi$ -Conjugated Porphyrin Arrays**, PAUL ANGIOLILLO, Saint Joseph's University, JEFF RAWSON, MICHAEL THERIEN, Duke University — *meso*-Ethyne bridged  $\pi$ -conjugated zinc porphyrin oligomers ( $PZn_n$  compounds) have been demonstrated to evince lowest excited singlet states that are globally delocalized. It has also previously been shown that hole-polaron states of these oligomers exhibit delocalization lengths that mirror the molecular spatial dimension, 7.5 nm in the case of the heptamer. Here we demonstrate that the electron-polaron states in  $PZn_n$  compounds also feature vast areal delocalization. This finding is evidenced by concurrent optical and electron spin resonance measurements, coupled with electronic structure calculations that suggest atypically small reorganization energies for one-electron reduction of these materials. These results are buttressed by electron spin relaxation measurements of  $PZn_n$  electron polarons that show that both  $T_1$  and  $T_2$  relaxation times are unusually large, on the order of  $10^3$  ns and  $10^2$  ns, respectively. Since rapid charge delocalization defines an important mechanism that mitigates Coulombic stabilization of photogenerated electron-hole pairs to create separated free charge carriers, and spin polarization lifetimes feature prominently in spin currents, these findings identify conjugated materials with exceptional optical, electronic, and spintronic properties.

**11:51AM Y33.00004 Magnetization Dynamics of Organic-based Magnetic Heterostructures**, MICHAEL CHILCOTE, YU LU, HAILONG WANG, FENGYUAN YANG, EZEKIEL JOHNSTON-HALPERIN, Dept. of Physics, The Ohio State University — We present temperature dependent ferromagnetic resonance measurements of both isolated magnetic films and bilayers, including all organic and organic/inorganic hybrid magnetic heterostructures. These results establish organic magnetic heterostructures as an exciting new materials platform for the exploration of the fundamental mechanisms driving magnetic ordering in organic-based materials and promise the extension of organic spintronics into the regime of dynamically-driven spin currents, such as those found in spin pumping. The low cost, low-temperature conformal deposition of organic-based thin film magnets makes them an attractive class of materials for device applications. For example, they offer the potential for novel applications in high frequency magnetoelectronics on flexible substrates. Our materials are of the form  $M[\text{Acceptor}]_x$  ( $M$  = transition metal,  $x \approx 2$ ), exhibit room temperature magnetic ordering, and provide the opportunity to tailor magnetic properties through the selection of the transition metal ions and organic ligands. In particular, we focus on ferrimagnetic films and heterostructures where  $M$  = vanadium and the organic ligands are tetracyanoethylene (TCNE), ethyl tricyanoethylene carboxylate (ETCEC), and methyl tricyanoethylene carboxylate (MeTCEC).

**12:03PM Y33.00005 Large Magnetoresistance at High Bias Voltage in Double-layer Organic Spin Valves<sup>1</sup>**, R. C. SUBEDI, S. H. LIANG, R. GENG, Department of Physics & Astronomy, University of Georgia, Athens, GA 30602, USA, Q.T. ZHANG, L. LOU, J. WANG, School of Materials Science and Engineering, Nanyang Technological University, Singapore 639798, Singapore, X. F. HAN, Beijing National Laboratory of Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, T. D. NGUYEN, Department of Physics & Astronomy, University of Georgia, Athens, GA 30602, USA — We report studies of magnetoresistance (MR) in double-layer organic spin valves (DOSV) using tris (8-hydroxyquinolino) aluminum ( $\text{Alq}_3$ ) spacers. The device exhibits three distinct resistance levels depending on the relative magnetizations of the ferromagnetic electrodes. We observed a much weaker bias voltage dependence of MR in the device compared to that in the conventional organic spin valve (OSV). The MR magnitude reduces by the factor of two at 0.7 V bias voltage in the DOSV compared to 0.02 V in the conventional OSV. Remarkably, the MR magnitude reaches 0.3% at 6 V bias in the DOSVs, the largest MR response ever reported in OSVs at this bias. Our finding may have a significant impact on achieving high efficient bipolar OSVs strictly performed at high voltages.

**12:15PM Y33.00006 Multi-scale modeling of spin transport in organic semiconductors**, SHAYAN HEMMATIYAN, Department of Physics, Texas AM University, College Station, Texas 77843, USA/Institut für Physik, Johannes Gutenberg Universität Mainz, Germany, AMAURY SOUZA, Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany, PASCAL KORDT, Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany, ERIK MCNELLIS, Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany, DENIS ANDRIENKO, Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany, JAIRO SINOVA, Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany — In this work, we present our theoretical framework to simulate simultaneously spin and charge transport in amorphous organic semiconductors. By combining several techniques e.g. molecular dynamics, density functional theory and kinetic Monte Carlo, we are able to study spin transport in the presence of anisotropy, thermal effects, magnetic and electric field effects in a realistic morphologies of amorphous organic systems. We apply our multi-scale approach to investigate the spin transport in amorphous  $\text{Alq}_3$  (Tris(8-hydroxyquinolino)aluminum) and address the underlying spin relaxation mechanism in this system as a function of temperature, bias voltage, magnetic field and sample thickness.

**12:27PM Y33.00007 Chromophoric disorder in conjugated polymers: the curious case of P3HT**, LENA SIMINE, Rice University, PETER ROSSKY, Dept. of Chemistry, Rice University — The origin of the broad absorption spectrum of conjugated polymers is discussed. Motivated by the open questions posed in the recent experimental literature, we investigate theoretically the chromophoric disorder in single molecule poly(3hexyl)thiophene (P3HT) at the atomic level using quantumclassical simulations. We reproduce the absorption spectrum and confirm qualitatively the prediction of simplified models the localization length of the first excited state decreases with increasing temperature. Counter to expectation, the same trend is observed for the average energy of the chromophore: in spite of a shorter localization length, the spectrum of the hot chromophore is redshifted with respect to its cold counterpart. We trace this peculiarity to the anharmonicity of the underlying torsional potential which allows preferential access to more planar interring conformations at high temperature. The contributions of bending to the transitional energies, the origin of inhomogeneous broadening and the possibility of classification of the chromophore as planar/twisted/bent at low and high temperatures are discussed.

**12:39PM Y33.00008 Varying the apparent conduction mechanism in polymer semiconductors**, EMILY G. BITTLE, HYUN WOOK RO, JAMES I. BASHAM, DEAN DELONGCHAMP, DAVID GUNDLACH, Natl Inst of Stds & Tech, OANA JURCHESCU, Wake Forest University — The weak van der Waals inter-molecular interactions in organic semiconductors (OSCs) result in large variations in transport behavior ranging from hopping to band-like. Accurately measuring and modelling charge transport is a prerequisite to establishing robust transport-microstructure correlations and developing predictive structure-function relationships for optimized materials design and processing. Field-effect transistors have become a favored test structure for parameterizing and benchmarking the electronic properties of OSCs due to their ease of fabrication, measurement, and possible use in commercial applications. However, correctly analyzing transistor current-voltage measurements to extract material properties has proven difficult, as parasitic effects influence the device electrical properties and mask intrinsic material properties. Here, we use impedance spectroscopy to evaluate the effects of contacts on device operation and extract the properties of the channel which we compare with conventional DC measurements. We apply this approach to model systems of the widely studied polymer regioregular poly(3-hexylthiophene-2,5-diyl) which we engineer through different solidification kinetics to achieve distinct, well characterized degrees of molecular order. When increasing the order we find that the transport changes from field enhanced to field independent. This study addresses the origins of transport behavior seen in OSCs while discerning non-linear contact effects from field dependent transport.

**12:51PM Y33.00009 Suppression of molecular vibrations in strained organic semiconductors**, TAKAYOSHI KUBO, ROGER HUSERMANN, JUNTO TSURUMI, JUNSHI SOEDA, YUGO OKADA, YU YAMASHITA, CHIKAHICO MITSUI, TOSHIHIRO OKAMOTO, HIROYUKI MATSUI, JUN TAKEYA, Univ of Tokyo, SUSUMU YANAGISAWA, Univ of the Ryukyus, NORIHISA AKAMATSU, ATSUSHI SHISHIDO, Tokyo Tech — The inherent softness of organic semiconductors, which makes them totally suited for flexible applications, also offers us an idea on the modulation of the charge transport in largely strained crystal structure. Here, solution-processed single crystal of 3,11-didecyldinaphtho[2,3-*d*:2',3'-*d'*]benzo[1,2-*b*:4,5-*b'*]dithiophene ( $\text{C}_{10}$ -DNBDT-NW)<sup>1</sup> is uniaxially and compressively strained for 3% simply by bending the flexible substrate. With this strain, the field-effect mobility increases dramatically from 9.7  $\text{cm}^2/\text{Vs}$  to 16.5  $\text{cm}^2/\text{Vs}$  by up to 70%, which is reversible and repeatable for successive bending. Combined with X-ray diffraction and low temperature measurement, a series of calculations based on density functional theory reveal the origin of the enhanced charge transport to be the suppression of the thermal fluctuation of the molecules rather than the slight change of the band structure. Our work shows that compression of the crystal structure directly hinders molecular vibrations and thus leads to the suppression of dynamic disorder, which is a unique mechanism in soft organic semiconductors.

**1:03PM Y33.00010 Illumination of Conjugated Polymer in Solution Alters its Conformation and Thermodynamics: The Role of Incident Light Intensity, Wavelength and Exposure Time**, BRIAN MORGAN, University of Tennessee, MARK DADMUN, University of Tennessee, Oak Ridge National Laboratory — The importance of chain structure in conjugated polymer-based material active layers and its relation to device efficiencies in OPVs, organic field transistors, and OLEDs, has been well established. However the influence of light absorption on the conjugated polymer structure is not well understood. We have employed small angle neutron scattering to investigate structural changes occurring in solutions of poly(3-hexylthiophene-2,5-diyl) with exposure to white light. Our previous results indicate significant change in the structure of the polymer upon illumination, an effect we attribute to an alteration in the thermodynamic interactions of the polymer with the surrounding solvent. In order to further our understanding of this phenomenon, we have studied the modulation of these light/dark structural changes as a function of solvent choice, incident light intensity, illumination wavelength, and light exposure duration. Analysis of this data allows refinement and increased control of these light-initiated effects, moving our efforts closer to the development of a powerful, non-destructive, and tunable method for controlling polymer conformation in solution and novel light-responsive materials.

**1:15PM Y33.00011 Real-time charge carrier motion in P3HT studied with Kelvin Probe Microscopy<sup>1</sup>**, CHLOE CASTANEDA, ALYINA ZAIDI, JASON MOSCATELLO, KATHERINE AIDALA, Mount Holyoke College — We have developed a technique that uses scanning probe microscopy (SPM) to study the real-time injection and extraction of charge carriers in organic semiconductor devices. We investigate P3HT (full name) in an inverted field effect transistor geometry with gold electrodes. By positioning the SPM tip at an individual location and using Kelvin probe microscopy to record the potential over time, we can record how the charge carriers respond to changing the backgate voltage while the source and drain electrodes are grounded. We see relatively fast screening for negative backgate voltages because holes are quickly injected into the P3HT film. The screening is slower for positive gate voltages, because some of these holes are trapped and therefore less mobile. We compare P3HT transistors with different fabrication procedures that are expected to change the trap distribution: no silanization of the oxide and no annealing, silanization and no annealing, and both silanization and annealing. By incrementally stepping the gate voltage, we probe different trap depths. The recorded change in potential over time is best fit by a double exponential, suggesting two physical mechanisms involved in screening.

<sup>1</sup>This work is supported by NSF grant DMR-0955348, and the Center for Hierarchical Manufacturing at the University of Massachusetts, Amherst (NSF CMMI-1025020).

**1:27PM Y33.00012 Spatially resolved charge transport study in discotic liquid crystalline organic semiconductors**, SANJOY PAUL, Department of Physics, Kent State University, ALEXANDER SEMYONOV, Department of Chemistry and Biochemistry, Kent State University, NATHAN J. DAWSON, KENNETH D. SINGER, Department of Physics, Case Western Reserve University, ROBERT J. TWIEG, Department of Chemistry and Biochemistry, Kent State University, BRETT ELLMAN, Department of Physics, Kent State University — Spatially resolved time-of-flight photogeneration and mobility have been measured on a discotic liquid crystalline organic semiconductor using scanning time-of-flight microscopy (STOFm). STOFm simultaneously obtains time-of-flight transients and polarized transmittance across the sample. Various shapes in time-of-flight transients were observed and extracted charge transport parameters such as photogeneration efficiency, mobility, and trapping show significant spatial variation. In some cases these can be linked to electrode surface inhomogeneities. Detailed measurement methodology, experimental results and challenges in their analysis will be discussed.

**1:39PM Y33.00013 The Effects of Stoichiometry on the Optical Properties of PTZ-TCNQ Charge Transfer Crystals**, IRIS STONE, JAYDEEP JOSHI, George Mason University, ROBERT SMITH, SCOTT MELIS, EDWARD VAN KEUREN, Georgetown University, PATRICK VORA, George Mason University — Charge transfer (CT) crystals are two-component organic materials formed by stacked pairs of donor and acceptor molecules. Depending on the choice of donor and acceptor molecules it is possible to achieve semiconducting, insulating, or metallic characteristics, making the CT crystal platform potentially transformative for applications in low-cost flexible electronics. The use of phenothiazine (PTZ) donors and tetracyanoquinodimethane (TCNQ) acceptors is predicted to result in a semiconducting state with high electron and hole mobilities, properties that are ideal for ambipolar transistors. Here, we seek to understand the effect of stoichiometry on the optical and electronic properties of PTZ:TCNQ CT crystals by comparing nanowires with 1:1 stoichiometry to a novel 3:1 stoichiometry using temperature-dependent optical spectroscopy. Ensemble photoluminescence and absorption measurements indicate that a CT state forms in the 1:1 sample, whereas the 3:1 sample exhibits weaker coupling between TCNQ and PTZ. These results support a strong correlation between stoichiometry and optical properties. Our observations give important insight into how the intermolecular coupling varies with stoichiometry and are crucial to future efforts to realize an organic ambipolar transistor.

**1:51PM Y33.00014 Quantitative Probes of Electron-Phonon Coupling in an Organic Charge-Transfer Material**, AARON RURY, SHAYNE SORENSON, ERIC DRISCOLL, JAHAN DAWLATY, University of Southern California — While organic charge transfer (CT) materials may provide alternatives to inorganic materials in electronics and photonics applications, properties central to applications remain understudied in these organic materials. Specifically, electron-phonon coupling plays a pivotal role in electronic applications yet this coupling in CT materials remains difficult to directly characterize. To better understand the suitability of organic CT materials for electronic applications, we have devised an experimental technique that can directly assess electron-phonon coupling in a model organic CT material. Upon non-resonant interaction with an ultrafast laser pulse, we show that coherent excitation of Raman-active lattice vibrations of quinhidrone, a 1:1 co-crystal of the hydroquinone and p-benzoquinone, modulates the energies of electronic transitions probed by a white light pulse. Using a well-established theoretical framework of vibrational quantum beat spectra across the probe bandwidth, we quantitatively extract the parameters describing these electronic transitions to characterize electron-phonon coupling in this material. In conjunction with temperature-dependent resonance Raman measurements, we assess the hypothesis that several sharp transitions in the near-IR correspond to previously unknown excitonic states of this material. These results and their interpretation set the foundation for further elucidation of the one of the most important parameters in the application of organic charge-transfer materials to electronics and photonics.

**2:03PM Y33.00015 Influence of structural fluctuations on lifetimes of adsorbate states at hybrid organic-semiconductor interfaces<sup>1</sup>**, M. MÜLLER, CIC nanoGUNE, San-Sebastián, D. SÁNCHEZ-PORTAL, CSIC, San-Sebastián, Spain, H. LIN, Univ. Milano-Bicocca, Italy, G. FRATESI, Univ. Milano, Italy, G.P. BRIVIO, Univ. Milano-Bicocca, Italy, A. SELLONI, Princeton Univ., USA — On the road towards a more realistic description of charge transfer processes at hybrid organic-semiconductor interfaces for photovoltaic applications we extend our first-principles scheme for the extraction of elastic linewidths to include the effects of structural fluctuations. Based on snapshots obtained from Car-Parinello molecular dynamics simulations at room temperature, we set up geometries in which dye molecules at interfaces are attached to a semi-infinite TiO<sub>2</sub> substrate. The elastic linewidths are computed using a Green's function method. This effectively introduces the coupling to a continuum of states in the substrate. In particular we investigate catechol and isonicotinic acid on rutile(110) and anatase(101) at the level of semi-local density functional theory. We perform multiple calculations of linewidths and peak-positions associated with the adsorbate's frontier orbitals for different geometric configurations to obtain a time-averaged analysis of such physical properties. We compare the results from the considered systems to understand the effects of dynamics onto interfacial charge transfer and systematically assess the dependence of the extracted elastic lifetimes on the relative alignment between adsorbate and substrate states.

**11:15AM Y35.00001 Collective synchronization of divisions in *Drosophila* development.**<sup>1</sup>, MASSIMO VERGASSOLA, Univ of California - San Diego — Mitoses in the early development of most metazoans are rapid and synchronized across the entire embryo. While diffusion is too slow, in vitro experiments have shown that waves of the cell-cycle regulator Cdk1 can transfer information rapidly across hundreds of microns. However, the signaling dynamics and the physical properties of chemical waves during embryonic development remain unclear. We develop FRET biosensors for the activity of Cdk1 and the checkpoint kinase Chk1 in *Drosophila* embryos and exploit them to measure waves in vivo. We demonstrate that Cdk1 chemical waves control mitotic waves and that their speed is regulated by the activity of Cdk1 during the S-phase (and not mitosis). We quantify the progressive slowdown of the waves with developmental cycles and identify its underlying control mechanism by the DNA replication checkpoint through the Chk1/Wee1 pathway. The global dynamics of the mitotic signaling network illustrates a novel control principle: the S-phase activity of Cdk1 regulates the speed of the mitotic wave, while the Cdk1 positive feedback ensures an invariantly rapid onset of mitosis. Mathematical modeling captures the speed of the waves and predicts a fundamental distinction between the S-phase Cdk1 trigger waves and the mitotic phase waves, which is illustrated by embryonic ablation experiments.

**11:51AM Y35.00002 Collective Calcium Dynamics in Networks of Communicating Cells**, TOMMY BYRD, Purdue University, GARRETT POTTER, BO SUN, Oregon State University, ANDREW MUGLER, Purdue University — Cells can sense and encode information about their environment with remarkable precision. These properties have been studied extensively for single cells, but intercellular communication is known to be important for both single- and multicellular organisms. Here, we examine calcium dynamics of fibroblast cells exposed to external ATP stimuli, and the effects of communication and stimulus strength on cells' response. Experimental results show that increasing communication strength induces a greater fraction of cells to exhibit oscillatory calcium dynamics, but the frequencies of oscillation do not systematically shift with ATP strength. We developed a model of calcium signaling by adding noise, communication, and cell-to-cell variability to the model of Tang and Othmer<sup>1</sup>. This model reproduces cells' increased tendency to oscillate as a function of communication strength, and frequency encoding is nearly removed at the global level. Our model therefore suggests that the propensity of cells to oscillate, rather than frequency encoding, determines the response to external ATP. These results suggest that the system lies near a critical boundary separating non-oscillatory and oscillatory calcium dynamics.

**12:03PM Y35.00003 Precision of multicellular gradient sensing with cell-cell communication**, ANDREW MUGLER, Department of Physics and Astronomy, Purdue University, ANDRE LEVCHENKO, Department of Biomedical Engineering and Yale Systems Biology Institute, Yale University, ILYA NEMENMAN, Departments of Physics and Biology, Emory University — Gradient sensing underlies diverse biological processes. In principle, bigger “detectors (cells or groups of cells) make better sensors, since then concentrations measured at the front and back of a detector are more different, and the gradient can be determined with higher precision. Indeed, experiments have shown that populations of cells detect gradients more precisely than single cells. However, this argument neglects the fact that information must be communicated between different parts of the detector, and the communication process introduces its own noise. Here we derive the fundamental limits to the precision of gradient sensing with cell-cell communication and temporal integration. We find that communication imposes its own sensory length scale, beyond which the precision cannot increase no matter how large the cell population grows. We also find that temporal integration couples the internal communication with the external signal diffusion, imposing an additional limit on the precision. We discuss how these limits can be improved by a strategy with two communicated molecular species, which we term “regional excitation/global inhibition. We compare our findings to experiments with communicating epithelial cells, and infer a sensor length scale of about 4 cells.

**12:15PM Y35.00004 Collective synchronization of self/non-self discrimination in T cell activation, across multiple spatio-temporal scales**, GREGOIRE ALTAN-BONNET, National Cancer Institute, Bethesda MD — The immune system is a collection of cells whose function is to eradicate pathogenic infections and malignant tumors while protecting healthy tissues. Recent work has delineated key molecular and cellular mechanisms associated with the ability to discriminate self from non-self agents. For example, structural studies have quantified the biophysical characteristics of antigenic molecules (those prone to trigger lymphocyte activation and a subsequent immune response). However, such molecular mechanisms were found to be highly unreliable at the individual cellular level. We will present recent efforts to build experimentally validated computational models of the immune responses at the collective cell level. Such models have become critical to delineate how higher-level integration through nonlinear amplification in signal transduction, dynamic feedback in lymphocyte differentiation and cell-to-cell communication allows the immune system to enforce reliable self/non-self discrimination at the organism level. In particular, we will present recent results demonstrating how T cells tune their antigen discrimination according to cytokine cues, and how competition for cytokine within polyclonal populations of cells shape the repertoire of responding clones. Additionally, we will present recent theoretical and experimental results demonstrating how competition between diffusion and consumption of cytokines determine the range of cell-cell communications within lymphoid organs. Finally, we will discuss how biochemically explicit models, combined with quantitative experimental validation, unravel the relevance of new feedbacks for immune regulations across multiple spatial and temporal scales.

**12:51PM Y35.00005 A generic spatial-stochastic framework for quantifying noisy information flow in multicellular systems**, THOMAS SOKOLOWSKI<sup>1</sup>, GAŠPER TKAČIK<sup>2</sup>, IST Austria — Spatio-temporal protein signals play a crucial role in communicating information within and between cells. However, their ability to convey signals robustly is hampered by noise in gene regulation and biochemical transport, occurring at low copy numbers. While we increasingly understand distinct strategies of biochemical noise control, it remains unclear how nature orchestrates them to maximize information flow. Our recent work extends our information-theoretic framework for gene regulation to an explicitly spatial setting. We constructed a stochastic model enabling fast calculation of local means and variances in a spatially coupled gene regulatory system, which we use for rigorous quantification of information flow in an ensemble of units sensing a spatially distributed input and exchanging information via diffusion. By applying our framework to the paradigmatic Bcd-Hbk system in early fly development, we demonstrate that diffusive coupling can be of substantial benefit in encoding positional information, and uncover a novel optimal regulatory strategy relying on spatial coupling. Thanks to the generic methodology employed, our framework is universally applicable for realistic predictive modeling and data-driven inference of multicellular systems engaging in noisy communication.

**1:03PM Y35.00006 Increased dimensionality of cell-cell communication can decrease the precision of gradient sensing<sup>1</sup>**, TYLER SMITH, Department of Physics, Emory University, ANDRE LEVCHENKO, Department of Biomedical Engineering and Yale Systems Biology Institute, Yale University, ILYA NEMENMAN, Department of Physics, Emory University, ANDREW MUGLER, Department of Physics and Astronomy, Purdue University — Gradient sensing is a biological computation that involves comparison of concentrations measured in at least two different locations. As such, the precision of gradient sensing is limited by the intrinsic stochasticity in the communication that brings such distributed information to the same location. We have recently analyzed such limitations experimentally and theoretically in multicellular gradient sensing in mammary epithelial cell organoids. For 1d chains of collectively sensing cells, the communication noise puts a severe constraint on how the accuracy of gradient sensing increases with the number of cells in the sensor. A question remains as to whether the effect of the noise can be mitigated by the extra spatial averaging allowed in sensing by 2d and 3d cellular organoids. Here we show using computer simulations that, counterintuitively, such spatial averaging decreases gradient sensitivity (while it increases concentration sensitivity). We explain the findings analytically and propose that a recently introduced Regional Excitation - Global Inhibition model of gradient sensing can overcome this limitation and use 2d or 3d spatial averaging to improve the sensing accuracy.

**1:27PM Y35.00008 Synthetic Quorum Sensing and Induced Aggregation in Model Microcapsule Colonies with Repressilator Feedback**, HENRY SHUM, VICTOR YASHIN, ANNA BALAZS, University of Pittsburgh — We model a system of synthetic microcapsules that communicate chemically by releasing nanoparticles or signaling molecules. These signaling species bind to receptors on the shells of capsules and modulate the target shells permeability, thereby controlling nanoparticle release from the target capsule. Using the repressilator regulatory network motif, whereby three species suppress the production of the next in a cyclic fashion, we show that large amplitude oscillations in nanoparticle release can emerge when many capsules are close together. This exemplifies quorum sensing, which is the ability of cells to gauge their population density and collectively initiate a new behavior once a critical density is reached. We present a physically realizable model in which the oscillations exhibited in crowded populations induce aggregation of the microcapsules, mimicking complex biological behavior of the slime mold *Dictyostelium discoideum* with only simple, synthetic components. We also show that the clusters can be dispersed and reformed repeatedly and controllably by addition of chemical stimuli, demonstrating possible applications in creating reconfigurable or programmable materials.

