**4:18PM C27.00010 Investigation of the physical properties of the new heavy fermion compounds Ce<sub>2</sub>MAI<sub>7</sub>Ge<sub>4</sub> (M = Co, Ir, Ni, Pd)**, NIRMAL GHIMIRE<sup>1</sup>, Los Alamos National Laboratory, SAMANTHA CARY, THOMAS ALBRECHT-SCHMITT, Florida State University, CRAIG BROWN, National Institute of Standards and Technology, SERENA ELEY, NICHOLAS WAKEHAM, PRISCILA ROSA, MARC JANOSCHEK, LEONARDO CIVALE, JOE THOMPSON, FILIP RONNING, ERIC BAUER, Los Alamos National Laboratory — Ce-based intermetallic compounds provide a fascinating ground to study several exotic physical phenomena due to the presence of competing low Kondo and RKKY interactions. One widely explored entity in these compounds is the quantum phase transition that is accessed by the suppression of the magnetic order down to absolute temperature by an external parameter such as magnetic field, chemical substitution, or pressure. Exotic phenomena like unconventional superconductivity and non-Fermi liquid behavior are ubiquitous in the vicinity of the quantum critical point. Quantum criticality in these Ce-based materials is often observed in layered, tetragonal systems such as the CeM<sub>2</sub>X<sub>2</sub> (M=transition metal; X=Si, Ge) or CeMIn<sub>5</sub> (M=Co, Rh, Ir) compounds. We present the structural and physical properties of a new family of heavy fermion compounds Ce<sub>2</sub>MAI<sub>7</sub>Ge<sub>4</sub> (M = Co, Ir, Ni, Pd) that crystallize in the tetragonal space group P-42<sub>1</sub>m. Ce<sub>2</sub>MAI<sub>7</sub>Ge<sub>4</sub> (M=Co, Ir, Ni) show complex magnetic order below 2 K, while Ce<sub>2</sub>PdAl<sub>7</sub>Ge<sub>4</sub> does not order magnetically down to 400 mK, and, instead, shows quantum critical behavior at low temperature.

**4:30PM C27.00011 Antiferromagnetic Kondo lattice in the layered compounds Re<sub>2</sub>NiGa<sub>9</sub>Ge<sub>2</sub> (Re=Ce, Pr, Sm)**, YANGLIN ZHU, JINYU LIU, JIN HU, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70018, DANIEL ADAMS, LEONARD SPINU, Department of Physics and AMRI, University of New Orleans, New Orleans, LA 70148, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, New Orleans, LA 70018. — Intermetallic compounds containing rare-earth/actinide elements with 4f/5f electrons have formed a special family of strongly correlated materials, i.e. heavy fermion systems. We have recently found a new layered rare earth intermetallic system showing moderate heavy fermion behavior: Re<sub>2</sub>NiGa<sub>9</sub>Ge<sub>2</sub> (Re=Ce, Sm, Pr). The Re=Ce and Sm members were previously synthesized [1], while their electronic properties have not been reported. We have recently grown single crystals of Re<sub>2</sub>NiGa<sub>9</sub>Ge<sub>2</sub> (Re=Ce, Sm, Pr) and characterized their electronic and magnetic properties. We find all these materials are antiferromagnetic, with  $T_N = 2.5$  K, 5 K, 3.4 K respectively for Re=Ce, Pr and Sm. Moreover, they also exhibit large values of electronic specific coefficient:  $\gamma \approx 101$  mJ mol-Ce<sup>-1</sup> K<sup>-2</sup> for Re=Ce, 368 mJ mol-Pr<sup>-1</sup> K<sup>-2</sup> for Re=Pr, and 196.4 mJ mol-Sm<sup>-1</sup> K<sup>-2</sup> for Re=Sm, indicating enhanced Kondo effect and the presence of AFM Kondo lattice. Our findings suggest that Re<sub>2</sub>NiGa<sub>9</sub>Ge<sub>2</sub> (Re=Ce, Pr, Sm) could be interesting candidate materials for exploring novel exotic properties of correlated electrons through external parameter tuning such as chemical substitution and pressure. **4:42PM C27.00012 High-resolution x-ray diffraction study of the heavy-fermion compound YbBiPt**, B. G. UELAND, S. M. SAUNDERS, S. L. BUD'KO, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, G. M. SCHMIEDESHOFF, Department of Physics, Occidental College, P. C. CANFIELD, A. KREYSSIG, A. I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University — YbBiPt is a heavy-fermion compound possessing significant short-range antiferromagnetic correlations below  $T^* = 0.7$  K, fragile antiferromagnetic order below  $T_N = 0.4$  K, a Kondo temperature of  $T_K \approx 1$  K, and crystalline-electric-field splitting (CEF) on the order of  $E/k_B = 1 - 10$  K. Its lattice is face-centered cubic at ambient temperature, but certain data, particularly those from studies aimed at determining the CEF level scheme, suggest that the lattice distorts at lower temperature. Here, we present results from high-energy x-ray diffraction experiments which show that, within our experimental resolution of  $\approx 6 - 10 \times 10^{-5}$  Å, no structural phase transition occurs between 1.5 and 50 K. Despite this result, we demonstrate that the compound's thermal expansion may be modeled using CEF level schemes appropriate for Yb<sup>3+</sup> residing on a site with either cubic or less than cubic point symmetry. Work at the Ames Laboratory was supported by the US DOE, BES, DMSE, under Contract No. DE-AC02-07CH11358. Work at Occidental College was supported by the NSF under DMR-1408598. This research used resources at the Advanced Photon Source a US DOE, Office of Science, User Facility.

**4:54PM C27.00013 Intermediate valence to heavy fermion through a quantum phase transition in  $\text{Yb}_3(\text{Rh}_{1-x}\text{T}_x)_4\text{Ge}_{13}$  ( $T = \text{Co, Ir}$ ) single crystals<sup>1</sup>**, BINOD RAI, EMILIA MOROSAN, Rice University, Houston TX, 77005 — Single crystals of  $\text{Yb}_3(\text{Rh}_{1-x}\text{T}_x)_4\text{Ge}_{13}$  ( $T = \text{Co, Ir}$ ) have been grown using the self-flux method. Powder X-ray diffraction data on these compounds are consistent with the cubic structure with space group  $Pm\bar{3}n$ . Intermediate valence behavior is observed in  $\text{Yb}_3(\text{Rh}_{1-x}\text{T}_x)_4\text{Ge}_{13}$  upon  $T = \text{Co}$  doping, while  $T = \text{Ir}$  doping drives the system into a heavy fermion state. Antiferromagnetic order is observed in the Ir-doped samples  $\text{Yb}_3(\text{Rh}_{1-x}\text{T}_x)_4\text{Ge}_{13}$  for  $0.5 < x \leq 1$  with  $T_N = 0.96$  K for  $\text{Yb}_3\text{Ir}_4\text{Ge}_{13}$ . With decreasing  $x$ , the magnetic order is suppressed towards a quantum critical point around  $x_c = 0.5$ , accompanied by non-Fermi liquid behavior evidenced by logarithmic divergence of the specific heat and linear temperature dependence of the resistivity. The Fermi liquid behavior is recovered with the application of large magnetic fields.

**5:06PM C27.00014 Electronic and Magnetic Properties of Cd-Doped  $\text{PuRhIn}_5$ <sup>1</sup>**, JIAN-XIN ZHU, Los Alamos National Laboratory — Since their discovery nearly a decade ago, plutonium-based superconductors have attracted considerable interest, which is now heightened by the latest discovery of superconductivity in other Pu-115 compounds. Within the generalized gradient approximation (GGA) of density functional theory and its combination with the dynamical mean-field theory, we present a study of electronic structure in the paramagnetic state of Cd-doped  $\text{PuRhIn}_5$ . A doping-induced delocalization-localization transition is identified. In addition, the spin-polarized GGA-based total energy calculations are performed to determine the magnetic exchange interactions in the pristine  $\text{PuRhIn}_5$ . The implication to the nature of quantum criticality is discussed.

<sup>1</sup>This work was carried out under the auspices of the National Nuclear Security Administration of the U.S. Department of Energy at LANL under Contract No. DE-AC52-06NA25396, and was supported by the LANL ASC Program.

**5:18PM C27.00015 Phenomenological Magnetic Model in Tsai-Type Approximants**, TAKANORI SUGIMOTO, TAKAMI TOHYAMA, Department of Applied Physics, Tokyo University of Science, TAKANOBU HIROTO, Department of Advanced Material Science, University of Tokyo, RYUJI TAMURA, Department of Applied Physics, Tokyo University of Science — Recent neutron diffraction study has reported a curious ferromagnetism in Tsai-type approximants  $\text{Au-Si-RE}$  ( $\text{RE}=\text{Tb, Dy, Ho}$ ), which have the same local structure as quasi-crystals with a translational symmetry simultaneously. In these materials, magnetic moments of rare-earth atoms have a single-ion anisotropy determined locally via spin-orbit coupling around crystal fields satisfying a distorted icosahedral crystal structure. We phenomenologically propose a possible magnetic model reproducing the magnetic structure and the thermodynamical quantities. The corresponding energies of the single-ion anisotropy and RKKY exchange couplings are also estimated by comparing magnetization curves and susceptibility of our model and experiments. Moreover, simulated annealing calculations with the energies in our model coincide with the strange ferromagnetism. In conclusion, a distortion of icosahedral cluster in body-centered cubic structure plays a key role to emerge the peculiar magnetic structure. Our magnetic model does not only explain magnetic behaviors in quasi-crystal approximants, but also can approach to a coexistence of a long-ranged order and a quasi-periodicity.

**Session C28 DMP: Quantum Anomalous Hall Effect I** 327 - Nikesh Koirala, Rutgers University

**2:30PM C28.00001 Achieving High-Temperature Ferromagnetic Topological Insulator**, FERHAT KATMIS, Massachusetts Institute of Technology — Topological insulators (TIs) are insulating materials that display conducting surface states protected by time-reversal symmetry, wherein electron spins are locked to their momentum. This unique property opens new opportunities for creating next-generation electronic and spintronic devices, including TI-based quantum computation. Introducing ferromagnetic order into a TI system without compromising its distinctive quantum coherent features could lead to a realization of several predicted novel physical phenomena. In particular, achieving robust long-range magnetic order at the TI surface at specific locations without introducing spin scattering centers could open up new possibilities for devices. Here, we demonstrate topologically enhanced interface magnetism by coupling a ferromagnetic insulator (FMI) to a TI ( $\text{Bi}_2\text{Se}_3$ ); this interfacial ferromagnetism persists up to room temperature, even though the FMI ( $\text{EuS}$ ) is known to order ferromagnetically only at low temperatures ( $<17$  K). The induced magnetism at the interface resulting from the large spin-orbit interaction and spin-momentum locking feature of the TI surface is found to greatly enhance the magnetic ordering (Curie) temperature of the TI/FMI bilayer system. Due to the short range nature of the ferromagnetic exchange interaction, the time-reversal symmetry is broken only near the surface of a TI, while leaving its bulk states unaffected. The topological magneto-electric response originating in such an engineered TI could allow for an efficient manipulation of the magnetization dynamics by an electric field, providing an energy efficient topological control mechanism for future spin-based technologies. Work supported by MIT MRSEC through the MRSEC Program of NSF under award number DMR-0819762, NSF Grant DMR-1207469, the ONR Grant N00014-13-1-0301, and the STC Center for Integrated Quantum Materials under NSF grant DMR-1231319.

**3:06PM C28.00002 Probing the Spin Transfer Efficiency at Topological Insulator/Ferromagnetic Insulator Interfaces<sup>1</sup>**, HAILONG WANG, JAMES KALLY, JOON SUE LEE, ANTHONY RICHARDELLA, SUSAN KEMPINGER, YU PAN, ERIC KAMP, NITIN SAMARTH, Pennsylvania State University, TAO LIU, HOUCHEUNG CHANG, MINGZHONG WU, Colorado State University, DANIELLE REIFSNYDER-HICKEY, ANDRE MKHOYAN, University of Minnesota — The development of next-generation spintronics devices has driven extensive studies of spin-charge conversion through measurement of the inverse spin Hall effect (ISHE) and ferromagnetic resonance (FMR) driven spin pumping of pure spin currents in ferromagnet/non-magnet bilayers. Topological insulators (TIs) such as the Bi-chalcogenides are naturally relevant in this context because the inherent spin-momentum locking in their surface states promises very efficient spin-charge conversion, although the first experimental studies have involved ferromagnetic metals that provide a shunting current path [e.g. Nature, 511,449 (2014)]. To circumvent the current shunting problem, we are growing and characterizing bilayers of TIs and the ferrimagnetic insulator  $\text{Y}_3\text{Fe}_5\text{O}_{12}$  (YIG). Here, we report measurements of FMR-driven spin pumping in TI/YIG bilayers, showing robust spin pumping signals at room temperature. Analysis of the ISHE voltages and FMR linewidth broadening show that, as in other studies of spin pumping into TIs [Nano Lett., 15 (10) (2015)], the interface condition presents a critical challenge for enhancing the spin conversion efficiency in these devices.

<sup>1</sup>Funded by C-SPIN/SRC/DARPA and ONR

**3:18PM C28.00003 Spin manipulation at the interface of a topological insulator/GaAs heterostructure<sup>1</sup>**, DONGXIA QU, Lawrence Livermore National Laboratory, XIAOYU CHE, XUFENG KOU, MURONG LANG, University of California, Los Angeles, JONATHAN CROWHURST, MICHAEL R. ARMSTRONG, JOSEPH ZAUG, Lawrence Livermore National Laboratory, KANG L. WANG, University of California, Los Angeles, GEORGE F. CHAPLINE, Lawrence Livermore National Laboratory, LAWRENCE LIVERMORE NATIONAL LABORATORY TEAM, UNIVERSITY OF CALIFORNIA, LOS ANGELES TEAM — One primary goal of spintronics is to discover materials and devices, which enable efficient electrical control of spins. The emerging field of topological insulator (TI) provides intriguing opportunities for spin generation and manipulation, owing to its strong spin-orbit character. Here we report that spins can be driven from a topological insulator thin film  $(\text{Bi}_{0.5}\text{Sb}_{0.5})_2\text{Te}_3$  into an adjacent semiconductor GaAs at room temperature. In a TI/GaAs heterostructure, a photo-induced spin current flows across the interface and induces an electrical current via the inverse spin Hall effect, which converts the spin current into a charge current. We find that the magnitude and direction of the helicity-dependent photocurrent can be controlled by gate-voltage, indicative of electric tuning of the spin configuration.

**3:30PM C28.00004 Spin Pumping into Topological Insulator  $\text{Bi}_2\text{Te}_3$** , FARIS BASHEER ABDULAHAD, JIN-HAN LIN, YUNG LIOU, WEN-KAI CHIU, Academia Sinica, JUN-ZHI LIANG, Fu Jen Catholic University, SHANG-FAN LEE, Academia Sinica — A spin chemical potential bias can induce a spin polarized current by the exchange interaction of a ferromagnet with the spin-momentum locking surface states of the topological insulators. We carried out our ferromagnetic resonance experiment in a  $\text{NiFe}/\text{Bi}_2\text{Te}_3$  heterostructure. Apart from the enhanced Gilbert damping constant, we observed strong enhancement of the effective magnetic field at low temperatures. The enhanced field decreased exponentially with increasing temperature at an energy scale of 2.5 meV, representing the strength of the exchange coupling. We attribute the enhanced field to the induced spin polarized current in the surface states of  $\text{Bi}_2\text{Te}_3$ .

**3:42PM C28.00005 Magnetic proximity effect in a topological insulator-magnetic insulator heterostructure**, WENMIN YANG, SHUO YANG, KEHUI WU, JIANWANG CAI, YONGQING LI, Institute of Physics Chinese Academy of Sciences — Ferromagnetic topological insulators (TIs) have become one of the most actively pursued materials in condensed matter physics due to their unique properties, where several exotic phenomena have been predicted and observed, such as the quantum anomalous Hall effect and the topological magneto-electric effect. In this talk, I will introduce the fabrication and characterization of a heterostructure consisting of a thin film of the topological insulator  $\text{Bi}_2\text{Se}_3$  and the magnetic insulator  $\text{Y}_3\text{Fe}_5\text{O}_{12}$  (YIG), and study the low temperature transport properties. Compared to non-magnetic  $\text{Bi}_2\text{Se}_3$ , the magnetoresistance (MR) of  $\text{Bi}_2\text{Se}_3$ -YIG deviates from the typical weak antilocalization behavior in low perpendicular magnetic fields. In parallel fields, we observe unusual negative MR and sharp MR jumps when single domains nucleate and annihilate. Furthermore, magnetization measurements reveal that this unusual MR correlates to domain wall configurations of the YIG layer. These results can be explained due to the appearance of a perpendicular magnetic exchange field at the interface. The understanding of the interfacial interaction is valuable to further reveal unique physics in TI based magnetic heterostructures.

**3:54PM C28.00006 Epitaxial Growth and Characterization of Iron Chalcogenide/Bismuth Chalcogenide Heterostructures**, THOMAS FLANAGAN, ABHINAV KANDALA, JOON SUE LEE, SUSAN E. KEMPINGER, ANTHONY RICHARDELLA, NITIN SAMARTH, Pennsylvania State University — Heterostructures consisting of topological insulators (TIs) interfaced with superconductors and with ferromagnets have been predicted to give rise to phenomena of both fundamental and applied interest. With superconductors, the region of proximity-induced superconductivity should have  $p_x + ip_y$  symmetry, and vortices in this region have been predicted to host Majorana modes, which may be useful as quantum bits. With ferromagnets, such phenomena as the topological magnetoelectric effect have been predicted. Iron chalcogenides, such as iron selenide and iron telluride, are ideal candidates for combining with TIs, since, with only minor changes to growth conditions, they can be superconducting, ferromagnetic, or antiferromagnetic. We describe the growth and characterization of heterostructures that combine thin films of the iron and bismuth chalcogenides, focusing on low temperature magnetoresistance measurements. Our measurements reveal a transient hysteretic magnetoresistance with surprisingly long relaxation times (minutes). This phenomenon appears to be a generic characteristic of all heterostructures that interface TIs with magnetic spins, albeit with structure-specific relaxation times. We discuss possible origins of this unusual phenomenon. Funded by ARO/MURI.

**4:06PM C28.00007 Epitaxial Growth of Two-Dimensional Stanene**, JINFENG JIA<sup>1</sup>, Shanghai Jiao Tong University — Ultrathin semiconductors present various novel electronic properties. The first experimental realized two-dimensional (2D) material is graphene. Searching 2D materials with heavy elements bring the attention to Si, Ge and Sn. 2D buckled Si-based silicene was realized by molecular beam epitaxy (MBE) growth. Ge-based germanene was realized by mechanical exfoliation. Sn-based stanene has its unique properties. Stanene and its derivatives can be 2D topological insulators (TI) with a very large band gap as proposed by first-principles calculations, or can support enhanced thermoelectric performance, topological superconductivity and the near-room-temperature quantum anomalous Hall (QAH) effect. For the first time, in this work, we report a successful fabrication of 2D stanene by MBE. The atomic and electronic structures were determined by scanning tunneling microscopy (STM) and angle-resolved photoemission spectroscopy (ARPES) in combination with first-principles calculations. This work will stimulate the experimental study and exploring the future application of stanene.

<sup>1</sup>In cooperation with Fengfeng Zhu, Wei-jiong Chen, Yong Xu, Chun-lei Gao, Dan-dan Guan, Canhua Liu, Dong Qian, Shou-Cheng Zhang

**4:18PM C28.00008 Topological Surface States in Sb Quantum Wells on GaSb(111)A Substrates<sup>1</sup>**, KAUSHINI WICKRAMASINGHE, CHOMANI GASPE, SHAYNE CAIRNS, NOLAN TEASDALE, TETSUYA MISHIMA, JOEL KEAY, METTHEW JOHNSON, SHEENA MURPHY, MICHAEL SANTOS, University of Oklahoma — A topoelectronic transition is predicted as a function of Sb quantum-well (QW) thickness. Bulk Sb is a semimetal with a negative bandgap, with neither the conduction band minimum nor the valence band maximum at the  $\Gamma$  point. Our goal is to measure the topological surface states by suppression of the bulk conductivity through quantum confinement and enhancement of the surface conductivity through remote n-type doping at the  $\Gamma$  point. Conductivity measurements on undoped QWs (0.7 to 6 nm thick) show a suppression of the bulk states, such that the surface conductivity is about 15% for a 3.6 nm QW. Hall-effect measurements, which nominally indicate p-type conduction, are complicated by the presence of both electrons and holes. We have begun experiments to populate the topological electron states by doping the GaSb barrier with Te atoms, creating donor states at the  $\Gamma$  point. At the  $\Gamma$  point of the QW, the topological electron states have a lower energy than the bulk conduction band minimum. We observe n-type conduction for a remotely-doped Sb QW with a 94 nm spacer between the doped GaSb layer and the Sb QW. We plan to make high-field magneto-transport measurements to verify that the Sb surface states are populated.

<sup>1</sup>This material is based upon work supported by the NSF under Grant No. DMR-1207537

**4:30PM C28.00009 First-principles study of topological surface states in  $\text{Bi}_2\text{Se}_3/\text{ZnSe}$  superlattices<sup>1</sup>**, KYUNGWHA PARK, Virginia Tech, Blacksburg, ZHIYI CHEN, LUKAS ZHAO, THOR AXTMANN GARCIA, MARIA TAMARGO, LIA KRUSIN-ELBAUM, The City College of New York, CUNY — Topological insulators (TIs) are interesting due to robustness of surface states within a bulk band gap in the presence of time reversal symmetry. Various TI heterostructures are based on the robustness of the topological surface states. Thus, it is crucial to understand how the topological surface states are influenced by interfaces. Recently  $\text{Bi}_2\text{Se}_3/\text{Zn}_x\text{Cd}_{1-x}\text{Se}$  superlattices grown by molecular beam epitaxy showed interesting magneto-transport properties such as a single two-dimensional conducting channel per TI layer with the Berry phase of  $\pi$ . Intrigued by this experiment, we investigate topological surface states of the  $\text{Bi}_2\text{Se}_3/\text{ZnSe}$  superlattice by using density-functional theory. Based on the stoichiometry and the charge balance of the ZnSe layer, when one side of the ZnSe layer is terminated with Zn in the superlattice, the other side must be terminated with Se. Using the superlattice model and two slab models with either a Zn-terminated or Se-terminated interface, we calculate the effect of the inherent asymmetry of the ZnSe layer on the topological surface states of  $\text{Bi}_2\text{Se}_3$ , and compare our result to the experiment.

<sup>1</sup>Funding from NSF DMR-1206354, DMR-1312483, DMR-1420634, HRD-0833180, and DOD-W911NF-13-1-0159, and Computer resources from SDSC Trestles under DMR060009N and VT ARC.

**4:42PM C28.00010 Experimental preparation of lateral Heterojunction  $\text{Sb}_2\text{Te}_3/\text{Bi}_2\text{Te}_3$  Nanoplates**, FUCONG FEI, FENGQI SONG, Nanjing Univ — For the first time, lateral heterojunction of  $\text{Sb}_2\text{Te}_3\text{-Bi}_2\text{Te}_3$  was successfully realized using a two-step solvothermal method. The two crystalline components were separated well by a sharp lattice-matched interface when the optimized procedure was used. Inspecting the heterojunction using high-resolution transmission electron microscopy showed that epitaxial growth occurred along the horizontal plane. The semiconducting temperature-resistance curve and crossjunction rectification were observed, which reveal a staggered-gap lateral heterojunction with a small junction voltage. Quantum correction from the weak antilocalization reveals the well-maintained transport of the topological surface state. This is appealing for a platform for spin filters and one-dimensional topological interface states. The relevant works on materials optimization and fabrication of spin devices are already under way. (Nanoletters 2015, 15, 5905–5911))

**4:54PM C28.00011 Nonlinear optical probe of interface ferromagnetism of  $\text{EuS-Bi}_2\text{Se}_3$  heterostructures**, CHANGMIN LEE, Department of Physics, MIT, FERHAT KATMIS, Francis Bitter Magnet Lab and Department of Physics, MIT, PABLO JARILLO-HERRERO, Department of Physics, MIT, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab and Department of Physics, MIT, NUH GEDIK, Department of Physics, MIT —  $\text{EuS-Bi}_2\text{Se}_3$  heterostructure is a novel magnetic topological insulator system with canted ferromagnetism induced at the interface between  $\text{EuS}$  and  $\text{Bi}_2\text{Se}_3$ . Here we use magnetic second harmonic generation (MSHG) to probe interface ferromagnetism of  $\text{EuS-Bi}_2\text{Se}_3$  heterostructures. MSHG is a powerful nonlinear optical technique that selectively probes magnetism at the surfaces and interfaces of a centrosymmetric material. In order to study how the thickness of the magnetic  $\text{EuS}$  layer affects interface ferromagnetism, we have grown  $\text{EuS-Bi}_2\text{Se}_3$  heterostructures with varying  $\text{EuS}$  thicknesses. We have also grown heterostructures in which the  $\text{EuS}$  thickness increases linearly across a single sample. We discuss how the magnetic layer thickness affects the strength and canting angle of interface magnetism.

**5:06PM C28.00012 Van Vleck Nature of Carrier-Free Ferromagnetic Order in Vanadium-Doped Three-Dimensional Topological Insulators**, MINGDA LI, CUI-ZU CHANG, MIT, LIJUN WU, JING TAO, Brookhaven National Lab, WEIWEI ZHAO, MOSES H W CHAN, Pennsylvania State University, JAGADEESH MOODERA, JU LI, MIT, YIMEI ZHU, Brookhaven National Lab, MIT TEAM, BROOKHAVEN NATIONAL LAB TEAM, PENNSYLVANIA STATE UNIVERSITY COLLABORATION — We experimentally demonstrate that the long-range ferromagnetic (FM) order in vanadium (V)-doped topological insulator  $\text{Sb}_2\text{Te}_3$  has the nature of van Vleck-type ferromagnetism, using the state-of-art low-temperature Electron Energy Loss Spectroscopy (EELS). Contrary to the temperature-independent  $\text{Te M}_{4,5}$  peak, there is an unusual redshift of the  $\text{V L}_3$  and  $\text{L}_2$  peak positions and unambiguous change of the  $\text{L}_3\text{:L}_2$  peak ratio at  $T=10\text{K}$ . Further high-order Green's function's EELS simulation and magnetotransport show that the shift of the peak position and change of the  $\text{L}_3\text{:L}_2$  ratio are originated from the development of the core-level FM order, indicating that in V-doped  $\text{Sb}_2\text{Te}_3$ , partially filled core states will also contribute to FM order. Since van Vleck magnetism is a result of summing over all states, this magnetization of core level verifies the van Vleck-type ferromagnetism in a direct manner.

**5:18PM C28.00013 Imaging Spatially Varying Magnetic Order in Proximity Induced Magnetic Topological Insulator**, AARON J. ROSENBERG, Stanford University, FERHAT KATMIS, MIT, YIHUA H. WANG, JOHN R. KIRTLEY, Stanford University, JAGADEESH S. MOODERA, MIT, KATHRYN A. MOLER, Stanford Institute for Materials and Energy Sciences, SLAC National Laboratories — Broken time-reversal symmetry on the surface states of a three dimensional topological insulator, such as  $\text{Bi}_2\text{Se}_3$ , results in quantized anomalous Hall conductance and is predicted to exhibit topological magneto-electric effects. We plan investigate how Dirac fermions interact with magnetism by imaging the magnetization of a topological insulator ( $\text{Bi}_2\text{Se}_3$ ) sandwiched between two ferromagnetic insulator layers ( $\text{EuS}$ ) with a scanning SQUID microscope. Cooling in an in-plane field leads to a magnetization that varies spatially on a micron scale, with 6-fold rotational symmetry. Understanding the origin of this magnetism may shed light on the exchange interaction and electronic properties of topological insulators.

**Monday, March 14, 2016 2:30PM - 5:30PM –**

**Session C29 DCMP DMP: Bi-based Topological Insulators** 328 - Seongshik Oh, Rutgers University

**2:30PM C29.00001 Nanoscale Andreev Reflection Spectroscopy on Bismuth-Chalcogenide Topological Insulators<sup>1</sup>**, C. R. GRANSTROM, I. FRIDMAN, University of Toronto, R. X. LIANG, University of British Columbia, H. LEI, C. PETROVIC, Brookhaven National Laboratory, SHUO YANG, K. H. WU, Chinese Academy of Sciences, J. Y. T. WEI, University of Toronto & Canadian Institute for Advanced Research — Andreev reflection (AR) is the basic mechanism underlying the superconducting proximity effect which, at the interface between a topological insulator (TI) and a spin-singlet superconductor, can induce chiral  $p$ -wave pairing in the TI. Despite this novel importance, it is not well understood how AR is affected by the unique attributes of a three-dimensional TI, namely the Dirac dispersion and helical spin-polarization of its surface states. In this work, we use both  $s$ -wave and  $d$ -wave<sup>2</sup> superconducting tips to perform AR spectroscopy at 4.2 K on flux-grown  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$  single crystals, as well as epitaxial  $\text{Bi}_2\text{Se}_3$  thin films grown on  $\text{SrTiO}_3$  substrates by molecular beam epitaxy. These AR measurements are complemented by scanning tunneling spectroscopy, in order to characterize the superconducting tip as well as the doping level and surface condition of the TI sample. Our data are analyzed using BTK theory, in light of the characteristic band structure of bismuth chalcogenides, to elucidate how the band structure affects the AR process.

**2:42PM C29.00002 Pressure-induced Lifshitz and Weyl Semi-metallic Phase Transitions in BiSb**, SOBHIT SINGH, Department of Physics and Astronomy, West Virginia University, Morgantown, WV-26505, IRAIS VALENCIA-JAIME, ANDRES GARCIA-CASTRO, Cinvestav-Unidad Querétaro, Querétaro-76230, México, FRANCISCO MUNÓZ, Departamento de Física, Facultad de Ciencias, Universidad de Chile, Casilla 653, Santiago 7800024, Chile, ALDO ROMERO, Department of Physics and Astronomy, West Virginia University, Morgantown, WV-26505 — By means of first-principle calculations, we report a non-magnetic stoichiometric crystal structure of BiSb with broken space-inversion symmetry. This structure belongs to the  $R\bar{3}m$  space group and it was obtained after a systematic study of the low-energy phases of  $\text{Bi}_{1-x}\text{Sb}_x$  ( $0 < x < 1$ ) compounds found by using minima hopping structure search method [1]. This structure is insulating in bulk and has non-trivial band topology. We observe pressure-induced Lifshitz and Weyl semi-metallic phases as electronic phase transitions in this system. The obtained Weyl semi-metallic phase exist in the 4.0 – 6.0 GPa pressure range. We find that a total 12 pairs of Weyl points, 12 monopoles and 12 antimonopoles, exist in the bulk Brillouin zone. The Weyl points with opposite chirality are located at different energy values yielding separate electron and hole Fermi-surfaces, which drives novel topological transport properties in this system. The surface state calculations reveal reminiscence of the Fermi-arcs at (001) surface of the BiSb slab, which further confirm the existence of Weyl semi-metallic phase in BiSb [2-4]. [1] J. Chem. Phys. 120, 9911 (2004) [2] Science 349, 622 (2015) [3] Nat Phys 11, 748 (2015) [4] Phys. Rev. X 5, 031013 (2015)

**2:54PM C29.00003 Ab initio study of the adsorption, diffusion, and intercalation of alkali metal atoms on the (0001) surface of the topological insulator  $\text{Bi}_2\text{Se}_3$** , MIKHAIL OTROKOV, Donostia International Physics Center, San Sebastian, Spain, ANASTASIA RYABISHCHENKOVA, Tomsk State University, Tomsk, Russia, MIGUEL ANGEL GOSALVEZ, Donostia International Physics Center, San Sebastian, Spain, VLADIMIR KUZNETSOV, Tomsk State University, Tomsk, Russia, EVGUENI CHULKOV, Donostia International Physics Center, San Sebastian, Spain — We present the results of an *ab initio* study of the adsorption, diffusion, and intercalation of alkali metal adatoms on the (0001) stepped surface of the topological insulator  $\text{Bi}_2\text{Se}_3$  for the case of low coverage. The calculations of the activation energies of the adatoms diffusion on the surface and in the van der Waals gaps near the steps, as well as the estimation of diffusion lengths, show that efficient intercalation through the steps is possible only for Li and Na. Data obtained for K, Rb, and Cs atoms indicate that their thermal desorption at high temperatures can start before intercalation. These results are discussed in the context of the experimental data available [?, ?].

**3:06PM C29.00004 Topological insulators are tunable waveguides for hyperbolic polaritons**, JIHI-SHENG WU, DIMITRI BASOV, MICHAEL FOGLER, University of California San Diego — We present a theoretical analysis showing that layered topological insulators, for example,  $\text{Bi}_2\text{Se}_3$  are optically hyperbolic materials in a range of THz frequencies. As such, these topological insulators possess deeply subdiffractive, highly directional collective modes: hyperbolic phonon-polaritons. We predict that in thin crystals the dispersion of these modes is split into discrete subbands and is strongly influenced by electron surface states. If the surface states are doped, then hybrid collective modes result from coupling of the phonon-polaritons with surface plasmons. The strength of the hybridization can be controlled by an external gate that varies the chemical potential of the surface states. We also show that momentum-dependence of the plasmon-phonon coupling leads to a polaritonic analog of the Goos-Hänchen effect. Directionality of the polaritonic rays and their tunable Goos-Hänchen shift are observable via THz nanoimaging.

**3:18PM C29.00005 ARPES study of the surface states and their aging in a topological insulator,  $\text{Bi}_2\text{Se}_3$** , KALOBARAN MAITI, Tata Institute of Fundamental Research — Topological insulators possess time reversal symmetry protected metallic surface states over the insulating bulk, where these surface states are expected to be immune to weak disorder, chemical passivation of the surface or temperature change. However, significant discrepancy from such behavior has been found experimentally in various materials. We studied the detailed electronic structure and its aging of a topological insulator,  $\text{Bi}_2\text{Se}_3$  employing high resolution photoemission spectroscopy. Both the band structure results and high resolution angle resolved photoemission data reveal significantly different surface electronic structure for different surface terminations. Furthermore, oxygen impurity on Se terminated surface exhibits an electron doping scenario, while oxygen on Bi terminated surface corresponds to a hole doping scenario. The intensity of the Dirac states reduces with aging indicating fragility of the topological order due to surface impurities. References

**3:30PM C29.00006 Interband Spin-Orbit Coupling in Topological Surface States Explored by Photoemission Spectroscopies**, ANDREW WEBER, STEFAN MUFF, MAURO FANCIULLI, J. HUGO DIL, (1) Ecole Polytechnique Federale de Lausanne (2) Swiss Light Source, Paul Scherrer Institute, QUINN GIBSON, HUIWEN JI, IVO PLETIKOSIC, ROBERT CAVA, Department of Chemistry, Princeton University, ALEXEI FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, ANTHONY CARUSO, Department of Physics, University of Missouri-Kansas City, JUREK SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory, ELIO VESCOVO, National Synchrotron Light Source, Brookhaven National Laboratory, TONICA VALLA, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory — Three-dimensional crystals with a topologically non-trivial band gap in the bulk Brillouin zone are typically classified by either Z2 topological invariants or by Chern number topological invariants. The Z2 topological band insulators are said to possess surface states protected by time-reversal-symmetry and topological crystalline insulators possess surface states protected by mirror-symmetry. Here we provide evidence, through spin- and angle-resolved photoemission spectroscopy and first-principles calculations of layered  $(\text{Bi}_2)_m(\text{Bi}_2\text{X}_3)_n$  ( $\text{X} = \text{Se, Te}$ ) materials, that surfaces of Z2 strong topological insulators can possess states protected by mirror-symmetry alone. The role of interband coupling in producing mirror-protected surface states with novel Fermi contours and spin-textures will be discussed, and an argument for the unification of Z2 and Chern number invariant classifications will be made.

**3:42PM C29.00007 Strong Zeeman effects in the Landau level spectrum of  $(\text{In}_x\text{Bi}_{1-x})_2\text{Se}_3$** , DANIEL WALKUP, WENWEN ZHOU, ILIJA ZELJKOVIC, Boston College, YOSHINORI OKADA, Boston College and Tohoku University, ZHENSONG REN, Boston College, KANE SCIPIONI, Boston College and University of Illinois at Urbana-Champaign, STEPHEN WILSON, Boston College and University of California Santa Barbara, VIDYA MADHAVAN, Boston College and University of Illinois at Urbana-Champaign — We investigate the surface states of  $(\text{In}_x\text{Bi}_{1-x})_2\text{Se}_3$  by scanning tunneling spectroscopy (STS) in the range  $0 \leq x \leq 3\%$ . We carefully examine the low-lying Landau levels of the topological surface states in attempt to extract the parameters of the surface-state Hamiltonian as a function of doping. Close examination of the data oblige us to index the Landau levels in a manner different to precedent on pristine  $\text{Bi}_2\text{Se}_3$ , and fits to the Landau level spectra yield large g-factors on the order of 40, which decrease with increasing x. The Landau levels of pristine  $\text{Bi}_2\text{Se}_3$  are also reexamined, yielding high g-factors roughly consistent with results obtained from magnetic oscillations, and suggesting a decrease in the surface-state Zeeman coupling with increasing In as the topological phase transition is approached.

**3:54PM C29.00008 Nonequilibrium spin texture within a thin layer below the surface of current-carrying topological insulator Bi<sub>2</sub>Se<sub>3</sub>: A first-principles quantum transport study<sup>1</sup>**, PO-HAO CHANG, BRANISLAV NIKOLIC, Univ of Delaware, TROELS MARKUSSEN, SREN SMIDSTRUP, KURT STOKBRO, QuantumWise — Using extension of nonequilibrium Green function combined with density functional theory (NEGF+DFT) formalism to situations involving noncollinear spins and spin-orbit coupling, we investigate microscopic details (on the 1 Å scale) of nonequilibrium spin density  $S(r)$  driven by unpolarized charge current injection into a ballistic thin film of Bi<sub>2</sub>Se<sub>3</sub> as prototypical topological insulator (TI) material. We find large nonzero component of  $S(r)$  in the direction transverse to current flow on the metallic surfaces of TI, as well as within few bulk atomic layers near the surfaces because of penetration of evanescent wavefunctions from the metallic surfaces into the bulk. In addition, an order of magnitude smaller components emerge in the perpendicular (within surfaces and nearly bulk regions of TI) and longitudinal (within bulk region of TI near its surface) directions, thereby creating a complex nonequilibrium spin texture. We also demonstrate how DFT calculations with properly optimized local orbital basis set can precisely match putatively more accurate calculations with plane wave basis set for the supercell of Bi<sub>2</sub>Se<sub>3</sub>.

**4:06PM C29.00009 Tunneling spectroscopy of a magnetic adatoms on topological insulator surfaces<sup>1</sup>**, M. MISIORNY, Chalmers Univ. of Technology, Göteborg, Sweden and Adam Mickiewicz Univ., Poznań, Poland, M. BJERNGAARD, Johns Hopkins Univ., Baltimore, USA and Univ. of Amsterdam, Amsterdam, The Netherlands, J. PAASKE, Univ. of Copenhagen, Copenhagen, Denmark — In this communication, we address the question of how the presence of a magnetic impurity on a topological insulator (TI) surface manifests in the inelastic electron tunneling spectroscopy (IETS) when such a system is probed by a STM. For this purpose, we consider a single magnetic adatom with arbitrary spin, whose dynamics is governed by the local magnetic anisotropy. The spin is exchange-coupled to two-dimensional helical surface electrons, corresponding to the surface of a three-dimensional TI like Bi<sub>2</sub>Se<sub>3</sub>, with its characteristic hexagonally warped Dirac cone band structure. Employing an effective exchange-tunneling model, we calculate the non-linear differential conductance from a spin-polarized STM tip to the helical substrate, valid in the perturbative regime of weak exchange-tunneling and including the nonequilibrium pumping of the adatom spin states. The interplay between the magnetic anisotropy and the spin-momentum locked surface electrons is shown to give a number of specific imprints in the IETS, which could be investigated by spin-resolved scanning tunneling spectroscopy. M. Misiorny, M. Bjerngaard and J. Paaske, manuscript in preparation

**4:18PM C29.00010 Laser-driven parametric instability and generation of entangled photon-plasmon states in graphene and topological insulators<sup>1</sup>**, ALEXEY BELYANIN, YONGRUI WANG, Texas AM University, IVAN OLADYSHKIN, MIKHAIL TOKMAN, Institute of Applied Physics, Russian Academy of Sciences — Massless Dirac electrons in graphene and on the surface of topological insulators such as Bi<sub>2</sub>Se<sub>3</sub> demonstrate strong nonlinear optical response and support tightly confined surface plasmon modes. Although both systems constitute an isotropic medium for low-energy in-plane electron excitations, their second-order nonlinear susceptibility becomes non-zero when its spatial dispersion is taken into account. In this case the anisotropy is induced by in-plane wave vectors of obliquely incident or in-plane propagating electromagnetic waves. In this work we show that a strong (0.1-1 MW/cm<sup>2</sup>) near-infrared or mid-infrared laser beam obliquely incident on graphene can experience a parametric instability with respect to decay into lower-frequency (idler) photons and THz surface plasmons. The parametric gain leads to efficient generation of THz plasmons. Furthermore, the parametric decay process gives rise to quantum entanglement of idler photon and surface plasmon states. This enables diagnostics and control of surface plasmons by detecting idler photons. A similar parametric process can be implemented in topological insulator thin films.

**4:30PM C29.00011 Electronic structures of topological insulators with non-conventional terminations<sup>1</sup>**, XIEGANG ZHU, YUN ZHANG, WEI FENG, BINGKAI YUAN, XINCHUN LAI, Science and Technology on Surface Physics and Chemistry Laboratory, Mianyang 621700, Sichuan, P. R. China — Until now, most works on topological insulators focus on the natural cleaving surfaces, *i.e.*, conventional terminations. However, researches on the non-conventional surfaces of TIs are hindered due to the difficulties in preparation of those surfaces and the existence of large number of dangling bonds on those surfaces. What is more, due to the complications in the surface lattice structures, DFT calculations on the non-conventional surfaces are not favorable. In this work, by adopting the tight binding method based Green's Function, we systematically studied the surface states of non-conventional terminations of topological insulator Bi<sub>2</sub>Te<sub>3</sub> and Bi<sub>2</sub>Se<sub>3</sub>. By using MBE, we manage to prepare topological insulator Bi<sub>2</sub>Te<sub>3</sub> thin films with fractional quintuple layer (FQL) termination. Scanning tunneling microscopy (STM) reveals that the as-grown Bi<sub>2</sub>Te<sub>3</sub> thin films may not necessarily terminate at the Van der Waals gap between two adjacent quintuple layers. The electronic structures of the FQL surfaces are studied in combination with quasi-particle interference (QPI) by scanning tunneling spectroscopy (STS). Our results suggest that the topological nature of SSs be preserved on non-conventional terminations. The robustness of the topological SSs is also demonstrated.

**4:42PM C29.00012 Role of spin-orbit scattering in quasiparticle interference**, YUHKI KOHSAKA, RIKEN CEMS, MANABU KANOU, Materials and Structures Laboratory, Tokyo Institute of Technology, TADASHI MACHIDA, KATSUYA IWAYA, TETSUO HANAGURI, RIKEN CEMS, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology — Quasiparticle interference measured by scanning tunneling spectroscopy is profoundly affected by spin textures in momentum space. In this spin effect, used to study spin-polarized electronic states with scanning tunneling spectroscopy, spin of electrons are usually supposed to be preserved unless magnetic impurities are doped. We report that electron spin is indeed not preserved but rotated by nonmagnetic impurities in the process of quasiparticle interference of a spin-polarized two-dimensional electron gas formed on the surface of a polar semiconductor BiTeI. The results imply that spin-orbit scattering plays a significant role in quasiparticle interference of materials where spin-orbit interaction is strong.

**4:54PM C29.00013 Considering a Topological Insulator as a Viscous Electronic Fluid**, THEODORE REBER, JONATHAN RAMEAU, JOHN SCHNEELOCH, RUIDAN ZHONG, GENDA GU, PETER JOHNSON, Brookhaven National Lab — Certain topological insulators' protected surface states may be better treated as hydrodynamic fluids than as collections of quasiparticles. We will present data showing that Bi<sub>0.5</sub>Sb<sub>1.5</sub>Se<sub>1.6</sub>Te<sub>1.4</sub> natively exists in the hydrodynamic regime at room temperature. A calculation of the viscosity finds that Bi<sub>0.5</sub>Sb<sub>1.5</sub>Se<sub>1.6</sub>Te<sub>1.4</sub> is surprisingly comparable to that of standard fluids such as water and helium, when normalized to the entropy of each system. This finite viscosity implies an unexpected method for current dissipation via turbulence.

**5:06PM C29.00014 Modification of the electronic band structure of the topological insulator  $\text{Bi}_2\text{Te}_3$  by the adsorption of the organic molecule Manganese Phthalocyanine**, ANDREW HEWITT, JONATHON BOLTERSDORF, PAUL MAGGARD, DANIEL DOUGHERTY, North Carolina State University — Topological insulators (TIs) have a spin-textured surface state protected by time-reversal symmetry within a bulk insulating gap. Typical approaches to breaking time-reversal symmetry have been to introduce dilute magnetic impurities into a solid-solution synthesis. Organic molecules offer another route for magnetic-doping of TIs. It has been shown that a coupling may exist, along with a new hybrid-interface state, between the magnetic molecule Manganese Phthalocyanine (MnPc) and the TI  $\text{Bi}_2\text{Te}_3$ . We report the modification of the electronic band structure by the adsorption of MnPc molecules as measured by ultraviolet photoelectron spectroscopy. We show a new state emerging below the Fermi level at less than a monolayer coverage of MnPc molecules. We also observe an *n*-doping effect as charge is transferred from the molecule to the TI substrate in agreement with recent work. We suggest that this interface system may have important implications for understanding the role of local time reversal symmetry breaking in TIs and in controlling spin injection into these novel materials.

**5:18PM C29.00015 Electrical Detection of Spin-to-Charge Conversion in a Topological Insulator  $\text{Bi}_2\text{Te}_3$** ,<sup>1</sup>, CONNIE H. LI, OLAF M.J. VAN 'T ERVE, Naval Research Laboratory, YAOYI LI, LIAN LI, University of Wisconsin, Milwaukee, BERRY T. JONKER, Naval Research Laboratory — Spin-momentum locking in topological insulators (TIs) dictates that an unpolarized charge current creates a net spin polarization. We recently demonstrated the first electrical detection of this spontaneous polarization in a transport geometry, using a ferromagnetic (FM) / tunnel barrier contact, where the projection of the TI surface state spin on the magnetization of detector is measured as a voltage [1]. Alternatively, if spins are injected into the TI surface state system, it is distinctively associated with a unique carrier momentum, and hence should generate a charge accumulation, similar to that of inverse spin Hall effect. Here we experimentally demonstrate both effects in the same device fabricated in  $\text{Bi}_2\text{Te}_3$ : the electrical detection of the spin accumulation generated by an unpolarized current flowing through the surface states, and that of the charge accumulation generated by spins injected into the surface states system. This reverse measurement is an independent confirmation of spin-momentum locking in the TI surface states, and offers additional avenue for spin manipulation. It further demonstrates the robustness and versatility of electrical access to the TI surface state spin system, an important step towards its utilization in TI-based spintronics devices.

## Monday, March 14, 2016 2:30PM - 5:30PM – Session C30 DMP DCMP: Novel Ferroic Systems 329 - R Ramesh, UC Berkeley

**2:30PM C30.00001 Moving Towards Domain Wall Devices in Ferroics**<sup>1</sup>, MARTY GREGG, Queens University Belfast — Domain walls in ferroelectric, ferroelastic and multiferroic oxides are distinct functional materials in their own right. They can be conducting, or even superconducting, when surrounding domains are insulating [1, 2]; they can demonstrate magnetism when the surrounding bulk is non-magnetic [3] and they can contain ordered electrical dipoles when the matrix containing them is non-polar [4]. Since domain walls can also be created, destroyed, and controllably moved from place to place, there is an amazing opportunity for us to design new forms of devices in which functionality is actively and dynamically deployed (now you see it; now you don't). This is the essence of the emerging field known as “domain wall nanoelectronics” [5]. In time, this arena of research could change the way we think of nanoscale functional devices, moving increasingly towards agile circuitry and neuromorphic device architectures. While the control of domain wall injection, movement and annihilation has been developed rather well in the nanomagnetism community (in race-track [6] and domain wall logic [7] research), similar research has not been widely performed in nanoscale ferroelectrics, ferroelastics and multiferroics. This talk will discuss progress that has been made to date and the way in which nanomagnetism research can be used as a source of inspiration. Site-specific domain wall injection and motion control in both proper and improper ferroelectrics using inhomogeneous electric and elastic fields, as well as dielectric patterning in uniaxial ferroelectrics, will be specifically considered [8]. As will be shown, sufficient control has been developed to allow the creation of a diode for domain wall motion in ferroelectrics, for example. [1] J. Seidel *et al.* Nat. **3:06PM C30.00002 Epitaxial Thin Films of Y doped  $\text{HfO}_2$** , CLAUDY SERRAO, ASIF KHAN, RAMESH RAMAMOORTHY, SAYEEF SALAHUDDIN, UC Berkeley — Hafnium oxide ( $\text{HfO}_2$ ) is one of a few metal oxides that is thermodynamically stable on silicon and silicon oxide. There has been renewed interest in  $\text{HfO}_2$  due to the recent discovery of ferroelectricity and antiferroelectricity in doped  $\text{HfO}_2$ . Typical ferroelectrics – such as strontium bismuth tantalate (SBT) and lead zirconium titanate (PZT) – contain elements that easily react with silicon and silicon oxide at elevated temperatures; therefore, such ferroelectrics are not suited for device applications. Meanwhile, ferroelectric  $\text{HfO}_2$  offers promise regarding integration with silicon. The stable phase of  $\text{HfO}_2$  at room temperature is monoclinic, but  $\text{HfO}_2$  can be stabilized in the tetragonal, orthorhombic or even cubic phase by suitable doping. We stabilized Y-doped  $\text{HfO}_2$  thin films using pulsed laser deposition. The strain state can be controlled using various perovskite substrates and controlled growth conditions. We report on Y-doped  $\text{HfO}_2$  domain structures from piezo-response force microscopy (PFM) and structural parameters via X-ray reciprocal space maps (RSM). We hope this work spurs further interest in strain-tuned ferroelectricity in doped  $\text{HfO}_2$ .

**3:18PM C30.00003 Ab initio study of  $\text{ZrO}_2$  monolayers epitaxial on Si**<sup>1</sup>, MEHMET DOGAN, DIVINE KUMAR, CHARLES AHN, FREDERICK WALKER, SOHRAB ISMAIL-BEIGI, Yale University — Growing thin films of crystalline metal oxides on semiconductors has been of much scientific interest because of their applications in electronic devices. One research goal is to achieve ferroelectricity in a crystalline and thin oxide film that is epitaxial on a semiconductor. This would enable the realization of non-volatile field-effect transistors where the state is encoded in the polarization direction of the oxide. We study oxides that are not ferroelectric in the bulk but become ferroelectric as an ultra-thin film on a semiconductor. Recent advances in epitaxial growth methods permit fabrication of such systems. We use density functional theory to study the interface between  $\text{ZrO}_2$  monolayers and Si (001). These monolayers have multiple metastable states. We present an analysis of these configurations and energy barriers between them. We consider the likely experimental situation where different configurations coexist to form a multi-domain system, and investigate domain dynamics. Furthermore, we demonstrate that the  $\text{ZrO}_2$  monolayers can be used as a buffer layer to induce ferroelectricity in perovskite oxides such as  $\text{SrTiO}_3$  on Si. We also show that these monolayers modify the transport properties of Si which would allow for the desired device applications.

**3:30PM C30.00004 Ferroelectric to paraelectric transition in  $\text{YCrO}_3$  revisited**, RAJEEV GUPTA, Department of Physics and Materials Science Programme, IIT Kanpur, Kanpur 208016, India, ASHISH MALL, Materials Science Programme, IIT Kanpur, Kanpur 208016, India, ASHISH GARG, Department of Materials Science and Engineering, IIT Kanpur, Kanpur 208016, India — X-ray diffraction (XRD) and Raman spectroscopy measurements are used to explore the origin of ferroelectricity in the orthorhombic ferroelectric oxide  $\text{YCrO}_3$ . Temperature dependent XRD studies carried out up to 900K and subsequent Reitveld refinement of the data shows that there is no evidence of any structural phase transition in  $\text{YCrO}_3$  across the ferroelectric to paraelectric phase transition at  $T_c = 470\text{K}$ . Temperature dependent unpolarized Raman spectroscopy measurements, from 300 K to 600 K, were carried out to investigate structural changes near  $T_c$  locally within the material. All Raman modes below  $600\text{ cm}^{-1}$  were assigned to phonon modes of Pnma structure and for further analysis of the Raman data, the line shape parameters were obtained by fitting a Lorentzian function to each peak. Surprisingly, despite absence of observation of any structural change in XRD measurements,  $\text{YCrO}_3$  shows a strong anomalous temperature variation near  $T_c$  in the peak positions and line widths for selected modes as a function of temperature. It is believed that  $\text{YCrO}_3$  is an improper ferroelectric and ferroelectricity arises due to local rotations of  $\text{CrO}_6$  octahedra leading to non-centrosymmetry. Our results seem to suggest that  $\text{YCrO}_3$  undergoes an iso-structural transition across  $T_c$ .

**3:42PM C30.00005 Phase Transitions in Nanoscale  $\text{SrTiO}_3$** , TIAN YU, HAN ZHANG, New Jersey Institute of Technology, MARK CROFT, Rutgers University, MEGAN SCOFIELD, DARA BOBB-SEMPLE, State University of New York at Stony Brook, JING TAO, Brookhaven National Laboratory, CHERNO JAYE, DANIEL FISHER, National Institute of Standards and Technology, STANISLAUS WONG, State University of New York at Stony Brook, TREVOR TYSON, New Jersey Institute of Technology — Free standing  $\text{SrTiO}_3$  has recently been shown to be polar for  $\sim 10\text{ nm}$  particles (APL 105, 091901 (2014)). We have conducted pressure dependent x-ray diffraction on monodispersed nanoscale samples with varying particle size. Distinctly different behavior is found in the diffraction patterns for sample with reduced size. The nature of the low temperature polar state under pressure will be discussed. The results are compared with reported work on bulk  $\text{SrTiO}_3$ . This work is supported by DOE Grant DE-FG02-07ER46402.

**3:54PM C30.00006 High-pressure synthesis of predicted oxynitride perovskite: Yttrium Silicon Oxynitride ( $\text{YSiO}_2\text{N}$ )**<sup>1</sup>, MUHTAR AHART, M. SOMAYAZULU, RAJASEKARAKUMAR VADAPPOO, Extreme Materials Initiative, Geophysical laboratory, Carnegie institution for Science, R. E. COHEN, Extreme Materials Initiative, Carnegie institution for Science; Department für Geo und Umweltwissenschaften, Ludwig-Maximilians-Universität, Germany — We synthesized the previously predicted [1] polar oxynitride perovskite in a diamond anvil cell with laser heating.  $\text{YSiO}_2\text{N}$  was predicted to have the polar  $P4mm$  structure with an effective spontaneous polarization of  $130\text{ }\mu\text{C}/\text{cm}^2$ . A mixture of Yttrium nitride (YN) and amorphous Silicon dioxide ( $\text{SiO}_2$ ) were loaded into a diamond anvil cell and laser heated at or above  $1200\text{ }^\circ\text{C}$  at  $12\text{ GPa}$ . The run products were investigated by x-ray diffraction, Raman spectroscopy, and second harmonic generation, for their phase and structural properties. The x-ray diffraction pattern ( $a = 3.235\text{ }\text{\AA}$ ,  $c = 4.485\text{ }\text{\AA}$ ) shows the phase formation of  $\text{YSiO}_2\text{N}$  and matches with the diffraction pattern derived from the first-principle predicted lattice parameters. However, minor unknown peaks are on the diffraction pattern indicating of the co-existence of other unknown phases. Further study of Raman spectroscopy observes the theoretically predicted modes, and second harmonic generation shows strong non-linear optical signal, which confirms the polar properties of  $\text{YSiO}_2\text{N}$ . [1] R. Caracas and R. E. Cohen, Appl. Phys. Lett. 91, 092902 (2007).

**4:06PM C30.00007 Ferroelectricity in corundum derivatives**<sup>1</sup>, MENG YE, DAVID VANDERBILT, Rutgers Univ — The search for new ferroelectric (FE) materials holds promise for broadening our understanding of FE mechanisms and extending the range of application of FE materials. The known FE materials  $\text{LiNbO}_3$  can be regarded as derived from the  $\text{Al}_2\text{O}_3$  corundum structure with cation ordering. Here we consider more general binary ( $\text{ABO}_3$ ) and ternary ( $\text{A}_2\text{BB}'\text{O}_6$ ) corundum derivatives as an extended class of potential FE materials, motivated by the fact that some members of this class have recently been synthesized. There are four structure types for these corundum derivatives, and the number of cation combinations is enormous, but in many cases the energy barriers for polarization reversal may be too large to allow FE behavior. Here we present a first-principles study of the polar structure, coherent FE barrier, and domain-wall switching barrier for a representative set of polar corundum derivatives, allowing us to identify several potentially new FE materials. We also discuss the conditions under which ferroelectricity is compatible with magnetic ordering. Finally, we identify several empirical measures that can provide a rule of thumb for estimating the barrier energies. Our results should assist in the experimental search for new FE materials in the corundum derivative family.

**4:18PM C30.00008 The origin of hyper-ferroelectricity in  $\text{LiBO}_3$  ( $B=\text{V, Nb, Ta, Os}$ )**, LIXIN HE, PENGFEI LI, XINGUO REN, G-C GUO, University of Science and Technology of China — The electronic and structural properties of  $\text{LiBO}_3$  ( $B=\text{V, Nb, Ta, Os}$ ) are investigated via first-principles methods. We show that  $\text{LiBO}_3$  are belong to the recently proposed hyperferroelectrics, i.e., they all have unstable longitudinal optical phonon modes. Especially, the ferroelectric-like instability in the metal  $\text{LiOsO}_3$  is a limiting case of a hyperferroelectrics, whose optical dielectric constant goes to infinity. We further show via an effective Hamiltonian that in contrast to normal proper ferroelectricity, in which the ferroelectric instability usually comes from long range coulomb interactions, the hyperferroelectric instability is due to the structure instability driven by the short range interactions. This could happen in systems with large ion size mismatches, which therefore provides a useful guidance in searching for novel hyperferroelectrics.

**4:30PM C30.00009 Ferroelectric switching pathways in  $\text{Ca}_3\text{Ti}_2\text{O}_7$  from first principles**, ELIZABETH NOWADNICK, ANDREW MULDER, CRAIG FENNIE, Cornell University — Hybrid improper ferroelectricity, where polarization can be induced via a trilinear coupling to two non-polar order parameters (in this case octahedral rotations), has recently been experimentally demonstrated in the  $n=2$  Ruddlesden-Popper compound  $\text{Ca}_3\text{Ti}_2\text{O}_7$ . The observation of an unexpectedly low ferroelectric switching barrier and abundant structural domains suggests that these domains may be critical to the switching process. Key issues that remain to be understood include what are the specific structural properties of  $\text{Ca}_3\text{Ti}_2\text{O}_7$  that enable this low-energy switching, and how these properties could be further optimized. To address these questions, we analyze the possible ferroelectric switching pathways that can be facilitated by the presence of orthorhombic twin domains and vertical stacking faults in the  $n=2$  Ruddlesden-Popper structure of  $\text{Ca}_3\text{Ti}_2\text{O}_7$ . Utilizing first principles methods, we calculate the energy barriers of the various switching pathways and study the evolution of the octahedral rotation and polar order parameters during these switching processes. These results offer insight into what is the likely switching mechanism in  $\text{Ca}_3\text{Ti}_2\text{O}_7$ , and which order parameter is primarily responsible for controlling the energy barriers.

**4:42PM C30.00010 An efficient ab-initio approach for the anharmonic properties of structurally complex ceramics<sup>1</sup>**, LIANG-FENG HUANG, JAMES M. RONDINELLI, Department of Materials Science and Engineering, Northwestern University — In the conventional quasiharmonic method for the simulation of crystal anharmonic properties (e.g., thermal expansion and thermomechanics), the phonon spectra of about ten (or more) volumes have to be calculated, which is often computationally prohibitive for complex ceramics with large unit cells. In this work, we describe an efficient alternative method, i.e., a self-consistent quasiharmonic approximation (SC-QHA) method, where the phonon modes of only two or three volumes are necessary. At the same time, it provides a convenient framework to analyze the microscopic origins underlying the anharmonic properties. We successfully apply the SC-QHA method to the hybrid improper ferroelectric  $\text{Ca}_3\text{Ti}_2\text{O}_7$  to explain the recent experimentally measured thermal expansion data [Senn, Phys. Rev. Lett., 114, 0(2015)], and related lattice dynamical properties in an efficient manner.

**4:54PM C30.00011 Polarization Domain Switching of Improper Hybrid Ferroelectric  $(\text{Ca},\text{Sr})_3\text{Ti}_2\text{O}_7$  Crystals<sup>1</sup>**, SEONG JOON LIM, BIN GAO, JAEWOOK KIM, FEI-TING HUANG, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials, Rutgers University, Piscataway, New Jersey, 08854, RCEM TEAM — The observation of switchable polarization loops at room temperature in  $(\text{Ca},\text{Sr})_3\text{Ti}_2\text{O}_7$ , induced by improper hybrid ferroelectricity, has drawn much attention. Since the ferroelectric polarization directly couples with structural distortions (oxygen octahedral tilting and rotation) in hybrid improper ferroelectrics, the energy barrier for polarization switching is predicted to be large, and the observation of ferroelectric polarization loops was a surprise. Furthermore, the observed complexity of the domain wall configuration in  $(\text{Ca},\text{Sr})_3\text{Ti}_2\text{O}_7$  may complicate the domain wall motion or the domain nucleation for polarization switching. Thus, it is imperative to understand the mechanism and dynamics of polarization domain switching. Particularly, it has to be clarified if polarization switching occurs through  $90^\circ$  or  $180^\circ$  switching. Comparing piezoresponse force microscope and polarized optical microscope images before and after applying electric fields consecutively, we explored the mechanism and dynamics of polarization domain switching.

**5:06PM C30.00012 Conducting Ferroelectric Walls, Domain Topology, and Domain Switching Kinetics in a Hybrid Improper Ferroelectric**, SANG-WOOK CHEONG, Rutgers Univ, RUTGERS CENTER FOR EMERGENT MATERIALS TEAM<sup>1</sup> — Charged polar interfaces such as charged ferroelectric domain walls or heterostructured interfaces of  $\text{ZnO}/(\text{Zn},\text{Mg})\text{O}$  and  $\text{LaAlO}_3/\text{SrTiO}_3$ , across which the normal component of electric polarization changes suddenly, can host large two-dimensional conduction. Charged ferroelectric domain walls can be highly conducting but energetically unfavored; however, they were found to be mysteriously abundant in hybrid improper ferroelectric  $(\text{Ca},\text{Sr})_3\text{Ti}_2\text{O}_7$  single crystals. From the exploration of antiphase domain boundaries, which are hidden in piezoresponse force microscopy, using dark-field electron microscopy, we have explored the macroscopic topology of polarization domains and antiphase domains. We found that the macroscopic domain topology is directly responsible for the presence of charged domain walls, and is closely related with the polarization domain switching mechanism in  $(\text{Ca},\text{Sr})_3\text{Ti}_2\text{O}_7$ .

Paris 06, UMR CNRS 7590, MNHN, IRD UMR, BRIGITTE LERIDON, ESPCI - UPMC - CNRS — Even though ferroelectric materials are well known and widely used in many applied fields, the families of compounds exhibiting ferroelectricity are just a few. Among them,  $\text{BaTiO}_3$  and its substitution-related compounds play a major role and have been widely investigated. We present here an experimental study on a new titanium-based perovskite structure. The synthesis and structural characterization (through XRD and Raman spectroscopy) of this material will be exposed, in excellent agreement with DFT calculations. We will demonstrate possible ferroelectricity at room temperature and discuss the probable microscopic mechanisms at play in this material.

**3:06PM C31.00002 Elucidation of Chemical Reactions by Two-Dimensional Resonance Raman Spectroscopy**, ANDREW MORAN, University of North Carolina — Two-dimensional (2D) Raman spectroscopies were proposed by Mukamel and Loring in 1985 as a method for resolving line broadening mechanisms of vibrational motions in liquids. Significant technical issues challenged the development of both five- and seven-pulse 2D Raman spectroscopies. For this reason, 2D Raman experiments were largely abandoned in 2002 following the first demonstrations of 2D infrared spectroscopies (i.e., an alternate approach for obtaining similar information). We have recently shown that 2D Raman experiments conducted under electronically resonant conditions are much less susceptible to the problems encountered in the earlier 2D Raman work, which was carried out off-resonance. In effect, Franck-Condon activity obviates the problematic selection rules encountered under electronically off-resonant conditions. In this presentation, I will discuss applications of 2D resonance Raman spectroscopies to photodissociation reactions of triiodide and myoglobin. It will be shown that vibrational resonances of the reactants and products can be displayed in separate dimensions of a 2D resonance Raman spectrum when the photo-dissociation reaction is fast compared to the vibrational period. Such 2D spectra expose correlations between the nonequilibrium geometry of the reactant and the distribution of vibrational quanta in the product, thereby yielding insight in the photo-dissociation mechanism. Our results suggest that the ability of 2D resonance Raman spectroscopy to detect correlations between reactants and products will generalize to other ultrafast processes such as electron transfer and energy transfer.

**3:42PM C31.00003 Photoexcited Nuclear Dynamics with Ab Initio Electronic Structure Theory: Is TD-DFT Ready For the Challenge?** , JOSEPH SUBOTNIK, University of Pennsylvania — In this talk, I will give a broad overview of our work in nonadiabatic dynamics, i.e. the dynamics of strongly coupled nuclear-electronic motion whereby the relaxation of a photo-excited electron leads to the heating up of phonons. I will briefly discuss how to model such nuclear motion beyond mean field theory. Armed with the proper framework, I will then focus on how to calculate one flavor of electron-phonon couplings, known as derivative couplings in the chemical literature. Derivative couplings are the matrix elements that couple adiabatic electronic states within the Born-Oppenheimer treatment, and I will show that these matrix elements show spurious poles using formal (frequency-independent) time-dependent density functional theory. To correct this TD-DFT failure, a simple approximation will be proposed and evaluated. Finally, time permitting, I will show some ab initio calculations whereby one can use TD-DFT derivative couplings to study electronic relaxation through a conical intersection.

**4:18PM C31.00004 Simulations of mean ionic activity coefficients and solubilities in aqueous electrolyte solutions<sup>1</sup>** , ATHANASSIOS PANAGIOTOPOULOS, Princeton University — Aqueous electrolyte solutions play an important role in industrial, geochemical and biological applications. The mean ionic activity coefficients quantify the deviation of salt chemical potential from ideal solution behavior; experimental measurements are available for many salts over broad ranges of concentration and temperature, but there have been practically no prior simulation results, because of sampling difficulties for explicit-solvent electrolyte solutions. We have developed a new approach for determination of activity coefficients of aqueous electrolytes [1]. Common fixed-point-charge models for water and ions are unable to reproduce simultaneously activity coefficients and solubilities. Polarizable models perform better, but still predict an incorrect temperature dependence of these properties [2]. [1] Z. Mester and A. Z. **4:54PM C31.00005 Chirality-sensitive microwave spectroscopy - application to terpene molecules** , MELANIE SCHNELL, Max Planck Institute for the Structure and Dynamics of Matter — Most molecules of biochemical relevance are chiral. Even though the physical properties of two enantiomers are nearly identical, they might exhibit completely different biochemical effects, such as different odor in the case of carvone. In nature and as products of chemical syntheses, chiral molecules often exist in mixtures with other chiral molecules. The analysis of these complex mixtures to identify the molecular components, to determine which enantiomers are present, and to measure the enantiomeric excesses (ee) is still one of the challenging and very important tasks of analytical chemistry. We recently experimentally demonstrated a new method of differentiating enantiomeric pairs of chiral molecules in the gas phase. It is based on broadband rotational spectroscopy and is a three-wave mixing process that involves a closed cycle of three rotational transitions. The phase of the acquired signal bares the signature of the enantiomer, as it depends upon the product of the transition dipole moments. Furthermore, because the signal amplitude is proportional to the ee, this technique allows not only for determining which enantiomer is in excess, but also by how much. A unique advantage of our technique is that it can also be applied to mixtures of chiral molecules, even when the molecules are very similar. In my lecture, I will introduce the technique and give an update on the recent developments.

**2:30PM C32.00001 Designer Nanocrystal Materials for Photovoltaics** , CHERIE KAGAN, University of Pennsylvania — Advances in synthetic methods allow a wide range of semiconductor nanocrystals (NCs) to be tailored in size and shape and to be used as building blocks in the design of NC solids. However, the long, insulating ligands commonly employed in the synthesis of colloidal NCs inhibit strong interparticle coupling and charge transport once NCs are assembled into the solids state as NC arrays. We will describe the range of short, compact ligand chemistries we employ to exchange the long, insulating ligands used in synthesis and to increase interparticle coupling. These ligand exchange processes can have a dramatic influence on NC surface chemistry as well as NC organization in the solids, showing examples of short-range order. Synergistically, we use 1) thermal evaporation and diffusion and 2) wet-chemical methods to introduce extrinsic impurities and non-stoichiometry to passivate surface traps and dope NC solids. NC coupling and doping provide control over the density of states and the carrier type, concentration, mobility, and lifetime, which we characterize by a range of electronic and spectroscopic techniques. We will describe the importance of engineering device interfaces to design NC materials for solar photovoltaics.

**3:06PM C32.00002 Towards a Dithiocarbamate Ligand for CdS Nanoparticle-based Photocatalysis** , ANDREW O'HARA, Department of Physics and Astronomy, Vanderbilt University, ANDREW D. LACROIX, Department of Chemistry, Vanderbilt University, SOKRATES T. PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, JANET E. MACDONALD, Department of Chemistry, Vanderbilt University — Photocatalysis of water into H<sub>2</sub> and O<sub>2</sub> presents a clean, renewable route for energy storage and production. Traditionally, most semiconducting nanoparticle research on photocatalysis has focused on the ability to reduce chemical systems using the photoexcited electron. Here we employ a combination of theory and experiments to develop a possible route towards the oxidation of chemical systems via the hole from photoexcitation using an asymmetric bipyridine ligand with conjugated dithiocarbamate ligand bound to the surface of cadmium sulfide nanorods. In particular, we use density functional theory to calculate the electronic levels and optical absorption of the designer ligand, free from the cadmium sulfide surface as well as attached to the surface, with and without the copper center. These calculations are compared with experimental UV/VIS absorption and fluorescence spectroscopy measurements to understand the role of copper chelation. Furthermore, theoretical comparisons are made with a related ligand known to oxidize water under an applied potential bias. Finally, we discuss whether we expect photocatalysis from the ligand and possible improvements to its design.

**3:18PM C32.00003 Influence of Defect States on Charge Transport in CuInSe<sub>2-x</sub>S<sub>x</sub> Quantum Dot Films** , HYEONG JIN YUN, ANDREW FIDLER, JAEHOON LIM, ADDIS FUHR, JEFFREY PIETRYGA, Los Alamos National Laboratory, SAM KEENE, MATT LAW, University of California, Irvine, VICTOR KLIMOV, Los Alamos National Laboratory, CENTER FOR ADVANCED SOLAR PHOTO-PHYSICS TEAM — CuInSe<sub>2-x</sub>S<sub>x</sub> quantum dots (QDs) are environmental-friendly alternatives to Cd- or Pb-based QDs for solar energy applications. The key to using QD thin films in opto-electronic devices like solar cells is understanding their charge-transport properties, which are known to be influenced by defects that can serve as carrier traps. Here, we combine field effect transistor (FET) and ultrafast transient photocurrent (u-TPC) measurements to obtain a more complete picture of the nature and role of trap states in CuInSe<sub>2-x</sub>S<sub>x</sub> QD thin films. FET devices employing indium contacts exhibit *n*-type transport with electron mobility of 5.34 10<sup>-4</sup> cm<sup>2</sup>/Vs, but they also indicate high concentrations of electrons in the films. Early-time dynamical signatures revealed in u-TPC suggest that this high carrier density arises from the presence of trap states in CuInSe<sub>2-x</sub>S<sub>x</sub> QDs. In order to reduce the density of trap states, atomic layer deposition was used to infill the CuInSe<sub>2-x</sub>S<sub>x</sub>-based devices with amorphous alumina, which results in both higher FET mobilities, and a reduction in trap-related decay signatures in u-TPC measurements.

**3:30PM C32.00004 Probing the interface between semiconducting nanocrystals and molecular metal chalcogenide surface ligands: insights from first principles<sup>1</sup>**, EMILIO SCALISE, STEFAN WIPPERMANN, Max Planck Institute fuer Eisenforschung GmbH, GIULIA GALLI, Institute for Molecular Engineering University of Chicago, DMITRI TALAPIN, Chemistry Department University of Chicago — Colloidal nanocrystals (NCs) are emerging as cost-effective materials offering exciting prospects for solar energy conversion, light emission and electronic applications. Recent experimental advances demonstrate the synthesis of fully inorganic nanocrystal solids from chemical solution processing. The properties of the NC-solids are heavily determined by the NCs surface and their interactions with the host matrix. However, information on the atomistic structure of such composites is hard to obtain, due to the complexity of the synthesis conditions and the unavailability of robust experimental techniques to probe nanointerfaces at the microscopic level. Here we present a systematic theoretical study of the interaction between InAs and InP NCs with  $\text{Sn}_2\text{S}_6^{4-}$  ligands. Employing a grand canonical ab initio thermodynamic approach we investigate the relative stability of a multitude of configurations possibly realized at the NC-ligand interface. Our study highlights the importance of different structural details and their strong impact on the resulting composite's properties. We show that to obtain a detailed understanding of experimental data it is necessary to take into account complex interfacial structures beyond simplified NC-ligand model interfaces.

**3:42PM C32.00005 Lifetime, Mobility, and Diffusion of Photoexcited Carriers in Ligand-Exchanged PbSe Nanocrystal Films Measured by Time-Resolved Terahertz Spectroscopy<sup>1</sup>**, SIMING LI, GLENN GUGLIETTA, Drexel University, YAOTING WU, NATALIE GOGOTSI, CHRISTOPHER MURRAY, University of Pennsylvania, JASON BAXTER, Drexel University — Colloidal semiconductor nanocrystals have been used as building blocks for electronic and optoelectronic devices ranging from field effect transistors to solar cells. Properties of the nanocrystal films depend sensitively on the choice of capping ligand to replace the insulating synthesis ligands. Thus far, ligands leading to the best performance in transistors result in poor solar cell performance, and vice versa. To understand this dichotomy, we used time-resolved terahertz spectroscopy to study the mobility and lifetime of PbSe nanocrystal films with five common ligand-exchange reagents. The films treated with different displacing ligands show more than an order of magnitude difference in the peak conductivities and a bifurcation of time-dynamics. Inorganic chalcogenide ligand-exchanges with  $\text{Na}_2\text{S}$  or  $\text{NH}_4\text{SCN}$  show high mobilities but nearly complete decay of transient photocurrent in 1.4 ns. In contrast, ligand exchanges with EDA, EDT, and TBAI show lower mobilities but longer lifetimes, resulting in longer diffusion lengths. This bifurcated behavior may explain the divergent performance of field-effect transistors and photovoltaics constructed from nanocrystal building blocks with different ligand exchanges. Ref: Guglietta et al., ACS Nano, 2015.

**3:54PM C32.00006 Biexciton Dissociation Efficiency at Quantum Dot-Oxide Interfaces**, MISCHA BONN, HAI WANG, ENRIQUE CANOVAS, Max Planck for Polymer Research — Harvesting multiexcitons populating semiconductor quantum dots (generated by carrier multiplication, CM) has been proposed as a path towards higher efficiencies in photovoltaic devices. Although CM efficiency has been widely interrogated in colloidal QD solutions, less focus has been placed on the physics regarding biexciton collection at electrodes. We investigate interfacial biexciton transfer dynamics from PbS quantum dots directly nucleated onto mesoporous  $\text{SnO}_2$  films as a function of impinging photon flux and photon energy. A priori, this system seems very well-suited for achieving efficient biexciton dissociation, as the ultrafast QD-to-oxide transfer rate for 800nm excitation is substantially faster than Auger relaxation. Remarkably, the biexciton dissociation efficiency is below the detection efficiency, i.e. essentially zero. This seemingly counterintuitive result can be understood by noting that efficient hot electron transfer at the QD-oxide interface can compete with CM within the QDs. Hot electron transfer is observed to occur on sub-100 fs timescales, nulling the CM efficiency. Implications of these results for solar energy conversion are discussed.

**4:06PM C32.00007 Matrix engineering, state filling, and charge transport in PbSe quantum dot solids**, MATT LAW, University of California, Irvine — Colloidal semiconductor quantum dots (QDs) are attractive building blocks for solar photovoltaics (PV). In this talk, I will highlight our recent progress in designing PbX (X = S, Se, Te) QD thin film absorbers for next-generation PV. Basic requirements for QD absorber layers include efficient light absorption, charge separation, charge transport, and long-term stability. I begin by discussing QD film fabrication, charge transport physics, insights from theory, and evidence that the carrier diffusion length is short and limited by electronic states in the QD band gap. Studies of carrier mobility as a function of basic film parameters such as inter-QD spacing, QD size, and QD size distribution have led to a better understanding of charge transport within highly disordered QD films. Efforts to improve carrier mobility by enhancing inter-dot electronic coupling, passivating surface states, and implementing surface doping will be highlighted. Engineering the inter-QD matrix to produce QD/inorganic or QD/organic nanocomposites is presented as a powerful way to optimize coupling, remove surface states, eliminate hysteretic charge trapping and ion motion, and achieve long-term environmental stability for high-performance, robust QD films that feature good carrier multiplication efficiency. New results on the use of atomic layer deposition infilling of QD films to yield all-inorganic QD transistors free of the bias-stress effect will be presented, and the likely role of ion transport in QD optoelectronics discussed. The use of infrared transmission spectroscopy to understand state filling and study charge transport in QD thin film transistors will be presented.

**4:42PM C32.00008 "Flash" synthesis of "giant" Mn-doped CdS/ZnSe/ZnS nanocrystals with ZnSe layer as hole quantum-well**, RUILIN XU, JIAYU ZHANG, Advanced Photonics Center, Southeast University — Usually, exciton-Mn energy transfer in Mn-doped CdS/ZnS nanocrystals (NCs) can readily outcompete the exciton trapping by an order of magnitude. However, with the accumulation of non-radiative defects in the giant shell during the rapid growth of the thick shell (up to ~20 monolayers in no more than 10 minutes), the photoluminescence (PL) quantum yield of this kind of giant NCs is significantly reduced by the accumulation of non-radiative defects during the rapid growth of thick shell. That is because the exciton-Mn energy transfer in Mn-doped CdS/ZnS NCs is significantly inhibited by the hole trapping as the major competing process, resulting from the insufficient hole-confinement in CdS/ZnS NCs. Accordingly flash synthesis of giant Mn-doped CdS/ZnSe/ZnS NCs with ZnSe layer as hole quantum-well is developed to suppress the inhibition. Meanwhile  $\text{Mn}^{2+}$  PL peak changes profoundly from ~620 nm to ~540 nm after addition of ZnSe layer. Studies are under the way to explore the relevant mechanisms.

**4:54PM C32.00009 Development of an improved molecular dynamics force field for surface-adsorption simulations of molybdenum disulfide**, GARY LEUTY, National Research Council/Air Force Research Lab, RAJIV BERRY, Air Force Research Laboratory, CHRISTOPHER MURATORE, University of Dayton, VIKAS VARSHNEY, Air Force Research Laboratory, HEATH TURNER, University of Alabama — Transition metal dichalcogenides (TMDs) such as molybdenum disulfide ( $\text{MoS}_2$ ) have garnered significant interest in recent years. With a layered structure similar to graphene, TMDs also have an intrinsic band gap. This band gap makes them an attractive alternative to graphene in many applications.  $\text{MoS}_2$  in particular has received attention due to the placement and tenability of its band gap, via functionalization, mechanical manipulation or physisorption. The latter of these is of interest in biosensor devices. Such applications are dependent on understanding physisorption on the  $\text{MoS}_2$  surface at the molecular level. This can be difficult experimentally but is possible via computer simulation techniques such as molecular dynamics (MD) simulations. MD simulations, however, require a force field accurate to the process modeled. Such a force field must correctly describe non-bonded interactions between substrate layers and between the surface and adsorbates. The force fields we are aware of have focused on intra-layer covalent bonding for structural and vibrational analysis. This work seeks to develop, through DFT and MD simulations with experimental characterization of surface adsorption, a more accurate parameterization for non-bonded interactions for  $\text{MoS}_2$ .

**2:30PM C33.00001 Exploring Strategies for High Dielectric Constant and Low Loss Polymer Dielectrics<sup>1</sup>**, LEI ZHU, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, OH 44106 — Polymer dielectrics having high dielectric constant, high temperature capability, and low loss are attractive for a broad range of applications such as film capacitors, gate dielectrics, artificial muscles, and electrocaloric cooling. Unfortunately, it is generally observed that higher polarization or dielectric constant tends to cause significantly enhanced dielectric loss. It is therefore highly desired that the fundamental physics of all types of polarization and loss mechanisms be thoroughly understood for dielectric polymers. In this presentation, we intend to explore advantages and disadvantages for different types of polarization. Among a number of approaches, dipolar polarization is promising for high dielectric constant and low loss polymer dielectrics, if the dipolar relaxation peak can be pushed to above the gigahertz range. In particular, dipolar glass, paraelectric, and relaxor ferroelectric polymers are discussed for the dipolar polarization approach.

<sup>1</sup>This work is supported by NSF Polymers Program (DMR-1402733).

**2:42PM C33.00002 Energy conversion in polyelectrolyte hydrogels<sup>1</sup>**, MONICA OLVERA DE LA CRUZ, AYKUT ERBAS, Northwestern University, OLVERA DE LA CRUZ TEAM — Energy conversion and storage have been an active field of research in nanotechnology parallel to recent interests towards renewable energy. Polyelectrolyte (PE) hydrogels have attracted considerable attention in this field due to their mechanical flexibility and stimuli-responsive properties. Ideally, when a hydrogel is deformed, applied mechanical work can be converted into electrostatic, elastic and steric-interaction energies. In this talk, we discuss the results of our extensive molecular dynamics simulations of PE hydrogels. We demonstrate that, on deformation, hydrogels adjust their deformed state predominantly by altering electrostatic interactions between their charged groups rather than excluded-volume and bond energies. This is due to the hydrogel's inherent tendency to preserve electro-neutrality in its interior, in combination with correlations imposed by backbone charges. Our findings are valid for a wide range of compression ratios and ionic strengths. The electrostatic-energy alterations that we observe in our MD simulations may induce pH or redox-potential changes inside the hydrogels. The resulting energetic difference can be harvested, for instance, analogously to a Carnot engine, or facilitated for sensor applications.