**1:39PM Y35.00009 Limits to collaborative concentration sensing in cell populations<sup>1</sup>**, SEAN FANCHER, ANDREW MUGLER, Department of Physics and Astronomy, Purdue University — Cells sense chemical concentrations with a precision that approaches the physical limit set by molecular diffusion. Recent experiments have vividly shown that cells can beat this limit when they communicate. We derive the physical limits to concentration sensing for cells that communicate over short distances by directly exchanging small molecules across their membranes (juxtacrine signaling), and over long distances by secreting and absorbing a diffusive messenger molecule (paracrine signaling). In the latter case, we find that the cell spacing that optimizes precision can be large, due to a tradeoff between maintaining communication strength and reducing signal cross-correlations. This leads to the surprising result that paracrine signaling allows more precise sensing than juxtacrine signaling for sufficiently large populations, even though this means that the cells are spaced far apart. We compare our results to recent experiments.

**11:15AM Y36.00001 Intermediate response of complex fluids with biophysical implications**, HAIM DIAMANT, Tel Aviv University — Over sufficiently large distances any complex fluid responds as a continuous medium, characterized by bulk viscoelastic moduli. But how large is “sufficiently large”? Close examination of the competing sub-asymptotic term reveals a distinctive spatio-temporal regime, intermediate between the small-scale and large-scale responses. In materials such as semiflexible polymer networks this regime governs the dynamics over a broad range of distances, pushing the crossover to the bulk behavior to a distance much larger than the structural correlation length. The validity of these findings has been confirmed by two-point microrheology of entangled F-actin networks, where the crossover distance was found to be of micron scale—i.e., relevant to biological cells.<sup>1</sup> We discuss consequences of the intermediate response for the fluctuations of small objects and membranes inside actin networks.

**11:27AM Y36.00002 Mechanical response of biopolymer double networks<sup>1</sup>**, JOSHUA CARROLL, MOUMITA DAS, Rochester Institute of Technology — We investigate a double network model of articular cartilage (AC) and characterize its equilibrium mechanical response. AC has very few cells and the extracellular matrix mainly determines its mechanical response. This matrix can be thought of as a double polymer network made of collagen and aggrecan. The collagen fibers are stiff and resist tension and compression forces, while aggrecans are flexible and control swelling and hydration. We construct a microscopic model made of two interconnected disordered polymer networks, with fiber elasticity chosen to qualitatively mimic the experimental system. We study the collective mechanical response of this double network as a function of the concentration and stiffness of the individual components as well as the strength of the connection between them using rigidity percolation theory. Our results may provide a better understanding of mechanisms underlying the mechanical resilience of AC, and more broadly may also lead to new perspectives on the mechanical response of multicomponent soft materials.

**11:39AM Y36.00003 The mechanics of endothelial gap formation**, JOYJIT CHATTORAJ, EMANUELA DEL GADO, Georgetown Univ, C. COREY HARDIN, Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, MA, RAMASWAMY KRISHNAN, Center for Vascular Biology Research, Beth Israel Deaconess Medical Center, Boston, MA — The vascular endothelium is a layer of specialized cells, referred to as endothelial cells (EC) that line the internal surfaces of blood vessels and are largely responsible for regulating the transit of fluids, solutes and immune system cells from the circulation, across the vessel wall, and into the tissues. We investigate the physics of the mechanical events that may proceed and eventually lead to dramatic increase of its permeability, leading to serious illness. In combination with experiments measuring local stresses and gap formation in EC in different conditions, we devise a minimal model based on an amorphous assembly of adhesive particles, subjected to an imposed tension. Numerical simulations of the model show that, as a function of the rate at which the tension is imposed, the system goes from an elastic regime in which small gaps increase in number to a plastic one, where pre-existing gaps increase in size, and internal stresses display large heterogeneities and long range correlations. This second regime bears intriguing similarities with the experimental finding in EC monolayers.

**11:51AM Y36.00004 A simple polymeric model describes cell nuclear mechanical response**, EDWARD BANIGAN, Department of Physics & Astronomy, Northwestern University, ANDREW STEPHENS, Department of Molecular Biosciences, Northwestern University, JOHN MARKO, Departments of Physics & Astronomy and Molecular Biosciences, Northwestern University — The cell nucleus must continually resist inter- and intracellular mechanical forces, and proper mechanical response is essential to basic cell biological functions as diverse as migration, differentiation, and gene regulation. Experiments probing nuclear mechanics reveal that the nucleus stiffens under strain, leading to two characteristic regimes of force response. This behavior depends sensitively on the intermediate filament protein lamin A, which comprises the outer layer of the nucleus, and the properties of the chromatin interior. To understand these mechanics, we study a simulation model of a polymeric shell encapsulating a semiflexible polymer. This minimalistic model qualitatively captures the typical experimental nuclear force-extension relation and observed nuclear morphologies. Using a Flory-like theory, we explain the simulation results and mathematically estimate the force-extension relation. The model and experiments suggest that chromatin organization is a dominant contributor to nuclear mechanics, while the lamina protects cell nuclei from large deformations.

**12:03PM Y36.00005 The Effect of Predators on Cholera Biofilms: If it Lyses, We Can Smash It**, ARBEN KALZIQI, ERYN BERNARDY, JACOB THOMAS, WILL RATCLIFF, BRIAN HAMMER, PETER YUNKER, Georgia Institute of Technology — Many microbes form biofilms dense clumps of cells and protein on surfaces. Biofilms are complex communities that facilitate the study of biological competition (e.g., two types of microbes may compete to form a biofilm in the same location) and interesting physics (e.g., the source of a biofilm's rigidity). *Vibrio cholerae* can produce biofilms which have a network-like structure; however, cholera can be genetically engineered to kill other cholera with different genotypes, which leaves behind a structureless slime rather than such a biofilm. Through mechanical creep testing of both predator-prey and non-predator populations, we found that the predator-prey population responds viscously and decreases in height with repeated compression, whereas the non-predator population responds elastically and maintains its original height. The current work suggests that cell lysis after killing disrupts biofilm formation, preventing microbial colonies from forming rigid networks.

**12:15PM Y36.00006 Mechanical Properties of a Primary Cilium Measured by Resonant Oscillation**, ANDREW RESNICK, Cleveland State University — Primary cilia are ubiquitous mammalian cellular substructures implicated in an ever-increasing number of regulatory pathways. The well-established 'ciliary hypothesis' states that physical bending of the cilium (for example, due to fluid flow) initiates signaling cascades, yet the mechanical properties of the cilium remain incompletely measured, resulting in confusion regarding the biological significance of flow-induced ciliary mechanotransduction. In this work we measure the mechanical properties of a primary cilium by using an optical trap to induce resonant oscillation of the structure. Our data indicate 1), the primary cilium is not a simple cantilevered beam, 2), the base of the cilium may be modeled as a nonlinear rotatory spring, the linear spring constant 'k' of the cilium base calculated to be  $(4.6 \pm 0.62) \times 10^{-12}$  N/rad and nonlinear spring constant ' $\alpha$ ' to be  $(-1 \pm 0.34) \times 10^{-10}$  N/rad<sup>2</sup>, and 3) the ciliary base may be an essential regulator of mechanotransduction signalling. Our method is also particularly suited to measure mechanical properties of nodal cilia, stereocilia, and motile cilia, anatomically similar structures with very different physiological functions.

**12:27PM Y36.00007 Composition and Humidity Response of the Black Widow Spider's Gumfoot Silk and its Implications on Adhesion**, DHARAMDEEP JAIN, CI ZHANG, LYDIA ROSE COOL, TODD A. BLACKLEDGE, CHRYS WEDEMIOTIS, TOSHIKAZU MIYOSHI, ALI DHINOJWALA, University of Akron — Humidity plays an important part in the performance of biomaterials such as pollen, gecko toe, wheat awns, bird feathers and dragline silk. Capture silk produced by web building spiders form an interesting class of humidity responsive biological glues. The adhesive properties of the widely studied 'viscid silk' produced by orbweb-weaving spiders is highly humidity sensitive. On the other hand, relatively less is known about the dependence of composition and humidity response towards adhesion for 'gumfoot' silk produced by cobweb-weaving spiders. In the present study, we investigate the gumfoot silk produced by Black Widow using adhesion mechanics, microscopy and spectroscopic methods. The results show the presence of hygroscopic salts, glycoproteins and previously known spider coating peptides in silk and their importance in the humidity response and adhesion. The current study elucidates the role of constituents of capture silk in its adhesion mechanism and offers insights to novel ways for fabricating bio-inspired adhesives.

**12:39PM Y36.00008 Flexibility of bacterial type IV pili determined using atomic force microscopy**, JOSH MOGYOROS, SHUN LU, University of Guelph, HANJEONG HARVEY, LORI BURROWS, McMaster University, ROBERT WICKHAM, JOHN DUTCHER, University of Guelph — Type IV pili (T4P) are very thin protein filaments extended and retracted from the surface of certain Gram-negative bacteria. Pili play a major role in processes such as adhesion, twitching motility and biofilm formation. We used atomic force microscopy (AFM) to perform force spectroscopy measurements on T4P of *P. aeruginosa*. Bacteria were adhered to the end of an AFM cantilever that was brought into contact with a substrate, allowing the pili to adhere. Force-separation curves were collected by retracting the cantilever, corresponding to the stretching of the T4P that was well described by the worm-like chain (WLC) model. Distinct peaks were observed in the distributions of the best-fit values of the persistence length  $L_p$  on two different surfaces, providing strong evidence for close-packed bundling of very flexible T4P [1]. Surprisingly, the most prominent value of  $L_p \sim 1$  nm is significantly less than the  $\sim 8$  nm length of the PilA subunit. We have investigated this intriguing result by refining our protocol to combine AFM with fluorescence microscopy to isolate a single bacterium on a colloidal probe, as well as critically examining the applicability of the WLC model. [1] S. Lu et al., Biophys. J. 108, 2865 (2015).

**12:51PM Y36.00009 Passage times of confined cancer cells and deformable particles flowing through a microfluidic channel**, ZEINA KHAN, NABIOLLAH KAMYABI, FAZLE HUSSAIN, SIVA VANAPALLI, Texas Tech University — Circulating tumor cells, the primary cause of cancer metastasis, have to navigate through tight extracellular matrix and capillaries. Unfortunately, understanding of the hydrodynamic interactions between cells and narrow vessel walls is lacking. Using a microfluidic channel of rectangular cross-section, we investigate cell hydrodynamic behavior by measuring cell confinement, passage time through the microchannel, and excess pressure drop. Testing with highly and lowly aggressive cancer cells shows that passage time may not always be indicative of cancer cell aggressiveness as the relationship among passage time, friction and rheology is complex. Transport of deformable particles including droplets of varying viscosity and interfacial tension, as well as elastic particles of different elastic moduli, reveals that passage times depend on particle size and, contrary to prior claims, on viscosity but not on elastic modulus. We also find that particle viscosity and not modulus controls the friction force and lubrication film thickness, suggesting that cancer cell viscosity rather than elasticity controls cell transport on short time-scales.

**1:03PM Y36.00010 Mechanics governs single-cell signaling and multi-cell robustness in biofilm infections.**<sup>1</sup> , VERNITA GORDON, The University of Texas at Austin — In biofilms, bacteria and other microbes are embedded in extracellular polymers (EPS). Multiple types of EPS can be produced by a single bacterial strain - the reasons for this redundancy are not well-understood. Our work suggests that different polymers may confer distinct mechanical benefits. Our model organism is *Pseudomonas aeruginosa*, an opportunistic human pathogen that forms chronic biofilm infections associated with increased antibiotic resistance and evasion of the immune defense. Biofilms initiate when bacteria attach to a surface, sense the surface, and change their gene expression. Changes in gene expression are regulated by a chemical signal, cyclic-di-GMP. We find that one EPS material, called "PEL," enhances surface sensing by increasing mechanical coupling of single bacteria to the surface. Measurements of bacterial motility suggest that PEL may increase frictional interactions between the surface and the bacteria. Consistent with this, we show that bacteria increase cyclic-di-GMP signaling in response to mechanical shear stress. Mechanosensing has long been known to be important to the function of cells in higher eukaryotes, but this is one of only a handful of studies showing that bacteria can sense and respond to mechanical forces. For the mature biofilm, the embedding polymer matrix can protect bacteria both chemically and mechanically. *P. aeruginosa* infections in the cystic fibrosis (CF) lung often last for decades, ample time for the infecting strain(s) to evolve. Production of another EPS material, alginate, is well-known to tend to increase over time in CF infections. Alginate chemically protects biofilms, but also makes them softer and weaker. Recently, it is being increasingly recognized that bacteria in chronic CF infections also evolve to increase PSL production. We use oscillatory bulk rheology to determine the unique contributions of EPS materials to biofilm mechanics. Unlike alginate, increased PSL stiffens biofilms. Increasing both PSL and alginate expression increases the energy cost to break the biofilm. We compare the elastic moduli of biofilms to estimated stresses exerted by phagocytotic immune cells, and infer that increased PSL could confer a mechanical fitness benefit.

**1:39PM Y36.00011 Suspended Solid-state Membranes on Glass Chips with Sub 1-pF Capacitance for Biomolecule Sensing Applications** , CHEN-CHI CHIEN, ADRIAN BALAN, REBECCA ENGELKE, MARIJA DRNDIC, University of Pennsylvania — Solid-state membranes are finding use in many applications in nanoelectronics and nanomedicine, from single molecule sensors to water filtration, and yet many of their electronics applications are limited by the current noise and low bandwidth stemming from the relatively high capacitance (more than 10 pF) of the membrane chips. To address this problem, we devised an integrated fabrication process to grow and define circular silicon nitride membranes on glass chips that successfully lower the chip capacitance to below 1 pF. We use these devices to demonstrate low-noise, high-bandwidth DNA translocation measurements. We also make use of this versatile, low-capacitance platform to suspend other thin, two-dimensional membranes such as graphene.

**11:15AM Y37.00001 Tearing Fracture of Polymer Foam Sheet**<sup>1</sup> , ATSUSHI TAKEI, KO OKUMURA, Ochanomizu Univ. — We study crack propagation in a sheet of polymer foam. The sheet was stretched, and an initial crack was introduced to induce the crack propagation. When the sheet width is shorter than the crack length, the energy release rate (ERR)  $G$  of the system is independent of the crack length and constant during the propagation. Under the constant ERR condition, we find that the crack propagates at a constant speed. We observed the crack propagation for various values of ERR by changing the width of the sheet and the applied strain. Depending on values  $G$  of ERR, the measured velocity of the crack propagation was in the range from 0.01 mm/s to 10000 mm/s. We also found power laws between the velocity of the crack  $V$  and  $G$ . While in the literature the power law with the exponent close to three ( $V \sim G^3$ ) has been reported, we found that polymer foam sheets have different exponents depending on physical characteristics of polymer foam. In this presentation, we report the experimental result and its analysis.

**11:27AM Y37.00002 Effect of system compliance on crack nucleation in soft materials** , SHRUTI RATTAN, ALFRED CROSBY, UMass Amherst — Puncture mechanics in soft materials is critical for the development of new surgical instruments, robot assisted-surgery as well as new materials used in personal protective equipment. However, analytical techniques to study this important deformation process are limited. We have previously described a simple experimental method to study the resistive forces and failure of a soft gel being indented with a small tip needle. We showed that puncture stresses can reach two orders of magnitude greater than the material modulus and that the force response is insensitive to the geometry of the indenter at large indentation depths. Currently, we are examining the influence of system compliance on crack nucleation (e.g. puncture) in soft gels. It is well known that system compliance influences the peak force in adhesion and traditional fracture experiments; however, its influence on crack nucleation is unresolved. We find that as the system becomes more compliant, lower peak forces required to puncture a gel of certain stiffness with the same indenter were measured. We are developing scaling relationships to relate the peak puncture force and system compliance. Our findings introduce new questions with regard to the possibility of intrinsic materials properties related to the critical stress and energy for crack nucleation in soft materials.

**11:39AM Y37.00003 Crack propagation in attractive colloidal systems** , LAURA ROSSI, TRIET DANG, University of Amsterdam, MAXIME LEFRANC, PAUL LE FLOCH, ELISABETH BOUCHAUD, ESPCI ParisTech, PETER SCHALL, University of Amsterdam — Despite its importance, the fracture of materials, especially the regime of slow, plastic fracture, remains poorly understood. This is especially true in amorphous materials, where local inhomogeneities and structural disorder are crucial to determine the mode of failure, yet they cannot be modeled with classical homogenization methods. We use new attractive colloidal systems to study fracture at time and length scales much longer than in molecular systems. In this specific project, we focus on gels made of fluorescent pNipam microgel particles aggregated via critical Casimir interactions, to analyze, at the microscopic level, nonlinear and dissipative processes in the material ahead of the propagating crack tip.

**11:51AM Y37.00004 Localized Plastic Deformation in Colloidal Micropillars** , DANIEL STRICKLAND, JYO LYN HOR, CARLOS ORTIZ, DAEYEON LEE, DANIEL GIANOLA, University of Pennsylvania — When driven beyond yield, many amorphous solids exhibit concentrated regions of large plastic strain referred to as shear bands. Shear bands are the result of localized, cooperative rearrangements of particles known as shear transformations (STs). STs are dilatatory: their operation results in an increase of free volume and local softening that leads to spatially concentrated plasticity. However, the evolution of STs into a macroscopic shear band remains poorly understood. To study the process, we perform compression experiments on amorphous colloidal micropillars. The micropillars, which are composed of fluorescent 3  $\mu\text{m}$  PMMA particles, are made freestanding so that shear banding instabilities are not suppressed by confining boundaries. During compression, we observe strong localization of strain in a band of the pillar. As deformation proceeds, the sheared region continues to dilate until it reaches the colloidal glass transition, at which point dilation terminates. We quantify a length scale by measuring the extent of spatial correlations in strain. This length scale decreases gradually with increasing dilation and becomes static beyond the glass transition. Our results reinforce the idea of yield as a stress-induced glass transition in amorphous solids.

**12:03PM Y37.00005 Theory of rate dependent fracture size effects**, ALESSANDRO TALONI, ALESSANDRO SELLERIO, STEFANO ZAPPERI, Center for Complexity and Biosystems - Physics Department, University of Milan La Statale" — The idea that the solid failure can be described by means of the Kramer theory, where the intrinsic energy barrier is reduced proportionally to the applied field, first appeared in material science to treat the kinetic fracture of solids under applied stresses and dates back to '40s. Most previous works focused on the thermal dependence of the average strength or the failure time in creep experiments and did not address the survival distribution and its size dependence. To this end, we start from recent theories developed for single-molecule pulling, where the molecule rate coefficient for rupture (or unbinding) is modified by the presence of an external time-dependent force, and we adjust it to a macroscopic elastic object. We generalize the extreme value theory to account for failures of materials with an explicit dependence on temperature, strain rate and size of the object. We show that in the limit of macroscopic objects, large strain rate and low temperature, thermal fluctuations are negligible and the usual extreme value theory is recovered. We provide the critical interpretation of several experiments in terms of our theory, furnishing a clearcut criterion for thermal effects to become relevant. [Phys. Rev. Applied, 024011]

**12:15PM Y37.00006 Major and minor slip-events in frictional stick-slip**<sup>1</sup>, GEORGIOS TSEKENIS, DEMET TATAR, SHMUEL RUBINSTEIN, DAVID WEITZ, MICHAEL AZIZ, FRANS SPAEPEN, Harvard Univ — Several universal phenomena characterize friction that are independent of the materials involved such as the logarithmic aging of the static friction coefficient and the logarithmic velocity weakening of the dynamic friction coefficient. We study dry friction between rough surfaces with programmed statistical profiles. By measuring the displacement field at the frictional interface we observe stick-slip behavior which reveals two kinds of slip: major events that tend to grow large and unbounded and minor events that usually stay small and bounded.

**12:27PM Y37.00007 Tribological Properties of Nanodiamonds in Aqueous Suspensions: Effect of the Surface Charge.**<sup>1</sup>, J. KRIM, ZIJIAN LIU, D.A. LEININGER, A. KOVILAND, A.I. SMIRNOV, North Carolina State University, O. SHENDAROVA, International Technology Center, Raleigh, NC, D.W. BRENNER, North Carolina State University — The presence of granular nanoparticulates, be they wear particles created naturally by frictional rubbing at a geological fault line or products introduced as lubricant additives, can dramatically alter friction at solid-liquid interfaces. Given the complexity of such systems, understanding system properties at a fundamental level is particularly challenging. The Quartz Crystal Microbalance (QCM) is an ideal tool for studies of material-liquid-nanoparticulate interfaces. We have employed it here to study the uptake and nanotribological properties of positively and negatively charged 5-15 nm diameter nanodiamonds dispersed in water[1] in the both the presence and absence of a macroscopic contact with the QCM electrode. The nanodiamonds were found to impact tribological performance at both nanometer and macroscopic scales. The tribological effects were highly sensitive to the sign of the charge: negatively (positively) charged particles were more weakly (strongly) bound and reduced (increased) frictional drag at the solid-liquid interface. For the macroscopic contacts, negatively charged nanodiamonds appeared to be displaced from the contact, while the positively charged ones were not. Overall, the negatively charged nanodiamonds were more stable in an aqueous dispersion for extended time periods.

**12:39PM Y37.00008 Transition from superlubrically sliding islands to pinned monolayer, demonstrated in Xe/Cu(111) (\*)**<sup>1</sup>, ROBERTO GUERRA, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy., ANDREA VANOSSI, CNR-IOM Democritos National Simulation Center, Via Bonomea 265, 34136 Trieste, Italy., ERIO TOSATTI, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy., TRIESTE NANOFRICTION TEAM — A molecular dynamics simulation case study of Xe on Cu(111) reveals unexpected information on the exceptionally smooth sliding state associated with incommensurate superlubricity which is argued to emerge in the large size limit of naturally incommensurate Xe islands. As coverage approaches a full monolayer, theory predicts an abrupt adhesion-driven two-dimensional density compression on the order of several per cent, implying a hysteretic jump from superlubric free islands to a pressurized  $\sqrt{2} \times \sqrt{2}$  commensurate (and pinned, and therefore immobile) monolayer. These results match with recent quartz crystal microbalance data which show remarkably large slip times with increasing submonolayer coverage, signalling superlubricity, followed by a dramatic drop to zero for the dense commensurate monolayer [1]. Careful analysis of this variety of island sliding phenomena should be essential in future applications of friction at crystal/adsorbate interfaces. (\*) Matching experimental work by M. Pierro, L. Bruschi, G. Mistura, G. Paolicelli, A. di Bona, S. Valeri. [1] M. Pierro, L. Bruschi, G. Mistura, G. Paolicelli, A. di Bona, S. Valeri, R. Guerra, A. Vannessi, E. **12:51PM Y37.00009 Elastic deformations disrupt structural superlubricity in large contacts**<sup>1</sup>, TRISTAN A. SHARP, Johns Hopkins University, LARS PASTEWKA, Karlsruher Institut für Technologie, MARK O. ROBBINS, Johns Hopkins University — Force microscopy experiments observe ultra-low friction between solids with incommensurate lattice structures. This phenomenon is referred to as superlubricity and is due to a cancellation of lateral forces because surfaces sample all relative local configurations with equal probability. We use simulations to show that elasticity disrupts superlubricity in sufficiently large circular contacts. The simulations include atomic-scale geometry and reach micron-scales. For rigid solids, cancellation is complete except at the contact boundary. The static friction force per contact area,  $\tau$ , falls as a power of contact radius,  $\tau \sim a^{-3/2}$ . Elastic deformations limit this cancellation when the contact radius  $a$  is larger than a characteristic length scale set by the core width of interfacial dislocations,  $b_{core}$ . For  $a > b_{core}$  sliding of moderately incommensurate contacts is dominated by dislocation motion and, at large  $a$ ,  $\tau$  approaches a constant value near the Peierls stress needed to move edge dislocations. Surprisingly, the stress in commensurate contacts drops to nearly the same value at large  $a$ . We conclude that true structural lubricity does not occur in large contacts, although the constant shear stress drops rapidly with  $b_{core}$ .

**1:03PM Y37.00010 Subharmonic Shapiro steps in sliding colloidal monolayers**<sup>1</sup>, ANDREA VANOSSI, CNR-IOM Democritos & SISSA, Trieste, Italy, STELLA PARONUZZI, SISSA, Trieste, Italy, GABRIELE FORNASIER, NICOLA MANINI, Dipartimento di Fisica, Università di Milano, Italy, GIUSEPPE E. SANTORO, SISSA, Trieste, Italy, ERIO TOSATTI, SISSA & ICTP, Trieste, Italy — We examine the possibility to observe dynamical mode locking, in the form of Shapiro steps, when a time-periodic potential modulation is applied to two mutually sliding incommensurate 2D lattices. Specifically we present realistic MD simulations of a monolayer of charged colloids that are dragged by an external force over an optically generated periodic potential, where the colloid sliding is enacted through the motion of soliton or antisoliton lines between locally commensurate domains. Clear integer Shapiro steps, with the synchronous rigid advancement of the whole monolayer, known from previous studies [1], are found. The jump between one step and the next during each AC cycle corresponding to particles jumping from one patch to the next, across the soliton boundary. We find additional smaller "subharmonic" steps. Here, the overall colloid advancement takes several AC cycles. At each cycle, different subsets of particles negotiate the soliton line between commensurate domains [2]. The wide parameter tunability of colloid monolayers makes these predictions potentially easy to access in an experimentally rich 2D geometry. [1] A. Libal et al., Phys. Rev. Lett. 96, 188301 (2006). **1:15PM Y37.00011 Superlubric-pinned Aubry transition of two dimensional monolayers in optical lattices.**<sup>1</sup> , DAVIDE MANDELLI, SISSA, Trieste, ANDREA VANOSI, CNR-IOM Democritos and SISSA, Trieste, NICOLA MANINI, University of Milano, ERIO TOSATTI, SISSA and ICTP, Trieste — Two-dimensional (2D) crystalline colloidal monolayers sliding over a laser-induced optical lattice “corrugation” potential emulate friction between ideal crystal surfaces. Static friction is always present when the monolayer and the optical lattices are commensurate, but when they are incommensurate the presence or absence of static friction depends upon the system parameters. In 1D, at the Aubry dynamical phase transition the static friction goes continuously from zero (superlubricity) to finite as the periodic corrugation strength is increased. We look for the Aubry-like transition in the more realistic 2D case of a monolayer in an incommensurate periodic potential using molecular dynamics simulations. Results confirm a clear and sharp 2D superlubric-pinned transition upon increasing corrugation strength. Unlike the 1D Aubry transition which is continuous, the 2D transition is first-order, with a jump of static friction. At the 2D Aubry transition there is no change of symmetry, a sudden rise of the colloid-colloid interaction energy, and a compensating drop of the colloid-corrugation energy. The observability of the superlubric-pinned colloid transition is proposed and discussed [1]. [1] D. Mandelli, et al., Phys. Rev. B, to be published (2015).

**1:27PM Y37.00012 Superlubricity in a nutshell.**<sup>1</sup> , ERIO TOSATTI, SISSA and ICTP, Trieste, DAVIDE MANDELLI, SISSA, Trieste, ANDREA VANOSI, CNR-IOM Democritos and SISSA, Trieste — Cold ion chains in optical lattices emulate the Frenkel-Kontorova model, whose frictional behavior depends on commensurability or incommensurability between the two lattices. In the latter and more interesting case, there are two different regimes: one with pinning and static friction, and one without pinning, called superlubric. Only in an infinite chain the two regimes exist, separated by a dynamical Aubry transition. A cold ion chain is necessarily finite and short, we nevertheless proposed that a clear remnant of that transition should persist in trapped ion chains[1]. Recent experiments showed how in fact a small number of ions suffices to demonstrate incommensuration effects, with a change of friction by orders of magnitude from matched to mismatched geometries[2]. Here we present simulation results suggesting for increasing optical lattice amplitude a clear vestigial Aubry transition for very few ions, with a weak dependence upon the ion number and a stronger one upon the relative mismatch. A properly chosen amplitude should therefore show the vestigial transition from pinning at small mismatch to superlubricity at large mismatch. Alternatively, a chain which at  $T=0$  is pinned at all mismatches could develop an Aubry transition at finite temperature to a state of “thermally induced superlubricity”, due to the thermal smearing of the optical lattice amplitude. **1:39PM Y37.00013 An Artificial Ising System with Phononic Excitations** , HAMED GHAFARI, W.ASHLEY GRIFFITH, University of Texas, PHILIP BENSON , School of Earth & Environmental Sciences, Burnaby Building, Burnaby Road, Portsmouth, M.H.B NASSERI, R.PAUL YOUNG, University of Toronto — Many intractable systems and problems can be reduced to a system of interacting spins. Here, we report mapping collective phononic excitations from different sources of crystal vibrations to spin systems. The phononic excitations in our experiments are due to micro and nano cracking (yielding crackling noises due to lattice distortion). We develop real time mapping of the multi-array sensors to a network-space and then mapping the excitation- networks to spin-like systems. We show that new mapped system satisfies the quench (impulsive) characteristics of the Ising model in 2D classical spin systems. In particular, we show that our artificial Ising system transits between two ground states and approaching the critical point accompanies with a very short time frozen regime, inducing formation of domains separated by kinks. For a cubic-test under a true triaxial test (3D case), we map the system to a 6-spin ring under a transversal-driving field where using functional multiplex networks, the vector components of the spin are inferred (i.e., XY model). By visualization of spin patterns of the ring per each event, we demonstrate that “kinks” (as defects) proliferate when system approach from above to its critical point. We support our observations with employing recorded acoustic excitations during distortion of crystal lattices in nano-indentation tests on different crystals (silicon and graphite), triaxial loading test on rock (poly-crystal) samples and a true 3D triaxial test.

**1:51PM Y37.00014 Fingering Instability of Debonding Soft Elastic Adhesives** , ELIE RAPHAEL, UMR GULLIVER CNRS ESPCI Paris, FALKO ZIEBERT, Albert-Ludwigs-Universitt Freiburg, THOMAS VILMIN, UMR GULLIVER CNRS ESPCI Paris — We study the crack-front fingering instability of an elastic adhesive tape that is peeled off a solid substrate. Our analysis is based on an energy approach using fracture mechanics and scaling laws and provides simple physical explanations for (i) the fact that the wavelength depends only on the thickness of the adhesive film and (ii) the threshold of the instability, and (iii) additionally estimates the characteristic size of the fingers.

**2:03PM Y37.00015 Gluing Soft Interfaces by Nanoparticles**<sup>1</sup> , ZHEN CAO, ANDREY DOBRYNIN, Univ of Akron — Using a combination of the molecular dynamics simulations and scaling analysis we studied reinforcement of interface between two soft gel-like materials by spherical nanoparticles. Analysis of the simulations shows that the depth of penetration of a nanoparticle into a gel is determined by a balance of the elastic energy of the gel and nanoparticle deformations and the surface energy of nanoparticle/gel interface. In order to evaluate work of adhesion of the reinforced interface, the potential of mean force for separation of two gels was calculated. These simulations showed that the gel separation proceeds through formation of necks connecting nanoparticles with two gels. The shapes of the necks are controlled by a fine interplay between nanoparticle/gel surface energies and elastic energy of the neck deformation. Our simulations showed that by introducing nanoparticles at soft interfaces, the work required for separation of two gels could be 10-100 times larger than the work of adhesion between two gels without nanoparticle reinforcement. These results provide insight in understanding the mechanism of gluing soft gels and biological tissues by nano- and micro-sized particles.

**11:15AM Y38.00001 Covalent Fusion of layered Incompatible Gels in Immiscible Solvents** , SANTIDAN BISWAS, AWANEESH SINGH, Univ of Pittsburgh, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University, ANNA C. BALAZS, Univ of Pittsburgh — We carry out dissipative particle dynamics (DPD) simulations to model a two layered stackable gel where the gels are incompatible and are present in immiscible solvent. The bottom layer of the gel is created first and then a solution of new initiators, monomers and cross-linkers is introduced on top of it. These components then undergo polymerization and form the second gel layer. We study all possible combinations of free radical polymerization (FRP) and atom transfer radical polymerization (ATRP) mechanisms with the two layers of the gel. For example, the bottom layer gel is created via ATRP, whereas the top layer gel follows FRP. Our focus is to do a systematic study of all these combinations and find out the factors responsible for combining two incompatible gels in immiscible solvents.

**11:27AM Y38.00002 Cyclic topology in polymer networks**, RUI WANG, ALFREDO ALEXANDER-KATZ, JEREMIAH JOHNSON, BRADLEY OLSEN, Massachusetts Institute of Technology — Despite the ubiquity of applications, much of our fundamental knowledge about polymer networks is based on an assumption of ideal end-linked structure. However, polymer networks invariably possess topological defects: loops of different orders which have profound effects on network properties. Here, we demonstrate that all different orders of cyclic topologies are a universal function of a single dimensionless parameter characterizing the conditions for network formation. The theory is in excellent agreement with both experimental measurements of hydrogel loop fractions and Monte Carlo simulations without any fitting parameters. We demonstrate the superposition of the dilution effect and chain-length effect on loop formation. The one-to-one correspondence between the network topology and primary loop fraction demonstrates that the entire network topology is characterized by measurement of just primary loops, a single chain topological feature. Different cyclic defects cannot vary independently, in contrast to the intuition that the densities of all topological species are freely adjustable.

**11:39AM Y38.00003 Capturing dissipation and adhesion using transient network theory**, MICHELLE SING, GARETH MCKINLEY, BRADLEY OLSEN, Massachusetts Institute of Technology — Associative networks are prevalent in many fields and are of interest for applications where it is important that these materials are capable of adhering to their surroundings and/or provide a mechanism for dissipating energy in high-impact systems. However, little is known about the particular molecular behavior that differentiates these materials from their non-dissipative and non-adhesive associative counterparts. Here, we modify our previous work using the Smoluchowski equation to model the full network chain end-to-end distance distribution while tracking the population of individual chain conformations for chains that undergo multiple reaction intermediate steps. Thus, instead of the binary associated/dissociated states traditionally studied, we incorporate the ability for chains to partially dissociate and associate. This partial association/dissociation results in stress relaxation due to chain extension. In steady shear and start-up of steady shear, dissipation within the network becomes a function of both the elastically stored energy and the bond energy released during dissociation events.

**11:51AM Y38.00004 Dynamics of Bottlebrush Networks: A Computational Study<sup>1</sup>**, ANDREY DOBRYNIN, ZHEN CAO, Univ of Akron, SERGEI SHEIKO, Univ of NC - Chapel Hill — We study dynamics of deformation of bottlebrush networks using molecular dynamics simulations and theoretical calculations. Analysis of our simulation results show that the dynamics of bottlebrush network deformation can be described by a Rouse model for polydisperse networks with effective Rouse time of the bottlebrush network strand,  $\tau_R = \tau_0 N_s^2 (N_{sc} + 1)$  where,  $N_s$  is the number-average degree of polymerization of the bottlebrush backbone strands between crosslinks,  $N_{sc}$  is the degree of polymerization of the side chains and  $\tau_0$  is a characteristic monomeric relaxation time. At time scales  $t$  smaller than the Rouse time,  $t < \tau_R$ , the time dependent network shear modulus decays with time as  $G(t) \propto \rho k_B T (\tau_0/t)^{1/2}$ , where  $\rho$  is the monomer number density. However, at the time scale  $t$  larger than the Rouse time of the bottlebrush strands between crosslinks, the network response is pure elastic with shear modulus  $G(t) = G_0$ , where  $G_0$  is the equilibrium shear modulus at small deformation. The stress evolution in the bottlebrush networks can be described by a universal function of  $t/\tau_R$ .

**12:03PM Y38.00005 Bottlebrush and comb-like elastomers as ultra-soft electrical and acoustically active materials<sup>1</sup>**, WILLIAM DANIEL, MOHAMMAD VATANKHAH-VARNOSFADERANI, ASHISH PANDYA, Univ of NC - Chapel Hill, JOANNA BURDYNKA, Carnegie Mellon University - CMU, BENJAMIN MORGAN, MATTHEW EVERHART, Univ of NC - Chapel Hill, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University - CMU, ANDREY DOBRYNIN, University of Akron- Akron, MICHAEL RUBINSTEIN, SERGEI SHEIKO, Univ of NC - Chapel Hill, UNC MIRT TEAM — Without swelling in a solvent, it is challenging to obtain materials with a modulus below  $10^5$  Pa, which is dictated by chain entanglements. We show that macromolecules can be disentangled by dense grafting of side chains to long polymer chains. The bottlebrush and comb-like architectures demonstrate a unique combination of flexibility and network dilution, leading to significant decrease of the entanglement modulus ( $G_e$ ) and increase of extensibility. Following theoretical predictions, it has been shown that the  $G_e$  is controlled by the polymerization degrees of sidechains ( $n_{sc}$ ) and grafting spacer ( $n_g$ ) as  $G_e \approx (n_g/n_{sc})^{1.5}$ . Using the reduced entanglement density, we developed solvent-free elastomers with moduli on the order of 100 Pa and excellent extensibility. Using bottlebrush architectures we have developed PDMS dielectric actuators with high deformation at low electric field strength. Additionally strong acoustic adsorption leads to materials showing shape and volume control in light opaque environments.

**12:15PM Y38.00006 Controlling Phase Separation of Tough Interpenetrating Polymer Networks via Addition of Amphiphilic Block Copolymers.**, BRIAN ROHDE, RAMANAN KRISHNAMOORTI, MEGAN ROBERTSON, Univ of Houston — Interpenetrating polymer networks (IPNs) offer a unique way to combine the mechanical properties of two thermoset systems. Often used to create a material that possesses both high toughness and tensile properties, here we use polydicyclopentadiene, cured via ring opening metathesis polymerization, to contribute high toughness and diglycidyl ether of bisphenol A cured via anhydride chemistry to contribute high tensile strength and modulus. As the uncompatibilized system reacts in the presence of one another, mesoscopic phase separation occurs and dictates the overall efficacy of combining mechanical properties. To control phase separation and drive the system towards more mechanically robust nanostructured IPNs, amphiphilic block copolymers of polybutadiene-*b*-polyethylene oxide, where one block possesses strong affinity to polyDCPD and the other the DGEBA, were added to the system. Here we present a systematic study of the influence of block copolymer composition in the overall blend on degree of phase separation and morphology using a combination of small-angle x-ray scattering (SAXS) and scanning electron microscopy (SEM) techniques. The resultant mechanical properties are then explored in an effort to link mechanical properties to blend morphology.

**12:27PM Y38.00007 Weak hydrogen bonding yields rigid, tough, and elastic hydrogels<sup>1</sup>**, SERGEI SHEIKO, XIAOBO HU, MOHAMMAD VATANKHAH-VARNOSFADERANI, JING ZHOU, QIAOXI LI, University of North Carolina at Chapel Hill, ANDREY DOBRYNIN, University of Akron — Unlike living tissues, synthetic hydrogels are inherently soft and brittle, particularly when built of hydrogen bonds. It remains challenging to design hydrogels that combine high rigidity, strength at break, extensibility, high elasticity. Through free-radical copolymerization of *N*,*N*-dimethylacrylamide and methacrylic acid, we have designed a network system based on tunable composition of covalent bonds (permanent cross-links) and hydrogen bonds (sacrificial and recoverable crosslinks) with the following rationale: 1) Maintain a high total number of cross-links to ensure high modulus; 2) Introduce a high fraction of H-bonding to ensure high energy dissipation; and 3) Incorporate a small fraction of permanent cross-links to ensure shape control. By tuning the chemical composition and microstructure we have obtained materials with superb mechanical properties. The hydrogels contain 70 wt% water (similar to living cartilage, skin, and ligaments), while display modulus of 28 MPa, strength of 2 MPa, fracture energy of  $9300 \text{ J}\cdot\text{m}^{-2}$ , extensibility of 800%, excellent fatigue-resistance, and great elasticity allowing for complete and fast strain recovery. The results agreed with theoretical predictions for modulus relaxation of dual networks with dynamic and permanent crosslinks.

<sup>1</sup>We gratefully acknowledge funding from the National Science Foundation (DMR 1122483, DMR 1407645, and DMR 1436201).

**12:39PM Y38.00008 Cavitation of a Physically Associating Gel**, SATISH MISHRA, SANTANU KUNDU, Mississippi State University — Self-assembly of block copolymers in selective solvents form ordered structures such as micelles, vesicles, and physically crosslinked gels due to difference in their interaction with solvents. These gels have wide range of applications in tissue engineering, food science and biomedical field due to their tunable properties and responsiveness with changing environmental conditions. Pressurization of a defect inside a physically associating gel can lead to elastic instability (cavitation) leading to failure of the gel. The failure behavior involves dissociation of physical networks. A thermoreversible, physically associating gel with different volume fractions of a triblock copolymer, poly (methyl methacrylate)-poly (n-butyl acrylate)-poly (methyl methacrylate) [PMMA-PnBA-PMMA] in 2-ethyl 1-hexanol, a midblock selective solvent, is considered here. Mechanical properties were investigated using shear rheology and cavitation experiments. The experimental data is fitted with a constitutive model that captures the stiffening behavior followed by softening behavior of a physical gel. Finite element analysis has been performed on cavitation rheology geometry to capture the failure behavior and to calculate energy release rate during cavitation experiments.

**12:51PM Y38.00009 Tough Stretchable Physically-Crosslinked Hydrogel Fiber Mats from Electrospun Statistical Copolymers.**, YIMING YANG, R.A. WEISS, BRYAN VOGT, University of Akron — Nature uses supramolecular interactions combined with hierarchical structures to produce water-laden materials with combination of properties that are challenging to obtain in synthetic systems. Here we describe a simple method based on electrospinning of a self-associating amphiphilic copolymer. Immersion of the copolymer mats in water generates supramolecular hydrogels that are crosslinked by association of the fluorinated hydrophobic moieties in the copolymer. These robust hydrogel fiber mats exhibit extensibility greater than 225 % and the elastic modulus can be comparable to the bulk hydrogel despite the porous structure of the as-spun mat. Moreover, the stress dissipation by re-arrangement of the physically associated network leads to coalescence of the fibers that propagates from the surfaces to the interior of the mat. Both the mechanical properties and this fiber coalescence behavior can be tuned by selection of the copolymer composition and the initial fiber dimensions. These tough, stretchable hydrogel fiber mats could find utility in a variety of biomedical applications due to their unique properties.

**1:03PM Y38.00010 Amphiphile-modified supramolecular hydrogels: optimized network structure and enhanced stiffness at "Goldilocks" amphiphile content**, CHAO WANG, BRYAN VOGT, R.A. WEISS, University of Akron — Hydrogels formed by hydrophobic physical crosslinks have high mechanical strength (larger than 100kPa). 1 Surfactants, such as sodium dodecyl sulfate (SDS), can be used to control the mechanical strength and modulus of these hydrogels. Here we describe the change in the viscoelastic behavior of physically crosslinked copolymer hydrogels synthesized from N,N-dimethylacrylamide (DMA) and 2-(N-ethylperfluoro-octane sulfonamido) ethyl methacrylate (FOSM) by the addition of a SDS solution. Without confinement, SDS dissociates the FOSM micelle-like microstructure and facilitates swelling, which decreases the crosslink density of the hydrogel and reduces the modulus and strength of the hydrogel. With 1-dimensional macroscopic confinement, similar behavior was observed, but only for soaking times in the salt solution smaller than 15 h. For longer times (larger than 15 h), SDS improved the mechanical strength and modulus of the hydrogel presumably by reducing the imperfections in the hydrogel network and forming complexes with FOSM. 1. Hao, J.; Weiss, R. a. Mechanical Behavior of Hybrid Hydrogels Composed of a Physical and a Chemical Network. Polymer 2013, 54, 21742182.

**1:15PM Y38.00011 Advancing Reversible Shape Memory by Tuning Network Architecture**, QIAOXI LI, JING ZHOU, MOHAMMAD VATANKHAH VARNOSFADERANI, University of North Carolina at Chapel Hill, DMYTRO NYKYPANCHUK, OLEG GANG, Brookhaven National Lab-CFN, SERGEI SHEIKO, University of North Carolina at Chapel Hill, UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL COLLABORATION, BROOKHAVEN NATIONAL LAB-CFN COLLABORATION — Recently, reversible shape memory (RSM) has been realized in conventional semi-crystalline elastomers without applying any external force and synthetic programming. The mechanism is ascribed to counteraction between thermodynamically driven relaxation of a strained polymer network and kinetically preferred self-seeding recrystallization of constrained network strands. In order to maximize RSM's performance in terms of (i) range of reversible strain, (ii) rate of strain recovery, and (iii) relaxation time of reversibility, we have designed a systematic series of networks with different topologies and crosslinking densities, including purposely introduced dangling chains and irregular meshes. Within a broad range of crosslink density ca. 50-1000 mol/m<sup>3</sup>, we have demonstrated that the RSM's properties improve significantly with increasing crosslink density, regardless of network topology. Actually, one of the most irregular networks with densest crosslinking allowed achieving up to 80% of the programmed strain being fully reversible, fast recovery rate up to 0.05 K<sup>-1</sup>, and less than 15% decrease of reversibility after hours of annealing at partial melt state. With this understanding and optimization of RSM, we pursue an idea of shape control through self-assembly of shape-memory particles. For this purpose, 3D printing has been employed to prepare large assemblies of particles possessing specific shapes and morphologies.

**1:27PM Y38.00012 Increasing the Mechanical Strength of Block Polymer Ion Gels Through the Stepwise Self-Assembly of a Thermoresponsive ABC Triblock Terpolymer**, CECILIA HALL, CAN ZHOU, SCOTT DANIELSEN, TIMOTHY LODGE, Univ of Minnesota - Twin Cities — Blends of network-forming block polymers and ionic liquids have remarkable potential for solid electrolytes, as they allow the combination of desirable mechanical and electrical properties. While ABA triblock copolymers have successfully been implemented as the network component of ion gels, these networks contain looped defects, where the endblocks of the polymer loop back into the same spherical core instead of forming a bridge between two cores. We demonstrate that the ABC triblock terpolymer poly(ethylene-*alt*-propylene)-*block*-poly(ethylene oxide)-*block*-poly(*N*-isopropylacrylamide) (PEP-*b*-PEO-*b*-PNIPAm) in the ionic liquid 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonate)imide forms a thermoreversible gel network with negligible looping defects. PEP-core micelles exist at all temperatures, while cooling causes association of the PNIPAm micelle corona to form a bridging network. Small-angle x-ray scattering and dynamic light scattering were used to characterize the high-temperature micelles. These gels show enhanced mechanical properties and the ability to form gels at lower concentrations than the corresponding thermoresponsive ABA triblock copolymers.

**1:39PM Y38.00013 Rheology and Relaxation Timescales of ABA Triblock Polymer Gels**, ANDREW PETERS, TIMOTHY LODGE, Univ of Minn - Minneapolis — When dissolved in a midblock selective solvent, ABA polymers form gels composed of aggregated end block micelles bridged by the midblocks. While much effort has been devoted to the study of the structure of these systems, the dynamics of these systems has received less attention. We examine the underlying mechanism of shear relaxation of ABA triblock polymer gels, especially as a function of chain length, composition, and concentration. Recent work using time-resolved small-angle neutron scattering of polystyrene (PS)-*block*-poly(ethylene-*alt*-propylene) (PEP) in squalane has elucidated many aspects of the dynamics of diblock chain exchange. By using rheology to study bulk relaxation phenomena of the triblock equivalent, PS-PEP-PS, we apply the knowledge gained from the chain exchange studies to bridge the gap between the molecular and macroscopic relaxation phenomena in PS-PEP-PS triblock gels.

**1:51PM Y38.00014 Non-continuum, anisotropic nanomechanics of random and aligned electrospun nanofiber matrices**, DAPHNEY CHERY, BIAO HAN, Drexel University, ROBERT MAUCK, VIVEK SHENOY, University of Pennsylvania, LIN HAN, Drexel University — Polymer nanofiber assemblies are widely used in cell culture and tissue engineering, while their nanomechanical characteristics have received little attention. In this study, to understand their nanoscale structure-mechanics relations, nanofibers of polycaprolactone (PCL) and poly(vinyl alcohol) (PVA) were fabricated via electrospinning, and tested via AFM-nanoindentation with a microspherical tip ( $R \approx 10 \mu\text{m}$ ) in PBS. For the hydrophobic, less-swollen PCL, a novel, non-continuum linear F-D dependence was observed, instead of the typical Hertzian  $F-D^{3/2}$  behavior, which is usually expected for continuum materials. This linear trend is likely resulted from the tensile stretch of a few individual nanofibers as they were indented in the normal plane. In contrast, for the hydrophilic, highly swollen PVA, the observed typical Hertzian response indicates the dominance of localized deformation within each nanofiber, which had swollen to become hydrogels. Furthermore, for both matrices, aligned fibers showed significantly higher stiffness than random fibers. These results provide a fundamental basis on the nanomechanics of biomaterials for specialized applications in cell phenotype and tissue repair.

**11:15AM Y39.00001 “Calibration-on-the-spot”: How to calibrate an EMCCD camera from its images<sup>1</sup>**, KIM I. MORTENSEN, HENRIK FLYVBJERG, Department of Micro- and Nanotechnology, Technical University of Denmark — In localization-based microscopy, super-resolution is obtained by analyzing isolated diffraction-limited spots imaged, typically, with EMCCD cameras. To compare experiments and calculate localization precision, the photon-to-signal amplification factor is needed but unknown without a calibration of the camera. Here we show how this can be done *post festum* from just a recorded image. We demonstrate this (i) theoretically, mathematically, (ii) by analyzing images recorded with an EMCCD camera, and (iii) by analyzing simulated EMCCD images for which we know the true values of parameters. In summary, our method of *calibration-on-the-spot* allows calibration of a camera with unknown settings from old images on file, with no other info needed. Consequently, *calibration-on-the-spot* also makes future camera calibrations before and after measurements unnecessary, because the calibration is encoded in recorded images during the measurement itself, and can at any later time be decoded with *calibration-on-the-spot*.