**2:54PM C33.00003 Sulfone-Containing Dipolar Glass Polymers with High Dielectric Constant and Low Loss Property<sup>1</sup>**, YUFENG ZHU, ZHONGBO ZHANG, MORTON LITT, LEI ZHU, Department of Macromolecular Science and Engineering, Case Western Reserve University, Cleveland, Ohio 44106 — Sulfone-containing polyoxetanes are designed and synthesized for high dielectric constant and low loss dipolar glasses. The precursor polymer, poly(3,3-bis(chloromethyl)oxetane) (PBCMO) is synthesized by bulk cationic polymerization with boron trifluoride diethyl etherate as initiator. The number-average molecular weight of PBCMO is 73 kDa, with a polydispersity of 1.53 as obtained from size-exclusion chromatography results. Post-modification of PBCMO yields the dipolar glass polymer, poly(3,3-bis(methylsulfonylmethyl)oxetane) (MST). Nuclear magnetic resonance result shows 100% conversion. Differential scanning calorimetry result indicates that MST has a glass transition temperature of ca. 120 C. Due to the large dipole moment (4.25 D) and small size of the side-chain sulfone groups, MST exhibits a high dielectric constant of 8.7 and a low dissipation factor of 0.01 at 25 C and 1 Hz. This study suggests that dipolar glass polymers with large dipole moments and small-sized dipoles in the side chains are promising candidates for high energy density and low loss dielectric applications.

<sup>1</sup>This work is supported by NSF Polymers Program (DMR-1402733).

**3:06PM C33.00004 Generalized Ferroelectricity in the Mesomorphic Phase of Nylon Polymers**, ZHONGBO ZHANG, LEI ZHU, MORTON LITT, Case Western Reserve Univ — Novel ferroelectric polymers, featured by narrow electric displacement-electric (D-E) hysteresis loop, are attractive for electric energy storage applications due to their high dielectric constant and low loss property. Currently, only poly(vinylidene fluoride) (PVDF)-based copolymers (e-beamed) and terpolymers show novel ferroelectric behavior. It is desired to achieve novel ferroelectricity in other polymers such as nylons by carefully modifying the chemical and crystal structures. In this presentation, isomorphic crystals are successfully achieved by copolymerization of nylon 11 and nylon 12 with different compositions. In this way, both chemical and structural defects (i.e., dangling amide groups and kinked bonds) are introduced into the mesomorphic phase. As a consequence, hydrogen bonding interaction is successfully weakened and thus enhanced ferroelectricity with higher maximum polarization and better polarizability is obtained. In addition, for the purpose of further disturbing the mesomorphic phase and pinning effect, partially methylated nylon copolymers are synthesized. With the help of N-methylation of amide groups, the methylated nylon copolymers show relatively narrow hysteresis loops, suggesting the pinning effect from the N-methylated amide moieties.

**3:18PM C33.00005 Nanostructure and free volume effects in enhancing the dielectric response of strongly dipolar polymers**, RUI DONG, North Carolina State Univ, YASH THAKUR, Penn State Univ, VIVEK RANJAN, North Carolina State Univ, MARCO BUONGIORNO NARDELLI, North Texas Univ, QIMING ZHANG, Penn State Univ, JERRY BERNHOLC, North Carolina State Univ — Materials for capacitive energy storage with high energy density and low loss are desired in many fields. We perform multiscale simulations to investigate several members of the aromatic polyurea family. We find that the disordered structures with misaligned chains have considerably larger dielectric constants, due to significant increase in the free volume, which leads to easier reorientation of dipolar groups in the presence of an electric field. Large segment motion is still not allowed below the glass transition temperature, upholding the very low loss at high field and elevated temperature that we observe experimentally. Optimization of the nanostructure and free volume effects thus provides a new, very promising pathway for the design of high-performance dielectrics for capacitive energy storage.

**3:30PM C33.00006 Azobenzene Modified Polymer Electrolyte Membrane for Ion Gating<sup>1</sup>**, CAMILO PIEDRAHITA, Univ of Akron, MIREILLE MBALLA, The Pennsylvania State University, RUIXUAN HE, THEIN KYU, Univ of Akron — By virtue of ion concentration gradient across cell membranes, neuron cells are highly polarized driving electrical potential difference (e.g., Gibbs law). To regulate and control ion movement, living cells have specific channels with gates that are permeable to cations, enabling or excluding them via charge polarity and size. This mechanism for generating and transmitting signals from one neuron to another controls body movement via brain function. By virtue of trans-cis isomerization, azobenzene derivative (AZO) has been heavily sought for ion-gating in biological cells as a means of signal generation and transmission through nervous systems. In this work, PEM consisted of PEGDA/SCN/LiTFSI was modified with AZO derivatives for gating of lithium ions. At low concentrations of azobenzene of 3 wt

**3:42PM C33.00007 Molecular Dynamics Simulation of Ion Solvation in Polymer Melts: Effects of Dielectric Inhomogeneity and Chain Connectivity on Solvation Energy of Ions<sup>1</sup>**, LIJUN LIU<sup>2</sup>, ISSEI NAKAMURA, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We study the ion solvation in block copolymer melts and polymer blends using molecular dynamics simulations. In our simulations, polymers are formed through the connection of beads that provide the dielectric response. Thus, we highlight the effect of the dielectric contrast between different species on the solvation energy of ions. We demonstrate the local enrichment of higher-dielectric components near ions, which corresponds well with the result of mean-field theories. Moreover, the chain connectivity significantly affects the reorientation of molecular dipoles in response to the electrostatic field from ions. Thus, we illustrate the marked difference in the solvation energy between the block copolymer and polymer blend. Importantly, the solvation energy substantially depends on the chain length of the polymers, in stark contrast to the Born solvation energy. We also show that our simulation results exhibit striking similarity to the result of the recent self-consistent mean field theories. However, for strongly correlated dipoles and ions, our simulations provide qualitatively opposite behaviors to these results, suggesting further development of the theoretical frameworks.

**3:54PM C33.00008 A new lattice Monte Carlo method for simulating dielectric inhomogeneity<sup>1</sup>**, XIAOZHENG DUAN, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences, ZHEN-GANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology, ISSEI NAKAMURA, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We present a new lattice Monte Carlo method for simulating systems involving dielectric contrast between different species by modifying an algorithm originally proposed by Maggs et al. The original algorithm is known to generate attractive interactions between particles that have different dielectric constant than the solvent. Here we show that such attractive force is spurious, arising from incorrectly biased statistical weight caused by the particle motion during the Monte Carlo moves. We propose a new, simple algorithm to resolve this erroneous sampling. We demonstrate the application of our algorithm by simulating an uncharged polymer in a solvent with different dielectric constant. Further, we show that the electrostatic fields in ionic crystals obtained from our simulations with a relatively small simulation box correspond well with results from the analytical solution. Thus, our Monte Carlo method avoids the need for the Ewald summation in conventional simulation methods for charged systems.

**4:06PM C33.00009 Effect of Eutectic Concentration on Conductivity in PEO:LiX Based Solid Polymer Electrolytes**, PENGFEI ZHAN, LALITHA GANAPATIBHOTLA<sup>1</sup>, JANNA MARANAS, The Pennsylvania State University — Polyethylene oxide (PEO) and lithium salt based solid polymer electrolytes (SPEs) have been widely proposed as a substitution for the liquid electrolyte in Li-ion batteries. As salt concentration varies, these systems demonstrate rich phase behavior. Conductivity as a function of salt concentration has been measured for decades and various concentration dependences have been observed. A PEO:LiX mixture can have one or two conductivity maximums, while some mixtures with salt of high ionic strength will have higher conductivity as the salt concentration decrease. The factors that affect the conductivity are specific for each sample. The universal factor that affects conductivity is still not clear. In this work, we measured the conductivity of a series of PEO:LiX mixtures and statistical analysis shows conductivity is affected by the concentration difference from the eutectic concentration ( $\Delta c$ ). The correlation with  $\Delta c$  is stronger than the correlation with glass transition temperature. We believe that at the eutectic concentration, during the solidification process, unique structures can form which aid conduction.

**4:18PM C33.00010 Status of Li-polymer batteries for vehicle applications**, VENKAT SRINIVASAN, Lawrence Berkeley National Lab — Polymer-based batteries have the potential to revolutionize energy storage because of their ability to allow lithium metal anodes to be used, thereby promising higher energy densities. In addition, there have been vast strides in tuning polymers specific to battery applications, including the use of mixed conductors that provide both electronic and ionic conduction, and multifunctional polymers that serve as, for example, conductors and binders. There has been renewed interest in this topic recently, in the context of solid-state batteries. However, it is still not clear if the properties of presently available solid electrolytes are sufficient to meet the targets for electric vehicle applications. In this talk, we will present a material-to-cell level analysis of solid electrolytes to access the status of presently available materials. Continuum scale models will be used with experiments to understand the underlying processes in the battery and to project energy and power capabilities of solid-state cells based on their material properties. The models use appropriate material properties, where available, and are compared to experimental data to ensure validity. The validated model is then used to estimate the cell-level energy and power capability following the testing protocols specific to electric vehicle application. This analysis helps to identify existing challenges and provides guidelines for research at both material and cell levels for this promising class of next-generation batteries.

**4:54PM C33.00011 Pendant Dynamics of Ethylene-Oxide Containing Polymers with Diverse Backbones<sup>1</sup>**, JOSHUA BARTELS, JING-HAN HELEN WANG, QUAN CHEN, JAMES RUNT, RALPH COLBY, Penn State University — In the last twenty years, a wide variety of ion conducting polymers have used ether oxygens to facilitate ion conduction, and it is therefore important to understand the dynamics of ether oxygens (EOs) when attached to different polymer backbones. Four different EO-containing polymer architectures are studied by dielectric spectroscopy to understand the backbone effect on the EO dipoles. Polysiloxanes, polyphosphazenes, polymethylmethacrylates, and a polyester ether are compared, with different EO pendant lengths for the siloxane and methylmethacrylate backbones. The flexible polysiloxanes and polyphosphazene backbones impart superior segmental mobility with a glass transition temperature 15 K lower than that of the organic backbone polymers. Short EO pendants are found to impart a lower static dielectric constant at comparable EO content as compared to longer EO pendants of either inorganic or organic backbones. The long-pendant polymethylmethacrylate polymers show two relaxations corresponding to fast EOs near the pendant tail end and slow EOs close to the slower backbone, whereas the long-pendant polysiloxane shows a single relaxation due to the siloxane backbone relaxing faster than the EO pendant.

**5:06PM C33.00012 Understanding self-assembly of charged–neutral block copolymer (BCP) and surfactant complexes using molecular dynamics (MD) simulation<sup>1</sup>**, MONOJOY GOSWAMI<sup>2</sup>, BOBBY SUMPTER<sup>3</sup>, Oak Ridge National Laboratory, MICHAEL KILBEY<sup>4</sup>, University of Tennessee, Knoxville — Here we report the formation of phase separated BCP-surfactant complexes resulting from the electrostatic self-assembly of charge-neutral block copolymers with oppositely charged surfactants. Complexation behaviors of oppositely charged polyelectrolytes has gained considerable attention in the field of soft condensed matter physics due to their potential application as functional nanomaterials for batteries, wastewater treatment and drug delivery systems. Numerous experiments have examined the self-assembled structures resulting from complexation of charge-neutral BCP and surfactants, however, there is a lack of comprehensive understanding at the fundamental level. To help bridge this gap, we use, MD simulations to study self-assembly and dynamics of the BCP-surfactant complex at the molecular level. Our results show an overcharging effect in BCPs with hydrophobic neutral blocks and a formation of core-shell colloidal structure. Hydrophilic neutral blocks, on the other hand, show stable, hairy colloidal structures with neutral blocks forming a loosely-bound, fuzzy outer layer. Our results qualitatively agree with previous SANS and SAXS experiments.

**5:18PM C33.00013 Charge transport and structural dynamics in nanoscale confined ionic liquids: role of the dimensionality of confinement<sup>1</sup>**, JOSHUA SANGORO, MAXIMILIAN HERES, TYLER COSBY, Univ of Tennessee, Knoxville — Charge transport and structural dynamics in systematic series of low molecular weight and polymerized ionic liquids (ILs) confined in nanopores and as thin films are investigated by broadband dielectric spectroscopy. Detailed analysis of the dielectric spectra of ILs confined in unidirectional nanopores with mean diameters down to 3 nm and ultra thin polymer films with thicknesses down to 5 nm reveal that the dimensionality of confinement plays a crucial role in determining the resultant ion transport properties in confined ionic liquids. In this talk, the impact of the dimensionality of confinement on ion transport and dynamics will be discussed within the framework of current theories of charge transport and glassy dynamics.

**2:30PM C34.00001 Pattern Formation in Polymer Blend Thin Films**, NIGEL CLARKE, SAM COVENEY, University of Sheffield — We introduce a model for thin films of multicomponent fluids which includes lateral and vertical phase separation, preferential component attraction at both surfaces, and surface roughening. We apply our model to thin films of binary polymer blends, and use simulations of different surface-blend interaction regimes to investigate pattern formation. We demonstrate that surface roughening couples to phase separation. For films undergoing lateral phase separation via a transient wetting layer, this results in distinct stages of roughening as the film evolves between different phase equilibria.

**2:42PM C34.00002 Intricacies of Polymer Dewetting: Nanoscaled Architectures for the Tailored Control of Polystyrene Thin Film Stability<sup>1</sup>**, JUSTIN CHEUNG, MANI SEN, ZHIZHAO CHEN, NAISHENG JIANG, MAYA ENDOH, TADANORI KOGA, Stony Brook University, SUSHIL SATIJA, National Institute of Standards and Technology — Recently, structural properties of polymer thin films have garnered attention for their relevance in the fields of organic photovoltaics and biosensors. The dewetting of polymer films poses an obstacle in the face of widespread implementation. For this study, we show that adsorbed polymer chains on a substrate surface play crucial roles in film stability. Polystyrene (PS) thin films (20 nm in thickness) with different molecular weights (Mw) on silicon (Si) substrates were used as a model. The PS films were annealed at high temperatures for several days, and Mw dependence on film stability was evidenced. At the same time, the annealed PS films were leached with a good solvent and the residue films (i.e., irreversibly adsorbed layers) were characterized by x-ray reflectivity (XR). We reveal strong correlation between film stability and two different interfacial structures of the adsorbed polymer chains: their opposing wettability against chemically identical free polymer chains results in a wetting-dewetting transition at the adsorbed polymer-free polymer interface. This is a unique aspect of polymer thin film stability and may be generalizable to other polymer systems regardless of the magnitude of solid-polymer attractive interactions.

**2:54PM C34.00003 Two-dimensional directed polymers anchored at curved edges**, BENJAMIN LOEWE, PAUL M. GOLDBART, Georgia Institute of Technology — It is well known that the equilibrium statistical mechanics of a liquid of mutually avoiding directed polymers in two dimensions can be analyzed by means of an analogy with the imaginary-time many-body quantum mechanics of a system of particles moving in one dimension <sup>1</sup>. In this approach, the polymers have commonly been considered to be anchored to a straight-edge boundary. It has recently been shown that topological obstacles that constrain the polymer configurations, such as point-like pins, can induce voids in which the polymer density profile is heavily suppressed <sup>2</sup>. Here, we extend this approach to the study of the equilibrium statistical mechanics of liquids of mutually avoiding directed polymers that are anchored at boundaries that form closed curves, either circular or (low-eccentricity) elliptic. Specifically, we study how the curvature and eccentricity of these boundaries modifies the free energy of the system. For the case of elliptic boundaries, we show that the eccentricity alters the ground state of the quantum system, and thereby influences the structure of any constraint-induced voids in the density profile.

**3:06PM C34.00004 Role of Corners in Fracture of Polymeric Adhesives**, MARK STEVENS, Sandia Natl Labs — Understanding the molecular mechanisms of deformation and failure in structural polymer adhesives is a challenging problem. About a decade ago, we performed MD simulations on coarse-grained models of epoxies or highly crosslinked polymer networks between solid adherends finding very large failure strains in contrast to experimental data. We now have performed similar tensile simulations except with open ends between two solid adherends. The open boundary and the presence of corners dramatically alters the fracture behavior. In contrast to systems with periodic boundaries, the failure strain decreases with increasing system size. This decrease greatly reduces the difference between simulation and experiment. In the open geometry, the sides of the polymer network contract inward forming wedge shaped corners where the crack initiation occurs. The deformation of the open ends is constrained by the minimal paths in the network connecting the two adherends, but the initiation of fracture is not related to the minimal paths. The crack initiation in the corners is consistent with a diverging stress in the corners according to fracture mechanics. The local stress in the corners becomes large well before failure, but in the direction parallel to the interface due to the deformation of the corners into the wedge shape.

**3:42PM C34.00005 Confinement Effects on Polymer Morphology and Properties<sup>1</sup>**, SPIROS H. ANASTASIADIS, KIRIAKI CHRISOPOULOU, ELENA PERIVOLARI, HELLEN PAPANANOU, Foundation for Research and Technology-Hellas and Univ. of Crete, Heraklion Crete, Greece — The behavior of polymers restricted in space or to surfaces/interfaces can be very different from that in the bulk. In this work, we investigate the morphology and thermal properties of poly(ethylene oxide), PEO, in nanohybrids containing two kinds of silica nanoparticles of largely different sizes in an attempt to bridge the case of severely confined polymers within the galleries of layered silicates with that of polymer-single nanoparticle nanocomposites. Hybrids with different ratio between the two silica nanoparticles were prepared in order to increase the level of confinement. The good dispersion of the nanoparticles was verified by transmission electron microscopy whereas the morphology and crystallization behavior were investigated with X-ray diffraction, Fourier transform infrared spectroscopy, differential scanning calorimetry and polarised optical microscopy. The polymer behavior in the three component systems is found indeed intermediate between that of PEO/montmorillonite and that of PEO/silica with a single-size particles. Moreover, the behavior can be tuned by varying the ratio of the large to the small nanoparticles.

**3:54PM C34.00006 Conjugated polyelectrolyte assembly at water-oil interfaces.**, FENG LIU, CAILI HUANG, RUSSELL THOMAS, University of Massachusetts-Amherst, RUSSELL TEAM — Conjugated polyelectrolytes featured with conjugated backbone and functional side chains are interesting optoelectronic materials and widely used to modify electrodes in electronic devices such as light emitting diodes and solar cells to enhance device performance. Conjugated polyelectrolyte can be designed to have alternating hydrophilic and hydrophobic side chains, and thus inducing interesting surface and interface properties. In this work, we using polyfluorene based material, to study its behavior at water-toluene interface. The aliphatic side-chains will favorably interact with toluene, and amine side-chains will interact with water, making this material a good surfactant. At interface the polymer chain is stretched to a Janus type of geometry. Flattened molecules will assemble into ultra thin films via pi-pi intermolecular stacking, and thus creating barriers between liquids. When liquid volume is reduced, jamming at interface will show up. These properties are strongly affected by the environment of the liquids, such as temperature and PH values, and polyelectrolyte diffusion to interfaces. This study leads to new methods to structure liquids using single component, which can be extended to applications such as electro-spinning or fabricate flow devices.

**4:06PM C34.00007 Neutron reflectivity as a tool to study the interdigitation of grafted polymer chains and its dynamics.**, LILIANE LEGER, FRDRIK RESTAGNO, Laboratoire de Physique des Solides, CNRS, Univ. Paris-Sud, Universit Paris-Saclay, 91405 Orsay Cedex, France, FABRICE COUSIN, FRANOIS BOUE, Laboratoire Lon-Brillouin, CEA, CNRS, 91191 Gif-sur-Yvette CEDEX FRANCE, ALEXIS CHENNEVIERE, Laboratoire de Physique des Solides, CNRS, Univ. Paris-Sud, Universit Paris-Saclay, 91405 Orsay Cedex, France — Three series of experiments aimed at characterizing the interdigitation between a brush and a melt, and based on neutron reflectivity, are presented and discussed. The density profile of brush chains has been analysed for series of annealing times, on h-PS brushes in contact with d-PS melts, as a function of molecular weights and grafting densities. We show that the relaxation dynamics of the brush chains can be modelled taking into account the long relaxation time of end tethered chains along with the reptation of the melt chains which accelerates the arm retraction process. Using a non-grafted layer with a thickness smaller than the equilibrium size of the brush when immersed into a thick melt allows one to apply chosen degrees of confinement to the brush. We show that the interdigitation dynamics is affected by such confinements, in a way reminiscent of the change of the glass transition temperature in nanometric PS films. Finally, when the upper d-PS layer is sheared above  $T_g$ , flow with large slip at the wall has been observed and interpreted in terms of stretching and expulsion of the grafted chains from the melt. We show how neutron reflectivity directly evidence this expulsion.

**4:18PM C34.00008 Controlling Valence of DNA-Coated Emulsion Droplets with Multiple Flavors of DNA**, ANGUS MCMULLEN, DYLAN BARGTEIL, DAVID PINE, JASNA BRUJIC, New York University — We explore the control of valence of DNA-coated emulsion droplets as a first step in developing DNA-directed self-assembly of emulsions. Emulsion droplets differ from solid colloids in that they are deformable and the DNA strands attached to them are free to move along the emulsion surface. The balance of binding energy and droplet deformation provides control over a droplet's valence via its ligand density. After binding, some DNA often remains unbound due to the entropic cost of DNA recruitment. In practice, therefore, the assembly kinetics yield a distribution in valence. Our goal is to control valence by altering the binding kinetics with multiple flavors of DNA. We coat one set of droplets with two DNA types,  $A$  and  $B$ , and two other sets with one complementary strand,  $A'$  or  $B'$ . When an  $AB$  droplet binds to an  $A'$  droplet, the adhesion patch depletes  $A$  strands, leaving the rest of the droplet coated with more  $B$  than  $A$  strands. This increases the chance that the next droplet to bind will be a  $B'$  rather than an  $A'$ . Controlling valence will allow us to build a wide array of soft structures, such as emulsion polymers or networks with a determined coordination number. This work was supported by the NSF MRSEC Program (DMR-0820341).

**4:30PM C34.00009 Unraveling the dynamics of aminopolymer/silica composites**, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, MILES SAKWA-NOVAK, Georgia Institute of Technology, ADAM HOLEWINSKI, University of Colorado Boulder, MATTHEW POTTER, Georgia Institute of Technology, GERNOT ROTHER, Oak Ridge National Laboratory, CHRISTOPHER JONES, Georgia Institute of Technology, BOBBY SUMPTER, Oak Ridge National Laboratory — The structure and dynamics of a model branched polymer, representing poly(ethylenimine), was investigated through coarse-grained molecular dynamics simulations and neutron scattering experiments. The monomer concentration and solvent quality were varied in the simulations and detailed comparisons between the calculated structural and dynamical properties of the unconfined polymer and those confined within an adsorbing and non-adsorbing cylindrical pore, representing the silica based structural support of the composite, were made. The simulations show a direct relationship in the structure of the polymer and the non-monotonic dynamics of the polymers as a function of monomer concentration within an adsorbing cylindrical pore. However, the non-monotonic behavior disappears for the case of the branched polymer within a non-adsorbing cylindrical pore. Overall the simulation results are in good agreement with quasi-elastic neutron scattering (QENS) studies of branched poly(ethylenimine) in mesoporous silica (SBA-15) of comparable size, suggesting an approach that can be a useful guide for understanding how to tune porous polymer composites for enhancing desired dynamical and structural behavior targeting carbon dioxide adsorption.

**4:42PM C34.00010 A new, non-destructive, real-time measurement technique of the surface area of aerogel during synthesis**, YANG SHEN, Tongji University, Shanghai, China, JEONGSEOP A. LEE, W. P. HALPERIN, Northwestern University — We have developed a new method of measuring surface area of silica aerogel during the synthesis stage using a standard pulsed NMR setup. The applicability of this method can be extended to a much broader type of chemical reactions yielding a rigid porous condensate whose surface relaxation rate differs substantially from its surrounding liquids. The number of various chemical species involved in the reaction poses little to no limitation to its applicability owing to the physics in the fast exchange limit. This is the main distinguishing feature from a conventional NMR or infrared spectroscopy method in which individual chemical bondings from various reaction intermediaries are tracked in time which is often difficult if not impossible due to complex reactions. The result from this technique yields a surface area that is analogous to the result from a well-established BET (Brunauer-Emmett-Teller) technique, but without the need for extraction or supercritical extraction of the porous medium. This work was supported by the DOE BES under grants No. DE-FG02-05ER46248. J. Lee, *et al.*, Phys Rev B., **90**, 174501 (2014). E. Collin, *et al.*, Phys Rev B., **80**, 094422 (2009).

**4:54PM C34.00011 PEE-PEO block copolymer exchange rate between micelles is detergent and temperature activated**, ALLEN SCHANTZ, PATRICK SABOE, Penn State University, HEE-YOUNG LEE, Kumoh National Institute of Technology, IAN SINES, Saint Gobain, PAUL BUTLER, NIST Center for Neutron Research, KYLE BISHOP, JANNA MARANAS, MANISH KUMAR, Penn State University — We examine the kinetics of polymer chain exchange between polymer/detergent micelles, a system relevant to the synthesis of protein-containing biomimetic membranes. Although chain exchange between polymer aggregates in water is too slow to observe, adding detergent allows us to determine chain exchange rates using time-resolved small-angle neutron scattering (TR-SANS). We examine a membrane-protein-relevant, vesicle-forming ultra-short polymer, Poly(ethyl ethylene)20-Poly(ethylene oxide)18 (PEE20-PEO18). PEE20-PEO18 is solubilized in mixed micelles with the membrane-protein-compatible non-ionic detergent octyl- $\beta$ -D-glucoside (OG). We show that OG activates block copolymer exchange, and obtain rate constants at two detergent concentrations above the CMC (critical micellar concentration) of OG. We find that chain exchange increases two orders of magnitude when temperature increases from 308 to 338 K, and that even a 1 mg/mL increase in OG concentration leads to a noticeable increase in exchange rate. We also calculate the activation energy for chain exchange and find that it is much higher than for lipid exchange. These findings explain the need for high detergent concentration and/or temperature to synthesize densely packed polymer/protein membranes.

**5:06PM C34.00012 Electrically Responsive Soft Photonic BCP Films**, ATSUSHI NORO, MAHO OHNO, YUSHU MATSUSHITA, Nagoya University — We report electro-responsive soft photonic films composed of lamellar-forming block copolymer/nonvolatile protic solvent/metal salt. Thin films of polystyrene-*b*-poly(2-vinylpyridine) (SP,  $M_n=153k$ ,  $\phi_S=0.57$ ,  $PDI=1.18$ ) were prepared by spin-coating of the solutions on ITO glass substrates, then mixture of glycol-based solvent and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) was added to the thin films, producing soft photonic films. If needed, the spin-coated SP thin films were ionized by iodomethane before addition of the mixture of glycol-based solvent and LiTFSI. TEM observations and U-SAXS measurements revealed that these photonic films kept lamellar structures after addition of the solvent, that is, the P phase was swollen selectively with the solvent. Systematic electro-responsiveness of photonic properties of the films was also confirmed by applying voltages to the films.

**5:18PM C34.00013 Face-on and Edge-on Orientation Transition and Self-epitaxial Crystallization of All-conjugated Diblock Copolymer<sup>1</sup>**, HUA YANG, YANCHUN HAN, Chinese Academy of Sci (CAS) — The orientation transition and self-epitaxial crystallization of all-conjugated diblock copolymers poly(*p*-phenylene)-block-(3-hexylthiophene) (PPP-*b*-P3HT, BmTn) were systematically investigated by in-situ temperature-resolved two-dimensional grazing incidence X-ray diffraction (2D GIXD) in step-by-step heating and cooling process. B39T18 was selected, the results of 2D GIXD showed that the PPP block crystal adopted a face-on orientation while the crystallization of P3HT block was hindered in as-casted films. Three different molecular orientations transition were obtained in self-epitaxial crystallization circles. First, P3HT crystallize with edge-on during the heating process and induced the PPP blocks crystallized with edge-on during the cooling process. Then, the as-casted film was heated in the melting temperature region of PPP blocks and isothermally crystallized. The partial melting of PPP blocks promoted the P3HT blocks crystallize in a face-on due to the steric limitation effect, PPP blocks crystallized with a face-on via the self-epitaxy during cooling. Furthermore, the face-on transformed to thermodynamically stable edge-on in the melt annealing process.

**2:30PM C35.00001 Using a stochastic field theory to understand group behavior in microswimmer suspensions**, PATRICK UNDERHILL, YUZHOU QIAN, PETER KRAMER, Rensselaer Polytech Inst — Active suspensions of microswimmers appear both in natural biological systems (e.g. bacteria or algae) and in synthetic systems. Even without external forcing they are out of equilibrium, which gives rise to interesting properties in both small and large concentrations of the particles. These properties have been observed in experiments as well as simulation/modeling approaches. It is important to understand how hydrodynamic interactions between active swimmers cause and/or alter the suspension properties including enhanced transport and mixing. One of the most successful approaches has been a mean field theory. However, in some situations the mean field theory makes predictions that differ significantly from experiments and direct (agent or particle based) simulations. There are also some quantities that cannot be calculated by the mean field theory. In this talk, we will describe our new approach which uses a stochastic field to overcome the limitations of the mean field assumption. It allows us to calculate how interactions between organisms alter the correlations and mixing in conditions where the mean field theory cannot.

**2:42PM C35.00002 ABSTRACT WITHDRAWN —**

**2:54PM C35.00003 Geometry and mechanics of growing bacterial colonies.**, ZHIHONG YOU, DANIEL PEARCE, Univ of Leiden, ANUPAM SENGUPTA, ETH Zurich, LUCA GIOMI, Univ of Leiden — Bacterial colonies are abundant on living and non-living surfaces, and are known to mediate a broad range of processes in ecology, medicine and industry. Although extensively researched from single cells up to the population levels a comprehensive biophysical picture, highlighting the cell-to-colony dynamics, is still lacking. Here, using numerical and analytical models, we study the mechanics of self-organization leading to the colony morphology of cells growing on a substrate with free boundary. We consider hard rods to mimic the growth of rod-shaped non-motile cells, and show that the colony, as a whole, does not form an ordered nematic phase, nor does it result in a purely disordered (isotropic) phase. Instead, different sizes of domains, in which cells are highly aligned at specific orientations, are found. The distribution of the domain sizes follows an exponential relation indicating the existence of a characteristic length scale that determines the domain size relative to that of the colony. A continuum theory, based on the hydrodynamics of liquid crystals, is built to account for these phenomena, and is applied to describe the buckling transition from a planar to three-dimensional (3D) colony. The theory supports preliminary experiments conducted with different strains of rod shaped bacterial cells, and reveals that the buckling transition can be regulated by varying the cell stiffness and aspect ratio. This work proposes that, in addition to biochemical pathways, the spatio-temporal organization in microbial colonies is significantly tuned by the biomechanical and geometric properties of the microbes in consideration.

**3:06PM C35.00004 Cell-cell interactions impacts on the rate of swarm expansion and the edge shape of a colony swarming *Pseudomonas aeruginosa*** , ABOUTALEB AMIRI, University of Notre Dame, Physics Deptment, GIORDANO TIERRA, Charles University in Prague, Mathematical Institute, ZHILIANG XU, University of Notre Dame, Applied computational Mathematics and Statistics , JOSHUA SHROUT, University of Notre Dame, Department of Civil and Environmental Engineering , MARK ALBER, University of Notre Dame, Physics Department, Department of Applied Computational Mathematics and Statistics — Collective motion has been observed by several bacterial species including the pathogenic bacterium *P. aeruginosa*. A flagellum at the pole is known to generate a self-propulsion motion. However, the role of type IV pili (TFP), distributed on the cell membrane, during swarming needs to be investigated in more details. In this work we introduce a model that combines the hydrodynamic and biophysical interactions in order to study the impact of the TFP interactions on swarming behavior of the colony. The model describes the motion and interactions of rod-shaped self propelled bacteria inside a thin liquid film. It also includes the equations describing the production and diffusion of surfactant rhamnolipids that is responsible for extraction of water from substrate, and Marangoni driven expansion of the thin liquid film by altering the surface tension. We show that TFP interactions are responsible for slower expansion rate of colonies of TFP deficient mutants compared to wild type. Experimental observations were used to calibrate the model and verify the model assumptions and predictions.

**3:18PM C35.00005 The 3-D spatial structure of multicellular aggregates can give them a competition-dependent growth advantage in early biofilm development** , VERNITA GORDON, U. Texas, Austin, KASPER KRAGH, U. Copenhagen, JAIME HUTCHISON, U. Texas, Austin, GAVIN MELAUGH, U. Edinburgh, CHRIS RODESNEY, U. Texas, Austin, ALED ROBERTS, U. Nottingham, YASUHIKO IRIE, U. Bath, PETER JENSEN, U. Copenhagen, STEPHEN DIGGLE, U. Nottingham, ROSALIND ALLEN, U. Edinburgh, THOMAS BJARNSHOLT, U. Copenhagen — Biofilms are structured communities of sessile microbes. Traditional models of biofilm development begin with single bacteria seeding a surface. However, biofilms can also be seeded by multicellular aggregates. How the three-dimensional structure of aggregates impacts the initiation and development of biofilms is not known. Here we use a combination of experiments and simulations to determine the impact of the seeding structure. We find that whether aggregates or single cells grow better depends on the density of single cells initially seeded. The density of single cells, which we take as our measure of the level of competition, impacts per-cell access to growth resource. The overall biomass accumulation arising from an aggregate is a combination of slow growth in the resource-limited interior, and faster growth on the sides and top. When competition is low, aggregates are disadvantaged, compared with single cells. However, when competition is high, aggregates are fitter than single cells, because the cells at the top of the aggregates have better access to growth resources than do high-density single cells on the surface.

**3:30PM C35.00006 Mechanical signaling coordinates the embryonic heart** , KEVIN CHIOU, JASON ROCKS, Department of Physics and Astronomy, University of Pennsylvania, BENJAMIN PROSSER, Department of Physiology, Penn Muscle Institute, University of Pennsylvania Perelman School of Medicine, DENNIS DISCHER, Molecular & Cell Biophysics Lab, University of Pennsylvania, ANDREA LIU, Department of Physics and Astronomy, University of Pennsylvania — The heart is an active material which relies on robust signaling mechanisms between cells in order to produce well-timed, coordinated beats. Heart tissue is composed primarily of active heart muscle cells (cardiomyocytes) embedded in a passive extracellular matrix. During a heartbeat, cardiomyocyte contractions are coordinated across the heart to form a wavefront that propagates through the tissue to pump blood. In the adult heart, this contractile wave is coordinated via intercellular electrical signaling. Here we present theoretical and experimental evidence for mechanical coordination of embryonic heartbeats. We model cardiomyocytes as mechanically excitable Eshelby inclusions embedded in an overdamped elastic-fluid biphasic medium. For physiological parameters, this model replicates recent experimental measurements of the contractile wavefront which are not captured by electrical signaling models. We additionally challenge our model by pharmacologically blocking gap junctions, inhibiting electrical signaling between myocytes. We find that while adult hearts stop beating almost immediately after gap junctions are blocked, embryonic hearts continue beating even at significantly higher concentrations, providing strong support for a mechanical signaling mechanism.

**3:42PM C35.00007 Jamming and Localization of Interacting Run-and-Tumble Particles** , RICHARD BLYTHE, MARTIN EVANS, ALEXANDER SLOWMAN, University of Edinburgh — Certain species of bacteria, notably *Escherichia coli*, exhibit a characteristic run-and-tumble motion comprising a sequence of straight-line runs at constant velocity interspersed with tumble events that randomize the direction of motion. In a many-body setting, this nonequilibrium dynamics can generate the phenomenon of motility-induced phase separation, which is also seen for a wide variety of self-propelled particles more generally. Whilst the propensity of self-propelled particles to phase separate is understood at a mesoscopic level, the origin of this behaviour in the inelastic collisions between particles implied by the microscopic dynamics is not. Here we present exact results for run-and-tumble particles in one dimension that reveal a richly-structured stationary state that comprises a superposition of three distinct physical states whose relative weights vary with the run and tumble rates, namely a jammed state, a localized state and a delocalized state.

**3:54PM C35.00008 Wing attachment position of fruit fly minimizes flight cost** , ROBERT NOEST, JANE WANG, Cornell University — Flight is energetically costly which means insects need to find ways to reduce their energy expenditure during sustained flight. Previous work has shown that insect muscles can recover some of the energy used for producing flapping motion. Moreover the form of flapping motions are efficient for generating the required force to balance the weight. In this talk, we show that one of the morphological parameters, the wing attachment point on a fly, is suitably located to further reduce the cost for flight, while allowing the fly to be close to stable. We investigate why this is the case and attempt to find a general rule for the optimal location of the wing hinge. Our analysis is based on computations of flapping free flight together with the Floquet stability analysis of periodic flight for descending, hovering and ascending cases.

**4:06PM C35.00009 Noise regulation and symmetry breaking during vertebrate body elongation.** , THIERRY EMONET, DIPJYOTI DAS, SCOTT A. HOLLEY, Yale University — Elongation of the vertebrate body axis is driven by collective cell migration and cell proliferation at the posteriorly advancing embryonic tailbud. Within the Zebrafish tailbud an ordered stream of cells symmetrically bifurcates to form the left and right halves of the presomitic mesoderm. Maintaining bilateral symmetry during this process is critical to avoid catastrophic spine deformation. Using direct comparison between experimental data and a simple model of cell migration we identified the dynamic regulation of the noise in the direction of motion of individual cells as a critical factor in maintaining symmetric cell flow. Genetic perturbations that reduced noise led to body axis deformation whereas an increase in noise led to retarded elongation as predicted by our model.

**4:18PM C35.00010 Spontaneous Planar Chiral Symmetry Breaking in Cells** , JEREMY HADIDJOJO, DAVID LUBENSKY, Univ of Michigan - Ann Arbor — Recent progress in animal development has highlighted the central role played by planar cell polarity (PCP) in epithelial tissue morphogenesis. Through PCP, cells have the ability to collectively polarize in the plane of the epithelium by localizing morphogenetic proteins along a certain axis. This allows direction-dependent modulation of tissue mechanical properties that can translate into the formation of complex, non-rotationally invariant shapes. Recent experimental observations<sup>[1]</sup> show that cells, in addition to being planar-polarized, can also spontaneously develop planar chirality, perhaps in the effort of making yet more complex shapes that are reflection non-invariant. In this talk we will present our work in characterizing general mechanisms that can lead to spontaneous chiral symmetry breaking in cells. We decompose interfacial concentration of polarity proteins in a hexagonal cell packing into irreducible representations. We find that in the case of polar concentration distributions, a chiral state can only be reached from a secondary instability after the cells are polarized. However in the case of nematic distributions, we show that a finite-amplitude (subcritical, or “first-order”) nematic transition can send the system from disorder directly to a chiral state. In addition, we find that perturbing the system by stretching the hexagonal packing enables direct (supercritical, or “second-order”) chiral transition in the nematic case. Finally, we do a Landau expansion to study competition between stretch-induced chirality and the tendency towards a non-chiral state in packings that have retained the full 6-fold symmetry. [1] K. Taniguchi *et al.*, Science (2011)

**4:30PM C35.00011 Epithelial Proliferation on Curved Toroidal Surfaces.** , YA-WEN CHANG, RICARDO CRUZ, ALEXANDROS FRAGKOPOULOS, Georgia Institute of Technology, SAMANTHA MARQUEZ, Yale University, ANDRES GARCIA, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Cellular environment influences a multitude of cellular functions by providing chemical and physical signals that modulate cell behavior, dynamics, development, and eventually survival. In strongly interacting epithelial cells, cells coordinate their behavior to respond to mechanical constraints in 2D. Local differences in tissue tension has also been shown to impact cell reproduction within an epithelial-cell sheet. Much less is known about how cells respond to out-of-plane curvatures. Here, we describe the proliferation of MDCK on toroidal hydrogel substrates, which unlike spheres or planes, have regions of both positive and negative Gaussian curvature. Additionally, the range of curvatures can be controlled by varying the size and aspect ratio of the torus, allowing us to quantify the relation between substrate curvature and cell proliferation.

**4:42PM C35.00012 Brownian microswimmer in a Poiseuille Flow** , LEONARDO APAZA-PILCO, Universidad Mayor de San Andres, MARIO SANDOVAL, Metropolitan Autonomous University — We study the two and three dimensional dynamics of a microswimmer at low-Reynolds-number in a Poiseuille flow and subject to thermal fluctuations. A deterministic analysis is also performed, and we find that under certain conditions the swimmer becomes hydrodynamically trapped thus performing periodic orbits. We provide an analytical expression where this trapping occur. A numerical solution for the coupled system of stochastic differential equations based on two parameters, the Peclet number and the ratio of the swimming velocity and the flow velocity, is also obtained. Based on this parameter space, it is found that the mean-square displacement (MSD) along the longitudinal axis (flow direction) is always quadratic in time, whereas along the transversal direction the mean-square displacement achieves a constant value due to the presence of physical boundaries. A comparison among the 2D and 3D MSD results are also discussed. Finally, the effect of the Poiseuille flow on the angular probability distribution for the two-dimensional motion is also computationally shown.

**4:54PM C35.00013 Synthetic electrophysiology: optically controlled oscillators in an engineered bioelectric tissue** , HAROLD MCNAMARA, HONGKANG ZHANG, CHRISTOPHER WERLEY, Harvard University, ADAM COHEN, Harvard University and HHMI — Multicellular electrical dynamics underlie crucial physiological functions, but the complexity of natural bioelectricity can obscure the relation of individual components (proteins, cells) to emergent system-level dynamics. Here we introduce optopatch-spiking HEK(OS-HEK) tissue, a minimal synthetic bioelectric tissue with 4 transgenic components that supports optical initiation of propagating electrical waves as well direct optical voltage readout. In conjunction with a home-built inverted microscope capable of patterned illumination, we use this tissue to probe the biophysical attributes of this excitable bioelectric medium, including dispersion relations, curvature-dependent wavefront propagation, electrotonic coupling, and effects of boundaries. We then used chemical patterning to define cellular circuits that support controllable oscillations and which retain memory for more than 2 hours (corresponding to  $10^4$  oscillations), constituting a substrate for binary bioelectric data storage. Finally, we use optical patterning of boundary conditions in a physically homogeneous tissue to design dynamically reconfigurable oscillators.

Session C36 GSOFT DPOLY: Soft Colloids: From Single Particle Properties to Bulk Phase Behavior and Dynamics 339 - Alberto Fernandez-Nieves, Georgia Institute of Technology

**2:30PM C36.00001 Superresolution Microscopy of the Volume Phase Transition of pNIPAM Microgels** , GAURASUNDAR MARC CONLEY, University of Fribourg, SOFI NJD, Lund University, MARCO BRAIBANTI, University of Fribourg, PETER SCHURTENBERGER, Lund University, FRANK SCHEFFOLD, University of Fribourg — Hierarchical polymer structures such as pNIPAM microgels have been extensively studied for their ability to undergo significant structural and physical transformations that can be controlled by external stimuli such as temperature, pH or solvent composition. Here we discuss in-situ three-dimensional superresolution microscopy of dye-labeled submicron sized PNIPAM microgels [1]. We use direct Stochastic Optical Reconstruction Microscopy (dSTORM) to study the internal density distribution and the particle-to-particle variability of the volume phase transition. Moreover we discuss the potential of this technique towards future applications to more complex architectures for example microgel with anisotropic shape or ones that are doped or decorated with nanoparticles. [1] G. M. Conley, S. Nojd, M. Braibanti, P. Schurtenberger, and F. Scheffold, submitted.

**2:42PM C36.00002 Swelling of Superabsorbent Poly(Sodium-Acrylate Acrylamide) Hydrogels and Influence of Chemical Structure on Internally Cured Mortar** , MATTHEW J. KRAFCIK, KENDRA A. ERK, Purdue University School of Materials Engineering — Superabsorbent hydrogel particles show promise as internal curing agents for high performance concrete (HPC). These gels can absorb and release large volumes of water and offer a solution to the problem of self-desiccation in HPC. However, the gels are sensitive to ions naturally present in concrete. This research connects swelling behavior with gel-ion interactions to optimize hydrogel performance for internal curing, reducing the chance of early-age cracking and increasing the durability of HPC. Four different hydrogels of poly(sodium-acrylate acrylamide) are synthesized and characterized with swelling tests in different salt solutions. Depending on solution pH, ionic character, and gel composition, different swelling behaviors are observed. As weight percent of acrylic acid increases, gels demonstrate higher swelling ratios in reverse osmosis water, but showed substantially decreased swelling when aqueous cations are present. Additionally, in multivalent cation solutions, overshoot peaks are present, whereby the gels have a peak swelling ratio but then deswell. Multivalent cations interact with deprotonated carboxylic acid groups, constricting the gel and expelling water. Mortar containing hydrogels showed reduced autogenous shrinkage and increased relative humidity.

**2:54PM C36.00003 Dynamics and filtration of microgel suspensions** , GERHARD NAEGELE, RAFAEL ROA, JONAS RIEST, Institute of Complex Systems, ICS-3, Forschungszentrum Juelich GmbH, 52425 Juelich, Germany — Microgel suspensions exhibit interesting transport properties determined by direct and hydrodynamic interactions. Using an annulus model to account for solvent permeability, we calculate the diffusion function and sedimentation coefficient of PNIPAM microgel suspensions, in excellent agreement with experimental results [1]. Moreover, an extension of our precise analytic methods to long-time properties including viscosity and self-diffusion coefficient is presented, with results compared to simulation and experimental data. The predicted transport properties are an important ingredient to the modeling of convective-diffusive transport in membrane ultrafiltration of permeable particles. The efficiency of the separation process depends on hydrodynamic boundary conditions, membrane properties and particle interactions. We calculate the concentration polarization layer and permeate flux at different operating conditions for cross-flow ultrafiltration of non-ionic [2] and ionic [3] microgels. Small microgel permeability already affects the filtration significantly [2].

### 3:06PM C36.00004 Soft particles with anisotropic interactions<sup>1</sup>, PETER SCHURTENBERGER, Lund University

— Responsive colloids such as thermo- or pH-sensitive microgels are ideal model systems to investigate the relationship between the nature of interparticle interactions and the plethora of self-assembled structures that can form in colloidal suspensions. They allow for a variation of the form, strength and range of the interaction potential almost at will. While microgels have extensively been used as model systems to investigate various condensed matter problems such as glass formation, jamming or crystallization, they can also be used to study systems with anisotropic interactions. Here we show results from a systematic investigation of the influence of softness and anisotropy on the structural and dynamic properties of strongly interacting suspensions. We focus first on ionic microgels.<sup>2 3</sup> Due to their large number of internal counterions they possess very large polarisabilities, and we can thus use external electrical ac fields to generate large dipolar contributions to the interparticle interaction potential. This leads to a number of new crystal phases, and we can trigger crystal-crystal phase transitions through the appropriate choice of the field strength.<sup>4 5</sup> We then show that this approach can be extended to more complex particle shapes<sup>6</sup> in an attempt to copy nature's well documented success in fabricating complex nanostructures such as virus shells via self assembly.<sup>8</sup>

### 3:42PM C36.00005 Glass transition and jamming in soft microgel suspensions: Relationship between alpha relaxation times and elastic energy scales

, JOHN HYATT, Georgia Inst of Tech, XIAOBO HU, University of North Carolina, L. ANDREW LYON, Chapman University, ALBERTO FERNANDEZ-NIEVES, Georgia Inst of Tech — Glassy and jammed states of soft colloidal matter combine several open questions — how are glassy and jammed states differentiated from one another and from equilibrium states of dense suspensions, and how should particle “softness” be quantified? We combine light scattering and rheological measurements of well-characterized soft microgel particles at various packing fractions and degrees of swelling to answer these questions. We identify several regimes of liquid, supercooled, glassy, and jammed behavior that correlate with an increasing elastic energy scale due to interparticle interactions. When this energy scale increases above  $k_B T$ , the entropically-driven glassy state gives way to a jammed state dominated by elastic interactions.

### 3:54PM C36.00006 Swelling, Compressibility, and Phase Behavior of Soft Ionic Microgels<sup>1</sup>

ALAN DENTON, Dept. of Physics, North Dakota State University — Soft colloids have inspired great attention recently for their rich and tunable materials properties. Particular interest has focused on microgels — microscopic cross-linked polymer gel particles that, when dispersed in water, become swollen and can acquire charge through dissociation of counterions. Electrostatic interparticle interactions strongly influence the structure and thermodynamics of ionic microgel suspensions\*. Permeability to solvent molecules and small ions creates a competition between elastic and electrostatic forces that determines equilibrium particle sizes. Swelling can be controlled by adjusting temperature, pH, and salt concentration, with applications to chemical/biosensing and targeted drug delivery. By combining molecular dynamics and Monte Carlo simulation with Poisson-Boltzmann theory of electrostatics and Flory-Rehner theory of swollen polymer networks, we investigate swelling and compressibility of ionic microgel particles and implications for thermodynamic phase behavior of bulk suspensions at concentrations approaching and exceeding hard-sphere close packing. Predictions for particle size and osmotic pressure are compared with available experimental data.

### 4:06PM C36.00007 Structure and Hydration of Highly Branched, Monodisperse Phytoglycogen Nanoparticles

, JOHN ATKINSON, University of Guelph, JONATHAN NICKELS, CHRISTOPHER STANLEY, SOULEYMANE DIALLO, JOHN KATSARAS, Oak Ridge National Laboratory, JOHN DUTCHER, University of Guelph — Monodisperse phytoglycogen nanoparticles are a promising, new soft colloidal nanomaterial with many applications in the personal care, food, nutraceutical and pharmaceutical industries. These applications rely on exceptional properties that emerge from the highly branched structure of phytoglycogen and its interaction with water, such as extraordinarily high water retention, and low viscosity and exceptional stability in water. The structure and hydration of the nanoparticles was characterized using small angle neutron scattering (SANS) and quasielastic neutron scattering (QENS). SANS allowed us to determine the size of the nanoparticles, evaluate their radial density profile, quantify the particle-to-particle spacing, and determine their water content. The results show clearly that the nanoparticles are highly hydrated, with each nanoparticle containing 250% of its mass in water, and that aqueous dispersions approach a jamming transition at  $\sim 25\%$  (w/w). QENS experiments provided an independent and consistent measure of the high level of hydration of the particles.

### 4:18PM C36.00008 High Deformability and Particle Size Distribution of Monodisperse Phytoglycogen Nanoparticles Revealed By Atomic Force Microscopy Imaging

, BENJAMIN BAYLIS, JOHN DUTCHER, University of Guelph — We have used atomic force microscopy (AFM) imaging in water to determine the volume of hydrated monodisperse phytoglycogen nanoparticles adsorbed onto mica surfaces. By significantly reducing the interaction between the AFM tip and the “sticky” nanoparticles, we were able to obtain high quality images. We found that the adsorbed particles are highly deformed, forming pancake-like objects on the hydrophilic mica surface. By measuring the distribution of particle volumes, we calculated the average effective spherical radius of the hydrated particles, and compared this value with that measured in solution using small angle neutron scattering. These measurements illustrate the distinct advantages of AFM imaging over other imaging techniques, namely the ability to measure the height of objects in a liquid environment.

### 4:30PM C36.00009 Rheology of Dilute Aqueous Dispersions of Monodisperse Phytoglycogen Nanoparticles

, HURMIZ SHAMANA, JOHN DUTCHER, University of Guelph — The viscosity of dilute colloidal dispersions is well described by the Einstein relation, which is linear in the volume fraction of the particles. For hard spheres, this allows the calculation of the specific volume of the spheres [1]. For soft colloidal particles, the analysis of the data can be complicated by the uptake of the solvent by the particles. We have measured the concentration dependence of the zero shear viscosity of dilute aqueous dispersions of monodisperse phytoglycogen nanoparticles, which absorb a large amount of water (each nanoparticle contains about 250% of its mass in water). By using values of the particle size and the hydrated and dehydrated molecular weights determined using neutron scattering, we can interpret the measured viscosity-concentration data in terms of the Einstein relation to obtain the particle density and corresponding volume fraction of the dispersions. [1] J.C. van der Werff et al., Phys. Rev. A 39, 795 (1989).

**4:42PM C36.00010 Ligand-Driven Phase Separation in Binary Particle Brush Materials<sup>1</sup>**, MICHAEL BOCKSTALLER, MICHAEL SCHMITT, JIANAN ZHANG, JIAJUN YAN, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon University — The tethering of polymer chains to the surface of nanoparticles (to form so-called 'particle brush materials') has emerged as an effective means to enable the bottom-up assembly of one-component hybrid materials with controlled microstructure and improved mechanical stability as well as novel optical or acoustic properties. The polymer-like interactions and response of these particle-brush materials suggest intriguing new opportunities to control structure formation in multicomponent particle mixtures. This contribution will demonstrate that polymer-ligand interactions can drive phase separation processes in mixed particle systems that share analogies to those of regular binary polymer blends. The role of particle size, density and degree of polymerization of tethered chains as well as the interaction parameter between the distinct tethered chains on the mechanism and kinetics of phase separation processes in mixed particle brush systems will be discussed. Ligand-driven phase separation will be shown to enable the efficient fabrication of monochromatic domain structured in mixed quantum dot systems that might find application in next generation quantum dot-enabled LEDs.

**4:54PM C36.00011 Colloidal models for anisotropic particles**, MARTIN GIRARD, MONICA OLVERA DE LA CRUZ, Northwestern Univ — Nanoparticles (NP) self-assembly is often thought as an equivalent to crystallization of atoms, where NP pairs exhibits effective potentials similar to atomic interactions. For the usual spherical NPs, this potential is only dependent on the distance between the particles due to symmetry. Use of anisotropic NPs provide an analog to atomic orbitals, leading to anisotropic effective potentials, which can be used to obtain new crystal lattices.

We express the effective potential of anisotropic NPs as the overlap between two functions, each of which is only dependent on the position and orientation of a single particle. Using a Fourier method, this contribution is expended into spherical harmonics and directly calculated in molecular dynamics simulations, reminiscent of energy calculations in quantum mechanics.

Using the effective potential of two spherical DNA-grafted NPs, we show an approximate method to obtain the Fourier components of an anisotropic shape, as well as the resulting simulations.

**5:06PM C36.00012 Mesoscale simulation of asphaltene aggregation<sup>1</sup>**, JIANG WANG, ANDREW FERGUSON, University of Illinois Urbana-Champaign — Asphaltenes constitute a heavy aromatic crude oil fraction that can aggregate and precipitate out of solution. Association is thought to proceed hierarchically according to the Yen-Mullins model, but the molecular mechanisms and pathways remain poorly understood. In this study, we perform molecular dynamics simulations of the aggregation of hundreds of asphaltenes over microseconds using the coarse-grained Martini force field. We identified a hierarchical self-assembly mechanism consistent with Yen-Mullins model, but the details of which are strongly dependent on asphaltene molecular structure. Monomeric asphaltenes first self-assemble into 1-D rod-like nanoaggregates, followed by the formation of clusters of nanoaggregates. At high concentrations, asphaltenes with short aliphatic side chains assemble into a percolating network with the binding of 1-D rods. Conversely, molecules with more and longer side chains cannot efficiently stack, producing a fractal network of 1-D rods suspended in a sea of interpenetrating aliphatic side chains. Our results provide the first molecularly-detailed validation of the full Yen-Mullins hierarchy, and are in good agreement with recent computational and experimental studies.

**5:18PM C36.00013 Optical Characterization of Temperature- and Composition-Dependent Microstructure in Asphalt Binders**, ADAM RAMM, Department of Physics, The University of Texas at Austin, SAKIB NAZMUS, AMIT BHASIN, Department of Civil Engineering, The University of Texas at Austin, MICHAEL DOWNER, Department of Physics, The University of Texas at Austin — We introduce noncontact optical microscopy and optical scattering to characterize asphalt binder microstructure at temperatures ranging from 15 to 85°C for two compositionally different asphalt binders. We benchmark optical measurements against rheometric measurements of the magnitude of the temperature-dependent bulk complex shear modulus  $|G^*(T)|$ . The main findings are: (1) Elongated ( $5 \times 1 \mu\text{m}$ ), striped microstructures (known from AFM studies as "bees" because they resemble bumble-bees) are resolved optically, found to reside primarily at the surface, and do not reappear immediately after a single heating-cooling cycle. (2) Smaller ( $1 \mu\text{m}^2$ ) microstructures with no observable internal structure (hereafter dubbed ants), are found to reside primarily in the bulk, to persist after multiple thermal cycles and to scatter light strongly. Optical scattering from "ants" decreases to zero with heating from 15 to 65°C, but recovers completely upon cooling back to 15°C, albeit with distinct hysteresis. (3) Rheometric measurements of  $|G^*(T)|$  reveal hysteresis that closely resembles that observed by optical scatter, suggesting that thermally-driven changes in microstructure volume fraction cause corresponding changes in  $|G^*(T)|$ .

**2:30PM C37.00001 Condensation on Slippery Asymmetric Bumps**, KYOO-CHUL PARK, Harvard University, PHILSEOK KIM, SLIPS Technologies, Inc., JOANNA AIZENBERG, Harvard University — Controlling dropwise condensation by designing surfaces that enable droplets to grow rapidly and be shed as quickly as possible is fundamental to water harvesting systems, thermal power generation, distillation towers, etc. However, cutting-edge approaches based on micro/nanoscale textures suffer from intrinsic trade-offs that make it difficult to optimize both growth and transport at once. Here we present a conceptually different design approach based on principles derived from Namib desert beetles, cacti, and pitcher plants that synergistically couples both aspects of condensation and outperforms other synthetic surfaces. Inspired by an unconventional interpretation of the role of the beetle's bump geometry in promoting condensation, we show how to maximize vapor diffusion flux at the apex of convex millimetric bumps by optimizing curvature and shape. Integrating this apex geometry with a widening slope analogous to cactus spines couples rapid drop growth with fast directional transport, by creating a free energy profile that drives the drop down the slope. This coupling is further enhanced by a slippery, pitcher plant-inspired coating that facilitates feedback between coalescence-driven growth and capillary-driven motion. We further observe an unprecedented six-fold higher exponent in growth rate and much faster shedding time compared to other surfaces. We envision that our fundamental understanding and rational design strategy can be applied to a wide range of phase change applications.

**2:42PM C37.00002 Long-lived Multifunctional Superhydrophobic Heterostructure via Molecular Self-supply**, YONGFENG HUANG, SHENG MENG, Institute of Physics, Chinese Academy of Sciences, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM — Superhydrophobic (SHO) surfaces with a large contact angle ( $\geq 150^\circ$ ) and low sliding angle ( $< 10^\circ$ ) are highly desirable in both fundamental science and myriad applications. Current approaches to fabricate such surfaces require calcinating at high temperatures, tedious and time-consuming treatments, toxic chemicals, and/or processing with intricate instruments. Long-duration SHO surfaces are even more challenging due to easy contamination by organic pollutants in dry conditions. To overcome these difficulties we design a simple approach via self-supplying of low surface tension chemicals to nanoparticles to fabricate multifunctional SHO heterostructures. Our method features room temperature, rapid processing, with environment-friendly raw materials. With multiple functions such as photocatalysis and transparency SHO surfaces extend their lifetime and enable self-sustaining environment maintenance.

**2:54PM C37.00003 Biphilic Surfaces for Enhanced Water Collection from Humid Air<sup>1</sup>**, JASON BENKOSKI, KONSTANTINOS GERASOPOULOS, WILLIAM LUEDEMAN, Johns Hopkins University APL — Surface wettability plays an important role in water recovery, distillation, dehumidification, and heat transfer. The efficiency of each process depends on the rate of droplet nucleation, droplet growth, and mass transfer. Unfortunately, hydrophilic surfaces are good at nucleation but poor at shedding. Hydrophobic surfaces are the reverse. Many plants and animals overcome this tradeoff through biphilic surfaces with patterned wettability. For example, the *Stenocara* beetle uses hydrophilic patches on a superhydrophobic background to collect fog from air. Cribellate spiders similarly collect fog on their webs through periodic spindle-knot structures. In this study, we investigate the effects of wettability patterns on the rate of water collection from humid air. The steady state rate of water collection per unit area is measured as a function of undercooling, angle of inclination, water contact angle, hydrophilic patch size, patch spacing, area fraction, and patch height relative to the hydrophobic background. We then model each pattern by comparing the potential and kinetic energy of a droplet as it rolls downwards at a fixed angle. The results indicate that the design rules for collecting fog differ from those for condensation from humid air.

**3:06PM C37.00004 Transition dynamics from macro- to micro-phase separation in asymmetric lipid bilayers<sup>1</sup>**, SHUNSUKE SHIMOBAYASHI, MASATOSHI ICHIKAWA, Department of Physics, Kyoto University, TAKASHI TANIGUCHI, Department of Chemical Engineering, Kyoto University — In general, phase separation in binary liquid mixtures completes by relaxation below the transition temperature. The coarsening dynamics to complete phase separation have been extensively investigated in binary mixture systems. In contrast, the reverse dynamics from macro- to micro-phase separation remains poorly understood because no appropriate experiments and models exist for investigating this phenomenon. In this talk, we present the direct observations of morphological transitions from macro- to micro-phase separation using micrometer-sized asymmetric lipid vesicles exposed to externally added glycolipids (GM1:monosialotetrahexosylganglioside). The transition occurs via stripe morphology as a metastable state. During the transition, monodisperse micro domains emerge through repeated scission events of the stripe domains. Moreover, we numerically confirmed the transitions by the time-dependent Ginzburg-Landau model, which describes phase separation and bending elastic membrane. Numerical results suggest crucial roles of the local spontaneous curvature induced by the local asymmetric lipid composition.

**3:18PM C37.00005 Bio-inspired design of geometrically interlocked 3D printed joints.<sup>1</sup>**, S KUMAR<sup>2</sup>, NOEL OLIVA<sup>3</sup>, Masdar Institute, Abu Dhabi, KUMAR'S LAB TEAM — The morphology of the adhesive-adherend interface significantly affects the mechanical behavior of adhesive joints. As seen in some biocomposites like human skull, or the nacre of some bivalve molluscs' shells, a geometrically interlocking architecture of interfaces creates toughening and strengthening mechanisms enhancing the mechanical properties of the joint. In an attempt to characterize this mechanical interlocking mechanism, this study is focused on computational and experimental investigation of a single-lap joint with a very simple geometrically interlocked interface design in which both adherends have a square waveform configuration of the joining surfaces. This square waveform configuration contains a positive and a negative rectangular teeth per cycle in such a way that the joint is symmetric about the mid-bondlength. Both physical tests performed on 3D printed prototypes of joints and computational results indicate that the joints with square waveform design have higher strength and damage tolerance than those of joints with flat interface. In order to identify an optimal design configuration of this interface, a systematic parametric study is conducted by varying the geometric and material properties of the non-flat interface.

**3:30PM C37.00006 Multiobjective topology optimization of trabecular Bone Structure in the spine and the femur: Implications for biomimicry<sup>1</sup>**, AHMED ELBANNA, DARIN PEETZ, University of Illinois Urbana Champaign — Bone is classically considered to be a self-optimizing structure in accordance with Wolff's law. However, while the structure's ability to adapt to changing stress patterns has been well documented, whether it is fully optimal for compliance is less certain (Sigmund, 2002). Given the complexity of many biological systems, it is expected that this structure serves several purposes. We present a multi-objective topology optimization formulation for trabecular bone in the human body at two locations: the vertebrae and the femur. We account for the effect of different conflicting objectives such as maximization of stiffness, maximization of surface area, and minimization of buckling susceptibility. Our formulation enables us to determine the relative role of each of these objective in optimizing the structure. Moreover, it provides an opportunity to explore what structural features have to evolve to meet a certain objective requirements that may have been absent otherwise. For example, inclusion of stability considerations introduce numerous horizontal and diagonal members in the topology in the case of human vertebrae under vertical loading. However, the stability is found to play a lesser role in the case of the femur bone optimization. Our formulation enables investigation of bone adaptation at different locations of the body as well as under different loading and boundary conditions (e.g. healthy and diseased discs for the case of the spine). We discuss the implications of our findings on developing design rules for bio-inspired and bio-mimetic architected materials.

**3:42PM C37.00007 Dynamics of spider glue adhesion: effect of surface energy and contact area**, GAURAV AMARPURI, YIZHOU CHEN, TODD BLACKLEDGE, ALI DHINOJWALA, University of Akron — Spider glue is a unique biological adhesive which is humidity responsive such that the adhesion continues to increase upto 100% relative humidity (RH) for some species. This is unlike synthetic adhesives that significantly drop in adhesion with an increase in humidity. However, most of adhesion data reported in literature have used clean hydrophilic glass substrate, unlike the hydrophobic, and charged insect cuticle surface that adheres to spider glue in nature. Previously, we have reported that the spider glue viscosity changes over five orders of magnitude with humidity. Here, we vary the surface energy and surface charge of the substrate to test the change in *Larinioides cornutus* spider glue adhesion with humidity. We find that an increase in both surface energy and surface charge density increases the droplet spreading and there exists an optimum droplet contact area where adhesion is maximized. Moreover, spider glue droplets act as reusable adhesive for low energy hydrophobic surface at the optimum humidity. These results explain why certain prey are caught more efficiently by spiders in their habitat. The mechanism by which spider species tune its glue adhesion for local prey capture can inspire new generation smart adhesives.

**3:54PM C37.00008 Understanding Cell Shape Phenotypes Associated with Stem Cell Differentiation Induced by Topographical Cues of Nanofiber Microenvironment.** , DESU CHEN, University of Maryland, SUMONA SARKAR, National Institute of Standards and Technology, WOLFGANG LOSERT, University of Maryland — It is increasingly important to understand cell responses to bioinspired material structures and topographies designed to guide cell functional alterations. In this study, we investigated association between early stage cell morphological response and osteogenic differentiation of human bone marrow stromal cells (hBMSCs) induced by poly( $\epsilon$ -caprolactone) (PCL) nanofiber scaffolds (PCL-NF). Accounting for both multi-parametric complexity and biological heterogeneity, we developed an analysis framework based on support vector machines and a multi-cell level averaging method (supercell) to determine the most pronounced cell shape features describing shape phenotypes of cells in PCL-NF compared to cells on flat PCL films. We found that smaller size and more dendritic shape were the major morphological responses of hBMSCs to PCL-NF on day 1 of cell culture. Further, we investigated the shape phenotypes of hBMSCs in PCL-NF of different fiber densities to monitor the transition between 2-D and 3-D topographies. We tracked the genotypic, phenotypic and morphological responses of hBMSCs to different fiber densities at multiple time points to identify correlations between hBMSCs differentiation and early stage morphology in PCL-NF scaffolds.

**4:06PM C37.00009 Exploring elasticity and energy dissipation in mussel-inspired hydrogel transient networks** , SCOTT GRINDY, ROBERT LEARSCH, NIELS HOLTEN-ANDERSEN, Massachusetts Inst of Tech-MIT — Dynamic, reversible crosslinks have been shown to specifically control the mechanical properties of a wide variety of mechanically tough and resilient biomaterials. We have shown that reversible histidine-metal ion interactions, known to contribute to the strong mechanical properties and self-healing nature of mussel byssal threads, can be used to control and engineer the temporally-hierarchical mechanical properties of model hydrogels orthogonally from the spatial structure of the material. Here, we explore the scaling relationships in our model networks to further inform our abilities to control the relative elasticity and energy dissipation on hierarchical timescales. Scaling arguments suggest that the elasticity is dominated by long-range entanglements, while the dissipation is controlled by the exchange kinetics of the transient crosslinks. Further, we show that by using UV light, we can further control the viscoelastic properties of our mussel-inspired hydrogels *in situ*. This process opens the door for creating biocompatible hydrogel materials with arbitrary spatial control over their viscoelastic mechanical properties. Overall, we show that by understanding the interplay between bio-inspired dynamic crosslinks and soft matter physics allows us to rationally design high-strength hydrogels for specific states of dynamic loading.

**4:18PM C37.00010 Toughening elastomers using mussel-inspired catechol-metal coordination complexes** , EMMANOUELA FILIPPIDI, THOMAS CHRISTIANI, MEGAN VALENTINE, J. HERBERT WAITE, JACOB ISRAELACHVILI, KOLLBE AHN, Univesity of California, Santa Barbara — Amorphous, covalently-linked elastomers possess excellent reversible extensibility and high failure strain compared to other materials. However, by nature, the large deformability compromises the Young's modulus and the toughness of the elastomer to low values ( $\sim$  2MPa) and imparts brittle fracture. We employ the mussel-inspired strategy of iron-catechol coordination bonding creating dynamic, reversible cross-links in addition to permanent chemical cross-links in an elastomer used in ambient, dry conditions. This simple additional energy dissipative mechanism results in increased modulus and toughness without affecting the network extensibility, which is based on the covalent network. Control of the chain relaxation time scales can be further tuned using the dynamic bonds, imparting mechanical rate dependent properties to the bulk material. The quantitative understanding of the time scales associated with the chain motion versus the metal coordination may provide another simple and independent control parameter in elastomeric material design.

**4:30PM C37.00011 Bacterial Flagella as a Model Rigid Rod of Tunable Shape** , WALTER SCHWENGER, Brandeis Univ, SEVIM YARDIMCI, The Francis Crick Institute, THOMAS GIBAUD, Ecole Normale Supérieure de Lyon, HENRY SNOW, Brandeis Univ, JEFF URBACH, Georgetown University, ZVONIMIR DOGIC, Brandeis Univ — In this research, we study the physical properties of suspensions of bacterial flagella from *Salmonella typhimurium* prepared in a variety of rigid polymorphic shapes. Flagella act as a rigid colloidal particle that can exhibit non-trivial geometry including helices of varying dimensions, straight rods, or a combination of the two in the same filament. By controlling the conditions in which flagella are prepared, the polymorphic shape assumed by the filament can be controlled. Utilizing different polymorphic shapes, we combine results from optical microscopy observations of single filaments with bulk rheological measurements to help understand the role that constituent colloidal geometry plays in complex bulk behavior.

**4:42PM C37.00012 Bio-Inspired Micromechanical Directional Acoustic Sensor<sup>1</sup>** , WILLIAM SWAN, Naval Postgraduate School, FABIO ALVES, Alion Science and Technology, GAMANI KARUNASIRI, Naval Postgraduate School — Conventional directional sound sensors employ an array of spatially separated microphones and the direction is determined using arrival times and amplitudes. In nature, insects such as the *Ormia ochracea* fly can determine the direction of sound using a hearing organ much smaller than the wavelength of sound it detects. The fly's eardrums are mechanically coupled, only separated by about 1 mm, and have remarkable directional sensitivity. A micromechanical sensor based on the fly's hearing system was designed and fabricated on a silicon on insulator (SOI) substrate using MEMS technology. The sensor consists of two 1 mm<sup>2</sup> wings connected using a bridge and to the substrate using two torsional legs. The dimensions of the sensor and material stiffness determine the frequency response of the sensor. The vibration of the wings in response to incident sound at the bending resonance was measured using a laser vibrometer and found to be about 1  $\mu$ m/Pa. The electronic response of the sensor to sound was measured using integrated comb finger capacitors and found to be about 25 V/Pa. The fabricated sensors showed good directional sensitivity. In this talk, the design, fabrication and characteristics of the directional sound sensor will be described.

**4:54PM C37.00013 Design of Catch-and-release System by Utilizing Thermo-responsive Gel-Hairpin Composites.** , YA LIU, University of Pittsburgh, OLGA KUKSENOK, clemson university, XIMIN HE, Arizona State University , ANNA BALAZS, University of Pittsburgh — Inspired by properties of aptamers that can bind (unbind) to target proteins in their specific hairpin (chain) conformation dependent on external temperature, we use computational modeling to design an effective catch-and-release device by attaching an array of thermo-responsive hairpins to the lower critical solution temperature (LCST) thermo-responsive gels. With an increase in temperature, the polymer network swells and the hairpins can catch the target nanoparticles in the upper mixture fluid. As the temperature decreases, the polymer network collapses and the hairpins unfold to a chain conformation, releasing the arrested particles into the lower fluid for collection. We pinpoint the optimal values for obtaining the robust structural changes of the hairpins and explore the effects of the shear flow on the catch-and-release process. Our approach can be utilized for the detection, separation, and sorting of the components within the multi-component mixtures.

**5:06PM C37.00014 TUNABLE ALLOSTERIC BEHAVIOR IN RANDOM SPRING NETWORKS** , JASON W. ROCKS, Dept. of Physcs and Astronomy, University of Pennsylvania, NIDHI PASHINE, IRMGARD BISCHOFBERGER, Dept. of Physics, University of Chicago, CARL P. GOODRICH, School of Engineering and Applied Sciences, Harvard University, SIDNEY R. NAGEL, Dept. of Physics, University of Chicago, ANDREA J. LIU, Dept. of Physcs and Astronomy, University of Pennsylvania — Many proteins and other macromolecules exhibit allosteric behavior in which the binding of a ligand to one site affects the activity at a second distant site. Inspired by this biological process, we present an algorithm to tune disordered spring networks to exhibit allostery-like behavior. When the positions of a pair of nodes at one site in a network are perturbed, we can precisely tune the response of nodes located at another distant site in the system by removing only a small fraction of the bonds. This algorithm can be used to create a wide variety of different response types: response nodes can be located far away from each other, a large number of response sites can be simultaneously controlled, and even multiple independent responses can be tuned into the system. In addition, this algorithm can be generalized to account for bond bending, geometric nonlinearities and nonlinear bond potentials. However, even linear calculations match surprisingly well with macroscopic experimental realizations made by laser cutting or 3D printing.

**5:18PM C37.00015 Mechanisms of branching reactions in melanin formation – Ab initio quantum engineering approach** —, RYO KISHIDA, Department of Applied Physics, Osaka University, SUSAN MEÑEZ ASPERA, HIDEAKI KASAI, National Institute of Technology, Akashi College — Melanin, a pigment found in animals, consists of two types of oligomeric unit: eumelanin and pheomelanin. The color of the skin, the hair, and the eyes is controlled by the ratio of eumelanin/pheomelanin production. Especially, dopachrome and dopaquinone are the precursor molecules of melanin which directly affect the composition of melanin through their branching reactions. Dopachrome is converted into two possible monomers of eumelanin. Dopaquinone can undergo both eumelanin and pheomelanin synthesis. To understand the mechanisms and controlling factors that govern the conversions, reactions of the two molecules are investigated using density functional theory-based first-principles calculations. Our results deepen mechanistic understanding of the reactions and open possibilities to design properties and functions of melanin. In this talk, we will discuss about the competitions of the branching reactions.

**2:30PM C38.00001 Self-assembly of Iron Oxide Nanoparticles on Liquid Surfaces by Using Miscible Solvent Pairs**, JIAYANG HU, DATONG ZHANG, KATHLEEN M. KENNEDY, IRVING P. HERMAN, Columbia University — Nanoparticle (NP) self-assembly on liquid-air interfaces by using immiscible solvent pairs is a fast and effective way to prepare two-dimensional (2D) close-packed superlattices. However, this technique is limited by the number of available solvent pairs that are immiscible with each other while being different in the dispersity of NPs. Here, we report forming 2D superlattices using toluene/dimethyl sulfoxide miscible solvent pairs. In-situ small angle X-ray scattering patterns from NP layers sitting on the meniscus agree with patterns expected from 2D tilted closed packed superlattices. Real time optical microscopy shows that after drop casting, most of NPs coagulate immediately and sink to the bottom over several days, but leave a continuous ML on the surface, without forming 3D clusters that are usually seen in the immiscible techniques generated by the coffee ring effect. TEM images show that NPs nucleate simultaneously on different parts on the liquid surface until they touch, therefore covering the whole surface.

**2:42PM C38.00002 The effects of surfactant dynamics on deposition patterns in evaporating colloidal drops**<sup>1</sup>, NARINA JUNG, HAEWON SEO, Mechanical and Nuclear Engineering, UNIST, PILWON KIM, Mathematical Science, UNIST, CHUN SANG YOO, Mechanical and Nuclear Engineering, UNIST — Evaporation of a colloidal droplet typically leaves ring-like deposit patterns on a substrate, now well-known as the coffee ring effect. We investigate the effect of surfactant dynamics on the deposition process in a drying droplet. A coarse grained model has been developed to simulate cases with Marangoni stresses, adsorption kinetics, and intermolecular interaction of surfactant particles and to examine the related deposit formation of colloidal particles. By using the two-dimensional lattice for the lateral cross-section of a droplet, we are able to capture the full dynamics of recirculating flows with surfactant and colloidal particles during drying. The roles of surfactant on droplet and colloidal particle dynamics are investigated by systematically varying parameters, such as the maximum area fraction and the initial concentration of surfactant. We further highlight important factors to generate Marangoni eddies.

**2:54PM C38.00003 Non-equilibrium colloidal assembly pathways via synergistic dipolar, depletion, and hydrodynamic interactions**, ANNA COUGHLAN, MICHAEL BEVAN, Johns Hopkins University — The ability to assemble nano- and micro- colloidal particles into ordered materials and controllable devices provides the basis for emerging technologies. However, current capabilities for manipulating colloidal assembly are limited by the degree of order, time to generate/reconfigure structures, and scalability to large areas. These limitations are due to problems with designing, controlling, and optimizing the thermodynamics and kinetics of colloidal assembly. Our approach is to provide viable non-equilibrium pathways for rapid assembly of defect free colloidal crystals using combinations of magnetic field and depletion mediated assembly. Results include video microscopy experiments and Stokesian Dynamic computer simulations of superparamagnetic colloidal particles experiencing depletion attraction in time varying magnetic fields. Findings show multi-body hydrodynamic interactions and magnetic dipole relaxation mechanisms are essential to capture assembly and annealing of attractive colloidal crystals. With the ability to measure, model and tune colloidal interactions and dynamics, we demonstrate the use of time varying fields to manipulate non-equilibrium pathways for the assembly, disassembly, and repair of colloidal microstructures.

**3:06PM C38.00004 Criterion for noise-induced synchronization: application to colloidal alignment**<sup>1</sup>, JONAH EATON, New York University, THOMAS A WITTEN, BRIAN MOTHS, University of Chicago — Asymmetric, self-assembled colloidal clusters can rotate stably as they descend under gravity. One may synchronize a dispersion of copies of such a cluster using a force that randomly switches between two different directions[1]. This is an instance of “noise-induced synchronization,” demonstrated broadly in dynamical systems that have a stable, periodic motion[2]. When such a system is perturbed by a prescribed transient force, it acquires a phase angle  $\psi$  that depends on its initial phase  $\phi$ . For our colloidal dispersion the probability distribution of phases  $\psi$  long after a switch in forcing is in general not uniform; thus the entropy  $H$  of the ensemble has decreased. The phase map  $\psi(\phi)$  provides strong constraints on the change  $\Delta H$  resulting from a switch: we show that the quantity  $\langle \log |d\psi/d\phi| \rangle$  is an upper bound on  $\langle \Delta H \rangle$ . Thus whenever  $\langle \log |d\psi/d\phi| \rangle < 0$ ,  $H$  must decrease indefinitely on average. Our simulations show that this average is a good guide to the actual synchronization behavior. This bound and other properties of  $\Delta H$  apply broadly to any dynamical system with a well-defined  $\psi(\phi)$ . [1] B. Moths, T. Witten. Phys Rev Lett, **110** 028301 (2013). [2] H. Nakao et al. Phys Rev E, **72** 026220 (2005).

**3:18PM C38.00005 Characterization of hyperuniformity in colloidal suspensions through small angle static light scattering.**, COLINE BRETZ, Compass (Solvay-CNRS-University of Pennsylvania), TIM STILL, University of Pennsylvania, DENIS BARTOLO, ENS Lyon, JEAN BAUDRY, ESPCI-CNRS, ARJUN YODH, University of Pennsylvania, REMI DREYFUS, Compass (Solvay-CNRS-University of Pennsylvania) — Hyperuniform materials have attracted increasing interest over the past decade due to their potential exciting photonic properties. Our work aims at exploring novel ways of assembling hyperuniform materials from colloidal suspensions. Three-dimensional systems of micrometer-sized colloids are considered and characterized by studying their structure factor using static small angle light scattering (SLS). A SLS set-up has been constructed for this purpose. Using an index-matched suspension of colloidal particles, we are able to record the structure factors of suspensions of micrometer-sized colloids in a three-dimensional cell. We will show how our apparatus allows us to follow the spatial organization of the colloids and characterize their hyperuniformity.

**3:30PM C38.00006 Nanoparticle interactions in electrolyte solutions: A classical density functional theory and molecular dynamics study**, K. MICHAEL SALERNO, AMALIE L. FRISCHKNECHT, MARK STEVENS, Sandia National Laboratories — We know that multivalent ions can dramatically alter the interactions between macroions, and we are interested in the fundamentals of nanoparticle interactions. We performed molecular dynamics (MD) simulations at the primitive model level and classical fluids density functional theory (DFT) calculations of negatively charged interacting nanoparticles, 2 - 7 nm in diameter, in solution with 1:1, 1:2, or 1:3 salt. We found qualitative agreement between the MD simulations and DFT calculations for the ion density profiles around the nanoparticles and for the interaction free energy between two nanoparticles. As expected, the nanoparticle interaction free energies depend strongly on the cation valence, with pure repulsion for a 1:1 salt, changing to attraction for multivalent cations due to formation of charge ordered structures. Attractive free energy depths can reach 10 kT for 7 nm diameter nanoparticles, indicating that kinetic arrest and aggregation may occur. The interaction free energies depend non-monotonically on the nanoparticle charge due to layering of the counterions around the nanoparticles for large nanoparticle charges.

**3:42PM C38.00007 Self-Assembly of DNA-coated colloids<sup>1</sup>**, DAVID PINE, New York Univ NYU — DNA-coated particles have emerged as a powerful tool for programming the self-assembly of colloids and nanoparticles. The power of this approach lies in the highly specific molecular recognition properties of DNA and in the thermal reversibility of the interactions between DNA strands attached to different particles. These two properties taken together can, in principle, direct the bottom-up self-assembly of different materials into almost any desired structure. Here we discuss the self-assembly of single and multi-component crystals of DNA-coated colloids.

**4:18PM C38.00008 Hierarchical assembly of anisotropic particles in AC electric fields.**, ISAAC TORRES DIAZ, BRADLEY RUPP, XIAOQING HUA, YUGUANG YANG, MICHAEL A. BEVAN, Johns Hopkins University — Hierarchical microstructures composed of colloids are of great interest for technological applications and advanced materials such as metamaterials and microfluidic devices. The dynamics of spherical colloidal particles has been analyzed previously for several systems, and has led to the control of the formation of perfect crystals using AC electric fields. However, spherical particles do not have a dependence on its orientation as anisotropic particles. Recently, researchers reported experiments showing the capabilities of anisotropic particles to assemble in different configurations, yet a detailed understanding of the mechanism and control is lacking. This work shows both theoretical and experimental results of the control of a colloidal system composed of anisotropic colloidal particles with a tri-axial ellipsoidal shape subjected to a non-uniform electric field close to a planar wall. We show that particles pack into different structures and orientations as a function of the applied electric field amplitude and frequency by taking into account dipole-field, dipole-dipole, and colloidal interactions. This analysis provides a theoretical framework for the equilibrium and non-equilibrium structures that can be formed via field mediated interaction, which are validated by experimental microscopy results, and can ultimately be used to engineer the hierarchical assembly of anisotropic particles.