**11:27AM Y39.00002 Live-cell thermometry with nitrogen vacancy centers in nanodiamonds**, HARISHANKAR JAYAKUMAR, Department of Physics, CUNY-City College of New York, HELMUT FEDDER, Department of Physics, University of Stuttgart, ANDREW CHEN, LIUDI YANG, CHENGHAO LI, Department of Biomedical Engineering, CUNY-City College of New York, JOERG WRACHTRUP, Department of Physics, University of Stuttgart, SIHONG WANG, Department of Biomedical Engineering, CUNY-City College of New York, CARLOS MERILES, Department of Physics, CUNY-City College of New York — The ability to measure temperature is typically affected by a tradeoff between sensitivity and spatial resolution. Good thermometers tend to be bulky systems and hence are ill-suited for thermal sensing with high spatial localization. Conversely, the signal resulting from nanoscale temperature probes is often impacted by noise to a level where the measurement precision becomes poor. Adding to the microscopist toolbox, the nitrogen vacancy (NV) center in diamond has recently emerged as a promising platform for high-sensitivity nanoscale thermometry [1,2]. Of particular interest are applications in living cells because diamond nanocrystals are biocompatible and can be chemically functionalized to target specific organelles. Here we report progress on the ability to probe and compare temperature within and between living cells using nanodiamond-hosted NV thermometry. We focus our study on cancerous cells, where atypical metabolic pathways arguably lead to changes in the way a cell generates heat, and thus on its temperature profile. 1. V. Acosta et al., *Phys. Rev. Lett.* **104**, 070801 (2010). 2. G. Kucsko et al., *Nature* **500**, 54 (2013).

**11:39AM Y39.00003 Production and NMR signal optimization of hyperpolarized <sup>13</sup>C-labeled amino acids**, CHRISTOPHER PARISH, PETER NIEDBALSKI, SARAH FERGUSON, ANDHIKA KISWANDHI, LLOYD LUMATA, University of Texas at Dallas — Amino acids are targeted nutrients for consumption by cancers to sustain their rapid growth and proliferation. <sup>13</sup>C-enriched amino acids are important metabolic tracers for cancer diagnostics using nuclear magnetic resonance (NMR) spectroscopy. Despite this diagnostic potential, <sup>13</sup>C NMR of amino acids however is hampered by the inherently low NMR sensitivity of the <sup>13</sup>C nuclei. In this work, we have employed a physics technique known as dynamic nuclear polarization (DNP) to enhance the NMR signals of <sup>13</sup>C-enriched amino acids. DNP works by transferring the high polarization of electrons to the nuclear spins via microwave irradiation at low temperature and high magnetic field. Using a fast dissolution method in which the frozen polarized samples are dissolved rapidly with superheated water, injectable solutions of <sup>13</sup>C-amino acids with highly enhanced NMR signals (by at least 5,000-fold) were produced at room temperature. Factors that affect the NMR signal enhancement levels such as the choice of free radical polarizing agents and sample preparation will be discussed along with the thermal mixing physics model of DNP. The authors would like to acknowledge the support by US Dept of Defense award no. W81XWH-14-1-0048 and Robert A. Welch Foundation grant no. AT-1877.

**11:51AM Y39.00004 Real-time tracking of dissociation of hyperpolarized <sup>89</sup>Y-DTPA: a model for degradation of open-chain Gd<sup>3+</sup> MRI contrast agents<sup>1</sup>**, SARAH FERGUSON, PETER NIEDBALSKI, CHRISTOPHER PARISH, ANDHIKA KISWANDHI, University of Texas at Dallas, ZOLTAN KOVACS, University of Texas Southwestern Medical Center, LLOYD LUMATA, University of Texas at Dallas — Gadolinium (Gd) complexes are widely used relaxation-based clinical contrast agents in magnetic resonance imaging (MRI). Gd-based MRI contrast agents with open-chain ligand such as Gd-DTPA, commercially known as magnevist, are less stable compared to Gd complexes with macrocyclic ligands such as GdDOTA (Dotarem). The dissociation of Gd-DTPA into Gd ion and DTPA ligand under certain biological conditions such as high zinc levels can potentially cause kidney damage. Since Gd is paramagnetic, direct NMR detection of the Gd-DTPA dissociation is quite challenging due to ultra-short relaxation times. In this work, we have investigated Y-DTPA as a model for Gd-DTPA dissociation under high zinc content solutions. Using dissolution dynamic nuclear polarization (DNP), the <sup>89</sup>Y NMR signal is amplified by several thousand-fold. Due to the relatively long T<sub>1</sub> relaxation time of <sup>89</sup>Y which translates to hyperpolarization lifetime of several minutes, the dissociation of Y-DTPA can be tracked in real-time by hyperpolarized <sup>89</sup>Y NMR spectroscopy. Dissociation kinetic rates and implications on the degradation of open-chain Gd<sup>3+</sup> MRI contrast agents will be discussed.

**12:03PM Y39.00005 Optimization of <sup>13</sup>C dynamic nuclear polarization: isotopic labeling of free radicals<sup>1</sup>**, PETER NIEDBALSKI, CHRISTOPHER PARISH, ANDHIKA KISWANDHI, LLOYD LUMATA, University of Texas at Dallas — Dynamic nuclear polarization (DNP) is a physics technique that amplifies the nuclear magnetic resonance (NMR) signals by transferring the high polarization of the electrons to the nuclear spins. Thus, the choice of free radical is crucial in DNP as it can directly affect the NMR signal enhancement levels, typically on the order of several thousand-fold in the liquid-state. In this study, we have investigated the efficiency of four variants of the well-known 4-oxo-TEMPO radical (normal 4-oxo-TEMPO plus its <sup>15</sup>N-enriched and/or perdeuterated variants) for use in DNP of an important metabolic tracer [1-<sup>13</sup>C]acetate. Though the variants have significant differences in electron paramagnetic resonance (EPR) spectra, we have found that changing the composition of the TEMPO radical through deuteration or <sup>15</sup>N doping yields no significant difference in <sup>13</sup>C DNP efficiency at 3.35 T and 1.2 K. On the other hand, deuteration of the solvent causes a significant increase of <sup>13</sup>C polarization that is consistent over all the 4-oxo-TEMPO variants. These findings are consistent with the thermal mixing model of DNP.

**12:27PM Y39.00007 Simulated biophysical experimental techniques for chlorhexidine in dmPC/cholesterol systems**, BRAD VAN OOSTEN, THAD HARROUN, Brock University — We have investigated the use of molecular dynamic simulations and the MARTINI force field to simulate isothermal titration calorimetry and differential scanning calorimetry techniques. The goal of these simulations was to observe how well they can reproduce the concentration effects of the addition of the small molecule chlorhexidine (CHX) into a model DMPC membrane containing varying concentrations of cholesterol. We constructed a coarse grained model for CHX compatible with the MARTINI force field. We were able to mimic an isothermal titration calorimetry experiment by repeatedly adding CHX into a DMPC membrane. With the increased concentration, we observed a decreasing affinity between CHX and the membrane as well as a resulting increase in the reaction time before the system was equilibrated. We then performed a controlled cooling of the membrane with various CHX concentrations to mimic a differential scanning calorimetry experiment. A change in membrane structure accompanied by a spike in the specific heat was measured at specific temperature  $T_m$  signaling a phase transition. We then varied the concentration of CHX as well as the addition of varying concentrations of cholesterol to observe trends in the change to  $T_m$  due to the addition of CHX and cholesterol.

**12:51PM Y39.00009 Direct simulation of amphiphilic nanoparticle mediated membrane inter-actions**, MUKARRAM TAHIR, ALFREDO ALEXANDER-KATZ, Massachusetts Inst of Tech-MIT — Membrane fusion is a critical step in the transport of biological cargo through membrane-bound compartments like vesicles. Membrane proteins that alleviate energy barriers for initial stalk formation and eventual rupture of the hemifusion intermediate during fusion generally assist this process. Gold nanoparticles functionalized with a combination of hydrophobic and hydrophilic alkanethiol ligands have recently been shown to induce membrane re-arrangements that are similar to those associated with these fusion proteins. In this work, we utilize molecular dynamics simulation to systematically design nanoparticles that exhibit targeted interactions with membranes. We introduce a method for rapidly parameterizing nanoparticle topology for the MARTINI biomolecular force field to permit long timescale simulation of their interactions with lipid bilayers. We leverage this model to investigate how ligand chemistry governs the nanoparticle's insertion efficacy and the perturbations it generates in the membrane environment. We further demonstrate through unbiased simulations that these nanoparticles can direct the fusion of lipid assemblies such as micelles and vesicles in a manner that mimics the function of biological fusion peptides and SNARE proteins.

**1:03PM Y39.00010 Exposure to TiO<sub>2</sub> nanoparticles increases Staphylococcus aureus infection of HeLa cells**, YAN XU, State Univ of NY- Stony Brook, MING-TZO WEI, Lehigh University, STEPHEN.G WALKER, HONG ZHAN WANG, CHRIS GONDON, PETER BRINK, State Univ of NY- Stony Brook, SHOSHANA GUTERMAN, Yeshiva University High School for Girls, EMMA ZAWACKI, University of California at Los Angeles, ELIANA APPLEBAUM, Stern College for Women, MIRIAM RAFAILOVICH, State Univ of NY- Stony Brook, H. DANIEL OUYANG, Lehigh University, TATSIANA MIRONAVA, State Univ of NY- Stony Brook — TiO<sub>2</sub> is one of the most common nanoparticles in industry from food additives to energy generation. Even though TiO<sub>2</sub> is also used as an anti-bacterial agent in combination with UV, we found that, in the absence of UV, exposure of HeLa cells to TiO<sub>2</sub> nanoparticles largely increased their risk of bacterial invasion. HeLa cells cultured with low dosage rutile and anatase TiO<sub>2</sub> nanoparticles (0.1 mg/ml) for 24 hrs prior to exposure to bacteria had 350% and 250% respectively more bacteria infected per cell. The increase was attributed to increased LDH leakage, and changes in the mechanical response of the cell membrane. On the other hand, macrophages exposed to TiO<sub>2</sub> particles ingested 40% fewer bacteria, further increasing the risk of infection. In combination, these two factors raise serious concerns regarding the impact of exposure to TiO<sub>2</sub> nanoparticles on the ability of organisms to resist bacterial infection.

**1:15PM Y39.00011 Effect of TiO<sub>2</sub> nanoparticles on adipose derived stromal cell differentiation, morphology, ECM deposition and its susceptibility to bacterial infections.**, TATSIANA MIRONAVA, YAN XU, MIRIAM RAFAILOVICH, Stony Brook University — The growing annual production of Titanium dioxide (TiO<sub>2</sub>) nanoparticles is proportional to an increase in the chances of occupational and consumer exposure. Considering, that these nanoparticles are currently being used in multiple personal care products many concerns have arisen about their health impact. Human skin is in constant contact with the external environment and is one of the most important routes of exposure to TiO<sub>2</sub>. In this study we have investigated the effect of two forms of TiO<sub>2</sub>, rutile and anatase, on human adipose derived stromal cells (ADSCs). Here, we focus on the effects of TiO<sub>2</sub> exposure on intracellular lipid accumulation and expression of adipogenic markers; on whether different forms of TiO<sub>2</sub> have similar effects on cell function; and whether nanoparticle localization inside cells correlates with loss of cell function. In addition presence of bacteria on the skin is taken into account in its complex interaction with ADSCs and TiO<sub>2</sub> nanoparticles. Altogether, the present study indicates that nanosized TiO<sub>2</sub> particles adversely effects the differentiation of ADSCs, have profound effects on cell function and increase the rate of bacterial infection.

**1:27PM Y39.00012 Effect of cell donor age on the cellular response to nanoparticle exposure.**, FAN YANG, MIRIAM RAFAILOVICH, TATSIANA MIRONAVA, Stony Brook University — As human age there are many significant changes that occur in the skin. Here we investigate how the age-dependent changes in dermal fibroblast mechanics affect cell response to the AuNPs nanoparticles. To analyze these processes we exposed cells from donors of different age groups to AuNPs of two different sizes. Our results indicate that there are significant changes in cell rigidity with age, which in turn lead to different penetration rates of AuNPs through cell membrane and overall nanoparticle toxicity. Cell proliferation results revealed that all cell groups exposed to the same concentration of AuNPs had a very similar decrease in cell proliferation and similar impact on cell morphology. However, recovery data demonstrated that the rate of recovery from the damage is much faster for neonatal cells as compared to 30- and 80-years old cell group. Therefore, we conclude that nanoparticle uptake depends on cell membrane mechanics that in turn is a function of cell donor age.

**1:39PM Y39.00013 Mechanics of Cellulose Synthase Complexes in Living Plant Cells<sup>1</sup>**, NINA ZEHFROOSH, Department of Physics, University of Massachusetts, Amherst, DERUI LIU, Biology Department, University of Massachusetts, Amherst, KIERAN P. RAMOS, Department of Physics, University of Massachusetts, Amherst, XIAOLI YANG, Biology Department, University of Massachusetts, Amherst, LORI S. GOLDNER, Department of Physics, University of Massachusetts, Amherst, TOBIAS I. BASKIN, Biology Department, University of Massachusetts, Amherst — The polymer cellulose is one of the major components of the world's biomass with unique and fascinating characteristics such as its high tensile strength, renewability, biodegradability, and biocompatibility. Because of these distinctive aspects, cellulose has been the subject of enormous scientific and industrial interest, yet there are still fundamental open questions about cellulose biosynthesis. Cellulose is synthesized by a complex of transmembrane proteins called "Cellulose Synthase A" (CESA) in the plasma membrane. Studying the dynamics and kinematics of the CESA complex will help reveal the mechanism of cellulose synthesis and permit the development and validation of models of CESA motility. To understand what drives these complexes through the cell membrane, we used total internal reflection fluorescence microscopy (TIRFM) and variable angle epi-fluorescence microscopy to track individual, fluorescently-labeled CESA complexes as they move in the hypocotyl and root of living plants. A mean square displacement analysis will be applied to distinguish ballistic, diffusional, and other forms of motion. We report on the results of these tracking experiments.

**1:51PM Y39.00014 Electronic measurements in an alternating magnetic field (AMF) for studying magnetic nanoparticle hyperthermia**, Z. BOEKLHEIDE, Z. A. HUSSEIN, S. HARTZELL, Lafayette College — Magnetic nanoparticle hyperthermia is a promising cancer treatment in which magnetic nanoparticles are injected into a tumor and then exposed to an alternating magnetic field (AMF). This process releases heat and damages tumor cells, but the exact mechanisms behind the effectiveness of this therapy are still unclear. Accurate sensors are required to monitor the temperature and, potentially, other parameters such as magnetic field or mechanical stress during clinical therapy or lab research. Often, optical rather than electronic temperature sensors are used to avoid eddy current self-heating in conducting parts in the AMF. However, eddy current heating is strongly dependent on the size and geometry of the conducting part, thus micro- and nano-scale electronics are a promising possibility for further exploration into magnetic nanoparticle hyperthermia. This presentation quantitatively discusses the eddy current self-heating of thin wires (thermocouples) and will also present a proof of concept thin film resistive thermometer and magnetic field sensor along with measurements of their eddy current self-heating. The results show that electronic measurements are feasible in an AMF with both thin wires and patterned thin film sensors under certain conditions.

**2:03PM Y39.00015 Non-invasive measurement of the blood pressure pulse using multiple PPGs<sup>1</sup>**, JOHN SEYMOUR, GARY PENNINGTON, Towson University — Heart disease, the leading cause of death in the US, may be spotted early on by looking at photoplethysmogram (PPG) data. This experiment explores a new method of continuously monitoring the blood pressure pulse with PPG data. In contrast to the traditional sphygmomanometer (cuff) method, which yields only the systolic and diastolic pressure during measurement, this method tracks the blood pressure pulse wave in a non-invasive continuous manner. This procedure allows for fast, inexpensive, and detailed analysis of the patient's blood pressure implementable on a large scale. We also explore the second derivative of the PPG data. In combination with the above method, the patient's heart risk can be effectively detected.

**11:15AM Y40.00001 Managing and capturing the physics of robotic systems**, JUSTIN WERFEL, Harvard University — Algorithmic and other theoretical analyses of robotic systems often use a discretized or otherwise idealized framework, while the real world is continuous-valued and noisy. This disconnect can make theoretical work sometimes problematic to apply successfully to real-world systems. One approach to bridging the separation can be to design hardware to take advantage of simple physical effects mechanically, in order to guide elements into a desired set of discrete attracting states. As a result, the system behavior can effectively approximate a discretized formalism, so that proofs based on an idealization remain directly relevant, while control can be made simpler. It is important to note, conversely, that such an approach does not make a physical instantiation unnecessary nor a purely theoretical treatment sufficient. Experiments with hardware in practice always reveal physical effects not originally accounted for in simulation or analytic modeling, which lead to unanticipated results and require nontrivial modifications to control algorithms in order to achieve desired outcomes. I will discuss these points in the context of swarm robotic systems recently developed at the Self-Organizing Systems Research Group at Harvard.

**11:27AM Y40.00002 Robot flow, clogging and jamming in confined spaces**, DARIA MONAENKOVA, VADIM LINEVICH, MICHAEL A.D. GOODISMAN, DANIEL I. GOLDMAN, Georgia Institute of Technology — We hypothesized that when a collection of robots operate in confined space, maximization of individual effort could negatively affect the collective performance by impeding the mobility of the individuals. To test our hypothesis, we built and programmed groups of 1-4 autonomous robotic diggers to construct a tunnel in a model cohesive soil. The robots' mobility, defined in terms of the residence time (T) required for a robot to move one body-length within the tunnel, was compared between groups of maximally active robots (mode 1), groups with different levels of activity between individuals (mode 2), and maximally active robots with a "giving up" behavior (mode 3), in which the robot ceased the attempt to excavate in a crowded tunnel. In small groups of two robots, T was ~3 sec and did not depend on the mode of operation. However, an increase in the number of robots caused an increase in T which depended upon mode. The residence time in groups of four robots in mode 1 (~9 sec) significantly exceeded the residence time in mode 2 and 3 (~4 sec), indicating that crowding was causing slower movement of individuals, particularly under maximum effort (mode 1). We will use our robophysical studies to discover principles of collective construction in subterranean social animals.

**11:39AM Y40.00003 Legged-locomotion on inclined granular media**, JENNIFER RIESER, FEIFEI QIAN, DANIEL GOLDMAN, Georgia Institute of Technology — Animals traverse a wide variety of complex environments, including situations in which the ground beneath them can yield (e.g. dry granular media in desert dunes). Locomotion strategies that are effective on level granular media can fail when traversing a granular slope. Taking inspiration from successful legged-locomotors in sandy, uneven settings, we explore the ability of a small (15 cm long, 100 g), six-c-shaped legged robot to run uphill in a bed of 1-mm-diameter poppy seeds, using an alternating tripod gait. Our fully automated experiments reveal that locomotor performance can depend sensitively on both environmental parameters such as the inclination angle and volume fraction of the substrate, and robot morphology and control parameters like leg shape, step frequency, and the friction between the feet of the robot and the substrate. We assess performance by measuring the average speed of the robot, and we find that the robot tends to perform better at higher step frequency and lower inclination angles, and that average speed decreases more rapidly with increasing angle for higher step frequency.

**11:51AM Y40.00004 Robotic and mathematical modeling reveal general principles of appendage control and coordination in terrestrial locomotion<sup>1</sup>** , BENJAMIN MCINROE, UC Berkeley, HENRY ASTLEY, Georgia Tech, CHAOHUI GONG, CMU Robotics Institute, SANDY KAWANO, NIMBioS, PERRIN SCHIEBEL, Georgia Tech, HOWIE CHOSET, CMU Robotics Institute, DANIEL I GOLDMAN, Georgia Tech — The transition from aquatic to terrestrial life presented new challenges to early walkers, necessitating robust locomotion on complex, flowable substrates (e.g. sand, mud). Locomotion on such substrates is sensitive to limb morphology and kinematics. Although early walker morphologies are known, principles of appendage control remain elusive. To reveal limb control strategies that facilitated the invasion of land, we study both robotic and mathematical models. Robot experiments show that an active tail is critical for robust locomotion on granular media, enabling locomotion even with poor foot placement and limited ability to lift the body. Using a granular resistive force theory model, we construct connection vector fields that reveal how appendage coordination and terrain inclination impact locomotor performance. This model replicates experimental results, showing that moving limbs/tail in phase is most effective (suggesting a locomotor template). Varying limb trajectories and contacts, we find gaits for which tail use can be neutral or harmful, suggesting limb-tail coordination to be a nontrivial aspect of locomotion. Our findings show that robot experiments coupled with geometric mechanics provide a general framework to reveal principles of robust terrestrial locomotion.

**12:03PM Y40.00005 Compliant Synergies in Locomotion** , MATTHEW TRAVERS, HOWIE CHOSET, Carnegie Mellon University, GOLDMAN @ GEORGIA TECH. PHYSICS DEPARTMENT COLLABORATION — Biological systems appear to have natural mechanisms that allow them to readily compensate for unexpected environmental variations when compared to their mechanical (i.e., robotic) counterparts. We hypothesize that the basis for this discrepancy is almost innate: what biology appears to be born with, built-in mechanisms for coordinating their many degrees of freedom, we struggle to “program.” We therefore look toward biology for inspiration. In particular, we are interested in kinematic synergies, low-dimensional representations that explicitly encode the underlying structure of how systems coordinate their internal degrees of freedom to achieve high-level tasks. In this work, we derive parametric representations of kinematic synergies and present a new compliant locomotion control framework that enables the parameters to be directly controlled in response to external disturbances. We present results of this framework implemented on two separate platforms, a snake-like and hexapod robot. Our results show that, using synergies, the locomotion control of these very different systems can be reduced to simple, extremely capable, and common forms, thus offering new insights into both robotic as well as biological locomotion in complex terrains.

**12:15PM Y40.00006 Instability and maneuverability of a multi-legged robot<sup>1</sup>** , SHINYA AOI, Kyoto University — Our previous study showed that a centipede like multi-legged robot composed of many modules, each of which has one pair of legs, produces body undulations through a supercritical Hopf bifurcation of walking in a straight line with parallel bodies when the gait speed increases over a critical value or when the body segment joint stiffness decreases below a critical value (Aoi et al., PRE 2013, featured by Nat Phys 2013). So far, it is unclear if centipedes actively produce or resist body undulations during their locomotion and the previous study discussed the underlying mechanism responsible for the body undulations in centipede locomotion based on the robot experimental results and dynamic analysis using a simplified physical model. Furthermore, centipedes produce agile locomotion despite many legs being in contact with the ground during their locomotion, which may impede their agile motions. The present study investigated the relationship between the instability of walking in a straight line and maneuverability of the robot using a quick turn task and some evaluation criteria for maneuverability.

**12:27PM Y40.00007 Are snakes particles or waves? Scattering of a limbless locomotor through a single slit** , FEIFEI QIAN, Georgia Institute of Technology, JIN DAI, CHAOHUI GONG, HOWIE CHOSET, Carnegie Mellon University, DANIEL GOLDMAN, Georgia Institute of Technology — Droplets on vertically vibrated fluid surfaces can walk and diffract through a single slit by a pilot wave hydrodynamic interaction [Couder, 2006; Bush, 2015]. Inspired by the correspondence between emergent macroscale dynamics and phenomena in quantum systems, we tested if robotic snakes, which resemble wave packets, behave emergently like particles or waves when interacting with an obstacle. In lab experiments and numerical simulations we measured how a multi-module snake-like robot swam through a single slit. We controlled the snake undulation gait as a fixed serpenoid traveling wave pattern with varying amplitude and initial phase, and we examined the snake trajectory as it swam through a slit with width  $d$ . Robot trajectories were straight before interaction with the slit, then exited at different scattering angle  $\theta$  after the interaction due to a complex interaction of the body wave with the slit. For fixed amplitude and large  $d$ , the snake passed through the slit with minimal interaction and  $\theta$  was  $\approx 0$ . For sufficiently small  $d$ ,  $\theta$  was finite and bimodally distributed, depending on the initial phase. For intermediate  $d$ ,  $\theta$  was sensitive to initial phase, and the width of the distribution of  $\theta$  increased with decreasing  $d$ .

**12:39PM Y40.00008 Multi-terrain locomotor interactions in flying snakes<sup>1</sup>** , ISAAC YEATON, GRANT BAUMGARDNER, SHANE ROSS, JOHN SOCHA, Virginia Tech — Arboreal snakes of the genus *Chrysopelea* are the only known snakes to glide. To execute aerial locomotion, a snake uses one of several stereotyped jumps from a tree into the air, while simultaneously flattening its body into an aerodynamically favorable shape. Large amplitude traveling waves are propagated posteriorly during the stable glide, while landing involves body wrapping, passive body compression, and energy absorption through compliance in the landing substrate to dissipate the accumulated kinetic energy from the glide. In all of these locomotor events, from interacting with cylindrical branches, falling through the air, grasping compliant tree branches and leaves, to landing on solid ground, snakes appropriate the same body morphology and perhaps the same basic neural mechanisms. Here we discuss our use of computational models and animal experiments to understand how flying snakes interact with and locomote on and through multiple media, potentially providing principles for legless locomotor designs.

**12:51PM Y40.00009 Aerodynamic control with passively pitching wings** , NICK GRAVISH, ROBERT WOOD, Harvard University — Flapping wings may pitch passively under aerodynamic and inertial loads. Such passive pitching is observed in flapping wing insect and robot flight. The effect of passive wing pitch on the control dynamics of flapping wing flight are unexplored. Here we demonstrate in simulation and experiment the critical role wing pitching plays in yaw control of a flapping wing robot. We study yaw torque generation by a flapping wing allowed to passively rotate in the pitch axis through a rotational spring. Yaw torque is generated through alternating fast and slow upstroke and downstroke. Yaw torque sensitively depends on both the rotational spring force law and spring stiffness, and at a critical spring stiffness a bifurcation in the yaw torque control relationship occurs. Simulation and experiment reveal the dynamics of this bifurcation and demonstrate that anomalous yaw torque from passively pitching wings is the result of aerodynamic and inertial coupling between the pitching and stroke-plane dynamics.

**1:03PM Y40.00010 Crucial advantages of tail use in the evolution of vertebrate terrestrial locomotion.** , HENRY ASTLEY, Georgia Inst of Tech, BENJAMIN MCINROE, U C Berkeley, SANDY KAWANO, National Institute for Mathematical and Biological Synthesis, RICK BLOB, Clemson University, DANIEL GOLDMAN, Georgia Inst of Tech — In the invasion of terrestrial environment, the first tetrapods faced the challenge of locomotion on flowable substrates (e.g. sand and mud), sometimes oriented at inclines. Although the morphology of many early tetrapods is known, robotic studies have revealed that effective locomotion on these substrates also depends strongly upon kinematics; slight differences in movements of the same appendage can lead to success or failure. Using a model organism (the mudskipper) and a robotic physical model, we demonstrate how muscular tails provided critical locomotor advantages on granular substrates that the first invaders of land likely encountered. Mudskippers use their tails for additional propulsion with increasing frequency as the slope of the granular material increases, and the decline in locomotor performance with slope is shallower when the tail is used. Experiments with a robotic model of the mudskipper showed that, while the tail did not always provide a benefit to locomotion, use of the tail made the robot's performance more robust, achieving effective locomotion on a wider range of slopes, limb postures and foot placements. These results suggest that, rather than simply being an inert appendage, the tails of early tetrapods were vital to their first forays into terrestrial habitats.

**1:15PM Y40.00011 Mutually opposing forces during locomotion can eliminate the tradeoff between maneuverability and stability** , NOAH COWAN, SHAHIN SEFATI, Johns Hopkins University, IZAAK NEVELN, Northwestern University, EATAI ROTH, TERENCE MITCHELL, Johns Hopkins University, JAMES SNYDER, MALCOLM MACIVER, Northwestern University, ERIC FORTUNE, New Jersey Institute of Technology — A surprising feature of animal locomotion is that organisms typically produce substantial forces in directions other than what is necessary to move the animal through its environment, such as perpendicular to, or counter to, the direction of travel. The effect of these forces has been difficult to observe because they are often mutually opposing and therefore cancel out. Using a combination of robotic physical modeling, computational modeling, and biological experiments, we discovered that these forces serve an important role: to simplify and enhance the control of locomotion. Specifically, we examined a well-suited model system, the glass knifefish *Eigenmannia virescens*, which produces mutually opposing forces during a hovering behavior. By systematically varying the locomotor parameters of our biomimetic robot, and measuring the resulting forces and kinematics, we demonstrated that the production and differential control of mutually opposing forces is a strategy that generates passive stabilization while simultaneously enhancing maneuverability. Mutually opposing forces during locomotion are widespread across animal taxa, and these results indicate that such forces can eliminate the tradeoff between stability and maneuverability, thereby simplifying robotic and neural control.

**1:27PM Y40.00012 A robotic platform for studying sea lion thrust production** , MEGAN LEFTWICH, RAHI PATEL, ADITYA KULKARNI, CHEN FRIEDMAN, The George Washington University — California Sea Lions are agile swimmers and, uniquely, use their foreflippers (rather than hind flipper undulation) to generate thrust. Recently, a sea lion flipper from a deceased subject was externally scanned in high detail for fluid dynamics research. The flipper's geometry is used in this work to build an accurate scaled down flipper model (approximately 68% of the full size span). The flipper model is placed in a water flume to obtain lift and drag force measurements. The unique trailing edge features are then examined for their effect on the measured forces by comparing to similar flipper models with a smooth trailing edge, sinusoidal trailing edge, and a saw-tooth trailing edge. Additionally, a robotic flipper is being designed and built, replicating the sea lion foreflipper anatomical structure. The robot is actuated by a set of servo motors and replicates the sea lion flipper clap motion based on previously extracted kinematics. The flipper tip speed is designed to match typical full scale Reynolds numbers for an acceleration from rest maneuver. The model is tested in the water flume as well to obtain the forces and flow structures during the thrust production phase of the flipper motion.

**1:39PM Y40.00013 Controlled locomotion of robots driven by a vibrating surface<sup>1</sup>** , PAUL UMBANHOWAR, KEVIN M. LYNCH, Northwestern University — Robots typically derive their powers of movement from onboard actuators and power sources, but other scenarios are possible where the external environment provides part or all of the necessary forcing and control. I will discuss details of a system where the robots are just planar solid objects and the requisite driving forces originate from frictional sliding-interactions with a periodically oscillated and nominally horizontal surface. For the robots to move, the temporal symmetry of the frictional forces must be broken, which is achieved here by modulating the normal force using vertical acceleration of the surface. Independent of the initial conditions and vibration waveform, a sliding locomotor reaches a unique velocity limit cycle at a given position. Its resulting motion can be described in terms of velocity fields which specify the robots cycle-averaged velocity as a function of position. Velocity fields with non-zero spatial divergence can be generated by combining translational and rotational surface motions; this allows the simultaneous and open-loop collection, dispersal, and transport of multiple robots. Fields and field sequences can simultaneously move multiple robots between arbitrary positions and, potentially, along arbitrary trajectories.

**1:51PM Y40.00014 Dynamical states in the sensorimotor loop of a rolling robot** , BULCSÚ SÁNDOR, TIM JAHN, LAURA MARTIN, RODRIGO ECHEVESTE, CLAUDIUS GROS, Institute for Theoretical Physics, Goethe University Frankfurt — We investigate the closed sensorimotor loop of a simple rolling robot as a dynamical system. Using the LpzRobots simulation package <sup>1</sup>, we construct robots with cylindrical body, controlled by a single proprioceptive neuron with a time dependent threshold. Despite its simplicity, we obtain a rich set of rolling modes, as a result of the self-organizing processes arising through the feedback within the sensorimotor loop. These rolling modes are robust against environmental noise, since they correspond to stable limit cycle attractors. However, for certain parameters they also allow for explorative behavior via internal noise induced switching. Furthermore, we also find a region of parameters in which the motion is fully embodied, where, in engineering terms, the engine powering the motion of the robot is turned on dynamically through the feedback of its very motion <sup>2</sup>.

**2:03PM Y40.00015 Vibration Propagation in Spider Webs<sup>1</sup>** , ROSS HATTON, ANDREW OTTO, Oregon State Univ, DAMIAN ELIAS, Univ. California, Berkeley — Due to their poor eyesight, spiders rely on web vibrations for situational awareness. Web-borne vibrations are used to determine the location of prey, predators, and potential mates. The influence of web geometry and composition on web vibrations is important for understanding spiders behavior and ecology. Past studies on web vibrations have experimentally measured the frequency response of web geometries by removing threads from existing webs. The full influence of web structure and tension distribution on vibration transmission; however, has not been addressed in prior work. We have constructed physical artificial webs and computer models to better understand the effect of web structure on vibration transmission. These models provide insight into the propagation of vibrations through the webs, the frequency response of the bare web, and the influence of the spider's mass and stiffness on the vibration transmission patterns.

**2:15PM Y40.00016 Proprioceptive Actuation Design for Dynamic Legged locomotion<sup>1</sup>**, SANGBAE KIM, PATRICK WENSING, MIT, BIOMIMETIC ROBOTICS LAB TEAM — Designing an actuator system for highly-dynamic legged locomotion exhibited by animals has been one of the grand challenges in robotics research. Conventional actuators designed for manufacturing applications have difficulty satisfying challenging requirements for high-speed locomotion, such as the need for high torque density and the ability to manage dynamic physical interactions. It is critical to introduce a new actuator design paradigm and provide guidelines for its incorporation in future mobile robots for research and industry. To this end, we suggest a paradigm called proprioceptive actuation, which enables highly- dynamic operation in legged machines. Proprioceptive actuation uses collocated force control at the joints to effectively control contact interactions at the feet under dynamic conditions. In the realm of legged machines, this paradigm provides a unique combination of high torque density, high-bandwidth force control, and the ability to mitigate impacts through backdrivability. Results show that the proposed design provides an impact mitigation factor that is comparable to other quadruped designs with series springs to handle impact. The paradigm is shown to enable the MIT Cheetah to manage the application of contact forces during dynamic bounding, with results given down to contact times of 85ms and peak forces over 450N. As a result, the MIT Cheetah achieves high-speed 3D running up to 13mph and jumping over an 18-inch high obstacle.

**11:15AM Y41.00001 Tension, cell shape and triple-junction angle anisotropy in the Drosophila germband<sup>1</sup>**, MONICA LACY, M. SHANE HUTSON, CHRISTIAN MEYER, XENA MCDONALD, Vanderbilt University — In the field of tissue mechanics, the embryonic development of Drosophila melanogaster offers many opportunities for study. One of Drosophila's most crucial morphogenetic stages is the retraction of an epithelial tissue called the germband. During retraction, the segments of the retracting germband, as well as the individual germband cells, elongate in response to forces from a connected tissue, the amnioserosa. Modeling of this elongation, based on tissue responses to laser wounding, has plotted the internal germband tension against the external amnioserosa stress, creating a phase space to determine points and regions corresponding to stable elongation. Although the resulting fits indicate a necessary opposition of internal and external forces, they are inconclusive regarding the exact balance. We will present results testing the model predictions by measuring cell shapes and the correlations between cell-edge directions and triple-junction angles. These measures resolve the ambiguity in pinpointing the internal-external force balance for each germband segment.

**11:27AM Y41.00002 Small angle x-ray diffraction through living muscle links the lattice structure to macroscopic material properties**, TRAVIS TUNE, Georgia Inst of Tech, TOM IRVING, Illinois Institute of Technology, SIMON SPONBERG, Georgia Inst of Tech — Muscle is a unique hierarchical material composed of millions of molecular motors arranged on filaments in a regular lattice structure. The macroscopic, material behavior of muscle can be characterized by its workloop, a periodically activated force-length curve. Muscle is capable of operating as a spring, motor, brake, or strut, defined by its workloop. We are interested in the multiscale physics of muscle that drive its energetic versatility – the ability of muscle to alter its function. Here we introduce a system of two muscles from the cockroach whose workloops are not explained by our current understanding of the determinants of workloop function (the classic force-length, force-velocity, and twitch response). Differences in material behavior may arise from structural differences in the muscles active lattice. Using the BIOCat beam at the Advanced Photon Source at Argonne NL, we tested for differences in the two muscles lattice structure. Small-angle x-ray scattering (SAXS) revealed a difference of 4-8

**11:39AM Y41.00003 Curvature dependent modulation of fish fin stiffness**, KHOI NGUYEN, Okinawa Institute of Science and Technology, NING YU, Brown University, MAHESH BANDI, Okinawa Institute of Science and Technology, MADHUSUDHAN VENKADESAN, Yale University, SHREYAS MANDRE, Brown University — Propulsion and maneuvering ability of fishes depends on the stiffness of their fins. However, increasing stiffness by simply adding material to thicken the fin would incur a substantial energetic cost associated with flapping the fin. We propose that fishes increase stiffness of the fin not by building thicker fins, but by geometrically coupling out-of-plane bending of the fin's rays with in-plane stretching of a stiff membrane that connects the rays. We present a model of fin elasticity for ray-finned fish, where we decompose the fin into a series of elastic beams (rays) with springy interconnections (membrane). In one limit, where the membranes are infinitely extensible, the fin's stiffness is no more than the sum of the stiffness of individual rays. At the other limit of an inextensible membrane, fin stiffness reaches an asymptotic maximum. The asymptote value increases monotonically with curvature. We propose that musculature at the base of the fin controls fin curvature, and thereby modulates stiffness.

**11:51AM Y41.00004 Heterogeneous Force Chains in Cellularized Biopolymer Network**, LONG LIANG, Department of Physics, Arizona State University, CHRISTOPHER ALLEN RUCKSACK JONES, BO SUN, Department of Physics, Oregon State University, YANG JIAO, Materials Science and Engineering, Arizona State University, Tempe, AZ — Biopolymer Networks play an important role in coordinating and regulating collective cellular dynamics via a number of signaling pathways. Here, we investigate the mechanical response of a model biopolymer network due to the active contraction of embedded cells. Specifically, a graph (bond-node) model derived from confocal microscopy data is used to represent the network microstructure, and cell contraction is modeled by applying correlated displacements at specific nodes, representing the focal adhesion sites. A force-based stochastic relaxation method is employed to obtain force-balanced network under cell contraction. We find that the majority of the forces are carried by a small number of heterogeneous force chains emerged from the contracting cells. The force chains consist of fiber segments that either possess a high degree of alignment before cell contraction or are aligned due to the reorientation induced by cell contraction. Large fluctuations of the forces along different force chains are observed. Importantly, the decay of the forces along the force chains is significantly slower than the decay of radially averaged forces in the system, suggesting that the fibrous nature of biopolymer network structure could support long-range mechanical signaling between cells.

**12:03PM Y41.00005 Three-Dimensional Cell Behavior in Microgels<sup>1</sup>**, TAPOMOY BHATTACHARJEE, GLYN PALMER, STEVEN GHIVIZZANI, BENJAMIN KESELOWSKY, W GREGORY SAWYER, THOMAS ANGELINI, University of Florida — The number of dimensions in which particles can freely move strongly influences the collective behavior that emerges from their individual fluctuations. Thus, in 2D systems of cells in petri-dishes, our growing understanding of collective migration may be insufficient to explain cell behavior in 3D tissues. To study cell behavior in 3D, polymer scaffolds are used. Contemporary designs of 3D cell growth scaffolds enable cell migration and proliferative expansion by incorporating of degradable motifs. Matrix degradation creates space for cells to move and proliferate. However, different cell types and experimental conditions require the design of different scaffolds to optimize degradation with specific cell behaviors. By contrast, liquid like solids made from packed microgels can yield under cell generated stresses, allowing for cell motion without the need for scaffold degradation. Moreover, the use of microgels as 3D culture media allows arranging cells in arbitrary structures, harvesting cells, and delivering drugs and nutrients. Preliminary data describing cell behavior in 3D microgel culture will be presented.

**12:15PM Y41.00006 Frequency-dependent micromechanics of cellularized biopolymer networks**, CHRIS JONES, JIHAN KIM, DAVID MCINTYRE, BO SUN, Oregon State University — Mechanical interactions between cells and the extracellular matrix (ECM) influence many cellular behaviors such as growth, differentiation, and migration. These are dynamic processes in which the cells actively remodel the ECM. Reconstituted collagen gel is a common model ECM for studying cell-ECM interactions *in vitro* because collagen is the most abundant component of mammalian ECM and gives the ECM its material stiffness. We embed micron-sized particles in collagen and use holographic optical tweezers to apply forces to the particles in multiple directions and over a range of frequencies up to 10 Hz. We calculate the local compliance and show that it is dependent on both the direction and frequency of the applied force. Performing the same measurement on many particles allows us to characterize the spatial inhomogeneity of the mechanical properties and shows that the compliance decreases at higher frequencies. Performing these measurements on cell-populated collagen gels shows that cellular remodeling of the ECM changes the mechanical properties of the collagen and we investigate whether this change is dependent on the local strain and distance from nearby cells.

**12:27PM Y41.00007 Asymmetries arising from the space-filling nature of vascular networks**, DAVID HUNT, VAN SAVAGE, University of California - Los Angeles — Cardiovascular networks span the body by branching across many generations of vessels. The structural features of the network that accomplish this density and ubiquity of capillaries are often called space-filling. Some strategies do not lead to biologically adaptive structures, requiring too much construction material or space, delivering resources too slowly, or using too much power to move blood through the system. We empirically measure the structure of real networks to compare with predictions of model networks that are space-filling and constrained by a few guiding biological principles. We devise a numerical method that enables the investigation of space-filling strategies and determination of which biological principles influence network structure. Optimization for only a single principle creates unrealistic networks that represent an extreme limit of the possible structures that could be observed in nature. We first study these extreme limits for two competing principles, minimal total material and minimal path lengths. We combine these two principles and enforce various thresholds for balance in the network hierarchy, which provides a novel approach that highlights the trade-offs faced by biological networks and yields predictions that better match empirical data.

**12:39PM Y41.00008 Spatio-temporal Model of Xenobiotic Distribution and Metabolism in an in Silico Mouse Liver Lobule<sup>1</sup>**, XIAO FU, JAMES SLUKA, SHERRY CLENDENON, JAMES GLAZIER, Indiana Univ - Bloomington, JENNIFER RYAN, KENNETH DUNN, Indiana Univ - Indianapolis, ZEMIN WANG, JAMES KLAUNIG, Indiana Univ - Bloomington — Our study aims to construct a structurally plausible in silico model of a mouse liver lobule to simulate the transport of xenobiotics and the production of their metabolites. We use a physiologically-based model to calculate blood-flow rates in a network of mouse liver sinusoids and simulate transport, uptake and biotransformation of xenobiotics within the in silico lobule. Using our base model, we then explore the effects of variations of compound-specific (diffusion, transport and metabolism) and compound-independent (temporal alteration of blood flow pattern) parameters, and examine their influence on the distribution of xenobiotics and metabolites. Our simulations show that the transport mechanism (diffusive and transporter-mediated) of xenobiotics and blood flow both impact the regional distribution of xenobiotics in a mouse hepatic lobule. Furthermore, differential expression of metabolic enzymes along each sinusoids portal to central axis, together with differential cellular availability of xenobiotics, induce non-uniform production of metabolites. Thus, the heterogeneity of the biochemical and biophysical properties of xenobiotics, along with the complexity of blood flow, result in different exposures to xenobiotics for hepatocytes at different lobular locations.

**12:51PM Y41.00009 Modeling oxygen transport in the placenta**, FILOCHE, Physique de la Matière Condensée, Université de Lorraine, S.M. 207, Boulevard S. P. 23, 54506 Vandœuvre-lès-Nancy Cedex, France — Efficient functioning of the placenta is essential for the health of the fetus. The placenta is a complex organ, the structure of which is based on its histological cross-section. The efficiency of oxygen transport from the mother to the fetus is determined by the estimate oxygen uptake of a placental unit. We have developed a model to estimate the incoming oxygen flow and the absorbing villous surface area. The villi density and the effective villi radius - are determined by the oxygen uptake. The oxygen uptake is also identified: maximal oxygen uptake is 22 healthy placental cross-sections demonstrate that the oxygen transport efficiency is rather low (around 30-40%). In this paper, we present a preliminary assessment in the human placenta.

**Session Y42 DPOLY: Renewable and Sustainable Polymers** 345 - Megan Robertson, University of Houston

**11:15AM Y42.00001 Sustainable epoxy and oxetane thermosets from photo-initiated cationic polymerization.**, CHANG RYU, Rensselaer Polytechnic Institute — A group of sustainable materials are proposed and produced from multifunctional epoxides and oxetanes obtained from renewable sources. Monomers are photopolymerized using diaryliodonium salts designed and synthesized by our group as initiator. A detailed investigation of the network formation of epoxidized linseed oil revealed that crosslinks is markedly dependent to the thickness and viscosity of substrate. Copolymerization studies of difunctional oxetane showed that limonene dioxide was effective in increasing the reaction rates and shorten the inherent induction period, also known as kick-starting effect. Such oxetane thermoset can achieve desirable curing rates and Tg compared to petroleum based epoxy used in applications such as large scale surface coatings.

**11:51AM Y42.00002 Structure and Dynamics of Cellulose Molecular Solutions**, HOWARD WANG, XIN ZHANG, University of Maryland, College Park, MADHUSUDAN TYAGI, YIMIN MAO, NIST Center for Neutron Research, ROBERT BRIBER, University of Maryland, College Park — Molecular dissolution of microcrystalline cellulose has been achieved through mixing with ionic liquid 1-Ethyl-3-methylimidazolium acetate (EMIMAc), and organic solvent dimethylformamide (DMF). The mechanism of cellulose dissolution in tertiary mixtures has been investigated by combining quasielastic and small angle neutron scattering (QENS and SANS). As SANS data show that cellulose chains take Gaussian-like conformations in homogenous solutions, which exhibit characteristics of having an upper critical solution temperature, the dynamic signals predominantly from EMIMAc molecules indicate strong association with cellulose in the dissolution state. The mean square displacement quantities support the observation of the stoichiometric 3:1 EMIMAc to cellulose unit molar ratio, which is a necessary criterion for the molecular dissolution of cellulose. Analyses of dynamics structure factors reveal the temperature dependence of a slow and a fast process for EMIMAc bound to cellulose and in DMF, respectively, as well as a very fast process due possibly to the rotational motion of methyl groups, which persisted to near the absolute zero.

**12:03PM Y42.00003 Thermodynamics of coil-hyperbranched poly(styrene-*b*-acrylated epoxidized soybean oil) block copolymers.** , FANG-YI LIN, AUSTIN HOHMANN, NACÚ HERNÁNDEZ, ERIC COCHRAN, Iowa State University — Here we present the phase behavior of a new type of coil-hyperbranched diblock copolymer: poly(styrene-*b*-acrylated epoxidized soybean oil), or PS-PAESO. PS-PAESO is an example of a biorenewable thermoplastic elastomer (bio-TPE). To date, we have shown that bio-TPEs can be economical commercial substitutes for their petrochemically derived analogues—such as poly(styrene-*b*-butadiene-*b*-styrene) (SBS)—in a range of applications including pressure sensitive adhesives and bitumen modification. From a polymer physics perspective, PS-PAESO is an interesting material in that it couples a linear coil-like block with a highly branched block. Thus in contrast to the past five decades of studies on linear AB diblock copolymers, coil-hyperbranched block copolymers are relatively unknown to the community and can be expected to deviate substantially from the standard “universal” phase behavior in the AB systems. To explore these new materials, we have constructed a library of PS-PAESO materials spanning a range of molecular weight and composition values. The phase transition behavior and the morphology information will be interpreted by isochronal temperature scanning in dynamic shear rheology, small angle X-ray scattering and the corresponding transmission electron microscopy.

**12:15PM Y42.00004 Mechanochemical modification of lignin and application of the modified lignin for thermoplastics and thermosets** , XIAOJIE GUO, JINWEN ZHANG, JUNNA XIN, Washington State University — In this work, mechanochemical modification of lignin and use of the modified lignin in thermoplastics and thermosets were studied. Oleated lignin was successfully prepared by transesterification between lignin and methyl, and the oleation reaction was performed in a solvent-free and room temperature ball milling process with a relatively short time. PLA/lignin blends were prepared through melt extrusion. Compared with the PLA/lignin blends, the PLA/oleated lignin blends exhibited finer dispersion of lignin in the blends, increased glass transition temperature and higher tensile properties, suggesting improved compatibility between lignin and PLA. Carboxylic and anhydride groups were also introduced into the structure of lignin via mechanochemical modification, and the resulting lignin derivatives were used as curing agents for epoxies. The dynamic mechanical properties and thermal stability of the cured epoxy resins were studied using dynamic mechanical analysis (DMA) and thermogravimetric analysis (TGA).

**12:27PM Y42.00005 Alignment of Fatty Acid-Derived Triblock Copolymers under Large Amplitude Oscillatory Shear** , WENYUE DING, SHU WANG, University of Houston, SAMEER KESAVA, ENRIQUE GOMEZ, The Pennsylvania State University, MEGAN ROBERTSON, University of Houston — Linear ABA triblock copolymers find widespread utilization as thermoplastic elastomers (TPEs): materials which exhibit elastomeric behavior at room temperature and can be readily processed at elevated temperatures. Traditional TPEs are derived from fossil fuels; however, the finite availability of petroleum and the environmental impact of petroleum processing has led to an increased interest in developing alternative sources for polymers. Vegetable oils and their fatty acids are promising replacements for petroleum sources due to their abundance, low cost, lack of toxicity, biodegradability and ease of functionalization that provides convenient routes to polymerization. In this study, triblock copolymer TPEs were synthesized containing lauryl and stearyl acrylate, derived from fatty acids found in vegetable oils. Small-angle X-ray scattering experiments revealed highly aligned triblock copolymer morphologies after the application of large amplitude oscillatory shear. The temperature and frequency dependence of the degree of alignment was investigated. In contrast to prior studies on shear-aligned morphologies in bulk and thin film block copolymers, hexagonal close packed and face centered cubic spherical structures were observed.

**12:39PM Y42.00006 PLA branching with anhydrides and tri-functional aziridine<sup>1</sup>** , LIANGLIANG GU, YUEWEN XU, RAJASEKHAR NAREDLA, THOMAS HOYE, CHRISTOPHER MACOSKO, Univ of Minn - Minneapolis — Branched PLA was prepared by melt blending with tri-functional aziridine (T-Az) and pyromellitic dianhydride (PMDA). <sup>1</sup>HNMR, gel permeation chromatography (GPC) and rheology were used to characterize the topological structures of branched PLA. Fast reaction between PLA carboxyl end group and T-Az resulted in 3-arm stars and increased the molecular weight. However, the 3-arm stars did not show strain hardening behavior under extensional flow. After modifying PLA hydroxyl end group with PMDA, PLA can react with T-Az on both chain ends and form long chain branched structure, which showed strain hardening in extension. It was found that that only 10% of the PLA hydroxyl end groups reacted with PMDA.