**4:30PM C38.00009 Quantitative Characterization of Surface Self-Assembly Imaging Using Shapelets<sup>1</sup>**, NASSER MOHIEDDIN ABUKHDEIR, ROBERT SUDERMAN, University of Waterloo, DANIEL J. LIZOTTE, University of Western Ontario — Microscopy and imaging of surface self-assembly phenomena have advanced significantly over the past decade. In order to determine structure/property relationships robust automated analysis of the resulting images is required, but has not advanced at an equally rapid pace. Recently, quantitative characterization techniques have been developed and applied, such as using bond-orientational order (BOO) theory. BOO-based methods have significant limitations in that they do not provide pixel-level resolution and are not robust in the presence of measurement noise. In this work, a fundamentally different method for automated quantitative characterization of surface self-assembly imaging is presented which uses a family of localized functions called "shapelets". The method is presented and applied to quantitative characterization of stripe and hexagonal patterns which are frequently observed in surface self-assembly. The shapelet-based method is shown to be general, highly accurate, and robust in the presence of measurement noise. It is able to efficiently determine local pattern characteristics such as pattern strength and orientation for the determination of structure/property relationships.

**4:42PM C38.00010 Micro-evaporators: a powerful tool to control the growth of dense organized colloidal materials<sup>1</sup>**, CELINE BUREL, CNRS/Solvay/UPenn, JACQUES LENG, LOF, UMR 5258 Solvay-CNRS-Bordeaux 1, BERTRAND DONNIO, REMI DREYFUS, CNRS-Solvay-UPenn, JEAN-BAPTISTE SALMON, LOF, UMR 5258 Solvay-CNRS-Bordeaux 1 — Latex colloids have been concentrated inside a microfluidic channel, referred to as a microevaporator, in a controlled way up to the formation of millimeter-long colloidal materials. The solvent of this colloidal dispersion is transported by pervaporation through a thin PDMS membrane sealing the channel, inducing a flow from the reservoir containing the dispersion, up to the tip of the channel. Thus, as pervaporation occurs, colloids get concentrated at the tip of the channel up to the growth of a packed bed of colloids. The frontier between the dilute dispersion and the concentrated jammed or crystalline phase is clearly delimited by a concentration front. The position of the latter was recorded by using direct videomicroscopy. We investigated the dynamics of growth of such concentrated materials by measuring the position of the concentration front as a function of time. From these data we also estimated the volume fraction of the colloids within the concentrated material using mass conservation. We found that the estimated values are much smaller than the expected volume fractions for a dense colloidal assembly. We finally propose some explanations for such a discrepancy.

**4:54PM C38.00011 Prediction of Binary Nanoparticle Superlattices from Soft Potentials<sup>1</sup>**, NATHAN HORST, Department of Materials Science and Engineering, Iowa State University, ALEX TRAVESSET, Department of Physics and Astronomy, Iowa State University — Driven by the hypothesis that a sufficiently continuous short-ranged potential is able to account for shell flexibility and phonon modes and therefore provides a more realistic description of nanoparticle interactions than a hard sphere model, we compute the solid phase diagram of particles of different radii interacting with an inverse power law potential. We explore 24 candidate lattices where the p-exponent, determining the short-range properties of the potential, is varied between p=12 and p=6, and optimize the free energy with respect to additional internal parameters. The phase diagrams contain the phases found in ongoing self-assembly experiments, including DNA programmable self-assembly and nanoparticles with capping ligands assembled by evaporation from an organic solvent. The resulting phase diagrams can be mapped quantitatively to existing experiments as a function of only two parameters: nanoparticle radius ratio ( $\gamma$ ) and softness asymmetry (SA).

**5:06PM C38.00012 Meniscus height controlled convective self-assembly<sup>1</sup>**, SATYAN CHOUDHARY, ALFRED CROSBY, University of Massachusetts Amherst — Convective self-assembly techniques based on the coffee-ring effect allow for the fabrication of materials with structural hierarchy and multi-functionality across a wide range of length scales. The coffee-ring effect describes deposition of non-volatiles at the edge of droplet due to capillary flow and pattern formations due to pinning and de-pinning of meniscus with the solvent evaporation. We demonstrate a novel convective self-assembly method which uses a piezo-actuated bending motion for driving the de-pinning step. In this method, a dilute solution of nanoparticles or polymers is trapped by capillary forces between a blade and substrate. As the blade oscillates with a fixed frequency and amplitude and the substrate translates at a fixed velocity, the height of the capillary meniscus oscillates. The meniscus height controls the contact angle of three phase contact line and at a critical angle de-pinning occurs. The combination of convective flux and continuously changing contact angle drives the assembly of the solute and subsequent de-pinning step, providing a direct means for producing linear assemblies. We demonstrate a new method for convective self-assembly at an accelerated rate when compared to other techniques, with control over deposit dimensions.

**5:18PM C38.00013 Strain-Temperature-Transformation (STT) Diagram for Soft Solids**, SHOUBO LI, WENTAO XIONG, XIAORONG WANG, Chemical Engineering, Tongji University, Shanghai — Soft materials comprise a variety of physical states that are easily deformed by shear stains or thermal fluctuations. They include suspensions, colloids, polymers, foams, gels, liquid crystals, and a number of biological materials. In this contribution, a generalized strain-temperature-transformation (STT) diagram for many soft materials is presented in which the physical states encountered are related to the strain and temperature changes. The boundary defined for the solid-to-liquid transformation in the STT diagram displays a surprising Z-shaped curve. We discuss this feature with respect to the physical nature of materials.

**2:30PM C39.00001 Stabilization of EphA2 dimers as a novel anti-cancer strategy**, DEO SINGH, FOZIA AHMED, MATT SALLOTO, KALINA HRISTOVA, Johns Hopkins University — We have recently shown that EphA2 receptors exist in a monomer-dimer equilibrium in the absence of ligand. The monomers promote tumorigenic activity and thus a therapeutic strategy that minimizes the monomer population may be beneficial in the clinic. The YSA peptide is an EphA2-targeting peptide that effectively delivers anticancer agents to cancer tumors. The quantitative measurements of the dimerization of EphA2 receptors in the presence of these peptides using quantitative spectral Forster resonance transfer (QS-FRET) methodology in conjunction with two-photon microscopy that has been developed recently in our lab suggests that this peptide stabilizes the EphA2 dimers. Thus, such peptides that stabilize the EphA2 dimers may be used for the treatment of some cancers that overexpress EphA2.

**2:42PM C39.00002 Criticality and Cancer Dormancy**, AMY WU, NIST, DAVID LIAO, UC San Francisco, VLADIMIR KIRLIN, CORINA TAMITA, SIMON LEVIN, JAMES STURM, ROBERT AUSTIN, Princeton University — The presence of driver mutations and subsequent clonal expansion by Darwinian evolution does not explain dormancy and re-emergence of cancer from a community of cancer and stromal cells. Dormancy appears to be a collective property of multiple cell communities including non-cancerous cells. At the simplest level, we view cancer cells interacting with stromal cells via complex, non-linear population dynamics, dynamics which can lead to very non-intuitive but perhaps deterministic and understandable progression dynamics of cancer. We explore here the dynamics of stromal-cancer cell populations in the presence of a chemotherapy drug gradient to determine to what extent the time-dependence of the populations can be quantitatively understood in spite of the underlying complexity of the individual agents. The surprising result is that a basic understanding, in a quantitative and predictive manner, can be achieved. It will be intriguing to move to predictive drug dosages, the population dynamics presented here provide a model system for the clinic.

## 2:54PM C39.00003 ABSTRACT WITHDRAWN –

**3:06PM C39.00004 Development as a Factor in the Evolution of Modularity in Biological Systems**, JESSICA LOWELL, Brandeis University — Biological networks and other systems tend to be modular in structure, with reuse of motifs and the ability to be separated into semi-independent units. The evolutionary forces that produce this modularity are a topic of active research, as modular solutions rarely emerge from models of biological evolution. Through simulations combining evolution and development, I investigate the role that development plays in the emergence of modularity, using a popular metric for network modularity and representing non-network structures as networks in which building blocks are nodes and connections between them are arcs. Preliminary results show that the modularities of structures evolved by an L-systems-based evolutionary developmental algorithm are higher than those evolved by a non-developmental evolutionary algorithm that models evolution in the same way. To ensure that these results are not specific to a single algorithm, I am conducting evolutionary developmental simulations using other methods for simulating development, evolving both networks and building-block structures. This study sheds light on the role of development as a factor in the origin of modularity in biological networks and other biological systems.

**3:18PM C39.00005 Mechanoregulatory tumor-stroma crosstalk in pancreatic cancer: Measurements of the effects of extracellular matrix mechanics on tumor growth behavior, and vice-versa, to inform therapeutics<sup>1</sup>**, JONATHAN CELLI, DUSTIN JONES, HAMID EL-HAMIDI, GWENDOLYN CRAMER, WILLIAM HANNA, ANDREW CAIDE, SEYEDEHROJIN JAFARI, University of Massachusetts Boston — The rheological properties of the extracellular matrix (ECM) have been shown to play key roles in regulating tumor growth behavior through mechanotransduction pathways. The role of the mechanical microenvironment may be particularly important tumors of the pancreas, noted for an abundance of rigid fibrotic stroma, implicated in therapeutic resistance. At the same time, cancer cells and their stromal partners (e.g. tumor associated fibroblasts) continually alter the mechanical microenvironment in response to extracellular physical and biochemical cues as part of a two-way mechanoregulatory dialog. Here, we describe experimental studies using 3D pancreatic cell cultures with customized mechanical properties, combined with optical microrheology to provide insight into tumor-driven matrix remodeling. Quantitative microscopy provides measurements of phenotypic changes accompanying systematic variation of ECM composition in collagen and laminin-rich basement membrane admixtures, while analysis of the trajectories of passive tracer particles embedded in ECM report dynamic changes in heterogeneity, microstructure and local shear modulus accompanying both ECM stiffening (fibrosis) processes, and ECM degradation near invading cells.

### 3:30PM C39.00006 Exploring Kupffer's Vescicle Through Self Propelled Particle Simulations

, KASSIDY LUNDY, Syracuse Univ, AGNIK DASGUPTA, JEFF AMACK, SUNY Upstate Medical University, M. LISA MANNING, Syracuse Univ — Early development is an important stage in the formation of functional, relatively healthy organisms. In zebrafish embryos, a transient organ in the tailbud called Kupffer's Vescicle (KV) is responsible for the initial left-right (L-R) asymmetry that results in asymmetric organ and tissue placement in the adult zebrafish. Originating as a collection of symmetrically organized monociliated cells, the KV experiences a shift in cell shapes over time that leaves more cells on the anterior or top side of the KV. This arrangement helps to generate a stronger counter-clockwise fluid flow across the anterior side of the organ, which is required for L-R asymmetry. In seeking to understand the source of the shape changes occurring within the KV, we simulate a Self Propelled Particle (SPP) model that includes parameters for cell polarization and speed. We model the KV as a large particle moving in a straight line with constant velocity to mimic the physical forces of the notochord acting on this organ, and we model the surrounding tailbud cells as smaller, slower active particles with an orientation that changes over time due to rotational noise. Our goal is to calculate the forces exerted on the KV by the surrounding tissue, to see if they are sufficient to explain the shape changes we observe in the KV that lead to L-R asymmetry.

### 3:42PM C39.00007 Systems-level analysis of the regulation and function of p53 dynamics in cancer.

, ERIC BATCHELOR, Natl Inst of Health - NIH — Living cells use complex signaling pathways to detect environmental stimuli and generate appropriate responses. As methods for quantifying intracellular signaling have improved, several signaling pathways have been found to transmit information using signals that pulse in time. The transcription factor p53 is a key tumor suppressor and stress-response regulator that exhibits pulsatile dynamics. In response to DNA double-strand breaks, the concentration of p53 in the cell nucleus increases in pulses with a fixed amplitude, duration, and period; the mean number of pulses increases with DNA damage. p53 regulates the expression of over 100 target genes involved in a range of cellular stress responses including apoptosis, cell cycle arrest, and changes in metabolism. p53 pulsing directly impacts p53 function: altering p53 dynamics by pharmacologically inhibiting p53 degradation changes patterns of target gene expression and cell fate. While p53 pulsing serves an important signaling function, it is less clear what it accomplishes mechanistically. Here we will describe our recent efforts to determine the impact of p53 pulsing on the dynamics and coordination of target gene expression.

### 4:18PM C39.00008 Cell-Substrate Adhesion by Amoeboid Cells<sup>1</sup>

, BRET FLANDERS, KRISHNA PANTA, Kansas State University — Amoeboid migration is a rapid ( $10 \mu\text{m min}^{-1}$ ) mode of migration that some tumor cells exhibit. To permit such rapid movement, the adhesive contacts between the cell and the substrate must be relatively short-lived and weak. In this study, we investigate the basic adhesive character of amoeboid cells (*D. discoideum*) in contact with silanized glass substrates. We observe the initiation and spreading of the adhesive contacts that these cells establish as they settle under gravity onto the substrate and relax towards mechanical equilibrium. The use of interference reflection microscopy and cellular tethering measurements have allowed us to determine the basic adhesive properties of the cell: the membrane-medium interfacial energy; the bending modulus; the equilibrium contact angle; and the work of adhesion. We find the time scale on which settling occurs to be longer than expected. Implications of these results on adhesion and migration will be discussed.

<sup>1</sup>The authors are grateful for support from NSF (CBET-1451903) and NIH (1R21EY026392).

### 4:30PM C39.00009 Fragmentation of cancer cells<sup>1</sup>

, SIVA VANAPALLI, NABIOLLAH KAMYABI, Texas Tech University — Tumor cells have to travel through blood capillaries to be able to metastasize and colonize in distant organs. Among the numerous cells that are shed by the primary tumor, very few survive in circulation. In vivo studies have shown that tumor cells can undergo breakup at microcapillary junctions affecting their survival. It is currently unclear what hydrodynamic and biomechanical factors contribute to fragmentation and moreover how different are the breakup dynamics of highly and weakly metastatic cells. In this study, we use microfluidics to investigate flow-induced breakup of prostate and breast cancer cells. We observe several different modes of breakup of cancer cells, which have striking similarities with breakup of viscous drops. We quantify the breakup time and find that highly metastatic cancer cells take longer to breakup than lowly metastatic cells suggesting that tumor cells may dynamically modify their deformability to avoid fragmentation. We also identify the role that cytoskeleton and membrane plays in the breakup process. Our study highlights the important role that tumor cell fragmentation plays in cancer metastasis.

### 4:42PM C39.00010 Blood based cell biopsy for early detection of cancer<sup>1</sup>

, CHA-MEI TANG, DANIEL ADAMS, Creatv MicroTech, Inc., DIANE ADAMS, Rutgers, the State Univrsity of New Jersey, R. KATHERINE ALPAUGH, Fox Chase Cancer Center, MASSIMO CRISTOFANILLI, Northwestern University, STUART MARTIN, University of Maryland School of Medicine, SARANYA CHUMSRI, Mayo Clinic Cancer Center, Jacksonville, JEFFREY MARKS, Duke University Medical Center — Early detection (ED) of cancer holds the promise for less aggressive treatments and better outcome. However, there are few accepted methods for ED. We report on a previously unknown blood cell found specifically in the peripheral blood of many solid tumors. They are defined as Cancer Associated Macrophage-Like cells (CAMLs) and are characterized by large size ( $25\text{-}300 \mu\text{m}$ ) and expression of cancer markers. CAMLs were isolated on precision filters during blood filtration. We conducted prospective studies in breast cancer (BC) to ascertain CAML prevalence, specificity and sensitivity in relation to disease status at clinical presentation. We report on two related but separate studies: 1) the isolation of CAMLs from patients with known invasive BC, compared to healthy volunteers and, 2) a double blind study conducted on women undergoing core needle biopsy to evaluate suspicious breast masses. The studies show that CAMLs are found in all stages of BC and suggest that detection of CAMLs can differentiate patients with BC from those with benign breast conditions and healthy individuals. This non-invasive blood test can be potentially used for ED of BC and other malignancies after validation studies with the advantage of a minimally invasive procedure and longitudinal monitoring.

**5:06PM C39.00012 Electron holes appear to trigger cancer-implicated mutations.**<sup>1</sup>, JOHN MILLER, MARTHA VILLAGRAN, University of Houston, Dept. of Physics & Texas Ctr. for Superconductivity — Malignant tumors are caused by mutations, which also affect their subsequent growth and evolution. We use a novel approach, computational DNA hole spectroscopy [M.Y. Suarez-Villagran & J.H. Miller, *Sci. Rep.* **5**, 13571 (2015)], to compute spectra of enhanced hole probability based on actual sequence data. A hole is a mobile site of positive charge created when an electron is removed, for example by radiation or contact with a mutagenic agent. Peaks in the hole spectrum depict sites where holes tend to localize and potentially trigger a base pair mismatch during replication. Our studies of reveal a correlation between hole spectrum peaks and spikes in human mutation frequencies. Importantly, we also find that hole peak positions that do *not* coincide with large variant frequencies often coincide with cancer-implicated mutations and/or (for coding DNA) encoded conserved amino acids. This enables combining hole spectra with variant data to identify critical base pairs and potential cancer 'driver' mutations. Such integration of DNA hole and variance spectra could also prove invaluable for pinpointing critical regions, and sites of driver mutations, in the vast non-protein-coding genome.

**5:18PM C39.00013 Tumorigenesis and Greenhouse-Effect System Dynamics: Phenomenally Diverse, but Noumenally Similar?**, SAI PRAKASH, Johns Hopkins University — We present a physicochemical model of tumorigenesis leading to cancer invasion and metastasis. The continuum-theoretic model, congruent with recent experiments, analyzes the plausibility of oncogenic neoplasia-induced cavitation or tensile yielding (plasticity) of the tumoral basement membrane (BM) to activate stromal invasion. The model abstracts a spheroid of normal and cancer cells that grows radially via water and nutrient influx while constrained by a stiffer BM and cell adhesion molecules. It is based on coupled fluid-solid mechanics and ATP-fueled mechano-damped cell kinetics, and uses empirical data alone as parameters. The model predicts the dynamic force and exergy (ATP) fields, and tumor size among other variables, and generates the sigmoidal dynamics of far-from-equilibrium biota. Simulations show that the tumor-membrane system, on neoplastic perturbation, evolves from one homeostatic steady state to another over time. Integrated with system dynamics theory, the model renders a key, emergent tissue-level feedback control perspective of malignancy: neoplastic tumors coupled with pathologically-softened BMs appear to participate in altered autoregulatory behavior, and likely undergo BM cavitation and stress-localized ruptures to their adhesome, with or without invadopiosis, thereby, initiating invasion. Serendipitously, the results also reveal a noumenal similarity of the tumor-membrane to the earth-atmosphere open reactive system as concerns self-regulation.

**2:30PM C40.00001 Hydraulic fracture and toughening of a brittle layer bonded to a hydrogel**, ALESSANDRO LUCANTONIO, GIOVANNI NOSELLI, SISSA - International School for Advanced Studies, XAVIER TREPAT, IBEC - Institute for Bioengineering of Catalonia, ANTONIO DESIMONE, SISSA - International School for Advanced Studies, MARINO ARROYO, UPC - Universitat Politècnica de Catalunya — Brittle materials fracture under tensile or shear stress. When stress attains a critical threshold, crack propagation becomes unstable and proceeds dynamically. In the presence of several precracks, a brittle material always propagates only the weakest crack, leading to catastrophic failure [1]. Here, we show that all these features of brittle fracture are radically modified when the material susceptible to cracking is bonded to a poroelastic medium, such as a hydrogel, a common situation in biological tissues [2]. In particular, we show that the brittle material can fracture in compression and can resist cracking in tension, thanks to the hydraulic coupling with the hydrogel. In the case of multiple cracks, we find that localized fracture occurs when the permeability of the hydrogel is high, whereas decreased permeability leads to toughening by promoting multiple cracking. Our results [3] may contribute to the understanding of fracture in biological tissues and provide inspiration for the design of tough, biomimetic materials.

**2:42PM C40.00002 Geometry and Mechanics of Thin Growing Bilayers**<sup>1</sup>, MATTEO PEZZULLA, GABRIEL SMITH, Boston University, PAOLA NARDINOCCHI, Sapienza Università di Roma, DOUGLAS HOLMES, Boston University — We investigate how thin sheets of arbitrary shapes morph under the isotropic in-plane expansion of their top surface, which may represent several stimuli such as nonuniform heating, local swelling and differential growth. Inspired by geometry, an analytical model is presented that rationalizes how the shape of the disk influences morphing, from the initial spherical bending to the final isometric limit. We introduce a new measure of slenderness that describes a sheet in terms of both thickness and plate shape. We find that the mean curvature of the isometric state is three fourth's the natural curvature, which we verify by numerics and experiments. We finally investigate the emergence of a preferred direction of bending in the isometric state, guided by numerical analyses. The scalability of our model suggests that it is suitable to describe the morphing of sheets spanning several orders of magnitude.

**2:54PM C40.00003 Buckling, driven by constrained phase separation, of toroid-shaped hydrogels**, MICHAEL S. DIMITRIYEV, YA-WEN CHANG, Georgia Institute of Technology, ANTON SOUSLOV, Universiteit Leiden, ALBERTO FERNANDEZ-NIEVES, PAUL M. GOLDBART, Georgia Institute of Technology — We investigate the buckling process observed in connection with the temperature-induced shrinking of an elastic toroid composed of hydrogel. Hydrogels are polymeric network media that become swollen when mixed with water, provided the temperature is low enough. As the temperature is increased beyond a certain point, such gels undergo a first-order de-swelling transition to a de-mixed state, in which the network segregates from the water, resulting in a shrunken phase. It is known that the rapid heating of swollen hydrogels beyond the de-swelling transition results in the formation of a shrunken-phase boundary region, or shell. This shell hinders the expulsion of fluid associated with the equilibration of the sample interior, and gives rise to a prolonged period of coexistence between shrunken and swollen domains in the interior of the sample. In contrast with the spherical case, toroidal samples have been observed to undergo a constrained phase separation that is accompanied by a global buckling (or "Pringling") deformation of the sample shape. We present a model of hydrogel toroid Pringling in which such deformations are driven by this phase separation process.

**3:06PM C40.00004 Modeling and design of the self-twisting of hydrogel bilayer strips** Authors: Jiayu Liu, Jingkai Guo, Tanvi Shroff, Changkyu Yoon, David Gracias & Thao D Nguyen, JIAYU LIU, JINGKAI GUO, TANVI SHROFF, CHANGKYU YOON, DAVID GRACIAS, THAO NGUYEN, Johns Hopkins University — Self-folding of hydrogels via heterogeneous swelling can be used to create complex, 3D structures. A bilayer structure with a thermo-responsive hydrogel layer, that swells with decreasing temperature, and a non-swelling layer can respond to a temperature change by either bending into a ring or twisting into a helix. The equilibrium structure depends on the thickness ratio of the two layers, the ratio of the width to thickness of the bilayer, as well as the stiffness of the two layers and equilibrium swelling ratio of the hydrogel. These parameters can be controlled using lithographic photopatterning and multilayer deposition techniques. To guide the design of the bilayer structures, we developed a finite element model of the bilayer structure. The constitutive model of the hydrogel is described by a free energy density that includes a quasi-incompressible Neo-Hookean component for the strain energy density of the polymer network and a Flory-Huggins component for the free-energy density of mixing of the polymer and solvent. We discussed how variations in the layer thickness, slenderness, stiffness, and equilibrium swelling ratio can be used to design self-folded rings of different curvatures and helices with different helix angle and diameters.

**3:18PM C40.00005 Mechanics of a leaf detaching from tree**, TIM ZEHNBAUER, SUNGHWAN JUNG, Virginia Tech — Deciduous trees shed their leaves through an abscission process. The abscission zone is formed at the base of the petiole, and consists of a top layer with weak walls and a bottom layer that expands and breaks the walls of the cells in the top layer. Although this process is well understood biologically, the mechanical principles underlying this shedding have received little attention. In the present study, we characterize the stress-strain relation of the petiole-branch connection failure over the seasons. The testing is done with a 1kN load cell, where the stem is pulled directly from the branch to make a stress-strain curve. The slope of the stress-strain curve, Young's modulus, is obtained using least squares linear regression of the curve. We show that Young's modulus stays constant from spring to late fall, while the maximum tensile strength falls. We are investigating the role of the shape of a leaf's petiole in this behavior.

**3:30PM C40.00006 ABSTRACT WITHDRAWN —**

**3:42PM C40.00007 The role of deformable structured surfaces on viscous forces during peeling**<sup>1</sup>, CHARLES DHONG, JOELLE FRECHETTE, Johns Hopkins University — It is known that tree frogs are able to adhere well in flooded environments, presumably due to their interconnected network of drainage channels formed by hexagonal epithelial cells in their toe pads. To investigate this effect, a patterned surface of hexagonally arranged cylindrical posts was brought close to a stationary substrate in a submerged, viscous fluid via a normal load, and then peeled off to measure a retraction force. Because these structured surfaces were made from PDMS, they are able to deform throughout the process. We find that these deformable surfaces further reduce the work required to peel apart the two surfaces, even when compared to previous studies in the same system with rigid structures, and we isolated these contributions independent of conservative forces. We then conducted experiments to compare the effect of deformation on the viscous forces and conservative forces. We find that there are several regimes where deformation either increases or decreases the retraction force since we have found that elasticity decreases retraction forces when considering viscous contributions but is also known to increase adhesion in the context of conservative forces.

**3:54PM C40.00008 Bio-inspired microfluidics: The case of the velvet worm**<sup>1</sup>, ANDRES CONCHA, PAULA MELLADO, Adolfo Ibanez university, BERNAL MORERA-BRENES, Laboratorio de Genetica Evolutiva, Universidad Nacional de Costa Rica, CRISTIANO SAMPAIO-COSTA, University of Sao Paulo., L. MAHADEVAN, School of Engineering and Sciences, Harvard University., JULIAN MONGE-NAJERA, Tropical Biology, Universidad de Costa Rica. — The rapid squirt of a proteinaceous slime jet endow velvet worms (Onychophora) with a unique mechanism for defense from predators and for capturing prey by entangling them in a disordered web that immobilizes their target. However, to date neither qualitative nor quantitative descriptions have been provided for this unique adaptation. We have investigated the mechanism that allows velvet worms the fast oscillatory motion of their oral papillae and the exiting liquid jet that oscillates with frequencies  $f \sim 30 - 60$  Hz. Using anatomical images and high speed videography, we show that even without fast muscular action of the papilla, a strong contraction of the slime reservoir and the geometry of the reservoir-papilla system suffices to accelerate the slime to speeds up to  $v \sim 5$  m/s in about  $\Delta t \sim 60$  ms. A theoretical analysis and a physical simulacrum allow us to infer that this fast oscillatory motion is the result of an elastohydrodynamic instability driven by the interplay between the elasticity of oral papillae and the fast unsteady flow during squirting. We propose several applications that can be implemented using this instability, ranging from high-throughput droplet production, printing, and micro-nanofiber production among others.

**4:06PM C40.00009 Nonlinear adhesion dynamics of confined lipid membranes**<sup>1</sup>, TUNG TO, THOMAS LE GOFF, OLIVIER PIERRE-LOUIS, Univ Lyon 1 UA 442 CNRS — Lipid membranes, which are ubiquitous objects in biological environments are often confined. For example, they can be sandwiched between a substrate and the cytoskeleton between cell adhesion, or between other membranes in stacks, or in the Golgi apparatus. We present a study of the nonlinear dynamics of membranes in a model system, where the membrane is confined between two flat walls. The dynamics derived from the lubrication approximation is highly nonlinear and nonlocal. The solution of this model in one dimension exhibits frozen states due to oscillatory interactions between membranes caused by the bending rigidity. We develop a kink model for these phenomena based on the historical work of Kawasaki and Otha<sup>2,3,4</sup>. In two dimensions, the dynamics is more complex, and depends strongly on the amount of excess area in the system. We discuss the relevance of our findings for experiments on model membranes, and for biological systems<sup>5</sup>.

**4:18PM C40.00010 Statistical Mechanics of Sliced Graphene Ribbons.**, MARK BOWICK, Syracuse University, EMILY RUSSELL, Google, RASTKO SKNEPNEK, University of Dundee, DAVID NELSON, Harvard University — Two-dimensional crystalline membranes have recently been realized experimentally in such systems as graphene and molybdenum disulfide, sparking a resurgence in interest in their statistical properties. Thermal fluctuations can significantly change the effective mechanical properties of these membranes, renormalizing both bending rigidity and elastic moduli so that thermal membranes are stiffer to bending than their bare bending rigidity would suggest. We use molecular dynamics simulations to examine the further effect of topology and geometry on the properties of thermal membranes, and find that the introduction of a slit suppresses the scale of thermal fluctuations.

**4:30PM C40.00011 Statistical mechanics of thin spherical shells**, ANDREJ KOSMRLJ, Princeton University, DAVID R. NELSON, Harvard University — We explore how thermal fluctuations affect the mechanics of thin amorphous spherical shells via renormalization group calculations. It is well known that for flat solid membranes thermal fluctuations effectively increase the bending rigidity and reduce the bulk and shear moduli. This is still true for spherical shells. However, the additional coupling between the shell curvature, the local in-plane stretching modes and the local out-of-plane undulations leads to novel phenomena. In spherical shells thermal fluctuations effectively produce negative surface tension, which is equivalent to applying external pressure. We find that small spherical shells are stable, but for sufficiently large shells this thermally generated pressure becomes big enough to crush spherical shells. Such shells can be reinflated by increasing internal pressure, where the effective shell size grows non-linearly as a function of internal pressure with a power law exponent characteristic for thermally fluctuating flat membranes under uniform tension.

**4:42PM C40.00012 Phyllotactic transformations as plastic deformations of tubular crystals with defects**, DANIEL BELLER, DAVID NELSON, Harvard University — Tubular crystals are 2D lattices in cylindrical topologies, which could be realized as assemblies of colloidal particles, and occur naturally in biological microtubules and in single-walled carbon nanotubes. Their geometry can be understood in the language of phyllotaxis borrowed from botany. We study the mechanics of plastic deformations in tubular crystals in response to tensile stress, as mediated by the formation and separation of dislocation pairs in a triangular lattice. Dislocation motion allows the growth of one phyllotactic arrangement at the expense of another, offering a low-energy, stepwise mode of plastic deformation in response to external stresses. Through theory and simulation, we examine how the tube's radius and helicity affects, and is in turn altered by, dislocation glide. The crystal's bending modulus is found to produce simple but important corrections to the tube's deformation mechanics.

**4:54PM C40.00013 Defect-driven shape instabilities in cohesive filament bundles<sup>1</sup>**, ISAAC BRUSS, University of Michigan, GREGORY GRASON, University of Massachusetts — When defects are incorporated into the lattice of a flexible 2D crystalline membrane, it buckles into a new configuration. Specifically, 5- and 7-fold disclinations produce conical- and saddle-like geometries respectively. For bundles composed of a crystalline array of cohesive flexible filaments, we propose a similar phenomena of defect-induced buckling. This revelation is fueled by a recently discovered mapping between the metric properties of a curved surface, and the inter-filament spacing within a deformed bundle. Using a combination of continuum elasticity theory and numerical simulations, we investigate the effects of defects in the cross section on a bundle's global structure. We find that positive disclinations promote the twisting of filaments around a central axis within the bundle, while negative disclinations promote twisting around two parallel axes simultaneously. Both instabilities are interpreted by means of their equivalent Gaussian curvature, and map appropriately to the corresponding membrane responses. Additionally, for 5-fold disclinations we uncover a new equilibria structure, torsional wrinkling, with the intriguing ability to focus gradients in filament tilt much like curvature-focusing for the analogous membrane.

**5:18PM C40.00015 The Effect of Loops in Connectivity Percolation**, VARDA F. HAGH, Arizona State University, M. F. THORPE, Arizona State University- Rudolf Peierls Centre for Theoretical Physics, University of Oxford — We introduce a new method that employs the concepts of redundancy and stress from rigidity theory to study the effect of loops in connectivity percolation. In the rigidity percolation redundant bonds are not necessary to maintain the rigidity of a network. These redundant bonds cause internal stress in some regions and as a result those regions carry finite forces that characterize them as over-constrained. In connectivity percolation the bonds that cause a loop correspond to redundant bonds in rigidity and all the bonds that are part of a loop are equivalent to over-constrained bonds in rigidity. To illustrate this we start with a network in 2D where all the bonds are present and remove the bonds randomly. Then using renormalization groups and numerical simulations we study the behavior of loops near percolation transition in hierarchical networks and lattices.

**2:30PM C41.00001 Flory theory or the two state cooperativity model: What describes back-folding of DNA in nanotubes?**, KEVIN DORFMAN, ABHIRAM MURALDIHAR, Univ of Minn - Minneapolis — Currently, there are two explanations available in the literature to describe the extension of semiflexible polymers, such as DNA, confined in nanotubes whose diameter is close to the persistence length. Almost a decade ago, Odijk (Phys. Rev. E, 2008, 77, 060901) used a Flory theory to derive a scaling law for the average extension of a semiflexible polymer confined in such a tube. More recently, Dai et al. (ACS Macro Lett. 1, 1046-1050) applied a two-state cooperativity model along the lines of the Zimm-Bragg model for helix coil transitions to explain the same phenomenon. Although the two theories are fundamentally different, there are simulation results supporting both approaches. In this talk, we will present results from Pruned-Enriched Rosenbluth Method (PERM) simulations of a discrete wormlike chain model, which show strong evidence supporting Odijk's Flory theory. Moreover, we will show that Odijk's scaling theory also predicts the contour length dependence of the chain extension. In contrast, we find that the cooperativity model predicts the average extension correctly only for the molecular weights used to parameterize the model.

**2:42PM C41.00002 Pore translocation of polymer chains with physical knots**, ANTONIO SUMA, ANGELO ROSA, CRISTIAN MICHELETTI, SISSA, International School for Advanced Studies, via Bonomea 265, I-34136 Trieste, Italy — The driven translocation of knotted chains through narrow pores has important implications for single-molecule manipulation contexts. Its complex phenomenology<sup>1</sup> is, however, still largely unexplored, both as a function of knot complexity and the magnitude of the driving, translocating force. We accordingly report on a systematic theoretical and computational investigation of both aspects. In particular we consider the case of flexible chains accommodating a large repertoire of knots that are driven through pores too narrow to allow for their passage. We show that the observed rich translocation phenomenology can be rationalised in a transparent mechanical framework that can further be used for predictive purposes<sup>2</sup>.

**2:54PM C41.00003 Intramolecular Fluctuation of DNA in Nanochannels via High-throughput Video Microscopy**, JULIAN SHEATS, Univ of Minn - Minneapolis, JEFFREY G. REIFENBERGER, HAN CAO, BioNano Genomics - San Diego, KEVIN D. DORFMAN, Univ of Minn - Minneapolis — Genome mapping is a promising technique that complements next generation sequencing. The distance between labels on barcoded DNA molecules is the main physical quantity employed by emerging nanochannel technologies used to construct genome maps. Here we analyze time resolved data of *E. coli* DNA in a commercial nanochannel genome mapping system to obtain the probability distribution underlying the distance between labels. Improving upon a previous study of this type<sup>1</sup>, this dynamic method avoids alignment to the reference genome, a process that is statistical in nature. The time-series analysis also allows for detection of a set of experimental artifacts present in static imaging, thereby filtering out several sources of potential systematic error. The resulting probability density remains left-skewed, supporting previous evidence. However, filtering out the artifacts resulted in a lower magnitude of skewness, which has implications for the statistical weights associated with the genome mapping algorithm.

**3:06PM C41.00004 Non-Equilibrium Dynamics of Nano-channel Confined DNA: A Brownian Dynamics Simulation Study**, ANIKET BHATTACHARYA, AIQUN HUANG, University of Central Florida, WALTER REISNER, McGill University, Canada — We carry out Brownian dynamics (BD) simulation for a semi-flexible polymer chain characterized by a contour length  $Na$  and a persistence length  $\ell_p$  confined inside a rectangular nanochannel to study its compression and retraction dynamics while being pushed on one end at a constant velocity by a “nano-dozer”. We study the evolution of one dimensional concentration profile  $c(x, t)$  and the chain extension  $R$  along the channel axis ( $x$ -axis) during both the contracting as well as the retracting phases as a function of the velocity of the nano-dozer, both in steady states and in transients. Furthermore, we measure the transverse fluctuations of the chain under contraction and retraction, and the amplitude of the density profile, and compare these simulation results with those obtained from an analytical model proposed by Khorshid *et al.* Our studies are guided by recent experimental results by Khorshid *et al.* (*Phys. Rev. Lett.*, **113**, 268104 (2014)) and provide further justification to use a one dimensional PDE approach to understand the non-equilibrium dynamics of confined polymers.

**3:18PM C41.00005 Dynamics of topological events within single molecules of DNA confined in nanochannels.**<sup>1</sup>, JEFFREY REIFENBERGER, BioNano Genomics, KEVIN DORFMAN, Dept. Chemical Engineering and Materials Science, University of Minnesota - Twin Cities, HAN CAO, BioNano Genomics — Genome mapping in nanochannels offers the ability to search for large genomic rearrangements within individual molecules of DNA often missed by sequencing techniques. This method labels DNA at specific sequence motifs such as ‘GCTCTTC’ with a cy3-like fluorophore and then stains the backbone of dsDNA with an intercalating dye. DNA is electrophoretically loaded into an array of nanofluidic channels and linearized in physically confined narrow conduits fabricated on the silicon chip. The fluorescently labeled sequence motifs, unique to long genomic regions, are optically imaged and digitized reflecting structural changes that can occur within cancer. However, some molecules of DNA confined within the ~42 nm wide nanochannels contain topological structures: knots, S-folds, and end-folds that could appear as false genomic rearrangements. We present a technique in which thousands of molecules of *E. coli* DNA are sequentially imaged in the nanochannels during several minutes allowing for topological events like diffusion of knots, unfolding at the ends, and spontaneous formation of S-folds to be measured. This technology will provide insights and a solution in error correction for making more accurate measurements.

**3:30PM C41.00006 Adsorption of annealed branched polymers on curved surfaces**, JEF WAGNER, Lawrence University, GONCA ERDEMCI-TANDOĞAN, ROYA ZANDI, University of California Riverside — Annealed branched polymers play important roles in many biological and industrial systems, notable among them single stranded RNA (ssRNA) that in solution takes on a branched secondary structure. Using a mean field theory, we both perturbatively and numerically examine the adsorption of annealed branched polymers on surfaces of several different geometries in a good solvent. Independent of the geometry of the wall, we observe that as branching density increases, surface tension decreases. However, we find a coupling between the branching density and curvature in that a further lowering of surface tension occurs when the wall curves towards the polymer, but the amount of lowering of surface tension decreases when the wall curves away from the polymer. This work was inspired by the idea of using functionalized gold nano-particles to bind RNA for gene delivery. Understanding the mechanisms involved with the adsorption of annealed branched polymers onto different surfaces will play a critical role in many biomedical technologies.

**3:42PM C41.00007 Depletion forces in collapsing a flexible chain molecule in a confined or free space**, CHANIL JEON, BAE-YEUN HA, University of Waterloo — A chain molecule can be entropically collapsed in a crowded medium whether confined or not. Qualitatively, the entropic (depletion) forces between monomers can be considered as effectively reducing the solvent quality, eventually making the excluded volume  $v$  negative. Here, we characterize these forces in collapsing a flexible polymer in three distinct spaces: free, cylindrical, and (2-dimensional) slit-like. A few general features characterize flexible-chain collapse. Let  $\phi_c$  be the volume fraction of crowders of size  $a_c$  each (in units of the monomer size). In all three cases, chain compaction depends on a single parameter, i.e., the ratio  $\phi_c/a_c$ ; there also exists a general relationship between  $\phi_c/a_c$  and  $v$ . Our results suggest that the action of depletion forces is local and insensitive to the geometry of a confined space, as assumed in an effective-solvent picture. They also offer a physical sense of average crowder sizes in a poly-disperse crowded medium.

**3:54PM C41.00008 Detection of ATP hydrolysis through motion of nanoconfined DNA**, MAEDEH ROUSHAN, GIDEON LIVSHITS, ZUBAIR AZAD, HONG WANG, ROBERT RIEHN, North Carolina State University — Confinement of DNA to nanochannels with a cross-section of  $100 \times 100 \text{ nm}^2$  and hundreds of micrometer long has previously been used to investigate the equilibrium binding properties of proteins to DNA. Here we report on the observation that a range of proteins which catalyze a modification of DNA, and that do so by hydrolyzing ATP, cause a net directed motion of nanochannel-confined DNA. We present a model for this observation that does not require any motor-like action of the protein and that is purely dependent on the catalytic properties.

**4:06PM C41.00009 Stochastic resonance during a polymer translocation process**, DEBASISH MONDAL, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — We study the translocation of a flexible polymer in a confined geometry subjected to a time-periodic external drive to explore stochastic resonance. We describe the equilibrium translocation process in terms of a Fokker-Planck description and use a discrete two-state model to describe the effect of the external driving force on the translocation dynamics. We observe that no stochastic resonance is possible if the associated free-energy barrier is purely entropic in nature. The polymer chain experiences a stochastic resonance effect only in presence of an energy threshold in terms of polymer-pore interaction. Once stochastic resonance is feasible, the chain entropy controls the optimal synchronization conditions significantly.

**4:18PM C41.00010 Strongly Non-equilibrium Dynamics of Nanochannel Confined DNA**, WALTER REISNER, McGill University — Nanoconfined DNA exhibits a wide-range of fascinating transient and steady-state non-equilibrium phenomena. Yet, while experiment, simulation and scaling analytics are converging on a comprehensive picture regarding the equilibrium behavior of nanochannel confined DNA, non-equilibrium behavior remains largely unexplored. In particular, while the DNA extension along the nanochannel is the key observable in equilibrium experiments, in the non-equilibrium case it is necessary to measure and model not just the extension but the molecule's full time-dependent one-dimensional concentration profile. Here, we apply controlled compressive forces to a nanochannel confined molecule via a nanodozer assay, whereby an optically trapped bead is slid down the channel at a constant speed. Upon contact with the molecule, a propagating concentration "shockwave" develops near the bead and the molecule is dynamically compressed. This experiment, a single-molecule implementation of a macroscopic cylinder-piston apparatus, can be used to observe the molecule response over a range of forcings and benchmark theoretical description of non-equilibrium behavior. We show that the dynamic concentration profiles, including both transient and steady-state response, can be modelled via a partial differential evolution equation combining nonlinear diffusion and convection. Lastly, we present preliminary results for dynamic compression of multiple confined molecules to explore regimes of segregation and mixing for multiple chains in confinement.

**4:54PM C41.00011 Role of small ion dynamics in driven translocation of polyelectrolytes through nanopores**, HARSHWARDHAN KATKAR, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — Nanopores have been proposed to be used for a variety of applications such as in DNA sequencing and as molecular separation devices. In the present study, we focus on the dynamics of small ions (counterions and salt ions) while a charged polymer translocates through a finite-length nanopore under the action of an externally applied electric field. Coarse-grained molecular dynamics simulations are performed to study the translocation process, taking both the long-range hydrodynamics and the long-range electrostatics into consideration. We address the role of small ion dynamics on the properties of a DNA in a confined region.

**5:06PM C41.00012 Free Energy of a Polymer in Slit-Like Confinement across the Odijk, moderate confinement, and Bulk Regimes**, ALBERT KAMANZI, JASON S. LEITH, McGill University, DAVID SEAN, University of Ottawa, DANIEL BERARD, ANDREW C. GUTHRIE, CHRISTOPHER M.J. MCFAUL, McGill University, GARY W. SLATER, University of Ottawa, HENDRICK W. DE HAAN, University of Ontario, Institute of Technology, SABRINA R. LESLIE, McGill University, MCGILL UNIVERSITY TEAM, UNIVERSITY OF OTTAWA, UNIVERSITY OF ONTARIO COLLABORATION — We directly measure the free energy of confinement for semi-flexible polymers from the nanoscale to bulk regimes in slit-like confinement. We use Convex Lens-induced Confinement (CLiC) microscopy of DNA to load and directly count molecules at equilibrium in a single chamber of smoothly increasing height. CLiC microscopy allows for direct visualization of polymers in free solution over long periods, as a function of tunable vertical confinement - from the millimeter to the nanometer scale, and within a single device. Our direct characterization of the free energy of confinement, across several orders of magnitude of applied confinement, agree with new simulations established in this work. We compare experimental results to the "de Gennes blob model", to theory published by Casassa, as well as to simulations by Chen and Sullivan, in appropriate regimes. This work establishes a robust platform for understanding and manipulating polymers at the nanoscale, with a wide range of applications to biomedical technologies.

**5:18PM C41.00013 Do Ions Flow Freely Through Confined DNA?**, ZUBAIR AZAD, ROBERT RIEHN, North Carolina State University — Double-stranded DNA in an aqueous solution is characterized by a strongly localized counter-ion cloud. Classical experiments have shown that the mobility of large DNA coils is independent of the number of basepairs, leading to an interpretation that the molecule can be understood as a collection of segments with constant mobility whose interactions are effectively screened from each other. This "free-draining" assumption posits that DNA and other electrolytes will not influence each other's mobility. In this talk, we call this assumption into question when the local concentration of DNA is increased beyond that of a self-avoiding random walk by nanoconfinement. We present translocation of DNA and fluorescent tracer ions under established chemical gradients, pressure-driven flow, and electrophoresis in nanochannels with cross sections that are 100 nm x 100 nm. We present evidence that interactions between the DNA and ionic tracers are a non-linear function of the applied fields.

**2:30PM C42.00001 Fluids Density Functional Theory of Diblock Copolymers for Electrolyte Applications<sup>1</sup>**, JONATHAN R. BROWN, LISA M. HALL, Ohio State University — We use classical, fluids density functional theory (fDFT) to study microphase separation in block copolymer systems. We are motivated by systems used as battery electrolytes or in other transport applications, in which the two blocks of the system have different mechanical, dielectric, and transport properties that allow one phase to act as a charge/penetrant carrier and the other to make the film mechanically strong. We find density profiles of penetrants, showing to what degree they segregate into the A phase and their concentration near the interface, depending on the penetrant-A and penetrant-B interaction strengths as well as the A-B segregation strength. We also study the effect of tapering, or adding a gradient region (taper) between the pure A and B blocks of an AB diblock copolymer; the taper changes in composition along its length from pure A to pure B (or from B to A for an inverse taper). The effect of both penetrants and tapering on microphase domain spacing as a function of segregation strength will be discussed. Adjusting taper length allows one to tune the phase behavior of the system for easier processing or access to specific desired microphase structures.

**2:42PM C42.00002 Unguided discovery of BCP self-assembly: challenges and outlook**, CAROL TSAI, KRIS DELANEY, GLENN FREDRICKSON, University of California, Santa Barbara — The unguided search for the stable phases of a block copolymer of a given composition and architecture is a problem of global optimization. The appeal of this pursuit arises from both a materials design perspective and also from the perspective of solving global optimization problems via heuristic algorithms. A diverse collection of such algorithms is available to employ, including evolutionary and swarm strategies. In this talk we discuss the development, successes, and challenges of a real-space genetic algorithm (GA)-SCFT method as applied to a diblock copolymer. We then consider alternative representations and algorithms for solving the forward problem in bulk block copolymer systems.

**2:54PM C42.00003 Orientational control of block copolymer microdomains by sub-tesla magnetic fields<sup>1</sup>** , MANESH GOPINADHAN, YOUNGWOON CHOO, XUNDA FENG, KOHSUKE KAWABATA, XIAOJUN DI, CHINEDUM OSUJI, Yale University — Magnetic fields offer a versatile approach to controlling the orientation of block copolymer (BCP) microdomains during self-assembly. To date however, such control has required the imposition of large magnetic fields (>3T), necessitating the use of complex magnet systems – either superconducting or very large conventional resistive magnets. Here we demonstrate the ability to direct BCP self-assembly using considerably smaller fields (<1T) which are accessible using simple rare-earth permanent magnets. The low field alignment is enabled by the presence of small quantities of mesogenic species that are blended into, and co-assemble with the liquid crystalline (LC) mesophase of the side-chain LC BCP under study. In situ SAXS experiments reveal a pronounced dependence of the critical alignment field strength on the stoichiometry of the blend, and the ability to generate aligned microdomains with orientational distribution coefficients exceeding 0.95 at sub-1 T fields for appropriate stoichiometries. The alignment response overall can be rationalized in terms of increased mobility and grain size due to the presence of the mesogenic additive. We use a permanent magnet to fabricate films with aligned nanopores, and the utility of this approach to generate complex BCP microdomain patterns in thin films by local field screening are highlighted.

**3:06PM C42.00004 Morphology of diblock copolymers under confinement** , DAVID ACKERMAN, BASKAR GANAPATHYSUBRAMANIAN, Iowa State University — The structure adopted by polymer chains is of particular interest for materials design. In particular, a great deal of effort has been made to study diblock polymers due to the importance they have in industrial applications. The bulk structure of most systems has been the most widely studied. However, when under the effect of confinement, the polymer chains are forced to adopt structures differing from the familiar bulk phases. As many applications utilize polymers in sizes and shapes that lead to these non bulk structures, the confinement effects are important. A commonly used tool for computationally determining structures is the continuum self-consistent field theory (SCFT). We discuss our highly scalable parallel framework for SCFT using real space methods (finite element) that is especially well suited to modelling complex geometries. This framework is capable of modeling both Gaussian and worm like chains. We illustrate the use of the software framework in determining structures under varying degrees of confinement. We detail the method used and present selected results from a systematic study of confinement using arbitrary structures.

**3:18PM C42.00005 Selective Stabilization of the Fddd Diblock Copolymer Microphase in an Applied Electric Field** , JONATHAN MARTIN, WEI LI, KRIS DELANEY, GLENN FREDRICKSON, Univ of California - Santa Barbara — Using self-consistent field theory, we explore the phase behavior of AB diblock copolymer melts in a uniform applied electric field. We assign an isotropic polarizability to each monomer type, such that the electric field selectively destabilizes AB interfaces that are perpendicular to the applied field. Under the mean-field approximation of the present model, lamellar and cylindrical structures align such that their AB interfaces are parallel to the electric field, and their relative stability with respect to the disordered phase is unchanged. Sphere and network phases do not have an axis of uniformity, so the preferred orientation for each of these phases must be identified by simulation. Small distortions in morphology are induced by the electric field for these phases, such that the free energy response includes non-harmonic terms. We compute the phase diagram for a melt in an applied electric field by comparing free energies of each morphology at its preferred orientation. We find that the stability regions for the sphere and network phases shrink with increasing electric field strength. Moreover, the double gyroid phase is relatively destabilized against the Fddd phase, extending the stability region for the Fddd phase to larger segregation strengths.

**3:30PM C42.00006 Process-directed self-assembly of copolymers** , MARCUS MULLER, Georg-August University, Goettingen, Germany, JIUZHOU TANG, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China — Using computer simulation and numerical self-consistent field theory of an unentangled diblock copolymer melt, we study the interplay between relaxation of molecular conformations from a highly stretched, non-equilibrium state and structure formation of the local, conserved density during self-assembly from a disordered state. In agreement with experiments, we observe that the planar elongation of molecular conformations in the initial, disordered state results in an alignment of lamella normals perpendicular to the stretch direction during the subsequent self-assembly. Although thermodynamically the parallel orientation is favored by the non-Gaussian conformations, the alignment of the lamella normal perpendicular to the stretch direction is characterized by the larger growth rate of composition fluctuations during the spinodal ordering process. Theoretical approaches to account for the transient, non-Gaussian conformations are discussed.

**3:42PM C42.00007 Morphology Control of Multicomponent Polymeric Surfactants Using Pressure<sup>1</sup>** , JUNHAN CHO, Dankook University — The development of nanoscale morphologies for a molten polymeric surfactant under pressure is investigated by using a recently formulated self-consistent field theory. A linear ABC block copolymer is taken as our model system that allows a disparity in the propensities for curved interfaces and pressure responses of ij-pairs. The interplay of those features lead the copolymer to new morphologies at a moderate segregation level and at ambient condition such as networks and pillars of 2-dimensional array. It is shown that pressure is an effective means of morphology control and identification for those new structures. The role of volume fluctuations in the development of those structures is discussed.

**3:54PM C42.00008 Analysis of Relaxation Spectra and Influence of Molecular Weight on the Dynamics of Block Copolymers<sup>1</sup>** , VAIDYANATHAN SETHURAMAN, VENKAT GANESAN, Univ of Texas, Austin — We use molecular dynamics simulations to study both the normal mode dynamics of block copolymers and the influence of MW on the dynamics of the block copolymer. We considered two models to isolate the specific effects arising from the morphological ordering and mobility disparities between the blocks. We effected an explicit normal mode analysis of the chain dynamics in the ordered phases in the directions parallel and perpendicular to the plane of the lamella. For systems with no mobility disparity between the blocks, our analysis demonstrates that the normal modes and their relaxations in the planes parallel and perpendicular to the lamella exhibit significant deviations from the Rouse modes. For systems in which the mobility of one of the blocks was frozen in the lamellar phase, the normal modes closely resembled the Rouse modes for tethered polymers. To understand the spatial inhomogeneities in segmental dynamics of lamellar diblock copolymer systems we probed the local average relaxation times and the dynamical heterogeneities as a function of distance from the interface. Scaling of our results indicate that the interfacial width of the ordered phases serves as the length scale underlying the spatial inhomogeneities in segmental dynamics of the fast monomers.

**4:06PM C42.00009 ABSTRACT WITHDRAWN —**

**4:18PM C42.00010 Acoustic and ultrasonic characterization constraints of self-healing (ethylene-co-methacrylic acid) copolymers**, KENNETH PESTKA II, JONATHAN BUCKLEY, Longwood University, STEPHEN KALISTA, Department of Biomedical Engineering, Rensselaer Polytechnic Institute, NICHOLAS BOWERS, Rollins College — Recent experiments indicate that small sample poly (ethylene-co-methacrylic acid) copolymers (EMAA copolymers) exhibit time dependent variation in their acoustic and ultrasonic resonant spectra after exposure to a damage event. However, due to the relatively soft nature of these thermoplastic materials, several experimental constraints affect efficacy of resonant spectral analysis. In this work we will address the effect of several characterization constraints on a self-healing EMAA ionomer (commercially known as Dupont Surlyn 8920) including the effects of transducer loading, continuous rapid resonant excitation and temporally separated long-term resonant excitation. In some circumstances, these experimental constraints can influence the time dependence of sample resonant frequency evolution, quality factor, and variation in spectral waveform. By quantifying these effects, robust characterization of post-damage self-healing EMAA samples is possible and will be presented.

**4:30PM C42.00011 The role of symmetry of chain extender in controlling the morphology of thermoplastic polyurethanes**, ONYENKACHI WAMUO, CHENG SONG, SHAW LING HSU, University of Massachusetts, Amherst — Although polyurethane is a well-studied subject, the specific role of chain extender in the alteration of segmental dynamics and morphology formation has yet to be elucidated. Relatively low molecular weight thermoplastic polyurethanes synthesized from a two-step polymerization method were utilized in this study. The effect of the symmetry of chain extenders used in the polymerization on the morphological behavior has been studied. Comparison has been made for a number of chain extenders, including a symmetric 1,4-butanediol or 1,6-hexanediol and an asymmetric 1,2-propanediol or 1,3-butanediol. Using a combination of thermal analysis, spectroscopy and mechanical properties measurements, the development of morphological features were determined as a function of time and temperature. The symmetric chain-extended polyurethanes promotes the formation of hydrogen bonding, shows two glass transition temperatures consistent with a phase separation behavior and furthermore gives a more rigid, less extensible mechanical property when compared with the asymmetric chain-extended polyurethanes. In the latter case, the reacted polymer exhibits poor chain packing thus limiting the formation of robust hydrogen bonding behavior. It showed a singular glass transition representative of a more phase mixed system and shows more extensibility in terms of its mechanical behavior.

**4:42PM C42.00012 Phase diagram of rod-coil diblock copolymer melts by self-consistent field theory**, DADONG YAN, Department of Physics, Beijing Normal University, JIUZHOU TANG, Institute of Chemistry, Chinese Academy of Sciences, YING JIANG, School of Chemistry and Environment, Beihang University, XINGHUA ZHANG, School of Science, Beijing Jiaotong University, JEFF CHEN, Department of Physics and Astronomy, University of Waterloo — A unified phase diagram is presented for rod-coil diblock copolymer melts in the isotropic phase regime as a function of the asymmetric parameter. The study is based on free-energy calculation, which incorporates three-dimensional spatial variations of the volume fraction with angular dependence. The wormlike-chain model is used in a self-consistent field treatment. Body-centered cubic, A15, hexagonal, gyroid, and lamellar structures where the rod segments are packed inside the convex rod-coil interface are found stable. As the conformational asymmetric parameter increases, the A15 phase region expands and the gyroid phase region reduces. The stability of the structures is analyzed by concepts such as packing frustration, spinodal limit, and interfacial curvature.

**4:54PM C42.00013 Temperature effects on the interfacial properties of semifluorinated diblock copolymer thin films.**<sup>1</sup>, UMESH SHRESTHA, Clemson University, STEPHEN CLARSON, University of Cincinnati, DVORA PERAHIA, Clemson University — The interfacial composition and structure of polymer films influence their response to external stimuli and their wetting behavior. Here we probe temperature effects on the interfacial morphology and surface energies of polytrifluoro propyl methyl siloxane-*b*-polystyrene (SiF-*b*-PS) films with SiF volume fraction of  $\varphi = 0.03$  to 0.46 using atomic force microscopy and surface tension measurement. Films were cast from toluene, selective for PS, and annealed at temperatures ranging from 75 to 210°C, below and above  $T_g$  of the PS block (~98°C). For  $\varphi = 0.03$  a network of small aggregates is formed and hardly changed over the temperature range studied. For  $\varphi = 0.16$  an asymmetric diblock, spherical aggregates at room temperature transformed to elongated ones at elevated temperatures whereas in the symmetric case, spherical assemblies at room temperature merged into larger structures. Independent of SiF fraction the contact angle increased with temperature which is indicative of migration of fluorine to the interface. Surprisingly, dewetting was not observed even annealing the film at much higher temperature than  $T_g$  of PS.

**5:06PM C42.00014 Evaluation of the end-to-end distance of chains solubilized in a polymer Langmuir monolayer by atomic force microscopy**, JIRO KUMAKI, Yamagata Univ — Polymer chain packing in two-dimensional (2D) condensed state is still not well understood. Direct observation of the chain packing in a monolayer should be the best way to understand this, however, it is still difficult even using atomic force microscopy (AFM) except for extraordinarily thick polymers. In this study, we successfully evaluate the end-to-end distance of the chains in a Langmuir-Blodgett monolayer composed of a conventional polymer by AFM. We successfully solubilized a small amount of a polystyrene-*b*-poly(methyl methacrylate)-*b*-polystyrene (PS-*b*-PMMA-*b*-PS) triblock copolymer in a PMMA Langmuir monolayer with the PS blocks being condensed as single-PS-block particles which could be used as a probe of the position of the chain ends. The evaluated end-to-end distance was 2.5 times longer than that of the 2D ideal chain, indicating the chains in the 2D monolayer are not strongly segregated but interpenetrates into other chains.

**5:18PM C42.00015 Block copolymer adsorbed layers on solids.**<sup>1</sup>, MANI SEN, Materials Science and Engineering (MSE), Stony Brook University (SBU), NY, NAISHENG JIANG, MSE, SBU, NY, BHOJE GOWD, CSIR-NIIST, India, MAYA ENDOH, TADANORI KOGA, MSE, SBU, NY — Block copolymer thin films offer a simple and effective route to fabricate highly ordered periodic microdomain structures. The fundamental, yet unsolved question is whether these highly oriented microdomain structures persist even near an impenetrable solid wall. We here report the adsorbed structures of polystyrene-block-poly(4-vinylpyridine) (PS-*block*-P4VP,  $M_w = 41,000$ , PS (weight fraction=0.81) formed on planar silicon substrates. Perpendicularly aligned cylindrical microdomains were created by solvent vapor annealing (Gowd et al., Soft Matter, 2014, 10, 7753), and the adsorbed layer was derived by solvent leaching with chloroform, a good solvent for the polymers and thereafter characterized by using atomic force microscopy, scanning electron microscopy, grazing incidence small angle x-ray scattering, and x-ray reflectivity. The results showed that both PS and P4VP chains lie flat on the substrate, forming a microphase-separated structure (MSS) without long-range order. Moreover, a spin-coated PS-*block*-P4VP thin film annealed under vacuum at 190 °C showed similar MSS on the substrate, indicating the generality of the interfacial polymer structure. Details will be discussed in the presentation.

**2:30PM C43.00001 Onset of erosion and sediment transport by a fluid flow over a granular bed<sup>1</sup>**, ARSHAD KUDROLLI, Clark Univ — Erosion and deposition of grains by a fluid flowing past the surface of a granular bed occurs in many natural and industrial processes. While considerable number of empirical studies has been conducted, very little is in fact known in detail on conditions which lead to erosion and deposition of sediments and their transport coefficients. We discuss a series of laboratory experiments to develop the physics of erosion starting with a single particle resting on a surface in a fluid flow. Fluorescent fluid-particle index matching techniques allow us to visualize not only the particles at the surface of a granular bed but also the flow within the bed and the individual particles within the bed. We will discuss the conditions governing the onset of particle motion under simple shear and their transport as a function of bed and fluid flow properties.

**3:06PM C43.00002 The cessation threshold of continuous sediment transport in Newtonian fluid<sup>1</sup>**, THOMAS PHTZ, Ocean College, Zhejiang University, ORENCIO DURAN, MARUM-Center for Marine Environmental Sciences, University of Bremen — One of the classical problems in sediment transport science is to predict the threshold Shields number below which a bed of loose sediment particles sheared by a homogeneous fluid flow ceases to move continuously. Depending on the particle-fluid density ratio ( $s$ ), it has been believed for many decades that this threshold is a consequence of either fluid forces being just strong enough to dislodge particles resting on the bed (small  $s$ , e.g., water) or of particle-bed impacts being just strong enough to eject sufficient bed particles (large  $s$ , e.g., air). However, here we find from state-of-the-art numerical simulations that particle-bed impacts play an important role in sustaining sediment transport regardless of  $s$ . Guided by these simulations, we propose a simple, unified analytical model of the cessation of continuous sediment transport, which is quantitatively consistent with measurements in water (the famous "Shields diagram") and air on Earth and Mars. This model predicts that sediment transport on Pluto (transport of nitrogen ice particles in a very thin nitrogen atmosphere) can be sustained under surface winds comparable to those on Earth and Mars. This might explain wind streaks on Pluto's surface which have puzzled the lead researchers of the New Horizons mission.

**3:18PM C43.00003 Rod Climbing of Suspensions**, YOUJING GUO, XIAORONG WANG, Chemical Engineering, Tongji University, Shanghai — We wish to report an unexpected effect observed for particle suspensions sucked to pass through a vertical pipe. Above a critical concentration, the suspension on the outside of the pipe may climb along the outside wall of the pipe and then display a surprising rod-climbing effect. Our study shows that the phenomenon is influenced mainly by the suspension composition, the pipe dimension and the suction speed. The effects of the pipe materials of different kinds are negligible. Increasing the suction force and the concentration increases the climbing height. Increasing the pipe diameter and wall thickness reduces the climbing effect. This behavior may be relevant to that the suspensions of the type described are all displaying markedly shear-thickening.

**3:30PM C43.00004 Laboratory investigations of granular and hydrodynamic processes in tide-water glacial fjords<sup>1</sup>**, MAC CATHLES, Michigan Society of Fellows, University of Michigan, OLUWATOYIN THOMPSON, JUSTIN BURTON, Department of Physics, Emory University — Accelerated warming in the past few decades has led to a dramatic increase in glacial activity. This is perhaps most apparent in tidewater glacial fjords, where gravitational flows from ice sheets are focused into narrow channels of thick, fast-flowing ice which terminate into the ocean. The result is a complex system involving both melting and iceberg calving which has a direct impact on the Earth's climate and sea level rise. However, there are numerous inherent difficulties in collecting field data from remote, ice-choked fjords. To address this, we use a laboratory scale model to measure aspects of tidewater glaciers which are not observable in nature. Our model has helped to uncover the source of glacial earthquakes, where floating, cubic-kilometer scaled icebergs capsize due to gravitational instability, and temporarily reverse the velocity of the glacier. In addition, we use our model to address two other important components of tidewater glaciers involving a granular ice mélange which applies stresses on the glacier, and the role of iceberg capsize in disrupting the stratified heat transport at the glacier's terminus.

<sup>1</sup>We acknowledge support from NSF DMR-1506446

**3:42PM C43.00005 A phase diagram for fluid-driven sediment transport<sup>1</sup>**, ABE CLARK, Yale University — When a fluid flows laterally over a granular bed, grains may be transported with the flow. This process shapes much of the natural world. The boundary between states with and without grain motion has been studied for decades. However, this boundary is not well understood, since the process whereby grains are transported involves the coupling of several complex phenomena: turbulent fluid flow near a rough boundary, Darcy flow through the pore structure of the granular bed, the yield strength of granular beds comprised of frictional grains with irregular shape, and inertial effects of grains that become entrained in the flow. In order to clarify the essential physics that governs the onset of granular motion, we study this process computationally by including only the minimal features and then adding complexities one by one. We start with a simple numerical model that includes only gravity, grain-grain interactions that are repulsive and frictionless, and a purely horizontal viscous fluid flow. By varying the fluid flow rate and the effective viscosity, we find behavior that is qualitatively consistent with a large collection of experimental data known as the Shields curve. Thus, our results suggest that the main features of this curve result from a competition between grain inertia and viscous damping. We find this phase diagram to be qualitatively insensitive to secondary effects, such as friction, irregular grain shape, and restitution losses.

**4:18PM C43.00006 The drag mechanics of an intruder moving in sheared granular medium<sup>1</sup>**, HU ZHENG, Hohai University, JONATHAN BARES, DONG WANG, ROBERT BEHRINGER, Duke University — We perform an experimental study on an intruder dragged at a constant force in a quasi-statically cyclic-sheared granular medium. A Teflon disk is embedded in a layer of bidisperse photoelastic disks. The granular medium is contained in a horizontal square cell, which can be deformed into a parallelogram with the same area, to produce simple shear. To explain the mechanism of intruder motion, we analyze the evolution under cyclic shear of multiple properties: coordination number, density, affine and non-affine motion of disk-granular system. We find that the motion of the intruder is strongly dependent on the fore-and-aft jam state of the intruder. The intruder can move along the drag force or opposite to the drag force, which is determined by the value of the drag force and the packing fraction of the granular system.

#### 4:30PM C43.00007 Dynamics of pull out in a granular material<sup>1</sup> , YUE ZHANG, ROBERT BEHRINGER, Duke Univ

— When an object is pulled out from a granular material, some striking phenomena can be observed. To visualize the pull out process in an experiment, we use grains composed of 2D photoelastic disks, from which circular intruders of different sizes are pulled out. We apply forces that are close to the minimum to initiate intruder motion. Then we find that the velocities of intruders depend exponentially on time, and equivalently the accelerations linearly vary with displacement. To better understand this dynamic system, we compute the drag force caused by the granular disks from the acceleration of the intruder. The result shows that the drag force depends linearly on the thickness of disks above the intruder. However, the drag force is much bigger than the weight of particles above the intruder. Additionally, we visualize the force chains formed inside the photoelastic disks and calculate the space-time evolution and curvature of those force chains. It is shown that curvatures obey the same distribution for circular intruders of different sizes.

#### 4:42PM C43.00008 How does particle shape affect the near jamming properties of granular materials? Pentagons vs. disks<sup>1</sup> , YIQIU ZHAO, JONATHAN BARES, BOB BEHRINGER, Duke University

— Understanding the role of particle shape in system-scale properties is a fundamental challenge in granular physics. We investigated the difference between the response of systems made of pentagons vs. more traditional disks. We performed isotropic compression experiments on 2D photoelastic pentagons and disks near the jamming transition. These experiments show qualitative and quantitative differences in the macroscopic responses of the two systems, such as shifts in the packing fraction at jamming onset and differences in the contact number evolution. Some of these differences are due to a reduction of packing order and the appearance of side-side contacts for the pentagons. We also examined the stress relaxation and dynamical heterogeneity of pentagon particles by performing cyclic compression to allow the system explore phase diagram. We contrast disk and pentagon evolution using four-point-susceptibility and  $G^2$  techniques.

#### 4:54PM C43.00009 The evolution of orientational order in sheared, 2D granular media of convex and concave elongated particles<sup>1</sup> , THEODORE MARSHALL, STEPHEN TEITEL, Univ of Rochester

— We simulate granular media consisting of elongated grains in two dimensions with a uniform background shear. We study the orientational distribution and rotation over a wide range of packing fractions, and find that the distribution reaches a stable steady-state under most initial conditions. The nematic director increases with the packing fraction, but the nematic order parameter exhibits non-monotonic behavior, which occurs well below jamming. We observe the evolution of the orientational distribution starting from configurations with the director out of alignment from its steady state orientation, and the evolution of highly ordered initial states. In general, the tumbling motion caused by the background shear causes such systems to reorder into the steady-state, but some dense, highly-ordered configurations maintain their order and exhibit wagging behavior. This can occur both above and below the jamming transition. These results for smooth, convex, spherocylindrical particles are contrasted with those for concave cross-like particles.

#### 5:06PM C43.00010 Stability and Structure of Star-Shape Granules<sup>1</sup> , YUCHEN ZHAO, JONATHAN BARES<sup>2</sup>, Duke Univ., Department of Physics, NC, KEVIN LIU, Julia R. Masterman Laboratory and Demonstration School, PA, MATTHEW ZHENG, North Carolina School of Science and Mathematics, NC, KAROLA DIERICH, ACHIM MENGES, Institute for Computational Design, University of Stuttgart, Stuttgart, Germany, ROBERT BEHRINGER, Duke Univ., Department of Physics, NC

— Columns made of convex noncohesive grains like sand collapse after being released from a confining container. While various architectures built by concave grains are stable. We explore why these structures are stable, and how stable they can be. We performed experiments by randomly pouring identical star-shape particles into hollow cylinders resting on glass or a roughened base, and then observed how stable these granular columns were after carefully lifting the cylinders. We used particles that are made of acrylics and have six 9 mm arms, which extend symmetrically in xyz directions. We investigated the probability of creating a stable column and other mechanical stability aspects. We define  $r$  as the weight fraction of particles that fall out of the column after the confining cylinder is removed.  $r$  gradually increases as the column height increases, or the column diameter decreases. We found high column stability when the inter-particle friction was greater. We also explored experiment conditions such as initial vibration of columns when they were confined and loading on the top. In order to understand the inner structure leading to stability, we obtained 3D CT reconstruction data of stable columns. We will discuss coordination number and orientation, etc.

#### 5:18PM C43.00011 Rheology of U-Shaped Granular Particles , MATTHEW HILL, SCOTT FRANKLIN, Rochester Institute of Technology

— We study the response of cylindrical samples of U-shaped granular particles (staples) to extensional loads. Samples elongate in discrete bursts (events) corresponding to particles rearranging and re-entangling. Previous research on samples of constant cross-sectional area found a Weibullian weakest-link theory could explain the distribution of yield points. We now vary the cross-sectional area, and find that the maximum yield pressure (force/area) is a function of particle number density and independent of area. The probability distribution function of important event characteristics the stress increase before an event and stress released during an event both fall off inversely with magnitude, reminiscent of avalanche dynamics. Fourier transforms of the fluctuating force (or stress) scales inversely with frequency, suggesting dry friction plays a role in the rearrangements. Finally, there is some evidence that dynamics are sensitive to the stiffness of the tensile testing machine, although an explanation for this behavior is unknown.

#### 2:30PM C44.00001 Universal Finite-Size Scaling around Topological Quantum Phase Transitions , TOBIAS GULDEN, MICHAEL JANAS, YUTING WANG, ALEX KAMENEV, University of Minnesota

— The critical point of a topological phase transition is described by a conformal field theory, where finite-size corrections to energy are uniquely related to its central charge. We investigate the behavior away from criticality and obtain a scaling function. In contrast to scaling functions for entanglement entropy it discriminates between phases with different topological indexes. This function appears to be universal for all five Altland-Zirnbauer symmetry classes with non-trivial topology in one spatial dimension. We obtain an analytic form of the scaling function and compare it with numerical results.

**2:42PM C44.00002 Long-range mutual information and topological uncertainty principle**, CHAO-MING JIAN, Stanford Univ, ISAAC KIM, Perimeter Institute, XIAO-LIANG QI, Stanford Univ — Ordered phases in Landau paradigm can be diagnosed by a local order parameter, whereas topologically ordered phases cannot be detected in such a way. In this paper, we propose long-range mutual information (LRMI) as a unified diagnostic for both conventional long-range order and topological order. Using the LRMI, we characterize orders in  $n+1D$  gapped systems as  $m$ -membrane condensates with  $0 \leq m \leq n-1$ . The familiar conventional order and  $2+1D$  topological orders are respectively identified as 0-membrane and 1-membrane condensates. We propose and study the topological uncertainty principle, which describes the non-commuting nature of non-local order parameters in topological orders.

**2:54PM C44.00003 Systematically Generated Two-Qubit Braids for Fibonacci Anyons**, DANIEL ZEUCH, Department of Physics and NHMFL, Florida State University, CAITLIN CARNAHAN, Department of Computer Science, Florida State University, N. E. BONESTEEL, Department of Physics and NHMFL, Florida State University — We show how two-qubit Fibonacci anyon braids can be generated using a simple iterative procedure which, in contrast to previous methods, does not require brute force search [1]. Our construction is closely related to that of [2], but with the new feature that it can be used for three-anyon qubits as well as four-anyon qubits. The iterative procedure we use, which was introduced by Reichardt [3], generates sequences of three-anyon weaves that asymptotically conserve the total charge of two of the three anyons, without control over the corresponding phase factors. The resulting two-qubit gates are independent of these factors and their length grows as  $\log 1/\epsilon$ , where  $\epsilon$  is the error, which is asymptotically better than the Solovay-Kitaev method.

**3:06PM C44.00004 Scaling and Topological Phase Transitions: Energy vs. Entropy**, YUTING WANG, TOBIAS GULDEN, MICHAEL JANAS, ALEX KAMENEV, Univ of Minnesota - Twin Cities — The critical point of a topological phase transition is described by a conformal field theory. Finite-size corrections give rise to a scaling function away from criticality for both energy and entanglement entropy of the system. While in the past the scaling function for the usual von Neumann entropy was found to be equal for the trivial and the topological side of the transition, we find that the scaling functions for energy and Renyi entropy with  $\alpha > 1$  are different for the two sides. This provides an easy tool to distinguish between the trivial and topological phases near criticality.

**3:18PM C44.00005 Ising anyons at finite temperature**, CHRIS SELF, Imperial College London, JAMES WOOTTON, University of Basel, SOFYAN IBLISDIR, Complutense University of Madrid, University of Barcelona, JIANNIS PACHOS, University of Leeds — Topological quantum computing offers a robust approach to quantum computation using braiding and fusion of anyonic particles. A particular type of anyons called Ising anyons are known to emerge from the microscopics of a spin lattice model called the Kitaev honeycomb<sup>1,2</sup>. We study the Ising anyon phase of the Kitaev honeycomb at finite temperature using Monte Carlo methods. We find evidence of the thermal fractionalization of the spins into Majorana modes, similar to the recent results of <sup>3</sup> who studied the non-Ising anyon phases of the model. We relate these findings to the finite temperature stability of the topological characteristics of the model. In addition we probe the thermal edge currents of the Kitaev honeycomb. Analogy to conformal field theory suggests that if the system has a boundary then at very low temperatures there should be a chiral edge current along that boundary that scales with  $T^2$ . By defining a microscopic current operator and taking its finite temperature expectation value we demonstrate edge currents that obey this scaling.

**3:30PM C44.00006 Robust Topological and Holographic Degeneracies of Classical Systems**, SEYYED MOHAMMAD SADEGH VAEZI, ZOHAR NUSSINOV, Washington University in St.Louis, GERARDO ORTIZ, Indiana University, Bloomington — We challenge the hypothesis that the ground states of a physical system whose degeneracy depends on topology must necessarily realize topological quantum order and display non-local entanglement. To this end, we introduce and study a classical rendition of the Toric Code model embedded on Riemann surfaces of different genus numbers. We find that the minimal ground state degeneracy (and those of all levels) depends on the topology of the embedding surface alone. As the ground states of this classical system may be distinguished by local measurements, a characteristic of Landau orders, this example illustrates that topological degeneracy is not a sufficient condition for topological quantum order. This conclusion is generic and, as shown, it applies to many other models. We also demonstrate that in certain lattice realizations of these models, and other theories, one can find a ground state entropy that is "holographic", i.e., extensive in the system's boundary.

**3:42PM C44.00007 Topological defects on the lattice**<sup>1</sup>, DAVID AASEN, Caltech, ROGER MONG, University of Pittsburgh, PAUL FENDLEY, Oxford — We construct defects in two-dimensional classical lattice models and one-dimensional quantum chains that are topologically invariant in the continuum limit. We show explicitly that these defect lines and their trivalent junctions commute with the transfer matrix/Hamiltonian. The resulting splitting and joining properties of the defect lines are exactly those of anyons in a topological phase. One useful consequence is an explicit definition of twisted boundary conditions that yield the precise shift in momentum quantization, and so provide a natural way of relating microscopic and macroscopic properties. Another is a generalization of Kramers-Wannier duality to a wide class of height models. Even more strikingly, we derive the modular transformation matrices explicitly and exactly from purely lattice considerations. We develop this construction for a variety of examples including the two-dimensional Ising model.

**3:54PM C44.00008 How quickly can anyons be braided?**, CHRISTINA KNAPP, Univ of California - Santa Barbara, DONG LIU, MENG CHENG, MICHAEL ZALETEL, PARSA BONDERSON, Microsoft Station Q, CHETAN NAYAK, Microsoft Station Q, Univ of California-Santa Barbara — Topological phases of matter are a potential platform for the storage and processing of quantum information with intrinsic error rates that decrease exponentially with inverse temperature. However, it is less well-understood how error rates depend on the speed with which anyons are braided. In general, adiabatic corrections to the Berry phase vanish inversely with the length of time for the braid, with faster decay occurring as the time-dependence is made smoother. Here, we show that such corrections will not affect quantum information encoded in a topological state unless topologically non-trivial quasiparticles are created. Moreover, we show how measurements that detect unintentionally created quasiparticles can be used to control this source of error.

**4:06PM C44.00009 Edge theory approach to topological entanglement entropy and other entanglement measures of (2+1) dimensional Chern-Simons theories on a general manifold** , XUEDA WEN, Physics Department, UIUC, SHUNJI MATSUURA, Niels Bohr Institute, University of Copenhagen & Yukawa Institute for Theoretical Physics, Kyoto University, SHINSEI RYU, Physics Department, UIUC — Topological entanglement entropy of (2+1) dimensional Chern-Simons gauge theories on a general manifold is usually calculated with Witten's method of surgeries and replica trick, in which the spacetime manifold under consideration is very complicated. In this work, we develop an edge theory approach, which greatly simplifies the calculation of topological entanglement entropy of a Chern-Simons theory. Our approach applies to a general manifold with arbitrary genus. The effect of braiding and fusion of Wilson lines can be straightforwardly calculated within our framework. In addition, our method can be generalized to the study of other entanglement measures such as mutual information and entanglement negativity of a topological quantum field theory on a general manifold.

**4:18PM C44.00010 Highly entangled tensor networks** , YINGFEI GU, DANIEL BULMASH, XIAO-LIANG QI, Stanford University — Tensor network states are used to represent many-body quantum state, e.g., a ground state of local Hamiltonian. In this talk, we will provide a systematic way to produce a family of highly entangled tensor network states. These states are entangled in a special way such that the entanglement entropy of a subsystem follows the Ryu-Takayanagi formula, i.e. the entropy is proportional to the minimal area geodesic surface bounding the boundary region. Our construction also provides an intuitive understanding of the Ryu-Takayanagi formula by relating it to a wave propagation process. We will present examples in various geometries.

**4:30PM C44.00011 Tensor network characterization of superconducting circuits** , GUILLAUME DUCLOS-CIANCI, Anyon Systems Inc., DAVID POULIN, Université de Sherbrooke, ALIREZA NAJAFI-YAZDI, Anyon Systems Inc. — Superconducting circuits are promising candidates in the development of reliable quantum computing devices. In principle, one can obtain the Hamiltonian of a generic superconducting circuit and solve for its eigenvalues to obtain its energy spectrum. In practice, however, the computational cost of calculating eigenvalues of a complex device with many degrees of freedom can become prohibitively expensive. In the present work, we investigate the application of tensor network algorithms to enable efficient and accurate characterization of superconducting circuits comprised of many components. Suitable validation test cases are performed to study the accuracy, computational efficiency and limitations of the proposed approach.

**4:42PM C44.00012 Direct Measurement of Topological Phases in Discrete-Time Quantum Walks: Theory<sup>1</sup>** , VINAY RAMASESH, EMMANUEL FLURIN, IRFAN SIDDIQI, NORMAN YAO, Department of Physics, UC Berkeley — Quantum walks have been intensively investigated theoretically, from initial studies motivated by their connection to classical randomized algorithms to more recent works demonstrating topological phenomena in these walks. In particular, quantum walks simulate dynamics under effective lattice Hamiltonians which feature spin-orbit coupling. Here, we demonstrate that by adding an additional coin operator which varies from step to step, one can perform a traversal of the effective Brillouin zone, analogous to a Bloch oscillation. The geometric phase picked up by the walker along the Bloch oscillation is a genuine signature of the walks topology, a quantity known in 1D as the Zak phase. Unlike previous interferometric proposals, our work requires neither spin-dependent Ramsey spectroscopy nor an external impurity with additional degrees of freedom. We develop a protocol, illustrating its use in a circuit QED system, which allows for the detection of the Zak phase.

<sup>1</sup>This research is supported by the ARO.

**4:54PM C44.00013 Direct Measurement of Topological Phases in Discrete-Time Quantum Walks - Experiment<sup>1</sup>** , EMMANUEL FLURIN, VINAY V RAMASESH, SHAY HACHOEN GOURGY, Quantum Nanoelectronics Laboratory, UC Berkeley, NORMAN Y YAO, Department of Physics, UC Berkeley, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — We perform quantum walks in a cavity QED architecture. Here a transmon qubit plays the role of the quantum coin, while a set of coherent states in an electromagnetic cavity forms the walker's lattice. The strong dispersive coupling between the transmon and cavity naturally implements coin-dependent translations of the walker state. The walk is performed by applying qubit rotations at equally spaced intervals; interestingly, such systems simulate dynamics under effective lattice Hamiltonians which feature strong spin-orbit coupling, leading to non-trivial band topology. By adding an additional step-dependent coin operator, we perform the first direct measurement of a quantum walk Zak phase, delineating between topologically trivial and non-trivial walks. The geometric phase is detected by implementing the quantum walk with the initial state of the walker in a superposition of a coherent state and the vacuum state, which does not partake in the walk. The Zak phase acquired by the walker thus leaves an imprint in the interference fringes of the resulting Schrödinger cat state. We observe these fringes by directly measuring the cavity Wigner function.

<sup>1</sup>This research is supported by the ARO.

**5:06PM C44.00014 On the physical realizability of quantum stochastic walks** , BRUNO TAKETANI, LUKE GOVIA, PETER SCHUHMACHER, FRANK WILHELM, Saarland University — Quantum walks are a promising framework that can be used to both understand and implement quantum information processing tasks. The recently developed quantum stochastic walk combines the concepts of a quantum walk and a classical random walk through open system evolution of a quantum system, and have been shown to have applications in as far reaching fields as artificial intelligence. However, nature puts significant constraints on the kind of open system evolutions that can be realized in a physical experiment. In this work, we discuss the restrictions on the allowed open system evolution, and the physical assumptions underpinning them. We then introduce a way to circumvent some of these restrictions, and simulate a more general quantum stochastic walk on a quantum computer, using a technique we call quantum trajectories on a quantum computer. We finally describe a circuit QED approach to implement discrete time quantum stochastic walks.

## 2:30PM C45.00001 Tunneling and Speedup in Permutation-Invariant Quantum Optimization

**Problem**, TAMEEM ALBASH, Univ of Southern California — Tunneling is often claimed to be the key mechanism underlying possible speedups in quantum optimization via the quantum adiabatic algorithm. Restricting ourselves to qubit-permutation invariant problems, we show that tunneling in these problems can be understood using the semi-classical potential derived from the spin-coherent path integral formalism. Using this, we show that the class of problems that fall under Reichardt's bound (1), i.e., have a constant gap and hence can be efficiently solved using the quantum adiabatic algorithm, do not exhibit tunneling in the large system-size limit. We proceed to construct problems that do not fall under Reichardt's bound but numerically have a constant gap and do exhibit tunneling. However, perhaps counter-intuitively, tunneling does not provide the most efficient mechanism for finding the solution to these problems. Instead, an evolution involving a sequence of diabatic transitions through many avoided level-crossings, involving no tunneling, is optimal and outperforms tunneling in the adiabatic regime. In yet another twist, we show that in this case, classical spin-vector dynamics is as efficient as the diabatic quantum evolution (2).

## 3:06PM C45.00002 Understanding Quantum Tunneling through Quantum Monte Carlo Simulations

, SERGIO BOIXO, SERGEI ISAKOV, Google Inc., GUGLIELMO MAZZOLA, ETH, VADIM SMELYANSKIY, Google Inc., ZHANG JIANG, Nasa Ames, HARTMUT NEVEN, Google Inc., MATTHIAS TROYER, ETH — The tunneling between the two ground states of an Ising ferromagnet is a typical example of many-body tunneling processes between two local minima, as they occur during quantum annealing. Performing quantum Monte Carlo (QMC) simulations we find that the QMC tunneling rate displays the same scaling (in the exponent) with system size, as the rate of incoherent tunneling. The scaling in both cases is  $O(\Delta^2)$ , where  $\Delta$  is the tunneling splitting. An important consequence is that QMC simulations can be used to predict the performance of a quantum annealer for tunneling through a barrier. Furthermore, by using open instead of periodic boundary conditions in imaginary time, equivalent to a projector QMC algorithm, we obtain a quadratic speedup for QMC, and achieve linear scaling in  $\Delta$ . We provide a physical understanding of these results and their range of applicability based on an instanton picture.

## 3:18PM C45.00003 Coupled Quantum Fluctuations and Quantum Annealing

, LAYLA HORMOZI, Massachusetts Institute of Technology, JAMIE KERMAN, MIT Lincoln Laboratory — We study the relative effectiveness of coupled quantum fluctuations, compared to single spin fluctuations, in the performance of quantum annealing. We focus on problem Hamiltonians resembling the Sherrington-Kirkpatrick model of Ising spin glass and compare the effectiveness of different types of fluctuations by numerically calculating the relative success probabilities and residual energies in fully-connected spin systems. We find that for a small class of instances coupled fluctuations can provide improvement over single spin fluctuations and analyze the properties of the corresponding class. Disclaimer: This research was funded by ODNI, IARPA via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

## 3:30PM C45.00004 Performance of error suppression schemes for adiabatic quantum computation in the presence of Markovian noise

, MILAD MARVIAN, DANIEL LIDAR, None — We investigate the performance of error suppression schemes for adiabatic quantum computation. Assuming a Markovian environment and using an adiabatic master equation we compare the rate of excitation from the ground subspace of the encoded Hamiltonian during the evolution to that of the unprotected Hamiltonian. For different forms of Markovian environments such as sub-Ohmic, Ohmic and super-Ohmic we identify the parameter thresholds for which encoding starts exhibiting its benefits.

## 3:42PM C45.00005 Coping with noise in programmable quantum annealers

, ALEJANDRO PERDOMO-ORTIZ, NASA/Ames Res Ctr — Solving real-world applications with quantum annealing algorithms requires overcoming several challenges, ranging from translating the computational problem at hand to the quantum-machine language, to tuning several other parameters of the quantum algorithm that have a significant impact on performance of the device. In this talk, we discuss these challenges, strategies developed to enhance performance, and also a more efficient implementation of several applications. For example, in <http://arxiv.org/abs/1503.05679> we proposed an method to measure residual systematic biases in the programmable parameters of large-scale quantum annealers. Although the method described there works from a practical point of view, a few questions were left unanswered. One of these puzzles was the observation of a broad distribution in the estimated effective qubit temperatures throughout the device. In this talk, we will present our progress in understanding these puzzles and how these new insights allow for a more effective bias correction protocol. We will present the impact of these new parameter setting and bias correction protocols in the performance of hard discrete optimization problems and in the successful implementation of quantum-assisted machine-learning algorithms.

## 3:54PM C45.00006 Does finite-temperature decoding deliver better optima for noisy Hamiltonians?

, ANDREW J. OCHOA, Department of Physics and Astronomy, Texas A&M University, KOHJI NISHIMURA, HIDETOSHI NISHIMORI, Department of Physics, Tokyo Institute of Technology, HELMUT G. KATZGRABER, Department of Physics and Astronomy, Texas A&M University — The minimization of an Ising spin-glass Hamiltonian is an NP-hard problem. Because many problems across disciplines can be mapped onto this class of Hamiltonian, novel efficient computing techniques are highly sought after. The recent development of quantum annealing machines promises to minimize these difficult problems more efficiently. However, the inherent noise found in these analog devices makes the minimization procedure difficult. While the machine might be working correctly, it might be minimizing a different Hamiltonian due to the inherent noise. This means that, in general, the ground-state configuration that correctly minimizes a noisy Hamiltonian might not minimize the noise-less Hamiltonian. Inspired by rigorous results that the energy of the noise-less ground-state configuration is equal to the expectation value of the energy of the noisy Hamiltonian at the (nonzero) Nishimori temperature [J. Phys. Soc. Jpn., 62, 40132930 (1993)], we numerically study the decoding probability of the original noise-less ground state with noisy Hamiltonians in two space dimensions, as well as the D-Wave Inc. Chimera topology. Our results suggest that thermal fluctuations might be beneficial during the optimization process in analog quantum annealing machines.

## 4:06PM C45.00007 Estimation of effective temperatures in a quantum annealer: Towards deep learning applications<sup>1</sup>

, JOHN REALPE-GÓMEZ, MARCELLO BENEDETTI, ALEJANDRO PERDOMO-ORTIZ, NASA/Ames Res Ctr — Sampling is at the core of deep learning and more general machine learning applications; an increase in its efficiency would have a significant impact across several domains. Recently, quantum annealers have been proposed as a potential candidate to speed up these tasks, but several limitations still bar them from being used effectively. One of the main limitations, and the focus of this work, is that using the device's experimentally accessible temperature as a reference for sampling purposes leads to very poor correlation with the Boltzmann distribution it is programmed to sample from. Based on quantum dynamical arguments, one can expect that if the device indeed happens to be sampling from a Boltzmann-like distribution, it will correspond to one with an instance-dependent effective temperature. Unless this unknown temperature can be unveiled, it might not be possible to effectively use a quantum annealer for Boltzmann sampling processes. In this work, we propose a strategy to overcome this challenge with a simple effective-temperature estimation algorithm. We provide a systematic study assessing the impact of the effective temperatures in the quantum-assisted training of Boltzmann machines, which can serve as a building block for deep learning architectures.

**4:18PM C45.00008 Hard scheduling problems for early quantum annealer**, ZHIHUI WANG, NASA Quantum Artificial Intelligence Laboratory; Univ Space Research Assn, TONY TRAN, BRYAN O'GORMAN, NASA Quantum Artificial Intelligence Laboratory, MINH DO, JEREMY FRANK, NASA Ames Research Center, ELEANOR RIEFFEL, NASA Quantum Artificial Intelligence Laboratory, NASA Ames Research Center, NASA QUANTUM ARTIFICIAL INTELLIGENCE LABORATORY TEAM, NASA PLANNING AND SCHEDULING GROUP TEAM — We present a parameterized family of single machine scheduling problem that exhibits an easy-hard-easy phase transition. As the parameter is varied, the problem goes through a fast transition from being almost trivial to find a solution to almost always has no solution, this sharp transition accompanies a peak in computational effort. While implementing realistic-sized problems on an early quantum annealing device is still a challenge in near future, using a benchmarking problem set of small size but in a well-defined hard family, one can gain insight to a how the solving time scales for the whole family.[1] We will report quantum annealing results on this and other related problems. [1] E. G. Rieffel, D. Venturelli, B. O'Gorman, M. B. Do, E. M. Prystay, and V. N. Smelyanskiy, Quantum Information Processing 14, 1 (2015).

**4:30PM C45.00009 Accurate Variational Description of Adiabatic Quantum Optimization**, GIUSEPPE CARLEO, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, BELA BAUER, Station Q, Microsoft Research, Santa Barbara, CA 93106-6105, USA, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland — Adiabatic quantum optimization (AQO) is a quantum computing protocol where a system is driven by a time-dependent Hamiltonian. The initial Hamiltonian has an easily prepared ground-state and the final Hamiltonian encodes some desired optimization problem. An adiabatic time evolution then yields a solution to the optimization problem. Several challenges emerge in the theoretical description of this protocol: on one hand, the exact simulation of quantum dynamics is exponentially complex in the size of the optimization problem. On the other hand, approximate approaches such as tensor network states (TNS) are limited to small instances by the amount of entanglement that can be encoded. I will present here an extension of the time-dependent Variational Monte Carlo approach to problems in AQO. This approach is based on a general class of (Jastrow-Feenberg) entangled states, whose parameters are evolved in time according to a stochastic variational principle. We demonstrate this approach for optimization problems of the Ising spin-glass type. A very good accuracy is achieved when compared to exact time-dependent TNS on small instances. We then apply this approach to larger problems, and discuss the efficiency of the quantum annealing scheme in comparison with its classical counterpart.

**4:42PM C45.00010 Optimizing Quantum Adiabatic Algorithm**, HONGYE HU, BIAO WU, Peking Univ — In quantum adiabatic algorithm, as the adiabatic parameter  $s(t)$  changes slowly from zero to one with finite rate, a transition to excited states inevitably occurs and this induces an intrinsic computational error. We show that this computational error depends not only on the total computation time  $T$  but also on the time derivatives of the adiabatic parameter  $s(t)$  at the beginning and the end of evolution. Previous work (Phys. Rev. A 82, 052305) also suggested this result. With six typical paths, we systematically demonstrate how to optimally design an adiabatic path to reduce the computational errors. Our method has a clear physical picture and also explains the pattern of computational error. In this paper we focus on quantum adiabatic search algorithm although our results are general.

**4:54PM C45.00011 Learning quantum annealing**, ELIZABETH BEHRMAN, JAMES STECK, Wichita State University — We propose and develop a new quantum algorithm, whereby a quantum system can learn to anneal to a desired ground state. We demonstrate successful learning of entanglement for a two-qubit system, then bootstrap to larger systems. We also show that the method is robust to noise and decoherence.

**5:06PM C45.00012 Josephson Circuits as Vector Quantum Spins**, GABRIEL SAMACH, ANDREW J. KERMAN, MIT Lincoln Laboratory — While superconducting circuits based on Josephson junction technology can be engineered to represent spins in the quantum transverse-field Ising model, no circuit architecture to date has succeeded in emulating the vector quantum spin models of interest for next-generation quantum annealers and quantum simulators. Here, we present novel Josephson circuits which may provide these capabilities. We discuss our rigorous quantum-mechanical simulations of these circuits, as well as the larger architectures they may enable. This research was funded by the Office of the Director of National Intelligence (ODNI) and the Intelligence Advanced Research Projects Activity (IARPA) under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

**5:18PM C45.00013 Distortion of a reduced equilibrium density matrix**, IRIS SCHWENK, MICHAEL MARTHALER, Karlsruhe Institute of Technology — We study a system coupled to external degrees of freedom, called bath, where we assume that the total system, consisting of system and bath is in equilibrium. An expansion in the coupling between system and bath leads to a general form of the reduced density matrix of the system as a function of the bath selfenergy. The coupling to the bath results in a renormalization of the energies of the system and in a change of the eigenbasis. We study the influence of bosonic degrees of freedom on the state of a six qubit system similar to the eight qubit unit cell of a quantum annealing processor examined by Lanting et al.<sup>1</sup>.

<sup>1</sup>T. Lanting et al., Phys. Rev. X 4, 021041 (2014).

**5:30PM C45.00014 Quantum annealing via quantum diffusion mediated by environment**, VADIM SMELYANSKIY, Google, DAVIDE VENTURELLI, University Space Research Association, ALEJANDRO PERDOMO-ORTÍZ, University of California Santa Cruz, SERGEI KNYSH, Stinger Ghaffarian Technologies, Inc, MARK DYKMAN, Department of Physics and Astronomy, Michigan State University — We show that quantum diffusion near the quantum critical point can provide an efficient mechanism of open-system quantum annealing. The analysis refers to an Ising spin chain in a slowly decreasing transverse field coupled to bosonic heat bath. The diffusion facilitates recombination of collective (multi-spin) excitations in the chain. It sharply slows down as the system moves away from the quantum critical region, leading to significant spatial fluctuations even in the absence of disorder. The excitation density reached by then non-monotonically depends on the annealing rate. We find that obtaining an approximate solution via diffusion-mediated quantum annealing can be faster than via classical Glauber dynamics or the closed-system Kibble-Zurek mechanism. We study the scaling of the excitation density with the temperature and coupling constant to environment.

Session C46 GIMS: Instrumentation II: Spectroscopy 311 - Angela Hight-Walker, NIST

**2:30PM C46.00001 Temperature Controlling Digital Cameras for Time-Resolved Angle-Resolved Photoemission Spectroscopy**, ALEXANDER NGUYEN, GREGORY AFFELDT, KENNETH GOTLIEB, ALESSANDRA LANZARA, University of California, Berkeley — Angle-resolved photoemission spectroscopy experiments (ARPES) use charged couple device (CCD) detectors to measure the spectra of various material. A CCD measures the number of photons that hit it; a problem with CCDs is that thermal energy can create false photon counts. By building a temperature controller the CCD's temperature is lowered to reduce the number of false counts, similarly, the temperature controller keeps the temperature stable reducing the randomness in false counts.

**2:42PM C46.00002 Towards Laser-based Angle-Resolved Photoemission Spectroscopy at Ultralow Temperatures**, TEJAS DESHPANDE, JOHN HARTER, California Institute of Technology, ALEXEI FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, DAVID HSIEH, California Institute of Technology — Recent technical advances in angle-resolved photoemission spectroscopy (ARPES) have enabled electronic structures of solids to be mapped at sub-Kelvin temperatures [1] or with sub-meV energy resolution [2]. However, achieving both conditions simultaneously remains an ongoing effort in the ARPES community. To this end, we discuss our progress in employing a laser-based source to perform ARPES of novel materials at ultralow temperatures.

**2:54PM C46.00003 Positron spectroscopy of 2D materials using an advanced high intensity positron beam<sup>1</sup>**, A MCDONALD, V CHIRAYATH, Z LIM, R GLADEN, M CHRYSLER, A FAIRCHILD, A KOYMEN, A WEISS, Univ of Texas, Arlington — An advanced high intensity variable energy positron beam (~1eV to 20keV) has been designed, tested and utilized for the first coincidence Doppler broadening (CDB) measurements on 6-8 layers graphene on polycrystalline Cu sample. The system is capable of simultaneous Positron annihilation induced Auger electron Spectroscopy (PAES) and CDB measurements giving it unparalleled sensitivity to chemical structure at external surfaces, interfaces and internal pore surfaces. The system has a 3m flight path up to a micro channel plate (MCP) for the Auger electrons emitted from the sample. This gives a superior energy resolution for PAES. A solid rare gas (Neon) moderator was used for the generation of the monoenergetic positron beam. The positrons were successfully transported to the sample chamber using axial magnetic field generated with a series of Helmholtz coils. We will discuss the PAES and coincidence Doppler broadening measurements on graphene-Cu sample and present an analysis of the gamma spectra which indicates that a fraction of the positrons implanted at energies 7-60eV can become trapped at the graphene/metal interface.

**3:06PM C46.00004 Stimulated Resonant X-Ray Emission in Solids**, ZHAO CHEN, DANIEL HIGLEY, Stanford University, MARKUS HANTSCHMANN, Helmholtz-Zentrum Berlin, VIRAT MEHTA, HGST, MARTIN BEYE, Helmholtz-Zentrum Berlin, WILLIAM SCHLOTTER, JOACHIM STOHR, SLAC — We present direct evidence of resonant stimulated X-Ray emission in magnetically patterned Co/Pd multilayers. At a free electron laser, we measure X-Ray transmission through Co/Pd of ultrafast (~2fs) X-Ray pulses at the Co  $L_3$  edge for fluences of up to 2 J/cm<sup>2</sup>/fs simultaneously in the transmission and scattering geometries. With increasing fluence, we observe a nonlinear decrease in first-order scattering intensity together with a compensating increase in transmitted forward intensity for all energies within the Co resonant absorption edge. At high enough fluences (>1 J/cm<sup>2</sup>/fs), the sample absorption spectrum and scattering intensity are both suppressed by over two orders of magnitude, leaving the sample effectively transparent to X-Rays. In our geometry, these two effects are indicative of elastic stimulated scattering, which favors forward transmission at the cost of scattered intensity in all other directions. We then show that our data is well-described by stimulated emission calculations using the optical Bloch equations. Our dual measurement serves as a pioneering study of X-Ray stimulated processes, and paves the way for experiments on realizing potentially powerful X-Ray spectroscopic techniques such as stimulated RIXS.

**3:18PM C46.00005 Extreme-ultraviolet ultrafast ARPES at high repetition rates**, JAN BUSS, HE WANG, YIMING XU, SEBASTIAN STOLL, LINGKUN ZENG, STEFAN ULONSKA, JONATHAN DENLINGER, ZAHID HUSSAIN, CHRIS JOZWIAK, ALESSANDRA LANZARA, ROBERT KAINDL, Lawrence Berkeley National Laboratory — Time- and angle-resolved photoemission spectroscopy (trARPES) represents a powerful approach to resolve the electronic structure and quasiparticle dynamics in complex materials, yet is often limited in either momentum space (incident photon energy), probe sensitivity (pulse repetition rate), or energy resolution. We demonstrate a novel table-top trARPES setup that combines a bright 50-kHz source of narrowband, extreme ultraviolet (XUV) pulses at 22.3 eV with UHV photoemission instrumentation to sensitively access dynamics for a large momentum space. The output of a high-power Ti:sapphire amplifier is split to provide the XUV probe and intense photoexcitation (up to mJ/cm<sup>2</sup>). A vacuum beamline delivers spectral and flux characterization, differential pumping, as well as XUV beam steering and toroidal refocusing onto the sample with high incident flux of 3x10<sup>11</sup> ph/s. Photoemission studies are carried out in a customized UHV chamber equipped with a hemispherical analyzer (R4000), six-axis sample cryostat, and side chambers for sample loading, storage and preparation. An ARPES energy resolution down to 70 meV with the direct XUV output is demonstrated. We will discuss initial applications of this setup including Fermi surface mapping and trARPES of complex materials.

**3:30PM C46.00006 Role of Spatial Chirp in High Harmonic Extreme Ultraviolet (XUV) Absorption Spectroscopy of Thin Films**, MING-FU LIN, University of Illinois at Urbana-Champaign — XUV light from high harmonic generation is an emerging new tool for studying ultrafast dynamics. Such sources have intrinsic “spatial chirp” that can cause significant periodic artifacts in absorption spectra of inhomogeneous samples. We show that a uniform thin-film morphology is required in order to obtain harmonic-structure free absorption spectra, especially for organometallic complexes that have strong non-resonant absorption features from the organic ligands. Demonstration of several static absorption spectra of different organometallic complexes and perovskite materials reveals elemental, oxidation state, and band structure specificity in agreement with theoretical results.

**3:42PM C46.00007 High Power Terahertz Fields Generated by an Arrayed Photoconductive Antenna Structure**, BENJAMIN GRABER, DONG HO WU, US Naval Research Laboratory, CHRISTOPHER KIM, Temple University — Terahertz spectroscopy has a wide array of scientific, commercial, and industrial applications. However, to date, terahertz signal strength of available commercial systems is limited to less than 100 uW in average terahertz power. It is expected that with enhanced terahertz power one may be able to obtain better terahertz spectral information, and enable more practical terahertz applications in real environments. In order to achieve this goal we experimentally constructed an arrayed photoconductive antenna structure, in which terahertz signals from a few photoconductive antennas are combined by adjusting every terahertz signals to be in phase. The collected signals from the multiple emitters are concentrated onto a small area so that the combined terahertz signal strength is over 1mW in average power and peak electric field over 16kV/m. The terahertz frequency spectrum of combined signals is unaltered and exactly the same as that of each individual photoconductive antenna, which spans from 100GHz to 3THz. Experimental details regarding power measurement, time domain signals, and frequency spectra analysis will be discussed. This prototype array structure appears to scale linearly with the addition of photoconductive antennas.

**3:54PM C46.00008 Terahertz nano-spectroscopy and imaging of superfluid surface plasmons in conventional and anisotropic superconductors**, H. T. STINSON, J. S. WU, B. Y. JIANG, University of California, San Diego, Z. FEI, Iowa State University, A. S. RODIN, National University of Singapore, B. CHAPLER, A. S. MCLEOD, University of California, San Diego, A. CASTRO NETO, National University of Singapore, Y. S. LEE, Soongsil University, M. M. FOGLER, D. N. BASOV, University of California, San Diego — We numerically model near-field spectroscopy and superfluid polariton imaging experiments on conventional and unconventional superconductors in the infrared and terahertz regime. Our modeling shows that near-field spectroscopy can measure the magnitude of the superconducting gap in Bardeen-Cooper-Schrieffer superconductors with nanoscale spatial resolution. We demonstrate how the same technique can measure the  $c$ -axis plasma frequency, and thus the  $c$ -axis superfluid density, of layered unconventional superconductors such as cuprates and pnictides with identical spatial resolution. We discuss the development of a cryogenic terahertz near-field microscope designed to perform these proposed experiments, and recent proof of principle results at room temperature.

**4:06PM C46.00009 Inkjet Printed Wire-Grid Polarizers for the THz Frequency Range<sup>1</sup>**, A. FARID, N. J. LAURITA, Johns Hopkins Univ, B. TEHRANI, J. HESTER, M. M. TENTZERIS, Georgia Institute of Technology, N. P. ARMITAGE, Johns Hopkins Univ — We have investigated the use of inkjet printing technology for the production of THz range wire-grid polarizers using time-domain terahertz spectroscopy. Such technology affords a cheap and reproducible way of quickly manufacturing THz range metamaterial structures. Thin silver-nanoparticle ink lines were printed using a Dimatix DMP-2831 printer. We investigated the optimal printing geometry of the polarizers by looking at a number of samples with printed wires of varying thickness and spacing. We also investigate the ultimate capabilities of these polarizers by investigating their properties when stacked.

## Monday, March 14, 2016 2:30PM - 5:30PM – Session C47 DCMP: Surface, Growth, and Morphology 312 -

**2:30PM C47.00001 Observation of heterodyne and homodyne mixing in X-ray photon correlation spectroscopy during thin film deposition<sup>1</sup>**, RANDALL HEADRICK, JEFFREY ULBRANDT, University of Vermont, MELIHA RAINVILLE, CHRISTA WAGENBACH, Boston University, SURESH NARAYANAN, ALEC SANDY, HUA ZHOU, Argonne National Laboratory, KARL LUDWIG, Boston University — The properties of artificially grown thin films are often strongly affected by the dynamic relationship between surface growth processes and subsurface structure. Coherent mixing of X-ray signals promises to provide an approach to better understand such processes. Continuously variable mixing of surface and bulk scattering signals during real-time studies of sputter deposition of a-Si and a-WiSi<sub>2</sub> films has been observed by controlling the X-ray penetration and escape depths in coherent grazing incidence small angle X-ray scattering (Co-GISAXS). Under conditions where the X-ray signal comes from both the growth surface and the thin film bulk, oscillations in temporal correlations arise from coherent interference between scattering from stationary bulk features and from the advancing surface. The absence of oscillations at larger in-plane wavevector transfer is interpreted as evidence that elongated bulk features propagate upward at the same velocity as the surface. Additionally, a highly surface sensitive mode is demonstrated that can access the surface dynamics independently of the subsurface structure.

**2:42PM C47.00002 Unusual “Explosive” Nucleation and Superdiffusion in Pb/Si(111)-7x7<sup>1</sup>**, M. T. HERSHBERGER, Iowa State University and Ames Laboratory, M. HUPALO, Ames Laboratory, P. A. THIEL, Iowa State University and Ames Laboratory, H. HATTAB, Ames Laboratory, M. HORN VON HOEGEN, University of Duisburg-Essen, M. C. TRINGIDES, Iowa State University and Ames Laboratory — The study of the recently found “explosive” nucleation on Pb/Si(111) was further investigated to understand the origin of the sharp transition in coverage and the presence of superdiffusive motion. After small stepwise depositions of ~0.03 ML spatial correlations in the growth direction of neighboring islands are observed. The island growth rates are much higher than what is expected in classical nucleation. Islands collect material many times larger than the amount deposited in the surrounding Voronoi areas contrary to classical expectations. Their centers of mass shift by large amounts, ~10nm, again confirming the directionality in their growth and that material must be arriving over mesoscale distances. The island size distributions do not agree with the expected sharply peaked classical distributions since only fully completed islands are observed. Further depositions show additional nucleation of smaller islands and with higher densities thus conforming that when the critical coverage is reached locally the island nucleation is still active. Comparisons will be made between the diffusion length deduced in these experiments and the one extracted from earlier LEEM experiments monitoring the refilling of an initial vacant area.

<sup>1</sup>Ames Laboratory is operated by the US-DOE under Contract No. DE-AC02-07CH11358.

**2:54PM C47.00003 Submonolayer island growth with anomalous diffusion<sup>1</sup>**, JACQUES AMAR, University of Toledo, MIKHAEEL SEMAAN, California State University, Long Beach — Island nucleation and growth play an important role in the early stages of thin-film growth. Of particular interest is the exponent  $\chi$  which describes the dependence of the peak island density on deposition flux, and which also depends sensitively on the critical island-size  $i$ . While the dependence of  $\chi$  on  $i$  is known for normal diffusion, the case of anomalous monomer diffusion is also of interest, since this appears to play a role in recent experiments. Here we derive general expressions for  $\chi$  which are valid for arbitrary substrate dimension, island fractal dimension, critical island size, and monomer diffusion exponent  $\mu$ . Excellent agreement is obtained between our predictions and kinetic Monte Carlo simulations carried out for the case of irreversible growth ( $i = 1$ ), and monomer superdiffusion with  $1 < \mu \leq 2$ , although unusually large crossover effects are also observed. These results also confirm and generalize a previous prediction for the case of ballistic diffusion ( $\mu = 2$ ). We also consider the case of monomer subdiffusion corresponding to  $0 \leq \mu < 1$ . Good agreement with our predictions for  $\chi(\mu)$  is also found in this case, although the general scaling behavior is more complex due to the presence of large fluctuations.

**3:06PM C47.00004 Interaction of Dysprosium with the Basal Plane of Graphite.**, PATRICIA THIEL, Ames Laboratory, EMMA KWOLEK, Iowa State University, HUAPING LEI, Key Laboratory of Materials Physics, Institute of Solid State Physics, CAS, YINGHUI ZHOU, Department of Physics, Xiamen University, ANN LII-ROSALES, Iowa State University, MARK WALLINGFORD, CAI-ZHUANG WANG, MICHAEL TRINGIDES, Ames Laboratory — We have studied adsorption, nucleation, growth, intercalation, and carburization of dysprosium (Dy) on graphite surfaces, and the way that these phenomena are influenced by surface defects. The experiments consist of scanning tunneling microscopy in ultrahigh vacuum. The condensation coefficient of Dy is strongly enhanced by surface defects. In the absence of defects, at room temperature, homogeneous nucleation can occur on terraces, consistent with DFT calculations of energetics. At room temperature, island shapes consist of a flat three-atom base, decorated by single-atom upper layers. Layer populations in such islands are analyzed in the context of a tailored analytic model, which provides information about interlayer mobility. At elevated temperature, Dy can intercalate with the graphite substrate and can form carbide.

**3:18PM C47.00005 Thermal evolution of Fe on  $Ge(111) - c(2 \times 8)$  surface and the effect of  $(\sqrt{3} \times \sqrt{3})$  Ag-Ge buffer layer**, TSU-YI FU, HUNG-CHANG HSU, MING-KUAN JHOU, JIA-YUAN WU, Department of Physics, National Taiwan Normal University — Using scanning tunneling microscopy, two systems of Fe deposition on a clean  $Ge(111) - c(2 \times 8)$  surface and surfaces with a  $(\sqrt{3} \times \sqrt{3})$   $R30^\circ$  Ag-Ge buffer layer were compared. Complex surface alloy structures were easily formed on Fe/Ge systems through annealing at 300-650 K. On clean  $Ge(111)$  surfaces, similar surface morphology evolution was observed when two different amounts of Fe were deposited. To reduce the complexity,  $(\sqrt{3} \times \sqrt{3})$   $R30^\circ$  Ag-Ge interface were used as buffer layers. The growth morphologies differed in the presence and absence of the buffer layers. After heat treatment to 570 K,  $(2 \times 2)$  reconstruction platform islands were formed in the Fe/Ge system, which transformed to three-dimensional (3D) islands at 640 K. With Ag buffer layer, only nanoparticle growth occurred and 3D islands were formed early at 570 K. Generally,  $\sqrt{19}$  ring clusters increased to break the order  $c(2 \times 8)$  reconstruction by increasing the temperature and disappeared at 640 K in Fe-Ge system, but only  $\sqrt{7}$  ring clusters appeared at 390 K with  $(\sqrt{3} \times \sqrt{3})$   $R30^\circ$  Ag-Ge buffer layer.

**3:30PM C47.00006 Free energy of steps using atomistic simulations<sup>1</sup>**, RODRIGO FREITAS, TIMOFEY FROLOV, MARK ASTA, Department of Materials Science and Engineering, University of California, Berkeley — The properties of solid-liquid interfaces are known to play critical roles in solidification processes. Particularly special importance is given to thermodynamic quantities that describe the equilibrium state of these surfaces. For example, on the solid-liquid-vapor heteroepitaxial growth of semiconductor nanowires the crystal nucleation process on the faceted solid-liquid interface is influenced by the solid-liquid and vapor-solid interfacial free energies, and also by the free energies of associated steps at these faceted interfaces. Crystal-growth theories and mesoscale simulation methods depend on quantitative information about these properties, which are often poorly characterized from experimental measurements. In this work we propose an extension of the capillary fluctuation method for calculation of the free energy of steps on faceted crystal surfaces. From equilibrium atomistic simulations of steps on (111) surfaces of Copper we computed accurately the step free energy for different step orientations. We show that the step free energy remains finite at all temperature up to the melting point and that the results obtained agree with the more well established method of thermodynamic integration if finite size effects are taken into account.

**3:42PM C47.00007 Low temperature Silicon epitaxy on bare Si (100) and H terminated Si (100) surfaces**, XIAO DENG, PRADEEP NAMBOODIRI, KAI LI, NIST - Natl Inst of Stds & Tech, XIQIAO WANG, University of Maryland, College Park, TONGBAO LI, Tongji University, Shanghai, China, RICHARD SILVER, NIST - Natl Inst of Stds & Tech — Silicon on Silicon growth morphology is studied using an ultrahigh vacuum scanning tunneling microscopy (UHV-STM) and transmission electron microscopy (TEM). Sub-monolayer to 18 nm of silicon was evaporated using an all-silicon sublimation source (SUSI) onto a UHV prepared Si (100) sample at 250C. The results are compared with the growth characteristics on hydrogen passivated surfaces (H: Si) under identical experimental conditions. STM images indicate that growth morphology of both Si on Si and Si on H: Si is of epitaxial nature at temperatures as low as 250C. For Si on bare Si growth at 250C, there exists a stable thickness regime where Si epitaxial growth front keeps the same morphology. Although the mobility of silicon is modestly affected on the H: Si surface because of the H atoms during the initial sub-monolayer regime, the growth proceeds epitaxially with the 3D island growth mode and noticeable surface roughening.

**3:54PM C47.00008 A diffuse interface model of grain boundary faceting<sup>1</sup>**, FADI ABDELJAWAD, DOUGLAS MEDLIN, JONATHAN ZIMMERMAN, KHALID HATTAR, STEPHEN FOILES, Sandia National Laboratories — Incorporating anisotropy into thermodynamic treatments of interfaces dates back to over a century ago. For a given orientation of two abutting grains in a pure metal, depressions in the grain boundary (GB) energy may exist as a function of GB inclination, defined by the plane normal. Therefore, an initially flat GB may facet resulting in a hill-and-valley structure. Herein, we present a diffuse interface model of GB faceting that is capable of capturing anisotropic GB energies and mobilities, and accounting for the excess energy due to facet junctions and their non-local interactions. The hallmark of our approach is the ability to independently examine the role of each of the interface properties on the faceting behavior. As a demonstration, we consider the  $\Sigma 5$  (001) tilt GB in iron, where faceting along the {310} and {210} planes was experimentally observed. Linear stability analysis and numerical examples highlight the role of junction energy and associated non-local interactions on the resulting facet length scales. On the whole, our modeling approach provides a general framework to examine the spatio-temporal evolution of highly anisotropic GBs in polycrystalline metals.

<sup>1</sup>Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under Contract DE-AC04-94AL85000

**4:06PM C47.00009 External-Field-Driven Nanopatterning on Crystalline Substrate Surfaces**, ASHISH KUMAR, DWAIPAYAN DASGUPTA, DIMITRIOS MAROUDAS, Univ of Mass - Amherst — Current-driven dynamics of single-layer epitaxial islands on fcc crystalline substrates can lead to surface pattern formation with significant implications for nanofabrication. We have developed and validated a fully nonlinear model of driven island evolution on {110}, {100} and {111} substrate surfaces due to diffusional mass transport along the island edge and accounting for edge diffusional anisotropy. We find that the migration speed of a morphologically stable island is inversely proportional to the island size,  $R$ , up to a critical size that marks the onset of island morphological transition; further increase in  $R$  triggers edge fingering and/or necking or dynamical transitions. We report formation of complex nanopatterns emerging from individual larger-than-critical islands with two different types of initial configuration: a slender, high-aspect-ratio island shape and an equilibrium, rounded morphology. We have developed a linear stability theory that explains the observed morphological instabilities. We characterize the nanopatterns formed and study the dependence of the nanopattern features on the duration of application of the electric field and the misorientation angle between a fast edge diffusion direction and the electric field direction.

**4:18PM C47.00010 Progress in Application of Generalized Wigner Distribution to Growth and Other Problems<sup>1</sup>**, T.L. EINSTEIN, JOSUE MORALES-CIFUENTES, Univ. Maryland, College Park, ALBERTO PIMPINELLI, Rice Quantum Institute, DIEGO LUIS GONZALEZ, Univ. del Valle, Cali, Colombia — We recap the use of the (single-parameter) Generalized Wigner Distribution (GWD) to analyze capture-zone distributions associated with submonolayer epitaxial growth<sup>2</sup>. We discuss recent applications to physical systems, as well as key simulations. We pay particular attention to how this method compares with other methods to assess the critical nucleus size characterizing growth. The following talk discusses a particular case when special insight is needed to reconcile the various methods. We discuss improvements that can be achieved by going to a 2-parameter fragmentation approach. At a much larger scale we have applied this approach to various distributions in socio-political phenomena (areas of secondary administrative units [e.g., counties] and distributions of subway stations).

<sup>2</sup>TLE, AP, DLG, J. Cryst. Growth 401, 67 (2014); TLE, JRM-C, AP, DLG, J. Phys. Conf. Ser. 640, 012024 (2015).

**4:30PM C47.00011 Role of Transient Mobility on Submonolayer Island Growth: Extensions and Testing<sup>1</sup>**, JOSUE MORALES CIFUENTES, THEODORE EINSTEIN, Univ of Maryland-College Park, ALBERTO PIMPINELLI, Rice Quantum Institute — In studies of epitaxial growth a major goal is assessing the smallest stable cluster ( $i + 1$  monomers, with  $i$  the critical nucleus size), by analyzing the capture zone distribution (CZD) or the scaling of incident flux  $F$  to the density of stable islands  $N$  ( $N \propto F^\alpha$ , with  $\alpha$  the growth exponent). As noted in the previous talk, the GWD has well described the data in several experiments, including submonolayer para-hexaphenyl (6P) on amorphous mica ( $i \approx 3$ ). Different scaling ( $F^\alpha$ ) for 6P at (small) large  $F$  is attributed to (DLA) ALA dynamics, i.e.  $i = (5)7 \pm 2$ .<sup>2</sup> Our recent theoretical work considered monomers propagating ballistically before thermalizing or attaching to islands, leading to scaling, non-monotonic crossover, and activation energies that account for the data and reconciling the values of  $i$ .<sup>3</sup> We present applications to other experimental systems: 6P on SiO<sub>2</sub> and pentacene (5A) on amorphous mica. We describe useful simplifying approximations, and preliminary kinetic Monte Carlo simulations including transient effects on growth.

**4:42PM C47.00012 Unravelling the “Silicene” Growth Mechanism Based on a Seeding Layer Approach<sup>1</sup>**, WEI JIANG, Univ of Utah, MIAO ZHOU, Chongqing University, FENG LIU, Univ of Utah, FENG LIU TEAM — Unlike *sp*<sup>2</sup> graphene, silicon atoms prefer to form *sp*<sup>3</sup> hybridized state that gives silicene a buckled geometry. To study how to grow flat silicene, we have investigated the structure and stability of multi-layer “silicene” using *ab initio* methods by introducing a “seeding layer” of silicene on which additional “silicene” layers are grown. The buckling height and the isotropic strain of the seeding layer is shown to play a key in affecting the structure, in particular the flatness of the growing layers. A phase diagram in the parameter space of buckling height and in-plane strain of the seeding layer is constructed to guide the growth of additional “silicene” layer. Furthermore, in contrast to monolayer silicene growth on Ag substrate which exhibits various patterns, only the  $\sqrt{3}\times\sqrt{3}$  pattern is found stable using large supercell calculations. Our calculations suggest that thermodynamically no silicene structures can survive beyond three layers. These results will shed useful lights on experimental growth of flat and low-buckled silicene and help explain existing experimental results.

**4:54PM C47.00013 Current-Driven Nanowire Formation on Crystalline Conducting Substrate Surfaces**, DWAIPAYAN DASGUPTA, ASHISH KUMAR, DIMITRIOS MAROUDAS, Univ of Mass - Amherst — Using a simulation study, we demonstrate a new, driven-assembly-based approach to single-layer nanowire formation on fcc crystalline substrate surfaces. In this approach, we manipulate individual epitaxial islands using an external electric field to drive the formation of single nanowires or arrays of them. We have developed and validated a fully nonlinear model of current-driven island evolution mediated by diffusional mass transport along the island edge and accounting for edge diffusional anisotropy and island coalescence and breakup. Using a linear stability theory, we analyze the morphological stability of islands with equilibrium shapes and predict the occurrence of morphological instability for islands larger than a critical size under the action of an electric field along the slowest edge diffusion direction on {110}, {100}, and {111} substrate surfaces. Consistent with the theoretical prediction, dynamical simulations show that large-size islands undergo a fingering instability which, following finger growth and, depending on the substrate orientation, necking instability, leads to formation of single or multiple nanowires. We find that the nanowires have constant widths, on the order of tens of nanometers, and explain analytically the nanowire dimensions.

**5:06PM C47.00014 Nonlinear Analysis of the Surface Morphological Stability of Stressed Crystalline Materials and Coherently Strained Epitaxial Thin Films**, LIN DU, DWAIPAYAN DASGUPTA, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — The competition between surface energy and elastic strain energy in surfaces of stressed solids may cause the Asaro-Tiller/Grinfeld (ATG) instability leading to surface cracking, which can be predicted by linear stability theory (LST). Self-consistent dynamical simulations based on a fully nonlinear surface evolution model reveal that, in addition to the ATG instability, long-wavelength perturbations from the planar surface morphology can also trigger a tip-splitting instability, causing the formation of a pattern of secondary ripples that cannot be predicted by LST. We have developed a weakly nonlinear stability theory that can explain the occurrence of such nonlinear rippling instabilities and predict the critical wavelength for secondary ripple formation as well as the number of secondary ripples that form on the surface as a function of perturbation wavelength. We also have applied the weakly nonlinear theory to study the surface morphological stability of a coherently strained epitaxial thin film on a crystalline elastic substrate. We find that, in addition to the Stranski-Krastanow instability, secondary rippling instabilities may also occur on the film surface, leading to formation of smaller-sized quantum dots (QDs) through tip splitting of larger QDs.

**5:18PM C47.00015 Triple line kinetics in solid-state dewetting<sup>1</sup>**, ASHWANI TRIPATHI, OLIVIER PIERRE-LOUIS, Univ Lyon I UA 442 CNRS — Solid-state dewetting has been studied in a large number of experimental systems, such as SOI (Si on amorphous SiO<sub>2</sub>)<sup>2</sup>, or metal films on various substrates<sup>3</sup>. Several theoretical approaches have been proposed in the past 10 years to understand this phenomena, ranging from Kinetic Monte Carlo to phase field, and continuum Mullins-like models. We present a continuum model<sup>4</sup> which addresses the question of the limit of validity of the usual approximation of a constant contact angle at the triple line between the solid, the film, and the vacuum (or vapor). Our results suggest that the Young relation is subject to systematic deviations, which could be measured in experiments. In addition, the so-called mass shedding effect, which leads to the breakup of the film at a finite distance from the triple-line, can be accelerated by orders of magnitude due to wetting effects.

**Session C48 GQI: Multimode Circuit QED and Strong Coupling** 349 - Benjamin Palmer, Laboratory of Physical Sciences, College Park

**2:30PM C48.00001 Multimode cavity QED 1: State preparation and readout**, RAVI NAIK, NELSON LEUNG, SRIVATSAN CHAKRAM, YAO LU, NATHAN EARNEST, Physics Department and James Franck Institute, University of Chicago, PETER GROSZKOWSKI, JENS KOCH, Department of Physics and Astronomy, Northwestern University, DAVID SCHUSTER, Physics Department and James Franck Institute, University of Chicago — Quantum information processing requires the creation of scalable architectures with long lived, highly coherent, readily addressable quantum states. A promising architecture consists of Fock states of photons in coupled superconducting microwave cavity arrays, with state preparation and readout achieved by coupling to superconducting qubits via circuit QED. We describe experiments on such multimode circuit QED devices consisting of 1D chains of 10-20 tunnel coupled 2D high-Q microwave resonators coupled to a single, flux-tunable transmon qubit. We use parametric sideband transitions [1], implemented via flux modulation of the transmon, to realize arbitrary states of the photonic qubits. We also discuss ongoing efforts to engineer multimode architectures comprised of coupled 3D microwave cavities in which photon lifetimes can exceed 10 ms [2]. [1] J. D. Strand et al, Physical Review B 87.22 (2013) [2] M. Reagor et al, Applied Physics Letters 102, 192604 (2013)

Multimode cavity QED 1: State preparation and readout

(Ravi Naik, Nelson Leung, Srivatsan Chakram, Yao Lu, Nate Earnest, Peter Groszkowski Jens Koch, David Shuster), but before a talk named:

Multimode cavity QED 3: Universal quantum gates

(Nelson Leung, Ravi Naik, Srivatsan Chakram, Yao Lu, Nate Earnest, Peter Groszkowski Jens Koch, David Shuster)

**2:42PM C48.00002 Multimode cavity QED 2: Parameter dependence of theoretical modeling**, PETER GROSZKOWSKI, Northwestern University, NELSON LEUNG, DAVID SCHUSTER, University of Chicago, JENS KOCH, Northwestern University — Superconducting circuits are a promising platform for future quantum information processing devices. While in recent years gate and readout fidelities have improved, they still benefit greatly from added intrinsic robustness and improved error resilience. In this talk, we present results from a new qubit array, where qubit manipulation and readout are achieved by interaction with a parametrically driven superconducting resonator. We provide insight into mode addressability as well as crosstalk, and their dependence on the system's size in various configurations.

Thank you!

**2:54PM C48.00003 Multimode cavity QED 3: Universal quantum gates**, NELSON LEUNG, RAVI NAIK, SRIVATSAN CHAKRAM, YAO LU, NATHAN EARNEST, Physics Department and James Franck Institute, University of Chicago, PETER GROSZKOWSKI, JENS KOCH, Department of Physics and Astronomy, Northwestern University, DAVID SCHUSTER, Physics Department and James Franck Institute, University of Chicago — A promising architecture for scalable quantum computation consists of photonic qubits in multimode superconducting cavities, coupled to superconducting qubits. In this talk, we describe schemes to implement pairwise universal gate operations between the photonic qubits. We use parametric sideband interactions [1] mediated by a superconducting qubit to realize arbitrary single photonic qubit gates, as well as the C-phase gate between arbitrary pairs of photonic qubits, thereby realizing universal gate operations. We also describe schemes to realize beam splitter and phase shifter elements in this multimode architecture, allowing for circuit QED realizations of linear optical quantum computation schemes. [1] J. D. Strand et al, Physical Review B 87.22 (2013)

**3:06PM C48.00004 Multimode cavity QED 4: Quantum state tomography**, SRIVATSAN CHAKRAM, NELSON LEUNG, RAVI NAIK, YAO LU, NATHAN EARNEST, Physics Department and James Franck Institute, University of Chicago, PETER GROSZKOWSKI, JENS KOCH, Northwestern University, DAVID SCHUSTER, Physics Department and James Franck Institute, University of Chicago — One of the challenges of large scale quantum information processing is the ability to perform quantum state tomography of massively entangled states. We implement multiplexed tomography of quantum states of multimode cavity arrays comprising several photonic qubits. Quantum state tomography is performed via sequential parametric transitions [1] with a single, flux-tunable transmon qubit, in conjunction with multimode photonic gates and transmon readout. We describe schemes to prepare and characterize W states of several modes of the multimode cavity, and our progress towards extending such schemes to multiphoton entangled states. The ability to create and measure arbitrary quantum states, in conjunction with the large coherence time of microwave cavities, makes multimode cavity QED a promising architecture for scalable quantum computation and bosonic quantum simulation. [1] J. D. Strand et al, Physical Review B 87.22 (2013)

**3:18PM C48.00005 Multimode Strong Coupling in Circuit QED**, NEEREJA SUNDARESAN, YANBING LIU, DARIUS SADRI, LASZLO SZOCS, DEVIN UNDERWOOD, MOEIN MALEKAKHLAGH, HAKAN TURECI, ANDREW HOUCK, Princeton University — We present experimental and theoretical studies in the multimode strong coupling (MMSC) regime of cavity quantum electrodynamics (QED). In MMSC, a single atom is simultaneously coupled to a large, but discrete, number of cavity harmonics, with atom-mode coupling strengths comparable to the free spectral range (FSR). This regime is readily accessible in circuit QED, by strongly coupling a transmon qubit to a low fundamental frequency microwave cavity. We present some key results from our original experiment (PRX 5, 021035, 2015), in which a transmon qubit, resonant with the 75th harmonic of a 90 MHz cavity, reached qubit-mode coupling strengths exceeding 30MHz. When this system is coherently driven, we observed complex multimode fluorescence, with the notable formation of ultra-narrow linewidths. To better understand these unique features of multimode resonance fluorescence we developed a quantum formalism, which attributes the spectral linewidth narrowing to the correlated spontaneous emission of doubly dressed states. Finally we will share preliminary experimental results from our continuing study of MMSC, this time from a system where qubit-mode coupling strengths approach and even exceed the FSR.

**3:30PM C48.00006 Multiphoton Quantum Rabi Oscillations in Ultrastrong Cavity QED**, ANTON FRISK KOCKUM, Center for Emergent Matter Science, RIKEN, Saitama 351-0198, Japan, LUIGI GARZIANO, ROBERTO STASSI, VINCENZO MACRI, SALVATORE SAVASTA, Dipartimento di Fisica e di Scienze della Terra, Università di Messina, I-98166 Messina, Italy, FRANCO NORI, Center for Emergent Matter Science, RIKEN, Saitama 351-0198, Japan — When an atom is strongly coupled to a cavity, the two systems can exchange a *single* photon through a coherent Rabi oscillation. This process enables precise quantum-state engineering and manipulation of atoms and photons in a cavity, which play a central role in quantum information and measurement. Recently, a new regime of cavity QED has been reached experimentally where the interaction between light and artificial atoms (qubits) becomes ultrastrong, *i.e.*, its strength is comparable to the atomic transition frequency or the resonance frequency of the cavity mode. Here we show that this regime can strongly modify the concept of vacuum Rabi oscillations, enabling multiphoton exchanges between the qubit and the resonator. We find that experimental state-of-the-art circuit-QED systems can undergo *two-* and *three-*photon vacuum Rabi oscillations. These anomalous Rabi oscillations can be exploited for the realization of efficient Fock-state sources of light and complex entangled states of qubits.

**3:42PM C48.00007 Ultrastrong coupling in a flux qubit-transmission line system**, POL FORN-DIAZ, JEAN-LUC ORGIAZZI, MARTIN OTTO, ALI YURTALAN, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada, BORJA PEROPADRE, Department of Chemistry and Chemical Biology, Harvard University, Cambridge MA, USA, JUAN-JOSE GARCIA-RIPOLL, Instituto de Fisica Fundamental IFF-CSIC, Madrid, Spain, CHRISTOPHER WILSON, ADRIAN LUPASCU, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada — Recent advances in circuit QED have enabled the study of light-matter interactions in new regimes of coupling strength. Experiments based on flux qubits coupled to resonators observed indications of the so-called ultrastrong coupling regime, where the coupling strength is comparable to the qubit energy splitting. We have realized an experiment where a flux qubit is coupled to an open transmission line with an adjustable coupling strength, which can be tuned into the ultrastrong coupling regime. When the coupling strength is low, the qubit behaves like an isolated dipole scatterer, reflecting over 97% of the incident coherent probe. At larger coupling strengths, the qubit linewidth exceeds its energy splitting, indicating that the system operates deeply in the ultrastrong coupling regime. We find that qualitative features of the qubit response evolve with the coupling strength in ways unexpected based on scattering calculations within the rotating-wave approximation. Some features of the evolution can be understood in the broader context of the spin-boson model.

**3:54PM C48.00008 Ultra-strong coupling in a transmon circuit architecture<sup>1</sup>**, SAL BOSMAN, MARIO GELY, VIBHOR SINGH, ALESSANDRO BRUNO, GARY STEELE, Delft Univ of Tech — New unexplored phenomena are predicted in cQED for the ultra-strong coupling (USC) regime and beyond. Here, we explore two strategies to increase the coupling between a transmon qubit and a microwave resonator. In the first approach, we increase the impedance of the resonator, enhancing its voltage zero-point fluctuations, and measure a vacuum Rabi splitting of 916 MHz. In a second approach, we create a transmon qubit by making a superconducting island suspended above the center conductor of the resonator and which is shorted to ground by two Josephson junctions. Doing so, we maximize the dipole moment of the qubit and observe a vacuum Rabi splitting of 1.2 GHz with a qubit linewidth of 1 MHz. This first transmon qubit in the USC regime improves the coherence time by a factor of 100 compared to other systems in the USC limit. Finally we predict that by combining both approaches, a coupling of  $\sim 3.6$  GHz is possible, reaching close to the deep strong coupling limit.

**4:06PM C48.00009 Deep strong coupling in a circuit QED system (1) - Introduction**<sup>-1</sup>, KOUICHI SEMBA, TOMOKO FUSE, FUMIKI YOSHIHARA, National Institute of Information and Communications Technology, Koganei, Tokyo, Japan, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar — Recently, light-matter interaction at the single-photon level has been demonstrated in superconducting circuits (circuit-QED). The interaction energy between a superconducting artificial atom and an excitation quantum of a harmonic oscillator in the microwave region has been shown to be very large, at least a few thousand times that of the atom-photon interaction obtained using Rydberg atoms [1]. It is also intriguing that, depending on the circuit design, the relevant physical parameters of this system can be controlled at will. In particular, an interaction energy as large as the transition energy of a superconducting artificial atom or a harmonic oscillator is possible, where totally new states, such as a spontaneously generated Schrödinger-cat-like correlated ground state of light and matter, have been predicted [2,3]. In this talk, I will introduce the motivation and the significance of the research, methods to achieve such a strong interaction, and a brief overview of the obtained results. [1] J. Johansson, S. Saito, T. Meno, H. Nakano, M. Ueda, K. Semba, and H. Takayanagi, Phys. Rev. Lett. 96, 127006 (2006). [2] S. Ashhab and Franco Nori, Phys. Rev. A 81, 042311 (2010). [3] S. Ashhab Phys. Rev. **4:18PM C48.00010 Deep strong coupling in a circuit QED system (2) - experiment**<sup>-1</sup>, TOMOKO FUSE, FUMIKI YOSHIHARA, National Institute of Information and Communications Technology, Koganei, Tokyo, Japan, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar, KOUICHI SEMBA, National Institute of Information and Communications Technology, Koganei, Tokyo, Japan — Among a variety of cavity/circuit-QED systems, the superconducting flux qubit is a promising candidate for increasing the coupling strength further because of its huge magnetic moment. Using a flux qubit,  $g/\omega_r = 0.12$  ( $g$ : coupling strength,  $\omega_r$ : bare resonator frequency) has been reported [1]. However,  $g/\omega_r$  is still lower than 1. Here, instead of the widely used coplanar waveguide (CPW) resonators, we use a lumped-element resonator consisting of an inductor (L) and a capacitor (C). While CPW resonators are distributed-element circuits and are therefore restricted by impedance matching constraints, one can freely choose the ratio,  $L/C$ , of a lumped-element resonator. This allows us to design a much smaller inductance and to make the zero-point current fluctuation much larger. Using a flux qubit and a lumped-element resonator, we have achieved  $g/\omega_r$  comparable to or larger than 1, which is the deep strong coupling regime, where a variety of interesting physics is expected [2]. In this presentation, the sample design and spectroscopy data will be shown. [1] T. Niemczyk et al., nature physics 6, 772 (2010). [2] S. Ashhab and F. Nori, PRA 81, 042311 (2010).

**4:30PM C48.00011 Deep strong coupling in a circuit QED system (3) - data and analysis**<sup>-1</sup>, FUMIKI YOSHIHARA, TOMOKO FUSE, KOUICHI SEMBA, National Institute of Information and Communications Technology, Koganei, Tokyo, Japan, SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar — We have experimentally achieved deep-strong coupling between a superconducting flux qubit and a superconducting LC circuit, where the coupling energy,  $\hbar g$ , exceeds both the transition energy of the flux qubit,  $\hbar\omega_q$ , and the resonant energy of the LC circuit,  $\hbar\omega_r$ . At the optimal flux bias of the flux qubit, the qubit-resonator system is described by the Rabi model, which is one of the simplest quantum models of atom-cavity systems. The Hamiltonian of the Rabi model can be written as  $\mathcal{H}_{\text{Rabi}} = -\frac{\hbar}{2}\omega_q\sigma_z + \hbar\omega_r(a^\dagger a + \frac{1}{2}) + \hbar g\sigma_x(a + a^\dagger)$ , where  $\sigma_{x(z)}$  is a Pauli matrix and  $a(a^\dagger)$  is an annihilation (creation) operator. In this presentation, we will show the spectroscopy data of qubit-resonator systems in the deep-strong-coupling regime. Transition frequencies calculated from  $\mathcal{H}_{\text{Rabi}}$  fit the measured data well. We have also observed that  $\hbar\omega_q$  is largely suppressed due to the Lamb shift caused by the deep-strong coupling to the resonator. In this regime, the ground state is predicted to be an entangled state of the qubit's persistent-current states and the resonator's coherent states.

<sup>1</sup>This work was supported by JSPS KAKENHI Grant Number 25220601.

**4:42PM C48.00012 Quantum electrodynamics near a photonic band-gap**, YANBING LIU, ANDREW HOUCK, Princeton University — Quantum electrodynamics predicts the localization of light around an atom in photonic band-gap (PBG) medium or photonic crystal. Here we report the first experimental realization of the strong coupling between a single artificial atom and an one dimensional PBG medium using superconducting circuits. In the photonic transport measurement, we observe an anomalous Lamb shift and a large band-edge avoided crossing when the artificial atom frequency is tuned across the band-edge. The persistent peak within the band-gap indicates the single photon bound state. Furthermore, we study the resonance fluorescence of this bound state, again demonstrating the breakdown of the Born-Markov approximation near the band-edge. This novel architecture can be directly generalized to study many-body quantum electrodynamics and to construct more complicated spin chain models.

**4:54PM C48.00013 Experimental study of a 72-site Jaynes-Cummings lattice in the nonlinear dispersive regime**, MATTIAS FITZPATRICK, NEEREJA SUNDARESAN, Princeton University, ANDY C. Y. LI, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — The building blocks of circuit-QED provide useful tools for the study of nonequilibrium and highly nonlinear behavior. In particular, the inherent dissipation in circuit-QED systems naturally gives rise to crossovers between different steady-states and dynamical phase transitions in even as few as two-site lattices. We explore the steady-state behavior of a 72-site Jaynes-Cummings lattice in the dispersive regime, highlighting the sharp transition in fluorescence at critical drive powers as well as strong nonlinear wave-mixing phenomena.

**5:06PM C48.00014 The driven-dissipative Jaynes-Cummings lattice in the nonlinear dispersive regime**, ANDY C. Y. LI, Northwestern University, MATTIAS FITZPATRICK, NEEREJA SUNDARESAN, ANDREW HOUCK, Princeton University, JENS KOCH, Northwestern University — Experiments studying circuit-QED lattices have great potential for advancing our understanding of nonequilibrium many-body phenomena, including dissipative and dynamical phase transitions. One particular model realizable in this architecture is the driven-dissipative Jaynes-Cummings lattice. Motivated by the experimental measurements in the Houck lab, we theoretically investigate the dispersive regime including sub-leading nonlinear contributions from Kerr terms, employing a semi-classical approximation and numerics based on the quantum master equation. We explore the features of the experimentally detected crossover which is observed for an increase of the driving strength beyond a certain threshold.

**5:18PM C48.00015 Spin-boson model with an engineered reservoir in circuit QED**<sup>1</sup>, FRANK DEPPE, M. HAEBERLEIN, P. EDER, J. GOETZ, M. FISCHER, F. WULSCHNER, E. XIE, K. G. FEDOROV, A. MARX, R. GROSS, Walther-Meissner-Institut; Technische Universität München; Nanosystems Initiative Munich, Germany — A superconducting qubit coupled to an open transmission line represents an implementation of the spin-boson model with an engineered environment. Using a flux qubit with a large mutual inductance to the transmission line, we confirm in a resonance fluorescence experiment that the spectral function  $J(\omega)$  of this environment is Ohmic over a frequency range of several gigahertz. Furthermore, partial reflectors implemented into the transmission line modify the spectral function of the transmission line. For weak enough reflectors, we find that the resulting broad peak can be interpreted in terms of an enhanced spontaneous emission rate. Our work [M. Haeberlein et al., arXiv:1506.09114 (2015)] lays the ground for future quantum simulations of other, more involved, impurity models with superconducting circuits.

<sup>1</sup>We acknowledge support by the German Research Foundation through SFB 631 and FE 1564/1-1, the EU project PROMISCE, and Elite Network of Bavaria through the program ExQM.

**5:30PM C48.00016 Strongly Correlated Photons at Full Transmission<sup>1</sup>**, YAO-LUNG L. FANG, HAROLD U. BARANGER, Duke Univ — We show how to make strongly correlated photons in a fully transmitted pulse. The system consists of three-level qubits (3LS) coupled to a one-dimensional waveguide. Our two-photon scattering approach naturally connects photon correlations with inelastic scattering. We find that the total inelastically scattered flux is much larger than in the case of two-level systems, making 3LS better candidates for experimental study of non-classical light. Strikingly, there is a further substantial increase in inelastic flux upon adding either more 3LS or a mirror. Typically, resonant probe photons at electromagnetically induced transparency are not correlated — the correlations occur off resonance and so involve backscattering. Remarkably, we show that for three qubits, the qubit frequencies and the pump beam can be engineered such that correlated photons are fully transmitted, thereby greatly improving the efficiency of generating photon correlation.

**2:30PM C50.00001 Suppression and Revival of Weak Localization of Ultra-Cold Atoms by Manipulation of Time-Reversal Symmetry<sup>1</sup>**, ALAIN ASPECT, Institut d'Optique Palaiseau — In the early 1980's, observation of a magneto-resistance anomaly in metallic thin films was attributed to the phenomenon of weak localization of electrons and to time-reversal symmetry breaking due to a magnetic field acting upon charged particles. We have observed weak localization of ultra-cold atoms in a 2D configuration, placed in a disordered potential created by a laser speckle. In order to manipulate time-reversal symmetry with our neutral atoms, we take advantage of the slow evolution of our system, and we observe the suppression and revival of weak localization when time reversal symmetry is cancelled and reestablished. References: K. Muller, J. Richard, V. V. Volchkov, V. Denechaud, P. Bouyer, A. Aspect, and V. Josse, "Suppression and Revival of Weak Localization through Control of Time-Reversal Symmetry," Physical Review Letters 114 (20) (2015) and references in.

**3:06PM C50.00002 Using subadditivity to reason about many-body localization on single disorder realizations.**, BRYAN CLARK, XIONGJIE YU, DAVID J. LUITZ, University of Illinois at Urbana Champaign — In the many-body localized (MBL) phase, the interplay of interactions and disorder prevents thermalization. Typically to reason about the many-body localized phase we average over many disorder realizations. It is interesting to ask in what ways we can we talk about MBL transitions for single disorder patterns. We show that subadditivity gives us a mechanism to make sense of MBL transitions on single disorder realizations and report what this implies for the average over disorder.

**3:18PM C50.00003 Many-Body Localization and Quantum Nonergodicity in a Model with a Single-Particle Mobility Edge<sup>1</sup>**, XIAOPENG LI, SRIRAM GANESHAN, J.H. PIXLEY, Univ of Maryland-College Park — We investigate many-body localization in the presence of a single-particle mobility edge. By considering an interacting deterministic model with an incommensurate potential in one dimension we find that the single-particle mobility edge in the noninteracting system leads to a many-body mobility edge in the corresponding interacting system for certain parameter regimes. Using exact diagonalization, we probe the mobility edge via energy resolved entanglement entropy (EE) and study the energy resolved applicability (or failure) of the eigenstate thermalization hypothesis (ETH). Our numerical results indicate that the transition separating area and volume law scaling of the EE does not coincide with the nonthermal to thermal transition. Consequently, there exists an extended nonergodic phase for an intermediate energy window where the many-body eigenstates violate the ETH while manifesting volume law EE scaling. We also establish that the model possesses an infinite temperature many-body localization transition despite the existence of a single-particle mobility edge. We propose a practical scheme to test our predictions in atomic optical lattice experiments which can directly probe the effects of the mobility edge.

**3:30PM C50.00004 Early Breakdown of Area-Law Entanglement at the Many-Body Delocalization Transition**, TRITHEP DEVAKUL, Princeton University, RAJIV SINGH, University of California, Davis — We introduce the numerical linked cluster expansion as a controlled numerical tool for the study of the many-body localization transition in a disordered system with continuous nonperturbative disorder. Our approach works directly in the thermodynamic limit, in any spatial dimension, and does not rely on any finite size scaling procedure. We study the onset of many-body delocalization through the breakdown of area-law entanglement in a generic many-body eigenstate. By looking for initial signs of an instability of the localized phase, we obtain a value for the critical disorder, which we believe should be a lower bound for the true value, that is higher than current best estimates from finite size studies. This implies that most current methods tend to overestimate the extent of the localized phase due to finite size effects making the localized phase appear stable at small length scales. We also study the mobility edge in these systems as a function of energy density, and we find that our conclusion is the same at all examined energies. Work based on Phys. Rev. Lett. 115, 187201.

**3:42PM C50.00005 Exponential Orthogonality Catastrophe in Single-Particle and Many-Body Localized Systems<sup>1</sup>**, DONG-LING DENG, J. H. PIXLEY, XIAOPENG LI, Dept. of Physics, University of Maryland — We investigate the statistical orthogonality catastrophe (StOC) in single-particle and many-body localized systems by studying the response of the many-body ground state to a local quench. Using scaling arguments and exact numerical calculations, we establish that the StOC gives rise to a wave function overlap between the pre- and post-quench ground states that has an *exponential* decay with the system size, in sharp contrast to the well-known power law Anderson orthogonality catastrophe in metallic systems. This exponential decay arises from a statistical charge transfer process where a particle can be effectively "transported" to an arbitrary lattice site. We show that in a many-body localized phase, this non-local transport and the associated exponential StOC phenomenon persist in the presence of interactions. We study the possible experimental consequences of the exponential StOC on the Loschmidt echo and spectral function, establishing that this phenomenon might be observable in cold atomic experiments through Ramsey interference and radio-frequency spectroscopy.

<sup>1</sup>We thank S.-T. Wang, Z.-X. Gong, Y.-L. Wu, J. D. Sau, and Z. Ovadyahu for discussions. This work is supported by LPS-MPO-CMTC, JQI-NSF-PFC, and ARO-Atomtronics-MURI. The authors acknowledge the University of Maryland supercomputing resources.

**3:54PM C50.00006 Many-body localization effects in a disordered system coupled to a delocalized chain**, KATHARINE HYATT, University of California - Santa Barbara, JAMES R. GARRISON, Univ of California - Santa Barbara, BELA BAUER, Station Q, Microsoft Research — The possibility of closed quantum systems that robustly violate quantum statistical mechanics has received a tremendous amount of interest in recent years. Using both numerical and analytical techniques, it has been established that weakly interacting disordered systems can be brought into a many-body localized regime, where the system does not conduct and does not equilibrate even for arbitrarily long times. The starting point for such a phase is usually taken to be an Anderson insulator where in the limit of vanishing interactions, all degrees of freedom of the system are localized. Here, we revisit this problem in a model where in the non-interacting limit, some degrees of freedom are localized while others remain delocalized. Such a system can be viewed as a model for a many-body localized system brought into contact with a small bath of a comparable number of degrees of freedom. We numerically study the effect of interactions on this system and find that generically, the entire system delocalizes. However, we find certain parameter regimes where results are consistent with localization of the entire system, an effect recently termed many-body proximity effect.

**4:06PM C50.00007 Fractional transport and photonic sub-diffusion in aperiodic dielectric metamaterials**, LUCA DAL NEGRO, YU WANG, SANDEEP INAMPUDI, Boston University, ECE Department — Using rigorous transfer matrix theory and full-vector Finite Difference Time Domain (FDTD) simulations in combination with Wavelet Transform Modulus Maxima analysis of multifractal spectra, we demonstrate all-dielectric aperiodic metamaterial structures that exhibit sub-diffusive photon transport properties that are widely tunable across the near-infrared spectral range. The proposed approach leverages the unprecedented spectral scalability offered by aperiodic photonic systems and demonstrates the possibility of achieving logarithmic Sinai sub-diffusion of photons for the first time. In particular we will show that the control of multifractal energy spectra and critical modes in aperiodic metamaterials with nanoscale dielectric components enables tuning of anomalous optical transport from sub- to super-diffusive dynamics, in close analogy with the electron dynamics in quasi-periodic potentials. Fractional diffusion equations models will be introduced for the efficient modeling of photon sub-diffusive processes in metamaterials and applications to diffraction-free propagation in aperiodic media will be provided. The ability to tailor photon transport phenomena in metamaterials with properties originating from aperiodic geometrical correlations can lead to novel functionalities and active devices that rely on anomalous photon sub-diffusion to control beam collimation and non-resonantly enhance light-matter interaction across multiple spectral bands.

**4:18PM C50.00008 Many-body localization protected quantum state transfer**, CHRIS R LAUMANN, University of Washington, NORMAN Y YAO, ASHVIN VISHWANATH, University of California, Berkeley — In thermal phases, the quantum coherence of individual degrees of freedom is rapidly lost to the environment. Many-body localized (MBL) phases limit the spread of this coherence and appear promising for quantum information applications. However, such applications require not just long coherence times but also a means to transport and manipulate information. We demonstrate that this can be done in a one dimensional model of interacting spins at infinite temperature. Our protocol utilizes protected qubits which emerge at the boundary between topological and trivial phases. State transfer occurs via dynamic shifts of this boundary and is shown to preserve quantum information. As an example, we discuss the implementation of a universal, two-qubit gate based upon MBL-protected quantum state transfer.

**4:30PM C50.00009 Transport of Light in disordered random media**, REGINE FRANK, Serin Physics Laboratory, E273 Department of Physics and Astronomy Rutgers University 136 Frelinghuysen Road Piscataway, NJ 08854-8019, USA, ANDREAS LUBATSCH, Georg-Simon-Ohm University of Applied Sciences, Nuremberg, Germany — The Anderson transition was originally proposed for electrons, however it has been soon searched for all kinds of waves in disordered media. This physics became extremely interesting with the application of high amplitude excitations, where the medium is supposed to respond with non-linear effects. In theory it is ever since a challenge to treat large random ensembles numerically, even if the medium is completely non-resonant or passive. We discuss in this talk transport of light with respect to a quantum field theoretical approach and we explain through comparison to other existing theories, what the advantages of state of the art theory in that field is, and why it is exciting.

**4:42PM C50.00010 Many body localization in the presence of a single particle mobility edge**, SUBROTO MUKERJEE, RANJAN MODAK, Indian Institute of Science — In one dimension, noninteracting particles can undergo a localization-delocalization transition in a quasiperiodic potential. Recent studies have suggested that this transition transforms into a many body localization transition upon the introduction of interactions. It has also been shown that mobility edges can appear in the single particle spectrum for certain types of quasiperiodic potentials. Here we investigate the effect of interactions in models with such mobility edges. Employing the technique of exact diagonalization for finite-sized systems, we calculate the level spacing distribution, time evolution of entanglement entropy, optical conductivity and return probability to characterize the nature of localization. The localization that develops in the presence of interactions in these systems appears to be different from regular Many-Body Localization (MBL) in that the growth of entanglement entropy with time is linear (like in a thermal phase) but saturates to a value much smaller than the thermal value (like for MBL). All other diagnostics seem consistent with regular MBL.

**4:54PM C50.00011 Energy Dependence and Scaling Property of Localization Length near a Gapped Flat Band<sup>1</sup>**, LI GE, College of Staten Island, CUNY, HAKAN TURECI, Princeton University — Using a tight-binding model for a one-dimensional Lieb lattice, we show that the localization length near a gapped flat band behaves differently from the typical Urbach tail in a band gap: instead of reducing monotonically as the energy  $E$  moves away from the flat band energy  $E_f$ , the presence of the flat band causes a nonmonotonic energy dependence of the localization length. This energy dependence follows a scaling property when the energy is within the spread ( $W$ ) of uniformly distributed diagonal disorder, i.e. the localization length is only a function of  $(E-E_f)/W$ . Several other lattices are compared to distinguish the effect of the flat band on the localization length, where we eliminate, shift, or duplicate the flat band, without changing the dispersion relations of other bands. Using the top right element of the Green's matrix, we derive an analytical relation between the density of states and the localization length, which shines light on these properties of the latter, including a summation rule for its inverse.

**5:06PM C50.00012 Spatial and temporal localization of light in two dimensions**, ROMAIN BACHELARD, Instituto de Física de São Carlos/Universidade de São Paulo — Despite decades of active research, punctuated by several contradictory experimental and theoretical claims, the mere existence of Anderson localization of light, a regime where light cannot propagate due to interference effects between randomly distributed scatterers, has not been demonstrated yet. Recent theoretical works suggest that the vectorial nature of light might actually prohibit localization. We here present a study on the scattering of light in two dimensions, a regime where both scalar or as a vectorial electromagnetic waves coexist. The scaling analysis reveals that although both kinds of wave present long-lived subradiant modes, only scalar ones do localize, supporting the theoretical claim in 3D. Yet we also observe a lack of correlation between lifetimes and localization length, calling for a differentiation between temporal (subradiant) and spatial (Anderson) localization. Finally, we discuss the implication of localization, following the original idea that the localization of the modes induces a metal to insulator transition, bringing transport to a halt. Indeed, in the case of light, the scattering is characterized by the presence of a few long-range (superradiant) modes, which appear to alter dramatically the transport properties.

**5:18PM C50.00013 Anderson Localization in Degenerate Spin-Orbit Coupled Fermi Gas with Disorder**<sup>1</sup>, SHENG LIU, XIANGFA ZHOU, GUANGCAN GUO, YONGSHENG ZHANG, Univ. of Sci. & Tech. of China — Competition between superconductivity and disorder plays an essential role in understanding the metal-insulator transition. Based on the Bogoliubov-de Gennes equation, we studied an *s*-wave superconductor with both spin-orbit coupling and disorder are presented. With increasing the strength of disorder, the mean superconducting order parameter will vanish while the energy gap will persist which indicates that the system undergoes a transition from a superconducting state to an insulating state which can be confirmed by calculating the inverse participation ratio. We also find that, if the strength of disorder is small, the superconducting order parameter and energy gap will decrease if we increase the strength of spin-orbit coupling and Zeeman field. In the large disorder limits, increasing the strength of spin-orbit coupling will increase the mean superconducting order parameter. This phenomena shows that the system is more insensitive to disorder if the spin-orbit coupling is presented. Numerical computing also shows that the whole system breaks up into several *superconducting islands* instead of being superconductive.

**2:30PM C51.00001 Fe<sub>2</sub>O<sub>3</sub> nanoparticles for airborne organophosphate detection**<sup>1</sup>, JOSHUA PHILLIPS, University of Alabama, JENNIFER SOLIZ, US Army Edgewood Chemical Biological Center, ADAM HAUSER, University of Alabama — Dire need for early detection of organophosphates (OP) exists in both civilian (pesticide/herbicide buildup) and military (G/V nerve agents) spheres. Nanoparticle materials are excellent candidates for the detection and/or decontamination of hazardous materials, owing to their large surface to volume ratios and tailored surface functionality. Within this category, metal oxides include structures that are stable with the range of normal environmental conditions (temperature, humidity), but have strong, specific reaction mechanisms (hydrolysis, oxidation, catalysis, stoichiometric reaction) with toxic compounds. In this talk, we will present on the suitability of Fe<sub>2</sub>O<sub>3</sub> nanoparticles as airborne organophosphate detectors. 23 nm particles were exposed to a series of organophosphate compounds (dimethyl methylphosphonate, dimethyl chlorophosphonate, diisopropyl methylphosphonate), and studied by x-ray magnetic circular dichroism and x-ray absorption spectroscopy to confirm the stoichiometric Fe<sub>2</sub>O<sub>3</sub> to FeO mechanism and determine magnetic sensor feasibility. AC Impedance Spectroscopy shows both high sensitivity and selectivity via frequency dependence in both impedance and resistivity, suggesting some feasibility for impedimetric devices.

<sup>1</sup>We acknowledge funding under Army Research Office STIR award W911F-15-1-0104. J.R.S. acknowledges funding from the Defense Threat Reduction Agency under Projects BA13PHM210 and BA07PRO104. J.R.S. also acknowledges funding under a NRC fellowship.

**2:42PM C51.00002 Towards a drift-free multi-level Phase Change Memory**, IBRAHIM CINAR, Bogazici University, SERVET OZDEMIR, University of Warwick, EGE CAN COGULU, New York University, AISHA GOKCE, Bogazici University, BARRY STIPE, JORDAN KATINE, HGST, A Western Digital Company, GULEN AKTAS, OZHAN OZATAY, Bogazici University — For ultra-high density data storage applications, Phase Change Memory (PCM) is considered a potentially disruptive technology. Yet, the long-term reliability of the logic levels corresponding to the resistance states of a PCM device is an important issue for a stable device operation since the resistance levels drift uncontrollably in time. The underlying mechanism for the resistance drift is considered as the structural relaxation and spontaneous crystallization at elevated temperatures. We fabricated a nanoscale single active layer-phase change memory cell with three resistance levels corresponding to crystalline, amorphous and intermediate states by controlling the current injection site geometry. For the intermediate state and the reset state, the activation energies and the trap distances have been found to be 0.021 eV and 0.235 eV, 1.31 nm and 7.56 nm, respectively. We attribute the ultra-low and weakly temperature dependent drift coefficient of the intermediate state ( $\nu=0.0016$ ) as opposed to that of the reset state ( $\nu=0.077$ ) as being due to the dominant contribution of the interfacial defects in electrical transport in the case of the mixed phase. Our results indicate that the engineering of interfacial defects will enable a drift-free multi-level PCM device design.

**2:54PM C51.00003 Sensing of NO<sub>2</sub> with Zirconium Hydroxide via Electrical Impedance Spectroscopy**<sup>1</sup>, COLEMAN HARRIS, The University of Alabama, JENNIFER SOLIZ, US Army Edgewood Chemical Biological Center, ANDREW KLEVITCH, The University of Alabama, JOSEPH ROSSIN, Guild Associates, Inc., AUGUSTUS FOUNTAIN III, GREGORY PETERSON, US Army Edgewood Chemical Biological Center, ADAM HAUSER, The University of Alabama — Nitrogen Dioxide (NO<sub>2</sub>) is a brown gas mainly produced as a byproduct of burning fossil fuels, such as automobiles and power plants. Nitrogen oxides can form acid rain and smog by reacting with air, can form toxic organic nitrates by reacting with soil, and can react with oxygen in water, destroying marine life due to a lack of breathable oxygen. Any concentration beyond 53 ppb (air quality standard) can cause irritation to the lungs and respiratory infections, and higher dosages can be fatal. As such, research in NO<sub>2</sub> detection is incredibly important to human welfare. Zirconium hydroxide (Zr(OH)<sub>4</sub>) has been investigated as a candidate NO<sub>2</sub> dielectric sensor using impedance spectroscopy analysis. Impedance changes of several orders of magnitude are seen down to our dosage minimum of 50 ppm•hr. Changes in impedance correlate with nitrogen and oxygen atomic ratio increases observed via X-ray photoelectron spectroscopy (XPS). The results indicate that Zr(OH)<sub>4</sub> may be a strong candidate for use in impedance-based NO<sub>2</sub> detection devices.

**3:06PM C51.00004 Laser Processing of Metal Oxides for Plasmonic Applications**<sup>1</sup>, HEUNGSOO KIM, Naval Research Laboratory, ERIC BRECKENFELD, National Research Council Fellow at Naval Research Laboratory, NICHOLAS CHARIPAR, ALBERTO PIQUE, Naval Research Laboratory — Noble metals such as Au and Ag have been used traditionally for plasmonic devices. However, conventional metals are not suitable for near infrared (IR) plasmonic applications due to their relatively large optical losses at these wavelengths. Metal oxides, on the other hand, have been considered for low loss metallic components in the near IR because they can provide a tunable carrier density by doping. The zero-cross-over permittivity values of these metal oxides, for example, can easily be tuned from 1.0 m to 3 m by adjusting doping levels. Optical losses in devices made from these metal oxide materials are generally found to be much lower than those obtained with conventional metals. We have investigated various laser processing techniques for synthesizing several types of metal oxides. First, pulsed laser deposition was used to grow metal oxide thin films such as, Al-doped ZnO, Sn-doped In<sub>2</sub>O<sub>3</sub> and VO<sub>2</sub>. Second, a laser sintering technique was used to improve the properties of solution-processed VO<sub>2</sub> coatings. Third, a laser printing technique was used to produce metal oxide films. We will present details on the use of laser processing techniques for synthesizing these metal oxides along with their electrical, optical, and structural properties.

**3:18PM C51.00005 Controlled Growth of Copper Oxide Nano-Wires through Direct Oxidation<sup>1</sup>**, JOANN HILMAN, RAVI NEUPANE, ANDREW J. YOST, TEYU CHIEN, Univ of Wyoming — Copper oxides, both Cu<sub>2</sub>O and CuO, have many applications in solar cells, sensors, and nano-electronics. The properties of the copper oxides are further influenced by the dimension of the materials, especially when made in nanoscale. In particular, the properties of the copper oxide nanowires could be tuned by their structures, lengths, and widths. While several methods have been reported to grow nanowires, direct oxidation is arguably the most economical one. This research examines the effects of oxidization duration and temperature in dry air environment on the development of copper oxide nanowires in order to achieve cost effective controllable growth. Using the direct oxidation method in dry air we have demonstrated growth of CuO nano-wires at temperatures as low as 300 C and as short as 1hr. Furthermore we have observed that the lengths and diameters of the CuO NWs can be controlled by the duration and temperature of the oxidation process.

**3:30PM C51.00006 Distinguishing the Photothermal and Photoinjection Effects in Vanadium Dioxide Nanowires<sup>1</sup>**, XI WANG, HANWEI GAO, Department of Physics, Florida State University — Vanadium dioxide (VO<sub>2</sub>) has drawn significant attention for its unique metal-to-insulator transition. The high electrical resistivity below the transition temperature is a result of the strong electron correlation with the assistance of lattice distortion. Theoretical calculations indicated that the strong inter-electron interactions might induce intriguing optoelectronic phenomena, such as the multiple exciton generation. However, the resistivity of VO<sub>2</sub> is temperature sensitive. Therefore, the light-induced conductivity in VO<sub>2</sub> has often been attributed to the photothermal effects. In this work, we distinguished the photothermal and photoinjection effects in VO<sub>2</sub> nanowires by varying the chopping frequency of the optical illumination. In our VO<sub>2</sub> nanowires, the relatively slow photothermal processes can be well suppressed when the chopping frequency >2 kHz, whereas the fast photoinjection component (direct photo-excitation of charge carriers) remains constant at all chopping frequencies. By separating the photothermal and photoinjection processes, our work set the basis for further studies of carrier dynamics under optical excitations in strongly correlated materials.