**12:51PM Y42.00007 Wear Characteristics of Oleophobic Coatings in Aerospace Applications** , HAMZA SHAMS, BILAL A. SIDDIQUI, DHA Suffa University (DSU), SAJID SALEEM, National University of Sciences and Technology (NUST) — This paper investigates the wear characteristics of oleophobic coatings when applied over Inconel 718, which has widespread applications in the aerospace industry. Coatings once applied were selectively exposed to controlled uni- and then multi-directional sand storm conditions. Size and speed of sand particles colliding with the work surface were carefully moderated to simulate sand storm conditions. Study of friction was performed using Lateral Force Microscopy (LFM) coupled with standard optical microscopy. The analysis has been used to devise a coefficient of friction value and in turn suggest wear behavior of the coated surface including the time associated with exposure of the base substrate. The analysis after validation aims to suggest methods for safe usage of these coatings for aerospace applications.

**1:03PM Y42.00008 The influence of starch oxidization and aluminate coupling agent on interfacial interaction, rheological behavior, mechanical and thermal properties of poly(propylene carbonate)/starch blends<sup>1</sup>** , GUO JIANG, SHUI-DONG ZHANG, HAN-XIONG HUANG, School of Mechanical & Automotive Engineering, South China University of Technology, THE KEY LABORATORY OF POLYMER PROCESSING ENGINEERING OF THE MINISTRY OF EDUCATION TEAM — Poly(propylene carbonate) (PPC) is a kind of new biodegradable polymer that is synthesized by copolymerization of propylene oxide and carbon dioxide. In this work, PPC end-capped with maleic anhydride (PPCMA)/thermoplastic starch (TPS), PPCMA/thermoplastic oxidized starch (TPOS) and PPCMA/AL-TPOS (TPOS modified by aluminate coupling agent) blends were prepared by melt blending to improve its thermal and mechanical properties. FTIR results showed that there existed hydrogen-bonding interaction between PPCMA and starch. SEM observation revealed that the compatibility between PPCMA and TPOS was improved by the oxidation of starch. The enhanced interfacial interactions between PPCMA and TPOS led to a better performance of PPC blends such as storage modulus ( $G'$ ), loss modulus ( $G''$ ), complex viscosity ( $\eta^*$ ), tensile strength and thermal properties. Furthermore, the modification of TPOS by aluminate coupling agent (AL) facilitated the dispersion of oxidized starch in PPC matrix, and resulted in increasing the tensile strength and thermal stability.

**11:15AM Y43.00001 Order-to-chaos transition in the hardness of random Boolean satisfiability problems**, MELINDA VARGA, Department of Physics, University of Notre Dame, ROBERT SUMI, MARIA ERCSEY-RAVASZ, Faculty of Physics, Babes-Bolyai University, Romania, ZOLTAN TOROCZKAI, Department of Physics, University of Notre Dame — Transient chaos is a phenomenon characterizing the dynamics of phase space trajectories evolving towards an attractor in physical systems. We show that transient chaos also appears in the dynamics of certain algorithms searching for solutions of constraint satisfaction problems (e.g., Sudoku). We present a study of the emergence of hardness in Boolean satisfiability ( $k$ -SAT) using an analog deterministic algorithm. Problem hardness is defined through the escape rate  $\kappa$ , an invariant measure of transient chaos, and it expresses the rate at which the trajectory approaches a solution. We show that the hardness in random  $k$ -SAT ensembles has a wide variation approximable by a lognormal distribution. We also show that when increasing the density of constraints  $\alpha$ , hardness appears through a second-order phase transition at  $\alpha_c$  in the random 3-SAT ensemble where dynamical trajectories become transiently chaotic, however, such transition does not occur for 2-SAT. This behavior also implies a novel type of transient chaos in which the escape rate has an exponential-algebraic dependence on the critical parameter. We demonstrate that the transition is generated by the appearance of non-solution basins in the solution space as the density of constraints is increased.

**11:27AM Y43.00002 Population Annealing: Theory and Application in Spin Glasses**<sup>1</sup>, JONATHAN MACHTA, Univ of Mass - Amherst, WENLONG WANG, HELMUT G. KATZGRABER, Texas A&M University — Population annealing is an efficient sequential Monte Carlo algorithm for simulating equilibrium states of systems with rough free energy landscapes. The theory of population annealing is presented, and systematic and statistical errors are discussed. The behavior of the algorithm is studied in the context of large-scale simulations of the three-dimensional Ising spin glass and the performance of the algorithm is compared to parallel tempering. It is found that the two algorithms are similar in efficiency though with different strengths and weaknesses.

<sup>1</sup>Supported by NSF DMR-1151387, DMR-1208046 and DMR-1507506

**11:39AM Y43.00003 Bond and temperature chaos in spin glasses revealed through thermal boundary conditions**<sup>1</sup>, WENLONG WANG, Texas AM Univ, JONATHAN MACHTA COLLABORATION<sup>2</sup>, HELMUT G. KATZGRABER COLLABORATION<sup>3</sup> — Spin glasses are complex systems with rugged energy landscapes that exhibit chaotic behavior. Unfortunately, despite decades of study, there is still no clear understanding of the chaotic behavior found in these systems. The use of thermal boundary conditions has become a useful approach to study such phenomena. Here we discuss how to efficiently simulate bond and temperature chaos using thermal boundary conditions and population annealing Monte Carlo. We provide a simple scaling argument for bond and temperature chaos, and present numerical results of the scaling exponents. Similarities and differences of bond chaos and temperature chaos are also discussed.

**11:51AM Y43.00004 Can we predict the difficulty of optimization problems without solving them?**, HELMUT G. KATZGRABER, CHAO FANG, RICHARD LAWRENCE, OLIVER MELCHERT, HUMBERTO MUNOZ-BAUZA, ANDREW J. OCHOA, WENLONG WANG, ZHENG ZHU, Texas A&M University — Surprisingly often. Based on previous results of a large-scale numerical study of the equilibrium three-dimensional Edwards-Anderson Ising spin glass where it was demonstrated that autocorrelation times are directly correlated with the roughness of the free-energy landscape [Phys. Rev. E 87, 012104 (2013)], we show that a generalized spin-glass order parameter can be used as a proxy to the computational difficulty of various paradigmatic optimization problems. Our results are illustrated with different optimization algorithms, as well as optimization problems. Furthermore, we show numerical evidence that the order-parameter distribution does mirror salient features in the free-energy landscape of complex systems for moderate system sizes.

**12:03PM Y43.00005 TemperSAT: A new efficient fair-sampling random  $k$ -SAT solver**, CHAO FANG, ZHENG ZHU, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University — The set membership problem is of great importance to many applications and, in particular, database searches for target groups. Recently, an approach to speed up set membership searches based on the NP-hard constraint-satisfaction problem (random  $k$ -SAT) has been developed [S. Weaver *et al.* JSAT 8, 129 (2014)]. However, the bottleneck of the approach lies in finding the solution to a large SAT formula efficiently and, in particular, a large number of independent solutions is needed to reduce the probability of false positives. Unfortunately, traditional random  $k$ -SAT solvers such as WalkSAT are biased when seeking solutions to the Boolean formulas. By porting parallel tempering Monte Carlo to the sampling of binary optimization problems, we introduce a new algorithm (TemperSAT) whose performance is comparable to current state-of-the-art SAT solvers for large  $k$  with the added benefit that theoretically it can find many independent solutions quickly. We illustrate our results by comparing to the currently fastest implementation of WalkSAT, WalkSAT/ $lm$ .

**12:15PM Y43.00006 ICANP2: Isoenergetic cluster algorithm for NP-complete Problems**, ZHENG ZHU, CHAO FANG, HELMUT G. KATZGRABER, Texas AM University — NP-complete optimization problems with Boolean variables are of fundamental importance in computer science, mathematics and physics. Most notably, the minimization of general spin-glass-like Hamiltonians remains a difficult numerical task. There has been a great interest in designing efficient heuristics to solve these computationally difficult problems. Inspired by the rejection-free isoenergetic cluster algorithm developed for Ising spin glasses [Phys. Rev. Lett. 115, 077201 (2015)], we present a generalized cluster update that can be applied to different NP-complete optimization problems with Boolean variables. The cluster updates allow for a wide-spread sampling of phase space, thus speeding up optimization. By carefully tuning the pseudo-temperature (needed to randomize the configurations) of the problem, we show that the method can efficiently tackle problems on topologies with a large site-percolation threshold. We illustrate the ICANP2 heuristic on paradigmatic optimization problems, such as the satisfiability problem and the vertex cover problem.

**12:27PM Y43.00007 ABSTRACT WITHDRAWN —**

**12:39PM Y43.00008 Lower-Critical Spin-Glass Dimension from 23 Sequenced Hierarchical Models**, MEHMET DEMIRTAS, Sabanci University and Cornell University, ASLI TUNCER, Istanbul Technical University, A. NIHAT BERKER, Sabanci University and MIT — The lower-critical dimension for the existence of the Ising spin-glass phase is calculated, numerically exactly, as  $d_L = 2.520$  for a sequence of hierarchical lattices, from an essentially exact (correlation coefficient  $R^2 = 0.999999$ ) near-linear fit to 23 different diminishing fractional dimensions. To obtain this result, the phase transition temperature between the disordered and spin-glass phases, the corresponding critical exponent  $y_T$ , and the runaway exponent  $y_R$  of the spin-glass phase are calculated for consecutive hierarchical lattices as dimension is lowered.[1]

**12:51PM Y43.00009 Odd  $q$ -State Clock Spin-Glass Models in Three Dimensions, Asymmetric Phase Diagrams, and Multiple Algebraically Ordered Phases**, EFE ILKER, Sabanci University and Case Western Reserve University, A. NIHAT BERKER, Sabanci University and MIT — Distinctive orderings and phase diagram structures are found, from renormalization-group theory, for odd  $q$ -state clock spin-glass models in  $d = 3$  dimensions [1]. These models exhibit asymmetric phase diagrams, as is also the case for quantum Heisenberg spin-glass models. No finite-temperature spin-glass phase occurs. For all odd  $q \geq 5$ , algebraically ordered antiferromagnetic phases [2,3] occur. One such phase is dominant and occurs for all  $q \geq 5$ . Other such phases occupy small low-temperature portions of the phase diagrams and occur for  $5 \leq q \leq 15$ . All algebraically ordered phases have the same structure, determined by an attractive finite-temperature sink fixed point where a dominant and a subdominant pair states have the only non-zero Boltzmann weights. The phase transition critical exponents quickly saturate to the high  $q$  value as previously observed for even  $q$ -state clock models [4].

**1:03PM Y43.00010 Spinodals of the Ising model on the order-4 pentagonal tiling of the hyperbolic plane**<sup>1</sup>, HOWARD L. RICHARDS, Physics, Marshall University — In the Euclidean plane, the Ising model on a regular lattice does not have a true spinodal – that is, there is no local minimum of the free energy that persists forever (in the limit of infinitely large systems) except for the global minimum, which characterizes the stable state. However, a local minimum can persist for a very long time, so the minimum can be referred to as a “metastable” state. The manner in which the metastable state decays depends on the strength of the magnetic field and the system size; the “thermodynamic spinodal” is the transition between systems large enough to contain a single critical droplet and systems that are too small to do so, and the “dynamic spinodal” marks the transition between decay as a Poisson process to decay that is “deterministic”, meaning the standard deviation of the lifetime of the metastable state is small compared with its mean value. However, in the hyperbolic plane, true metastability exists, and evidence shows that the thermodynamic spinodal and dynamic spinodal are numerically close to the true spinodal, the field below which the metastable state cannot decay through the nucleation and growth of droplets.

**1:15PM Y43.00011 Weak confinement in the three-state Potts Field Theory**, SERGEI RUTKEVICH, Univ Duisburg-Essen — Kink topological excitations are quite common in one-dimensional quantum ferromagnetic systems with the spontaneously broken discrete symmetry. Application of the external magnetic field  $h$  induces the long-range attractive force between kinks leading to their confinement. While in the Ising Field Theory the particle sector in the confinement regime contains only the two-kink bound states (“the mesons”), in the three-state Potts Field Theory (PFT) the three-kink bound states (“the baryons”) can exist as well. In the weak confinement regime, which is realized at small external magnetic fields, the meson masses in the PFT can be determined analytically in the leading order in  $h$  by means of the solution of a quantum-mechanical problem for two non-relativistic particles interacting with a linear attractive potential, and my means of the WKB method. The masses of lightest baryons in the three-state PFT were calculated by the numerical solution of a three-particle quantum-mechanical problem. The obtained mass spectra for the PFT mesons and baryons were confirmed recently by Lencés and Takács in numerical calculations based on the truncated conformal space approach.

Session Y48 GQI: Decoherence in Superconducting Qubits: Noise 349 - Frederick Wellstood, University of Maryland

**11:15AM Y48.00001 Design and Simulation of Microwave Attenuators for Superconducting Quantum Devices**, JAY LEFEBVRE, Department of Physics, University of Maryland, College Park, JEN-HAO YEH, Laboratory for Physical Sciences, College Park, MD and Department of Physics, University of Maryland, College Park, MD, FREDERICK WELLSTOOD, Department of Physics, University of Maryland, College Park, MD and Joint Quantum Institute, University of Maryland, College Park, BENJAMIN PALMER, Laboratory for Physical Sciences, College Park, MD and Department of Physics, University of Maryland, College Park, MD — We have found that dephasing times for quantum superconducting transmons operating nominally at  $T = 20$  mK can be limited by thermal photons in the read-out cavity due to non-equilibrium noise on our input microwave line. In an effort to reduce this noise, we have used finite-element simulations to design attenuators that provide better thermalization of the input microwave signals being delivered to our devices. Our thermal simulations incorporate both electron-phonon decoupling effects due to dissipated power in each element of the attenuator as well as phonon thermal conduction and Kapitza boundary effects. We combine the resulting thermal map with a thermal noise model of each dissipative element of the filter to estimate the effective noise temperature of our filter design.

**11:27AM Y48.00002 Cavity Dephasing in Transmon Qubits from Non-equilibrium Noise**, JEN-HAO YEH, Laboratory for Physical Sciences, College Park, MD and Department of Physics, University of Maryland, College Park, MD, JAY LEFEBVRE, Department of Physics, University of Maryland, College Park, MD, FREDERICK WELLSTOOD, Department of Physics, University of Maryland, College Park, MD and Joint Quantum Institute, University of Maryland, College Park, MD, BENJAMIN PALMER, Laboratory for Physical Sciences, College Park, MD and Department of Physics, University of Maryland, College Park, MD — The dephasing times for transmon qubits in a 3D cavity can be limited by coupling of the cavity input and output lines to non-equilibrium noise from higher temperature stages. In our system, the dominant source of thermal photons in the cavity is the last microwave attenuator in the microwave input line which is mounted on the 20 mK stage. Guided by thermal and microwave simulations, we have fabricated microwave attenuators and tested them in a 3D transmon measurement system. The performance of the attenuators was quantified by measuring the Ramsey decay time of a transmon qubit as a function of the temperature of the mixing chamber and power dissipated in the attenuator. Based on the Ramsey decay times and properties of the transmon-cavity system, we estimate the effective output noise temperature of the attenuator and compare our results to simulations.

**11:39AM Y48.00003 Qubit dephasing due to photon shot noise from coherent and thermal sources<sup>1</sup>**, S. GUSTAVSSON, F. YAN, A. KAMAL, T. P. ORLANDO, W. D. OLIVER, MIT, J. BIRENBAUM, A. SEARS, D. HOVER, T. GUDMUNDSEN, J. YODER, MIT Lincoln Laboratory — We investigate qubit dephasing due to photon shot noise in a superconducting flux qubit transversally coupled to a coplanar microwave resonator. Due to the AC Stark effect, photon fluctuations in the resonator cause frequency shifts of the qubit, which in turn lead to dephasing. While this is universally understood, we have made the first quantitative spectroscopy of this noise for both thermal (i.e., residual photons from higher temperature stages) and coherent photons (residual photons from the readout and control pulses). We find that the bandwidth of the shot noise from thermal and coherent photons differ by approximately a factor of two, which we attribute to differences in the correlation time for the two noise sources. By comparing the results with noise spectra measured without any externally applied photons, we conclude that the qubit coherence times in our setup were limited by photon shot noise from thermal radiation, with an average resonator photon population of 0.006. Equipped with this knowledge, we improved the filtering for thermal noise and thereby improved the qubit coherence times by more than a factor of two, with T2 echo times approaching 100  $\mu$ s. From the measured T2 decay, we determine an upper bound on the residual photon population of 0.0004.

**11:51AM Y48.00004 Suppression of photon shot noise dephasing in a tunable coupling superconducting qubit**, GENG YAN ZHANG, YANBING LIU, JAMES RAFTERY, ANDREW HOUCK, Princeton University — We report on the suppression of photon shot noise dephasing in a tunable coupling qubit (TCQ). This is achieved by eliminating the dispersive coupling rate,  $\chi$ , between the TCQ and the readout cavity. We observe that the coherence time approaches twice the relaxation time and becomes less sensitive to thermal photon noise when  $\chi$  is tuned close to zero. Experimental results of tunable  $\chi$  and its impact on qubit coherence will be presented.

**12:03PM Y48.00005 Dephasing of superconducting asymmetric transmon qubits**, M. HUTCHINGS, MATTHEW WARE, YEBIN LIU, Syracuse university, JARED B. HERTZBERG, JERRY M. CHOW, IBM T.J. Watson Research Center, Yorktown Heights, NY 10598, USA, B. L. T. PLOURDE, Syracuse university — As quantum computing implementations based on superconducting qubits increase in scale and complexity, fabrication tolerances and frequency crowding make it desirable to have layouts with at least some of the qubit frequencies being tunable. Split-junction transmon qubits allow for the tuning of qubit energy levels with a magnetic flux. However, this tunability can lead to excess dephasing due to flux noise. By making the two junctions asymmetric, the modulation range of the qubit energy bands can be reduced along with the sensitivity to flux noise. Such asymmetric transmons have been used previously for demonstrations of flux-modulated first-order sideband transitions between a qubit and cavity. We will report on the sensitivity of qubit dephasing to magnetic flux noise for different junction asymmetry. For large asymmetries, of the order of 10:1, the dephasing due to flux noise is greatly reduced compared to a symmetric junction device, whilst still maintaining a useful level of frequency tunability.

**12:15PM Y48.00006 Paramagnetic Spins on -Al<sub>2</sub>O<sub>3</sub> with Varied Surface Termination<sup>1</sup>**, KEITH RAY, Lawrence Livermore National Laboratory, DONGHWA LEE, Chonnam National University, NICOLE ADELSTEIN, San Francisco State University, JONATHAN DUBOIS, VINCENZO LORDI, Lawrence Livermore National Laboratory — Superconducting qubits (SQs) are promising building blocks for a quantum computer, however, coherence in SQs is reduced by unintended coupling to magnetic noise sources. The microscopic origins of the magnetic noise have not been satisfactorily characterized. Building on previous computational studies [PRL 112, 017001 (2014)] of magnetic spins induced by molecules adsorbed on bare Al terminated Al<sub>2</sub>O<sub>3</sub>, we present a density functional theory investigation of magnetic noise associated with other Al<sub>2</sub>O<sub>3</sub> surfaces likely to be encountered in experiment. We calculate the exchange interaction between native defects and adsorbed molecules, as well as the magnetic states energy splitting and anisotropy, on fully hydroxylated Al<sub>2</sub>O<sub>3</sub>, with and without a water over-layer. We also present simulated x-ray adsorption and x-ray magnetic circular dichroism spectra of these systems with the aim of aiding experimental surface characterization.

<sup>1</sup>This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344.

**12:27PM Y48.00007 Suppression of 1/f Flux Noise in Superconducting Quantum Circuits**, PRADEEP KUMAR, University of Wisconsin, Madison, JOHN FREELAND, Advanced Photon Source, Argonne National Lab, Argonne, IL, CLARE YU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA, ZHE WANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai, China, HUI WANG<sup>1</sup>, CHUNTAI SHI<sup>2</sup>, Department of Physics and Astronomy, University of California, Irvine, CA, DAVID PAPPAS, National Institute of Standards and Technology, Boulder, CO, ROBERT MCDERMOTT, University of Wisconsin, Madison — Low frequency 1/f magnetic flux noise is a dominant contributor to dephasing in superconducting quantum circuits. It is believed that the noise is due to a high density of unpaired magnetic defect states at the surface of the superconducting thin films. We have performed X-ray absorption spectroscopy (XAS) and X-ray magnetic circular dichroism (XMCD) experiments that point to adsorbed molecular oxygen as the dominant source of magnetism in these films. By improving the vacuum environment of our superconducting devices, we have achieved a significant reduction in surface magnetic susceptibility and 1/f flux noise power spectral density. These results open the door to realization of superconducting qubits with improved dephasing times.

**12:39PM Y48.00008 Measurement of the Magnetic Flux Noise Spectrum in Superconducting Xmon Transmon Quantum Bits**, BEN CHIARO, UC - Santa Barbara, D. SANK, J. KELLY, Google - Santa Barbara, Z. CHEN, B. CAMPBELL, A. DUNSWORTH, P. O'MALLEY, C. NEILL, C. QUINTANA, A. VAINSENCHE, J. WENNER, UC - Santa Barbara, R. BAREND, Y. CHEN, A. FOWLER, E. JEFFREY, A. MIGRANT, J. MUTUS, P. ROUSHAN, T. WHITE, Google - Santa Barbara, J. M. MARTINIS, UC - Santa Barbara and Google - Santa Barbara — Dephasing induced by magnetic flux noise limits the performance of modern superconducting quantum processors. We measure the flux noise power spectrum in planar, frequency-tunable, Xmon transmon quantum bits (qubits), with several SQUID loop geometries. We extend the Ramsey Tomography Oscilloscope (RTO) technique by rapid sampling up to 1 MHz, without state reset, to measure the flux noise power spectrum between 10<sup>-2</sup> and 10<sup>5</sup> Hz. The RTO measurements are combined with idle gate randomized benchmarking and Ramsey decay to give a more complete picture of dephasing in SQUID-based devices.

**12:51PM Y48.00009 1/f noise driven qubit dynamics in presence of a bosonic thermostat**, KOSTYANTYN KECHEDZHI, FEDIR VASKO, ANDRE PETUKHOV, NASA Ames Research Center, Mail Stop 269-3, Moffet Field, CA 94035, VADIM SMELYANSKIY, Google, Venice, CA 90291, US — Motivated by observations of distinct sources of noise in superconducting flux qubits over a wide frequency range, we analyze a qubit, a two level system, coupled to two microscopic sources of noise: 1/f low frequency noise and the Ohmic high frequency noise. The noise sources are treated as independent and characterized by different temperatures. We analyze the steady state regime of the resulting out-of-equilibrium dynamics focusing in particular on the effects of the interplay of the two types of noise on spectroscopic characteristics of the qubit. We calculate both analytically and numerically the steady state population of the qubit energy levels, relaxation and dephasing times and effective renormalization of the qubit's energy level splitting.

**1:03PM Y48.00010 1/f permittivity noise probed uniformly in a film with two level systems: The power law of field saturation and the relationship to loss**, KEVIN OSBORN, Laboratory for Physical Sciences and Joint Quantum Institute, ARUNA RAMANAYAKA, BAHMAN SARABI, Laboratory for Physical Sciences and University of Maryland Physics Dept., U. OF MARYLAND TEAM — Noise from atomic tunneling two-level systems (TSs) limit the performance of various superconducting devices, ranging in application from astronomy to quantum computing. We study superconducting resonators with films containing TS and measure the resulting 1/f frequency noise caused by resonant TS. The resonators are designed such that they apply a uniform ac electric field to the films which allows a direct measurement of permittivity noise in the film as a function the electric field. An intrinsic value of noise is found as well as the power law for ac-field saturation. The temperature dependence of 1/f noise below 200 mK fits to a relationship found previously in high-Q resonators. However, our data lead us to a model different than a previous experimental study; in our work TS phenomena are modeled with frequency diffusion. Our measured noise times the temperature is found to be the same to within error in the different films when normalized to the loss tangent at low temperature, despite dramatically different loss tangents. Following from the general nature of the TS models, we expect the same permittivity noise in many other devices.

**1:15PM Y48.00011 Flux noise due to magnetic impurities in superconducting circuits: Optimal spin texture and role of phase transition<sup>1</sup>**, ROGÉRIO DE SOUSA, Department of Physics and Astronomy, University of Victoria, British Columbia, Canada — Superconducting quantum interference devices (SQUIDs) and other superconducting circuits are limited by intrinsic flux noise with spectral density  $1/f^\alpha$  with  $\alpha < 1$  whose origin is believed to be due to spin impurities. We present a theory of flux noise in the presence of phase transitions and arbitrary spin textures in the impurity spin system [1]. At higher temperatures we find that the spin-spin correlation length scale (describing, e.g., the average size of ferromagnetic spin clusters) greatly impacts the scaling of flux noise with wire geometry. At lower temperatures we find that flux noise is quite sensitive to the particular spin texture realized by the spin system ground state. Remarkably, we show that flux-noise is exactly equal to zero when the spins form a poloidal texture. Flux noise is nonzero for other spin textures, but gets reduced in the presence of correlated ferromagnetic fluctuations between the top and bottom wire surfaces, where the flux vectors are antiparallel. This demonstrates the idea of engineering spin textures and/or intersurface correlation as a method to reduce flux noise in superconducting circuits.

**1:27PM Y48.00012 Spin noise and magnetic screening of impurities in a BCS superconductor<sup>1</sup>**, MATTHIAS LE DALL, Department of Physics and Astronomy, University of Victoria, British Columbia, Canada, LUIS G. G. V. DIAS DA SILVA, Instituto de Física, Universidade de São Paulo, Brazil, ROGÉRIO DE SOUSA, Department of Physics and Astronomy, University of Victoria, British Columbia, Canada — The coupling of a localized impurity to a BCS superconductor (SC) leads to the formation of impurity Cooper-pairs via the proximity effect, generating two bound states within the SC energy gap, the so-called Yu-Rusinov-Shiba (YSR) states. They are similar to the Andreev Bound States that originate from Andreev reflection, e.g. when the impurity is hosted in a Josephson junction, and are known to produce sharp sub-gap resonances in charge noise [de Sousa et al., PRB 2009], providing a natural explanation for the observation of microresonators in superconducting devices [Simmonds et al., PRL 2004]. Here we present a theory for the spin noise generated by magnetic impurities in a SC, and discuss the impact of the Shiba states on models of flux noise in superconducting qubits. We use a combination of analytical methods and the numerical renormalization group technique to calculate the spin noise of an Anderson impurity in a SC, unveiling the competition between the proximity effect and Kondo correlations. Both mechanisms produce magnetic screening and a corresponding reduction in spin noise, giving rise to new insights on the kinds of impurities that are responsible for the observed  $1/f^\alpha$  flux noise in superconducting circuits.

<sup>1</sup>This research is supported by NSERC CRD/478366-2015.

**1:39PM Y48.00013 Geometrical Effects in Noise Spectra of Superconducting Flux Qubits<sup>1</sup>**, ANDRE PETUKHOV, NASA Ames Research Center, Moffett Field, California, VADIM SMELYANSKIY, Google Inc, Venice, California, JOHN MARTINIS, University of California, Santa Barbara and Google Inc, Santa Barbara, California — We present theoretical study of geometrical effects related to spin diffusion in superconducting flux qubits. We adopt a model of a long superconducting wire surrounded by a thin oxide layer with spins distributed uniformly over cross-sectional area of the oxide layer. Using a continuous transformation from a round cylinder to a flat wire strip, we demonstrate that the noise spectral density tends to a power law  $S(\omega) \propto (\omega/\Gamma)^{-s}$  with  $s \gtrsim 3/4$ , approaching  $s = 3/4$  for very thin wires. The  $\omega^{-s}$  dependence is valid in a broad frequency range above  $\omega \gtrsim \Gamma$  stretching up to four orders of magnitude in units of characteristic diffusion decay rate  $\Gamma \sim 1 - 10^2$  Hz. The effect is highly sensitive to a cross-sectional aspect ratio of a thin wire thus revealing its geometrical origin. We substantiate our findings by detailed comparison with available experimental data and conclude that  $3/4$  power law distinguishes spin diffusion flux noise from generic “ $1/f$ ” family.

<sup>1</sup>Supported by the AFRL Information Directorate under grant F4HBKC4162G001

**1:51PM Y48.00014 Suppression of dephasing by qubit motion in superconducting circuits<sup>1</sup>**, D.V. AVERIN, Dep-t of Physics and Astronomy, Stony Brook University, SUNY, K. HU, Y. P. ZHONG, C. SONG, H. WANG, Dep-t of Physics, Zhejiang University, China, S. HAN, Dep-t of Physics and Astronomy, University of Kansas — We suggest and demonstrate a protocol which suppresses dephasing due to the low-frequency noise by qubit motion, i.e., transfer of the logical qubit of information in a system of  $n \geq 2$  physical qubits. The protocol requires only the nearest-neighbor coupling and is applicable to different qubit structures. Motion of a logical qubit limits the correlation time of the effective noise seen by this qubit and suppresses its decoherence rate. This effect is qualitatively similar to the dynamic decoupling, but relies on the different resource: additional physical qubits, not extra control pulses. In this respect, suggested protocol can serve as the basis for an alternative approach to scalable quantum circuits. We further analyze its effectiveness against noises with arbitrary correlations. Our analysis, together with experiments using up to three superconducting qubits, shows that for the realistic uncorrelated noises, qubit motion increases the dephasing time of the logical qubit as  $\sqrt{n}$ . In general, the protocol provides a diagnostic tool for measurements of the noise correlations.

**2:03PM Y48.00015 Long range correlations by local dissipation in lattice waveguide QED**, BAPTISTE ROYER, ARNE L. GRIMSMO, Univ of Sherbrooke, ALEXANDRE BLAIS, Univ of Sherbrooke, CIFAR — In waveguide QED, superconducting qubits acting as artificial atoms are coupled to 1D superconducting transmission lines playing the role of common bath for the qubits. By controlling their effective separation and coupling to the transmission line, it is possible to engineer various types of dissipation-induced interactions between the qubits. In this talk, we consider the situation where multiple superconducting qubits are coupled to a lattice of superconducting transmission lines. We show that this can lead to the creation of highly entangled dark states using local dissipation only. Using tensor networks techniques, we study such large-scale highly-correlated systems.

**11:15AM Y50.00001 Nanoscale Radiative Heat Transfer between Graphene Ribbon Arrays<sup>1</sup>**

, ZHUOMIN ZHANG<sup>2</sup>, XIANGLEI LIU<sup>3</sup>, Georgia Institute of Technology — Near-field radiative heat transfer between two graphene sheets can exceed that between blackbodies due to surface plasmons excited by the graphene sheet. This study shows that, by patterning a single layer of graphene sheet into ribbons, a giant enhancement of the near-field radiative heat flux, by more than one order of magnitude higher than that between two graphene sheets, can be achieved. The mechanism lies in that when the graphene sheet is patterned into an array of ribbons, the closed circular dispersion of graphene plasmons is opened to become hyperbolic, leading to broadband singularities of density of states. Extremely high-k evanescent waves can now couple with hyperbolic graphene plasmons. Exact numerical simulations are used by combining the scattering theory and rigorous coupled-wave analysis. Furthermore, effective medium calculations are used to support the arguments and provide clear physical insights. The findings from this study may open promising pathways for highly efficient thermal management, energy harvesting, and subwavelength thermal imaging.

**11:27AM Y50.00002 Failure of local FDT in fluctuation-induced interactions.**

, DIEGO DALVIT, Los Alamos National Laboratory, FRANCESCO INTRAVAIA, Max-Born Institute, Germany, RYAN BEHUNIN, Yale University, CARSTEN HENKEL, University of Potsdam, Germany, KURT BUSCH, Humboldt University, Germany — In the study of non-equilibrium fluctuation-induced interactions (e.g., quantum friction, near-field heat transfer, and non-equilibrium Casimir forces) the local fluctuation-dissipation theorem (FDT) is widely used without much justification. Here, we report the failure of the local FDT in a specific example of quantum friction of an atom moving at constant velocity above a surface. A generalized non-equilibrium FDT is derived, which contains a contribution akin to the local FDT and an additional one corresponding to a velocity-dependent current term. We show that in the low-velocity limit the frictional force arising from the current term is of the same order of magnitude as that predicted by the local FDT, which underestimates the total force by almost 50 percent.

**11:39AM Y50.00003 Fluctuation-Induced Interactions in external magnetic fields: Casimir force and Radiative Heat Transfer**

, RAUL ESQUIVEL-SIRVENT, Univ Nacl Autonoma de Mexico — Thermally induced electromagnetic fields give rise to the Casimir force and the near field heat transfer between two bodies separated by a gap. These phenomena are described by Rytov's theory of fluctuating electromagnetic fields and both the Casimir force and the near field heat transfer depend on the local dielectric function of the bodies. In this work we present a theoretical calculation on the modulation of fluctuation-induced interactions in the presence of an external magnetic field. The system consists of two parallel plates separated by a gap  $d$ . Each plate is isotropic and has a local dielectric function. Applying an external magnetic field parallel to the plates, in the so called Voigt configuration, the plates become anisotropic. In particular, we consider plates of InSb. For the Casimir force the two plates are kept at the same temperature and the external field reduces the magnitude of the force. Similarly if the two plates are kept at different temperature the near field radiative heat transfer is modulated by the magnitude of the external magnetic field. The results are extended to semiconducting quantum wells. In both cases, the excitation of magnetoplasmons provides an explanation for the observed effect.

**11:51AM Y50.00004 Short distance expansion for fluctuation induced interactions**

, THORSTEN EMIG, CNRS and MIT, GIUSEPPE BIMONTE, Universita' di Napoli Federico II — Fluctuation induced interactions become most prominent in close to proximity to surfaces. Examples include van der Waals and Casimir forces, heat transfer, and spectral shifts for atoms and molecules. In many situations, the surfaces are curved or structured which makes the computation of the interaction in general complicated. Here we present a versatile and powerful approach to this problem which is based on a derivative expansion. It applies to distances much smaller than the radii of surface curvature. Explicit results include orientational effects for anisotropic particles, thermal effects, and spectral modifications.

**12:03PM Y50.00005 Unified boundary conditions and Casimir forces for fields with arbitrary spin<sup>1</sup>**

, ROBERT BENNETT, University of Freiburg, ADAM STOKES, University of Leeds — The electromagnetic Casimir effect is well-known and has been extensively studied for the last half-century. This attractive force between parallel plates arises from the imposition of boundary conditions upon the fluctuating spin-1 photon field, so a natural further question is whether fields of different spin can cause similar forces when confined in the same way. However, so far it has not been clear what the appropriate boundary conditions for physically-confined spinor fields may be. Here we present work that generalises the physically well-motivated electromagnetic boundary conditions to fields of arbitrary spin, thus arriving at physically reasonable boundary conditions<sup>2</sup> and Casimir forces<sup>3</sup> for a selection of interesting fields. For example, the so-called 'bag model' boundary conditions from nuclear physics emerge from our generalised boundary condition as a special case, as do the linearised gravity boundary conditions suggested in a remarkable recent proposal<sup>4</sup> concerning possible measurement of gravitonic Casimir forces.

**12:39PM Y50.00008 Parameterization of lattice spacings for lipid multilayers in ionic solutions** , HORIA PETRACHE, Indiana University Purdue University Indianapolis, MERRELL JOHNSON, Indiana University Purdue University Fort Wayne, DANIEL HARRIES, The Hebrew University of Jerusalem, SOENKE SEIFERT, Argonne National Laboratory — Lipids, which are molecules found in biological cells, form highly regular layered structures called multilamellar lipid vesicles (MLVs). The repeat lattice spacings of MLVs depend on van der Waals and electrostatic forces between neighboring membranes and are sensitive to the presence of salt. For example, addition of salt ions such as sodium and potassium makes the MLVs swell, primarily due to changes in electrical polarizabilities. However, a more complicated behavior is found in some ionic solutions such as those containing lithium ions. Using x-ray scattering, we show experimentally how the interactions between membranes depend on the type of monovalent ions and construct parameterizations of MLVs swelling curves that can help analyze van der Waals interactions.

**12:51PM Y50.00009 Johnson-Nyquist Noise Coupling Formulation of Near-Field Heat Transfer for 1D Conductors** , MIKA PRUNNILA, SAMPO LAAKSO, DAVID GUNNARSSON, VTT Technical Research Centre of Finland — Near-field heat transfer has been formulated using different levels of theoretical sophistication and complexity ranging from fluctuational electrodynamics to quasi-static Coulomb interaction description. Our goal is to find a simple description for the near-field heat transfer between coupled 1D electron systems (conductors). We will show that by considering distributed Johnson-Nyquist voltage sources, arising from the dissipative part of the electron systems' response, a compact fundamental formula for the near-field heat transfer can be found. We will describe the details of the derivation and discuss the regime of validity of our approach. Several special cases will be considered and experimental configurations will be discussed. The presented analysis is especially suitable for closely spaced graphene ribbons and nanowires. We will also show that by including inductive responses, which are necessary at high frequencies, speed of light emerges in the heat flow formula, thereby showing the link between fundamental physical quantities/constants and near-field heat transfer in coupled 1D systems. Our formulation also provides the possibility to use different boundary conditions for the physical system and this enables design of near-field heat transfer circuits.

**11:15AM Y52.00001 A fully controllable Kondo system: Coupling a flux qubit and an ultracold Fermi gas** , KELLY PATTON, School of Science and Technology, Georgia Gwinnett College — We show that a composite spin-1/2 Kondo system can be formed by coupling a superconducting quantum interference device (SQUID) to the internal hyperfine states of a trapped ultracold atomic Fermi gas. Here, the SQUID, or flux qubit, acts as an effective magnetic impurity that induces spin-flip scattering near the Fermi energies of the trapped gas. Although the ultracold gas and SQUID are at vastly different temperatures, the formation of a strongly correlated Kondo state between the two systems is found when the gas is cooled below the Kondo temperature. We find that the Kondo temperature of this hybrid system is within current experimental limits. Furthermore, the momentum distribution of the trapped fermions is calculated. We find that it clearly contains an experimental signature of this correlated state and the associated Kondo screening length. In addition to probing Kondo physics, the controllability of this system can be used to systematically explore the relaxation and equilibration of a strongly correlated system that has been initially prepared in a selected nonequilibrium state.

**11:27AM Y52.00002 Broken selection rule in the quantum Rabi model** , GUILLERMO ROMERO, University of Santiago of Chile, POL FORN-DÍAZ<sup>1</sup>, University of Waterloo, C. J. P. M. HARMANS, TU Delft, ENRIQUE SOLANO, University of the Basque Country, HANS MOOIJ, TU Delft — We report the spectroscopic observation of a resonant transition that breaks a selection rule in the quantum Rabi model, implemented using an *LC* resonator and a superconducting qubit. The eigenstates of the system consist of a superposition of bare qubit-oscillator states with a relative sign. In the limit of low qubit-oscillator coupling strength, the matrix element between excited eigenstates of different sign is very small in presence of an oscillator drive, establishing a sign-preserving selection rule. Here, our qubit-resonator system operates in the ultrastrong coupling regime, where the coupling strength is 10% of the resonator frequency, allowing sign-changing transitions to be activated and, therefore, detected. This work shows that sign-changing transitions are an unambiguous, distinctive signature of systems operating in the ultrastrong coupling regime of the quantum Rabi model. These results pave the way to further studies of sign-preserving selection rules in multiqubit and multiphoton models.

**11:39AM Y52.00003 "Magnetic" refrigeration in synthetic quantum magnets** , MICHAEL ZALETEL, Station Q, Microsoft Research , NORMAN YAO, Department of Physics, UC Berkeley — The advent of ultracold atomic systems has promised to expand upon our understanding of strongly correlated quantum ground states; by contrast to their material cousins, cold atomic experiments benefit from unique tools such as direct optical imaging and tunable short- and long-range interactions. However, despite advances in coherent quantum control, ultracold atoms remain much too hot. Although sub-nanokelvin temperatures are the norm in experiments, the entropy of the system remains extensively far above the ground state. One strategy to combat this is to shift the entropy elsewhere for example, placing a gapless system near a gapped system can effectively "cool" the latter. In this talk, we will demonstrate that typical atomic systems can act as their own coolant. As an example, we consider a 1D optical lattice geometry where spin-1 atoms interact via a generic AKLT-type Hamiltonian. We will discuss why decreasing the density of atoms in one region is sufficient to cool the complementary portion of the system to the ground state, wherein coherent edge dynamics are observed.

**11:51AM Y52.00004 Dissipative topological insulator with fractional winding number and single edge state** , TONY LEE, Indiana University-Purdue University Indianapolis (IUPUI) — Photonic experiments offer an opportunity to find novel topological states. We consider a one-dimensional tight-binding model in the presence of gain and loss as well as long-range hopping. The system is described by a non-Hermitian Hamiltonian with PT symmetry and exceptional points. The unique feature of the model is that the Hamiltonian encircles an exceptional point in momentum space, leading to novel topological features. The winding number has a fractional value 1/2 because the Brillouin zone has a periodicity of 4 $\pi$  instead of 2 $\pi$ . There is only one edge state due to the coalescence of eigenvectors. The edge state is topologically protected by a chiral symmetry but disappears when the bulk gap closes. We also discuss experimental realization with optical waveguides.

**12:03PM Y52.00005 Simulating the Generalized Gibbs Ensemble (GGE): A Hilbert space Monte Carlo approach**, VINCENZO ALBA, SISSA — By combining classical Monte Carlo and Bethe ansatz techniques we devise a numerical method to construct the Truncated Generalized Gibbs Ensemble (TGGE) for the spin-1/2 isotropic Heisenberg (XXX) chain. The key idea is to sample the Hilbert space of the model with the appropriate GGE probability measure. The method can be extended to other integrable systems, such as the Lieb-Liniger model. We benchmark the approach focusing on GGE expectation values of several local observables. As finite-size effects decay exponentially with system size, moderately large chains are sufficient to extract thermodynamic quantities. The Monte Carlo results are in agreement with both the Thermodynamic Bethe Ansatz (TBA) and the Quantum Transfer Matrix approach (QTM). Remarkably, it is possible to extract in a simple way the steady-state Bethe-Gaudin-Takahashi (BGT) roots distributions, which encode complete information about the GGE expectation values in the thermodynamic limit. Finally, it is straightforward to simulate extensions of the GGE, in which, besides the local integral of motion (local charges), one includes arbitrary functions of the BGT roots. As an example, we include in the GGE the first non-trivial quasi-local integral of motion.

**12:15PM Y52.00006 Minimally entangled typical thermal states versus matrix product purifications for the simulation of equilibrium states and time evolution**, MORITZ BINDER, THOMAS BARTHEL, Duke Univ — We compare matrix product purifications and minimally entangled typical thermal states (METTS) for the simulation of equilibrium states and finite-temperature response functions of strongly correlated quantum many-body systems. For METTS, we highlight the interplay of statistical and DMRG truncation errors, discuss the use of self-averaging effects, and describe schemes for the computation of response functions. We assess the computation costs and accuracies of the two methods for critical and gapped spin chains and the Bose-Hubbard model. For the same computation cost, purifications yield more accurate results than METTS except for temperatures well below the systems energy gap. (Phys. Rev. B 92, 125119 (2015))

**12:27PM Y52.00007 Interacting Bose gas confined in a Kronig-Penney potential<sup>1</sup>**, O. A. RODRÍGUEZ, Posgrado en Ciencias Físicas, UNAM, M. A. SOLÍS, Instituto de Física, UNAM — We analyze the effect of the 1D periodic Kronig-Penney potential, composed of barriers of width  $b$  and separated a distance  $a$ , over an interacting Bose gas. At  $T = 0$ , the Gross-Pitaevskii equation is solved analytically in terms of the Jacobi elliptic functions for repulsive or attractive interaction between bosons. By applying the boundary conditions for periodic solutions as well as the normalization of the wave function, we arrive to a set of nonlinear equations from which we obtain the density profile and the chemical potential of the condensate as a function of the particle momentum. The profiles for attractive and repulsive interactions are compared with that of the non-interacting case. For attractive interaction we are able to observe a pronounced spatial localization in the middle of every two barriers. We reproduce the well known results when the Kronig-Penney potential becomes a Dirac Comb.

**12:39PM Y52.00008 Concept of contact spectrum and its applications in atomic quantum Hall states<sup>1</sup>**, MINGYUAN HE, SHAO-LIANG ZHANG, HON-MING CHAN, QI ZHOU, Department of Physics, The Chinese University of Hong Kong — A unique feature of ultracold atoms is the separation of length scales,  $r_0 \ll k_F^{-1}$ , where  $k_F$  and  $r_0$  are the Fermi momentum characterizing the average particle distance and the range of interaction between atoms respectively. For  $s$ -wave scattering, Shina Tan discovered that such diluteness leads to universal relations, all of which are governed by contact, among a wide range of thermodynamic quantities. In this talk, I will show that the concept of contact can be generalized to an arbitrary partial-wave scattering. Contact of all partial-wave scatterings form a contact spectrum, which establishes universal thermodynamic relations with notable differences from those in the presence of  $s$ -wave scattering alone. Moreover, such a contact spectrum has an interesting connection with a special bipartite entanglement spectrum of atomic quantum Hall states, and enables an intrinsic probe of these highly correlated states using two-body short-ranged correlations.

**12:51PM Y52.00009 Energy transfer in mesoscopic vibrational systems enabled by eigenfrequency fluctuations**, JUAN ATALAYA<sup>1</sup>, Michigan State University — Energy transfer between low-frequency vibrational modes can be achieved by means of nonlinear coupling if their eigenfrequencies fulfill certain nonlinear resonance conditions. Because of the discreteness of the vibrational spectrum at low frequencies, such conditions may be difficult to satisfy for most low-frequency modes in typical mesoscopic vibrational systems. Fluctuations of the vibrational eigenfrequencies can also be relatively strong in such systems. We show that energy transfer between modes can occur in the absence of nonlinear resonance if frequency fluctuations are allowed. The case of three modes with cubic nonlinear coupling and no damping is particularly interesting. It is found that the system has a non-thermal equilibrium state which depends only on the initial conditions. The rate at which the system approaches to such state is determined by the parameters such as the noise strength and correlation time, the nonlinearity strength and the detuning from exact nonlinear resonance. We also discuss the case of many weakly coupled modes. Our results shed light on the problem of energy relaxation of low-frequency vibrational modes into the continuum of high-frequency vibrational modes. The results have been obtained with Mark Dykman.

**1:03PM Y52.00010 Quantum memory and phase gate in Optical cavities based on EIT<sup>1</sup>**, HALYNE BORGES, CELSO VILLAS-BÔAS, Federal University of São Carlos — In this work we investigate theoretically the implementation of an optical quantum memory in a system composed by a single atom, trapped in a high finesse optical cavity. In order to analyse the feasibility of implementing a quantum memory in the atom-cavity system based on the EIT phenomenon, we investigated in detail which parameter configuration the memory efficiency is optimized considering the two different setups. Our results shows that for a asymmetric one-sided cavity, which is the experimental setup commonly used to observe the EIT effect, the memory efficiency value saturates at about 8.5%. Meanwhile, for an one-sided cavity, we observe for a sufficiently high value of the coupling constant  $g$ , the efficiency has its maximum value increased considerably, close to 100%. However, this experimental setup is not suitable to observe cavity-EIT in the transmission spectrum, being necessary another kind of experiment, such as measurements phase difference field that leaves the cavity induced by the control field. Considering this configuration we also showed the implementation of a quantum phase gate based on the same nonlinear effect, where the pulse probe can experience a phase shift on the order of  $\pi$ , due to the presence or absence of a control pulse.

**1:15PM Y52.00011 Beyond quantum-classical analogies: high time for agreement?** , MICHELE MARROCCO, ENEA — Lately, many quantum-classical analogies have been investigated and published in many acknowledged journals. Such a surge of research on conceptual connections between quantum and classical physics forces us to ask whether the correspondence between the quantum and classical interpretation of the reality is deeper than the correspondence principle stated by Bohr. Here, after a short introduction to quantum-classical analogies from the recent literature, we try to examine the question from the perspective of a possible agreement between quantum and classical laws. A paradigmatic example is given in the striking equivalence between the classical Mie theory of electromagnetic scattering from spherical scatterers and the corresponding quantum-mechanical wave scattering analyzed in terms of partial waves. The key features that make the correspondence possible are examined and finally employed to deal with the fundamental blackbody problem that marks the initial separation between classical and quantum physics. The procedure allows us to recover the blackbody spectrum in classical terms and the proof is rich in consequences. Among them, the strong analogy between the quantum vacuum and its classical counterpart.

**1:27PM Y52.00012 Application of axiomatic formal theory to the Abraham–Minkowski controversy** , MICHAEL CRENSHAW, USArmy AMRDEC — Continuum electrodynamics is an axiomatic formal theory whose axioms are the macroscopic Maxwell equations. We demonstrate that valid theorems of the formal theory are inconsistent with conservation laws and with special relativity because continuum electrodynamics allows transformations of the Maxwell equations that constitute an improper tensor transformation that changes the conservation properties, the relativity properties, and the space-time embedding of the coupled equations of motion. The inconsistencies are resolved by a reformulation of physical principles in a flat non-Minkowski material spacetime in which the timelike coordinate corresponds to  $ct/n$ . Applying Lagrangian field theory, we derive equations of motion for the macroscopic electric and magnetic fields in a simple dielectric medium. We construct a new formal theory of continuum electrodynamics and we derive a tensor energy-momentum continuity theorem that trivially resolves the century-old Abraham–Minkowski momentum controversy. We derive the theory of special relativity in a dielectric, including the material Lorentz factor and the material Lorentz transformation. We derive the momentum of a polariton in the context of material special relativity to confirm the resolution of the Abraham-Minkowski debate.