**3:42PM C51.00007 Electronic properties of epitaxial Ge/AlAs heterostructures on Si and GaAs<sup>1</sup>**, J. J. HEREMANS, YUANTAO XIE, Virginia Tech, Department of Physics, M. K. HUDAIT, M. CLAVEL, P. S. GOLEY, Virginia Tech, Department of Electrical and Computer Engineering — Ge, with high electron and hole mobilities, has advantages over Si for low-power high-speed nanoscale logic. We report on the MBE growth of Ge/AlAs/GaAs and Ge/AlAs/GaAs/Si structures, where the Ge/AlAs band offsets provide carrier confinement inside the Ge layer. We studied the confinement of carriers in the Ge layer, the effect of the AlAs buffer layer, and the effects of a growth pause and growth temperature, correlated to structural and morphological properties. Magnetotransport and quantum transport measurements were obtained down to 390 mK and in magnetic fields up to 9 T. A weak-localization signal, in contrast to antilocalization, indicates absence of spin-orbit interaction and hence electron confinement in the Ge rather than in the III-V layers. For the Ge/AlAs/GaAs/Si structure a low-temperature sheet carrier density  $1.4 \times 10^{14} \text{ cm}^{-2}$  and mobility  $390 \text{ cm}^2/\text{Vs}$  were obtained, with similar values at 290 K, while at 200 K a maximum in mobility is reached of  $470 \text{ cm}^2/\text{Vs}$ . For the Ge/AlAs/GaAs structures a mobility up to  $260 \text{ cm}^2/\text{Vs}$  was obtained at  $2 \times 10^{13} \text{ cm}^{-2}$  at 290 K. The Ge/AlAs/GaAs structures have also shown phonon-limited scattering vs temperature, attesting to the quality of interfaces.

**3:54PM C51.00008 Spectroscopic and structural studies of energetically efficient transport in nanocontacts to NiSi nanowires<sup>1</sup>**, A. STEIN, BNL-CFN, Upton, NY, 11973, USA, I. A. H. FARHAT, Khalifa University, AMS Dept. and KSRC, 127788, Abu Dhabi, UAE, N. LACEVIC, Univ. of Melbourne, Australia, S. K. BAZUHAIR, S. S. AZHAR, KSRC, 127788, Abu Dhabi, UAE, A. F. ISAKOVIC, Khalifa University, AMS Dept. and KSRC, 127788, Abu Dhabi, UAE — Understanding correlations between mechanical, thermal, structural and electronic transport properties of different nanocontact geometries to nanowires, such as Au/Cu-NiSi-Si, remain one of the major goals of nanodevices reliability and scalability research. Aiming to clarify the failure modes and processes that affect the energy efficiency of transport and switching in constrained nanocontact geometries, such as end contacts, we conducted the structural, spectroscopic, and noise correlation studies. We show how the spatial (in)homogeneity at and in the near vicinity of the interface affects the transport performance of the nanojunctions. Mobile Ni clusters are identified at the nanojunction interface via Raman spectromicroscopy and their influence on charge transport is analyzed. We also show that the noise correlation spectra and micro-X-ray stress-strain studies in the nanojunctions are effective tools in predicting the energy efficiency of the nanojunctions. A computational study of the interfacial properties of metal/Ni-Si via DFT and MD simulations is implemented.

**4:06PM C51.00009 Memristive switching of ZnO nanorod mesh<sup>1</sup>**, PUZYREV YEVGENIY, Vanderbilt University, XIAO SHEN, University of Memphis, KAI NI, XUAN ZHANG, JORDAN HACHTEL, Vanderbilt University, BO CHOI, Vanderbilt Institute of Nanoscience, MATTHEW CHISHOLM, Oak Ridge National Laboratory, DANIEL FLEETWOOD, RONALD SCHRIMPF, SOKRATES PANTELIDES, Vanderbilt University — We present a combined experimental and theoretical study of memristive switching in a self-assembled mesh of ZnO nanorods. A ZnO nanorod mesh spans the area between Ag contacts in a device that exhibits hysteresis with large ON/OFF ratio, reaching ION/IOFF values of 104. We show that switching behavior depends critically on the geometry of the nanorod mesh. We employ density functional theory (DFT) calculations to deduce the mechanism for resistive switching for the nanorod mesh. Redistribution of Ag atoms, driven by an electrical field, leads to the formation and evolution of a conducting path through nanorods. Field-induced migration of Ag atoms changes the doping level of nanorods and modulates their conductivity. Using static DFT and nudged-elastic-band calculations, we investigate the energy of interaction between Ag clusters and a ZnO surface, including migration barriers of Ag atoms. Current-voltage (I-V) characteristics are modeled using percolation theory in a nanorod mesh. To describe the dynamics of SET/RESET phenomena, model parameters include the experimentally observed nanorod geometry and the energetics of Ag on ZnO surfaces, obtained from DFT calculations.

**4:18PM C51.00010 Field effect in perovskite heterostructures based on BaSnO<sub>3</sub> and BaHfO<sub>3</sub>**, YOUNG MO KIM, CHULKWON PARK, USEONG KIM, JUYEON SHIN, YOUJUNG KIM, KOOKRIN CHAR, Seoul National University — Perovskite La-doped BaSnO<sub>3</sub> (BLSO) was reported to possess high electron mobility and excellent oxygen stability [1]. We fabricated a field effect transistor on SrTiO<sub>3</sub> substrate using BLSO as a channel layer and BaHfO<sub>3</sub> (BHO) as a gate insulator. To reduce the threading dislocations and enhance the electrical properties of the channel, undoped BaSnO<sub>3</sub> (BSO) buffer layer was grown on SrTiO<sub>3</sub> substrates before the channel layer deposition. X-ray diffraction measurement confirms the epitaxial growth of BHO on BSO. We investigated optical and dielectric properties of the BHO gate insulator; the optical bandgap and the dielectric constant were measured to be 6.1 eV and 37.8, respectively. Using BHO as the gate insulator, we obtained the conductivity modulation in the channel by field effect. We will report on the electrical properties of the field effect transistor such as the output characteristics, the transfer characteristics, the  $I_{on}/I_{off}$  ratio, the subthreshold swing and the field effect mobility. [1] H. J. Kim, U. Kim *et al.*, Appl. Phys. Express **5**, 061102 (2012).

**4:30PM C51.00011 Characterization of Quasi-Metallic Tunnel-Field-Effect-Transistors**, ABDULRAHMAN ALHUSSAIN, FADHEL ALSAFFAR, King Abdulaziz City for Science and Technology, STEPHEN CRONIN, University of Southern California, MOH AMER, King Abdulaziz City for Science and Technology, KING ABDULAZIZ CITY FOR SCIENCE AND TECHNOLOGY TEAM, UNIVERSITY OF SOUTHERN CALIFORNIA COLLABORATION — Band-to-band tunneling mechanism has proven to be a promising alternative to thermionic diffusion for ultra-fast switching applications. Tunneling Field-Effect-Transistors (TFETs), which primarily operate based on tunneling current, can offer low turn-on voltage with low sub-threshold swing[1]. Here, we demonstrate TFETs based on suspended, ultra-clean, quasi-metallic carbon nanotube pn devices. These devices exhibit a subthreshold swing as low as 2mV/decade, with a current  $I_{on}/I_{off}$  ratio in the order of 105 at cryogenic temperatures. At room temperature, however, the current is dominated by the diffusion of carriers, which degrades the  $I_{on}/I_{off}$  ratio and the subthreshold swing. We also explore the effect of the schottky contacts on the tunneling current by adding two back-to-back diodes to the tunneling current model. Our results provide evidence that the effect of the schottky contacts can be significant when quasi-metallic nanotubes exhibit band-to-band tunneling. Our results show that quasi-metallic carbon nanotubes can be potential candidates for future nanoelectronics. References: [1] A. M. Ionescu and H. Riel, "Tunnel field-effect transistors as energy-efficient electronic switches," Nature, vol. 479, pp. 329-337, 2011.

**4:42PM C51.00012 Structural and electronic properties of BAlN alloy<sup>1</sup>**, JIMMY-XUAN SHEN, Dept. of Physics Univ of California - Santa Barbara, DARSHANA WICKRAMARATNE, CHRIS G VAN DE WALLE, Materials Dept., UC Santa Barbara — Designs of far-UV emitters using BAlN as the barrier layer and AlN as the active layer are being considered. Realization of BAlN alloys is complicated by the fact that BN is most stable in a hexagonal structure, which is different from the ground-state wurtzite structure of AlN. Enabling such designs requires a fundamental understanding of the composition dependent electronic structure of BAlN. Using first-principles simulations based on a hybrid functional, we investigate the band gaps, band-gap bowing, and miscibility of BAlN using explicit alloy calculations. The results from these calculations are used to determine the band offsets between AlN and BAlN that are essential to assess the performance of UV-emitting devices.

<sup>1</sup>This work is supported by NSF.

**4:54PM C51.00013 Sources of Shockley-Read-Hall recombination in III-nitride light emitters<sup>1</sup>**, CYRUS E. DREYER, Department of Physics and Astronomy, Rutgers University, AUDRIUS ALKAUSKAS, Center for Physical Sciences and Technology, Vilnius, Lithuania and Kaunas University of Technology, Kaunas, Lithuania, JOHN L. LYONS, Center for Functional Nanomaterials, Brookhaven National Laboratory, JAMES S. SPECK, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara — Group-III nitrides are the key materials for high efficiency light-emitting diodes in the blue part of the visible spectrum, and a large research effort is aimed at extending this success to the green and the yellow range, where nitride LEDs are significantly less efficient. Though it has been noted that the efficiency of III-nitride devices may be limited by Shockley-Read-Hall recombination at point defects, the microscopic mechanism and defects responsible are unknown. Based on first-principles calculations of defect formation energies, charge-state transition levels, and nonradiative capture coefficients, we describe a mechanism by which complexes between gallium vacancies and oxygen and/or hydrogen can act as efficient channels for nonradiative recombination in InGaN alloys. The dependence of these quantities on alloy composition is analyzed. We find that modest concentrations of the proposed defect complexes, around  $10^{16}\text{cm}^{-3}$ , can give rise to Shockley-Read-Hall coefficients  $A = (10^7 - 10^9)\text{s}^{-1}$ . The resulting nonradiative recombination can significantly reduce the internal quantum efficiency of optoelectronic devices.

**5:06PM C51.00014 A first-principles study of pyroelectricity in GaN and ZnO**, JIAN LIU, MARIA V. FERNÁNDEZ-SERRA, PHILIP B. ALLEN, State Univ of NY- Stony Brook — We present first-principles calculations on the primary pyroelectric coefficients for wurtzite GaN and ZnO. The primary pyroelectricity is attributed to the anharmonic atomic displacements of the Born effective charges on the cations and anions. We show that the primary pyroelectricity is the major part of the total pyroelectricity at low temperatures, while the secondary pyroelectricity becomes comparable with the primary pyroelectricity at high temperatures. Our calculations show that contributions from the acoustic and the optical phonon modes to the primary pyroelectric coefficient can be well described by the corresponding Debye and Einstein functions respectively.

**5:18PM C51.00015 Resistive switching in nanodevices**, H. RAEBIGER, Yokohama Nat'l Univ., Yokohama, Japan and Univ. Federal do ABC, Santo André, SP, Brazil, A. C. M. PADILHA, Univ. Federal do ABC, Santo André, SP, Brazil, A. R. ROCHA, Univ. Estadual Paulista, São Paulo, SP, Brazil, G. M. DALPIAN, Univ. Federal do ABC, Santo André, SP, Brazil — A nanoscale metal/insulator/metal sandwich structure device may exhibit multiple resistive states, and switching between these states can be controlled by bias voltage. However, the underlying physical mechanism is poorly understood. We present an electronic mechanism that explains multiple resistive states in such devices due to multiple solutions of Poisson's equation. These solutions describe spontaneously charged states characterized by different (convex and concave) 'band bendings'. For an insulator with mainly donor type defects, the low-resistivity state is characterized by a negatively charged insulator due to convex band bending, and the high-resistivity state by a positively charged insulator due to concave band bending; vice versa for insulators with mainly acceptor type defects. We show that the coexistence of such states, and switching between them is determined by defect/impurity abundance, device size, and basic material properties.

**2:30PM C52.00001 Melting of Vortex Lattice in Bose-Einstein Condensate in Presence of Disorder**<sup>1</sup>, BISHWAJYOTI DEY, Department of Physics, SP Pune University, Pune 411007, India. — We study the vortex lattice dynamics in Bose-Einstein condensate (BEC) in presence of single impurity as well as random impurities or disorder. The single impurity is modeled by a Gaussian function while disorder is introduced in the system by a uniform random potential. Such potentials can be created experimentally by lasers. We solve the time-dependent Gross-Pitaevskii equation in two-dimensions using split-step Crank-Nicolson method. We first show that a single vortex can be pinned by an impurity. We then show that even a single impurity can distort the vortex lattice. For sufficiently strong impurity potential, the vortex lattice gets pinned to the impurity. We also show that a new type of giant hole with hidden vortices inside it can be created in the vortex lattice by a cluster of impurities. In presence of random impurity potential or disorder, the vortices get pinned at random positions leading to melting of the vortex lattice. We further show that the vortex lattice melting can also be induced by the pseudorandom potential generated by the superposition of two optical lattices. The absence of long-range order in the melted vortex lattice is demonstrated from the structure factor profile and the histogram of the distance between each pair of vortices.

**2:42PM C52.00002 From Vortex Rings to Hopfions in 3d Bose-Einstein Condensates**, PANAYOTIS KEVREKIDIS, UMass, Amherst — In this talk we report a number of recent results on three-dimensional topological states. Motivated by our earlier work on vortices, we develop a two-fold approach for studying vortex rings. We analytically and numerically explore their emergence through an instability from planar or ring dark soliton states in the small amplitude/weak nonlinearity limit. We also analytically and numerically explore the opposite, particle based limit of large density/large nonlinearity in the Thomas-Fermi regime. We connect these two analytically tractable limits through detailed numerical computations revealing the spectral and nonlinear stability of such states. We also explore a series of other states, including so-called Hopfions, and dark-soliton-shells examining both their regimes of stability in 3d atomic BECs, as well as their mechanisms and manifestations of dynamical instabilities.

**2:54PM C52.00003 Equation of Motion of a Quantum Vortex.**, TIMOTHY COX, University of British Columbia, PHILIP STAMP, University of British Columbia and the Pacific Institute of Theoretical Physics — Understanding the motion of vortices in quantum fluids is key to understanding the dynamics of such fluids. The motion of quantum vortices has long been understood in terms of the Hall-Vinen-Iordanski (HVI) equations. A fully quantum mechanical treatment of vortex motion in a two-dimensional Bose superfluid<sup>[1]</sup> leads to a modified version of the HVI equations which include significant history dependent forces and a fluctuating noise force. The dynamics deviates from that described by the HVI equations when the frequency of motion is higher than the temperature. We describe the consequences of the memory and noise for the motion of a single superfluid vortex as well as the circumstances under which their effects should be experimentally observable. <sup>[1]</sup> Thompson and Stamp, Phys Rev Lett. 108, 184501 (2012)

**3:06PM C52.00004 Helicity in superfluids**, HRIDESH KEDIA, DUSTIN KLECKNER, University of Chicago, DAVIDE PROMENT, University of East Anglia, WILLIAM T.M. IRVINE, University of Chicago — Ideal fluid flow conserves a special quantity known as helicity, in addition to energy, momentum and angular momentum. Helicity can be understood as a measure of the knottedness of vortex lines of the flow, providing an important geometric tool to study diverse physical systems such as turbulent fluids and plasmas. Since superfluids flow without resistance just like ideal (Euler) fluids, a natural question arises: Is there an extra conserved quantity akin to helicity in superfluids? We address the question of a "superfluid helicity" theoretically and examine its consequences in numerical simulations.

**3:18PM C52.00005 Finite temperature and density depletion effects on persistent current state transitions and critical velocity of a toroidal Bose-Einstein condensate**, AVINASH KUMAR, STEPHEN ECKEL, FRED JENDRZEJEWSKI<sup>1</sup>, Joint Quantum Institute, University of Maryland, GRETCHEN CAMPBELL, Joint Quantum Institute, University of Maryland, NIST — We study the decay of a persistent, quantized current state in a toroidal geometry. Our experiment involves trapping neutral <sup>23</sup>Na atoms in an all optical "target trap" shaped potential. This potential consists of a disc surrounded by an annular potential. A current in a superfluid can be sustained only below a critical current. This critical current can be tuned by introducing a density perturbation which depletes the local density. The decay time of a persistent current state can also be controlled by enhancing fluctuations of the system thermally. We study the decay at four different temperatures between 30 nK and 190 nK. For each temperature we record the decay at four different perturbation strengths. We find that increasing the magnitude of the density depletion or the temperature leads to a faster decay, and have seen the decay constant change by over two orders of magnitude. We also studied the size of hysteresis loop between different current states as a function of temperature, allowing us to extract a critical velocity. We find that the discrepancies between the experimentally extracted critical velocity and theoretically calculated critical velocity (using local-density approximation) decreases as the temperature is decreased.

**3:30PM C52.00006 Finite-temperature energy landscapes in rotating ring BECs**<sup>1</sup>, BRENNAN COHELEACH, CLAYTON HELLER, MARK EDWARDS, Georgia Southern Univ, STEVE ECKEL, AVINASH KUMAR, CHARLES CLARK, GRETCHEN CAMPBELL, Joint Quantum Institute — In a recent experiment conducted at NIST a ring Bose-Einstein condensate (BEC) was prepared in a unit angular momentum circulation state. A barrier was then slowly raised and left on for a variable hold time and then turned off. The final circulation of the BEC was studied as a function of hold time and barrier energy height. This procedure was carried out for several well-characterized non-zero temperatures. We have studied the energetics of this process under the assumption that a vortex is initially present in the center of the ring BEC and then travels out of the ring through the density notch created by the barrier. We have computed the energy per particle of the condensate system for a variable location of the vortex by solving the time-dependent Generalized Gross-Pitaevskii (GGP) equation in imaginary time. To account for finite-temperature we solved self-consistently for the condensate fraction as a function of temperature in thermal equilibrium for fixed total particle number. This yielded the non-condensate density which appears in the GGP affecting the energy of the vortex. We also modeled the dynamics of the vortex using the ZNG formalism.

**3:42PM C52.00007 Cold atoms in one-dimensional rings: a Luttinger liquid approach to precision measurement.**<sup>1</sup>, STEPHEN RAGOLE, JQI, QuICS, and University of Maryland, JACOB TAYLOR, JQI, QuICS, University of Maryland, and National Institute of Standards and Technology — Recent experiments have realized ring shaped traps for ultracold atoms. We consider the one-dimensional limit of these ring systems with a moving weak barrier, such as a blue-detuned laser beam. In this limit, we employ Luttinger liquid theory and find an analogy with the superconducting charge qubit. In particular, we find that strongly-interacting atoms in such a system could be used for precision rotation sensing. We compare the performance of this new sensor to the state of the art non-interacting atom interferometry.

**3:54PM C52.00008 Resonant wavepackets and shock waves in an atomtronic SQUID<sup>1</sup>**, YI-HSIEH WANG, A. KUMAR, Joint Quantum Institute, F. JENDRZEJEWSKI, Ruprecht-Karls-Universität, RYAN M. WILSON, The United States Naval Academy, MARK EDWARDS, Georgia Southern University, S. ECKEL, G. K. CAMPBELL, CHARLES W. CLARK, Joint Quantum Institute — The fundamental dynamics of ultracold atomtronic devices are reflected in their phonon modes of excitation. We probe such a spectrum by applying a harmonically driven potential barrier to a <sup>23</sup>Na Bose-Einstein condensate in a ring-shaped trap<sup>2</sup>. This perturbation excites phonon wavepackets. When excited resonantly, these wavepackets display a regular periodic structure. The resonant frequencies depend upon the particular configuration of the barrier, but are commensurate with the orbital frequency of a Bogoliubov sound wave traveling around the ring. Energy transfer to the condensate over many cycles of the periodic wavepacket motion causes enhanced atom loss from the trap at resonant frequencies. Solutions of the time-dependent Gross-Pitaevskii equation exhibit quantitative agreement with the experimental data. We also observe the generation of supersonic shock waves under conditions of strong excitation, and collisions of two shock wavepackets.

**4:06PM C52.00009 Anomalous hysteresis in a spinor atom-SQUID**, RANCHU MATHEW, Joint Quantum Institute, University of Maryland, EITE TIESINGA, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland — Over the past few years, there has been a concerted effort at NIST studying the atomic analogue of a Superconducting Quantum Interference Device (SQUID) [Eckel S. et al., Nature (London) 506, 200 (2014)]. The atom-SQUID consists of a Bose-Einstein condensate (BEC) in a ring trap with a rotating external potential or weak link. The system displays persistent currents and hysteresis as a function of rotation rate. We investigate the effect of the spin degree of freedom of an atom and a rotating vector potential, which mixes spin sublevels, on the hysteresis pattern by performing a numerical analysis of the Gross-Pitaevskii equation. For a spinless BEC the winding number of the BEC changes by one unit as the rotation of the potential is slowly changed beyond a critical value. In contrast, in a certain parameter regime for a spinor BEC with a vector potential the winding number changes by two units instead of one. To explain this anomalous phenomenon, we calculate the energies of the two saddle-points of the mean-field energy functional, which mediate the transitions to states which differs by one and two units of winding number.

**4:18PM C52.00010 Transport in a capacitive ultracold atomtronic circuit<sup>1</sup>**, MARK EDWARDS, BENJAMIN ELLER, Georgia Southern Univ, STEVE ECKEL, CHARLES CLARK, Joint Quantum Institute — A recent NIST experiment<sup>2</sup> studied the transport of a gaseous Bose-Einstein condensate (BEC) confined in an atomtronic “dumbbell” circuit. The optically created condensate potential consisted of a tight harmonic potential in the vertical direction confining the BEC to a horizontal plane. The horizontal potential consisted of two cylindrical wells separated by a channel produced by a harmonic oscillator potential transverse to the line joining the wells. The BEC, formed in the “source” well, was released to flow toward the “drain” well. The evolution of this system was shown to be reproduced by a model electronic circuit consisting of a charged capacitor,  $C$ , in series with an inductor,  $L$ , and a parallel combination of a resistor,  $R$ , and a Josephson junction. We modeled this system with the Gross-Pitaevskii (GP) equation and found good agreement with the data provided that the confining potential is carefully reproduced. The GP simulations show behavior, not detectable in the experiment, that atoms can jump out of the dumbbell area after filling up the drain well. We also present the dependence of  $R$  and  $L$  on the channel shape.

**4:30PM C52.00011 Collective modes of trapped Bose-Einstein condensates undergoing adiabatic deformation from filled-sphere to thin-shell geometries<sup>1</sup>**, COURTNEY LANNERT, Smith College, KUEI SUN, The University of Texas at Dallas, KARMELA PADAVI'C, SMITHA VISHVESHVARA, University of Illinois at Urbana-Champaign — Collective modes of a trapped Bose-Einstein condensate (BEC) are closely related to the ground-state density profile and are experimentally measurable. They are particularly useful for characterizing a BECs three-dimensional structure that cannot be well resolved by the two-dimensional absorption imaging. In this context, it is essential to understand the signatures of collective modes of a BEC in various typical geometries and how they change with the geometry. Here, we study a BEC confined in a spherical trap that is tunable to shape the BEC to be a filled sphere, a thin shell, or any crossover stage between them. We employ hydrodynamic treatments and real-time simulations of the Gross-Pitaevskii equation to obtain the collective modes. We find a set of radial modes that can distinguish a sphere from a shell, and an oscillation frequency dip in a crossover region where the central density becomes low. We also explore the angular modes and find a crucial role of the shell BECs inner boundary, which the sphere BEC lacks. Our findings ought to help future experimental investigations on recently realized BECs in bubble-trap potentials.

**4:42PM C52.00012 Gravitational Effects on Collective Modes of Superfluid Shells**, KARMELA PADAVI'C, University of Illinois at Urbana-Champaign, KUEI SUN, The University of Texas at Dallas, COURTNEY LANNERT, Smith College, SMITHA VISHVESHVARA, University of Illinois at Urbana-Champaign — We study the effects of gravity on collective excitations of shell-shaped Bose-Einstein condensates (BECs). Superfluid shells are of general interest as examples of hollow geometries that can be produced in ultracold atoms in bubble-trap potentials or optical lattices. Our approach to analyzing superfluid shells is based on a Gross-Pitaevskii mean field theory and hydrodynamic equations derived from it. Considering a spherically symmetric BEC in general, there are distinct collective excitation spectra for the cases of a fully filled sphere and a very thin shell. Furthermore, an adiabatic change in the potential producing a slow transition from one geometry to the other shows a characteristic evolution. Given that in most realistic experimental conditions gravity cannot be neglected we investigate its effects on the equilibrium profile and the collective modes in the very thin shell limit. We analytically obtain the full excitation spectrum for the thin shell geometry and account for gravity perturbatively at length and energy scales that describe a stable matter-wave bubble. We find that gravity breaks spherical symmetry of the equilibrium density profile and affects the collective excitations by coupling adjacent modes in the angular direction.

**4:54PM C52.00013 Classical and quantum dissipation of bright solitons in a bosonic superfluid**, DMITRY K. EFIMKIN, Condensed Matter Theory Center, University of Maryland, United States, JOHANNES B. HOFMANN, Condensed Matter Theory Center, University of Maryland, United States and TCM Group, Cavendish Laboratory, University of Cambridge, United Kingdom, VICTOR GALITSKI, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, United States — We consider the quantum dissipation of a bright soliton in a quasi-one-dimensional bosonic superfluid. The dissipation appears due to interaction of the soliton with Bogoliubov excitations, which act as a bath for the soliton. Using a collective coordinate approach and the Keldysh formalism, we derive a Langevin equation for the soliton motion which contains both a friction and a stochastic force. We argue that due to the integrability of the original problem, Ohmic friction is absent, rendering the dynamics non-Markovian. We furthermore show that the resulting friction can be interpreted as the backreaction of Bogoliubov quasiparticles emitted by an accelerating soliton, which represents an analogue of the Abraham-Lorentz force known in electrodynamics.

**5:06PM C52.00014 Interacting multiple zero mode formulation for a dark soliton in a Bose-Einstein condensate** , JUNICHI TAKAHASHI, YUSUKE NAKAMURA, YOSHIYA YAMANAKA, Waseda Univ. — The system of Bose-Einstein condensate (BEC) has a zero-mode (ZM) associated with the spontaneous breakdown of the global phase symmetry. However, to formulate the ZMs in quantum field theory for a finite-size system with spontaneous breakdown of symmetries is not trivial, for in the naive Bogoliubov theory one encounters difficulties such as phase diffusion, the absence of a definite criterion for determining the ground state, and infrared divergences. In order to remove this difficulty, we have recently proposed the new treatment of the ZM, which enable us to introduce a unique ground state in the ZM sector<sup>1</sup>. Using this ground state, we have evaluated the quantum fluctuation for the phase of condensate. In this presentation, we consider an atomic BEC system with a dark soliton that contains two ZMs corresponding to spontaneous breakdown of the global phase and translational symmetries. In our treatment, the original non-linear interaction of the field operator brings us the interaction between the two ZMs. We evaluate the standard deviations of the ZM operators and see how the mutual interaction between the two ZMs affects them.

**2:30PM C53.00001 First-principles temperature-dependent phonons and elastic constants** , LIN YANG, Lawrence Livermore National Laboratory, CA — Calculations of thermodynamic properties of materials from first-principles are critical for equation of state and materials strength modeling. Here we present the thermodynamic properties of a select set of metals based on density functional theory. In particular, we present elastic constants and lattice dynamics for body-centered cubic metals obtained from first-principles molecular dynamics and a self-consistent phonon approach. In order to calculate the thermodynamic properties, we make use of fluctuation formulas associated with the canonical ensemble form of *ab initio* molecular dynamics (AIMD). This procedure is efficient and takes into account the anharmonic contributions to the equilibrium thermodynamic properties. In the self-consistent lattice dynamics approach, the phonon dispersions at finite temperature are determined from small displacements along normal modes associated with the chosen temperature. This method provides an efficient and accurate technique for phonon spectrum and finite-temperature acoustic sound speeds and elastic constants. We found that both methods provide consistent results for the temperature- and pressure-dependent elastic moduli. The AIMD include full anharmonicity but suffers from statistical errors of the order of 5%. The self-consistent phonon method, on the other hand, has less statistical uncertainty but does not explicitly account for electron-phonon coupling. At ambient pressure, our calculations (both methods) agree quite well with experimental data. This work performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

**3:06PM C53.00002 The ReaxFF method - new applications and developments** , ADRI VAN DUIN, Penn State — The ReaxFF method provides a highly transferable simulation method for atomistic scale simulations on chemical reactions at the nanosecond and nanometer scale. It combines concepts of bond-order based potentials with a polarizable charge distribution. Since its initial development for hydrocarbons in 2001, we have found that this concept is transferable to applications to elements all across the periodic table, including all first row elements, metals, ceramics and ionic materials. For all these elements and associated materials we have demonstrated that ReaxFF can reproduce quantum mechanics-based structures, reaction energies and reaction barriers with reasonable accuracy, enabling the method to predict reaction kinetics in complicated, multi-material environments at a relatively modest computational expense. This presentation will describe the current concepts of the ReaxFF method, the current status of the various ReaxFF codes, including parallel implementations and recently developed hybrid Grand Canonical Monte Carlo options - which significantly increase its application areas. Also, we will present an overview of recent applications to a range of materials of increasing complexity, with a focus on applications to combustion, biomaterials, batteries, tribology and catalysis.

**3:42PM C53.00003 Discovering chemistry with an ab initio nanoreactor** , TODD MARTINEZ, Stanford University and SLAC National Accelerator Laboratory — Traditional approaches for modeling chemical reaction networks such as those involved in combustion have focused on identifying individual reactions and using theoretical approaches to explore the underlying mechanisms. Recent advances involving graphical processing units (GPUs), commodity products developed for the videogaming industry, have made it possible to consider a distinct approach wherein one attempts to discover chemical reactions and mechanisms. We provide a brief summary of these developments and then discuss the concept behind the “ab initio nanoreactor” which explores the space of possible chemical reactions and molecular species for a given stoichiometry. The nanoreactor concept is exemplified with an example to the Urey-Miller reaction network which has been previously advanced as a potential model for prebiotic chemistry. We briefly discuss some of the future directions envisioned for the development of this nanoreactor concept.

**4:18PM C53.00004 Multi-petaflop/s quantum and reactive molecular dynamics simulations** , AIICHIRO NAKANO, University of Southern California — We have developed a divide-conquer-recombine algorithmic framework for large quantum molecular dynamics (QMD) and reactive molecular dynamics (RMD) simulations. The algorithms have achieved parallel efficiency over 0.98 on 786,432 IBM Blue Gene/Q processors for 39.8 trillion electronic degrees-of-freedom QMD in the framework of density functional theory and 67.6 billion-atom RMD. We will discuss several applications including (1) 16,616-atom QMD simulation of rapid hydrogen production from water using metallic alloy nanoparticles, (2) 6,400-atom nonadiabatic QMD simulation of exciton dynamics for efficient solar cells, and (3) 112 million-atom RMD simulation of nanocarbon synthesis by high temperature oxidation of SiC nanoparticles.

**2:30PM C54.00001 Ballistic Hot Electron Transport in Heteroepitaxial SrRuO<sub>3</sub> Metal-Base Transistors**, BRIAN KIM, Stanford University, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, TAKEAKI YAJIMA, The University of Tokyo, CHRISTOPHER BELL, University of Bristol, HAROLD HWANG, Stanford University — Perovskite oxide heterostructures is a rapidly emerging field significant for interface-induced electronic and magnetic reconstructions, resulting in novel phases distinct from those found in the bulk counterparts. Notably, utilizing device structures is an effective way to probe these interface-induced phases. One of the most prevalent device structures that has been adopted so far is a three-terminal field-effect geometry, used to probe in-plane electronic transport properties. However, the out-of-plane three-terminal device geometry, though less studied due to its complexity, is also useful in many aspects. In the metal-base transistor (MBT), for instance, ballistic transport of hot electrons injected across a Schottky diode emitter can be used to probe hot electron properties of the metal-base, providing information on inelastic scattering mechanisms, electron confinement effects, and intervalley transfer. One promising model system for the metal-base is SrRuO<sub>3</sub> (SRO), characterized by intermediate electron correlations with unusual transport properties. Here we present an all-perovskite oxide heteroepitaxial MBT using SRO as a metal-base layer. Successful MBT operation for various metal-base layer thicknesses was achieved, from which the hot electron attenuation length of SRO was deduced. These results form a foundation on which to examine the properties of hot electrons in strongly correlated systems using the out-of-plane three-terminal device geometry.

**2:42PM C54.00002 Nondiffusive thermal transport increases temperature rise in RRAM filaments**, KEITH REGNER, JONATHAN MALEN, Carnegie Mellon University — Resistive-switching memory (RRAM) offers benefits to nonvolatile memory systems due to scalability, fast switching, and easy fabrication. In RRAM, electrical stimulation switches the resistance of a metal-insulator-metal memory cell. A low-resistance state is achieved during the set process, when a conductive filament (CF) is formed by dielectric breakdown. During the reset process, disruption of the CF restores the device to a high-resistance state. Studies suggest that dissolution of the CF during the reset process occurs when the CF reaches a critical temperature due to Joule heating. Typically, the heat diffusion equation with bulk thermal properties is used to model the thermal processes both within the CF and the surrounding oxide. It is well known, however, that heat transport is nondiffusive when experimental length scales are comparable to energy carrier mean free paths (MFPs). We suggest that heat transport in RRAM is nondiffusive by determining the phonon MFP spectrum in TiO<sub>2</sub> (i.e., a promising material for RRAM) and showing that MFPs that contribute significantly to heat transport are comparable to the diameter of the CF. Thus, we approximate the CF as an infinitely long cylinder embedded in crystalline rutile TiO<sub>2</sub> and develop an approximate analytical solution to the BTE in the TiO<sub>2</sub>. We find that the surface temperature of the CF predicted by the BTE is larger than that predicted by the heat diffusion equation. If the heat diffusion equation is used to model thermal transport in RRAM, a reduced effective TiO<sub>2</sub> thermal conductivity should be used.

**2:54PM C54.00003 AC Josephson effect without superconductivity, and other effects of radio frequency quantum nanoelectronics**, XAVIER WAINANT, BENOIT GAURY, JOSEPH WESTON, INAC, CEA Grenoble, France — With single coherent electron sources and electronic interferometers now available in the lab, the time resolved dynamics of electrons can now be probed directly. I will discuss how a fast raise of voltage propagates inside an electronic interferometer and leads to an oscillating current of well controlled frequency. This phenomena is the normal counterpart to the AC Josephson effect. I will also briefly advertize our software for computing quantum transport properties, Kwant (<http://kwant-project.org>) and its time-dependent extension T-Kwant.

**3:06PM C54.00004 Orbital magnetoresistance of two-dimensional electron systems in the hydrodynamic regime<sup>1</sup>**, ANTON ANDREEV, University of Washington, ALEX LEVCHENKO, University of Wisconsin-Madison — We develop a theory of magnetoresistance of two-dimensional electron systems in the hydrodynamic regime. It applies to two-dimensional semiconductor structures with strongly correlated carriers when the electron-electron scattering length is sufficiently short. We find that the magnetoresistance is positive quadratic at weak fields. Although the resistivity is governed by both viscosity and thermal conductivity of the electron fluid, the temperature dependence of magnetoresistance depends on the viscosity only. This enables extraction of viscosity of the electron liquid from magnetotransport measurements.

**3:18PM C54.00005 The effect of split gate dimensions on the electrostatic potential and 0.7 anomaly within one-dimensional quantum wires on a modulation doped GaAs/AlGaAs heterostructure**, L. W. SMITH\*, H. AL-TAIE, A. A. J. LESAGE, K. J. THOMAS, F. SFIGAKIS, P. SEE, J. P. GRIFFITHS, I. FARRER, G. A. C. JONES, D. A. RITCHIE, M. J. KELLY, C. G. SMITH, University of Cambridge, Cavendish Laboratory — We use a multiplexing scheme to measure the conductance properties of 95 split gates of 7 different gate dimensions fabricated on a GaAs/AlGaAs chip, in a single cool down [1]. The number of devices for which conductance is accurately quantized reduces as the gate length increases. However, even the devices for which conductance is accurately quantized in units of  $2e^2/h$  show no correlation between the length of electrostatic potential barrier in the channel and the gate length, using a saddle point model to estimate the barrier length. Further, the strength of coupling between the gates and the 1D channel does not increase with gate length beyond 0.7  $\mu\text{m}$ . The background electrostatic profile appears as significant as the gate dimension in determining device behavior. We find a clear correlation between the curvature of the electrostatic barrier along the channel and the strength of the “0.7 anomaly” which identifies the electrostatic length of the channel as the principal factor governing the conductance of the 0.7 anomaly.

[1] L. W. Smith *et al.*, arXiv:1508.03085

**3:30PM C54.00006 Electron Energy Levels in the 1D-2D Transition<sup>1</sup>**, MICHAEL PEPPER, KUMAR SANJEEV, KALARIKAD THOMAS, GRAHAM CREETH, DAVID ENGLISH, London Centre for Nanotechnology, University College London, DAVID RITCHIE, University College London, JONATHAN GRIFFITHS, IAN FARRER, GERAINT JONES, Cavendish Laboratory, University of Cambridge — Using GaAs-AlGaAs heterostructures we have investigated the behaviour of electron energy levels with relaxation of the potential confining a 2D electron gas into a 1D configuration. In the ballistic regime of transport, when the conductance shows quantized plateaux, different types of behaviour are found according to the spins of interacting levels, whether a magnetic field is applied and lifting of the momentum degeneracy with a source-drain voltage. We have observed both crossing and anti-crossing of levels and have investigated the manner in which they can be mutually converted. In the presence of a magnetic field levels can cross and lock together as the confinement is altered in a way which is characteristic of parallel channels. The overall behaviour is discussed in terms of electron interactions and the wavefunction flexibility allowed by the increasing two dimensionality of the electron distribution as the confinement is weakened.

**3:42PM C54.00007 Single-electron devices fabricated using double-angle deposition and plasma oxidation**, Y. HONG, Z. S. BARCIKOWSKI, A. N. RAMANAYAKA, M. D. STEWART JR., N. M. ZIMMERMAN, J. M. POMEROY, National Institute of Standards and Technology, QUANTUM PROCESSES AND METROLOGY GROUP TEAM — We report on development of plasma oxidized, single-electron transistors (SETs) where we seek low-capacitance and small-area Al/AIOx/Al tunnel junctions with small charge offset drift. Performance of metal-based SET quantum devices and superconducting devices has suffered from long-term charge offset drift, high defect densities and charge noise. We use plasma oxidation to lower defect densities of the oxide layer, and adjustable deposition angles to control the overlapping areas for Al/AIOx/Al tunnel junctions. Current-voltage and charge offset drift measurements are planned for cryogenic temperatures. Other electrical properties will be measured at room temperature. We hope to see Coulomb blockade oscillations on these devices and better charge offset stability than typical Al/AIOx/Al SETs.

**3:54PM C54.00008 Quantum point contacts on two-dimensional electron gases with a strong spin-orbit coupling<sup>1</sup>**, JOON SUE LEE, California NanoSystems Institute, Univ of California, Santa Barbara, MIHIR PENDAHARKAR, Department of Electrical and Computer Engineering, Univ of California, Santa Barbara, BORZOYEH SHOJAEI, Materials Department, Univ of California, Santa Barbara, ANTHONY P. MCFADDEN, Department of Electrical and Computer Engineering, Univ of California, Santa Barbara, CHRIS PALMSTRM, Materials Department and Department of Electrical and Computer Engineering, Univ of California, Santa Barbara — Studies of electrical transport in one-dimensional semiconductors in a presence of a strong spin-orbit interaction are crucial not only for exploring the emergent phenomena, such as topological superconductivity, but also for potential spintronic applications by controlling of the electron spins. We investigate the electrical transport properties of one-dimensional confinement defined by electrostatic potentials on large area two-dimensional electron gases of InAs and InSb, which have a strong spin-orbit coupling. The high-quality InAs and InSb quantum wells are grown on antimonide buffers by molecular beam epitaxy, and the gate-tunable regions are created using Al<sub>2</sub>O<sub>3</sub> or HfO<sub>2</sub> gate dielectrics by atomic layer deposition. We will discuss the modulation of spin-orbit coupling in the two-dimensional electron gases and the spin-orbit-induced spin splitting by the split-gate quantum point contacts.

**4:06PM C54.00009 Quenching Plasma Waves in Two Dimensional Electron Gas by a Femtosecond Laser Pulse**, MICHAEL SHUR, Rensselaer Polytech Inst, SERGEY RUDIN AND GREG RUPPER COLLABORATION<sup>1</sup>, ANDREY MURAVIEV COLLABORATION<sup>2</sup> — Plasmonic detectors of terahertz (THz) radiation using the plasma wave excitation in 2D electron gas are capable of detecting ultra short THz pulses. To study the plasma wave propagation and decay, we used femtosecond laser pulses to quench the plasma waves excited by a short THz pulse. The femtosecond laser pulse generates a large concentration of the electron-hole pairs effectively shorting the 2D electron gas channel and dramatically increasing the channel conductance. Immediately after the application of the femtosecond laser pulse, the equivalent circuit of the device reduces to the source and drain contact resistances connected by a short. The total response charge is equal to the integral of the current induced by the THz pulse from the moment of the THz pulse application to the moment of the femtosecond laser pulse application. This current is determined by the plasma wave rectification. Registering the charge as a function of the time delay between the THz and laser pulses allowed us to follow the plasmonic wave decay. We observed the decaying oscillations in a sample with a partially gated channel. The decay depends on the gate bias and reflects the interplay between the gated and ungated plasmons in the device channel.

**4:18PM C54.00010 Evidence for a New Intermediate Phase in a Strongly Correlated 2D System near Wigner Crystallization<sup>1</sup>**, XUAN GAO, RICHARD QIU, NICHOLAS GOBLE, Case Western Reserve University, ALEX SERAFIN, LIANG YIN, JIAN-SHENG XIA, NEIL SULLIVAN, National High Magnetic Field Laboratory and University of Florida, LOREN PFEIFFER, KEN WEST, Princeton University — How the two dimensional (2D) quantum Wigner crystal (WC) transforms into the metallic liquid phase remains an outstanding problem in physics. In theories considering the 2D WC to liquid transition in the clean limit, it was suggested that a number of intermediate phases might exist. We have studied the transformation between the metallic fluid phase and the low magnetic field reentrant insulating phase (RIP) which was interpreted as due to the WC [Qiu et al, PRL 108, 106404 (2012)], in a strongly correlated 2D hole system in GaAs quantum well with large interaction parameter  $r_s$  ( $\sim 20-30$ ) and high mobility. Instead of a sharp transition, we found that increasing density (or lowering  $r_s$ ) drives the RIP into a state where the incipient RIP coexists with Fermi liquid. This apparent mixture phase intermediate between Fermi liquid and WC also exhibits a non-trivial temperature dependent resistivity behavior which can be qualitatively understood by the reversed melting of WC in the mixture, in analogy to the Pomeranchuk effect in the solid-liquid mixture of Helium-3. Reference: R. Qiu et al, arXiv:1509.07463.

**4:30PM C54.00011 Electron bilayers in an undoped Si/SiGe double-quantum-well heterostructure**, TZU-MING LU, DOMINIQUE LAROCHE, Sandia National laboratories, SHIH-HSIEN HUANG, National Taiwan University, ERIK NIELSEN, Sandia National laboratories, YEN CHUANG, JIUN-YUN LI, CHEEWEE LIU, National Taiwan University — We report the design, fabrication, and the magneto-transport study of an undoped Si/SiGe double quantum well heterostructure. We show that employing asymmetric quantum wells for our single-side-gated devices allows us to observe a cross-over from single-layer-like to bi-layer-like behavior in the mobility-density dependence. We also observe an integer quantum Hall state at filling factor  $\nu = 2$ , which is expected to arise from inter-layer effects for Si electrons. This state could be due to either inter-layer coherence, or the symmetric-antisymmetric tunneling gap. This work has been supported by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy (DOE). Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**4:42PM C54.00012 What carries heat in novel 2D semiconductors?**, ANDREA CEPPELLOTTI, Ecole Polytechnique Federale de Lausanne, Switzerland, GIORGIA FUGALLO, Ecole Polytechnique, Paris, France, LORENZO PAULATTO, FRANCESCO MAURI, Sorbonne Universites, Paris, France, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne, Switzerland — When materials are scaled down to the microscopic scale, or when dimensionality is reduced, thermal transport exhibits new intriguing behaviors that are not present in conventional bulk crystals. While phonons are typically considered to be the excitations responsible for carrying heat through a crystal, as dimensionality is reduced, the motion of phonons driven by a temperature perturbation becomes correlated, and collective excitations of many phonons arise [1]. This leads to a wealth of complex phenomena, such as very high thermal conductivity (the highest known conductivities are indeed found in 2D materials), or wave-like heat diffusion, with second sound, hitherto found only in a few exotic materials at cryogenic temperatures, routinely present at room temperature [2]. In this contribution, we show that heat transport in crystals can be described exactly with the kinetic theory of a gas of collective phonon excitations, termed relaxons. In this way, it is possible to recover a microscopic interpretation based on mean free paths and relaxation times without any simplification of the linearised phonon Boltzmann equation. [1] G. Fugallo, A. Cepellotti, et al., Nano Lett. 14, 6109 (2014) [2] A. Cepellotti, et al., Nat. Commun. 6, 6400 (2015)

**4:54PM C54.00013 Coherent dynamics of Landau-Levels in modulation doped GaAs quantum wells at high magnetic fields<sup>1</sup>** , CUNMING LIU, JAGANNATH PAUL, University of South Florida, JOHN RENO, CINT, Sandia National Laboratories, STEPHEN MCGILL, National High Magnetic Field Laboratory, DAVID HILTON, University of Alabama at Birmingham, DENIS KARAIKAI, University of South Florida — By using two-dimensional Fourier transform spectroscopy, we investigate the dynamics of Landau-Levels formed in modulation doped GaAs/AlGaAs quantum wells of 18 nm thickness at high magnetic fields and low temperature. The measurements show interesting dephasing dynamics and linewidth dependency as a function of the magnetic field. The work at USF and UAB was supported by the National Science Foundation under grant number DMR-1409473. The work at NHMFL, FSU was supported by the National Science Foundation under grant numbers DMR-1157490 and DMR-1229217. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

**5:06PM C54.00014 Probing Carrier Transport across Patterned Interfaces with Ballistic Electron Emission Microscopy** , WESTLY NOLTING, CHRISTOPHER DURCAN, ROBERT BALSANO, College of Nanoscale Science and Engineering, VINCENT LABELLA, SUNY Polytechnic Institute — Electron scattering from sidewalls within aggressively scaled metallic interconnects dramatically increases the resistance, since the mean free path (~40 nm) is larger than the dimensions of the structure. One method to study hot-electron scattering in nm-thick metallic films is Ballistic Electron Emission Microscopy (BEEM), which is an STM based technique. In this work, we perform BEEM imaging and scattering measurements on lithographically patterned nanoscale oxide “fin” structures with a Schottky diode interface to determine its ability to measure sidewall scattering. This is accomplished by acquiring data from BEEM images and spectra on a regularly spaced grid and fitting the results to determine both the Schottky barrier height and the amplitude of the spectra. The amplitude of the spectra is related to the scattering in the film and interface. The position of fin structures is then determined by mapping both the Schottky height and amplitude over a square micron to observe scattering at the interface caused by the patterned structures. The fabrication of the patterned 50-nm-pitched sidewall structures and the preliminary BEEM imaging measurements on these structures will be presented.

**Session C55 FPS DBIO: The Physics of Epidemics** Hilton Baltimore Holiday Ballroom 6 - Walter Beyerler, Sandia National Labs

**2:30PM C55.00001 Mitigating Infectious Disease Outbreaks<sup>1</sup>** , VICTORIA DAVEY, Department of Veterans Affairs — The emergence of new, transmissible infections poses a significant threat to human populations. As the 2009 novel influenza A/H1N1 pandemic and the 2014-2015 Ebola epidemic demonstrate, we have observed the effects of rapid spread of illness in non-immune populations and experienced disturbing uncertainty about future potential for human suffering and societal disruption. Clinical and epidemiologic characteristics of a newly emerged infectious organism are usually gathered in retrospect as the outbreak evolves and affects populations. Knowledge of potential effects of outbreaks and epidemics and most importantly, mitigation at community, regional, national and global levels is needed to inform policy that will prepare and protect people. Study of possible outcomes of evolving epidemics and application of mitigation strategies is not possible in observational or experimental research designs, but computational modeling allows conduct of ‘virtual’ experiments. Results of well-designed computer simulations can aid in the selection and implementation of strategies that limit illness and death, and maintain systems of healthcare and other critical resources that are vital to public protection.

Session D20 DCMP FOEP: Special Outreach Session: Science and Cooking 310 -

**7:30PM D20.00001 Science and Cooking** — Many chefs are developing new approaches to prepare and present their cuisine using materials common to many physics labs, such as liquid nitrogen, foams, emulsions and hydrogels. In fact, the ingredients and methods of modern cooking can provide a wonderful inspiration to the teaching of introductory science. This talk will explore the physics of cooking and will include demonstrations. The science of several innovative techniques in cooking, including foams and the use of gelation, as well as more common processes, will be explored. The talk is inspired by a course taught at Harvard University through a collaboration of professors and well-known chefs. Presented by David Weitz, Harvard University.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**

Session E1 DCMP: Recent Developments in Hybrid Semiconductor-Superconductor Junctions

Ballroom I - Yong Chen, Purdue University

**8:00AM E1.00001 Finite Momentum Pairing and Spatially Varying Order Parameter in Proximitized HgTe Quantum Wells**, AMIR YACOBY, Harvard University — Conventional s-wave superconductivity is understood to arise from singlet pairing of electrons with opposite Fermi momenta, forming Cooper pairs whose net momentum is zero. Several recent studies have focused on structures where such conventional s-wave superconductors are coupled to systems with an unusual configuration of electronic spin and momentum at the Fermi surface. Under these conditions, the nature of the paired state can be modified and the system may even undergo a topological phase transition. Here we present measurements and theoretical calculations of several HgTe quantum wells coupled to either aluminum or niobium superconductors and subject to a magnetic field in the plane of the quantum well. By studying the oscillatory response of Josephson interference to the magnitude of the in-plane magnetic field, we find that the induced pairing within the quantum well oscillates between singlet and triplet pairing and is spatially varying. Cooper pairs acquire a tunable momentum that grows with magnetic field strength, directly reflecting the response of the spin-dependent Fermi surfaces to the in-plane magnetic field. Our new understanding of the interplay between spin physics and superconductivity introduces a way to spatially engineer the order parameter, as well as a general framework within which to investigate electronic spin texture at the Fermi surface of materials.

**8:36AM E1.00002 S-TI-S Josephson junction networks: a platform for exploring and exploiting topological states and Majorana fermions**, DALE J VAN HARLINGEN, Univ of Illinois - Urbana — We are studying the transport properties of hybrid superconductor-topological insulator nanoscale devices fabricated by depositing superconductor electrodes onto the surface of topological insulators. In top-gated lateral Nb-Bi<sub>2</sub>Se<sub>3</sub>-Nb junctions, we have measured the Josephson supercurrent and conductance as a function of geometry, temperature, and gate voltage in order to determine the nature of the electronic transport. The supercurrent exhibits a sharp drop as a function of gate voltage that may be explained by the relocation of the topological surface state from above to below trivial conducting surface states formed by band-banding near the surface. We find that the magnetic field modulation of the supercurrent in Josephson junctions and dc SQUIDs exhibits anomalous features consistent with a  $4\pi$ -periodic  $\sin(\varphi/2)$ -component in the junction current-phase relation that may arise from the nucleation of Majorana bound states in the junction. We are exploring circuits for imaging, manipulating, and braiding these exotic excitations and schemes for reading out their parity. In collaboration with Aaron Finck, Erik Huemiller, Cihan Kurter, Vladimir Oryanchik, Martin Stehno, and Can Zhang.

**9:12AM E1.00003 Induced superconductivity in high mobility two dimensional electron gas in GaAs heterostructures**, LEONID P. ROKHINSON, Purdue University — Search for Majorana fermions renewed interest in semiconductor-superconductor interfaces, while a quest for higher order non-Abelian excitations demands formation of superconducting contacts to materials with fractionalized excitations, e.g. a two-dimensional electron gas in a fractional quantum Hall regime. Here we report induced superconductivity in high mobility two-dimensional electron gas in GaAs heterostructures and development of highly transparent semiconductor-superconductor ohmic contacts. Supercurrent with characteristic temperature dependence of a ballistic junction has been observed across  $0.6 \mu\text{m}$ , a regime previously achieved only in point contacts but essential to the formation of well separated non-Abelian states. High critical fields ( $> 16 \text{ Tesla}$ ) in NbN contacts enables investigation of an interplay between superconductivity and strongly correlated states in a two dimensional electron gas at high magnetic fields.

**9:48AM E1.00004 Proximity induced topological superconductivity and Majorana fermions**, CARLO BEENAKKER, Leiden University — Topological states of matter are a source of low-energy quasiparticles, bound to a defect or propagating along the surface. In a superconductor these are Majorana fermions, described by a real rather than a complex wave function. The absence of complex phase factors promises protection against decoherence in quantum computations based on topological superconductivity. The early theoretical models that produced Majorana fermions relied on an exotic superconducting order, with spin-triplet Cooper pairs in a chiral  $p$ -wave orbital state. A recent alternative is to start from a conventional spin-singlet superconductor and use the proximity effect to induce a topologically nontrivial superconducting state in a material with strong spin-orbit coupling. In this talk we give an overview of some of the manifestations of a real Majorana wave function that are waiting to be observed. In particular, we discuss how shot noise measurements can provide for a purely electrical method of detection of charge-neutral Majorana edge modes.

**10:24AM E1.00005 Milestones toward Majorana-based quantum computing<sup>1</sup>**, JASON ALICEA, Caltech — Experiments on nanowire-based Majorana platforms now appear poised to move beyond the preliminary problem of zero-mode detection and towards loftier goals of realizing non-Abelian statistics and quantum information applications. Using an approach that synthesizes recent materials growth breakthroughs with tools long successfully deployed in quantum-dot research, I will outline a number of relatively modest milestones that progressively bridge the gap between the current state of the art and these grand longer-term challenges. The intermediate Majorana experiments surveyed in this talk should be broadly adaptable to other approaches as well.

Session E2 DCOMP DCMP: Computational Methods for Improved Transparent Conducting Oxides Ballroom II - Giulia Galli, Univ of Chicago

## 8:00AM E2.00001 Structure and Properties of Amorphous Transparent Conducting Oxides<sup>1</sup>,

JULIA MEDVEDEVA, Missouri University of Science and Technology — Driven by technological appeal, the research area of amorphous oxide semiconductors has grown tremendously since the first demonstration of the unique properties of amorphous indium oxide more than a decade ago. Today, amorphous oxides, such as a-ITO, a-IZO, a-IGZO, or a-ZITO, exhibit the optical, electrical, thermal, and mechanical properties that are comparable or even superior to those possessed by their crystalline counterparts, pushing the latter out of the market. Large-area uniformity, low-cost low-temperature deposition, high carrier mobility, optical transparency, and mechanical flexibility make these materials appealing for next-generation thin-film electronics. Yet, the structural variations associated with crystalline-to-amorphous transition as well as their role in carrier generation and transport properties of these oxides are far from being understood. Although amorphous oxides lack grain boundaries, factors like (i) size and distribution of nanocrystalline inclusions; (ii) spatial distribution and clustering of incorporated cations in multicomponent oxides; (iii) formation of trap defects; and (iv) piezoelectric effects associated with internal strains, will contribute to electron scattering. In this work, ab-initio molecular dynamics (MD) and accurate density-functional approaches are employed to understand how the properties of amorphous ternary and quaternary oxides depend on quench rates, cation compositions, and oxygen stoichiometries. The MD results, combined with thorough experimental characterization, reveal that interplay between the local and long-range structural preferences of the constituent oxides gives rise to a complex composition-dependent structural behavior in the amorphous oxides. The proposed network models of metal-oxygen polyhedra help explain the observed intriguing electrical and optical properties in In-based oxides and suggest ways to broaden the phase space of amorphous oxide semiconductors with tunable properties.

<sup>1</sup>The work is supported by NSF-MRSEC program

## 8:36AM E2.00002 Quasiparticle energies, excitonic effects, and dielectric screening in transparent conducting oxides ,

ANDRÉ SCHLEIFE, University of Illinois at Urbana-Champaign — Using the power of high-performance super computers, computational materials scientists nowadays employ highly accurate quantum-mechanical approaches to reliably predict materials properties. In particular, many-body perturbation theory is an excellent framework for performing theoretical spectroscopy on novel materials including transparent conducting oxides, since this framework accurately describes quasiparticle and excitonic effects.

We recently used hybrid exchange-correlation functionals and an efficient implementation of the Bethe-Salpeter approach to investigate several important transparent conducting oxides. Despite their exceptional potential for applications in photovoltaics and optoelectronics their optical properties oftentimes remain poorly understood: Our calculations explain the optical spectrum of bixbyite indium oxide over a very large photon energy range, which allows us to discuss the importance of quasiparticle and excitonic effects at low photon energies around the absorption onset, but also for excitations up to 40 eV. We show that in this regime the energy dependence of the electronic self energy cannot be neglected. Furthermore, we investigated the influence of excitonic effects on optical absorption for lanthanum-aluminum oxide and hafnium oxide. Their complicated conduction band structures require an accurate description of quasiparticle energies and we find that for these strongly polar materials, a contribution of the lattice polarizability to dielectric screening needs to be taken into account. We discuss how this affects the electron-hole interaction and find a strong influence on excitonic effects.

The deep understanding of electronic excitations that can be obtained using these modern first-principles techniques, eventually will allow for computational materials design, e.g. of band gaps, densities of states, and optical properties of transparent conducting oxides and other materials with societally important applications.

## 9:12AM E2.00003 Limits of transparency of transparent conducting oxides<sup>1</sup> ,

HARTWIN PEELAERS, University of California, Santa Barbara — A fundamental understanding of the factors that limit transparency in transparent conducting oxides (TCOs) is essential for further progress in materials and applications. These materials have a sufficiently large band gap, so that direct optical transitions do not lead to absorption of light within the visible spectrum. Since the presence of free carriers is essential for conductivity and thus for device applications, this introduces the possibility of additional absorption processes. In particular, indirect processes are possible, and these will constitute a fundamental limit of the material. The Drude theory is widely used to describe free-carrier absorption, but it is phenomenological in nature and tends to work poorly at shorter wavelengths, where band-structure effects are important.

We will present calculations of phonon- and defect-assisted free-carrier absorption in a TCO completely from first principles [1]. We will focus in detail on SnO<sub>2</sub>, but the methodology is general and we will also compare the results obtained for other TCO materials such as In<sub>2</sub>O<sub>3</sub>. These calculations provide not just quantitative results but also deeper insights in the mechanisms that govern absorption processes, which is essential for engineering improved materials to be used in more efficient devices.

<sup>1</sup>This work was performed in collaboration with E. Kioupakis and C.G. Van de Walle and was supported by ARO and NSF.

## 9:48AM E2.00004 High-throughput search for improved transparent conducting oxides ,

ANNA MIGLIO, Universit  catholique de Louvain — High-throughput methodologies are a very useful computational tool to explore the space of binary and ternary oxides. We use these methods to search for new and improved transparent conducting oxides (TCOs). TCOs exhibit both visible transparency and good carrier mobility and underpin many energy and electronic applications (e.g. photovoltaics, transparent transistors). We find several potential new n-type and p-type TCOs with a low effective mass. Combining different ab initio approaches, we characterize candidate oxides by their effective mass (mobility), band gap (transparency) and dopability. We present several compounds, not considered previously as TCOs, and discuss the chemical rationale for their promising properties. This analysis is useful to formulate design strategies for future high mobility oxides and has led to follow-up studies including preliminary experimental characterization of a p-type TCO candidate with unexpected chemistry. G. Hautier, A. Miglio, D. Waroquiers, G.-M. Rignanese, and X. Gonze, How Does Chemistry Influence Electron Effective Mass in Oxides? A High-Throughput Computational Analysis, Chem. Mater. 26, 5447 (2014). G. Hautier, A. Miglio, G. Ceder, G.-M. Rignanese, and X. Gonze, Identification and design principles of low hole effective mass p-type transparent conducting oxides, Nature Commun. 4, 2292 (2013).

## 10:24AM E2.00005 Hybrid functional studies of defects and hole polarons in oxides. ,

JOEL VARLEY, Lawrence Livermore Natl Lab — Transparent conducting oxides (TCOs) are ubiquitous, appearing in windows, flat-panel displays, solar cells, solid-state lighting, and transistors that all exploit TCOs' combination of high electrical conductivity and optical transparency. Thanks to this large and growing list of applications, there has been a surge of interest in the science of these materials, focusing on the fundamental properties and doping opportunities in traditional TCOs as well as the exploration of promising new candidate materials. Hybrid density functional theory has proven instrumental in elucidating the physics of TCOs. One example is the study of dopants and defects that determine the conductivity. Accurate formation energies and charge-state transition levels can now be obtained thanks to the accurate electronic structure provided by a hybrid functional. This allows us to address the origins of unintentional conductivity: for SnO<sub>2</sub>, In<sub>2</sub>O<sub>3</sub>, and Ga<sub>2</sub>O<sub>3</sub>, we demonstrate that this is *not* due to native defects such as oxygen vacancies, but must be attributed to unintentional incorporation of impurities. We can also provide guidelines for achieving higher doping levels, suggesting several impurities as candidate donors with high solubility. Limitations on doping due to the formation or incorporation of compensating centers are addressed as well. Hybrid functional calculations also overcome the shortcomings associated with traditional local or semi-local functionals, which do not properly describe charge localization. Hybrid functionals accurately describe polaron formation, i.e., the self-trapping of holes when p-type doping of the oxide materials is attempted. Consequences of polaron formation for optical characterization of the material will be discussed. This work was performed in collaboration with Anderson Janotti and Chris G. Van de Walle, and was in part under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**

**Session E3 GMAG DCMF: A New Approach to the Kitaev Quantum Spin Liquid** Ballroom III -

Young-June Kim, Univ of Toronto

**8:00AM E3.00001 Possible Observation of fractionalized excitations in a Relativistic Mott Insulator**, KENNETH BURCH, Boston College — The combination of electronic correlation and spin-orbit coupling is thought to precipitate a variety of highly unusual electronic phases in solids, including topological and quantum spin liquid states. I will discuss our recent optical measurements that provide evidence for the relativistic Mott Insulating ground state of  $\alpha$ -RuCl<sub>3</sub>. Furthermore I will discuss the broad-continuum of scattering we observe, whose energy and temperature dependence suggest the presence of fractionalized excitations emerging from a quantum spin-liquid.

**8:36AM E3.00002 Inelastic neutron scattering evidence for Kitaev quantum spin liquid physics in  $\alpha$ -RuCl<sub>3</sub>**<sup>1</sup>, STEPHEN NAGLER, Oak Ridge National Laboratory — The magnetic semiconductor  $\alpha$ -RuCl<sub>3</sub> is composed of very weakly coupled honeycomb layers of edge-sharing RuCl<sub>6</sub> octahedra. The Ru<sup>3+</sup> ion has 5 *d* electrons in the low spin state, and the system is expected to have an effective  $J = \frac{1}{2}$  single ion ground state with an interacting spin Hamiltonian containing Kitaev-like terms. Inelastic neutron scattering [1] on powders and single crystals has been used to determine the energy scale of the magnetic interactions and the overall form of the magnetic fluctuations. The results indicate that the Kitaev term is significant. Moreover, detailed measurements of the response show evidence for the fractionalized excitations that are characteristic of the Kitaev quantum spin liquid.

<sup>1</sup>Research supported by the Scientific User Facilities Division, Basic Energy Sciences, US Department of Energy

**9:12AM E3.00003 Magnetic and Crystal Structure of  $\alpha$ -RuCl<sub>3</sub>**, JENNIFER SEARS, University of Toronto — The layered honeycomb material  $\alpha$ -RuCl<sub>3</sub> has been proposed as a candidate material to show significant bond-dependent Kitaev type interactions [1]. This has prompted several recent studies of magnetism in this material that have found evidence for multiple magnetic transitions in the temperature range of 8-14 K [2,3,4]. We will present elastic neutron scattering measurements collected using a co-aligned array of  $\alpha$ -RuCl<sub>3</sub> crystals, identifying zigzag magnetic order within the honeycomb planes with an ordering temperature of  $\sim 8$  K [2]. It has been reported that the ordering temperature depends on the *c* axis periodicity of the layered structure, with ordering temperatures of 8 and 14 K for three and two-layer periodicity respectively [3]. While the in-plane magnetic order has been identified, it is clear that a complete understanding of magnetic ordering and interactions will depend on the three dimensional structure of the crystal. Evidence of a structural transition at  $\sim 150$  K has been reported [4] and questions remain about the structural details, in particular the stacking of the honeycomb layers. We will present x-ray diffraction measurements investigating the low and high temperature structures and stacking disorder in  $\alpha$ -RuCl<sub>3</sub>. Finally, we will present inelastic neutron scattering measurements of magnetic excitations in this material.

Work done in collaboration with K. W. Plumb (Johns Hopkins University), J. P. Clancy, Young-June Kim (University of Toronto), J. Britten (McMaster University), Yu-Sheng Chen (Argonne National Laboratory), Y. Qiu, Y. Zhao, D. Parshall, and J. W. Lynn (NCNR).

**9:48AM E3.00004 XY-like frustrated magnetic phase transitions in  $\alpha$ -RuCl<sub>3</sub>**, HIDEKAZU TANAKA, Tokyo Institute of Technology — It is known that a honeycomb-lattice antiferromagnet with the nearest-neighbor exchange interaction undergoes a conventional magnetic ordering even for the spin-1/2 case. However, when a certain amount of second-neighbor exchange interaction or anisotropic exchange interaction exists, the honeycomb-lattice quantum magnet exhibits an unusual ground state. In the last decade, spin-1/2 quantum magnets on honeycomb lattices have been attracting considerable attention from the viewpoints of the frustrated  $J_1 - J_2$  model and the Kitaev-Heisenberg model, both of which can exhibit the spin liquid state in some parameter range.

$\alpha$ -RuCl<sub>3</sub> is a layered compound, in which magnetic Ru<sup>3+</sup> ions with the 4*d*<sup>5</sup> electronic state form a honeycomb lattice. We have investigated the magnetic properties of  $\alpha$ -RuCl<sub>3</sub> via magnetization and specific heat measurements using single crystals. It was observed that  $\alpha$ -RuCl<sub>3</sub> undergoes a structural phase transition at  $T_t \simeq 150$  K accompanied by fairly large hysteresis. The magnetizations and magnetic susceptibilities are strongly anisotropic, which mainly arise from the anisotropic *g*-factors. These *g*-factors and the obtained entropy indicate that the effective spin of Ru<sup>3+</sup> is one-half, which results from the low-spin state. Specific heat data show that magnetic ordering occurs in four steps at zero magnetic field. The magnetic phase diagram is obtained. The successive magnetic phase transitions can be ascribed to the competition among exchange interactions. We discuss the strongly anisotropic *g*-factors and deduce that the exchange interaction is strongly XY-like. Main results of this talk was published in Phys. Rev. B 91, 094422 (2015).

**10:24AM E3.00005 Manifestations of Kitaev physics in thermodynamic properties of hexagonal iridates and  $\alpha$ -RuCl<sub>3</sub>**<sup>1</sup>, ALEXANDER TSIRLIN, Experimental Physics VI, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, Germany — Kitaev model is hard to achieve in real materials. Best candidates available so far are hexagonal iridates M<sub>2</sub>IrO<sub>3</sub> (M = Li and Na) and the recently discovered  $\alpha$ -RuCl<sub>3</sub> featuring hexagonal layers coupled by weak van der Waals bonding. I will review recent progress in crystal growth of these materials and compare their thermodynamic properties. Both hexagonal iridates and  $\alpha$ -RuCl<sub>3</sub> feature highly anisotropic Curie-Weiss temperatures that not only differ in magnitude but also change sign depending on the direction of the applied magnetic field. Néel temperatures are largely suppressed compared to the energy scale of the Curie-Weiss temperatures. These experimental observations will be linked to features of the electronic structure and to structural peculiarities associated with deviations from the ideal hexagonal symmetry. I will also discuss how the different nature of ligand atoms affects electronic structure and magnetic superexchange.

<sup>1</sup>This work has been done in collaboration with M. Majumder, M. Schmidt, M. Baenitz, F. Freund, and P. Gegenwart

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**

**Session E4 DPOLY: Polymer Physics Prize** Ballroom IV - Stephen Cheng, University of Akron

**8:00AM E4.00001 Polymer Physics Prize: Designing "Materials that Compute": Exploiting the Properties of Self-oscillating Polymer Gels**, ANNA BALAZS, University of Pittsburgh — Lightweight, deformable materials that can sense and respond to human touch and motion can be the basis of future wearable computers, where the material itself will be capable of performing computations. To facilitate the creation of "materials that compute", we draw from two emerging modalities for computation: chemical computing, which relies on reaction-diffusion mechanisms to perform operations, and oscillatory computing, which performs pattern recognition through synchronization of coupled oscillators. Chemical computing systems, however, suffer from the fact that the reacting species are coupled only locally; the coupling is limited by diffusion as the chemical waves propagate throughout the system. Additionally, oscillatory computing systems have not utilized a potentially wearable material. To address both these limitations, we develop the first model for coupling self-oscillating polymer gels to a piezoelectric (PZ) micro-electro-mechanical system (MEMS). The resulting transduction between chemo-mechanical and electrical energy creates signals that can be propagated quickly over long distances and thus, permits remote, non-diffusively coupled oscillators to communicate and synchronize. The oscillators can be organized into arbitrary topologies because the electrical connections lift the limitations of diffusive coupling. Using our model, we predict the synchronization behavior that can be used for computational tasks, ultimately enabling "materials that compute".

**8:36AM E4.00002 Reaction-Diffusion Patterns in Structured Media**, IRVING EPSTEIN, Department of Chemistry, Brandeis University, Waltham, MA — I will look at pattern formation in the Belousov-Zhabotinsky (BZ) oscillating chemical reaction in media that are structured at length scales ranging from ten nanometers to a few centimeters. A reverse microemulsion consisting of nanometer diameter droplets of water containing the reactants dispersed in oil allows the physical structure (size, spacing) of the droplets and their chemical composition to be controlled independently, enabling one to generate a remarkable variety of stationary and moving patterns, including Turing structures, ordinary and antispirals, packet waves and spatiotemporal chaos. One- and two-dimensional arrays of aqueous droplets in oil generated by microfluidic techniques have diameters of the order of 100 micrometers and produce a different array of patterns that can be precisely controlled with light. In particular, circular arrays of droplets provide a testing ground for some of Turing's ideas about morphogenesis. By attaching the BZ catalyst to a polymer that shrinks and swells in response to changes in the redox state of the catalyst, one can construct gel materials that transduce chemical changes to mechanical motion, a phenomenon modeled with considerable success by the Balazs group. If time permits, I will also discuss the BZ reaction in coupled macroscopic flow reactors that mimic small neural networks.

**9:12AM E4.00003 Modeling Anisotropic Self-Assembly of Isotropic Objects: from Hairy Nanoparticles to Methylcellulose Fibrils<sup>1</sup>**, VALERIY GINZBURG, The Dow Chemical Company — Spontaneous symmetry breaking and formation of anisotropic structures from apparently isotropic building blocks is an exciting and not fully understood topic. I will discuss two examples of such self-assembly. The first example is related to the assembly of "hairy" nanoparticles in homopolymer matrices<sup>1</sup>. The particles can assemble into long strings (they can also form other morphologies, as well) even though the shape of each particle and the distribution of ligands on the particle surface is spherically symmetric. Using the approach developed by Thompson, Ginzburg, Matsen, and Balazs<sup>2</sup>, we show that presence of other particles can re-distribute the ligands and effectively "polarize" the particle-particle interaction, giving rise to the formation of 1d particle strings<sup>3</sup>. In the second example, we consider aqueous solutions of methylcellulose (MC) polymers. It has been shown recently<sup>4</sup> that at high temperature, the polymers form high-aspect ratio "fibrils" with diameter ~15 nm and length in the hundreds of nanometers. Using coarse-grained Molecular Dynamics (CG-MD), we propose that the "fibrils" are result of one-dimensional self-assembly of single molecule "rings". Each MC polymer chain is forced into a ring because of the balance between internal chain rigidity (favoring more expanded configuration) and unfavorable polymer-water interactions (favoring more collapsed conformation). We also develop a theory predicting rheology and phase behavior of aqueous MC, and validate it against experimental data<sup>5</sup>. Both examples show that anisotropic self-assembly can show up in unexpected places, and various theoretical tools are needed to successfully model it. 1. P. **9:48AM E4.00004 Functional, Responsive Materials Assembled from Recombinant Oleosin.**, DANIEL HAMMER, University of Pennsylvania — Biological cells are surrounded by a plasma membrane made primarily of phospholipids that form a bilayer. This membrane is permselective and compartmentalizes the cell. A simple form of artificial cell is the vesicle, in which a phospholipid bilayer membrane surrounds an aqueous solution. However, there is no a priori reason why a membrane needs to be made of phospholipids. It could be made of any surfactant that forms a bilayer. We have assembled membranes and other structures from the recombinant plant protein oleosin. The ability to assemble from a recombinant protein means that every molecule is identical, we have complete control over the sequence, and hence can build in designer functionality with high fidelity, including adhesion and enzymatic activity. Such incorporation is trivial using the tools of molecular biology. We find that while many variants of oleosin make membranes, others make micelles and sheets. We show how the type of supramolecular structure can be altered by the conditions of solvent, such as ionic strength, and the architecture of the surfactant itself. We show that protease cleavable domains can be incorporated within oleosin, and be engineered to protect other functional domains such as adhesive motifs, to make responsive materials whose activity and shape depend on the action of proteases. We will also present the idea of making "Franken"-oleosins, where large domains of native oleosin are replaced with domains from other functional proteins, to make hybrids conferred by the donor protein. Thus, we can view oleosin as a template upon which a vast array of designer functionalities can be imparted..

**10:24AM E4.00005 Moving HAIRS: Towards adaptive, homeostatic materials**, JOANNA AIZENBERG, Harvard — Dynamic structures that respond reversibly to changes in their environment are central to self-regulating thermal and lighting systems, targeted drug delivery, sensors, and self-propelled locomotion. Since an adaptive change requires energy input, an ideal strategy would be to design materials that harvest energy directly from the environment and use it to drive an appropriate response. This lecture will present the design of a novel class of reconfigurable materials that use surfaces bearing arrays of nanostructures put in motion by environment-responsive gels. Their unique hybrid architecture, and chemical and mechanical properties can be optimized to confer a wide range of adaptive behaviors. Using both experimental and modeling approaches, we are developing these hydrogel-actuated integrated responsive systems (HAIRS) as new materials with reversible optical and wetting properties, as a multifunctional platform for controlling cell differentiation and function, and as a first homeostatic system with autonomous self-regulation.

**Session E5 GMAG DMP: Magnetic Thin Films and Multilayers** 301 - Madhukar Reddy, Lam Research Corporation

**8:00AM E5.00001 Spin-orbit coupling of 3d transition metal atoms on MgO/Ag**, SHRUBA GANGOPADHYAY, University of California, Davis, BARBARA JONES, IBM Research Almaden — Spin-orbit coupling is normally predominant for high Z metal atoms, but we observe Fe and Co showing significant orbital moments on a MgO/Ag surface. DFT results show that on MgO/Ag both Co and Fe prefer O top binding sites. Calculation of orbital moments using DFT is always challenging, and we compare two DFT based protocols to calculate orbital moments. Our calculations show the magnitude of orbital moments strongly dependent on a number of factors including the number of Ag layers in our unit cell and the approximation we are using. Our results exhibit significant agreement with scanning tunneling microscopy (STM) and XMCD experiments. We show that Co retains its full atomic orbital moment on the O top site of MgO whereas the orbital moment for Fe is somewhat less than its atomic orbital moment.

**8:12AM E5.00002 Enhancement of the Co magnetic moment in bcc  $\text{Co}_{1-x}\text{Mn}_x$  on  $\text{MgO}^1$** , RYAN SNOW, HARSH BHATKAR, Montana State University, ALPHA N'DIAYE, ELKE ARENHOLZ, Lawrence Berkeley National Laboratories, YVES IDZERDA, Montana State University, MONTANA STATE UNIVERSITY TEAM, LAWRENCE BERKELEY NATIONAL LABORATORIES TEAM — Using X-ray absorption spectroscopy (XAS) and X-ray magnetic circular dichroism (MCD), we show that the elemental Co moment for MBE grown thin films of bcc  $\text{Co}_{1-x}\text{Mn}_x$  grown on  $\text{MgO}(001)$  is enhanced by 40% to a maximum value of  $2.1 \mu_B$  at  $x=0.24$ . The net Mn moment is found to align parallel with Co for all concentrations and remains roughly constant until  $x=0.3$ , then drops steadily, up to  $x=0.7$ , where the total moment of the film abruptly collapses to zero. Using a low-concentration Mn moment of  $3.0 \mu_B$ , the average magnetization lies directly on the Slater-Pauling (SP) curve for concentrations up to about  $x=0.25$ , where it reaches a maximum moment of  $2.3 \mu_B/\text{atom}$ . This peak is slightly shifted and the slope is steeper on the high-Mn concentration side of the peak relative to the standard SP curve. This is in stark contrast to the fcc CoMn and hcp CoCr bulk behavior which shows only a rapid total moment reduction with Mn concentration.

**8:24AM E5.00003 Cap-Induced Magnetic Anisotropy in Ultra-thin Fe/ $\text{MgO}(001)$  Films<sup>1</sup>**, TOBIAS BROWN-HEFT, Materials Department, University of California Santa Barbara, MIHIR PENDHARKAR, Electrical and Computer Engineering Department, University of California Santa Barbara, ELIZABETH LEE, Engineering Department, Harvey Mudd College, Claremont, CA, CHRIS PALMSTROM, Electrical and Computer Engineering Department & Materials Department, University of California Santa Barbara — Magnetic anisotropy plays an important role in the design of spintronic devices. Perpendicular magnetic anisotropy (PMA) is preferred for magnetic tunnel junctions because the resulting energy barrier between magnetization states can be very high and this allows enhanced device scalability suitable for magnetic random access memory applications. Interface induced anisotropy is often used to control magnetic easy axes. For example, the Fe/ $\text{MgO}(001)$  system has been predicted to exhibit PMA in the ultrathin Fe limit. We have used *in-situ* magneto optic Kerr effect and *ex-situ* SQUID to study the changes in anisotropy constants between bare Fe/ $\text{MgO}(001)$  films and those capped with  $\text{MgO}$ , Pt, and Ta. In some cases in-plane anisotropy terms reverse sign after capping. We also observe transitions from superparamagnetic to ferromagnetic behavior induced by capping layers. Perpendicular anisotropy is observed for Pt/Fe/ $\text{MgO}(001)$  films after annealing to 300C. These effects are characterized and incorporated into a magnetic simulation that accurately reproduces the behavior of the films.

**8:36AM E5.00004 Thickness quantization in a reorientation transition**, DAVID VENUS, GENGMIN HE, HARRISON WINCH, RANDY BELANGER, McMaster University — The reorientation transition of an ultrathin film from perpendicular to in-plane magnetization is driven by a competition between shape and surface anisotropy. It is accompanied by a "stripe" domain structure that evolves as the reorientation progresses. Often, an  $n$  layer film has stable perpendicular magnetization and an  $n+1$  layer film has stable in-plane magnetization. If the domain walls are not pinned, the long-range stripe domain pattern averages over this structure so that the transition occurs at a non-integer layer thickness. We report *in situ* experimental measurements of the magnetic susceptibility (via MOKE) of the reorientation transition in Fe/2 ML Ni/W(110) films as a function of thickness as they are deposited at room temperature. In addition to a peak at the reorientation transition, we observe a strong precursor due to thickness quantization in atomic layers. This peak is described quantitatively by the response of small islands of thickness 3 layers with in-plane anisotropy in a sea of 2 layers Fe with perpendicular anisotropy. The fitted parameters give an estimate of the island size at which the response disappears. This size corresponds to a domain wall thickness, so that the islands become locally in-plane, demonstrating the self-consistency of the model.

**8:48AM E5.00005 Spin and orbital magnetic moments of Fe and Co in Co/Fe and Fe/Co multilayers on Si from  $L_{2,3}$  edge X-ray Magnetic Circular Dichroism Spectroscopy<sup>1</sup>**, KRISHNAMURTHY VEMURU, George Mason University, Fairfax, Virginia, RICHARD ROSENBERG, Advanced Photon Source, Argonne National Laboratory, Lemont, Illinois, GARY MANKEY, The University of Alabama, Tuscaloosa, Alabama — Nanostructured FeCo thin films are interesting for magnetic recording applications due to their high saturation magnetization, high Curie temperature and low magnetocrystalline anisotropy. It is desirable to know how the magnetism is modified by the nanostructure. We report Fe  $L_{2,3}$  edge and Co  $L_{2,3}$  edge x-ray magnetic circular dichroism (XMCD) investigations of element specific spin and orbital magnetism of Fe and Co in two multilayer samples: (S1) Si/ $\text{SiO}_2$ /[Co 0.8 nm/Fe 1.6 nm] $\times 32/\text{W}$  (2nm) and (S2) Si/ $\text{SiO}_2$ /[Co 1.6 nm/Fe 0.8 nm] $\times 32/\text{W}$  (2nm) thin films at room temperature. Sum rule analysis of XMCD at Fe  $L_{2,3}$  edge in sample S1 shows that the orbital moment of Fe is strongly enhanced and the spin moment is strongly reduced as compared to the values found in bulk Fe. Details of sum rule analysis will be presented to compare and contrast spin magnetic moments and orbital magnetic moments of Fe and Co in the two multilayer samples.

**9:00AM E5.00006 Direct Mapping of Magnetic and Structural Profiles of Electric Field Moderated Oxygen Migration**, DUSTIN A. GILBERT, ALEXANDER J. GRUTTER, BRIAN J. KIRBY, JULIE A. BORCHERS, BRIAN B. MARANVILLE, National Institute of Standards and Technology, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, KAI LIU, University of California, Davis — Recent studies on metal/oxide heterostructures have demonstrated control of interfacial magnetic anisotropy and saturation magnetization in ultrathin (5 ML) Co films through electric-field controlled oxygen migration. This approach presents a promising route to realizing next-generation, ultralow power sensor and data-storage technologies. Here we demonstrate magnetoelectric coupling moderated by electrically-driven oxygen migration in much thicker  $\text{AlOx}(1 \text{ nm})/\text{GdOx}(2 \text{ nm})/\text{Co}(15 \text{ nm})$  heterostructures. Using polarized neutron reflectometry, we present direct, quantitative depth profiling of the magnetization and oxygen concentration in these systems. Electro-thermal conditioning moves oxygen from  $\text{AlOx}$  and  $\text{GdOx}$  base-layers throughout the entire thickness of the 15 nm Co layer, resulting in a suppressed magnetization. Switching the electric field polarity semi-reversibly ejects oxygen preferentially from the  $\text{GdOx}/\text{Co}$  interface, partially recovering the magnetization and establishing a practical limit to this approach. First order reversal curve diagrams show that the conditioned samples exhibit two distinct magnetic phases, while the as-grown samples are single phase, suggesting that the treatments alters the Co film microstructure. X-ray spectroscopy confirms the oxidation states of the Co and Gd, and suggest that the  $\text{GdOx}$  acts to transmit oxygen but does not source or sink it.

**9:12AM E5.00007 Magnetic localization limit in  $T_C$  graded ferromagnetic thin films**, BRIAN KIRBY, National Institute of Standards and Technology, LORENZO FALLARINO, PATRICIA RIEGO, MATTEO PANCALDI, ANDREAS BERGER, CIC nanoGUNE Consolider, CASEY MILLER, Rochester Institute of Technology — We have recently demonstrated that the effective Curie temperature ( $T_C$ ) of a ferromagnetic alloy thin film can be continuously varied as a function of depth via a corresponding compositional gradient.[1] This work showed that the effective  $T_C$  can be made to vary continuously over tens of nm. However, over a short enough distance, the system must become localized, with exchange coupling dominating the effects of the compositional gradient. Understanding this localization limit is important for potential applications, as it dictates the length-scale below which this technique stops being a viable engineering tool (at least for itinerant ferromagnets and their thermodynamic properties). To determine the localization limit in this class of system, we have fabricated a series of  $\text{Co}[1-x]\text{Cr}[x]$  alloy films, where  $x$  varies sinusoidally between 0.28 (nominal  $T_C \approx 250 \text{ K}$ ) and 0.22 ( $T_C > 300 \text{ K}$ ), and have used polarized neutron reflectometry to study samples of differing oscillation wavelength. These measurements confirm the desired sinusoidal pattern was achieved, and reveal the temperature-dependence of the magnetic depth profile. Results will be presented in the context of mean-field simulations. [1] arXiv:1510.07535 [cond-mat.mtrl-sci].

**9:24AM E5.00008 Magnetic Irreversibility in VO<sub>2</sub>/Ni Bilayers.** , JOSE DE LA VENTA, JOSH LAUZIER, LOGAN SUTTON, Colorado State Univ — The temperature dependence of the coercivity and magnetization of VO<sub>2</sub>/Ni bilayers was studied. VO<sub>2</sub> exhibits a well-known Structural Phase Transition (SPT) at 330-340 K, from a low temperature monoclinic (M) to a high temperature rutile (R) structure. The SPT of VO<sub>2</sub> induces an inverse magnetoelastic effect that strongly modifies the coercivity and magnetization of the Ni films. In addition, the growth conditions allow tuning of the magnetic properties. Ni films deposited on top of VO<sub>2</sub> (M) show an irreversible change in the coercivity after the first cycle through the high temperature phase, with a corresponding change in the surface morphology of VO<sub>2</sub>. On the other hand, the Ni films grown on top of VO<sub>2</sub> (R) do not show this irreversibility. These results indicate that properties of magnetic films are strongly affected by the strain induced by materials that undergo SPT and that it is possible to control the magnetic properties by tuning the growth conditions.

**9:36AM E5.00009 Layer Resolved Imaging of Magnetic Domain Motion in Epitaxial Heterostructures** , SIOAN ZOHAR, YONGSEONG CHOI, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, DAVID LOVE, RHODRI MANSELL, CRISPIN BARNES, Cavendish Laboratory, University of Cambridge, J J Thomson Avenue, CB3 0HE Cambridge, United Kingdom, DAVID KEAVNEY, RICHARD ROSENBERG, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA — We use X-ray Excited Luminescence Microscopy (XELM) to image the elemental and layer resolved magnetic domain structure of an epitaxial Fe/Cr wedge/Co heterostructure in the presence of large magnetic fields. The observed magnetic domains exhibit several unique behaviors that depend on the Cr thickness (tCr) modulated interlayer exchange coupling (IEC) strength. For Cr thickness tCr < 0.34 nm and tCr > 1.5 nm, strongly coupled parallel Co-Fe reversal and weakly coupled layer independent reversal are observed, respectively. The transition between these two reversal mechanisms for 0.34 < tCr < 1.5 nm is described by a combination of IEC guided domain wall motion and stationary zig zag domain walls. We observe domain walls nucleated at switching field minima are guided by IEC spatial gradients and collapse at switching field maxima.

**9:48AM E5.00010 Magnetic profile of a graphene wrapped ferromagnetic surface** , TIMOTHY CHARLTON, Science & Technology Facilities Council, DAVID LOVE, RAZAN ABOLJADAYEL, R. WEATHERUP, P. MONTEIRO, ADRIAN IONESCU, C. H. W BARNES, Cavendish Laboratory, Dept. of Physics, University of Cambridge — Graphene has one of the highest electron mobilities at room temperature, making it ideal for next generation electronic devices. However, due to its small spin-orbit coupling it is not possible to manipulate spins directly in a pristine graphene monolayer. This may be overcome by proximity to a ferromagnet. Recent theoretical and experimental publications [1] indicate that on a Ni surface the graphene band structure is spin split. The authors used XMCD to measure the magnetic moment induced on the  $\pi$ -electrons in graphene due to the proximity effect with Ni, obtaining a value between 0.05-0.10  $\mu_B$  per C atom. We have produced a uniform graphene layer grown by a CVD process directly a Ni coated substrate (the catalyst). By varying key growth parameters (temperature & pressure) the interaction between graphene and the catalyst can be tuned to provide strong epitaxial alignment between graphene and Ni or a more weakly oriented rotated alignment. We will present results showing a magnetic enhancement at the ferromagnet - C interface extracted from recent polarized neutron reflectivity measurement on both epitaxial and rotated graphene wrapped ferromagnetic surfaces. [1] V. Karpan, et al., Phys. Rev. B 78, 195419 (2008), M. Weser, et al., Appl. Phys. Lett. 96, 012504 (2010)

**10:00AM E5.00011 Self Exchange Bias and Bi-stable Magneto-Resistance States in Amorphous TbFeCo and TbSmFeCo Thin Films.**<sup>1</sup> , CHUNG MA, XIAOPU LI, JIWEI LU, JOSEPH POON, Univ of Virginia, RYAN COMES, ARUN DEVARAJ, STEVEN SPURGEON, Pacific Northwest National Laboratory — Amorphous ferrimagnetic TbFeCo and TbSmFeCo thin films are found to exhibit strong perpendicular magnetic anisotropy. Self exchange bias effect and bi-stable magneto-resistance states are observed near compensation temperature by magnetic hysteresis loop, anomalous Hall effect and transverse magneto-resistance measurements. Atom probe tomography, scanning transmission electron microscopy, and energy dispersive spectroscopy mapping have revealed two nanoscale amorphous phases with different Tb concentration distributed within the amorphous films. The observed exchange anisotropy originates from the exchange interaction between the two nanoscale amorphous phases. Exchange bias effect is used for increasing stability in spin valves and magnetic tunneling junctions. This study opens up a new platform for using amorphous ferrimagnetic thin films that require no epitaxial growth in nanodevices..

<sup>1</sup>The work was supported by the Defense Threat Reduction Agency grant and the U.S. Department of Energy.

**10:12AM E5.00012 Angular dependence of exchange bias and magnetization reversal controlled by electric-field-induced competing anisotropies.** , YONGGANG ZHAO, AITIAN CHEN, PEISEN LI, Tsinghua University, XU ZHANG, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, RENCI PENG, Tsinghua University, HAO-LIANG HUANG, University of Science and Technology of China, LVKUAN ZOU, XIAOLI ZHENG, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, SEN ZHANG, College of National University of Defense Technology, PEIXIAN MIAO, Tsinghua University, YALIN LU, University of Science and Technology of China, JIAN CAI, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, CE-WEN NAN, Tsinghua University — Combination of exchange-biased systems and FE materials gives a new avenue to study angular dependence of exchange bias and achieve reversible electric-field-controlled magnetization reversal. We study the angular dependence of electric-field-controlled exchange bias and magnetization reversal in CoFeB/IrMn/Pb(Mg<sub>1/3</sub>Nb<sub>2/3</sub>)<sub>0.7</sub>Ti<sub>0.3</sub>O<sub>3</sub>. It is demonstrated that the ratio of the exchange-coupled unidirectional anisotropy and the uniaxial anisotropy of the FM layer, as well as their relative orientation can be dramatically and continuously tuned via electric fields. Simulations confirm that the electric-field-controlled exchange bias originates from the competition between the uniaxial anisotropy induced by the piezostain and the exchange-coupled unidirectional anisotropy. Moreover, electric-field-controlled magnetization reversal was realized at zero magnetic field.

**10:24AM E5.00013 Rationale for contrasting phonon confinement and interface localization effect in FeAg and FeCr multilayers**<sup>1</sup> , SAMPYO HONG, TALAT RAHMAN, University of Central Florida — We have performed density functional theory based calculations to investigate the propensity for formation of FeAg and FeCr multilayers. A perfect lattice match between Fe and Ag layers at the FeAg interface was obtained by modeling 45 rotated Ag(100) layers epitaxially on bcc Fe(100). In comparison, the FeCr interface was modeled by epitaxial layers of bcc Fe(100) and Cr(100). In FeAg, we find the signature peak of Fe bulk phonons (35 meV) to be substantially diminished and the low energy peaks to be remarkably enhanced, in qualitative agreement with experiment [1]. In contrast, the phonon density of state in the FeCr multilayers do not show any outstanding feature except a slight decrease in the 35 meV peak for the Fe layer at the interface, as compared to that of the middle Fe layer in excellent agreement with experiment [2]. The magnetic moment of the interfacial Fe atoms is larger than those Fe atoms in other layers, as a result of charge transfer from Fe to Ag at the interface. As compared to the middle layers, more spin-up and less spin-down states are occupied at the interface in such a way that Fe donates a large number of spin-down electrons to Ag but receives only a few spin-up electrons from the latter because of the almost fully occupied Ag d-band. [1] B. Roldan Cuenya et al., to be published. [2] Roldan et al, Phys. Rev. B 77, 165410 (2008).

**10:36AM E5.00014 Magneto-optical mapping of the domain wall pinning potential in ferro-magnetic films<sup>1</sup>**, ROBERT BADEA, JESSE BEREZOVSKY, Case Western Reserve Univ — The propagation of domain walls in ferromagnetic films is influenced by defects which suppress and pin the motion of the domain walls. We map the nanoscale effective pinning potential in a ferromagnetic film by raster scanning a single ferromagnetic vortex domain and measuring the hysteretic displacement vs. applied magnetic field.[1] We use a differential magneto-optical microscopy technique which yields spatial sensitivity of  $\sim 10$  nm to measure the motion of the vortex domain.[2] Using a simple algorithm, we extract the effective pinning potential from the measured vortex displacement vs. applied field. The resulting effective pinning potential maps reveal different types of nanoscale pinning features which we attribute to different structural defects of the film. By comparing the pinning map to atomic force microscopy maps, we identify correlations between pinning sites and topographic features. [1] R. Badea, and J. Berezovsky, cond-mat/1510.07059, (2015). **10:48AM E5.00015 Kinetic Monte Carlo simulations of thermally activated magnetization reversal in dual-layer Exchange Coupled Composite recording media.**, M. L. PLUMER, A. M. ALMUDALLAL, J. I. MERCER, J. P. WHITEHEAD, Memorial University of Newfoundland, T. J. FAL, University of Colorado at Colorado Springs — The kinetic Monte Carlo (KMC) method developed for thermally activated magnetic reversal processes in single-layer recording media [1] has been extended to study dual-layer Exchange Coupled Composition (ECC) media used in current and next generations of disc drives [2]. The attempt frequency is derived from the Langer formalism with the saddle point determined using a variant of Bellman Ford algorithm. Complication (such as stagnation) arising from coupled grains having metastable states are addressed. MH-hysteresis loops are calculated over a wide range of anisotropy ratios, sweep rates and inter-layer coupling parameter. Results are compared with standard micromagnetics at fast sweep rates and experimental results at slow sweep rates.

**Session E6 GMAG DMP FIAP: Spin Excitations in Ultrathin Films, Nanostructures and Domain Walls** 302 - Behrouz Khodadadi, University of Alabama

**8:00AM E6.00001 Nonlinear spin-wave excitations at low magnetic bias fields**, GEORG WOLTERSDORF, Martin Luther University Halle — We investigate experimentally and theoretically the nonlinear magnetization dynamics in magnetic films at low magnetic bias fields. Nonlinear magnetization dynamics is essential for the operation of numerous spintronic devices ranging from magnetic memory to spin torque microwave generators. Examples are microwave-assisted switching of magnetic structures and the generation of spin currents at low bias fields by high-amplitude ferromagnetic resonance. In the experiments we use X-ray magnetic circular dichroism to determine the number density of excited magnons in magnetically soft  $\text{Ni}_{80}\text{Fe}_{20}$  thin films. Our data show that the common Suhl instability model of nonlinear ferromagnetic resonance is not adequate for the description of the nonlinear behavior in the low magnetic field limit. Here we derive a model of parametric spin-wave excitation, which correctly predicts nonlinear threshold amplitudes and decay rates at high and at low magnetic bias fields. In fact, a series of critical spin-wave modes with fast oscillations of the amplitude and phase is found, generalizing the theory of parametric spin-wave excitation to large modulation amplitudes. For these modes, we also find pronounced frequency locking effects that may be used for synchronization purposes in magnonic devices. By using this effect, effective spin-wave sources based on parametric spin-wave excitation may be realized. Our results also show that it is not required to invoke a wave vector-dependent damping parameter in the interpretation of nonlinear magnetic resonance experiments performed at low bias fields.

**8:36AM E6.00002 Spin torque ferromagnetic resonance in Heusler based magnetic tunnel junctions**, JIE ZHANG, TIMOTHY PHUNG, AAKASH PUSHUP, JAEWOO JEONG, YARI FERRANTE, CHARLES RETTNER, BRIAN P. HUGHES, SEE-HUN YANG, STUART S.P. PARKIN, IBM Almaden Res Ctr — Heusler compounds are of interest as electrode materials for use in magnetic tunnel junctions (MTJs) due to their half metallic character, which leads to high spin polarization and high tunneling magnetoresistance. Whilst much work has focused on the influence of the half metallic character of the Heusler compounds on the magnetoresistance of MTJs, there is much less work investigating the influence of this electronic structure on the spin transfer torque. Here, we investigate the bias dependence of the anti-damping like and field-like spin transfer torque components as a function of the bias voltage in symmetric ( $\text{CoMnSi}/\text{MgO}/\text{CoMnSi}$ ) and asymmetric ( $\text{CoMnSi}/\text{MgO}/\text{CoFe}$ ) structure magnetic tunnel junctions using spin transfer torque ferromagnetic resonance. Lastly, we report on the effect of asymmetric bias dependence of the differential conductance on the spin transfer torque.

**8:48AM E6.00003 Parametric excitation of magnetization by electric field**, YU-JIN CHEN, HAN KYU LEE, Univ of California - Irvine, ROMAN VERBA, Institute of Magnetism, Kyiv, Ukraine, JORDAN KATINE, HGST, VASIL TIBERKEVICH, ANDREI SLAVIN, Oakland University, IGOR BARSUKOV, ILYA KRIVOROTOV, Univ of California - Irvine — Manipulation of magnetization by electric field is of primary importance for development of low-power spintronic devices. We present the first experimental demonstration of parametric generation of magnetic oscillations by electric field. We realize the parametric generation in  $\text{CoFeB}/\text{MgO}/\text{SAF}$  nanoscale magnetic tunnel junctions (MTJs). The magnetization of the free layer is perpendicular to the sample plane while the magnetizations of the synthetic antiferromagnet (SAF) lie in the plane. We apply microwave voltage to the MTJ at  $2f$ , where  $f$  is the ferromagnetic resonance frequency of the free layer. In this configuration, the oscillations can only be driven parametrically via voltage-controlled magnetic anisotropy (VCMA) whereby electric field across the MgO barrier modulates the free layer anisotropy. The parametrically driven oscillations are detected via microwave voltage from the MTJ near  $f$  and show resonant character, observed only in a narrow range of drive frequencies near  $2f$ . The excitation also exhibits a well-pronounced threshold drive voltage of approximately 0.1 Volts. Our work demonstrates a low threshold for parametric excitation of magnetization by VCMA that holds promise for the development of energy-efficient nanoscale spin wave devices.

**9:00AM E6.00004 Control of Spin Wave Band Structure in YIG using Electric Fields<sup>1</sup>**, GLADE SIETSEMA, MICHAEL E. FLATTÉ, University of Iowa — It has previously been shown that a uniform electric field can be used to modify the dispersion relations of spin waves in a YIG slab<sup>2</sup>. The application of the electric field results in a Dzyaloshinsky-Moriya interaction, which then produces a linear shift of the spin wave frequencies<sup>3</sup>. In this work we consider the effects of a periodically varying electric field on a slab of YIG. The spin wave frequencies and linewidths of the system are obtained from the Landau-Lifshitz-Gilbert equation using the plane-wave expansion method. We demonstrate that the periodic variation of the electric field opens band gaps in the spin wave dispersion relations. A band gap width of several hundred MHz is observed when the electric field strength is alternating between 0 and  $8 \cdot 10^7$  V/m over a length scale of 200 nm. The frequency and width of these band gaps can be tuned by adjusting the electric field strength and the lattice constant associated with the periodicity, and quality factors on the order of 100 can be achieved.

**9:12AM E6.00005 Measuring magnon propagation in magnonic crystals at millikelvin temperatures<sup>1</sup>** , ALEXY KARENOWSKA, ARJAN VAN LOO, RICHARD MORRIS, SANDOKO KOSEN, University of Oxford, Department of Physics, ANDRII CHUMAK, ALEXANDER SERGA, BURKARD HILLEBRANDS, Technische Universitaet Kaiserslautern — Magnon systems are increasingly widely recognized as a potential basis for solid-state quantum information processing. Propagating magnons are readily excited over the same range of microwave frequencies as are used in established quantum circuit technologies, and couple readily to electromagnetic fields. These facts, in combination with the relatively slow speeds and highly tunable dispersion of the excitations, make them a particularly interesting proposition in the context of quantum devices. Here, we present the first experimental study of microwave-frequency magnonic crystals (magnon systems with an artificially engineered bandgap) at millikelvin temperatures. Our magnonic crystals were prepared by etching grooves into a magnon waveguide made from a film of the magnetic insulator, yttrium iron garnet. The high signal-to-noise afforded by our low-temperature measurement environment makes it possible to make detailed observations of the dispersion of externally excited propagating magnon modes within the crystals. Our results lead us to suggest a range of device applications of dispersion-engineered magnonic systems in the context of microwave-circuit based quantum information processing.

**9:24AM E6.00006 Torque-mixing Magnetic Resonance Spectroscopy** , JOSEPH LOSBY, FATEMEH FANI SANI, Univ. of Alberta, Dept. of Physics and National Institute for Nanotechnology, DYLAN GRANDMONT, Univ. of Alberta, Department of Physics, ZHU DIAO, Univ. of Alberta, Dept. of Physics and National Institute for Nanotechnology, MIRO BELOV, National Institute for Nanotechnology, JACOB BURGESS, SHAWN COMPTON, WAYNE HIEBERT, Univ. of Alberta, Dept. of Physics and National Institute for Nanotechnology, DOUG VICK, National Institute for Nanotechnology, KAVEH MOHAMMAD, ELHAM SALIMI, GREGORY BRIDGES, DOUGLAS THOMSON, Electrical and Computer Engineering, University of Alberta, MARK FREEMAN, Univ. of Alberta, Dept. of Physics and National Institute for Nanotechnology — A universal, mechanical torque method for magnetic resonance spectroscopy is presented. In analogy to resonance detection by induction, a signal proportional to the transverse component of a precessing dipole moment can be measured as a pure mechanical torque in broadband, frequency-swept spectroscopy. Comprehensive electron spin resonance of a single-crystal, mesoscopic yttrium iron garnet disk at room temperature are presented to demonstrate the method. The rich detail allows analysis of even complex 3D spin textures.

**9:36AM E6.00007 Ferromagnetic resonance of a YIG film in the low frequency regime** , JOHN KETTERSON, Northwestern University, Evanston, IL., SCOTT GRUDICHAK, Lawrence University, Appleton, WI., JOSEPH SKLENAR, Northwestern University, Evanston, IL., C. C. TSAI, Chang Jung Christian University, Tainan 71101, Taiwan., MOONGYU JANG, Hallym University, Chuncheon, 200-702 South Korea., QINGHUI YANG, HUAIWU ZHANG, State Key Laboratory of Electronic Films and Integrated Devices, University of Electronic Science and Technology, Chengdu, Sichuan, 610054, China., SEONGJAE LEE, Research Institute for Natural Sciences, Hanyang University, Seoul, 133-791 South Korea. — An improved method for characterizing the magnetic anisotropy of films with cubic symmetry is described and is applied to an yttrium iron garnet (111) film. Analysis of the FMR spectra performed both in-plane and out-of-plane from 0.7 to 8 GHz yielded the magnetic anisotropy constants as well as the saturation magnetization. The field at which FMR occurs is sensitive to anisotropy constants in the low frequency ( $\sim 2$  GHz) regime and when the orientation of the magnetic field is nearly normal to the sample plane; the restoring force on the magnetization arising from the magnetocrystalline anisotropy fields is then comparable to that from the external field, thereby allowing the anisotropy constants to be determined with greater accuracy. Work at Northwestern was supported by the US DOE, Office of Basic Energy Sciences, Materials Science and Engineering Division under grant number DE-SC0014424. The film growth was supported by the National Natural Science Foundation of China (NSFC) under Grants 51272036 and 51002021 and 51472046.

**9:48AM E6.00008 Current driven asymmetric domain wall propagation** , CHIRAG GARG, Max Planck Institute for Microstructure Physics, Halle, AAKASH PUSHP, TIMOTHY PHUNG, SEE-HUN YANG, BRIAN P. HUGHES, CHARLES RETTNER, IBM Almaden Research Center, San Jose, California, STUART S.P. PARKIN, Max Planck Institute for Microstructure Physics, Halle — In ultrathin magnetic heterostructures, the presence of spin-orbit coupling gives rise to chiral Neel walls which are stabilized by the Dzyaloshinskii-Moriya Interaction (DMI), and also to a highly efficient chiral spin torque mechanism. In straight nanowires, the current-driven propagation of alternating Néel DWs without the presence of an in-plane field is equivalent, leading to the lock-step motion of several DWs in a nanowire. Here, we show that by engineering the structure in which the domain walls propagate, which in our case is in the shape of a Y-shaped junction, the DW propagation process becomes selective to the polarity of the DWs even in the absence of any externally applied magnetic fields. We remarkably find that after splitting at the Y-shaped junction, the DW velocity in one branch remains largely unaffected compared to its initial velocity whereas simultaneously the DW velocity in the other branch decreases by as much as 10-90%. We show that this large change in the DW velocity in a particular branch depends on the relative angle between the local magnetization of the DW and the spin current emanating from the underlying heavy-metal layer in these nanowires.

**10:00AM E6.00009 Notch-Boosted Domain Wall Propagation in Magnetic Nanowires<sup>1</sup>** , XIANG RONG WANG, Hong Kong University of Science and Technology, HUIYANG YUAN, Hong Kong Univ of Sci & Tech — Magnetic domain wall (DW) motion along a nanowire underpins many proposals of spintronic devices. High DW propagation velocity is obviously important because it determines the device speed. Thus it is interesting to search for effective control knobs of DW dynamics. We report a counter-intuitive finding that notches in an otherwise homogeneous magnetic nanowire can boost current-induced domain wall (DW) propagation. DW motion in notch-modulated wires can be classified into three phases: 1) A DW is pinned around a notch when the current density is below the depinning current density. 2) DW propagation velocity above the depinning current density is boosted by notches when non-adiabatic spin-transfer torque strength is smaller than the Gilbert damping constant. The boost can be many-fold. 3) DW propagation velocity is hindered when non-adiabatic spin-transfer torque strength is larger than the Gilbert damping constant.

**10:12AM E6.00010 Magnetic domain walls as reconfigurable spin-wave nano-channels<sup>1</sup>**, KAI WAGNER, 1. Helmholtz-Zentrum Dresden - Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany. ;2. TU Dresden, Dresden, Germany — Research efforts to utilize spin waves as information carriers for wave based logic in micro- and nano-structured ferromagnetic materials have increased tremendously over the recent years [1,2]. However, finding efficient means of tailoring and downscaling guided spin-wave propagation in two dimensions, while maintaining energy efficiency and reconfigurability, still remains a delicate challenge.

Here we target these challenges by spin-wave transport inside nanometer-scaled potential wells formed along magnetic domain walls. For this, we investigate the magnetization dynamics of a rectangular-like element in a Landau state exhibiting a so called 180° wall along its center. By microwave antennae the rf-excitation is constricted to one end of the domain wall and the spin-wave intensities are recorded by means of Brillouin-Light Scattering microscopy revealing channelled transport. Additional micromagnetic simulations [3] with pulsed as well as cw-excitation are performed to yield further insight into this class of modes.

We find several spin-wave modes quantized along the width of the domain wall yet with well defined wave vectors along the wall, exhibiting positive dispersion. In a final step, we demonstrate the flexibility of these spin-wave nano-channels based on domain walls. In contrast to wave guides realised by fixed geometries, domain walls can be easily manipulated. Here we utilize small external fields to control its position with nanometer precision over a micrometer range, while still enabling transport. Domain walls thus, open the perspective for reprogrammable and yet non-volatile spin-wave waveguides of nanometer width.

**10:48AM E6.00011 Studying Kittel-like modes in a 3D YIG disk using Torque-mixing Magnetic Resonance Spectroscopy**, FATEMEH FANI SANI, JOSEPH LOSBY, Univ. of Alberta, Department of Physics and National Institute for Nanotechnology, DYLAN GRANDMONT, Univ. of Alberta, Department of Physics, ZHU DIAO, Univ. of Alberta, Department of Physics and National Institute for Nanotechnology, MIRO BELOV, National Institute for Nanotechnology, JACOB BURGESS, SHAWN COMPTON, Univ. of Alberta, Department of Physics and National Institute for Nanotechnology, WAYNE HIEBERT, DOUG VICK, National Institute for Nanotechnology, KAVEH MOHAMMAD, ELHAM SALIMI, GREGORY BRIDGES, DOUGLAS THOMSON, Electrical and Computer Engineering, University of Manitoba, MARK FREEMAN, Univ. of Alberta, Department of Physics and National Institute for Nanotechnology — We report a study of ferrimagnetic resonance in a mesoscopic, single-crystalline YIG disk using torque-mixing magnetic resonance spectroscopy (TMRS). The Kittel model for magnetic resonance is a touchstone in measuring fundamental magnetic properties for magnetic films, which does not significantly depend on the film size. In 3D structures, ladders of confined resonance modes are observed, and these can exhibit the non-monotonic evolution of frequency with field familiar from Kittel modes. TMRS is a tool uniquely suited for observing this physics in individual 3D structures, on account of its combination of high sensitivity and broadband capability coupled with fine frequency resolution.

**8:00AM E7.00001 Capacitance of thin film solar cells: violating the depletion approximation**, THADDEUS COX, ALEXANDER OGLE, JENNIFER HEATH, Linfield College — Capacitance measurements of solar cells are able to detect minute changes in charge in the material. For that reason, capacitance is used in many methods to electrically characterize the solar cell. Standard interpretations of capacitance relies on many assumptions, which, if wrong can skew the results. In some solar cells where a back contact barrier is suspected, measurements at high forward bias can be used. We have seen that apparent signatures of a back contact barrier in Cu(In,Ga)Se<sub>2</sub> may actually be the first signs of a negative contribution to capacitance. We will discuss the implications of negative capacitance, and its relationship to other electronic characteristics of the device.

**8:12AM E7.00002 Time-dependent efficiency measurements of donor-acceptor, dye-sensitized polymer solar cells.**, KYLE BANDACCARI, GRACE CHESMORE, PARISA TAJALLI-TEHRANI VALVERDE, MITCHEL BUGAJ, BRIAN MCNELIS, RICHARD BARBER, JR., Santa Clara University — The fullerene/polymer active layer pairing of PCBM/P3HT has become the model system within the field of polymer solar cell research. A large body of work concerned with reporting improved efficiencies for this system exists, but truly quantitative studies of device lifetime and long-term degradation tendencies are much rarer. Here, we report the effects of two donor-acceptor diazo dye sensitizers on efficiency and lifetime upon addition into the PCBM/P3HT active layer at varied concentrations. The electrical and efficiency measurements were supplemented by time-dependent UV-visible spectroscopy studies and morphology investigations via atomic-force microscopy (AFM). This pairing with spectroscopy offers an internal check on the data as the rate of change in absorbance of the active layer correlates almost exactly to the rate of power conversion efficiency decrease. Additionally, AFM imaging reveals different morphology patterns when dye concentrations and functionalities change. Such observations suggest that such small-molecule sensitizers exert yet undetermined effects on the organization of components within the active layer at the molecular level.

**8:24AM E7.00003 Quantitative study of stress levels in AT and BT cut quartz crystal microbalances associated with surface laser irradiation.<sup>1</sup>**, L.H. GOODMAN, E.S. BILILIGN, B.J. MCCANN, B.W. KELLER, K. STEVENS, S.G. KENNY, J. KRIM, North Carolina State University — The frequency response of an AT cut Quartz Crystal Microbalance (QCM) to laser irradiation has been increasingly studied in recent years, as the combination of photons with materials on a QCM's electrodes enables fundamental studies of topics that span biophysics to photovoltaics. In order for such studies to advance, however, the impact of heating effects associated with laser irradiation of the QCM must be accounted for. Prior studies reached qualitative conclusions that laser irradiation induces stress QCM's arising from non-uniform thermal expansion, but did not quantitatively measure the degree of stress. Secondary effects such as surface film desorption and/or changes in temperature were also reported to be present. We report here a study of the frequency response of AT and BT cut QCM's to laser irradiation. AT and BT cut QCM's have similar response to mass adsorption, but opposite frequency response to stress levels, allowing the stress levels induced by the laser light to be quantitatively measured when the results are compared. Studies were performed in both vacuum and air, to control for the presence of adsorbed films. As expected, system designs that minimize temperature gradients result in less of an effect.

**8:36AM E7.00004 Photovoltaic performance parameters at the nanoscale from in situ I-V curve measurements**, SADIA NASEEM, ELIZABETH TENNYSON, MARINA LEITE, University of Maryland College Park — Monocrystalline photovoltaic (PV) devices exhibit higher efficiencies than polycrystalline devices, but the high manufacturing costs associated with single crystal solar cells pose a hindrance to their wide implementation. Polycrystalline  $\text{CuIn}_x\text{Ga}_{(1-x)}\text{Se}_2$  (CIGS) material with high optical absorbance and low cost/Watt, is a promising alternative. Yet, the efficiency of this low-cost technology is still substantially lower than the theoretical values estimated by the Shockley-Queisser limit. This is likely due to microstructural non-uniformities, which cannot be accessed by macroscopic light I-V measurements. Therefore, we spatially resolve the electrical response of these devices by 'local' I-Vs. For that, we utilize a 100x objective as a local excitation source and LabVIEW to map the PV performance with sub-microns scale resolution through extrapolation of key parameters from pixel by pixel I-V curves. Extraction of performance parameters such as short-circuit current, open-circuit voltage fill factor, and maximum power point can provide useful information regarding optimal microstructural characteristics. This information is not only valuable for CIGS-based devices, but also will be an essential tool for maximizing performance across all PV technologies.

**8:48AM E7.00005 Optimizing Hydrogen Storage by Doping the  $\text{LiBH}_4 + \text{MgH}_2$  Reaction with Various Niobium Based Oxides**, PAUL HORNUNG, ROBERT WALKO, ANDREW WENZEL, RICHARD WRIGHT, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — In this study, the effects of doping the dehydrogenation reaction of  $\text{MgH}_2 + 2\text{LiBH}_4$  was combined with 5 mole% of three different Niobium based oxides ( $\text{Nb}_2\text{O}_5$ ,  $\text{NbO}_2$ , and  $\text{LiNbO}_3$ ). The compounds were mixed using high energy ball milling, and then heated using an air tight heating stage. We looked for changes in the Raman spectra as temperature increased (up to 350C) as an indication of hydrogen desorption reaction. We found that milled  $\text{LiBH}_4$  undergoes significant changes in Raman spectra during heating to 130C.  $\text{MgH}_2$  undergoes significant changes when comparing before and after milling—but in each case, the spectral peaks remain unchanged during heating to 350C. The sample with  $\text{LiNbO}_3$  exhibited a concrete change in Raman spectrum at 300 C while the sample doped with  $\text{Nb}_2\text{O}_5$  underwent a change in spectra at 170C. The sample doped with  $\text{NbO}_2$  showed little change in spectra when the samples were heated up to 350C. Further studies are underway to examine the nature of the changes in the Raman spectra using X-ray diffraction and residual gas analysis.

**9:00AM E7.00006 Electromotive force and current in a superconducting solenoid with limited length induced by a bar magnet and a monopole<sup>1</sup>**, LIANXI MA, Blinn College - Bryan — The magnetic flux  $\Phi_B$ , electromotive force, EMF, and current  $I_{in}$ , induced by a moving magnetic bar and an imaginary magnetic monopole in a superconducting solenoid of multiple turns and length  $L$ , are numerically calculated. The magnetic field of the bar magnet is approximated with the magnetic field along  $z$  axis of a solenoid with length  $l$  and radius  $a$  and current  $I$ , while the magnetic field of the monopole is supposed to be inversely proportional to  $r^2$ . Calculations show that, for a bar magnet,  $\Phi_B$  and  $I_{in}$  essentially saturate when the bar moves inside superconducting solenoid, so EMF is zero while  $I_{in}$  is constant. EMF is only induced when the bar enters and exits the solenoid and  $I_{in}$  is zero after the bar leaves the solenoid. For a magnetic monopole,  $\Phi_B$  is discontinuous (from positive maximum to negative maximum) when it moves through each turn of the superconducting solenoid, but EMF caused by  $d\Phi_B/dt$  is continuous while the EMF induced by the a moving monopole is a delta function (moving monopole produces a ring-shaped  $E$  field). The total  $\text{EMF}_{Tot}$  in solenoid is the superposition of EMF of each turn of coil and the plateau appears. The current  $I_{in}$  continues to grow while the monopole leaves the solenoid.

<sup>1</sup>Thanks to Dr. Liancun Zheng and Mr. Lin Liu for verifying my calculation

**9:12AM E7.00007 Optimizing Production of Superconducting Bulk YBCO Crystals: Effects of Initial Temperature and Growth Time<sup>1</sup>**, ERIN JOLLEY, CONNOR SHEA, JANET HUNTING, M.C. SULLIVAN, Ithaca College — We present our work on increasing both pinning force and critical temperature of bulk YBCO superconducting crystals. We optimized temperature profiles for growing bulk  $\text{YBaCuO}$  superconductors by varying (a) temperature and (b) growth time. We synthesize the precursor materials, superconducting  $\text{Y}_1\text{Ba}_2\text{Cu}_3\text{O}_7$  (Y-123) and non-superconducting  $\text{Y}_2\text{Ba}_1\text{Cu}_1\text{O}_5$  (Y-211), and mix the two in a 1:0.4 molar ratio before beginning melt textured growth. We heat the mixture to a temperature above the melting point of Y-123 but below the melting point of Y-211, where it is held until the Y-123 melts and the Y-211 impurities disperse in the mixture. The mixture is then quickly cooled to an initial temperature (a) near the peritectic point, and is then slowly cooled for 30-100 hours (b) to allow steady growth of large domain Y-123 crystals. We will discuss the effects of different initial temperatures near the peritectic point and growth times on the pinning force and critical temperature of these samples.

<sup>1</sup>This work was supported by NSF grant DMR-1305637, and made use of the Cornell Center for Materials Research Shared Facilities which are supported through the NSF MRSEC program (grant DMR-1120296).

**9:24AM E7.00008 The Effect of Impurities on the Superconductivity of BSCCO-2212**, JOHN VASTOLA, RICHARD KLEMM, University of Central Florida — BSCCO-2212 is a high-temperature cuprate superconductor whose electronic structure is currently poorly understood. In particular, it is unclear whether its order parameter is consistent with s-wave or d-wave behavior. Leggett has suggested that its order parameter might take a certain form that is consistent with d-wave behavior. While some experiments on the surface of BSCCO seem to support this conclusion, other experiments have suggested that its order parameter is instead s-wave in the bulk. We present some quantum field theoretic calculations in the spirit of Abrikosov and Gorkov's approach to the theory of superconductivity that suggest that such an order parameter cannot be correct. We will demonstrate that having such an order parameter would mean that BSCCO's critical temperature would go to zero if it is sufficiently impure, contradicting experimental evidence otherwise. Because this would not happen with a d-wave order parameter, these calculations lend support to the hypothesis that BSCCO is s-wave.

**9:36AM E7.00009 Superconductivity and anti-ferromagnetism through Bose-Fermi mixture on optical lattices.**, JEREMY BRACKETT, THEJA DE SILVA, Augusta University — Motivated by the recent experimental progress with ultra-cold atoms, we investigate the physics of a Bose-Fermi mixture on a two dimensional optical lattice. We treat the system parameters such that 2-component fermions are in a deep external trap and weakly interacting bosons are in a shallow external trap, however both of these atoms are subjected to the same optical lattice. In this parameter regime, the bosons form a Bose-Einstein condensate and mediate an attractive interaction between fermions through low energy Bose excitations. As a result, the dynamics of the fermions can be described by the single band Hubbard model that involves on-site repulsive interaction and elementary excitation mediated attractive interactions. Using a mean field theory, we derive an effective action up to the quartic order in both d-wave superconducting and anti-ferromagnetic order parameters. Using this Landau energy functional, we then discuss the phase transition and study the competition and/or cooperation of anti-ferromagnetism and d-wave superconductivity in the system.

**9:48AM E7.00010 Coexistence of anti-ferromagnetism and anisotropic superconductivity in iron pnictides.**, JOSEPH NEWMAN, THEJA DE SILVA, Augusta University — By treating both anti-ferromagnetism (AFM) and superconductivity (SC) on an equal footing, we investigate the possible coexistence of AFM and SC of recently found high-temperature superconducting compounds. Assuming that the electron pairing is mediated by the spin fluctuations and using a mean-field theory, we derive a set of gap equations for both AFM and SC order parameters. In the spirit of the second order phase transition, we then linearize the gap equations using various base functions for superconducting order to include the different pairing symmetries. By analyzing the solution of our linearized equations, we then discuss the possible coexistence of AFM and anisotropic SC in these compounds.

**10:00AM E7.00011 Optimization of the high frequency magneto-impedance effect in Co-based amorphous ribbons<sup>1</sup>**, V. ORTIZ, Univ. of Puerto Rico at Mayaguez, T. EGGERS, M.H. PHAN, Univ. of South Florida — The magnetic field dependence of the impedance, known as magneto-impedance (MI), was measured as a function of excitation frequency in Co-based amorphous ribbons. An optimization of the MI profile on the high frequency regime (100 MHz – 1000 MHz) was attempted through annealing techniques. Current annealing was performed with different annealing amplitudes ranging from 200 mA up to 1 A. Field annealing was also performed by raising the temperature of the sample through Joule heating and applying an external magnetic field of 55 Oe transversal to the ribbon. It was found that annealing at low current improved the MI response at lower frequencies, between 100 MHz and 300 MHz. On the other hand annealing at higher amplitude, past the Curie temperature ( $T_c$ ) favored higher frequencies. These findings provide good guidance toward the optimization of the MI response of Co-based amorphous ribbons for high-frequency sensor applications.

**10:12AM E7.00012 Charge density wave phase transitions in Tantalum Disulfide<sup>1</sup>**, MARC REYNAUD, MICHAEL ALTVATER, ADITYA SRIPAL, ALICE HUANG, GUOHONG LI, EVA Y. ANDREI, Rutgers University, Physics and Astronomy, RUI ZHAO, JOSHUA ROBINSON, The Pennsylvania State University, Materials Science and Engineering, Center for Two- Dimensional and Layered Materials — The discovery of transition metal dichalcogenides has reopened the interest in charge density wave physics. By looking at the phase transition properties, it is possible to create switches with properties exceeding the traditional FETs. In this work, we fabricated 2D nanoscale switches made of 1T-TaS<sub>2</sub> and graphene. We tested the transport properties between the Mott insulating state and the conductive state of the switch. Our work will provide insight on possibilities for the production of ideal switches and transistor logic.

<sup>1</sup>The work is supported by DOE-FG02-99ER45742, NSF DMR 1207108, NSF EFRI2-DARE 13-583

**10:24AM E7.00013 Dielectric and electro-optic measurements of nematic liquid crystals doped with carbon nanotubes<sup>1</sup>**, MATTHEW PETERSON, Tufts University, GEORGI GEORGIEV, Assumption College, TIMOTHY ATHERTON, PEGGY CEBE, Tufts University — We studied the effects of carbon nanotubes (CNTs) on the dielectric and electro-optic properties of nematic 5CB liquid crystals (LCs). Samples containing 0.01%, 0.10% and 1.00% CNTs by weight were prepared. Anti- parallel rubbed cells with a nominal thickness of 10  $\mu$ m were prepared using indium tin oxide coated glass cells and a polyimide alignment layer. The capacitance and dissipation factor were measured using an Agilent 4284A precision LCR meter. From these measurements, the complex dielectric permittivity was determined as a function of frequency. Analysis of the low frequency regime ( $f < 1000$  Hz) indicates that 5CB samples containing CNTs have a higher conductance than neat samples. The Fréedericksz transition critical voltage was noted by a sharp increase in capacitance after an initial plateau. Numerical simulations of CNT-facilitated switching show that polarization induced on the nanotubes from capacitive effects can significantly reduce the critical voltage in DC electric fields, in agreement with experimental results. Measurements of the critical voltage over a range of frequencies will also be presented.

<sup>1</sup>Research was supported by the National Science Foundation, DMR1206010.

**10:36AM E7.00014 NaAlH<sub>4</sub> Mixed with Carbon Nanotubes, Fullerene, and Titanium to Yield the Lowest Temperature for Hydrogen Desorption.**, JENNIFER HILDEBRAND, PATRICK MCFADDEN, SANGA KIM, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — Recent research in hydrogen storage has improved dehydrogenation methods with solid-state compounds. NaAlH<sub>4</sub> is a complex hydrides which release hydrogen at a lower temperature making the compound a great candidate for hydrogen storage. However, a catalyst should be combined with NaAlH<sub>4</sub> to release the lowest desorption temperature. Prior research showed that interaction of NaAlH<sub>4</sub> with nanotube or fullerene effectively weakens the Al-H bonds causing hydrogen desorption at lower temperatures. In the present study, NaAlH<sub>4</sub> is ball milled with three of these catalysts: titanium, carbon nanotubes and fullerene and the milling time is varied from 10 to 30 minutes to compare the dehydrogenation rates in each setup. The phase structures were identified using the X-ray diffraction. Of these catalysts, the fullerene yielded the most interesting result showing nanostructuring of the hydride during ball milling. The possibility of “shot peening” of the NaAlH<sub>4</sub> by the fullerenes is explored.

**10:48AM E7.00015 Simulation of the Effects of Cooling Techniques on Turbine Blade Heat Transfer<sup>1</sup>**, VINCE SHAW, None, MARCO FATUZZO, Xavier University, Cincinnati, OH — Increases in the performance demands of turbo machinery has stimulated the development many new technologies over the last half century. With applications that spread beyond marine, aviation, and power generation, improvements in gas turbine technologies provide a vast impact. High temperatures within the combustion chamber of the gas turbine engine are known to cause an increase in thermal efficiency and power produced by the engine. However, since operating temperatures of these engines reach above 1000 K within the turbine section, the need for advances in material science and cooling techniques to produce functioning engines under these high thermal and dynamic stresses is crucial. As with all research and development, costs related to the production of prototypes can be reduced through the use of computational simulations. By making use of Ansys Simulation Software, the effects of turbine cooling techniques were analyzed.

<sup>1</sup>Simulation of the Effects of Cooling Techniques on Turbine Blade Heat Transfer

**Tuesday, March 15, 2016 8:00AM - 10:24AM –**

**Session E8 DCMP: Superconductivity: Transport Properties** 304 - Philip Adams, Louisiana State University

**8:00AM E8.00001 Charge transport in the electron-doped cuprate superconductors**, YANGMU LI, WOJCIECH TABIS, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, EUGENE MOTOYAMA, Department of Physics, Stanford University, Stanford, California 94305, USA, GUICHUAN YU, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, NEVEN BARIIC, Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA — Recent studies of the normal-state charge transport of the hole-doped cuprates have revealed that, in the pseudogap phase at moderate doping, the behavior of the charge carriers is that of a Fermi-liquid: The scattering rate exhibits quadratic temperature and frequency dependencies [1,2], and the magnetoresistance obeys Kohlers rule [3]. The cotangent of the Hall angle, which in a parabolic single-band model corresponds to the scattering rate, is also quadratic in temperature, and moreover doping and compound independent, and hence universal [4]. Importantly, this observable is insensitive to the opening of the pseudogap. In light of these findings, we will revisit the charge-transport in the electron-doped cuprates [5]. [1] N. Bariic et al., Proc. Natl. Acad. Sci. USA 110, 12235 (2013); [2] S. I. Mirzaei et al., Proc. Natl. Acad. Sci. USA 110, 5774 (2013); [3] M. K. Chan et al., Phys. Rev. Lett. 113, 177005 (2014); [4] N. Bariic et al., arXiv:1507.07885 (2015); [5] N. P. Armitage et al., Rev. Mod. Phys. 82, 2421 (2010).

**8:12AM E8.00002 Multiple sign reversal of the Hall effect in electron-doped superconductor  $\text{Pr}_{0.9}\text{LaCe}_{0.1}\text{CuO}_{4\pm\delta}$  thin films**, BEIYI ZHU, Institute of Physics, Chinese Academy of Sciences — We have investigated the temperature and field dependence of the Hall resistivity of the electron-doped  $\text{Pr}_{0.9}\text{LaCe}_{0.1}\text{CuO}_{4\pm\delta}$  (PLCCO) superconducting thin films ( $T_{c0} = 22$  K). In the low magnetic field region ( $0.03 \sim 0.1$  T), a concrete triple sign reversal of the Hall resistivity  $\rho_{xy}$  has been observed in the  $\rho_{xy}(T)$  curve. With the increase of the magnetic field, the Hall resistivity  $\rho_{xy}(T)$  suffers triple, double, single sign reversal transitions and it will be completely disappear around 4.5 T. We contribute the triple sign reversal to the competition between the hole and the electron carriers in our electron-doped samples and a fourth sign reversal may be expected in the regime of the two-band system.

**8:24AM E8.00003 HIGH FIELD MAGNETORESISTANCE NEAR OPTIMAL DOPING IN  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$** , JOSE A. GALVIS, PAULA GIRALDO-GALLO, SCOTT RIGGS, ZACHARY STEGEN, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, USA, BRAD RAMSHAW, KIMBERLY MODIC, ROSS MCDONALD, National High Magnetic Field Laboratory, Los Alamos National Laboratory, Los Alamos, NM, USA., IVAN BOZOVIC, Brookhaven National Laboratory, Upton, NY 11973, USA., ARKADY SHEKHTER, GREG BOEBINGER, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL, USA — An outstanding experimental feature of the metallic behavior of all high-temperature superconductors near optimal doping is the linear-in-temperature resistivity observed over a wide temperature range. Although metallic quantum criticality in these systems has been proposed to be the origin of this anomalous temperature dependence, its manifestation in the magnetotransport, yet to be determined, can become a source of important insight into the physics of these compounds. The experimental challenge is to measure normal state magnetoresistance in a broad range of magnetic fields, always limited by the  $H_{c2}$  on the lower side and the available magnetic fields on the higher. Here we report magnetoresistance measurements in thin films of  $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ , for magnetic fields beyond 65 T — well above the highest fields used in previous studies of this system. We discuss the signature for quantum criticality based upon the high-field magnetoresistance measurements over a broad temperature range.

**8:36AM E8.00004 Fermi surface anisotropy in the cuprates**, BRAD RAMSHAW, Los Alamos Natl Lab — Broken rotational ( $C_4$ ) symmetry is a distinguishing feature for a number of experiments in the underdoped high- $T_c$  cuprates, including electrical resistivity, neutron scattering, Nernst coefficient, and scanning tunneling microscopy. This broken symmetry has not been observed on the Fermi surface, however, with or without the presence of an applied magnetic field. We measure the angle-dependent magnetoresistance—a quantity known to be extremely sensitive to the geometry and symmetry of the Fermi surface—of  $\text{YBa}_2\text{Cu}_3\text{O}_{6.58}$ , and find that the Fermi surface has a clear two-fold symmetry, breaking the  $C_4$  symmetry of the copper-oxide plane. We discuss the implications of this finding, including how it fits with recent X-ray measurements in high magnetic fields.

**8:48AM E8.00005 Onset field for Fermi-surface reconstruction in the cuprate superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_y$** , GAEL GRISSONNANCHE, FRANCIS LALIBERTE, SOPHIE DUFOUR-BEAUSEJOUR, ALEXIS RIOPEL, SVEN BADOUX, MICHAEL CAQUETTE-MANSOUR, MARCIN MATUSIAK, ALEXANDRE JUNEAU-FECTEAU, PATRICK BOURGEOIS-HOPE, OLIVIER CYR-CHOINIRE, University of Sherbrooke, JAMES BAGLO, BRAD RAMSHAW, RUIXING LIANG, DOUG BONN, WALTER HARDY, University of British Columbia, STEFFEN KRAEMER, DAVID LEBOEUF, Laboratoire National des Champs Magnétiques Intenses (Grenoble), DAVID GRAF, National High Magnetic Field Laboratory (Tallahassee), NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke — Discovery of quantum oscillations in underdoped cuprates [1] at low temperature and high magnetic field revealed the Fermi surface to contain a small closed electron pocket. It is thought to result from a reconstruction by charge order, but whether it is the order seen by NMR [2], and ultrasound [3] above a threshold field or the short-range modulations seen by X-ray diffraction in zero field is unclear [4]. Here we report measurements of the thermal Hall conductivity in  $\text{YBa}_2\text{Cu}_3\text{O}_y$  to show that Fermi-surface reconstruction occurs only above a sharply defined onset field, equal to the transition field seen in ultrasound. This reveals that electrons do not experience long-range broken translational symmetry in the zero-field ground state. [1] Doiron-Leyraud et al., Nature 447,565 (2007) [2] Wu et al., Nature 477,191 (2011) [3] LeBoeuf et al., Nat. Phys. 9,79 (2013) [4] Ghiringhelli et al. Science 337, 821-825 (2012)

**9:00AM E8.00006 Vortex creep and thermal depinning within strong pinning theory**, ROLAND WILLA, MARTIN BUCHACEK, VADIM B. GESHKENBEIN, GIANNI BLATTER, Institute for Theoretical Physics, ETH Zurich, 8093 Zurich, Switzerland — Vortex pinning in type-II superconductors can occur through the collective action of many pins (weak collective pinning scenario) or through plastic deformations induced by a low density of defects (strong pinning scenario). For the latter case, a new formalism has recently been developed [1-4] to provide a quantitative link between the microscopic pinning landscape and experimentally accessible quantities describing pinning on a macroscopic level. Examples are the critical current density  $j_c$ , the  $I$ - $V$  characteristics, or the  $ac$  Campbell length  $\lambda_C$ . Inspired by the original work of Larkin and Brazovskii [5,6] on density wave pinning, we have extended the strong pinning formalism to account for thermal depinning of flux lines and vortex creep. [1] G. Blatter, V. B. Geshkenbein, and J. A. G. Koopmann, Phys. Rev. Lett. **92**, 067009 (2004). [2] A. U. Thomann, V. B. Geshkenbein, and G. Blatter, Phys. Rev. Lett. **108**, 217001 (2012). [3] R. Willa, V. B. Geshkenbein, and G. Blatter, Phys. Rev. B **92**, 134501 (2015). [4] R. Willa, V. B. Geshkenbein, R. Prozorov and G. Blatter, Phys. Rev. Lett. (in press). [5] A. Larkin and S. Brazovskii, Solid State Communications **93**, 275 (1995). [6] S. Brazovskii and A. Larkin, Synthetic Metals **86**, 2223 (1997).

**9:12AM E8.00007 Anomalous high-field-induced phase in underdoped  $\text{La}_{1.7}\text{Eu}_{0.2}\text{Sr}_{0.1}\text{CuO}_4$** <sup>1</sup>, ZHENZHONG SHI, P. BAITY, DRAGANA POPOVIĆ, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., T. SASAGAWA, Tokyo Inst. of Tech. — We have investigated transport properties of the underdoped, stripe-ordered  $\text{La}_{1.7}\text{Eu}_{0.2}\text{Sr}_{0.1}\text{CuO}_4$  single crystals near their magnetic-field-driven superconducting transition for  $0.016 \leq T$  (K)  $\leq 40$  and magnetic fields  $H$  up to 18 T. At very low  $T$  ( $< 0.06$  K), an anomalous high-field-induced phase (HFIP) emerges in both the in-plane and out-of-plane resistivity measurements. Two temperature-independent crossing points in the magnetoresistance are identified near the boundaries of the HFIP. In addition, the HFIP exhibits signatures of glassiness, such as hysteretic behavior and memory of magnetic history. Differential resistance studies reveal nontrivial, non-Ohmic behavior, suggesting the possible presence of a vortex glass in the HFIP. A possible  $H$ - $T$  phase diagram for the underdoped  $\text{La}_{1.7}\text{Eu}_{0.2}\text{Sr}_{0.1}\text{CuO}_4$  and the nature of the HFIP will be discussed.

**9:24AM E8.00008 Resistance Fluctuation Spectroscopy of Charge Stripes and Intertwined Orders in the Phase Diagram of  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$** <sup>1</sup>, ADAM WEIS, MOUNIR FIZARI, DAVID HAMILTON, AZTON WELLS, JUSTIN LANE, University of Illinois at Urbana-Champaign, SO RA CHUNG, Belmont University, PATHIKUMAR SELLAPPAN, WALTRAUD KRIVEN, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — The unusual phase diagram of  $\text{La}_{2-x}\text{Ba}_x\text{CuO}_4$  (LBCO) near  $x=1/8$  doping suggests a complex intertwined relationship between high-temperature superconductivity, charge stripes, spin order, and phase coherence. The charge stripe state's short-range conductance anisotropy may be observable as fluctuations in resistance. In thin film LBCO devices grown by pulsed laser deposition, our time-resolved resistance measurements have revealed an onset of resistance noise at dopings and critical temperatures consistent with charge stripes. The phase diagram of LBCO is explored by comparing the noise onset signature of charge order to measurements of superconductivity, the Hall effect, and other phenomena. I will briefly discuss the relevance of our results in LBCO thin films and crystals to a proposed "pair-density-wave" state near  $x=1/8$ .

**9:36AM E8.00009 Avalanches and hysteresis at the structural transition in stripe-ordered  $\text{La}_{1.48}\text{Nd}_{0.4}\text{Sr}_{0.12}\text{CuO}_4$** <sup>1</sup>, P. G. BAITY, GARIMA SARASWAT, DRAGANA POPOVIĆ, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., T. SASAGAWA, Tokyo Inst. of Tech. — The coupling or intertwining of lattice, spin and charge orders and their effects on superconductivity are of great current interest in the physics of cuprates. The rare-earth-doped cuprate  $\text{La}_{1.48}\text{Nd}_{0.4}\text{Sr}_{0.12}\text{CuO}_4$  (LNSCO), for example, exhibits a first-order structural phase transition (SPT) from the low-temperature orthorhombic (LTO) to the low-temperature tetragonal (LTT) phase, with the onset of the static charge stripe order roughly coinciding with the SPT. We present out-of-plane magnetoresistance measurements around the LTO-LTT transition in LNSCO single crystals with  $H \parallel c$  up to 12 T and  $H \parallel ab$  up to 9 T. Hysteresis is observed for both field orientations, but for  $H \parallel c$  we also find evidence for the existence of metastable states and collective dynamics in the form of avalanches and return point memory. Such behavior indicates that, in LNSCO, the LTO-LTT structural transition can be driven with  $H$ . A detailed analysis of the avalanche statistics is used to determine their size and field dependence, and to extract information about the domain structure and dynamics of domain walls. Our results shed light on the interplay of lattice, spin and charge degrees of freedom in stripe-ordered La-based cuprates.

**9:48AM E8.00010 Shot noise measurement in a strongly correlated material**, PANPAN ZHOU, WILL HARDY, Department of Physics and Astronomy, Rice University, ETHAN CHO, SHANE CYBART, ROBERT DYNES, Department of Physics, University of California, San Diego, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — In strongly correlated materials, the motion of an electron is strongly affected by interactions with other electrons, leading to many interesting phenomena including metal-insulator transitions, colossal magnetoresistance, and high temperature superconductivity. Shot noise is one experimental probe for electronic correlations beyond simple electronic transport. Shot noise, which originates from the discrete nature of the charge-carrying particles, can be strongly affected by electronic correlations. Here we report initial shot noise measurements in tunnel junctions prepared from a  $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$  film sample, with nanoscale junctions written by focused helium ion beam. We will discuss a comparison of the shot noise between the YBCO film sample and standard tunnel junctions, as a function of temperature and bias, and the implications of these results.

**10:00AM E8.00011 Power-law Optical Conductivity from Unparticles: Application to the Cuprates**<sup>1</sup>, KRIDSANAPHONG LIMTRAGOOL, PHILIP PHILLIPS, Univ of Illinois - Urbana — We calculate the optical conductivity using several models for unparticle or scale-invariant matter. Within a Gaussian action for unparticles that is gauged with Wilson lines, we find that the conductivity computed from the Kubo formalism with vertex corrections yields no non-trivial deviation from the free-theory result. This result obtains because at the Gaussian level, unparticles are just a superposition of particle fields and hence any transport property must be consistent with free theory. Beyond the Gaussian approach, we adopt the continuous mass formulation of unparticles and calculate the Drude conductivity directly. We show that unparticles in this context can be tailored to yield an algebraic conductivity that scales as  $\omega^{-2/3}$  with the associated phase angle between the imaginary and real parts of  $\arctan \frac{\sigma_2}{\sigma_1} = 60^\circ$  as is seen in the cuprates. Our results indicate that at each frequency in the scaling regime, excitations on all energy scales contribute. Hence, incoherence is at the heart of the power-law in the optical conductivity in strongly correlated systems such as the cuprates.

**10:12AM E8.00012 Optical Measurements of Thermal Diffusivity in Strange Metals**, JIECHENG ZHANG, E. M. LEVENSON-FALK, AHARON KAPITULNIK, Stanford Univ — Thermal transport measurements of strongly correlated electronic systems provide key insight into their emerging collective behavior. For example, high- $T_c$  superconductors exhibit different regimes of unusual transport with bad metallicity at high temperatures, a pseudogap-dominated transport at intermediate temperatures, and the interplay with superconductivity at low temperatures. We present optical non-contact measurements of local thermal diffusivity in such materials. In our apparatus we focus a laser spot onto the surface of the investigated sample; the laser power is then modulated to create a periodic, point-like heat source. Another laser is focused nearby on the surface where the local reflectivity is measured. Since the reflectivity is temperature-dependent, it serves as a contactless probe of temperature oscillations due to the heat source. By measuring the temperature profile on the surface of the sample as a function of modulation frequency, we extract the thermal diffusivity of the material. We will present measurements of the temperature dependence and anisotropy of diffusivity in various strange metals, and discuss further applications of the apparatus.

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**  
**Session E11 DMP GMAG: Electronic Structure and Magnetism in Fe-based Superconductors I**  
 307 - Qimiao Si, Rice University

**8:00AM E11.00001 The role of Hund's coupling in the correlations and the nematicity of iron superconductors**<sup>1</sup>, ELENA BASCONES, Instituto de Ciencia de Materiales de Madrid — Since their discovery in 2008 the strength and the nature of correlations in iron superconductors have been widely discussed [1]. Understanding the correlations is key to unveil the nature of the superconducting, nematic and magnetic instabilities which appear in the phase diagram. Due to their multi-orbital character, correlations in iron superconductors are strongly affected by Hund's coupling and these materials have been classified by some authors as Hund metals. For a long time there has been a strong controversy on the nature of correlations induced by Hund's coupling and its relation to Mott physics. While some authors describe Hund metals as strongly correlated systems which are not in proximity to a Mott insulating state, others, have described iron superconductors as doped Mott insulators. In the talk, after some introduction, I will first show our recent results which show that while the spin polarization of the atoms, promoted by Hund's coupling induces strong correlations, this does not necessarily mean that the total charge is more localized [2]. On the contrary, in some cases this polarization promotes itinerancy [2]. I will then present a generic framework to address the correlations in iron superconductors and discuss the role of Hund's coupling in the nematicity of iron superconductors, with special emphasis on FeSe. [1] Magnetic interactions in iron superconductors: a review, E. Bascones, B. Valenzuela and M.J. Calderon, (in press) arXiv:1503.04223 [2] Electronic correlations in Hund metals. L. Fanfarillo and E. Bascones, Phys. Rev. B 92, 075136 (2015)

**8:36AM E11.00002 Itinerancy-Enhanced Quantum Fluctuation of Magnetic Moments in Iron-Based Superconductors<sup>1</sup>**, YU-TING TAM, DAO-XIN YAO, Sun Yat-sen university, WEI KU, Brookhaven National Laboratory — We investigate the influence of itinerant carriers on dynamics and fluctuation of local moments in Fe-based superconductors, via linear spin-wave analysis of a spin-fermion model containing both itinerant and local degrees of freedom. Surprisingly against the common lore, instead of enhancing the  $(\pi,0)$  order, itinerant carriers with well nested Fermi surfaces are found to induce a significant amount of *spatial* and temporal quantum fluctuation that leads to the observed small ordered moment. Interestingly, the underlying mechanism is shown to be intra-pocket nesting-associated long-range coupling rather than the previously believed ferromagnetic double-exchange effect. This challenges the validity of ferromagnetically compensated first-neighbor coupling reported from short-range fitting to the experimental dispersion, which turns out to result instead from the ferro-orbital order that is also found instrumental in stabilizing the magnetic order.

**8:48AM E11.00003 Competing magnetic fluctuations in iron pnictide superconductors: role of ferromagnetic spin correlations revealed by NMR<sup>1</sup>**, YUJI FURUKAWA, PAUL WIECKI, BEAS ROY, DAVID C. JOHNSTON, SERGEY L. BUD'KO, PAUL C. CANFIELD, Ames Laboratory, Dept. of Phys. and Astro, Iowa State Univ., COLLABORATION — The role of magnetic fluctuations in iron pnictide superconductors has been extensively studied since their discovery. As the parent materials have antiferromagnetic (AFM) ground states, attention has been focused on stripe-type AFM fluctuations, which are widely believed to give rise to the Cooper pairing in the systems. On the other hand, according to density functional theory calculations, the static magnetic susceptibility is enhanced at not only the stripe-type AFM but also ferromagnetic (FM) wavevectors. Nevertheless, FM fluctuations have not been investigated microscopically. In this talk, based on <sup>75</sup>As NMR data [1,2], we report clear evidence for the existence of strong FM correlations in the hole-doped  $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$  and electron-doped  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ . We will discuss the role of FM spin correlations in the occurrence of superconductivity in these systems. [1] P. Wiecki, et al., Phys. Rev. B **91**, 220406 (2015). [2] P. Wiecki, et al., Phys. Rev. Lett. **115**, 137001 (2015).

**9:00AM E11.00004 Spin-liquid polymorphism in an underdoped iron-chalcogenide superconductor<sup>1</sup>**, IGOR ZALIZNYAK, Brookhaven National Laboratory, ANDREI SAVICI, MARK LUMSDEN, Oak Ridge National Laboratory, ALEXEI TSVELIK, Brookhaven Natl Lab, RONGWEI HU, Rutgers University, CEDOMIR PETROVIC, Brookhaven National Laboratory — We report neutron scattering measurements which reveal spin-liquid polymorphism in an 11 iron chalcogenide superconductor. It occurs when a poorly metallic magnetic state of FeTe is driven toward superconductivity by substitution of a small amount of tellurium with isoelectronic sulfur. We observe a liquid-like magnetic response, which is described by the coexistence of two disordered magnetic phases with different local structures whose relative abundance depends on temperature. One is the ferromagnetic (FM) plaquette phase observed in undoped, nonsuperconducting FeTe, which preserves the  $C_4$  symmetry of the underlying square lattice and is favored at high temperatures, whereas the other is the antiferromagnetic plaquette phase with broken  $C_4$  symmetry, which emerges with doping and is predominant at low temperatures. These findings suggest the coexistence of and competition between two distinct liquid states, and a liquid-liquid phase transformation between these states, in the electronic spin system of  $\text{FeTe}_{1-x}(\text{S,Se})_x$ . Our results shed light on many recent experimental data in unconventional superconductors. The phase with lower,  $C_2$  local symmetry, whose emergence precedes superconductivity, naturally accounts for a propensity to electronic nematic states.

**9:12AM E11.00005 Studying the morphology of the magnetic  $C_4$  phase in the 122 superconductors.**, KEITH TADDEI, Northern Illinois University, JARED ALLRED, University of Alabama, DANIEL BUGARIS, Argonne National Laboratory, MATTHEW KROGSTAD, Northern Illinois University, SAUL LAPIDUS, Advanced Photon Source ANL, RYAN STADEL, Northern Illinois University, DUCK CHUNG, HELMUT CLAUS, Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern Illinois University, DENNIS BROWN, Northern Illinois University, STEPHAN ROSENKRANZ, RAYMOND OSBORN, Argonne National Laboratory, OMAR CHMAISSEM, Northern Illinois University — The iron based superconductors continue to prove an exciting system for the study of superconductivity: the recent discovery of a reentrant tetragonal phase with SDW magnetic ordering has opened new avenues to study the competition between microscopically coexistent superconductivity and magnetism. This intriguing new phase is not only an exceedingly rare example of a magnetic structure with two ordering vectors, and consequently a confirmation of itinerant magnetism, but has also allowed for the determination of spin fluctuations as the driving mechanism behind the phase evolution in these materials. Evidence has been mounting of the universality of  $C_4$  in the hole doped iron pnictides providing a useful playground for the comparison of how this phase behaves as it is stabilized out of different parent compounds and through different dopant atoms. Here all members of the hole doped family which show the  $C_4$  phase will be compared and the parameters which appear to tune the phase's extent in temperature and phase space will be discussed.

**9:24AM E11.00006 Itinerant Double-Q Spin-Density Wave in Iron Arsenide Superconductors<sup>1</sup>**, RAYMOND OSBORN, Argonne Natl Lab, JARED ALLRED, University of Alabama, OMAR CHMAISSEM, STEPHAN ROSENKRANZ, Argonne Natl Lab, DENNIS BROWN, Northern Illinois University, KEITH TADDEI, MATTHEW KROGSTAD, DANIEL BUGARIS, DUCK-YOUNG CHUNG, HELMUT CLAUS, SAUL LAPIDUS, MERCOURI KANATZIDIS, Argonne Natl Lab, JIAN KANG, RAFAEL FERNANDES, University of Minnesota, ILYA EREMIN, Ruhr-Universität Bochum — The recent observation of a tetragonal magnetic ( $C_4$ ) phase in hole-doped iron arsenide superconductors has provided evidence of a magnetic origin for the electronic nematicity in the  $C_2$  phase of these compounds. Now, Mössbauer data shows that the new phase also establishes the itinerant character of the antiferromagnetism of these materials and the primary role played by magnetic over orbital degrees of freedom. Neutron diffraction had shown that the magnetic order in the  $C_4$  phase was compatible with a double-Q structure arising from a collinear spin-density wave along both the X and Y directions simultaneously. The coherent superposition of the two modulations produces a non-uniform magnetic structure, in which the spin amplitudes vanish on half of the sites and double on the others, a uniquely itinerant effect that is incompatible with local moment magnetism. Mössbauer spectra in the  $C_4$  phase confirm this double-Q structure, with 50% of the spectral weight in a zero-moment peak and 50% with double the magnetic splitting seen in the  $C_2$  phase.

**9:36AM E11.00007 ABSTRACT WITHDRAWN —**

**9:48AM E11.00008 Emergent Ising degrees of freedom in the  $J_1$ - $J_2$ - $J_3$  model for the iron tellurides**, GUANGHUA ZHANG, Ames Laboratory, Dept of Physics and Astronomy, Iowa State University, RAFAEL FERNANDES, School of Physics and Astronomy, University of Minnesota, REBECCA FLINT, Ames Laboratory, Dept of Physics and Astronomy, Iowa State University — The iron-telluride family of superconductors form a double-stripe [ $\mathbf{Q} = (\pi/2, \pi/2)$ ] magnetic order, which can be captured within a  $J_1 - J_2 - J_3$  Heisenberg model in the regime  $J_3 \gg J_2 \gg J_1$ . Intriguingly, besides breaking spin-rotational symmetry, the ground state manifold has three additional Ising degrees of freedom. Via their coupling to the lattice, they give rise to a monoclinic distortion and to two non-uniform lattice distortions with wave-vector  $(\pi, \pi)$ . Because the ground state is four-fold degenerate (mod rotations in spin space), only two of these Ising order parameters are independent. Here we introduce an effective field theory to treat all Ising order parameters, as well as magnetic order. All three transitions (corresponding to the condensations of two Ising and one magnetic order parameter) are simultaneous and first order in three dimensions, but lower dimensionality (or equivalently weaker interlayer coupling) and weaker magnetoelastic coupling can split the three transitions, and in some cases allows for two separate Ising phase transitions.

**10:00AM E11.00009 Non-Fermi liquid behavior in quantum critical iron-pnictide metal  $\text{Ba}(\text{Fe,Ni,Co})_2\text{As}_2$** , YASUYUKI NAKAJIMA, KEVIN KIRSHENBAUM, ALEX HUGHES, CHRISTOPHER ECKBERG, RENXIONG WANG, TRISTIN METZ, SHANTA SAHA, JOHNPIERRE PAGLIONE, Univ of Maryland-College Park — The breakdown of Landau's Fermi liquid theory has been believed to be induced by quantum fluctuations in the vicinity of a quantum critical point (QCP), occasionally accompanied by exotic superconductivity in the strongly correlated electron systems, such as cuprate and iron pnictide superconductors [1]. However, the superconducting dome of such materials with high  $T_c$  precludes us from investigating the interplay between quantum fluctuations and the exotic superconductivity. We report non-Fermi liquid behavior associated with quantum fluctuations in the transport and thermodynamic properties of the non-superconducting iron pnictide  $\text{Ba}(\text{Fe,Co,Ni})_2\text{As}_2$ , which allows us to elucidate the behavior on cooling down to near absolute zero without distractions from the superconductivity. We will discuss the evolution of non-Fermi liquid behavior with magnetic field, highlighting the presence of field tuned QCP. [1] T. Shibauchi et al., Annu. Rev. Condens. Matter Phys. 5, 113 (2014).

**10:12AM E11.00010 Spin-fluctuation induced non-Fermi-liquid behaviour with suppressed superconductivity in  $\text{LiFe}_{1-x}\text{Co}_x\text{As}$** , HU MIAO, YAOMIN DAI, Brookhaven National Laboratory, LINGYI XING, XIANCHENG WANG, Institute of physics, Chinese Academy of Sciences, PENGSHUAI WANG, Renmin University, HONG XIAO, TIAN QIAN, PIERRE RICHARD, XIANGGANG QIU, Institute of physics, Chinese Academy of Sciences, WEIQIANG YU, Renmin University, CHANGQING JIN, ZIQIANG WANG, Institute of physics, Chinese Academy of Sciences, P. D. JOHNSON, C. C HOMES, Brookhaven National Laboratory, HONG DING, Institute of physics, Chinese Academy of Sciences — We study a series of  $\text{LiFe}_{1-x}\text{Co}_x\text{As}$  compounds with different Co concentrations by transport, optical spectroscopy, angle-resolved photoemission spectroscopy, and nuclear magnetic resonance. We observe a Fermi-liquid to non-Fermi-liquid to Fermi-liquid (FL-NFL-FL) crossover alongside a monotonic suppression of the superconductivity with increasing Co content. In parallel to the FL-NFL-FL crossover, we find that both the low-energy spin fluctuations and Fermi surface nesting are enhanced and then diminished, strongly suggesting that the NFL behaviour in  $\text{LiFe}_{1-x}\text{Co}_x\text{As}$  is induced by low-energy spin fluctuations that are very likely tuned by Fermi surface nesting. Our study reveals a unique phase diagram of  $\text{LiFe}_{1-x}\text{Co}_x\text{As}$  where the region of NFL is moved to the boundary of the superconducting phase, implying that they are probably governed by different mechanisms.

**10:24AM E11.00011 Study of non-Fermi Liquid behavior from partial nesting in multi-orbital superconductors.**, CHANDAN SETTY, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Partial nesting between two connected or disconnected regions of the Fermi surface leads to fractional powers of the Coulomb scattering lifetime as a function of temperature and frequency. This result is first demonstrated for a toy band structure where partial nesting occurs within a single band and between different regions of the Brillouin zone. A comparison is then made to a multiband scenario by studying the scattering rate of an effective two orbital model that was proposed in the context of multi-orbital superconductors. In the process, various model independent factors affecting the temperature exponent,  $n$ , are identified. The logarithmically divergent contributions of the lowest order vertex correction to the multi-orbital susceptibility, and the role played by nesting in suppressing these divergences is analyzed. The relevance of these results is discussed keeping the recently observed anomalous resistivity in the Co doped Iron superconductor  $\text{LiFeAs}$  as a backdrop.

**10:36AM E11.00012 Sensitivity of quantum critical pairing to Fermi surface topology: a Quantum Monte Carlo study**, XIAOYU WANG, University of Minnesota, YONI SCHATTNER, EREZ BERG, Weizmann Institute of Science, RAFAEL FERNANDES, University of Minnesota — In many iron-based and copper-based materials, unconventional superconductivity appears in close proximity to an antiferromagnetic instability. This fact has motivated intense theoretical investigations of the impact of magnetic fluctuations, particularly those associated with the putative quantum critical point (QCP), on the formation of the Cooper pairs. Although significant advance has been achieved using analytical methods to solve the so-called spin-fermion model, in which low-energy electronic states couple to quantum critical bosonic fluctuations, there remain significant challenges in establishing a perturbative scheme that accounts for both non-Fermi liquid behavior and superconductivity near the QCP. Here we present a sign-problem-free Quantum Monte Carlo (QMC) study of the spin-fermion model for a generic two-band Hamiltonian. We show that properties of the Fermi surface topology beyond the existence of hot spots play a fundamental role in determining the superconducting properties. In particular, we find that proximity to perfect nesting strongly suppresses the enhancement of the pairing susceptibility promoted by the QCP. We also compare our QMC results with an Eliashberg analysis of the quantum critical problem.

**10:48AM E11.00013 Density Functional Theory insights into the mechanism of noncollinear incommensurate spin density waves in Iron Arsenide.**, ROBERT SCHOONMAKER, STEWART CLARK, TOM LANCASTER, THOMAS FRAWLEY, PETER HATTON, Durham University — Iron arsenide intersects interesting physics between novel superconductors and other helical magnetic ordering in Pnma metal arsenide materials. Recent diffraction data has found a more complex ordering than a simple helical incommensurate spin density wave. Instead iron arsenide exhibits a definite chirality to the helimagnetism, an ellipticity in the spiral not aligned with the crystal axis, and resonant diffraction peaks forbidden by the Pnma symmetry. From non-magnetic and collinear density functional theory calculations we present insight into the mechanisms for the formation of this helimagnetic state. We find that ferromagnetic superexchange is a likely mechanism for the spin ordering and that the noncollinear ordering under this regime is caused by the spins on neighbouring irons arranging to minimise direct exchange between iron atoms, and also minimize disruption of the ferromagnetic superexchange between privileged iron-arsenic pairs. To explain the forbidden peaks in the diffraction we have performed second-order spin-orbit perturbation calculations on the nonmagnetic calculation, which finds that the orbital ordering on the iron atoms coupled to the helimagnetism will lead to the otherwise symmetry-forbidden peaks.

Session E12 FIAP DMP: Mechanisms for Long Carrier Lifetimes and High Detectivities from Novel Ga-free Narrow Gap III-V Semiconductor Superlattices 308 - Michael Flatte, Univ of Iowa

**8:00AM E12.00001 Ga-free InAs/InAsSb type-II superlattice and its applications to IR lasers and photodetectors**, YONG-HANG ZHANG, Arizona State University — This talk will review the research on Ga-free InAs/InAsSb type-II superlattices (T2SL), especially their growth, structural and electronic properties, and applications to IR lasers and photodetectors with the following highlights: 1) Review of the previous study of InAs/InAsSb T2SL and its application to IR lasers and photodetectors in the 90's. 2) Long minority carrier lifetime up to 12.8  $\mu$ s in mid-wavelength infrared (MWIR) InAs/InAsSb T2SL was observed at 15 K, and 412 ns for long-wavelength infrared (LWIR) InAs/InAsSb T2SL were measured using time-resolved photoluminescence. The record long carrier lifetime in the MWIR range is due to carrier localization, which is confirmed by a 3 meV blue shift of the photoluminescence peak energy with increasing temperature from 15 K to 50 K, along with a photoluminescence linewidth broadening up to 40 K. In contrast, no carrier localization is observed in the LWIR T2SL. Modeling results show that carrier localization is stronger in shorter period (9.9 nm) MWIR T2SL as compared to longer period (24.2 nm) LWIR T2SL, indicating that the carrier localization originates mainly from InAs/InAsSb interface disorder. Although carrier localization enhances carrier lifetimes, it also adversely affects carrier transport. 3) Pressure-dependent photoluminescence (PL) experiments under hydrostatic pressures up to 2.16 GPa were conducted on a MWIR InAs/InAsSb T2SL structure at different pump laser excitation powers and sample temperatures. The results show a pressure coefficient of the T2SL transition was found to be  $93.2 \text{ meV/GPa}^{-1}$ ; a clear change in the dominant photo-generated carrier recombination mechanism from radiative to defect related, providing evidence for a defect level situated at 0.18 0.01 eV above the conduction band edge of InAs at ambient pressure. 4) LWIR InAs/InAsSb T2SL nBn photodetectors on GaSb substrates were demonstrated. The typical device consisted of a 2.2 micron thick absorber layer and has a 50% cutoff wavelength of 13.2  $\mu$ m, a measured dark current density of  $5 \times 10^{-4} \text{ A/cm}^2$  at 77 K under a bias of -0.3 V, a peak responsivity of 0.24 A/W at 12  $\mu$ m and a maximum RA product of 300 ohm-cm<sup>2</sup> at 77 K. The calculated generation-recombination noise limited specific detectivity ( $D^*$ ) and experimentally measured  $D^*$  at 12  $\mu$ m and 77 K are  $1 \times 10^{10} \text{ (cm-Hz}^{1/2})/\text{W}$  and  $1 \times 10^8 \text{ (cm-Hz}^{1/2})/\text{W}$ , respectively.

**8:36AM E12.00002 MWIR GaSb-based infrared detectors utilizing InAsPSb absorbers**, JIN KIM, Sandia National Lab — No abstract available.

**9:12AM E12.00003 Identification of dominant recombination mechanisms in narrow-bandgap InAs/InAsSb type-II superlattices and InAsSb alloys**, THOMAS BOGGESE, The University of Iowa — InAs/Ga(In)Sb type-II superlattices (T2SL) have been extensively studied for both advanced emitter and detector technologies associated with mid-wave (MWIR), long-wave (LWIR), and very-long-wave (VLWIR) infrared applications. The type-II band alignment, together with control of both the layer thicknesses and the alloy composition, provide a rich environment for band structure engineering, including band gap tuning and suppression of Auger recombination. Unfortunately, the InAs/Ga(In)Sb MWIR T2SLs have been found to have minority carrier lifetimes persistently below 100 ns, even at cryogenic temperatures. Such short lifetimes are problematic for detector applications and suggest that this material system will not compete with HgCdTe for IR detector applications. On the other hand, the report by Steenberg, et al., [1] of much longer minority carrier recombination lifetimes ( $>412 \text{ ns}$  at 77K) in a longwave (8.2  $\mu$ m) InAs/InAsSb T2SL suggests that the “Ga-free” superlattices could be competitive for IR detector applications. We will discuss all-optical measurements of carrier lifetimes as a function of temperature and injected carrier density in InAs/InAsSb T2SLs with a broad range of sample designs based on variations in alloy composition and/or layer thickness. Minority carrier lifetimes ranging from 4.5 s for a 9.2 m-band-gap T2SL to 18 s for a 4.2 m-band-gap T2SL have been measured at 77 K. This research was performed in collaboration with Y. Aytac, B.V. Olson, J.K. Kim, E.A. Shaner, J.F. Klem, S.D. Hawkins, and M.E. Flatté. [1] Steenberg, et al., Appl. Phys. Lett. Vol. 99, 251110 (2011).

**9:48AM E12.00004 Design of MWIR Type-II Superlattices for Infrared Photon Detectors<sup>1</sup>**, CHRISTOPH GREIN, University of Illinois at Chicago — The Type II InAs/GaInSb and InAs/InAsSb superlattices are material systems for implementation as photodetector absorbers in infrared imaging applications. In addition to cutoff wavelengths spanning the infrared spectrum, they offer degrees of freedom in their materials design (e.g. layer thicknesses, alloy compositions, number of layers in one superlattice period) that permit the optimization of an infrared photon detector's figures of merit such as detectivity through the tuning of material properties like generation/recombination lifetimes and optical absorption. We describe efforts to obtain accurate electronic band structures of superlattice semiconductors with infrared energy gaps, and employing them to evaluate nonradiative minority carrier lifetimes. Simple device models are utilized to suggest potential performance enhancements that arise from employing superlattices as infrared absorber. We also discuss current efforts to simulate the molecular beam epitaxial growth of InAs/InAsSb superlattices to predict dominant native point defects and other growth nonidealities.

<sup>1</sup>Design of MWIR Type-II Superlattices for Infrared Photon Detectors

**10:24AM E12.00005 Identification of Defect Candidates and their Effects on Carrier Lifetimes and Dark Currents in InAs/InAsSb Strained-Layer Superlattices for Infrared Detectors**, NICHOLAS KIOUSSIS, Physics Department, Cal State Univ - Northridge — The InAs/GaSb and InAs/InAsSb type-II strain-layer superlattices (T2SLS) are of great importance and show great promise for mid-wave and long-wave infrared (IR) detectors for a variety of civil and military applications. The T2SLS offer several advantages over present day detection technologies including suppressed Auger recombination relative to the bulk MCT material, high quantum efficiencies, and commercial availability of low defect density substrates. While the T2SLS detectors are approaching the empirical Rule-07 benchmark of MCT's performance level, the dark-current density is still significantly higher than that of bulk MCT detectors. One of the major origins of dark current is associated with the Shockley-Read- Hall (SRH) process in the depletion region of the detector. I will present results of ab initio electronic structure calculations of the stability of a wide range of point defects [As and In vacancies, In, As and Sb antisites, In interstitials, As interstitials, and Sb interstitials] in various charged states in bulk InAs, InSb, and InAsSb systems and T2SLS. I will also present results of the transition energy levels. The calculations reveal that compared to defects in bulk materials, the formation and defect properties in InAs/InAsSb T2SLS can be affected by various structural features, such as strain, interface, and local chemical environment. I will present examples where the effect of strain or local chemical environment shifts the transition energy levels of certain point defects either above or below the conduction band minimum, thus suppressing their contribution to the SRH recombination.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**  
**Session E13 DAMOP: Exploring Topological Physics with Cold Atoms** 309 -

**8:00AM E13.00001 From Berry's Phase to Wilson Lines in a Honeycomb Optical Lattice** , MONIKA SCHLEIER-SMITH, Department of Physics, Stanford University — I will report on methods for fully characterizing the topology and geometry of Bloch bands in optical lattices. Using a Bose-Einstein condensate as a momentum-resolved probe, we study a paradigmatic model system, the honeycomb lattice. Its salient features are two Dirac points, each producing a half-quantum of Berry flux similar to the magnetic flux of an infinitesimally narrow solenoid. We have detected this singular Berry flux by forming an Aharonov-Bohm-type interferometer in momentum space.<sup>1</sup> Our technique is broadly applicable to mapping out the Berry curvature or directly measuring the Chern number of a single band. I will furthermore show how interband dynamics can reveal the matrix-valued Wilson line, the generalization of Berry's phase to the multi-band setting.<sup>2</sup> In the simple case where the Wilson line is path-independent and Abelian, it serves as a powerful tool for tomographic reconstruction of the band eigenstates.