**1:39PM Y52.00013 Particle beams carrying orbital angular momentum, charge, mass and spin** , TEUNTJE TIJSSEN, H H Wills Physics Laboratory, University of Bristol, ARMEN HAYRAPETYAN, JOERG GOETTE, Max Planck Institute for the Physics of Complex Systems, Dresden, MARK DENNIS, H H Wills Physics Laboratory, University of Bristol — Electron beams carrying vortices and angular momentum have been of much experimental and theoretical interest in recent years. In addition, optical vortex beams are a well-established field in optics and photonics. In both cases, the orbital angular momentum associated with the beams axial vortex has effects on the overall spin of the beam, due to spin-orbit interactions. A simple model of these systems are Bessel beam solutions (of either the Dirac equation or Maxwell equations) with a nonzero azimuthal quantum number, which are found by separation in cylindrical coordinates. Here, we generalize this approach, considering the classical field theory of Bessel beams for particles which are either massive or massless, uncharged or charged and of a variety of different spins ( $0, \frac{1}{2}, 1, \dots$ ). We regard the spin and helicity states and different forms of spin-orbit terms that arise. Moreover, we analyse the induced electromagnetic field when the particles carry charge. Most importantly, this unified field theory approach leads to the prediction of effects for vortex beams of neutrons, mesons and neutrinos.

**1:51PM Y52.00014 Harmonic Fractions and an Integer Power Law to Demonstrate a Relationship of the Neutron to the Properties of Hydrogen and Cosmic Observables** , D. W. CHAKERES, Department of Radiology, The Ohio State University, Columbus, OH, 43210, R. VENTO, Retired, Columbus State Community College, Columbus, OH, 43215, D. I. PANCHENKO, J. A. TOBAR, S. S. MOSES, V. M. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA, 94508 — Power laws and harmonic oscillator systems represent a ubiquitous relationship among many physical phenomena. This study demonstrates a close power law relationship of the annihilation frequency of the neutron, approximately  $2.27 \cdot 10^{23}$  Hz, when used as a dimensionless base, to fundamental quantum properties of hydrogen and present-day cosmic observables. The following set of the three smallest integers:  $\{-1, 0, 1\}$ , and the set of partial harmonic fractions:  $\{3/2, 1/2, 2/3, -3/4, 4/5\}$ , are associated with each physical entity investigated as a frequency equivalent. They are listed as follows: twice the maximum energy of a cosmic ray,  $3/2$ ; the base identity of the neutron,  $1$ ; the Bohr radius,  $4/5$ ; Rydberg's constant,  $2/3$ ; twice the peak spectral radiance of cosmic microwave background radiation,  $1/2$ ; Planck's constant,  $0$ ; the Sun's galactic radius,  $-1/2$ ; the Sun's galactic period,  $-2/3$ ; Hubble's constant,  $-3/4$ ; the dimension of the observable universe,  $-4/5$ ; and twice the gravitational binding energy of the electron in hydrogen,  $-1$ . When viewed in the physically equivalent frequency domain, the neutron partitions an abundance of physical constants from the very small to the very large.

**2:03PM Y52.00015 Branching ratio, transition frequency and lifetime measurements in  $^{88}\text{Sr}^+$  with trapped ions<sup>1</sup>** , HELENA ZHANG, MICHAEL GUTIERREZ, GUANG HAO LOW, ISAAC CHUANG, Massachusetts Inst of Tech-MIT — Precise measurements of atomic properties, such as branching ratios and transition frequencies and lifetimes, are important in the study of astrophysical objects as well as verification of relativistic many-body theories. We report on a new measurement of the branching ratio of the  $5P_{1/2}$  and  $5P_{3/2}$  states in  $^{88}\text{Sr}^+$  to  $10^{-4}$  fractional uncertainty, a  $10^3$  times improvement over current results, using ions confined in a Paul trap. Using a fiber frequency comb and pulsed spectroscopy, we measure the absolute frequencies of the  $5S_{1/2} - 5P_{1/2}$  and  $5S_{1/2} - 5P_{3/2}$  transitions to within 200 kHz, previously only known to tens of MHz. By fitting the fluorescence curve of the ion with optical Bloch equations, we obtain a new measurement for the lifetime of the  $5P_{1/2}$  and  $5P_{3/2}$  states without using a pulsed laser source.

**11:15AM Y53.00001 Scanning Tunneling Microscopy Study of Graphene/Cuprate Heterostructures.** , MINGHAO CHENG, ALEXANDER KERELSKY, XINJUE ZHONG, DA WANG, YUFENG HAO, JAMES HONE, XIAOYANG ZHU, AHBAY PASUPATHY, Columbia University in the City of New York — We study the properties of single-layer graphene co-laminated to BSCCO-2212 single crystals using UHV-Low Temperature-STM. Samples were prepared by transferring large-area single layer graphene grown on copper substrate using the chemical vapor deposition to the freshly-cleaved surface of a BSCCO single crystal in an inert atmosphere. Under optimal conditions, the graphene acts as a protective film for the freshly-cleaved surface of BSCCO allowing for high-quality spectroscopic measurements to be performed subsequently. We will show evidence of this protection from topographic imaging of the BSCCO through the graphene monolayer. More interestingly, the d-wave superconductivity of BSCCO couples to the Dirac Fermions of graphene via the proximity effect. We will describe the signatures of this coupling as probed by point spectroscopy and spectroscopic imaging in the STM.

**11:27AM Y53.00002 Experimental study of electrical conduction across high-Tc superconductor-graphene interfaces<sup>1</sup>**, DAVID PERCONTE, FABIAN CUELLAR, MARIE-BLANDINE MARTIN, BRUNO DLUBAK, MAELIS PIQUEMAL-BANCI, ROZENN BERNARD, JUAN TRASTOY, CONSTANCE MOREAU-LUCHAIRE, PIERRE SENEOR, JAVIER VILLEGAS, Unite Mixte de Physique CNRS/Thales, PIRAN KIDAMBI, JOHN ROBERTSON, STEPHAN HOFMANN, Cambridge University, Eng. Dept. — Proximity-induced superconductivity presents unusual features in graphene (i.e. specular Andreev reflection [1]) due to its particular electronic structure. It has been theoretically discussed that, if a d-wave superconductor is put contact with graphene, the latter will sustain d-wave superconductivity, and further unusual features (such as oscillatory behavior) should be observed in the superconductor-graphene junction conductance [2]. Motivated by these prospects, we experimentally investigate YBCO-graphene junctions. We will show differential conductance measurements as a function of temperature, magnetic field, and graphene doping. The observed behavior will be discussed in the frame of the theory developed in [1,2,3]. [1] C.W.J. Beenakker, Phys. Rev. Lett. 97, 067007 (2006); [2] J. Linder et al., Phys. Rev. **11:39AM Y53.00003 Proximity superconductivity in graphene Landau levels**, GAURAV CHAUDHARY, Univ of Texas, Austin, XIAO LI, Univ of Maryland, College Park, ALLAN MACDONALD, Univ of Texas, Austin — We study monolayer graphene sheets in the quantum Hall regime that are proximity coupled to an s-wave superconducting thin film. At magnetic fields near  $H_{c2}$  triangular vortex lattice states form in the superconductor and induce similar vortex lattice states in the graphene sheets. We use the Bogoliubov-de Gennes theory to study the properties of quasiparticle excitations in the graphene sheets, and find that the quantized Hall conductance survives even in such a vortex lattice state. We further explore the possibility of realizing topological superconductivity in such a system. In addition, we propose that under some circumstances the vortex cores may host zero-energy bound states which are Majorana fermions.

**11:51AM Y53.00004 ABSTRACT WITHDRAWN —**

**12:03PM Y53.00005 Proximity Effect at Graphene - High Tc Superconductor Junctions**, DA WANG, EN-MIN SHIH, GHIDEWON AREFE, YOUNGDUCK KIM, DREW EDELBERG, ERICK ANDRADE, DENNIS WANG, JAMES HONE, CORY DEAN, ABHAY PASUPATHY, Columbia university, DEPARTMENT OF PHYSICS, COLUMBIA UNIVERSITY, NEW YORK, NY 10027, USA COLLABORATION — The proximity effect is a well-known mesoscopic phenomenon where Cooper pairs from a superconductor (S) enter into a normal metal (N) that is well coupled to it. Since graphene was discovered a decade ago, the proximity effect at superconductor-graphene junctions has been extensively studied and interesting phenomena such as specular Andreev reflection and ballistic transport at graphene Josephson junctions have been observed. However, superconductors used in these experiments to date are of conventional low Tc, such as aluminum (Tc=1.2K), NbSe2 (Tc=7K), and MoRe (Tc=8K). Understanding how the proximity effect works between high-Tc superconductors (pnictides and cuprates) and the Dirac Fermions of graphene remains largely unexplored. The chief technical challenge here is to create high-quality junctions between high-Tc superconductors and graphene. In this work, we will introduce a home-made setup that allows us to exfoliate, transfer and encapsulate superconductor-graphene junctions in a well controlled inert atmosphere. Transport measurements of the proximity effect at graphene-iron pnictide (FeSe, FeTeSe) and graphene-cuprate (BSCCO) junctions will be described.

**12:15PM Y53.00006 Proximity superconductivity in ballistic graphene at high magnetic fields**, J. R. PRANCE, Department of Physics, University of Lancaster, Lancaster, UK, M. BEN SHALOM, M. J. ZHU, V. I. FALKO, A. MISHCHENKO, A. V. KRETININ, K. S. NOVOSELOV, C. R. WOODS, School of Physics and Astronomy, University of Manchester, Oxford Road, M13 9PL Manchester, UK, K. WATANABE, T. TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba, 305-0044 Japan, A. K. GEIM, School of Physics and Astronomy, University of Manchester, Oxford Road, M13 9PL Manchester, UK — We present measurements of the superconducting proximity effect in graphene-based Josephson junctions with a mean free path of several microns, which exceeds the junctions' length [1]. The junctions exhibit low contact resistance and large supercurrents. We observe Fabry-Pérot oscillations in the normal-state resistance and the critical current of the junctions. The proximity effect is mostly suppressed in magnetic fields of <10 mT showing the conventional Fraunhofer interference pattern; however, unexpectedly, a weak proximity effect survives in magnetic fields as high as 1 T. Superconducting states randomly appear and disappear as a function of field and carrier concentration, and each exhibits a supercurrent carrying capacity close to the universal limit of  $e\Delta/h$  where  $\Delta$  is the superconducting gap of the contacts. We attribute the high-field supercurrent to mesoscopic Andreev states that persist near graphene edges. Our work reveals new proximity regimes that can be controlled by quantum confinement and cyclotron motion. [1] Ben Shalom et al., arXiv:1504.03286 (2015)

**12:27PM Y53.00007 Proximity induced Superconductivity in Epitaxial Graphene<sup>1</sup>**, FABIAN D. NATTERER, NIST/CNST, JEONGHOON HA, NIST/CNST - UMD, HONGWOO BAEK, NIST/CNST - Seoul National University, DUMING ZHANG, WILLIAM CULLEN, NIST/CNST - UMD, NIKOLAI B. ZHITENEV, NIST/CNST, YOUNG KUK, Seoul National University, JOSEPH A. STROSCIO, NIST/CNST — The intimate electrical contact of a superconductor with a normal metal leads to an exchange of carriers through their boundary. Cooper pairs leak into the normal metal via Andreev reflection and enable the normal metal to acquire superconducting-like properties. The electron-hole conversion process in graphene is prominent due to relativistic quantum mechanics governing low energy chiral carriers in a multi-valley system. In the present experiment, we reveal spatial measurements of the proximity effect in graphene from a graphene-superconductor interface. Superconducting aluminum films were grown on epitaxial graphene on SiC. The aluminum films were discontinuous with networks of trenches in the film morphology reaching down to the substrate to exposed graphene terraces. Scanning tunneling spectra measured on the graphene terraces show a clear decay of the superconducting gap width with increasing separation from the graphene-aluminum edges. The decay length for the superconducting energy gap extends beyond 400 nm. Subtle deviations in the exponentially decaying energy gap were also observed on a much smaller length scale of tens of nanometers.

**12:39PM Y53.00008 Contact spectroscopy on S/TI/N devices: Induced pairing on the surface of a topological insulator<sup>1</sup>**, MARTIN P. STEHNO, PROSPER NGABONZIZA, MARIEKE SNELDER, University of Twente, HIROAKI MYOREN, Saitama University, YU PAN, ANNE DE VISSER, Y. HUANG, MARK S. GOLDEN, University of Amsterdam, ALEXANDER BRINKMAN, University of Twente — Translating concepts of topological quantum computation into applications requires fine-tuning of parameters in the model Hamiltonians of candidate systems. Such level of control has proven difficult to achieve in devices where superconductors are used to induce pairing in topological insulator (TI) materials. While local probe experiments have indicated features of p-wave superconducting correlations in TIs (as suggested by theory), results on extended devices often remain ambiguous. We present contact spectroscopy data on superconductor/topological insulator/normal metal devices with bulk-insulating TI material and compare these with bulk conducting samples. We discuss the magnitude of the induced gap and unusual features in the conductance traces of the bulk-insulating samples that may suggest the presence of p-wave type correlations in the TI.

**12:51PM Y53.00009 Signatures of Induced Superconductivity in NbTi Contacted InAs Quantum Wells<sup>1</sup>**, ANTHONY MCFADDEN, ECE Department, University of California - Santa Barbara, JAVAD SHABANI, Physics Department, City College of New York, BORZOYEH SHOJAEI, Materials Department, University of California - Santa Barbara, JOON SUE LEE, California NanoSystems Institute, University of California - Santa Barbara, CHRIS PALMSTRM, ECE and Materials Department, University of California - Santa Barbara — We have studied electrical transport through InAs quantum wells grown by MBE with unannealed superconducting NbTi contacts deposited *ex-situ* and patterned by optical photolithography. Characterization of the InAs 2DEG's without superconducting contacts yields typical mobilities greater than 100,000 cm<sup>2</sup>/Vs at a density of 4e11 cm<sup>-2</sup>. NbTi-InAs-NbTi (SNS) and NbTi-InAs (SN) devices with dimensions greater than 1 μm are fabricated using optical lithography. Although the dimensions of the fabricated SNS devices are too large to observe a supercurrent, signatures of superconductivity induced in the InAs are present. We observe two superconducting critical temperatures: one of the NbTi leads ( $T_c \sim 8K$ ), and a second ( $T_c < 4.5K$ ) attributed to superconductivity induced in the InAs channel.  $dI/dV$  vs  $V$  spectroscopy on SNS junctions below the second critical temperature shows a conductance maximum at zero applied voltage while conductance minima appear at finite bias voltage which is attributed to the presence of an induced superconducting gap in the InAs quantum well.

**1:03PM Y53.00010 Large superconducting double-gap, a pronounced pseudogap and evidence for proximity-induced topological superconductivity in the Bi<sub>2</sub>Te<sub>3</sub>/Fe<sub>1+y</sub>Te interfacial superconductor<sup>1</sup>**, J. Y. SHEN, M. Q. HE, Q. L. HE, K. T. LAW, I. K. SOU, R. LORTZ, Department of Physics, Hong Kong University of Science and Technology, A. P. PETROVIC, School of Physical and Mathematical Sciences, Nanyang Technological University — We investigate directional point-contact spectroscopy on a Bi<sub>2</sub>Te<sub>3</sub>/Fe<sub>1+y</sub>Te heterostructure, fabricated via van der Waals epitaxy, which is interfacial superconducting with an onset  $T_C$  at 12K and zero resistance below 8K. A large superconducting twin-gap structure is seen down to 0.27K, together with a zero bias conductance peak. The anisotropic smaller gap ( $\Delta_1$ ) is around 5 meV at 0.27K and closes at 8K, while the other one ( $\Delta_2$ ), as large as 12 meV, is isotropic and eventually evolves into a pseudogap closing at 40K. Both, the two-gap BTK and Dynes models can well reproduce our data, demonstrating  $\Delta_1$  should be associated with the proximity-induced superconductivity in the topological Bi<sub>2</sub>Te<sub>3</sub> layer, while  $\Delta_2$  may be attributed to an intrinsically-doped FeTe thin film at the interface.

**1:15PM Y53.00011 Proximity-induced superconducting gap in low-dimensional materials**, CHRISTOPHER REEG, DMITRII MASLOV, Univ of Florida - Gainesville — The ability to induce a sizable gap in the excitation spectrum of a metal placed in contact with a conventional superconductor has become increasingly important in recent years in the context of engineering a topological superconductor. Conventional studies of the proximity effect involving sufficiently bulky metals have shown that Andreev reflection processes at the superconductor/metal interface induce a nonzero pairing amplitude in the metal but do not endow it with a gap. Conversely, when the metal is an atomically thin layer, the tunneling of Cooper pairs can induce an excitation gap equal to the bulk gap of the superconductor (provided that the superconductor/metal interface is sufficiently transparent). We study how these two seemingly different views of the proximity effect evolve into one another as the thickness of the metal is changed. More specifically, we show that there is a thickness scale associated with the decrease of the induced gap, and that this scale is much larger than the Fermi wavelength. As a result, by proximity to most conventional superconductors, a sizable excitation gap can be induced in metals that are tens of atomic layers thick.

**1:27PM Y53.00012 General conditions for proximity induced odd-frequency superconductivity in two-dimensional electronic systems<sup>1</sup>**, ENRICO ROSSI, Department of Physics, College of William and Mary, CHRISTOPHER TRIOLA, Nordita and Center for Quantum Materials (CQM), DRISS BADIANE, Department of Physics, College of William and Mary, ALEXANDER V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory; Nordita and Center for Quantum Materials (CQM) — We obtain the general conditions for the emergence of odd-frequency superconducting pairing in a two-dimensional (2D) electronic system proximity-coupled to a superconductor, making minimal assumptions about both the 2D system and the superconductor. Using our general results we show that a simple heterostructure formed by a monolayer of a group VI transition metal dichalcogenide, such as molybdenum disulfide, and an s-wave superconductor with Rashba spin-orbit coupling will exhibit odd-frequency superconducting pairing.

**1:39PM Y53.00013 Growth and fabrication of proximity-coupled topological quantum wire circuits from thin InAs films**, CAROLYN KAN, CHI XUE, YANG BAI, JAMES ECKSTEIN, Univ of Illinois - Urbana — The realization of topological states in strongly spin orbit coupled semiconductors proximity-coupled to conventional superconductors requires delicate materials engineering. Key areas for improvement include the crystalline quality of the semiconductor itself, but a high-quality interface between the semiconductor and superconductor is essential. Recent results have demonstrated the necessity of forming an in situ interface to eliminate the soft gap observed in earlier experiments. While much work has focused on vertically grown nanowires, we take a lithographic approach to fabricating quantum wires out of MBE-grown thin films, which allow for increased flexibility and scalability of device structures. Notably, our films are grown entirely in situ in linked MBE systems, vastly improving interface transmission and cleanliness. Aspects of growth architecture aimed toward increasing the InAs mobility, such as substrate choice and layer structure, are also discussed.

**1:51PM Y53.00014 Superfluid density through 2D superconductor junctions.**, HYOUNGDO NAM, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, Austin, TX 78712, USA. — As S. Qin et al. [1] reported, two monolayer (2 ML) lead film on a silicon (111) substrate has one of two different atomic structures on the silicon substrate: the unstrained 1x1 and the pseudomorphically strained  $\sqrt{3} \times \sqrt{3}$  (i.e. the same lattice constant as the Si  $\sqrt{3} \times \sqrt{3}$  lattice). Most interestingly, although these two different regions show the same quantum well state features, they have different  $T_c$ 's (5 K and 4 K). These two different regions of 2 ML film naturally form superconductor-superconductor (SS or SS') junctions along silicon step edges. Physical connection of the junction is only 1 ML thickness because of the step height difference of substrate. We will present this study of SS (or SS') junction system using scanning tunneling microscopy/spectroscopy and *in-situ* double-coil mutual inductance measurement. The transition of superconducting gaps across either SS or SS' junctions should show how to locally affect each other. Double coil measurement show a global  $T_c$  close to the lower  $T_c$  region with sizable superfluid density. We will discuss the phase rigidity and its relationship to the superfluid density in this ultra-thin Pb film that is only 2 ML thick. [1] 'Superconductivity at the two-dimensional limit' S. Qin, J. Kim, Q. Niu, and C. K. Shih, *Science* **324**, 1314 (2009).

Session Y55 DBIO DCOMP DPOLY: Physics of Proteins: Pushing the Envelope on Understanding and Designing Function Hilton Baltimore Holiday Ballroom 6 - Wouter Hoff, Oklahoma State University

**11:15AM Y55.00001 Enhancing MD simulations of proteins using vague and combinatorics information** , KEN DILL, Stony Brook University — We have developed MELD, a method that 'melds' together replica-exchange molecular dynamics simulations with external information. Traditionally, accelerating MD simulations has only been possible by using information that is precise and correct. In contrast, MELD allows us to leverage information that is vague or corrupted. For example, we give generic instructives, such as 'make a hydrophobic core', 'make good secondary structures', or 'search only compact structures'. Normally, such information implies a loss of ability to compute free energies and populations. But, MELD satisfies detailed balance. We show that it can fold small proteins much faster than brute-force MD can, that it gives reasonable populations, and that it can succeed in CASP, the blind protein-structure prediction event.

**11:51AM Y55.00002 Molecular and cellular constraints on proteins** , TANJA KORTEEMME, UCSF — Engineering proteins with new sequences, structures and functions has many exciting practical applications, and provides new ways to dissect design principles for function. Recent successes in computational protein design provide a cause for optimism. Yet many functions are currently too complex to engineer predictively, and successful design of new biological activities also requires an understanding of the functional pressures acting on proteins in the context of cells and organisms. I will present two vignettes describing our progress with dissecting both molecular and cellular constraints on protein function. In the first, we characterized the cost and benefit of protein production upon sequence perturbations in a classic system for gene regulation, the *lac* operon. Our results were unexpected in light of the common assumption that the dominant fitness costs are due to protein *expression*. Instead, we discovered a direct linear relationship between cost and *lac* permease *activity*, not protein or mRNA production. The magnitude of the cost of permease activity, relative to protein production, has consequences for regulation. Our model predicts an advantage of direct regulation of protein *activity* (not just expression), providing a new explanation for the long-known mechanism of "inducer exclusion" that inhibits transport through the permease. Similar pressures and cost/benefit tradeoffs may be key to engineering synthetic systems with improved fitness. In the second vignette, I will describe our recent efforts to develop computational approaches that predict protein sequences consistent with multiple functional conformations. We expect such "multi-constraint" models to improve predictions of functional sequences determined by deep mutational scanning in bacteria, to provide insights into how the balance between functional conformations shapes sequence space, and to highlight molecular and cellular constraints that cannot be captured by the model.

**12:27PM Y55.00003 Response of proteins to mechanical force** , DAVE THIRUMALAI, Univ of Maryland-College Park — No abstract available.

**1:03PM Y55.00004 Kinetic Cooperativity, Loop Dynamics, and Allostery from NMR and MD simulations** , RAFAEL BRUSCHWEILER, The Ohio State University — The hallmark of glucokinase (GCK), which catalyzes the phosphorylation of glucose during glycolysis, is its kinetic cooperativity whose understanding at atomic detail has remained open since its discovery over 40 years ago. I will discuss how the origin of kinetic cooperativity is rooted in intramolecular protein dynamics using NMR relaxation data of 17 isoleucines distributed over all parts of GCK. Residues of glucose-free GCK located in the small domain display a distinct exchange behavior involving multiple conformers that are substantially populated, whereas in the glucose-bound form these dynamic processes are quenched. The conformational exchange process directly competes with the enzymatic turnover at physiological glucose concentrations, thereby generating the sigmoidal rate dependence that defines kinetic cooperativity. The flexible nature of protein loops and the timescales of their dynamics are critical for many biologically important events at the molecular level, such as protein interaction and recognition processes. Based on a library of proteins, rules about loop dynamics in terms of amplitude and timescales can be derived using molecular dynamics (MD) simulations and NMR data. These rules have been implemented in the new web server ToeLoop (for Timescales Of Every Loop) that permits the prediction of loop dynamics based on an average 3D protein structure (<http://spin.ccic.ohio-state.edu/index.php/loop/index>).

**1:39PM Y55.00005 Unraveling protein catalysis through neutron diffraction.** , DEAN MYLES, Neutron Science Directorate, Oak Ridge National Laboratory, Oak Ridge, TN. 37831 — Neutron scattering and diffraction are exquisitely sensitive to the location, concentration and dynamics of hydrogen atoms in materials and provide a powerful tool for the characterization of structure-function and interfacial relationships in biological systems. Modern neutron scattering facilities offer access to a sophisticated, non-destructive suite of instruments for biophysical characterization that provide spatial and dynamic information spanning from Angstroms to microns and from picoseconds to microseconds, respectively. Applications range from atomic-resolution analysis of individual hydrogen atoms in enzymes, through to multi-scale analysis of hierarchical structures and assemblies in biological complexes, membranes and in living cells. Here we describe how the precise location of protein and water hydrogen atoms using neutron diffraction provides a more complete description of the atomic and electronic structures of proteins, enabling key questions concerning enzyme reaction mechanisms, molecular recognition and binding and protein-water interactions to be addressed. Current work is focused on understanding how molecular structure and dynamics control function in photosynthetic, cell signaling and DNA repair proteins. We will highlight recent studies that provide detailed understanding of the physiochemical mechanisms through which proteins recognize ligands and catalyze reactions, and help to define and understand the key principles involved.