**8:36AM E13.00002 Geometric "charge" pumping with a Bose-Einstein condensate** , IAN SPIELMAN, JQI, NIST and the University of Maryland — We realized a quantum "charge" pump for a Bose-Einstein condensate (BEC) in a novel bipartite magnetic lattice, whose bands are characterized by non-trivial topological invariants: the Zak phases. For each band, the Zak phase is determined by that band's integrated Berry curvature, a geometric quantity defined at each crystal momentum. We probed this Berry curvature in a charge pump experiment, by periodically and adiabatically driving the system. Unlike topological charge pumps in filled bands that yield quantized pumping, our BEC occupied just a single crystal momentum state allowing us to access its band's local geometry. Like topological charge pumps, for each pump cycle we observed an overall displacement (here, not quantized) and a temporal modulation of the atomic wavepacket's position in each unit cell, i.e., the polarization. Our magnetic lattice enabled us to observe this modulation by measuring the BEC's magnetization. While our periodic drive shifted the lattice potential by one unit cell per cycle, the displacement of the BEC, solely determined by the underlying Berry curvature, was always less than the lattice's displacement.

**9:12AM E13.00003 Measuring Chern numbers in Atomic Gases: 2D and 4D Quantum Hall Physics in the Lab** , NATHAN GOLDMAN, Université Libre de Bruxelles (ULB) — Optical-lattice experiments have recently succeeded in probing the geometry of 2D Bloch bands with cold neutral atoms. Beyond these local geometrical effects, which are captured by the Berry curvature, 2D Bloch bands may also display non-trivial topology, a global property captured by a topological invariant (e.g. the first Chern number). Such topological properties have dramatic consequences on the transport of non-interacting atoms, such as quantized responses whenever the bands are uniformly populated. In this talk, I will start with the first experimental demonstration of topological transport in a gas of neutral particles, which revealed the Chern number through a cold-atom analogue of quantum-Hall measurements<sup>1</sup>. I will then describe how this Chern-number measurement could be extended in order to probe the topology of higher-dimensional systems. In particular, I will show how the *second Chern number* – an emblematic topological invariant associated with 4D Bloch bands – could be extracted from an atomic gas, using a 3D optical lattice extended by a synthetic dimension<sup>2</sup>. Finally, I will describe a general scheme by which optical lattices of subwavelength spacing could be realized<sup>3</sup>. This method leads to topological band structures with significantly enhanced energy scales, offering an interesting route towards the experimental realization of strongly-correlated topological states with cold atoms.

**9:48AM E13.00004 Experimental Realization of the Harper-Hofstadter Model** , COLIN KENNEDY, MIT — Extensions of Berry's phase and the quantum Hall effect have led to the discovery of new states of matter with topological properties. Traditionally, this has been achieved using magnetic fields or spin-orbit interactions, which couple only to charged particles. For neutral ultracold atoms, synthetic magnetic fields have been created that are strong enough to realize the Harper-Hofstadter model. In this talk, I report on work studying Bose-Einstein condensation in the Harper-Hofstadter Hamiltonian with one-half flux quantum per lattice unit cell. The diffraction pattern of the superfluid state directly shows the momentum distribution of the wavefunction, which is gauge-dependent, and it reveals both the reduced symmetry of the vector potential and the degeneracy of the ground state. I present an adiabatic, many-body state preparation protocol via the Mott insulating phase and show the superfluid ground state in a three-dimensional lattice with moderate interactions. I will discuss progress towards a triple-superlattice implementation as well as prospects for exploring exotic states close to the Mott transition.

**10:24AM E13.00005 Topological Charge Pumping with Cold Atoms** , YOSHIRO TAKAHASHI, Kyoto University — More than 30 years ago, Thouless considered an interesting phenomenon of quantum transport of an electron gas in an infinite one-dimensional periodic potential, driven in a periodic cycle. The charge pumped by this Thouless pump is a topological quantum number and does not depend on a smooth change of parameters. Importantly, this charge pumping shares the same topological origin as the integer quantum Hall effect. In spite of the importance in a topological quantum physics, this Thouless pump has never been realized in any system. In this study, we successfully realize the Thouless topological pump by exploiting the controllability of ultracold atoms in an optical superlattice. The charge pumping is detected as a shift of the center of mass of an atomic cloud measured with in situ absorption imaging. We extract the Chern number of the system from the average shift of the center of mass per pumping cycle. The topological nature of the pump is revealed by the clear dependence on the topology of the pumping trajectories in parameter space of our superlattice. We will describe the detail of our experiments using fermionic ytterbium atoms and also discuss the prospects of our research.

Session E14 CSWP: Understand and Improve the Status of Women in Physics 310 - Cha-Mei Tang, Creatv MicroTech. Inc.

**8:00AM E14.00001 Reversing into Meritocracy: Shifting the Culture of Physics** , EDMUND BERTSCHINGER, Massachusetts Institute of Technology — Culture is the dark energy of our lives: it is an invisible force that shapes our environment for work and life. Physics culture often includes the assumption that people have equal access to resources and opportunities regardless of gender, race, or any other demographic characteristic. Numerous studies show this is false, yet the invisible force of meritocracy shapes many departments, and its passive acceptance can foster inequitable working environments. Department chairs and other leaders play a key role in shifting institutional culture to leverage the power of diversity, improve student and employee success, and enhance the quality of life for everyone. I will describe steps taken at MIT to shift our cultural direction so that we are not driving in reverse on the highway of meritocracy.

**8:36AM E14.00002 New research on women's low participation in science and technology**<sup>1</sup> , JANE STOUT, Computing Research Association — It is well known that women have historically been and continue to be grossly underrepresented in technical fields (i.e., the physical sciences, engineering, and computing). This presentation will address the following research questions: What dissuades women from entering into a technical career track, and what are women's experiences like within technical fields? At the same time, this presentation will acknowledge a shortcoming of decades of social science research and interventions designed to improve women's interest and persistence in technical fields: a narrow definition of "women". Given that the majority of women in colleges and universities (i.e., the typical sites of social science research) tend to be affluent and/or White, STEM education research that relies on convenience samples at colleges and universities paints a skewed picture of gender issues in technical fields. This presentation will showcase research findings that call into question conventional conceptions of gender disparities in technical fields. Specifically, the presentation will emphasize the importance of recognizing that women constitute more than their gender; women come from a diverse array of backgrounds, which no doubt play a role in the experience of being a woman in technical fields. By understanding the experiences of women from a broad array of demographics groups, the STEM education community can develop a corresponding set of strategies to recruit and retain women with diverse interests, experiences, and values (e.g., first generation versus second college students; women of different racial/ethnic backgrounds). The aim of this presentation is to promote social science research and interventions that acknowledge the nuanced experiences of diverse women in technical fields, in order to address the seemingly intractable problem of women's underrepresentation in technical fields.

**Session E15 DMP: 2D Devices: Mobility and Energy Relaxation** 314 - Wenjuan Zhu, University of Illinois at Urbana-Champaign

**8:00AM E15.00001 Graphene based GHz detectors.**<sup>1</sup> , ANTHONY K BOYD, ASEE Postdoctoral Fellow in-residence at U.S. Naval Research Lab, Washington DC, ABDEL EL FATIMY, PAOLA BARBARA, Georgetown University, ANINDYA NATH, George Mason University Postdoctoral fellow in-residence at U.S. Naval Research Lab, Washington DC, PAUL M CAMPBELL, RACHAEL MYERS-WARD, U.S. Naval Research Laboratory, KEVIN DANIELS, NRC Postdoctoral fellow in-residence at U.S. Naval Research Lab, Washington DC, D. KURT GASKILL, U.S. Naval Research Laboratory — Graphene demonstrates great promise as a detector over a wide spectral range especially in the GHz range. This is because absorption is enhanced due to the Drude contribution. In the GHz range there are viable detection mechanisms for graphene devices. With this in mind, two types of GHz detectors are fabricated on epitaxial graphene using a lift off resist-based clean lithography process to produce low contact resistance.[1] Both device types use asymmetry for detection, consistent with recent thoughts of the photothermoelectric effect (PTE) mechanism. The first is an antenna coupled device. It utilizes two dissimilar contact metals and the work function difference produces the asymmetry. The other device is a field effect transistor constructed with an asymmetric top gate that creates a PN junction and facilitates tuning the photovoltaic response. The response of both device types, tested from 100GHz to 170GHz, are reported. 1. Nath Anindya et al Applied Physics Letters 104, 224102 (2014)

**8:12AM E15.00002 Optimization of thermoelectric power factor in ion-gated ultrathin WSe2 single crystals** , YIJIN ZHANG, MASARO YOSHIDA, TAKAHIKO IIZUKA, RYUJI SUZUKI, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo, SUNAO SHIMIZU, RIKEN Center for Emergent Matter Science — We report an electric field tuning of the thermopower in ultrathin WSe2 single crystals over a wide range of carrier concentration by using electric double-layer (EDL) technique. We fabricated a micro-sized EDL transistor with on-chip heaters and thermometers for an ultrathin flake of WSe2. We succeeded in the optimization of power factor not only in the hole but also in the electron side, which has never been chemically accessed. The maximized values of power factor are one-order larger than that obtained by changing chemical composition, reflecting the clean nature of electrostatic carrier doping.

**8:24AM E15.00003 Quantum lifetime in BN-encapsulated graphene devices** , JESSE BALGLEY, SCOTT DIETRICH, Columbia University, LEI WANG, Cornell University, VITTO HAN, BO WEN, YUANDA GAO, JAMES HONE, CORY DEAN, Columbia University — Encapsulating monolayer graphene in BN has lead to vastly enhanced device quality, leading to significantly increased mobility and quantum lifetimes on the order of picoseconds. However, magnetoresistance measurements in the quantum Hall regime reveal remnant disorder that continues to inhibit transport measurement. Here we report a study of the Shubnikov-de Haas oscillations in very high mobility devices. Comparison of the mean scattering and quantum lifetimes suggest that remote impurities remain the dominant scattering mechanism. The source of this remnant disorder, and the consequence for mobility enhancement in BN-supported 2D materials beyond graphene is discussed.

**8:36AM E15.00004 Velocity Saturation of Hot Carriers in Two-Dimensional Transistors<sup>1</sup>**, JONATHAN BIRD, University at Buffalo — Two-dimensional (2D) materials, including graphene and transition-metal dichalcogenides, have emerged in recent years as possible “channel-replacement” materials for use in future generations of post-CMOS devices. Realizing the full potential of these materials requires strategies to maximize their current-carrying capacity, while minimizing Joule losses to its environment. A major source of dissipation for hot carriers in any semiconductor is spontaneous optical-phonon emission, resulting in saturation of the drift velocity. In this presentation, I discuss the results of studies of velocity saturation in both graphene and molybdenum-disulphide transistors, emphasizing how this phenomenon impacts resulting transistor operation. While in graphene the large intrinsic optical-phonon energies promise high saturation velocities, experiments to date have revealed a significant degradation of the drift velocity that arises from the loss of energy from hot carriers to the underlying substrate. I discuss here how this problem can be overcome by implementing a strategy of nanosecond electrical pulsing [H. Ramamoorthy et al., Nano Lett., under review], as a means to drive graphene’s hot carriers much faster than substrate heating can occur. In this way we achieve saturation velocities that approach the Fermi velocity near the Dirac point, and which exceed those reported for suspended graphene and for devices fabricated on boron nitride substrates. Corresponding current densities reach those found in carbon nanotubes, and in graphene-on-diamond transistors. In this sense we are able to “free” graphene from the influence of its substrate, revealing a pathway to achieve the superior electrical performance promised by this material. Velocity saturation is also found to be important for the operation of monolayer molybdenum-disulphide transistors, where it limits the drain current observed in saturation [G. He et al., Nano Lett. **15**, 5052 (2015)]. The implications of these results for 2D transistor performance will be explored in my presentation.

**9:12AM E15.00005 Electrical Transport in Ultra-Short Atomically Thin Devices**, MATHIAS BOLAND, M. JAVAD FARROKHI, MOHSEN NASSERI, DOUGLAS STRACHAN, University of Kentucky — Ultra-short nanoscale devices that incorporate atomically-thin materials have the potential to be the smallest electronics. These materials represent the ultimate size-scaling in the vertical dimension and could be ideal as channel, electrode, and dielectric materials for a variety of applications – especially for ultrafast electronics. Such extremely-scaled devices can show unique transport characteristics that depended sensitively on their atomic-scale configurations. Here we report several atomically-thin ultra-short device schemes we have been developing which includes those consisting of single and bilayer graphene channels. Electrical transport measurements show very unique characteristics between these ultra-short devices that are highly sensitive to the atomic layer number. This sensitivity suggests that these ultra-short devices are strongly dependent on the unique chiral nature of the charge carriers in these atomically-thin channel materials.

**9:24AM E15.00006 Chemical assembly of atomically thin transistors and circuits in a large scale**, MERVIN ZHAO, YU YE, Univ of California - Berkeley, YIMO HAN, Cornell University, YANG XIA, HANYU ZHU, YUAN WANG, Univ of California - Berkeley, DAVID MULLER, Cornell University, XIANG ZHANG, Univ of California - Berkeley — Next-generation electronics calls for new materials beyond silicon for increased functionality, performance, and scaling in integrated circuits. 2D gapless graphene and semiconducting TMDCs have emerged as promising electronic materials due to their atomic thickness, chemical stability and scalability. However, difficulties in the assembly of 2D electronic structures arise in the precise spatial control over the conducting and semiconducting crystals, typically relying on physically transferring them. Ultimately, this renders them unsuitable for an industrial scale and impedes the maturity of integrating atomic elements in modern electronics. Here, we report the large-scale spatially controlled synthesis of the single-layer MoS<sub>2</sub> laterally in electrical contact with graphene using a seeded growth method. TEM studies reveal that the single-layer MoS<sub>2</sub> nucleates at the edge of the graphene, creating a lateral van der Waals heterostructure. The graphene allows for electrical injection into MoS<sub>2</sub>, creating 2D atomic transistors with high transconductance, on-off ratios, and mobility. In addition, we assemble 2D logic circuits, such as a heterostructure NMOS inverter with a high voltage gain, up to 70.

**9:36AM E15.00007 Nonlinear Ballistic Transport in Graphene Devices**, M. JAVAD FARROKHI, MATHIAS BOLAND, MOHSEN NASSERI, DOUGLAS STRACHAN, University of Kentucky — Through the extreme size scaling of electronic devices, there is great potential to achieve highly efficient and ultrafast electronics. By scaling down the channel length in graphene transistors to the point where the mean free path exceeds the relevant channel length, the electron transport can transition from a diffusive regime to an intrinsic ballistic regime. In such a regime, both quantum tunneling at the electrode-channel interface and the screening length, as determined by electrode-channel barrier width, can have a strong effect on current nonlinearity and asymmetric gate response. Here we discuss our experimental results on nanogap electrodes to graphene channels that show quantitative agreement with an intrinsic ballistic model. Moreover, this behavior persists to room temperature and on standard oxide substrates, providing strong evidence for a new regime of nonlinearity in graphene devices that could be of potential use for electronic applications.

**9:48AM E15.00008 Resonant high harmonic generation in a ballistic graphene transistor with an AC driven gate**, TOMAS LOFWANDER, YEVGENIY KORNIYENKO, OLEKSII SHEVTSOV, Chalmers University of Technology — We report a theoretical study of time-dependent transport in a ballistic graphene field effect transistor. We develop a model based on Floquet theory describing Dirac electron transmission through a harmonically driven potential barrier. Photon-assisted tunneling results in excitation of quasibound states at the barrier. Under resonance condition, the excitation of the quasibound states leads to promotion of higher-order sidebands and enhanced higher harmonics of the source-drain conductance. The resonances in the main transmission channel are of the Fano form, while they are of the Breit-Wigner form for sidebands. We discuss the possibility of utilizing the resonances in prospective ballistic high-frequency devices, in particular frequency multipliers.

**10:00AM E15.00009 Substrate dependence of Hall and Field-effect mobilities in few-layer MoS<sub>2</sub> field-effect transistors<sup>1</sup>**, BHIM CHAMLAGAIN, MEEGHAGE PERERA, HSUEN-JEN CHUANG, ARTHUR BOWMAN, UPENDRA RIJAL, KRAIG ANDREWS, JOSEPH KLESKO, CHARLES WINTER, ZHIXIAN ZHOU, Wayne State University — In this work, we systematically study the Hall and field-effect mobilities of few-layer MoS<sub>2</sub> FETs fabricated on different substrates. Hall bar devices were fabricated on SiO<sub>2</sub> and hBN to directly measure carrier density. Standard four-probe transport measurement and Hall effect measurement were carried out for a wide temperature range to determine the carrier mobility and understand the scattering mechanisms. By comparing field-effect and Hall mobilities, we demonstrate that the intrinsic drift mobility of multi-layer MoS<sub>2</sub> in the high carrier density metallic region is independent of substrate and sample thickness. While the optical-phonon scattering remains the dominant scattering mechanism in MoS<sub>2</sub> devices on h-BN down to ~100 K, extrinsic scattering mechanisms start to degrade the carrier mobility of MoS<sub>2</sub> on all other substrates below ~200 K.

**10:12AM E15.00010 ABSTRACT WITHDRAWN —**

**10:24AM E15.00011 What Makes Effective Gating Possible in Two-Dimensional Heterostructures?**<sup>1</sup>, IGOR ZUTIC, University at Buffalo, PREDRAG LAZIC, Rudjer Boskovic Institute, KIRILL D. BELASHCHENKO, University of Nebraska-Lincoln — Electrostatic gating provides a way to obtain key functionalities in modern electronic devices and to qualitatively alter materials properties. While electrostatic description of such gating gives guidance for related doping effects, inherent quantum properties of gating provide opportunities for intriguing modification of materials and unexplored devices. Using first-principles calculations for Co/bilayer graphene, Co/BN, and Co/benzene, as well as a simple physical model, we show that magnetic heterostructures with two-dimensional layered materials can manifest tunable magnetic proximity effects [1]. van der Waals bonding is identified as a requirement for large electronic structure changes by gating. In particular, the magnitude and sign of spin polarization in physisorbed graphene can be controlled by gating, which is important for spintronic devices [2,3]. [1] P. Lazić, K. D. Belashchenko, and I. Žutić, arXiv:1510.05404. [2] P. Lazić, G. M. Sipahi, R. K. Kawakami, and I. Žutić, Phys. Rev. B **90**, 085429 (2014). [3] H. Dery et al., IEEE Trans. Electron. Dev. **59**, 259 (2012).

**10:36AM E15.00012 Highly sensitive hBN/graphene hot electron bolometers with a Johnson noise readout**, DMITRI EFETOV, Massachusetts Institute of Technology, YUANDA GAO, Columbia University, EVAN WALSH, REN-JYE SHIUE, GABRIELE GROSSO, CHENG PENG, Massachusetts Institute of Technology, JAMES HONE, Columbia University, KIN CHUN FONG, BBN Raytheon, DIRK ENGLUND, Massachusetts Institute of Technology — Graphene has remarkable opto-electronic and thermo-electric properties that make it an exciting functional material for various photo-detection applications. In particular, owed to graphenes unique combination of an exceedingly low electronic heat capacity and a strongly suppressed electron-phonon thermal conductivity  $G_{th}$ , the electronic and phononic temperatures are highly decoupled allowing an operation principle as a hot electron bolometer (HEB). Here we demonstrate highly sensitive HEBs made of high quality hBN/graphene/hBN stacks and employ a direct electronic temperature read out scheme via Johnson noise thermometry (JNT). We perform combined pump-probe and JNT measurements to demonstrate strongly damped  $C_e$  and  $G_{th}$  in the ultra-low impurity  $\sigma_i = 10^9 \text{ cm}^{-2}$  hBN/G/hBN stacks, which result in unprecedented photo-detection sensitivity and noise equivalent power for graphene HEBs.

**10:48AM E15.00013 Design and fabrication of an antenna-coupled graphene terahertz mixer**<sup>1</sup>, EDWARD LEONG, Univ of Maryland-College Park, JAKE CONNERS, CHEUK-YU E. TONG, PAUL K. GRIMES, LINGZHEN ZENG, Harvard-Smithsonian Center for Astrophysics, MARTIN MITTENDORFF, THOMAS E. MURPHY, Univ of Maryland-College Park — Graphene has shown promise for tunable terahertz (THz) technology, including detectors, modulators, filters, and emitters. Graphene exhibits a significant change in conductivity when the Fermi energy is altered by applying a gate voltage. Near the Dirac point, graphene field effect transistors (FETs) show a strongly nonlinear response (i.e. a strong change in resistivity with applied voltage) that can be exploited to provide efficient rectification and mixing of THz signals. Although rectification in graphene field-effect transistors has been demonstrated, heterodyne mixing in the THz band has not been explored. We examine a THz graphene mixer using an antenna-coupled graphene FET configuration. We will discuss the antenna and graphene device design optimized for heterodyne mixing 0.35 THz. In addition, fabrication and preliminary measurements of a lower frequency prototype will be presented to demonstrate the principle of the operation.

**Session E16 DMP: Graphene and Graphene Nanoribbons** 315 - Jing Kong, MIT

**8:00AM E16.00001 Observation of dopant-induced impurity states in bottom-up graphene nanoribbons**, ZAHRA PEDRAMRAZI, CHEN CHEN, TOMAS MARANGONI, RYAN CLOKE, TING CAO, STEVEN LOUIE, FELIX FISCHER, MICHAEL CROMMIE, Univ of California - Berkeley — Graphene nanoribbons (GNRs) provide a means for inducing energy gaps in graphene and are a promising candidate for many nanotechnological applications. New bottom-up fabrication techniques allow the structure of GNRs to be tuned with atomic precision, thus providing new opportunities for modifying their electronic structure. Here we report the synthesis of bottom-up armchair GNRs (AGNRs) with isolated substitutional boron-dopant centers; thus creating localized impurity states in the GNR. These impurities are realized via dilute doping of pristine  $n=7$  AGNRs with sparse boron-containing monomer units, resulting in uniform-width  $n=7$  AGNR segments where only two carbon atoms have been substitutionally replaced by boron atoms. Scanning tunneling microscopy (STM) and spectroscopy (STS) were performed to study the electronic structure of these AGNR impurity systems, enabling us to observe localized mid-gap impurity states.

**8:12AM E16.00002 Bottom-up Synthesis of N=13 Sulfur-doped Graphene Nanoribbons.**, TRINITY JOSHI, GIANG NGUYEN, FRANCESCA TOMA, TING CAO, ZAHRA PEDRAMRAZI, CHEN CHEN, DANIEL RIZZO, CHRISTOPHER BRONNER, YEN-CHIA CHEN, STEVEN LOUIE, FELIX FISCHER, MICHAEL CROMMIE, University of California, Berkeley — Substitutional doping of graphene nanoribbons (GNRs) with heteroatoms is a principal strategy to fine-tune the electronic structure of GNRs for future device applications. Up to now, however, edge-doping in bottom-up fabricated GNRs has exclusively relied on the introduction of nitrogen heteroatoms in the form of pyridine and pyrimidine rings along the edges of chevron GNRs. Here we report the bottom-up synthesis and characterization of atomically-precise  $N=13$  armchair graphene nanoribbons (S-13-AGNRs) wherein alternating  $(CH)_2$  groups lining the edges of the GNRs have been replaced by sulfur atoms. We study the resultant GNR with scanning tunneling microscopy (STM) and spectroscopy (STS). Our experimental results are consistent with first-principles simulations of the S-13-AGNR electronic structure.

**8:24AM E16.00003 Bottom-up fabrication and characterization of boron doped N=7 armchair graphene nanoribbons**, GIANG D. NGUYEN, ARASH A. OMRANI, HSIN-ZON TSAI, DANIEL J. RIZZO, TRINITY JOSHI, CHRISTOPHER BRONNER, RYAN R. CLOKE, TOMAS MARANGONI, TING CAO, GRIFFIN F. RODGERS, WON-WOO CHOI, Univ of California - Berkeley, STEVEN G. LOUIE, Univ of California - Berkeley and Lawrence Berkeley National Laboratory, FELIX R. FISCHER, MICHAEL F. CROMMIE, Univ of California - Berkeley and Kavli Energy NanoSciences Institute, and Lawrence Berkeley National Laboratory — Graphene nanoribbons (GNRs) have recently attracted great interest because of their novel electronic and magnetic properties, as well as the significant potential they have for device applications. Although several top-down techniques exist for fabricating GNRs, only bottom-up synthesis of GNRs from molecular precursors yields nanoribbons with atomic-scale structural control. Here we report the successful bottom-up fabrication boron doped  $N=7$  armchair graphene nanoribbons. Substitutional boron atoms were incorporated into the GNRs' central backbone, thus placing boron's empty p-orbital in conjugation with the extended  $\pi$  system of the GNR. Topographic and local electronic structure characterization was performed via STM and CO-tip-functionalized nc-AFM, and compared to DFT simulations.

**8:36AM E16.00004 Structure and Electronic Properties of Polymer Chains and Graphene Nanoribbon Formed by Molecular Self-Assembly on Au(111).** , CHUANXU MA, MIGUEL A. FUENTES-CABRERA, BOBBY G. SUMPTER, KUNLUN HONG, AN-PING LI, Oak Ridge National Laboratory, ZHONGCAN XIAO, WENCHANG LU, J. BERNHOLC, North Carolina State University — Graphene nanoribbons (GNRs) with bandgaps are promising building blocks for ultra-fast electronics. Bottom-up synthesis of GNRs from aromatic hydrocarbon molecules has been proven to be an effective way to control GNR's width with atomically precise edge structures. Using scanning tunneling microscopy (STM), we study the formation of both linear polymer chains and narrow GNRs in the bottom-up self-assembly process with the DBBA molecules as the precursor on Au(111). The linear polymer chains are formed after the deposition of DBBA and 200 C annealing for 30 min. The polymers can be converted to 7-AGNRs (seven-carbon wide armchair GNRs) after 400 C annealing. Interestingly, second-layer polymer is seen to survive on the GNRs during the annealing process. This result indicates that the Au(111) substrate plays an important role in the dehydrogenation process and the formation of GNRs, which is confirmed by our DFT calculations. Electronically, the polymers show a bandgap of 3.4 eV, much larger than that of GNRs. After annealing at 500 C for 30 min, wider GNRs can form: 14-AGNR, 21-AGNR. The 7-AGNR shows a typical edge state at -1.1 eV, while for 14-AGNR it is at -1.35 eV. Moreover, junctions of GNRs with different widths can be formed with pronounced boundary states.

**8:48AM E16.00005 Graphene Nanoribbons Anchored to a SiC Substrate.** , LILIA WOODS, NAM LE, University of South Florida, Department of Physics — Due to their exceptional fundamental characteristics graphene nanoribbons play a major role in the development of future nano-technological applications. The high chemical reactivity of the graphene nanoribbon edges can be utilized to create modified materials. Using first principles simulations we explore this possibility to construct patterned systems composed of anchored ribbons of zigzag edges covalently bonded to a SiC substrate. The hybrid edge states are found to possess interesting electronic and magnetic properties, which alter the overall behavior of the entire system as compared to the behavior of the individual components. It is found that the van der Waals interactions are important for the overall stability and structure of the anchored ribbons. Also, spin-polarization effects play a profound role in the electronic structure and associated density of states. The hybrid graphene/SiC zigzag edges are analyzed in terms of their transport characteristics as well.

**9:00AM E16.00006 Pseudospin dephasing in relaxed shape armchair graphene nanoribbons** , SANJAY PRABHAKAR, RODERICK MELNIK, Wilfrid Laurier University, LUIS BONILLA, Universidad Carlos III de Madrid — In this presentation, we argue that the Zeeman pseudospin splitting energy might not be neglected for smaller widths of the graphene nanoribbons (GNRs). Mathematically valid study shows that the pseudospin splitting energy breaks the symmetry of degeneracy due to ripple induced Zeeman effect in GNRs originating from electromechanical effects. We estimate the spin relaxation time caused by in-plane phonon modes for possible application in straintronics and quantum information processing. We acknowledge Natural Sciences and Engineering Research Council of Canada and Canada Research Chair programs for their financial support.

**9:12AM E16.00007 Decay patterns of edge states at reconstructed armchair graphene edges<sup>1</sup>** , CHANGWON PARK, ORNL, USA, JISOON IHM, Seoul National Univ., Korea, GUNN KIM, Sejong Univ., Korea — Density functional theory calculations are used to investigate the electronic structures of localized states at reconstructed armchair graphene edges. We consider graphene nanoribbons with two different edge types and obtain the energy band structures and charge densities of the edge states. By examining the imaginary part of the wave vector in the forbidden energy region, we reveal the decay behavior of the wave functions in graphene. The complex band structures of graphene in the armchair and zigzag directions are presented in the first-principles framework.

**9:24AM E16.00008 Orientationally Misaligned Zipping of Lateral Graphene and Boron Nitride Nanoribbons with Minimized Strain Energy and Enhanced Half-Metallicity<sup>1</sup>** , JIANG ZENG, University of Science and Technology of China, WEI CHEN, Harvard University, PING CUI, University of Science and Technology of China, DONG-BO ZHANG, Beijing Computational Science Research Center, ZHENYU ZHANG, University of Science and Technology of China — Lateral heterostructures of two-dimensional materials may exhibit various intriguing emergent properties. Yet when specified to the orientationally aligned heterojunctions of zigzag graphene and hexagonal boron nitride (hBN) nanoribbons, realizations of the high expectations on their properties encounter two standing hurdles. First, the rapid accumulation of strain energy prevents large-scale fabrication. Secondly, the pronounced half-metallicity predicted for freestanding graphene nanoribbons is severely suppressed. By properly tailoring orientational misalignment between zigzag graphene and chiral hBN nanoribbons, here we present a facile approach to overcome both obstacles. Our first-principles calculations show that the strain energy accumulation in such heterojunctions is significantly diminished for a range of misalignments. More strikingly, the half-metallicity is substantially enhanced from the orientationally aligned case, back to be comparable in magnitude with the freestanding case. The restored half-metallicity is largely attributed to the recovered superexchange interaction between the opposite heterojunction interfaces. The present findings may have important implications in eventual realization of graphene-based spintronics.

**9:36AM E16.00009 First principles-based moiré model for incommensurate graphene on BN<sup>1</sup>** , CATALIN SPATARU, KONRAD THURMER, Sandia National Labs — Various properties of supported graphene films depend strongly on the exact positions of carbon atoms with respect to the underlying substrate. While density functional theory (DFT) can predict atom position in many systems, it cannot be applied straightforwardly to systems that are incommensurate or have large unit cells, such as graphene on a BN surface. We address these limitations by developing a simple moiré model with parameters derived from DFT calculations for systems strained into commensurate structures with manageable unit cell sizes. Our moiré model, which takes into account the flexural rigidity of graphene and includes the influence of the substrate, is able to reproduce the DFT-relaxed carbon positions with an accuracy of <0.01 Å. We then apply this model to the unstrained C/BN system and predict how structure and energy vary with azimuthal orientation of the graphene sheet with respect to the BN substrate.

**10:00AM E16.00011 A first-principles study on Magnetic and Electronic properties of Graphane vacancies Dots.**

, BI-RU WU, Department of Natural science, Center for General Education, Chang Gung University, Kueishan 333, CHIH-KAI YANG, Graduate Institute of Applied Physics, National Chengchi University, Taipei 11605 — Graphane is the end product of the complete hydrogenation of graphene. The incomplete hydrogenation of graphene produces hydrogen vacancies in graphane. Hydrogen vacancies can alter the electronic structure of graphane and therefore tune the electronic, magnetic, and optical properties of the composite. In this paper, we use a first-principles density functional calculation to investigate a variety of well-separated clusters of hydrogen vacancies in graphane with magnetism, including the geometrical shapes of triangles, parallelograms, and rectangles. The results indicate that energy levels caused by the missing H are generated in the broad band gap of pure graphane. All triangular clusters of H vacancies are magnetic, the larger the triangle the higher the magnetic moment. The defect levels introduced by the missing H in triangular and parallelogram clusters are spin-polarized and can find application in optical transition. Parallelograms and open-ended rectangles are antiferromagnetic and can be used for nanoscale registration of digital information.

**10:12AM E16.00012 Influence of Spatial Inhomogeneity on Electronic and Magneto Transport in Graphene.**<sup>1</sup>

, BERNARD MATIS, BRIAN HOUSTON, JEFFREY BALDWIN, Naval Research Laboratory — We discuss room temperature electronic and magnetotransport measurements of polycrystalline graphene, grown by chemical vapor deposition, on a SiO<sub>2</sub> dielectric. The measured graphene devices are intentionally spatially inhomogeneous such that the length of the sample is much greater (>1000 times) than the average grain size. At magnetic field  $B = 0$  T the electronic transport is well described by a diffusive transport model with contributions from grain boundary scattering significantly larger in the high charge carrier density limit. We find the largest percent change in the magnetoresistivity occurs at the film's Dirac point where the magnetotransport is largely dependent upon charge disorder. Away from the Dirac point we find a modified expression for the charge carrier density dependence of the magnetoresistivity with respect to the case of single-crystal graphene.

**10:24AM E16.00013 Spontaneous and Thermally Enhanced Charge Transfer at Graphene-Silica Interface**

, KWANGHEE PARK, Department of Chemistry, Pohang University of Science and Technology, SUNMIN RYU<sup>1</sup>, Department of Chemistry, Division of Advanced Materials Science, Pohang University of Science and Technology — Low dimensional carbon materials undergo spontaneous hole doping in the ambient conditions. Thermal annealing enhances the degree of the charge transfer in silica-supported graphene exposed to oxygen and water vapor. In this work, we investigated the mechanisms responsible for the charge transfer using Raman spectroscopy and water contact angle measurements. Mechanically exfoliated graphene samples were annealed at various temperatures in a range of 100 to 1000 °C to induce the hole doping. While the annealing-induced charge density of graphene increased with increasing annealing temperature up to 700 °C, it decreased as increasing the temperature further higher. Graphene samples prepared in a low humidity condition lead to significantly decreased hole doping suggesting that water contained in the samples plays a key role. We will propose and discuss a charge transfer mechanism that involves thermal hydroxylation and rehydroxylation of silica surfaces.

**10:36AM E16.00014 Scrolling of Suspended CVD Graphene Sheets**

, OLEG MARTYNOV, SINCHUL YEOM, MARC BOCKRATH, Univ of California - Riverside, UC: RIVERSIDE TEAM — Carbon Nanoscrolls, one dimensional spiral forms of graphitic carbon, have attracted recent interest due to their novel proposed properties [1]. Although various production methods and studies of carbon nanoscrolls have been performed, low yield and poor controllability of their synthesis have slowed progress in this field. Suspended graphene membranes and carbon nanotubes have been predicted as promising systems for the formation of graphene scrolls [2]. We have suspended chemical vapor deposition (CVD)-grown graphene over large holes in a Si/SiO<sub>2</sub> substrate to make suspended membranes upon which nanotubes are placed. Initial experiments have been performed showing that tears or cuts of the suspended sheet can initiate scrolling. Our latest progress towards carbon nanotube initiated formation of graphene scrolls and suspended CVD graphene scrolling, along with measurements of these novel structures will be presented. [1] E. Perim et al., Front. Mater., 1:31 (2014); [2] E. Perim et al., J. Appl. Phys. 113, 054306 (2013)

**8:00AM E17.00001 Quasi-bound states in strained graphene**

, DARIO BAHAMON, Mackenzie Presbyterian University, ZENAN QI, HAROLD PARK, Boston University, VITOR PAREIRA, National University of Singapore, DAVID CAMPBELL, Boston University — In this work, we explore the possibility of manipulating electronic states in graphene nanostructures by mechanical means. Specifically, we use molecular dynamics and tight-binding models to access the electronic and transport properties of strained graphene nanobubbles and graphene kirigami. We establish that low energy electrons can be confined in the arms of the kirigami and within the nanobubbles; under different load conditions the coupling between confined states and continuous states is modified creating different conductance line-shapes.

**8:12AM E17.00002 Probing Graphene on Micropatterned Strain Arrays**

, JOHN HENRY HINNEFELD, NADYA MASON, Univ of Illinois - Urbana — The generation of enormous pseudo-magnetic fields in graphene by the application of carefully designed strain profiles opens a promising window onto an otherwise unattainable high-field regime. A central challenge in exploiting graphene's access to this regime is the difficulty of controllably generating the required strain profiles. Here, we report the tunable fabrication of nano-scale strain feature arrays, as well as optical, mechanical, and other measurements of graphene deposited on substrates prepared by this method. We describe the signatures of strain present in our measurements, and discuss the potential for further experimental exploration of this system.

**8:24AM E17.00003 Current and Noise Saturation in Graphene Superlattice.**<sup>1</sup>, WEI YANG, Laboratoire Pierre Aigrain, ENS-CNRS, XIAOBO LU, Institute of Physics, Chinese Academy of Sciences, SIMON BERTHOU, QUENTIN WILMART, MOHAMED BOUKHICHA, CHRISTOPHE VOISIN, Laboratoire Pierre Aigrain, ENS-CNRS, GUANGYU ZHANG, Institute of Physics, Chinese Academy of Sciences, BERNARD PLACAIS, Laboratoire Pierre Aigrain, ENS-CNRS — One of the merits of graphene is that the Fermi level can be easily tuned by electrical gating, which render charge carriers n type or p type, or even insulating around the Dirac point (DP). By aligning graphene on top of Boron Nitride (BN), the presence of graphene superlattice makes transport properties even more versatile owing to the emergence of secondary Dirac points (SDPs). Here we present a study of high electric field performance of graphene superlattice obtained from epitaxial approach. By using microwave cavity, noise produced from graphene by joule heating is recorded up to 5GHz. Current and noise saturation are observed and investigated. Depending on Fermi energy, saturation can be attributed to intrinsic optical or remote surface polar phonon scattering at a doping far away from DP, while no saturation are found around DP. Moreover, noise saturation is identified around Fermi energy between DP and SDP, which can be attributed to the influence of van Hove singularity arising from the superlattice. Lastly, saturation due to the bias induced shift of DP, or so called Dirac fermion pinch-off, is well observed by local top gate technique.

**8:36AM E17.00004 Valley polarization in graphene with out-of-plane deformations**<sup>1</sup>, DAWEI ZHAI, NANCY SANDLER, Department of Physics and Astronomy, Ohio University — At low energy, the energy dispersion of graphene shows a conical valley structure with the conduction and valence bands touching at the Dirac points. The existence of two inequivalent Dirac points in the Brillouin zone, thus two valleys, suggests they may be used as new degrees of freedom to carry information. Several schemes based on different mechanisms have been advanced to achieve valley separation in this material, however the proposed setups remain challenging for experimental observation. In this work we investigate graphene with out-of-plane deformations- one of the most naturally occurring and practically realizable settings, as a candidate system to produce valley polarization. Local strains produced by the deformations serve as scattering potentials for electronic states. A second-order Born approximation calculation based on the continuum model reveals the existence of valley polarization and its dependence on the geometrical parameters of the deformations. We characterize the efficiency of valley filtering for different geometries and energies and discuss their implementation in currently available experimental setups.

**8:48AM E17.00005 Tuning transport properties on graphene multiterminal structures by mechanical deformations**, ANDREA LATGE, VANESSA TORRES, Univ. Federal Fluminense, RJ-Brazil, DAIARA FARIA, Univ. do Estado do Rio de Janeiro, RJ-Brazil — The realization of mechanical strain on graphene structures is viewed as a promise route to tune electronic and transport properties such as changing energy band-gaps and promoting localization of states. Using continuum models, mechanical deformations are described by effective gauge fields, mirrored as pseudomagnetic fields that may reach quite high values. Interesting symmetry features are developed due to out of plane deformations on graphene; lift sublattice symmetry was predicted and observed in centrosymmetric bumps and strained nanobubbles [1]. Here we discuss the effects of Gaussian-like strain on a hexagonal graphene flake connected to three leads, modeled as perfect graphene nanoribbons. The Green function formalism is used within a tight-binding approximation. For this particular deformation sharp resonant states are achieved depending on the strained structure details. We also study a fold-strained structure [2] in which the three leads are deformed extending up to the very center of the hexagonal flake. We show that conductance suppressions can be controlled by the strain intensity and important transport features are modeled by the electronic band structure of the leads. [1]RC-Bastos et al., Phys. Rev. B 91, 125408 (2015).[2]HLim et al., Nat. Commun. 6, 8601(2015).

**9:00AM E17.00006 Fold assisted transport in graphene systems**<sup>1</sup>, RAMON CARRILLO-BASTOS, Univ. Autonoma de Baja California, BC, Mexico, DAIARA FARIA, Univ. do Estado de Rio de Janeiro, RJ, Brazil, YUHANG JIANG, JINHAI MAO, GUOHONG LI, EVA Y. ANDREI, Rutgers Univ., NJ, USA, ANDREA LATGE, Univ. Federal Fluminense, RJ, Brazil, NANCY SANDLER, Ohio University, OH, USA — Sasaki pointed out that a constant uniaxial strain applied along the zigzag direction in graphene causes localized states, akin to edge states in nanoribbons[1]. These states are dispersionless and can carry ballistic transport. Recent experiments reported the presence of ballistic channels in graphene grown on SiC characterized with STM spectroscopy[2, 3]. In this work, we show that out-of plane deformations in the form of folds produce states as those predicted by Sasaki. Using tight-binding calculations and recursive Greens function methods, we obtain conductance, density of states (DOS), local density of states, and band structure (BS) for graphene nanoribbons with zigzag termination. Regions with enhanced DOS are identified in the deformed area corresponding to states in new flattened bands in the BS and new ballistic channels in the conductance. Adjusting the fold parameters, desired properties of these states can be tailored. Our results show that folds could serve as pathways for electronic transport and open the possibility of circuitry design within a simple graphene membrane. [1]Sasaki et al., J. Phys. Soc. Jpn. 75 (2006). [2]Baringhaus et al., Nature 506 (2014). [3]Palacio et al., Nano Lett. 15 (2015).

**9:12AM E17.00007 Helium adsorption potential near mechanically deformed graphene**, NATHAN NICHOLS, VALERI KOTOV, ADRIAN DEL MAESTRO, University of Vermont — Mechanical strain modifies the van der Waals interactions of neutral adatoms near two-dimensional materials like graphene and commonly used parameters for helium interacting with carbon do not capture these effects. Using the polarization function of strained graphene, we have compared the long-distance Lifshitz dispersion force with an effective potential computed from the sum of two-body interactions. The resulting optimized many-body adsorption potential exhibits an anisotropic minimum that is displaced higher above the graphene sheet as uniaxial strain is increased. The competing energy scales introduced by strain open up the possibility of mechanically tuning novel anisotropic adsorbed superfluid phases of helium on graphene.

**9:24AM E17.00008 Elastic Solitons and Vortices in Bilayer Graphene**, JOSEPHINE YU, Montgomery Blair High School, HARSH MATHUR, Case Western Reserve University — Using electron microscopy Alden et al [PNAS 110, 11256 (2013)] find that in strained bilayer graphene regions of stable AB and BA stacking are separated by domain walls. Vortex-like defects are also observed at the intersections of three domain walls; scanning transmission electron microscopy reveals that the vortex cores have an unstable AA stacking. We develop a continuum elasticity model that describes the relative displacement of the two layers of graphene. In addition to the usual gradient energy cost we posit a nonlinear potential for the displacement field that favors AB and BA stackings and disfavors the AA stacking. In our model the domain walls appear as soliton solutions to a double sine-Gordon equation. We find that the ratio of the width of domain walls with tensile strain to those with shear strain is  $\sim 1.63$ , in excellent agreement with observations. We study the stability and oscillatory modes of the domain walls motivated by experimental observations that show the domain walls undergoing damped oscillations. Estimates of the vortex core size based on our model are in agreement with the experiment. A homotopy analysis of bilayer graphene vortices shows that they carry non-abelian topological charge.

**9:36AM E17.00009 Graphene on a curved substrate with a controllable curvature: Device fabrication and transport measurements**, YIXUAN CHEN, SHAUN MILLS, YING LIU, Pennsylvania State University — In monolayer graphene, the local deviation of carbon positions from the perfect lattice has been predicted to lead to a pseudo magnetic field with measurable effects. A striking confirmation of this effect is the observation of Landau levels that are attributed to a pseudo magnetic field in excess of 300 T in graphene nanobubbles. However, typical experimental methods of generating such local deviations in graphene rely on strain accompanied by a surface curvature. Whether a surface curvature alone can produce measurable effects in graphene has not been explored experimentally. It is therefore of interest to study graphene in a system that decouples strain from surface curvature. Of particular interest is its response to an external magnetic field. We developed a grayscale electron beam lithography technique for preparing PMMA substructures with a continuously variable radius of curvature from  $\sim 100$  nm to  $\sim 1$   $\mu$ m. Magnetoelectrical transport measurements on exfoliated graphene supported by these substructures are being carried out. The flexibility of this process may be further exploited in the study of the bilayer and trilayer graphene systems. We will also study hybrid structures of 2D superconductors and graphene.

**9:48AM E17.00010 Graphene with out-of-plane deformations and external magnetic fields<sup>1</sup>**, DAIARA FARIA, UERJ, RJ Brazil, RAMON CARRILLO BASTOS, Univ. Autonoma de Baja California, BC Mexico, FRANCISCO MIRELES, Univ. Nacional de Mexico, BC Mexico, ANDREA LATGE, Univ. Federal Fluminense, RJ Brazil, NANCY SANDLER, Ohio University, OH USA — Microscopic measurements in corrugated graphene have helped to elucidate how its electronic properties are affected in deformed regions, confirming the pseudomagnetic description for strained graphene. As the pseudofields reverse sign at each valley, an enhancement of the local density of states (LDOS) was found with broken sublattice symmetry in strained regions[1,2]. As a consequence, these systems have been proposed as a viable way to obtain valley filters. In graphene ribbons with a centrosymmetric deformation, the LDOS modification was predicted to be accompanied with a decrease in conductance, pointing to the presence of confined states [3]. To further characterize these states, we investigate the effect of strain in the presence of an external magnetic field, using a tight-binding model and recursive Greens function techniques. Anomalous conductance and DOS features are consistent with interpretation in terms of Fano resonances appearing for bound states in the continuum. We discuss the robustness of the sublattice asymmetry against the magnetic field and the possibility of exploring the valley separation in chosen spatial regions. [1]Mashoff et al. NanoLetters 10 (2010). [2]Schneider et al. 91 (2015). [3]Carrillo-Bastos et al. PRB 90 (2014).

**10:00AM E17.00011 Towards Quantum Strain Engineering in Ultra-short Ballistic Graphene Devices**, ANDREW MCRAE, VAHID TAYARI, SIMEON HANKS, ALEXANDRE CHAMPAGNE, Concordia University — We report our progress towards combining ultra-short and clean suspended graphene transistors [1] with mechanical breakjunction (MCBJ) instrumentation to create a widely tunable quantum strain engineering platform for graphene electronics. We first present data from our electromigrated ultra-short ( $\sim 10$  to 50 nm) suspended graphene transistors, which show ballistic transport [1], and demonstrate that we can tailor the length and shape of the suspended graphene by adjusting the electromigration parameters. We observe Fabry-Pérot interferences, which correspond to coherent transport not only in the suspended graphene channel, but also in the suspended graphene contacts connecting to the channel. We then describe the MCBJ assembly we use to bend the substrate in-situ at low temperature. Using long suspended cantilever contacts, this instrumentation allows strains up to  $\sim 10\%$  for device lengths  $\sim 10$  nm. The assembly is hosted in a cryostat operating down to 0.3 K and in magnetic fields up to 9 T. We finally report on our progress towards the application of large uniaxial strain for graphene strain transistors, and graphene NEMS with tunable frequencies approaching the THz range. [1] V. Tayari *et al.*, Nano. Lett. 15, 1 (2015)

**10:12AM E17.00012 Local Probes of Strain Texture and Individual Atomic Dopant Sites in Monolayer MoS<sub>2</sub>**, ALEX H. FRAGAPANE, ALEX W. CONTRYMAN, HONG LI, Stanford University, XIAOFENG QIAN, SINA MOEINI ARDAKANI, MIT, YONGJI GONG, XINGLI WANG, Rice University, JEFFREY M. WEISSE, CHI HWAN LEE, JIHENG ZHAO, Stanford University, PULICKEL M. AJAYAN, Rice University, JU LI, MIT, XIAOLIN ZHENG, HARI C. MANOHARAN, Stanford University — The 2D semiconductor MoS<sub>2</sub> is an optically active material uniquely responsive to local perturbations. As an atomically thin membrane with exceptional strength, it can embed wide band gap variations overlapping the visible light spectrum when subjected to biaxial strain, where the modified electronic potential emanating from point-induced tensile strain perturbations mimics the Coulomb potential in a mesoscopic atom. We have realized this “artificial atom” concept via monolayer nanoindentation, and demonstrate that a synthetic superlattice of these building blocks forms an optoelectronic crystal capable of broadband light absorption and efficient funneling of photogenerated excitons to points of maximum strain at the artificial-atom nuclei. We also investigate the effects of individual atomic dopant sites through STM/STS, and visualize the atomic-scale local band structure changes. The modification of 2D semiconductors through methods such as strain texturing and doping connects to applications in next generation optoelectronics and photovoltaics.

**10:24AM E17.00013 Effects of Strain on CVD-Grown Few-Layered Terrace Structures of MoS<sub>2</sub><sup>1</sup>**, AMBER MCCREARY, Penn State University, R. GHOSH, Univ. Texas at Austin, M. AMANI, U.S. Army Research Lab, J. WANG, Univ. of Connecticut, K.-A. DUERLOO, Stanford Univ., A. SHARMA, K. JARVIS, Univ. of Texas at Austin, E. REED, Stanford Univ., A. DONGARE, Univ. of Connecticut, S.K. BANERJEE, Univ. of Texas at Austin, M. TERRONES, Penn State Univ., R. NAMBURU, M. DUBEY, U.S. Army Research Lab — In this report, we used CVD-grown terrace MoS<sub>2</sub> layers to study how the number and size of the layers affected the physical properties under uniaxial and biaxial tensile strain. Interestingly, we observed significant shifts in both the Raman in-plane mode (as high as  $-5.2$   $\text{cm}^{-1}$ ) and photoluminescence (PL) energy (as high as  $-88$  meV) for the few-layered MoS<sub>2</sub> under approximately 1.5% applied uniaxial tensile strain. The observed results were compared to monolayers and few-layers of MoS<sub>2</sub> previously reported. We also observed slippage between the layers which resulted in a hysteresis of the Raman and PL spectra during further applications of strain. Through DFT calculations, we contended that this random layer slippage was due to defects present in CVD-grown materials. This work demonstrates that the properties of CVD-grown few-layered MoS<sub>2</sub> studied here can be tuned under strain as well as, if not better than, it's exfoliated monolayered counterpart.

**10:36AM E17.00014 First-Principles Computation of Graphene's Phonon Anharmonicity**, MORDECHAI KORNBLUTH, CHRIS A. MARIANETTI, Columbia University, Department of Applied Physics and Applied Mathematics — Here we use density-functional theory to compute an interatomic potential for graphene, including anharmonicities up to at least fourth order. We generate all group-theoretically allowed terms within a hexagon via the recently-developed slave mode expansion. This expands the potential in terms of the normal modes of overlapping hexagons, while obeying the space group symmetry and homogeneity of free space. We further introduce the notion of cooperative modes, which combine strain and  $q = 0$  phonons to yield the same pure mode amplitude on each hexagon. Within the cooperative subspace, cooperative modes allow for arbitrarily-precise meshing to directly compute energies, or calculation of the anharmonic coefficients via finite-difference. We demonstrate the power of our approach in the context of strained graphene, which is known to have a novel strain-driven soft mode at the  $K$ -point. We identify the dominant anharmonic terms which drive the soft  $K$  mode, and study the role of finite temperatures using molecular dynamics and Monte-Carlo simulations.

**8:00AM E18.00001 Role of transparency of platinum-ferromagnet interface in determining intrinsic magnitude of spin Hall effect** , WEI HAN, International Center for Quantum Materials, Peking University — The spin Hall effect (SHE) converts charge current to pure spin currents in orthogonal directions in materials that have significant spin-orbit coupling. The efficiency of the conversion is described by the spin Hall Angle (SHA). The SHA can most readily be inferred by using the generated spin currents to excite or rotate the magnetization of ferromagnetic films or nano-elements via spin-transfer torques. Some of the largest spin torque derived spin Hall angles (ST-SHA) have been reported in platinum. In this talk, I will discuss that the transparency of the Pt-ferromagnet interface to the spin current plays a central role in determining the magnitude of the ST-SHA [1]. Using spin torque ferromagnetic resonance (ST-FMR) measurements, we measure a much larger ST-SHA in Pt/cobalt (0.11) compared to Pt/permalloy (0.05) bilayers when the interfaces are assumed to be completely transparent. Taking into account the transparency of these interfaces, as derived from spin-mixing conductances, we find that the intrinsic SHA in platinum has a much higher value of 0.19 0.04 as compared to the ST-SHA. The importance of the interface transparency is further exemplified by the insertion of atomically thin magnetic layers at the Pt/permalloy interface that we show strongly modulates the magnitude of the ST-SHA. Improving the interface transparency can make the SHE more effective for spintronic applications and is critical to understanding the fundamental origin of the SHE. [1] W. Zhang\*, Wei Han\*, Xin Jiang, See-Hun Yang and Stuart S. P. Parkin, Nature Physics, 11, 496–502 (2015).

**8:36AM E18.00002 Multi-directional Spin Transport at Interfaces with Spin-Orbit Coupling** , VIVEK AMIN, Center for Nanoscale Science and Technology, NIST / Maryland NanoCenter, Univ. of Maryland, MARK STILES, Center for Nanoscale Science and Technology, NIST — Spin transport remains poorly understood in multilayer systems with interfacial spin-orbit coupling. Currently, drift-diffusion models cannot accurately treat this phenomenon, since the important consequences of interfacial spin-orbit scattering remain uncharacterized in a systematic way. Here we present boundary conditions suitable for drift-diffusion models that capture the phenomenology of interfacial spin-orbit coupling. To access their viability we compare solutions of the drift-diffusion and Boltzmann equations in a Co/Pt bilayer, since the latter approach yields a momentum-dependent distribution function equipped to describe spin-orbit scattering. A key result is that in-plane electric fields create spin accumulations and spin currents polarized in all directions, which describes a generalization of the Rashba-Edelstein and spin Hall effects. In heavy metal/ferromagnet bilayers, this phenomenon provides a mechanism for the creation of damping-like and field-like torques; it also leads to possible reinterpretations of experiments in which interfacial torques are thought to be suppressed. We discuss the interpretation of experiments involving spin orbit torque, spin pumping/memory loss, the Rashba-Edelstein effect, and the spin Hall magnetoresistance.

**8:48AM E18.00003 Spin-Hall Non-Local Transport Mediated by a Magnetic Insulator<sup>1</sup>** , MASSOUD RAMEZANI MASIR, HUA CHEN, Department of physics, University of Texas at Austin, Texas 78712, USA, INTI SODEMANN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, ALLAN. H. MACDONALD, Department of physics, University of Texas at Austin, Texas 78712, USA — Magnetic systems with easy-plane order support dissipationless spin supercurrents that can lead to non-local coupling between electrically separated conductors. Recently the electrical properties of a system containing two magnetic multilayer stacks with perpendicular magnetic anisotropy electrodes and a shared easy-plane magnetic layer have been discussed. In this research we discuss a closely related system in which the two conducting channels that are coupled by the easy-plane magnetic layer are co-planar thin film metals with large spin Hall effects. We theoretically explained the non-local relationship between the current-voltage relationships of two thin film metallic conductors. Coupling occurs because both conductors inject spins into the magnetic insulator and because this information is communicated between conductors via exchange interactions within the magnetic system. We investigate the non-local transport properties of the system in the macrospin and long thin nanomagnet limits, deriving conditions for the critical currents and using solutions to the Landau-Lifshitz-Gilbert equation to characterize the dynamic steady state case.

**9:00AM E18.00004 Nonlocal anomalous Hall effect<sup>1</sup>** , SHULEI ZHANG, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri — Anomalous Hall effect (AHE) is a distinctive transport property of ferromagnetic metals arising from spin orbit coupling (SOC) in concert with spontaneous spin polarization. Nonetheless, recent experiments have shown that the effect also appears in a nonmagnetic metal in contact with a magnetic insulator. The main puzzle lies in the apparent absence of spin polarized electrons in the non-magnetic metal. Here, we theoretically demonstrate that the scattering of electrons from a rough metal-insulator interface is generally spin-dependent, which results in mutual conversion between spin and charge currents flowing in the plane of the layer. It is the current-carrying spin polarized electrons and the spin Hall effect in the bulk of the metal layer that conspire to generate the AH current. This novel AHE differs from the conventional one only in the spatial separation of the SOC and the magnetization, so we name it as nonlocal AHE. In contrast to other previously proposed mechanisms (e.g., spin Hall AHE and magnetic proximity effect (MPE)), the nonlocal AHE appears on the *first order* of spin Hall angle and does *not* rely on the induced moments in the metal layer, which make it experimentally detectable by contrasting the AH current directions of two layered structures such as Pt/Cu/YIG and  $\beta$ -Ta/Cu/YIG (with a thin inserted Cu layer to eliminate the MPE). We predict that the directions of the AH currents in these two trilayers would be *opposite* since the spin Hall angles of Pt and  $\beta$ -Ta are of opposite signs.

**9:12AM E18.00005 Spin Hall effects from mesoscopic ferromagnetic NiFe thin films** , CHUAN QIN, SHUHAN CHEN, YUNJIAO CAI, YI JI, University of Delaware — The spin Hall effect (SHE) and inverse spin Hall effect (ISHE) have been explored primarily in nonmagnetic heavy metals such as Pt. In this work, we probe SHE/ISHE from mesoscopic ferromagnetic NiFe (Py) films in nonlocal lateral structures. The structure consists of a Py spin injector/detector (F1), a Cu channel, and a second Py stripe (F2) where SHE/ISHE occurs. Low-resistance AlOx layers are placed at all interfaces. For SHE, a charge current passes through F2, and a nonlocal voltage is detected between F1 and Cu. For ISHE, a charge current is injected from F1 into Cu, and the nonlocal voltage is measured between two ends of F2. The in-plane magnetic field is applied perpendicular to F1/F2 stripes. For both measurements, the nonlocal signal for large positive field is different from that of large negative field owing to the SHE/ISHE. Using a simple model, the apparent spin Hall angle (assuming long Py spin diffusion length) of Py is estimated to be 0.010 at 295K and 0.017 at 4.5K.

**9:24AM E18.00006 Demonstration of Kirchhoff's First Law for Pure Spin Currents** , JOSEPH BATLEY, M. C. ROSAMOND, M. ALI, E. H. LINFIELD, G. BURNELL, B. J. HICKEY, University of Leeds — In conventional electronics a fundamental component of circuit design is the principle of fan-out, which allows multiple operations to be performed in order to build up complex logical procedures. A fan-out device relies on the condition that electrical currents obey Kirchhoff's laws and in order for spin-logic to be viable, the same must be shown for pure spin currents. Both fan-out and fan-in experiments have been performed to observe how spin currents behave in a multi-terminal circuit. The development of a 3-dimensional nonlocal IV and matrix fitting method provides information about each spin current, along with the thermal current generated at the injection point, and how they interact with each other. The fan-out geometry demonstrates that a pure spin current will divide between the different branches in a circuit, with a magnitude determined through the spin resistances of each arm. The fan-in measurements demonstrate that two pure spin currents will add and subtract with each other in a conventional manner expected from Kirchhoff's first law. These experiments have demonstrated the symmetry of pure spin currents with respect to the injection current and shown that they obey Kirchhoff's current law.

**9:36AM E18.00007 ABSTRACT WITHDRAWN —**

**9:48AM E18.00008 Anomalous Hall effect driven by dipolar spin waves in uniform ferromagnets**, KOJI SATO, AIMR, Tohoku University, KEI YAMAMOTO, Kobe University, EIJI SAITOH, AIMR, Tohoku University, HIROSHI KOHNO, Nagoya University — An anomalous Hall effect is shown to arise from the exchange interaction of conduction electrons with dipolar spin waves in ferromagnets. This effect exists even in homogeneous ferromagnets without relativistic spin-orbit coupling. The leading contribution to the Hall conductivity is proportional to the chiral spin correlation of dynamical spin textures and is physically understood in terms of the skew scattering by dipolar magnons.

**10:00AM E18.00009 Strong Spin Hall effect in PtMn**, YONGXI OU, SHENGJIE SHI, DANIEL RALPH, ROBERT BUHRMAN, Cornell Univ — Recent reports indicate that certain metallic antiferromagnets (AFM) can exhibit a significant spin Hall effect. Here we report a large damping-like spin torque efficiency ( $\xi_{DL}$ ) in PtMn/ferromagnet(FM) bilayer structures, determined from both FM-thickness-dependent spin-torque ferromagnetic resonance (ST-FMR), and harmonic response (HR) measurements of layers with perpendicular magnetic anisotropy (PMA). We find that  $\xi_{DL}$  can vary from  $<0.1$  to  $>0.15$ , depending on the thickness of PtMn, the stacking order of the samples, and the choice of the FM material. The field-like spin torque efficiency ( $\xi_{FL}$ ) is also quite variable,  $0 < |\xi_{FL}| < 0.5$ . The large broadening of the ST-FMR linewidth suggests extra spin attenuation at the AFM/FM interface that is possibly due to intermixing. The PtMn/FeCoB/MgO structures that exhibit PMA have a comparatively low switching current density and an unusual asymmetric switching phase diagram. These results indicate that AFM PtMn has significant potential both for advancing the understanding the physics of the spin Hall effect in Pt alloys, and for enabling new spintronics functionality.

**10:12AM E18.00010 Large anomalous Hall effect in Pt interfaced with perpendicular anisotropy ferrimagnetic insulator<sup>1</sup>**, CHI TANG, PATHIKUMAR SELLAPPAN, YAWEN LIU, JAVIER GARAY, JING SHI, University of California-Riverside, SHINES TEAM — We demonstrate the strain induced perpendicular magnetic anisotropy (PMA) in a ferrimagnetic insulator (FMI),  $Tm_3Fe_5O_{12}$  (TIG) and the first observation of large anomalous Hall effect (AHE) in TIG/Pt bilayers. Atomically flat TIG films were deposited by a laser molecular beam epitaxy system on (111)-orientated substituted gadolinium gallium garnet substrates. The strength of PMA could be effectively tuned by controlling the oxygen pressure during deposition. Sharp squared anomalous Hall hysteresis loops were observed in bilayers of TIG/Pt over a range of thicknesses of Pt, with the maximum AHE conductivity reaching 1 S/cm at room temperature. The AHE vanishes when a 5 nm Cu layer was inserted between Pt and TIG, strongly indicating the proximity-induced ferromagnetism in Pt. The large AHE in the bilayer structures demonstrates a potential use of PMA-FMI related heterostructures in spintronics.

**10:24AM E18.00011 Direct measurement of spin accumulation in the Cu layer due to spin currents from Co**, ROOPALI KUKREJA, UC San Diego — Spin transport is the key for reading or writing bits in spintronic devices by utilizing the Giant Magnetoresistance effect or the spin transfer torque effect. Spin currents have also been shown to play important role in the ultrafast manipulation of magnetization via all optical switching. Hence, detailed understanding of spin currents from ferromagnet to non-magnets is a crucial step in development of spintronic devices. However, directly observing these spin currents is extremely challenging due to magnetic moment injected into non-magnet being very small, less than 1/10000 of a regular ferromagnet. In this talk, I will present our recent measurements on the spin currents from a thin film Co ferromagnet into non-magnetic Cu metal in a nanopillar device. We have developed an extremely sensitive spectro-microscopy detection method based on element specific x-ray magnetic circular dichroism where current pulses driving the spin currents into the Cu layer are synchronized with the synchrotron x-ray photons. The sensitivity of this 'lock-in' technique has allowed us to detect the extremely small transient Cu magnetization. We observe two spin currents induced effects in the Cu layer. The first effect is the transiently induced magnetization which occurs in bulk of the Cu layer due to spin accumulation and has a magnitude of 0.00003  $\mu B$  per atom. The second effect occurs at the Co/Cu interface where we observe a 10% increase or 0.004  $\mu B$  per atom for the hybridized Cu atoms due to spin torque-alignment.

**Session E19 GMAG DMP: Magnetic Oxide Thin Films and Heterostructures: Novel Interfacial Phenomena** 318 - Ho Nyung Lee, Oak Ridge National Laboratory

**8:00AM E19.00001 Controlled lateral anisotropy in correlated manganite heterostructures by interface-engineered oxygen octahedral coupling**, MARK HUIJIBEN<sup>1</sup>, MESA+ Institute for Nanotechnology, University of Twente — Ultimate miniaturization of magnetic random access memory (MRAM) devices is expected by the utilization of spin-transfer torques, because they present an efficient means to switch elements with a very high magnetic anisotropy. To overcome the low switching speed in current collinearly magnetized devices, new routes are being explored to realize magnetic tunnel junction stacks with non-collinear magnetization between two magnetic electrodes. Controlled in-plane rotation of the magnetic easy axis in manganite heterostructures by tailoring the interface oxygen network would provide a promising direction for non-collinear magnetization in correlated oxide magnetic tunneling junctions. Here, we demonstrate how to manipulate magnetic and electronic anisotropic properties in manganite heterostructures by engineering the oxygen network on the unit-cell level. The strong oxygen octahedral coupling is found to transfer the octahedral rotation, present in the NdGaO<sub>3</sub> (NGO) substrate, to the La<sub>2</sub>/3Sr<sub>1</sub>/3MnO<sub>3</sub> (LSMO) film in the interface region. This causes an unexpected realignment of the magnetic easy axis along the short axis of the LSMO unit cell as well as the presence of a giant anisotropic transport in these ultrathin LSMO films. As a result we possess control of the lateral magnetic and electronic anisotropies by atomic scale design of the oxygen octahedral rotation.

**8:36AM E19.00002 Interfacial Control of Magnetic Properties at LaMnO<sub>3</sub>/LaNiO<sub>3</sub> Interfaces**, MARTA GIBERT, University of Geneva, MICHEL VIRET, CEA Saclay, ALMUDENA TORRES-PARDO, University of Paris-Sud, Complutense University of Madrid, CINTHIA PIAMONTEZE, SLS-PSI, PAVLO ZUBKO, University of Geneva, University College London, NICOLAS JAOUEN, Synchrotron SOLEIL, JEAN-MARC TONNERRE, CNRS Institut Neel, ALEXANDRA MOUGIN, University of Paris-Sud, JENNIFER FOWLIE, SARA CATALANO, University of Geneva, ALEXANDRE GLOTER, ODILE STPHAN, University of Paris-Sud, JEAN-MARC TRISCONI, University of Geneva — The functional properties of oxide heterostructures ultimately rely on how the electronic and structural mismatches occurring at interfaces are accommodated by the chosen materials combination. We discuss here LaMnO<sub>3</sub>/LaNiO<sub>3</sub> heterostructures, which display an intrinsic interface structural asymmetry depending on the growth sequence with the LaMnO<sub>3</sub>-on-LaNiO<sub>3</sub> interface being sharper than the LaNiO<sub>3</sub>-on-LaMnO<sub>3</sub> one, which exhibits 2-3 unit cells intermixing [1]. Using a variety of synchrotron-based techniques, we show that the degree of intermixing at the monolayer scale allows interface-driven properties such as charge transfer and the induced magnetic moment in the nickelate layer to be controlled. Further, our results demonstrate that the magnetic state of strained LaMnO<sub>3</sub> thin films dramatically depends on interface reconstructions. [1] Gibert *et al.*, NanoLetters in press.

**8:48AM E19.00003 Understanding the Origin of Ferromagnetism in  $\text{LaNiO}_3/\text{CaMnO}_3$  Superlattices**, CHARLES FLINT, Stanford University, ALPHA N'DIAYE, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, YURI SUZUKI, Stanford University — Interfacial ferromagnetism (FM) in transition metal oxide heterostructures is a promising route for engineering new low-dimensional devices. In 2001, FM was discovered in  $\text{CaRuO}_3/\text{CaMnO}_3$  superlattices (SLs), which is attributed to an itinerant electron-mediated Mn-Mn double-exchange (DE). Since then we have discovered interfacial FM in  $(\text{LaNiO}_3)_N/(\text{CaMnO}_3)_8$  SLs that is consistent with this DE interaction<sup>1</sup>. Now we have explored even further reduced dimensionality by fabricating  $[(\text{LNO})_{n=2-7}/(\text{CMO})_4]_{10}$  SLs. Transport measurements confirmed a thickness dependent metal-insulator transition, with insulating films for  $N < 4$ . Bulk magnetometry measurements reveal interfacial FM in insulating and conducting SLs. Since there are no itinerant electrons in the insulating SLs, this FM must arise from a different source. Using x-ray absorption spectroscopy and magnetic circular dichroism, we have identified the coexistence of  $\text{Ni}^{2+}$  and  $\text{Ni}^{3+}$  and Ni magnetism. We therefore speculate that the FM in insulating SLs originates from a Mn-Ni superexchange interaction. We discuss the role of these interactions in interfacial FM and methods for controlling them.

**9:00AM E19.00004 Exploring interfacial ferromagnetism in manganite-based superlattices**, DI YI, CHARLES FLINT, YURI SUZUKI, Department of Applied Physics, Stanford University — Heterointerface of complex oxides provides a rich playground to explore the emergent phenomena that are not found in bulk. In particular, emergent interfacial ferromagnetism has been successfully demonstrated in heterostructures composed of materials which are paramagnetic and antiferromagnetic in bulk. In our previous work, leakage of itinerant electrons from a paramagnetic metal to an antiferromagnetic insulator has been shown to give rise to interfacial ferromagnetism in  $\text{CaMnO}_3$ -based superlattices. However interfacial ferromagnetism in insulating superlattices suggests a more complicated scenario. Therefore a thorough investigation of coupling between charge, lattice and spin degrees of freedom is necessary. In this talk, we focus on the  $\text{NdNiO}_3/\text{CaMnO}_3$  system. By choosing a paramagnetic layer that undergoes a metal-insulator transition, we can explore the role of electron itinerancy in interfacial ferromagnetism in the same sample to eliminate the inconsistencies that may originate from the deposition of multiple samples. We demonstrate that  $\text{NdNiO}_3$  exhibits a metal-insulator transition as a function of temperature, which can be tuned as a function of film thickness. We have also grown  $\text{NdNiO}_3/\text{CaMnO}_3$  heterostructures with excellent crystallinity. Preliminary transport measurements indicate that the presence of an adjacent  $\text{CaMnO}_3$  layer also affects the transport in  $\text{NdNiO}_3$  so that charge transfer from the itinerant layer into the adjacent antiferromagnetic insulating  $\text{CaMnO}_3$  is likely not the only contribution to interfacial ferromagnetism.

**9:12AM E19.00005 Magnetotransport in  $\text{LaNiO}_3/\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  superlattices with non-collinear magnetic ordering**, JASON HOFFMAN, University of British Columbia, STEPHEN WU, Argonne National Laboratory, BRIAN KIRBY, National Institute of Standards and Technology, ANAND BHATTACHARYA, Argonne National Laboratory — Non-collinear magnetic textures can give rise to exotic charge and spin transport behaviors, and may allow for the control of magnetism using small electric currents. While these textures have been observed in a number of bulk materials and in thin films, realizing non-collinear magnetism in heterostructures presents new avenues to tune their properties using tailored interfaces and gate electric fields. We have previously used polarized neutron reflectometry (PNR) to demonstrate that superlattices of paramagnetic  $\text{LaNiO}_3$  (LNO) and ferromagnetic  $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$  (LSMO) adopt a non-collinear magnetic structure. In this work, we characterize the non-collinearity as a function of temperature and magnetic field using anisotropic magnetoresistance (AMR) and Nernst effect measurements. We observe rotational hysteresis at low fields, while the magnitude of the AMR is found to vary non-monotonically with applied field. To understand this behavior, we develop a simple free-energy model that includes contributions from biaxial anisotropy, Zeeman energy, and exchange coupling between the LSMO and the LNO layers. From this analysis, we are able to extract the orientation of the magnetization of the individual LSMO layers, which agrees well with the values measured using PNR.

**9:24AM E19.00006 Influence of quantum confinement and strain on orbital polarization of strained four-layer  $\text{LaNiO}_3$  superlattices: a DFT+DMFT study**<sup>1</sup>, HYOWON PARK, University of Illinois at Chicago, ANDREW MILLIS, CHRIS MARIANETTI, Columbia University — Here we use the combination of density functional theory and dynamical mean field theory to study Ni d orbital polarization in strained  $\text{LaNiO}_3/\text{LaAlO}_3$  superlattices consisting of four layers of nominally metallic  $\text{NiO}_2$  and four layers of insulating  $\text{AlO}_2$  separated by  $\text{LaO}$  layers. The layer-resolved orbital polarization is calculated as a function of strain and analysed in terms of structural, quantum confinement, and correlation effects. The overall dependence of orbital polarization on strain in superlattices is qualitatively consistent with recent X-ray absorption spectroscopy and resonant reflectometry data. However, interesting differences of detail are found depending on the sign of strain. Under tensile strain, the two inequivalent Ni ions display orbital polarization similar to that calculated for strained bulk  $\text{LaNiO}_3$  and observed in experiment. Compressive strain produces a larger dependence of orbital polarization on Ni position and even the inner Ni layer exhibits orbital polarization different from that calculated for strained bulk  $\text{LaNiO}_3$ . The quantum confinement effect is as important as the strain effect and more stronger for tensile strain.

<sup>1</sup>This work is supported by DOE ER-046169 and FAME, one of six centers of STARnet, a Semiconductor Research Corporation program sponsored by MARCO and DARPA.

**9:36AM E19.00007 Interfacial Symmetry Control of Emergent Ferromagnetism**, ALEXANDER GRUTTER, JULIE BORCHERS, BRIAN KIRBY, Natl Inst of Stds and Tech, CHUNYONG HE, University of California, Berkeley, ELKE ARENHOLZ, Lawrence Berkeley National Lab, ARTURAS VAILIONIS, CHARLES FLINT, YURI SUZUKI, Stanford University — Atomically precise complex oxide heterostructures provide model systems for the discovery of new emergent phenomena since their magnetism, structure and electronic properties are strongly coupled. Octahedral tilts and rotations have been shown to alter the magnetic properties of complex oxide heterostructures, but typically induce small, gradual magnetic changes. Here, we demonstrate sharp switching between ferromagnetic and antiferromagnetic order at the emergent ferromagnetic interfaces of  $\text{CaRuO}_3/\text{CaMnO}_3$  superlattices. Through synchrotron X-ray diffraction and neutron reflectometry, we show that octahedral distortions in superlattices with an odd number of  $\text{CaMnO}_3$  unit cells in each layer are symmetry mismatched across the interface. In this case, the rotation symmetry switches across the interface, reducing orbital overlap, suppressing charge transfer from Ru to Mn, and disrupting the interfacial double exchange. This disruption switches half of the interfaces from ferromagnetic to antiferromagnetic and lowers the saturation magnetic of the superlattice from 1.0 to 0.5  $\mu_B$ /interfacial Mn. By targeting a purely interfacial emergent magnetic system, we achieve drastic alterations to the magnetic ground state with extremely small changes in layer thickness.

**9:48AM E19.00008 4d electron Ruthenate systems: their unique and new magnetic properties**, SEUNGRAN LEE, YEONGJAE SHIN, CCES-IBS, Seoul 151-747, Republic of Korea, M.S. ANWAR, YUSUKE SUGIMOTO, Dept. of Physics, Graduate School of Science, Kyoto Uni., Kyoto 606-8502, MINCHEOL LEE, SUNGJIN KANG, CCES-IBS, Seoul 151-747, Republic of Korea, SHINGO YONEZAWA, YOSHITERU MAENO, Dept. of Physics, Graduate School of Science, Kyoto Uni., Kyoto 606-8502, TAEWON NOH, CCES-IBS, Seoul 151-747, Republic of Korea — The Ruddlesden-Popper series (PR) of  $\text{Sr}_{n+1}\text{Ru}_n\text{O}_{3n+1}$  has attract much interest of their unique physical properties. Among them,  $\text{SrRuO}_3$  ( $n = \infty$ ) (SRO) is the only ferromagnetic metallic oxide especially in Ru 4d transition metal oxides. Bulk SRO has orthorhombic structure showing the Curie temperature ( $T_C$ )  $\sim 160$  K. It is well known that  $\text{RuO}_6$  octahedral distortion plays critical roles in its magnetic properties. In film systems, such  $\text{RuO}_6$  octahedra can be easily controlled by strain-engineering. In this talk, with high quality SRO films fully strained (-1.7%-1%) using various substrates, we systematically studied their structural changes and associated magnetic properties. Compared to theoretical predictions, the structural changes can be explained, while the magnetic property changes cannot be understood. Surprisingly, when SRO113 is grown on its PR series of  $\text{Sr}_2\text{RuO}_4$  ( $n=1$ ) (SRO214) single crystal, the exact substrate of SRO214 magnetization results in strongly enhanced magnetization ( $M \propto 3 \mu_B/\text{Ru}$ ,  $T_C \sim 160$  K), which has never found SRO113 (001) since the low-spin configuration of SRO113 prevent M never exceed  $2 \mu_B/\text{Ru}$ . The mystery of M in SRO113 (especially SRO113/SRO214) will be further discussed.

**10:00AM E19.00009 Chemical Ordering Modulated Electronic Phase Separation and Macroscopic Properties in Colossal Magnetoresistance Manganites**, YINYAN ZHU, KAI DU, LIFENG YIN, JIAN SHEN, Fudan University, LOW-DIMENSIONAL MATERIAL PHYSICS TEAM — Using unit cell by unit cell superlattice growth technique, we determine the role of chemical ordering of the Pr dopant in a colossal magnetoresistance  $(\text{La}_{1-y}\text{Pr}_y)_{1-x}\text{Ca}_x\text{MnO}_3$  (LPCMO) system, which has been well known for its large length scale electronic phase separation (EPS) phenomena. Our experimental results show that the chemical ordering of Pr leads to dramatic reduction of the length scale of EPS. Moreover, compared to the conventional Pr-disordered LPCMO system, the Pr-ordered LPCMO system has ~100 K higher metal-insulator transition temperature. We have further investigated the n-dependence of the physical properties of the  $(\text{LCMO})_{2n}/(\text{PCMO})_n$  superlattices. Magnetic and transport measurements indicate that the physical properties change nonmonotonically with increasing n, reaching a minimum for both the Curie temperature and the meta-insulator transition temperature. The crossover thickness thus reflects the characteristic correlation length scale along the vertical direction of the superlattice. For superlattices with n smaller than the correlation length, we combine MFM studies and model calculations to explain the weakened ferromagnetism and metallicity with increasing n.

**10:12AM E19.00010 Polarized Neutron Reflectometry Study of Tunable Metal-insulator Superlattices<sup>1</sup>**, QIANG WANG, YAOHUA LIU, SUZANNE TE VELTHUIS, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, MICHAEL FITZSIMMONS, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge TN 37831, USA, DAISUKE OKUYAMA, Institute of Multidisciplinary Research for Advanced Materials (IMRAM), Tohoku University, Sendai 980-8577, Japan, MASAO NAKAMURA, MASASHI KAWASAKI, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science (CEMS), Wako, 351-0198, Japan — Superlattices composed of equal thickness of ferromagnetic (FM) metal  $\text{La}_{0.5}\text{Sr}_{0.5}\text{MnO}_3$  (LSMO) and charge-orbital ordered (COO) insulator  $\text{Pr}_{0.5}\text{Ca}_{0.5}\text{MnO}_3$  (PCMO) on (011)-oriented  $(\text{LaAlO}_3)_{0.3}(\text{Sr}_2\text{AlTaO}_6)_{0.7}$  substrate have been investigated using polarized neutron reflectometry. In a 200-Oe magnetic field, the magnetization depth profile shows strong temperature dependence. Between the FM transition temperature of LSMO and the COO transition temperature of PCMO, a uniform magnetization throughout the superlattices was obtained. Below the COO transition temperature of PCMO, the magnetization depth profile shows a strong contrast between the LSMO and PCMO regions. At 5000 Oe, both LSMO and PCMO show magnetizations close to their bulk saturation value at low temperature. Our result demonstrates the tunability of the PCMO/LSMO superlattices' magnetic structure with field and temperature and the behavior of this system could be explained as the result of coexistence of the FM and COO phases and their competition.

**10:24AM E19.00011 Superparamagnetism at oxide interfaces revealed by scanning SQUID-on-tip microscopy**, YONATHAN ANAHORY, L. EMBON, Weizmann Institute of Science, C.J. LI, National University of Singapore, S. BANERJEE, A. MELTZER, H. R. NAREN, A. YAKOVENKO, J. CUPPENS, Y. MYASOEDOV, M. L. RAPPAPORT, Weizmann Institute of Science, M. E. HUBER, University of Colorado Denver, K. MICHAELI, Weizmann Institute of Science, T. VENKATESAN, A. ARIANDO, National University of Singapore, E. ZELDOV, Weizmann Institute of Science — Our novel scanning SQUID-on-tip technique[1] is used to study nanoscale magnetism present in systems such as atomically sharp oxide heterostructures. Here we report a new emergent phenomenon at the  $\text{LaMnO}_3/\text{SrTiO}_3$  interface in which an antiferromagnetic insulator abruptly transforms into a magnetic state that exhibits unexpected nanoscale superparamagnetic dynamics. Upon increasing the thickness of  $\text{LaMnO}_3$  above five unit cells, our scanning nanoSQUID-on-tip microscopy shows spontaneous formation of isolated magnetic islands of 10 to 50 nm diameter, which display random moment reversals by thermal activation or in response to an in-plane magnetic field[2]. Our charge reconstruction model of the polar  $\text{LaMnO}_3/\text{SrTiO}_3$  heterostructure describes the sharp emergence of thermodynamic phase separation leading to nucleation of metallic ferromagnetic islands in an insulating antiferromagnetic matrix. The model further suggests that the nearby superparamagnetic-ferromagnetic transition can be gate tuned, holding potential for applications in magnetic storage and spintronics. [1] D. Vasyukov *et al*, Nature Nanotech. 8, 639 (2013) [2] Y. Anahory *et al*, arXiv:1509.01895

**10:36AM E19.00012 Giant structural modulation & abnormal ferromagnetism in ferroelectric & ultrathin ferromagnetic digital superlattices<sup>1</sup>**, HANGWEN GUO, ZHEN WANG, MOHAMMAD SAGHAYEZHIAN, LINA CHEN, RONGYING JIN, WARD PLUMMER, JIANDI ZHANG, Louisiana State University, SHUAI DONG, Southeast University, China — The nature of magnetoelectric coupling in oxide heterostructure remains interesting but illusive, largely because the complex nature of interface intermixing and diffusion. In this work, we present our ability to fabricate superlattices consist of ferroelectric BTO & ferromagnetic LSMO, with minimum interfacial intermixing confined within half a unit cell. Such high quality superlattices with sharp interfaces allow us to explore magnetoelectric coupling effect into ultrathin region (reduced dimensionality) and observe ferroelectric induced abnormal magnetic behavior. A detailed STEM study reveals that the traditional electron/hole carrier doping scenario does not play a major role. Instead, distinct modulation of lattice displacement and octahedron tilting is responsible for the coupling effect and abnormal magnetic behavior. Our study highlights the importance of structural-property relationship in oxide heterostructures.

**8:00AM E20.00001 Dynamics of the matrix in DMS Type-II quantum dot systems<sup>1</sup>**, COLLIN R. BROWN, VINCE R. WHITESIDE, IAN R. SELLERS, Department of Physics & Astronomy, University of Oklahoma, Norman, Oklahoma 73019, USA, ATHOS PETROU, Department of Physics, University at Buffalo SUNY, Buffalo, New York 14260, USA, W-C. CHOU, Department of Electro-physics, National Chiao Tung University, Hsinchu 300, Taiwan — Magnetic field, temperature, and polarization dependent continuous wave photoluminescence spectroscopy (PL) is used to study two related Type-II quantum dots (QDs). These techniques were used to study how the location of magnetic impurities affects the formation of magnetic polarons in these two (related) systems. The  $\text{ZnMnTe}/\text{ZnSe}$  system has Mn impurities located within the QDs, with (ideally) no Mn in the surrounding ZnSe matrix. The  $\text{ZnTe}/\text{ZnMnSe}$  QDs have Mn impurities grown within the matrix, which ideally is excluded from the QDs. For both these systems, the holes are confined within the dots, while the electrons are located in the surrounding matrix. The location of the Mn and its coupling with the spin of the corresponding carrier leads to distinct characteristics for each system. Due to difficulties growing these systems, some diffusion of Mn during the growth of these samples is suspected, leading to a percentage of magnetic impurities unintentionally located in the non-magnetic region for both samples. The emission from the matrix in particular was studied to determine the effect/composition of Mn in this region and its contribution to the characteristics of the QDs.

**8:12AM E20.00002 Mn<sup>2+</sup>-Doped CdSe/CdS Core/Multishell Colloidal Quantum Wells Enabling Tunable Carrier-Dopant Exchange Interactions<sup>1</sup>**, SAVAS DELIKANLI, Bilkent University, THOMAS SCRACE, JOSEPH MURPHY, BIBLOP BARMAN, YUTSUNG TSAI, PEIYAO ZHANG, State University of New York, University at Buffalo, PEDRO LUDWIG HERNANDEZ-MARTINEZ, Nanyang Technological University, JOSEPH CHRISTODOULIDES, Naval Research Laboratory, ALEXANDER N. CARTWRIGHT, ATHOS PETROU, State University of New York, University at Buffalo, HILMI VOLKAN DEMIR, Nanyang Technological University — We report the manifestations of carrier-dopant exchange interactions in colloidal Mn<sup>2+</sup>-doped CdSe/CdS core/multishell quantum wells. In our solution-processed quantum well heterostructures, Mn<sup>2+</sup> was incorporated by growing a Cd<sub>0.985</sub>Mn<sub>0.015</sub>S monolayer shell on undoped CdSe nanoplatelets using the colloidal atomic layer deposition technique. The carrier-magnetic ion exchange interaction effects are tunable through wave function engineering. This is realized by controlling the spatial overlap between the carrier wave functions with the manganese ions through adjusting the location, composition, and number of the CdSe, Cd<sub>1-x</sub>Mn<sub>x</sub>S, and CdS layers. Our colloidal quantum wells, which exhibit magneto-optical properties analogous to those of epitaxially grown quantum wells, offer new opportunities for solution-processed spin-based semiconductor devices.

**8:24AM E20.00003 Time resolved photoluminescence study of CdSe/CdMnS/CdS core/shell/shell nanoplatelets heterostructures<sup>1</sup>**, THOMAS SCRACE, State Univ of NY - Buffalo, SAVAS DELIKANLI, MEHMET ZAFER AKGUL, Bilkent University, JOSEPH MURPHY, TIM THOMAY, PEIYAO ZHANG, TENZIN NORDEN, ALEXANDER CARTWRIGHT, ATHOS PETROU, State Univ of NY - Buffalo, HILMI VOLKAN DEMIR, Bilkent University — We have recorded the time evolution of the photoluminescence (PL) for CdSe/CdMnS/CdS core/shell/shell solution-processed nanoplatelets (NP) using ultrafast pulses at 400 nm and 514 nm. Our NPs consist of a core with 5 monolayers (1.5 nm) of CdSe and average lateral dimensions of 55 × 10 nm<sup>2</sup>. Using 400 nm pulses we excite electron-hole pairs above the CdS shell bandgap; with 514 nm pulses we excite only in the CdSe core. The holes are primarily localized in the CdSe core, while the electrons are delocalized. Our measurements show that at  $\Delta t = 0$ , the peak PL energy for both kind of excitations is the same. As a function of time, both types of excitations result in a red-shift. The red shift of with 400 nm excitation is 60 meV and is described by two time scales:  $\tau_1 = 270$  ps and  $\tau_2 = 2.5$  ns. The red shift with the 514 nm excitation is 30 meV and is described by a single time scale:  $\tau_2 = 2.5$  ns. These results are discussed in terms of dipole layer formation[1]. [1] Gu, Y et. al. Phys. Rev. B 71 045340 (2005).

**8:36AM E20.00004 Spin-orbit twisted spin-flip waves in CdMnTe quantum wells<sup>1</sup>**, SHAHRZAD KARIMI, University of Missouri, FLORENT PEREZ, Institut des Nanosciences de Paris, CNRS/Universite Paris VI, FLORENT BABOUX, Laboratoire de Photonique et de Nanostructures, LPN/CNRS, IRENE D'AMICO, University of York, GIOVANNI VIGNALE, CARSTEN ULLRICH, University of Missouri — We present a numerical study of spin-flip wave dispersions in a spin-polarized electron gas in a dilute magnetic semiconductor heterostructure, using time-dependent density-functional response theory. The system under study is an n-doped CdMnTe quantum well with an in-plane magnetic field. Rashba and Dresselhaus spin-orbit coupling induces a wavevector-dependent spin splitting in the conduction bands. The spin waves hence travel through a spin-orbit twisted medium. We calculate the spin-wave dispersion to second order in spin-orbit coupling, including impurity scattering effects. Our results are compared with recent inelastic light scattering experiments.

**8:48AM E20.00005 Magnetic properties of nano-patterned GaMnAs films grown on ZnCdSe buffer layers<sup>1</sup>**, SINING DONG, XIANG LI, VASILY KANZYUBA, TAEHEE YOO, XINYU LIU, MALGORZATA DOBROWOLSKA, JACEK FURDYNA, Physics Department, University of Notre Dame — Magnetic semiconductor nanostructures are attracting intense attention, both because of their fundamental physical properties, and because of the promise which they hold for building smaller, faster and more energy-efficient devices. In this study we report successful MBE growth of GaMnAs films on the GaAs (100) substrates with ZnCdSe buffer layers, which results in perpendicular magnetic easy axis in the GaMnAs films. The GaMnAs/ZnCdSe films have been etched into nano-stripe shapes with various widths below 200nm by e-beam lithography, which resulted in a new geometry of interest for perpendicular magnetic recording. Magnetic anisotropy of as-grown GaMnAs films and nano-stripes was then studied by SQUID magnetometry. The results indicate that the GaMnAs films consist of magnetic domains with magnetization normal to the film plane, having rather high coercivity, which survives after nanofabrication. This is also confirmed by the dynamics of the domain motion as shown by AC susceptibility measurements. These findings are of interest for understanding the magnetic anisotropy mechanisms in GaMnAs and its domain structures, as well as for designing of nano-sized spintronic devices which require hard ferromagnetic behavior with perpendicular easy axes.

**9:00AM E20.00006 Gate tunable spin exchange interaction and inversion of magnetoresistance in ferromagnetic ZnO nanowire**, VIJAYAKUMAR MODEPALLI, MI-JIN JIN, JUNGMIN PARK, JUNHYEON JO, JI-HYUN KIM, JEONG MIN BAIK, Ulsan national institute of science and technology, JEONGYONG KIM, Sungkyunkwan University, JUNG-WOO YOO, Ulsan national institute of science and technology — Tuning magnetism in diluted magnetic semiconductor (DMS) is one of the central issue to the development of future spintronic device applications. Particularly, realizing such control in nanostructure has received growing attention. Here, we report the dramatic change of MR in ferromagnetic ZnO nanowire with varied gate voltages (+50 V to -40 V) at different temperatures (2 K to 50 K). The MR signal was greatly influenced by the gate voltage induced carrier concentrations which results the inversion of MR from positive to negative sign while pertaining the coexistence of both parts before inversion in the range of -2T to 2T. The origin of negative MR is mainly due to spin scattering while the positive one is due to a field induced change in relative populations of conduction bands with different conductivities. The extracted spin exchange related parameter was well tuned with the varied gate voltages at different temperatures. More importantly this type of gate tuning of spin exchange interactions in ferromagnetic single ZnO nanowire is well suitable for future spintronic device applications.

**9:12AM E20.00007 The State of the Art in (Cd,Mn)Te Heterostructures: Fundamentals and Applications**<sup>1</sup>, TOMASZ WOJCIOWICZ, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland — In my talk I will review recent progress in the MBE technology of (Cd,Mn)Te nanostructures containing two dimensional electron gas (2DEG) that led to the first ever observation of fractional quantum Hall effect in magnetic system [1]. This opens new directions in spintronics. I will first discuss already demonstrated applications of such high mobility magnetic-2DEG system for: a) THz and microwave radiation induced zero-bias generation of pure spin currents and very efficient magnetic field induced conversion of them into spin polarized electric current [2]; b) clear demonstration of THz radiation from spin-waves excited via efficient Raman generation process [3]; c) experimental demonstration of working principles of a new type of spin transistor based on controlling the spin transmission via tunable Landau-Zener transitions in spatially modulated spin-split bands [4]. I will also explain the possibility to use magnetic-2DEG for developing of a new system where non-Abelian excitations can not only be created, but also manipulated in a two-dimensional plane. The system is based on high mobility CdTe quantum wells with engineered placement of Mn atoms, where sign of the Lande g-factor can be locally controlled by electrostatic gates at high magnetic fields. Such a system may allow for building a new platform for topologically protected quantum information processing. I will also present results demonstrating electrostatic control of 2D gas polarization in a quantum Hall regime [5].

**9:48AM E20.00008 Structural and Optical properties of Er doped ZnO diluted magnetic semiconductor nano thin films produced by sol gel method.**<sup>1</sup>, A. TOLGA TASCI, OZGUR OZTURK, ELIF ASIKUZUN, KASTAMONU UNIVERSITY, LUTFI ARDA, Bahcesehir University, SUKRU CELIK, Sinop University, CABIR TERZIOGLU, Abant Izzet Baysal University — Undoped and Er doped ZnO ( $Zn_{1-x}Er_xO$ ) transparent semiconductor thin films were coated using sol-gel method on non-alkali glass. Erbium was doped 1%, 2%, 3%, 4% and 5% ratio. Methanol and monoethanolamine were used as solvent and stabilizer. In this study, the effect of Er doping was examined on the structural and optical properties of ZnO DMS thin films. XRD, SEM and UV-VIS-NIR spectrometer measurements were performed for the structural and optical characterization. XRD results showed that, all of Er doped ZnO thin films have a hexagonal structure. The optical transmittance of rare earth element (Er) doped ZnO thin films were increased. The Er doped ZnO thin films showed high transparency ( $>84$ ) in the visible region (400-700 nm).

<sup>1</sup>This research has been supported by the Kastamonu University Scientific Research Projects Coordination Department under the Grant No. KUBAP-03/2013-41 and the Scientific and Technological Research Council of Turkey (TUBITAK) Project No. 114F259.

**10:00AM E20.00009 Microstructural and Optical properties of transition metal (Cu) doped ZnO diluted magnetic semiconductor nano thin films fabricated by sol gel method.**<sup>1</sup>, OZGUR OZTURK, ELIF ASIKUZUN, A. TOLGA TASCI, Kastamonu University, LUTFI ARDA, Bahcesehir University, SEVIM DEMIROZU SENOL, Abant Izzet Baysal University, SUKRU CELIK, Sinop University, CABIR TERZIOGLU, Abant Izzet Baysal University — Undoped and Cu (Copper) doped ZnO ( $Zn_{1-x}Cu_xO$ ) semiconductor thin films were produced by using sol-gel method. Cu was doped 1%, 2%, 3%, 4% and 5% ratio. Methanol and monoethanolamine (MEA) were used as solvent and stabilizer. In this study, the effect of Cu doping was investigated on microstructural and optical properties of ZnO DMS thin films. XRD, SEM, AFM and UV-VIS spectrometer measurements were performed for the microstructural and optical characterization. XRD, SEM and AFM results were showed that all of Cu doped ZnO based thin films have a hexagonal structure. The grain size of Cu doped ZnO thin films and morphology of surface were changed with increasing Cu doping. The optical transmittance of transition metal (Cu) doped ZnO thin films were decreased with doping. **Keywords:** Diluted Magnetic Semiconductor (DMS), Thin Film, Cu-doping, Bandgap Energy, ZnO.

<sup>1</sup>This research has been supported by the Kastamonu University Scientific Research Projects Coordination Department under the Grant No. KU-BAP-05/2015-12 and the Scientific and Technological Research Council of Turkey (TUBITAK) Project No. 114F259.

**10:12AM E20.00010 Oxygen vacancies induced Spin polarized current in Co-doped ZnO by Andreev reflection technique**, KUNG-SHANG YANG, HSIUNG CHOU, WEN LING CHAN, BO-YU CHEN, Department of Physics, NSYSU, Kaohsiung 804, Taiwan, SHANG-FAN LEE COLLABORATION<sup>1</sup> — Dilute magnetic semiconductor (DMO) is a semiconducting system with spin-polarized carriers and magnetic properties. However, since most studies had been focused on existence of FM, the proportion of spin-polarized current (SPC) in DMO is far from being determined. We used Point-contact Andreev reflection measurements on various  $Zn_{0.95}Co_{0.05}O$  thin films, with controlled oxygen vacancies by sputtering in various  $H_2$  partial pressure with Ar atmosphere. We found that conductance versus voltage (G-V) spectra suppresses as oxygen vacancy concentration increases. It indicates oxygen vacancies play significant role in inducing the SPC. To understand the origin of spin polarized current at the interface of the superconducting tip/CZO system, we use modified Blonder-Tinkham-Klapwijk (MBTK) model in ballistic and diffusive regime to interpret GV curve. The extracted SPC value were up to 70% in ballistic regime and 65% in diffusive regime. The results suggest tiny routes have been formed by oxygen vacancies which are extended throughout the whole films. This result confirmed that MBTK model in ballistic regime is more suitable for our GV spectra and this explains the observation of such a high SPC

**10:24AM E20.00011 Study of the new diluted magnetic semiconductors based on the doping of iron-based superconductors**, LI ZHANG, SHAN FENG, LINXIAN LI, SHAOLEI WANG, YUKE LI, China Jiliang University — Diluted magnetic semiconductors(DMSs) have attracted increasing attention because of their potential applications in spintronics. Recently, a series of new bulk DMS materials [1,2] were synthesized by doping in the 122 and 1111 phases of iron-based superconductors(Fe-SC), which sheds light on the DMS research[3]. In this report, we have synthesized two systems of 1111 phases of DMSs based on Fe-SC materials ( $La_{1-x}Sr_x$ ) ( $Ag_{0.925}Mn_{0.075}SO$  ( $x=0, 0.025, 0.05, 0.075$  and  $0.1$ ) and ( $Y_{1-x}Sr_x$ ) ( $Cu_{0.925}Mn_{0.075}SO$  ( $x=0, 0.025, 0.05, 0.075$  and  $0.1$ ) by solid state method. The structure and electrical, magnetic and optical properties have been investigated by means of XRD, 4KCCS, MPMS, PL, UV-Vis and Raman technique, respectively. Some interesting phenomena are found (Such as the Curie temperature  $T_c$  and band-gap energy  $E_g$  change regularly with the dopants addition). The results are helpful to clarify the intrinsic mechanism of the DMSs, and will provide new insights on the fabrication and application of devices based on these materials. This work was supported by the National Science Foundation of China (Grant No 61376094). **Session E21 DCMP DCOMP: Experimental Techniques and Results: Static and Dynamic High-Pressure Physics** 320 - Audrey Grockowiak, National High Magnetic Field Laboratory

**8:00AM E21.00001 High-Pressure Electrical, Raman, and Structural Measurements on Lithium Sulfide<sup>1</sup>**, KATHRYN HAM, YOGESH VOHRA, GEORGIY TSOI, Univ of Alabama - Birmingham — High-Pressure studies have been conducted on Lithium Sulfide ( $\text{Li}_2\text{S}$ ) to 55 GPa, with electrical, structural, and Raman measurements. Due to the highly reactive nature of the sample in air, the loading was conducted in a glove bag under an inert Argon atmosphere. Four probe electrical measurements using designer diamond anvils showed characteristic semiconducting behavior in  $\text{Li}_2\text{S}$  up to 33 GPa from ambient temperature to 10 K.  $\text{Li}_2\text{S}$  was compressed to 55 GPa and angle dispersive X-Ray data was collected at the Advanced Photon Source, Argonne National Lab, which showed a phase transition from a face centered cubic phase to a primitive orthorhombic phase. Raman data was obtained for  $\text{Li}_2\text{S}$  at ambient conditions after decompression from 55 GPa. The Raman Spectrum showed the characteristic peak for  $\text{Li}_2\text{S}$  at 372.5 wavenumbers, but had an additional uncharacteristic peak at 327.4 wavenumbers. There is a possibility that the additional uncharacteristic Raman peak is due to the decomposition of  $\text{Li}_2\text{S}$  at high pressure.

<sup>1</sup>This research used resources of the Advanced Photon Source, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Lab, Contract No. DE-AC02-06CH11357.; DOE-NNSA Grant No. DE-NA0002014.

**8:12AM E21.00002 Pressure tuning the lattice and optical response of  $\text{Ag}_2\text{S}$** , ZHAO ZHAO, Department of Physics, Stanford University, HUA WEI, Department of Materials Science and Engineering, University of Tennessee, WENDY MAO, Photon Science, SLAC; Department of Geological Sciences, Stanford University — Silver chalcogenides  $\text{Ag}_2\text{E}$  ( $\text{E} = \text{S}, \text{Se}, \text{and Te}$ ) is a group of materials attracting intense scientific and industrial interest recently. The ability to tune their crystal structure and electronic structure away from their pristine states opens up new optics and opto-electronics applications. In this work, we systematically studied the high pressure structural and optical behavior of  $\text{Ag}_2\text{S}$  by in-situ angle dispersive X-ray Diffraction (XRD) and Infrared (IR) measurements in a diamond anvil cell. Though a series of structural transitions and lattice contractions, the structural symmetrization of  $\text{Ag}_2\text{S}$  is seen from the decrease of  $\beta$  from  $99^\circ$  to  $90^\circ$ . The IR transmission and reflection measurements showed that pressure continuously tuned semiconducting  $\text{Ag}_2\text{S}$  to metallic at around 22 GPa. By Drude model analysis of the IR reflectivity, the optical conductivity shows radical evolution. In particular, the highest DC conductivity reaches  $100 \Omega^{-1}\text{cm}^{-1}$  at 40 GPa. Our results highlight pressure's dramatic role in tuning the lattice and electronic state of silver chalcogenides.

**8:24AM E21.00003 Synthesis and Characterization of Bulk BC8 Si**, HAIDONG ZHANG, TIMOTHY STROBEL, Geophysical Laboratory, Carnegie Institution of Washington — Silicon, an essential element for modern industry, has several allotropes existing at ambient conditions. Among them, one of the most important phases is the metastable Si-III (BC8) structure. Although it has been known since 1960s, experimental characterization of its properties is still rare primarily due to lack of large bulk samples. Common methods produce BC8 Si samples with the size of micrometers in dimension, preventing definitive experimental measurements. In this work we report synthesis of phase pure bulk BC8 Si with the size of a few millimeters through the multi-anvil press method. The structure was confirmed by powder X-ray diffraction and further supported by the Raman spectrum. Its electrical resistance exhibits clear temperature dependence, increasing from 300 K to 2K. A crossover region occurs around 80 K to 100 K, showing a stronger dependence below 80 K. We also report its optical properties, thermal stability and phonon density of states.

**8:36AM E21.00004 Experimental Equation of State of Hafnium Metal to 210 GPa<sup>1</sup>**, YOGESH VOHRA, JEFFREY MONTGOMERY, SPENCER SMITH, GEORGIY TSOI, University of Alabama at Birmingham — The equation of state of hafnium metal has been measured using a platinum pressure marker to 210 GPa. Beveled diamonds with 35 micron central flats were used to compress a sample consisting of a mixture of platinum and hafnium that was packed with 6 nm diamond powder. It was hoped that this geometry would provide an alternative method of creating a second-stage pressure region to reach multi-megabar pressures. Powder diffraction patterns were collected across the high-pressure region using an x-ray beam collimated to  $1 \times 2$  microns in a grid with a spacing of 1 micron. At the highest loads, a pressure gradient of 90 GPa was observed across the sample. This gradient allows for the construction of an equation of state over this range from data collected in only 3 minutes of synchrotron x-ray time. A new analysis program suite employing a measurement of spectral overlap has been developed to identify the multiple structures present, fit lattice parameters, and analyze the newly available gradient information.

<sup>1</sup>This work was supported by the Department of Energy (DOE) National Nuclear Security Administration under grant number DE-NA0002014.

**8:48AM E21.00005 Molecular crystals as precursors for poly-nitrogen<sup>1</sup>**, GUSTAV BORSTAD, JENNIFER CIEZAK-JENKINS, US Army Research Laboratory — The application of pressure to matter results in dramatic modifications of its properties. The compression of molecular crystals first eliminates “empty” space between the molecules. It then alters the electron density distribution, favoring the increase of atomic coordination and the formation of polymers. The polymerization of low-Z compounds into covalently-bonded networks in three dimensions tend to generate materials characterized by superconductivity, super-hardness, and high-energy density.<sup>1</sup> Poly-nitrogen (analogous to diamond) has been synthesized under extreme conditions above 100 GPa and 2000 K in diamond anvil cells, but could not be recovered to ambient conditions.<sup>2</sup> A useful form of poly-nitrogen would have to be synthesized at low-pressure with enhanced stability at ambient conditions. The changes in the intermolecular and intramolecular interactions with pressure play a crucial role in the synthesizing and stabilizing of the structure as well as in tuning its properties. In this talk, we provide Raman and x-ray diffraction data on nitrogen-containing compound biuret and compare it to work on other possible poly-nitrogen precursors. References [1] W. Grochala *et al.*, *Angew. Chem. Int. Ed.* **46**, 3620 (2007). [2] M. I. Eremets *et al.*, *Nat. Mater.* **3**, 558 (2004).

**9:00AM E21.00006 High-pressure thermal properties of liquid, crystalline, and amorphous  $\text{H}_2\text{O}$** , ZACHARY GEBALLE, VIKTOR STRUZHUKIN, Carnegie Inst of Washington — We have developed a new technique to measure thermal conductivity and heat capacity of any insulator compressed inside a diamond anvil cell. The method uses Joule heating of a platinum foil or thin-film that is pressed against the sample. Electrical current oscillates at frequencies up to 300 kHz and we infer the amplitude of temperature oscillation via a third-harmonic voltage measurement. The melting and freezing of water in a diamond cell, including 30 K hysteresis, is documented with this new technique when temperature is varied over hours. We will also present calorimetry results using cooling timescales from seconds to milliseconds, which may be short enough to pass through “no-man’s land” into the stability field of glassy water.

**9:12AM E21.00007 High Pressure XANES studies on Mn doped Bi<sub>2</sub>Te<sub>3</sub>**, BRIAN LIGHT, RAVHI KUMAR, JASON BAKER, Univ of Nevada - Las Vegas, PRABHAKARAN DHARMALINGAM, Clarendon Laboratory, University of Oxford, UK, CHANGYONG PARK, Univ of Nevada - Las Vegas, UNLV TEAM, HPCAT AND CARNEGIE INSTITUTE OF WASHINGTON COLLABORATION — Bi<sub>2</sub>Te<sub>3</sub>, Bi<sub>2</sub>Se<sub>3</sub>, and Sb<sub>2</sub>Te<sub>3</sub> are narrow band-gap semiconductors have been extensively studied along with their alloys due to their promising technological applications as thermoelectric materials. More recently pressure induced superconductivity and structural transition have been observed in these materials around 7 GPa [1,2]. Here we have performed high pressure x-ray near edge spectroscopy (XANES) measurements at Bi L-III edge on Mn (0.1) doped Bi<sub>2</sub>Te<sub>3</sub> samples to understand the variation of the Bi valence across the pressure induced superconductivity regime. We have inferred notable changes in the Bi valence at high pressure conditions. The results will be discussed in detail. Work at the University of Nevada Las Vegas (ALC) is funded by U.S. Department of Energy Award DE-SC0001928. Portions of this work were performed at HPCAT (Sector 16), Advanced Photon Source (APS), Argonne National Laboratory. HPCAT is supported by DOE-BES, DOE-NNSA, NSF, and the W.M. Keck Foundation. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH1135.

**9:24AM E21.00008 Equation of state of palladium hydride and deuteride to 100 GPa<sup>1</sup>**, KEENAN BROWNSBERGER, Whitworth University, MUHTAR AHART, MADDURY SOMAYAZULU, STEPHEN GRAMSCH, RUSSELL HEMLEY, Carnegie Institution of Washington — To study the behavior of palladium hydrides under pressure, we loaded palladium foils in hydrogen or deuterium environments in two separate diamond anvil cells. We subsequently measured x-ray diffraction up to 100 GPa at room temperature. No structural phase transition was observed for either PdD<sub>x</sub> or PdH<sub>x</sub> between 0 GPa and 100 GPa. The pressure-volume data were fitted with the third-order Birch-Murnaghan equation of state, which gave an initial volume of 10.8 cm<sup>3</sup>/mol, a bulk modulus of 153 GPa, and its derivative of 4.3 for palladium hydride. An initial volume of 10.6 cm<sup>3</sup>/mol, a bulk modulus of 162 GPa, and its pressure derivative of 4.6 were determined for palladium deuteride. From initial volumes, we conclude that  $x=1$  for both PdD<sub>x</sub> and PdH<sub>x</sub>. This work is supported by the Carnegie-DOE Alliance Center.

<sup>1</sup> EOS of palladium hydride and deuteride to 100 GPa

**9:36AM E21.00009 Development of safety containment system for experiments on radioactive and other hazardous materials with large volume Paris-Edinburgh press at APS and first measurements on depleted-uranium**, MATTHEW JACOBSEN, NENAD VELISAVLJEVIC, Los Alamos National Laboratory — Recent technical developments using the large volume Paris-Edinburgh press platform have enabled x-ray synchrotron studies at high pressure and temperature conditions (Kono, Y. *et al. Rev. Sci. Instrum.* **83**, 033905 (2012)). However, application for hazardous materials requires special handling due to safety issues, reactivity, or other challenges. Facility safety requirements require adequate containment for operation in the variety of environments available. In this talk, we will present a containment setup developed to enable studies of such materials. In particular, studies of the phase diagram of uranium using ultrasonic interferometry to determine the elasticity, mechanical, and thermal properties will be discussed. These results present the first high pressure studies of combined elasticity and thermal properties of depleted uranium metal as well as demonstration of a containment system for making such measurements.

**9:48AM E21.00010 NMR in a Diamond Anvil Pressure Cell**, MATTHEW LAWSON, Univ of California - Davis, ADAM DIOGUARDI, Los Alamos National Lab, SAMUEL WEIR, LLNL, BLAINE BUSH, Univ of California - Davis, MIHINDRA DUNUWILLE, SHANTI DEEMYAD, University of Utah, NICHLAS CURRO, Univ of California - Davis — We present recent advances in the use of diamond anvil pressure cells in nuclear magnetic resonance measurements. This technique allows access to new regions of the phase diagrams of iron pnictide and heavy fermion materials, and promises to allow NMR experiments under pressures not previously accessible.

**10:00AM E21.00011 Reactive decomposition of low density PMDI foam subject to shock compression<sup>1</sup>**, SCOTT ALEXANDER, WILLIAM REINHART, AARON BRUNDAGE, DAVID PETERSON, Sandia National Laboratories — Low density polymethylene diisocyanate (PMDI) foam with a density of 5.4 pounds per cubic foot (0.087 g/cc) was tested to determine the equation of state properties under shock compression over the pressure range of 0.58 - 3.4 GPa. This pressure range encompasses a region approximately 1.0-1.2 GPa within which the foam undergoes reactive decomposition resulting in significant volume expansion of approximately three times the volume prior to reaction. This volume expansion has a significant effect on the high pressure equation of state. Previous work on similar foam was conducted only up to the region where volume expansion occurs and extrapolation of that data to higher pressure results in a significant error. It is now clear that new models are required to account for the reactive decomposition of this class of foam. The results of plate impact tests will be presented and discussed including details of the unique challenges associated with shock compression of low density foams.

<sup>1</sup>Sandia National Labs is a multi-program lab managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corp., for the U.S. Dept. of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:12AM E21.00012 Modeling shock-driven reaction in low density PMDI foam<sup>1</sup>**, AARON BRUNDAGE, C. SCOTT ALEXANDER, WILLIAM REINHART, DAVID PETERSON, Sandia National Laboratories — Shock experiments on low density polyurethane foams reveal evidence of reaction at low impact pressures. However, these reaction thresholds are not evident over the low pressures reported for historical Hugoniot data of highly distended polyurethane at densities below 0.1 g/cc. To fill this gap, impact data given in a companion paper for polymethylene diisocyanate (PMDI) foam with a density of 0.087 g/cc were acquired for model validation. An equation of state (EOS) was developed to predict the shock response of these highly distended materials over the full range of impact conditions representing compaction of the inert material, low-pressure decomposition, and compression of the reaction products. A tabular SESAME EOS of the reaction products was generated using the JCZS database in the TIGER equilibrium code. In particular, the Arrhenius Burn EOS, a two-state model which transitions from an unreacted to a reacted state using single step Arrhenius kinetics, as implemented in the shock physics code CTH, was modified to include a statistical distribution of states. Hence, a single EOS is presented that predicts the onset to reaction due to shock loading in PMDI-based polyurethane foams.

**10:24AM E21.00013 Static Pressure Above 300 GPa Using Chemical Vapor Deposited Two-stage Diamond Micro-anvils<sup>1</sup>**, JEFFREY MONTGOMERY, GOPI SAMUDRALA, GEORGIY TSOI, SPENCER SMITH, YOGESH VOHRA, University of Alabama at Birmingham — Two-stage diamond micro-anvils were grown via chemical vapor deposition (CVD) on beveled diamond anvils with 30 micron central flats. These anvils were used to compress a pre-indented rhenium foil to pressures in excess of 300 Gigapascals (GPa) at relatively small applied loads. Powder diffraction patterns were collected across the high-pressure region using an x-ray beam collimated to 1x2 microns in a grid with a spacing of 1 micron. While multi-megabar pressures were seen across the entire second stage, the highest pressure regions were confined to areas of a few microns in diameter. These were observed at points near the edge of the second stage with nearby pressure gradients as high as 100 GPa/micron. The transmitted x-rays show that the second stage plastically deformed while maintaining multi-megabar pressures. This may have created a second-stage gasket consisting of CVD diamond and rhenium that supported the pressure gradient without substantial external confining pressure. Further improvements in two-stage diamond micro-anvils would require controlling the geometry and microcrystalline/nanocrystalline diamond content during CVD growth process.

<sup>1</sup>This work was supported by the Department of Energy (DOE)/National Nuclear Security Administration under grant number DE-NA0002014.

**10:36AM E21.00014 High-pressure X-ray diffraction, Raman, and computational studies of MgCl<sub>2</sub> up to 1 Mbar: Extensive pressure stability of the  $\beta$ -MgCl<sub>2</sub> layered structure.<sup>1</sup>**, ELISSAIO STAVROU, JOSEPH ZAUG, SORIN BASTEA, I-FENG KUO, JONATHAN CROWHURST, Lawrence Livermore National Laboratory, BORA KALKAN, MARTIN KUNZ, Advanced Light Source, Lawrence Berkeley Laboratory, ZUZANA KONOPKOVA, Deutsches Elektronen-Synchrotron (HASYLAB) — Magnesium chloride with the rhombohedral layered CdCl<sub>2</sub>-type structure ( $\alpha$ -MgCl<sub>2</sub>) has been studied using x-ray diffraction and Raman spectroscopy up to 1 Mbar. The results reveal a second-order phase transition to a hexagonal layered CdI<sub>2</sub>-type structure at 0.7 GPa. This phase transition affects the stacking of the Cl anions, resulting to a shorter *c*-axis. An anisotropic compression along *c*-axis was observed during initial compression; altered above 10 GPa due to the repulsion between adjacent Cl-layers. According to previous theoretical studies, a series of phase transitions towards, initially, the 3D rutile (6-fold Mg cations) at 17 GPa and to fluorite structure (8-fold Mg cations) at 70 GPa are proposed. According to our experimental study MgCl<sub>2</sub> remains in a 2D layered structure up to 1Mbar keeping the 6-fold coordination of Mg cations. This observation contradicts with the general structural behavior of compressed AB<sub>2</sub> compounds; we conducted *ab-initio* calculations to elucidate the mechanisms that extend the remarkable structural stability of MgCl<sub>2</sub>.

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**  
**Session E22 DCOMP: Predicting and Classifying Materials via High-Throughput Databases and Machine Learning I** 321 - Gus Hart, Brigham Young University

**8:00AM E22.00001 Novel energy materials through structural search**, MAXIMILIAN AMSLER, Northwestern University, STEFAN GOEDECKER, Basel University, CHRIS WOLVERTON, Northwestern University — Sophisticated structure prediction methods have been developed and become essential tools when designing new materials with desired properties. Their successful applications to many systems at various conditions and the increasing amount of available computational power have strongly contributed to their popularity. The Minima Hopping Method (MHM) is a powerful tool to find low energy structures given only the chemical composition of a system and allows the prediction of structures at any boundary condition. Recently, not only the thermodynamic ground states, but also metastable phases accessible through various synthesis methods have drawn considerable interest for energy applications. We present the discovery of novel energy materials, ranging from low-density silicon allotropes with improved absorption in the visible to thermoelectric materials, by optimizing the MHM to imitate synthesis pathways.

**8:12AM E22.00002 High-throughput Screening and Statistical Learning for the Design of Transparent Conducting Oxides**, CHRISTOPHER SUTTON, LUCA GHIRINGHELLI, MATTHIAS SCHEFFLER, Fritz Haber Institute of the Max Planck Society — Transparent conducting oxides (TCOs) represent a class of well-developed and commercialized wide-bandgap semiconductors that are crucial for many electronic devices. Al, Ga, and In-based sesquioxides are investigated as new TCOs motivated by very intriguing recent experimental work that has demonstrated bandgap engineering in ternary (Al<sub>x</sub>Ga<sub>1-x</sub>Y)2O<sub>3</sub> ranging from 3.8 eV to 7.5 eV by adjusting the ratio of In/Ga[1] and Ga/Al.[2] We employed DFT-based cluster expansion (CE) models combined with fast stochastic optimization techniques (e.g., Wang-Landau and diffusive nested sampling) in order to efficiently search for stable and metastable configurations of (Al<sub>x</sub>Ga<sub>1-x</sub>Y)2O<sub>3</sub> at various lattice structures. The approach also allows for a consideration of the effect of entropy on the relative stability of ternary TCOs. Statistical learning/compressed sensing is being used to efficiently identify a structure-property relationship between the targeted properties (e.g., mobilities and optical transparency) and the fundamental chemical and physical parameters that control these properties. **8:24AM E22.00003 Many-body physics via machine learning<sup>1</sup>**, LOUIS-FRANCOIS ARSENAULT, Columbia Univ, O. ANATOLE VON LILIENFELD, Basel Univ, ANDREW J. MILLIS, Columbia Univ — We demonstrate a method for the use of machine learning (ML) to solve the equations of many-body physics, which are functional equations linking a bare to an interacting Greens function (or self-energy) offering transferable power of prediction for physical quantities for both the forward and the reverse engineering problem of materials. Functions are represented by coefficients in an orthogonal polynomial expansion and kernel ridge regression is used. The method is demonstrated using as an example a database built from Dynamical Mean Field theory (DMFT) calculations on the three dimensional Hubbard model. We discuss the extension to a database for real materials. We also discuss some new area of investigation concerning high throughput predictions for real materials by offering a perspective of how our scheme is general enough for applications to other problems involving the inversion of integral equations from the integrated knowledge such as the analytical continuation of the Greens function and the reconstruction of lattice structures from X-ray spectra.

### 8:36AM E22.00004 Deep Wavelet Scattering for Quantum Energy Regression<sup>1</sup>, MATTHEW HIRN,

Michigan State University — Physical functionals are usually computed as solutions of variational problems or from solutions of partial differential equations, which may require huge computations for complex systems. Quantum chemistry calculations of ground state molecular energies is such an example. Indeed, if  $x$  is a quantum molecular state, then the ground state energy  $E_0(x)$  is the minimum eigenvalue solution of the time independent Schrödinger Equation, which is computationally intensive for large systems. Machine learning algorithms do not simulate the physical system but estimate solutions by interpolating values provided by a training set of known examples  $\{(x_i, E_0(x_i))\}_{i \leq n}$ . However, precise interpolations may require a number of examples that is exponential in the system dimension, and are thus intractable. This curse of dimensionality may be circumvented by computing interpolations in smaller approximation spaces, which take advantage of physical invariants. Linear regressions of  $E_0$  over a dictionary  $\Phi = \{\phi_k\}_k$  compute an approximation  $\tilde{E}_0$  as:  $\tilde{E}_0(x) = \sum_k w_k \phi_k(x)$ , where the weights  $\{w_k\}_k$  are selected to minimize the error between  $E_0$  and  $\tilde{E}_0$  on the training set. The key to such a regression approach then lies in the design of the dictionary  $\Phi$ . It must be intricate enough to capture the essential variability of  $E_0(x)$  over the molecular states  $x$  of interest, while simple enough so that evaluation of  $\Phi(x)$  is significantly less intensive than a direct quantum mechanical computation (or approximation) of  $E_0(x)$ . In this talk we present a novel dictionary  $\Phi$  for the regression of quantum mechanical energies based on the *scattering transform* of an intermediate, approximate electron density representation  $\rho_x$  of the state  $x$ . The scattering transform has the architecture of a deep convolutional network, composed of an alternating sequence of linear filters and nonlinear maps. Whereas in many deep learning tasks the linear filters are learned from the training data, here the physical properties of  $E_0$  (invariance to isometric transformations of the state  $x$ , stable to deformations of  $x$ ) are leveraged to design a collection of linear filters  $\rho_x * \psi_\lambda$  for an appropriate wavelet  $\psi$ . These linear filters are composed with the nonlinear modulus operator, and the process is iterated upon so that at each layer stable, invariant features are extracted:  $\phi_k(x) = |||\rho_x * \psi_{\lambda_1} * \psi_{\lambda_2} * \dots * \psi_{\lambda_m}|||$ ,  $k = (\lambda_1, \dots, \lambda_m)$ ,  $m = 1, 2, \dots$ . The scattering transform thus encodes not only interactions at multiple scales (in the first layer,  $m = 1$ ), but also features that encode complex phenomena resulting from a cascade of interactions across scales (in subsequent layers,  $m \geq 2$ ). Numerical experiments give state of the art accuracy over data bases of organic molecules, while theoretical results guarantee performance for the component of the ground state energy resulting from Coulombic interactions.

### 9:12AM E22.00005 Machine learning bandgaps of double perovskites<sup>1</sup>, GHANSHYAM PILANIA, Los Alamos

Natl Lab, ARUN MANNODI-KANAKKITHODI, University of Connecticut, BLAS UBERUAGA, Los Alamos Natl Lab, RAMPI RAMPRASAD, University of Connecticut, JAMES GUBERNATIS, TURAB LOOKMAN, Los Alamos Natl Lab — The ability to make rapid and accurate predictions of bandgaps for double perovskites is of much practical interest for a range of applications. While quantum mechanical computations for high-fidelity bandgaps are enormously computation-time intensive and thus impractical in high throughput studies, informatics-based statistical learning approaches can be a promising alternative. Here we demonstrate a systematic feature-engineering approach and a robust learning framework for efficient and accurate predictions of electronic bandgaps for double perovskites. After evaluating a set of nearly 1.2 million features, we identify several elemental features of the constituent atomic species as the most crucial and relevant predictors. The developed models are validated and tested using the best practices of data science (on a dataset of more than 1300 double perovskite bandgaps) and further analyzed to rationalize their prediction performance.

### 9:24AM E22.00006 A Multi-Objective Optimization Technique to Model the Pareto Front of Organic Dielectric Polymers<sup>1</sup>, J. E. GUBERNATIS, Theoretical Division, Los Alamos National Laboratory, A. MANNODI-KANAKKITHODI,

R. RAMPRASAD, Department of Materials Science and Engineering, University of Connecticut, G. PILANIA, Materials Science and Engineering Division, Los Alamos National Laboratory, T. LOOKMAN, Theoretical Division, Los Alamos National Laboratory — Multi-objective optimization is an area of decision making that is concerned with mathematical optimization problems involving more than one objective simultaneously. Here we describe two new Monte Carlo methods for this type of optimization in the context of their application to the problem of designing polymers with more desirable dielectric and optical properties. We present results of applying these Monte Carlo methods to a two-objective problem (maximizing the total static band dielectric constant and energy gap) and a three objective problem (maximizing the ionic and electronic contributions to the static band dielectric constant and energy gap) of a 6-block organic polymer. Our objective functions were constructed from high throughput DFT calculations of 4-block polymers, following the method of Sharma et al., Nature Communications 5, 4845 (2014) and Mannodi-Kanakkithodi et al., Scientific Reports, submitted. Our high throughput and Monte Carlo methods of analysis extend to general N-block organic polymers.

<sup>1</sup>This work was supported in part by the LDRD DR program of the Los Alamos National Laboratory and in part by a Multidisciplinary University Research Initiative (MURI) grant from the Office of Naval Research.

### 9:36AM E22.00007 A New Silicon Allotrope with a Direct Band Gap for Optoelectronic Ap-

plications, YAGUANG GUO, QIAN WANG, Peking University, YOSHIYUKI KAWAZOE, Tohoku University, PURU JENA, Virginia Commonwealth University, PEKING UNIVERSITY TEAM, KAWAZOE COLLABORATION, JENA COLLABORATION — Silicon structures with direct band gaps have been hotly pursued for solar cell applications. To effectively harvest the sunlight in the whole frequency region, it is a good strategy to use arrays consisting of Si structures with different direct band gaps. However, the structure with a direct band gap about 0.6 eV has been missing according to current progress made in the direction. Here we report our findings that the missing structure can be constructed by using Si triangles as the building blocks, which is stable dynamically and thermally, not only exhibiting the desirable band gap, but also showing high intrinsic mobility and low mass density. These advantages over the existing Si structures would motivate new experimental effort in this direction.

### 9:48AM E22.00008 A comprehensive polymer dataset for accelerated property prediction and design, HUAN TRAN, ARUN KUMAR MANNODI-KANAKKITHODI, CHIHO KIM, University of Connecticut, VINIT SHARMA, Oak Ridge National

Laboratory, GHANSHYAM PILANIA, Los Alamos National Laboratory, RAMPI RAMPRASAD, University of Connecticut — Emerging computation- and data-driven approaches are particularly useful for rationally designing materials with targeted properties. In principle, these approaches rely on identifying structure-property relationships by learning from a dataset of sufficiently large number of relevant materials. The learned information can then be used to rapidly predict the properties of materials not already in the dataset, thus accelerating the design of materials with preferable properties. Here, we report the development of a dataset of 1,065 polymers and related materials, which is available at <http://khazana.uconn.edu/>. This dataset is uniformly prepared using first-principles calculations with structures obtained either from other sources or by using structure search methods. Because the immediate target of this work is to assist the design of high dielectric constant polymers, it is initially designed to include the optimized structures, atomization energies, band gaps, and dielectric constants. The dataset will be progressively expanded by accumulating new materials and including additional properties calculated for the optimized structures provided. We discuss some information “learned” from the dataset and suggest that it may be used as the playground for further data-mining work.

**10:00AM E22.00009 Application of Machine Learning tools to recognition of molecular patterns in STM images<sup>1</sup>**, ARTEM MAKSOV, UT/ORNL Bredesen Center, MAXIM ZIATDINOV, ORNL, SHINTARO FUJII, MANABU KIGUCHI, Tokyo Institute of Technology, SHUHEI HIGASHIBAYASHI, Institute for Molecular Science, HIDEHIRO SAKURAI, Osaka University, SERGEI KALININ, BOBBY SUMPTER, ORNL — The ability to utilize individual molecules and molecular assemblies as data storage elements has motivated scientist for years, concurrent with the continuous effort to shrink a size of data storage devices in microelectronics industry. One of the critical issues in this effort lies in being able to identify individual molecular assembly units (patterns), on a large scale in an automated fashion of complete information extraction. Here we present a novel method of applying machine learning techniques for extraction of positional and rotational information from scanning tunneling microscopy (STM) images of  $\pi$ -bowl sumanene molecules on gold. We use Markov Random Field (MRF) model to decode the polar rotational states for each molecule in a large scale STM image of molecular film. We further develop an algorithm that uses a convolutional Neural Network combined with MRF and input from density functional theory to classify molecules into different azimuthal rotational classes. Our results demonstrate that a molecular film is partitioned into distinctive azimuthal rotational domains consisting typically of 20-30 molecules. In each domain, the “bowl-down” molecules are generally surrounded by six nearest neighbor molecules in “bowl-up” configuration, and the resultant overall structure form a periodic lattice of rotational and polar states within each domain.

<sup>1</sup>Research was supported by the US Department of Energy.

**10:12AM E22.00010 Accurate Models of Formation Enthalpy Created using Machine Learning and Voronoi Tessellations**, LOGAN WARD, ROSANNE LIU, AMAR KRISHNA, VINAY HEGDE, ANKIT AGRAWAL, ALOK CHOUDHARY, CHRIS WOLVERTON, Northwestern Univ — Several groups in the past decade have used high-throughput Density Functional Theory to predict the properties of hundreds of thousands of compounds. These databases provide the unique capability of being able to quickly query the properties of many compounds. Here, we explore how these datasets can also be used to create models that can predict the properties of compounds at rates several orders of magnitude faster than DFT. Our method relies on using Voronoi tessellations to derive attributes that quantitatively characterize the local environment around each atom, which then are used as input to a machine learning model. In this presentation, we will discuss the application of this technique to predicting the formation enthalpy of compounds using data from the Open Quantum Materials Database (OQMD). To date, we have found that this technique can be used to create models that are about twice as accurate as those created using the Coulomb Matrix and Partial Radial Distribution approaches and are equally as fast to evaluate.

**10:24AM E22.00011 Description of interatomic interactions with neural networks<sup>1</sup>**, SAMAD HAJINAZAR, JUNPING SHAO, ALEKSEY N. KOLMOGOROV, Physics Department, Binghamton University — Neural networks are a promising alternative to traditional classical potentials for describing interatomic interactions. Recent research in the field has demonstrated how arbitrary atomic environments can be represented with sets of general functions which serve as an input for the machine learning tool. We have implemented a neural network formalism in the MAISE package [1] and developed a protocol for automated generation of accurate models for multi-component systems. Our tests illustrate the performance of neural networks and known classical potentials for a range of chemical compositions and atomic configurations. [1] Module for Ab Initio Structure Evolution, <http://maise-guide.org>

<sup>1</sup>Supported by NSF Grant DMR-1410514

**10:36AM E22.00012 Learning targeted materials properties from data**, TURAB LOOKMAN, PRASANNA V BALACHANDRAN, XUE DEZHEN, JAMES THEILER, JOHN HOGDEN, Los Alamos Natl Lab — We compare several strategies using a data set of 223 M<sub>2</sub>AX family of compounds for which the elastic properties [bulk (B), shear (G), and Young's (E) modulus] have been computed using density functional theory. The strategy is decomposed into two steps: a *regressor* is trained to predict elastic properties in terms of elementary orbital radii of the individual components of the materials; and a *selector* uses these predictions to choose the next material to investigate. The ultimate goal is to obtain a material with desired elastic properties. We examine how the choice of data set size, regressor and selector impact the results.

**10:48AM E22.00013 Neural-network-biased genetic algorithms for materials design<sup>1</sup>**, TARAK PATRA, VENKATESH MEENAKSHISUNDARAM, DAVID SIMMONS, The University of Akron — Machine learning tools have been progressively adopted by the materials science community to accelerate design of materials with targeted properties. However, in the search for new materials exhibiting properties and performance beyond that previously achieved, machine learning approaches are frequently limited by two major shortcomings. First, they are intrinsically interpolative. They are therefore better suited to the optimization of properties within the known range of accessible behavior than to the discovery of new materials with extremal behavior. Second, they require the availability of large datasets, which in some fields are not available and would be prohibitively expensive to produce. Here we describe a new strategy for combining genetic algorithms, neural networks and other machine learning tools, and molecular simulation to discover materials with extremal properties in the absence of pre-existing data. Predictions from progressively constructed machine learning tools are employed to bias the evolution of a genetic algorithm, with fitness evaluations performed via direct molecular dynamics simulation. We survey several initial materials design problems we have addressed with this framework and compare its performance to that of standard genetic algorithm approaches.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**

**Session E23 DMP: Metamaterial Devices and Applications** 322 - Jeremy Munday, University of Maryland

**8:00AM E23.00001 Dielectric metasurfaces**, JASON VALENTINE, Vanderbilt University — While plasmonics metasurfaces have seen much development over the past several years, they still face throughput limitations due to ohmic losses. On the other hand, dielectric resonators and associated metasurfaces can eliminate the issue of ohmic loss while still providing the freedom to engineer the optical properties of the composite. In this talk, I will present our recent efforts to harness this freedom using metasurfaces formed from silicon and fabricated using CMOS-compatible techniques. Operating in the telecommunications band, I will discuss how we have used this platform to realize a number of novel functionalities including wavefront control, near-perfect reflection, and high quality factor resonances. In many cases the optical performance of these silicon-based metasurfaces can surpass their plasmonic counterparts. Furthermore, for some cases the surfaces are more amenable to large-area fabrication techniques.

**8:36AM E23.00002 Reconfigurable Infrared Phased-Array Semiconductor Metasurfaces**, JON SCHULLER, Univ of California - Santa Barbara — The ability to engineer the scattering *phase* of metamaterial constituents offers tremendous potential for constructing new classes of beam steering, shaping, and focusing technologies. Current methods for engineering phase rely on static geometry-based effects. In this talk we describe methods to *dynamically* tune the scattering phase of infrared semiconductor nanoantennas. We fabricate spherical silicon and germanium nanoparticles via femtosecond laser ablation and demonstrate size-dependent multipolar resonances throughout the infrared frequency range. We experimentally demonstrate that the resonance frequencies shift with doping, according to simple Drude models of free-carrier refraction. Using a combination of theoretical and analytical calculations we show that dynamically tuning free-carrier concentration can enable reconfigurable optical antennas and metasurfaces. Such dynamic tuning will enable reconfigurable photonic devices based on optical antenna and metamaterial concepts.

**8:48AM E23.00003 Electromechanical control of flat optical devices**, TAPASHREE ROY, Argonne National Lab, SHUYAN ZHANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University, IL WOONG JUNG, Argonne National Lab, FEDERICO CAPASSO, John A. Paulson School of Engineering and Applied Sciences, Harvard University, DANIEL LOPEZ, Argonne National Lab — In the recent times flat optical elements, like lenses and beam deflectors, have come to the forefront of scientific research. These devices, also referred to as metasurfaces, use metal or dielectric resonators, arbitrarily spaced with subwavelength resolution on a two dimensional plane, to mimic the phase profile of any conventional bulk optical device and beyond. Such metasurface-based planar devices are compact and lightweight compared to their conventional bulky counterparts. However, most of these nanostructured devices have so far been passive. In this work we introduce an important concept of actively controlling these flat optical devices. A prototype: an electromechanically controlled plasmonic flat lens focusing mid infrared signal in reflection will be presented. The lens is fabricated on a 2.8 micron thin membrane following photolithography processes and integrated with a micro electromechanical system (MEMS) device. When electrostatically actuated, the MEMS platform controls the mechanical tilt angle of the lens along two orthogonal axes by about 16 degrees that in turn controls the scanning of the focal spot. Such actively controlled miniaturized optical devices promise to provide faster, more efficient and often enhanced functionalities.

**9:00AM E23.00004 Dynamic tuning of lattice plasmon lasers with long coherence characteristics**, THANG HOANG, Department of Physics, Duke University, ANKUN YANG, Department of Materials Science and Engineering, Northwestern University, GEORGE SCHATZ, Department of Chemistry, Northwestern University, TERI ODOM, Department of Materials Science and Engineering, Department of Chemistry, Northwestern University, MAIKEN MIKKELSEN, Department of Physics, Department of Electrical and Computer Engineering, Duke University — Here, we experimentally demonstrate dynamic tuning of an optically-pumped lattice plasmon laser based on arrays of gold nanoparticles and liquid gain materials [A. Yang, T. B. Hoang et al., Nature Communications 6, 6939 (2015)]. The structure consists of an array of 120 nm diameter gold disks with a height of 50 nm and 600 nm spacing. A liquid gain material composed of IR-140 dye molecules dissolved in a variety of organic solvents is placed on top of the disks and held in place by a thin glass coverslip. At a lasing wavelength of 860 nm, time-resolved measurements show a dramatic reduction of the decay time from 1 ns to less than 20 ps when the optical excitation power density increases from below to above the lasing threshold, indicating the transition from spontaneous to stimulated emission. By changing the dielectric environment surrounding the gold disks in real time, the lasing wavelength can be dynamically tuned over a 55 nm range. Finally, we will discuss recent experiments where we probe both the temporal and spatial coherence properties of the lattice plasmon laser. This advance of tunable plasmon lasers offer prospects to enhance and detect weak physical and chemical processes on the nanoscale in real time.

**9:12AM E23.00005 Nanophotonic interactions between organic excitons and plasmonic metasurfaces**, DEIRDRE OCARROLL, Rutgers University — Thin-film organic semiconductor materials are emerging as energy-efficient, versatile alternatives to inorganic semiconductors for display and solid-state lighting applications. Additionally, thin-film organic laser and photovoltaic technologies, while not yet competitive with inorganic semiconductor-based analogues, can exhibit small device embodied energies (due to comparatively low temperature and low energy-use fabrication processes) which is of interest for reducing overall device cost. To improve energy conversion efficiency in thin-film organic optoelectronics, light management using nanophotonic structures is necessary. Here, our recent work on improving light trapping and light extraction in organic semiconductor thin films using nanostructured silver plasmonic metasurfaces will be presented [1,2]. Numerous optical phenomena, such as absorption induced scattering, out-of-plane waveguiding and morphology-dependent surface plasmon outcoupling, are identified due to exciton-plasmon coupling between the organic semiconductor and the metasurface. Ways in which these phenomena can be controlled and optimized for particular optoelectronic applications will be presented. Work done in collaboration with C. Petoukhoff and Z. Shen. [1] C. E. Petoukhoff, D. M. O'Carroll, Absorption-Induced Scattering and Surface Plasmon Out-Coupling from Absorber-Coated Plasmonic Metasurfaces. Nat. Commun. 6, 7899-1-13 (2015). [2] Z. Shen, D. M. O'Carroll, Nanoporous Silver Thin Films: Multifunctional Platforms for Influencing Chain Morphology and Optical Properties of Conjugated Polymers. Adv. Funct. Mater. 25, 3302-3313 (2015).

**9:48AM E23.00006 High sensitivity plasmonic sensor based on sharp cavities**, MICHAEL J. NAUGHTON, JUAN M. MERLO, CHAOBIN YANG, YITZI M. CALM, MICHAEL J. BURNS, Boston College — Surface plasmon resonance sensors have been demonstrated as among the most useful applications of the surface plasmon phenomena. SPR sensors are sensitive enough to detect low refractive index shifts, a critical factor in many biological applications [1]. We present a SPR sensor based on sharp cavities. An antipillar template is fabricated in PDMS and the resulting cavities are coated with a thin film of Ag. Optimization of the Ag film thickness allows one to tune and enhance the optical transmittance and response sensitivity. We also report that the proposed sensor demonstrates sensitivity at one, and likely several, orders of magnitude higher than the maximum sensitivity reported in the literature for different, similar, devices [2]. Numerical calculations show that the sensitivity is due to the strong confinement of localized plasmons inside the cavities, particularly at the sharpest ends. [1] S. Zeng, D. Baillargeat, H. P. Hod, K. T. Yong, Chem. Soc. Rev. 43, 3426 (2014). [2] M. R. Gartia, A. Hsiao, A. Pokhriyal, S. Seo, G. Kulsharova, B. T. Cunningham, T. C. Bond, G. L. Liu. Adv. Opt. Mat., 1, 68 (2013).

**10:00AM E23.00007 An ultrathin invisibility skin cloak for visible light**, ZI JING WONG, XINGJIE NI, MICHAEL MREJEN, YUAN WANG, XIANG ZHANG, University of California, Berkeley — Metamaterial-based optical cloaks have thus far used volumetric distribution of the material properties to gradually bend light and thereby obscure the cloaked region. Hence, they are bulky and hard to scale up to macroscopic sizes. In addition, typical carpet cloaks introduce unnecessary phase shifts in the reflected light, making the cloaks detectable. Here, we demonstrate experimentally an ultrathin invisibility skin cloak wrapped over an object. This skin cloak conceals a three-dimensional arbitrarily shaped object by complete restoration of the phase of the reflected light at 730-nanometer wavelength. The skin cloak comprises a metasurface with distributed phase shifts rerouting light and rendering the object invisible. In contrast to bulky cloaks with volumetric index variation, our device is only 80 nanometer (about one-ninth of the wavelength) thick and potentially scalable to hide macroscopic objects.

**10:12AM E23.00008 Fabrication of tunable infrared metamaterials using atomic calligraphy**<sup>1</sup>, JEREMY REEVES, THOMAS STARK, LAWRENCE BARRETT, RICHARD LALLY, DAVID BISHOP, Boston University — Metamaterials with dynamically variable spectral response to incident radiation through the use of a deformable substrate have so far been limited to the IR and longer wavelength regimes. Such materials, with unit cells a few to tens of microns across, can readily be fabricated using existing lithography techniques. Extending these metamaterials to shorter wavelengths and into the visible spectrum requires a proportional shrinking of the unit cell to be patterned over a large area. The reduced structure size leads to a strong reduction in the throughput of the chosen fabrication technique [1]. Here, we investigate the prospects for the use of atomic calligraphy [2] to pattern arbitrary infrared metamaterials with high throughput. Atomic calligraphy provides a scalable technique for the manufacture of metamaterials with high precision while allowing for writing on a variety of substrates, including deformable materials. We consider the electromagnetic response of these tunable materials and possibilities to develop metamaterials with resonances in the visible spectrum.

**10:24AM E23.00009 Wireless transmission by plasmonic antennas**, JUAN M MERLO, YITZI M. CALM, AARON H. ROSE, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College — Radio frequency (RF) communication is fundamental to many modern technologies. The idea of a simple rescaling of RF theory to the visible frequency range is not a direct issue [1,2], due in part to the finite conductivity in the optical range of commonly-used metals (e.g. Ag, Au). In this context, wireless communication using plasmonic antennas is a very recent concept with potential importance in an on-chip technology application. Here, we propose a plasmonic antenna system capable of wireless transmission-at-a-distance equivalent to at least four free-space wavelengths from the emitter. We demonstrate that it is possible to transmit information with maximum signal strength of -6.9 dB at three free-space wavelengths with a signal-to-noise ratio of -13 dB, good enough to be considered as an efficient wireless system. Theoretical calculations agree with our experimental results and open the possibility to future optimizations of the proposed plasmonic wireless system. [1] Y. Wang, K. Kempa, B. Kimball, J. B. Carlson, G. Benham, W. Z. Li, T. Kempa, J. Rybczynski, A. Herczynski, Appl. Phys. Lett. 85, 2607 (2004). [2] L. Novotny, Phys. Rev. Lett. 98, 266802 (2007).

**10:36AM E23.00010 A Metamaterial-Inspired Approach to RF Energy Harvesting**, CLAYTON FOWLER, JIANGFENG ZHOU, University of South Florida — We demonstrate an RF energy harvesting rectenna design based on a metamaterial perfect absorber (MPA). With the embedded Schottky diodes, the rectenna converts captured RF energy to DC currents. The Fabry-Perot cavity resonance of the MPA greatly improves the amount of energy captured and hence improves the rectification efficiency. Furthermore, the FP resonance exhibits high Q-factor and significantly increases the voltage across the Schottky diodes. This leads to a factor of 16 improvement of RF-DC conversion efficiency at ambient intensity level.

**10:48AM E23.00011 Influences of the Mie resonance on reflectance spectra of Si nanopillar arrays with different wetting states**, SUJUNG KIM, MINJI GWON, Ewha Womans University, JIAQI LI, imec, KU Leuven, XIUMEI XU, imec, SUN-KYUNG KIM, Kyung Hee University, EUNSONGYI LEE, University of Manchester, DONG-WOOK KIM, Ewha Womans University, CHANG CHEN, imec, KU Leuven — The reflectance spectra of crystalline Si nanopillar (SiNP) arrays with various diameters were investigated by finite-difference time-domain (FDTD) simulations. The spectra exhibited distinct features depending on the wetting states. The FDTD-simulated reflectance dips of the 40-nm-diameter SiNP array were in good agreement with those estimated from destructive interference conditions at the top and bottom of the SiNPs: the SiNP arrays and the surrounding medium were treated as one optically homogeneous medium with an effective permittivity estimated from the effective medium approximation (EMA) model. However, the dip positions of the simulated spectra for 70-, 100-, and 130-nm-diameter SiNP arrays deviated from the results of interference calculations, particularly for short wavelengths. The optical reflectance spectra were significantly affected by the strong diameter-dependent Mie resonances in SiNPs, which were sensitive to the refractive index of the surrounding medium (i.e., the wetting state). Optical reflectance measurements provide an easy and efficient means of inspecting the wetting behavior of nano-patterned surfaces.

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**  
**Session E24 DMP DCOMP: Many-Body Perturbation Theory for Electronic Excitations: Computational Advances** 323 - Volker Blum, Duke University

**8:00AM E24.00001 Plasmon Pole Approximations within a GW Sternheimer implementation**, VINCENT GOSSELIN, MICHEL COTE, Univ of Montreal — We use an implementation of the GW approximation that exploits a Sternheimer equation and a Lanczos procedure to circumvent the resource intensive sum over all bands and inversion of the dielectric matrix. I will present further improvement of the method that uses Plasmon Pole approximations to evaluate the integral over all frequencies analytically. A comparison study between the von Linden-Horsh and Engel-Farid approaches for energy levels of various molecules along with benchmarking of the computational resources needed by the method will be discussed.

**8:12AM E24.00002 Inclusion of the electron-phonon interaction in the BerkeleyGW computational package<sup>1</sup>**, DEREK VIGIL-FOWLER, STEPHAN LANY, Natl Renewable Energy Lab — The BerkeleyGW package is a highly optimized and efficient code for calculating, among others, the dielectric response, bandstructures, lifetimes, and optical absorption of materials from nanostructures and two-dimensional sheets to bulk materials. In the past the only interactions included in BerkeleyGW were electron-electron interactions, with other packages being used to include the effect of, say, electron-phonon interactions. One common approach is to use Wannier functions to interpolate all needed quantities to a very fine grids in energy and momentum, which leads to very accurate electron-phonon couplings and lifetimes. However, in materials with complex, even unknown, chemical environments the generation of Wannier functions can be quite time consuming and constitutes another step in an already difficult calculation. The BerkeleyGW package has a wavefunction-based interpolation scheme that is used in solving the Bethe-Salpeter equation and which is much more easily automated than Wannier interpolation. In this talk, we discuss results for the carrier lifetimes due to the electron-phonon interaction using this interpolation scheme. In particular, we discuss the computational efficiency and scalability, and the prospects for applying this method to a wide range of materials to get first principles lifetimes, and related quantities, such as mobilities and diffusion lengths.

**8:24AM E24.00003 Large-scale GW software development<sup>1</sup>**, MINJUNG KIM, SUBHASISH MANDAL, Department of Applied Physics, Yale University, ERIC MIKIDA, PRATEEK JINDAL, ERIC BOHM, NIKHIL JAIN, LAXMIKANT KALE, Department of Computer Science, University of Illinois at Urbana-Champaign, GLENN MARTYNA, IBM T. J. Watson Research Center, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — Electronic excitations are important in understanding and designing many functional materials. In terms of *ab initio* methods, the GW and Bethe-Salpeter Equation (GW-BSE) beyond DFT methods have proved successful in describing excited states in many materials. However, the heavy computational loads and large memory requirements have hindered their routine applicability by the materials physics community. We summarize some of our collaborative efforts to develop a new software framework designed for GW calculations on massively parallel supercomputers. Our GW code is interfaced with the plane-wave pseudopotential *ab initio* molecular dynamics software "OpenAtom" which is based on the Charm++ parallel library [1]. The computation of the electronic polarizability is one of the most expensive parts of any GW calculation. We describe our strategy that uses a real-space representation to avoid the large number of fast Fourier transforms (FFTs) common to most GW methods. We also describe an eigendecomposition of the plasmon modes from the resulting dielectric matrix that enhances efficiency. [1] Bohm *et al.*, IBM J. RES. & DEV. vol. 52 no. 1/2, 2008

**8:36AM E24.00004 Towards highly scalable GW calculations<sup>1</sup>**, SUBHASISH MANDAL, MINJUNG KIM, Department of Applied Physics, Yale University, ERIC MIKIDA, ERIC BOHM, PRATEEK JINDAL, NIKHIL JAIN, Department of Computer Science, University of Illinois at Urbana Champaign, LAXMIKANT V. KALE, Department of Computer Science, University of Illinois at UrbanaChampaign, GLENN J. MARTYNA, IBM T. J. Watson Research Center, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — The GW and Bethe-Salpeter Equation (GW-BSE) approach is an accurate and useful method beyond DFT to describe excited states of materials. However over the past few decades, most *ab initio* GW calculations used have been confined to small units of cells of bulk-like materials due to the extreme computational demands of the approach. We will present our collaborative efforts to develop new software that permits large scale GW calculations more efficiently: our GW software is interfaced with the *ab initio* plane wave pseudopotential OpenAtom software (<http://charm.cs.uiuc.edu/OpenAtom/>) that uses the Charm++ parallel framework. Here, we focus on describing our work on computing the static (so called “COHSEX”) GW self-energy. We describe the advantages of our real-space approach for quasi-particle calculations and provide information on scaling behavior of the resulting algorithms.

<sup>1</sup> NSF ACI-1339804

**8:48AM E24.00005 Accurate Ionization Potentials and Electron Affinities of Acceptor Molecules: A Benchmark of GW Methods**, NOA MAROM, JOSEPH KNIGHT, XIAOPENG WANG, Tulane University, LUKAS GALLANDI, University of Potsdam, Germany, OLGA DOLGOUNITCHEVA, Auburn University, XINGUO REN, USTC, VINCENT ORTIZ, Auburn University, PATRICK RINKE, Aalto University, Finland, THOMAS KORZDORFER, University of Potsdam, Germany — The performance of different GW methods is assessed for a set of 24 organic acceptors. Errors are evaluated with respect to coupled cluster singles, doubles, perturbative triples [CCSD(T)] reference data for the vertical ionization potentials (IPs) and electron affinities (EAs), extrapolated to the complete basis set limit. Additional comparisons are made to experimental data, where available. We consider fully self-consistent GW (scGW), partial self-consistency in the Green's function (scGW<sub>0</sub>), non-self-consistent G<sub>0</sub>W<sub>0</sub> based on several mean-field starting points, and a “beyond GW” second order screened exchange (SOSEX) correction to G<sub>0</sub>W<sub>0</sub>. The best performers overall are G<sub>0</sub>W<sub>0</sub>+SOSEX and G<sub>0</sub>W<sub>0</sub> based on an IP-tuned long range corrected hybrid functional with the former being more accurate for EAs and the latter for IPs. Both provide a balanced treatment of localized vs. delocalized states and valence spectra in good agreement with photoemission spectroscopy (PES) experiments.

**9:00AM E24.00006 Extrapolation of G<sub>0</sub>W<sub>0</sub> energy levels from small basis sets for elements from H to Cl**, TONG ZHU, VOLKER BLUM, MEMS Department, Duke University, Durham, NC 27708 — G<sub>0</sub>W<sub>0</sub> calculations based on orbitals from a density-functional theory reference are widely used to predict carrier levels in molecular and inorganic materials. Their computational feasibility, however, is limited by the need to evaluate slow-converging sums over unoccupied states, requiring large basis sets paired with unfavorable scaling exponents to evaluate the self-energy. In the quantum chemistry literature, complete basis set (CBS) extrapolation strategies have been used successfully to overcome this problem for total energies. We here apply the principle of basis set extrapolation to G<sub>0</sub>W<sub>0</sub> energy levels. For a set of 49 small molecules and clusters containing the elements H, Li through F, and Na through Cl, we test established extrapolation strategies based on Dunning's correlation-consistent (cc) basis sets (aug)-cc-pVNZ (N=2-5), as well as numeric atom-centered NAO-VCC-nZ (n=2-5) basis sets in the FHI-aims all-electron code. For the occupied and lowest unoccupied levels, different extrapolation strategies agree within ±50 meV based on large 4Z and 5Z basis sets. We show that extrapolation based on much smaller 2Z and 3Z basis sets with largest errors ± 100 meV based on a refinement of the NAO-VCC-nZ basis sets.

**9:12AM E24.00007 The Sternheimer-GW method and the spectral signatures of plasmonic polarons<sup>1</sup>**, FELICIANO GIUSTINO, University of Oxford — During the past three decades the GW method has emerged among the most promising electronic structure techniques for predictive calculations of quasiparticle band structures. In order to simplify the GW work-flow while at the same time improving the calculation accuracy, we developed the Sternheimer-GW method [1]. In Sternheimer-GW both the screened Coulomb interaction and the electron Green's function are evaluated by using exclusively occupied Kohn-Sham states, as in density-functional perturbation theory. In this talk I will review the basics of Sternheimer-GW, and I will discuss two recent applications to semiconductors and superconductors. In the case of semiconductors we calculated complete energy- and momentum-resolved spectral functions by combining Sternheimer-GW with the cumulant expansion approach. This study revealed the existence of band structure replicas which arise from electron-plasmon interactions [2]. In the case of superconductors we calculated the Coulomb pseudo-potential from first principles, and combined this approach with the Eliashberg theory of the superconducting critical temperature [3]. **9:48AM E24.00008 Combination of Hedin's GW and dynamical mean-field theory tested on H<sub>2</sub> molecule**, JUHO LEE, KRISTJAN HAULE, Rutgers University — We compare various flavors of “GW+DMFT” approach with LDA+DMFT for the simplest strongly correlated system, the H<sub>2</sub> molecule. The following GW+DMFT methodologies are compared: (i) the fully self-consistent GW+DMFT, (ii) the quasi-particle self-consistent QS-GW+DMFT with dynamic double-counting, (iii) QS-GW+DMFT with static double-counting schemes. We found that fully self-consistent GW+DMFT with exact double-counting yields very precise spectra around equilibrium H-H distance, as well as reasonable total energy (comparable to LDA+DMFT). However, this scheme breaks down in the correlated regime due to causality violation. The QS-GW+DMFT approaches, which are not derivable from a functional, yield similar spectra as full GW+DMFT near equilibrium distance, and in static double-counting schemes, can also be extended into correlated regime. However, the total energy of these approaches is much worse than the total energy of LDA+DMFT. In summary, this toy model of correlated physics suggests that QS-GW+DMFT with constant double-counting should give accurate predictions of spectra, but not total energy, while LDA+DMFT gives very precise total energy, but somewhat less precise spectra.

**10:00AM E24.00009 Electron-phonon coupling using many-body GW theory<sup>1</sup>**, BARTOMEU MONSER-RAT, DAVID VANDERBILT, Rutgers University — Electron-phonon coupling drives a plethora of phenomena, such as superconductivity in metals, or the temperature dependence of optical properties in semiconductors. There is increasing evidence that semi-local density functional theory (DFT) is not adequate for the description of electron-phonon coupling, and instead effects such as electronic correlation need to be included. Unfortunately, methods beyond semi-local DFT are computationally demanding, limiting the study of these phenomena. In this talk we will introduce the idea of “thermal lines”, which can be used to explore the vibrational phase space of solids and molecules at small computational cost. In particular, we will describe how thermal lines can be exploited to calculate the temperature dependence of band structures beyond semi-local DFT, by using many-body GW theory, or by including the effects of spin-orbit coupling. We will present first-principles results showing the effects of electron correlation on the strength of electron-phonon coupling, and the effects of electron-phonon coupling on topological states of matter.

**10:12AM E24.00010 Plane wave based selfconsistent solution of the GW Dyson equation<sup>1</sup>**, LIN-WANG WANG, HUAWEI CAO, Lawrence Berkeley Natl Lab — We have developed a selfconsistent procedure to calculate the full Dyson equation based on plane wave basis set. The whole formalism is based on the Greens function matrix of the plane wave G-vector. There is no truncation of the conduction band when the dielectric function is calculated. The Dyson equation is the variational minimum solution of the total energy in terms of the Greens function. The calculation uses the "space-time" method, with special algorithm for imaginary time integration and Fourier transformation. We have tested isolated molecules and periodic systems. The effects of selfconsistency compared to the G0W0 results will be presented. We will also discuss some special techniques used in the k-point summation for the periodic system. Massive parallelization is used to carry out such calculations.

**10:24AM E24.00011 Post-GW energies from an extended Bethe-Salpeter scheme**, EMANUELE MAGGIO, Univ of Vienna, GEORG KRESSE, University of Vienna — Hedin's breakthrough in many-body physics is a computationally manageable scheme to implicitly account for many-body effects thanks to the introduction of a self-energy, whose expression is known but in practice approximated by truncation at some order in the inter-particle interaction. Hedin's scheme allows the computation of quasi-particle addition and removal energies. The introduction of an added particle (or hole) to the system will trigger the formation of higher order neutral excitations (particle/hole pairs formation). The widespread GW approximation only partially accounts for these effects by replacing the bare interparticle interaction with a dressed one. Other effects are contained in the vertex function and are typically disregarded. In the present work, we move beyond the GW level by including vertex effects in the self-energy. This is implemented by expressing the self-energy in terms of the reducible two-particle scattering amplitude. The latter is related to the kernel of the Bethe-Salpeter equation and to the corresponding polarisation propagator. The proposed implementation allows us to evaluate the quality of quasi-particle spectra for a range of realistic solids and molecular systems.

**10:36AM E24.00012 GW Calculations of Materials on the Intel Xeon-Phi Architecture<sup>1</sup>**, JACK DESLIPPE, LBNL, FELIPE H. DA JORNADA, UC Berkeley and LBNL, DEREK VIGIL-FOWLER, NREL, ARIEL BILLER, Weizmann Institute of Science, JAMES R. CHELIKOWSKY, UT Austin, STEVEN G. LOUIE, UC Berkeley and LBNL — Intel Xeon-Phi processors are expected to power a large number of High-Performance Computing (HPC) systems around the United States and the world in the near future. We evaluate the ability of GW and pre-requisite Density Functional Theory (DFT) calculations for materials on utilizing the Xeon-Phi architecture. We describe the optimization process and performance improvements achieved. We find that the GW method, like other higher level Many-Body methods beyond standard local/semilocal approximations to Kohn-Sham DFT, is particularly well suited for many-core architectures due to the ability to exploit a large amount of parallelism over plane-waves, band-pairs and frequencies.

**10:48AM E24.00013 Recent Advances in Modeling Transition Metal Oxides for Photo-electrochemistry<sup>1</sup>**, MAYTAL CASPARY TOROKER, Department of Materials Science and Engineering, Technion - Israel Institute of Technology — Computational research offers a wide range of opportunities for materials science and engineering, especially in the energy arena where there is a need for understanding how material composition and structure control energy conversion, and for designing materials that could improve conversion efficiency. Potential inexpensive materials for energy conversion devices are metal oxides. However, their conversion efficiency is limited by at least one of several factors: a too large band gap for efficiently absorbing solar energy, similar conduction and valence band edge characters that may lead to unfavorably high electron-hole recombination rates, a valence band edge that is not positioned well for oxidizing water, low stability, low electronic conductivity, and low surface reactivity. I will show how we model metal oxides with ab-initio methods, primarily DFT+U. Our previous results show that doping with lithium, sodium, or hydrogen could improve iron (II) oxide's electronic properties, and alloying with zinc or nickel could improve iron (II) oxide's optical properties. Furthermore, doping nickel (II) oxide with lithium could improve several key properties including solar energy absorption. In this talk I will highlight new results on our understanding of the mechanism of iron (III) oxide's surface reactivity. Our theoretical insights bring us a step closer towards understanding how to design better materials for photo-electrochemistry. References: 1. O. Neufeld and M. **Session E25 DCMP: Superconductivity: Vortex matter** 324 - Valentin Taufour, Ames Laboratory

**8:00AM E25.00001 A quantitative model for flux flow resistivity and Nernst effect of vortex fluid in high-temperature superconductors**, RONG LI, ZHEN-SU SHE, College of Engineering, Peking University, LAN YIN, School of Physics, Peking University, STATE KEY LABORATORY FOR TURBULENCE AND COMPLEX SYSTEMS TEAM — Transport properties of vortex fluid in high-temperature superconductors have been described in terms of viscous dynamics of magnetic and thermal vortices. We have constructed a quantitative model by extending the Bardeen-Stephen model of damping viscosity to include the contributions of flux pinning in low temperature and vortex-vortex interaction in high magnetic field. A uniformly accurate description of flux flow resistivity and Nernst signal is achieved for empirical data over a wide range of temperature and magnetic field strength. A discrepancy of three orders of magnitude between data and Anderson model of Nernst signal is pointed out, suggesting the existence of anomalous transport in high-temperature superconductor beyond mere quantum and thermal fluctuations. The model enables to derive a set of physical parameters characterizing the vortex dynamics from the Nernst signal, as we illustrate with an analysis of six samples of Bi<sub>2</sub>Sr<sub>2- $\gamma$</sub> La <sub>$\gamma$</sub> CuO<sub>6</sub> and Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+ $\delta$</sub> .

**8:12AM E25.00002 In-plane electronic anisotropy from core states of tilted vortices.**, HERMANN SUDEROW, Univ Autonoma de Madrid, JOSE AUGUSTO GALVIS, National high magnetic field laboratory, EDWIN HERRERA, ISABEL GUILLAMON, SEBASTIAN VIEIRA, Univ Autonoma de Madrid — Magnetic field enters type II superconductors in form of quantized vortices. Each vortex has a core with the superconducting wavefunction vanishing at its center. Quasiparticles at the vortex core form bound states whose radial extension depends on the superconducting gap value and Fermi surface shape. In the layered superconductor 2H-NbSe<sub>2</sub> vortex cores have been studied using scanning tunneling microscopy (STM) mostly with magnetic fields applied perpendicular to the layers. It is found that vortices have a six-fold star shape due to the in-plane anisotropy of the superconducting gap and of the electronic density of states. Here we study vortex core states with the magnetic field applied parallel to the layers. We find that the vortex cores change their shape depending on the angle of the tilted magnetic field with respect to the in-plane crystalline directions, providing a lateral view of the electronic structure.

**8:24AM E25.00003 Characterization of vortex pinning through the Campbell length**, ROLAND WILLA, VADIM B. GESHKENBEIN, GIANNI BLATTER, Institute for Theoretical Physics, ETH Zurich, 8093 Zurich, Switzerland — Vortex pinning is decisive in establishing dissipation-free current flow in a type-II superconductor; knowledge and optimization of the pinning landscape (pinscape) is of major importance for applications. The *ac* magnetic response, characterized by the Campbell penetration depth  $\lambda_C$  [1], provides valuable information on the pinscape, besides the critical current density  $j_c$ . While microscopic derivations of  $j_c$  are available both in the weak and strong pinning limits, this is not the case for the Campbell length, whose understanding has remained on a phenomenological level so far. Based on the microscopic theory of strong pinning, we have established a proper link between the Campbell length and the pinscape parameters. This new quantitative formalism [2] captures all experimentally observed signatures [3], among which are the dependence of  $\lambda_C$  on the vortex state preparation and the hysteresis in  $\lambda_C$  upon thermal cycling the field-cooled state. [1] A.M. Campbell, J Phys C: Solid State Physics 2, 1492 (1969), *ibid.* 4, 3186 (1971) [2] R. Willa, V.B. Geshkenbein, and G. Blatter, PRB 92, 134501 (2015), R. Willa, V.B. Geshkenbein, R. Prozorov and G. Blatter, PRL in press [3] R. Prozorov et al., PRB 67, 184501 (2003), H. Kim et al., PRB 87, 094515 (2013)

**8:36AM E25.00004 Observation of RF-induced flux lattice annealing (RIFLA) in cuprate high temperature superconductors**, GUOQING WU, XIANGHUA ZENG, XIAO-SHAN YE, Yangzhou Uni., BING WU, Fayetteville State Uni., GERARD GAIDOS, W. G. CLARK, UCLA — We report the annealing of a strained flux lattice (FL) in cuprate high temperature superconductors, by the RF pulses used to obtain the NMR spin-echo signal and by a series of RF pulses that are input into the sample coil in a tuned NMR probe circuit. The strained FL is prepared by changing the alignment and/or magnitude of the applied magnetic field at temperatures well below the superconducting transition temperature, which leaves the FL pinned in a non-equilibrium configuration. We provide a very sensitive measure of the phenomenon. This new observation enriches the phenomenon of FL, and indicates that shaking the flux lattice by the applied RF pulses (including both the spin-echo pulses and the pulses input to the sample coil circuit) progressively causes the flux lattice to change to a lower free energy configuration. Supported by NSF China grant : 61474096

**8:48AM E25.00005 Dynamic and Structural Studies of Metastable Vortex Lattice Domains in  $\text{MgB}_2$** <sup>1</sup>, E.R. DE WAARD, S.J. KUHN, C. RASTOVSKI, M.R. ESKILDSEN, University of Notre Dame, A. LEISHMAN, Kent State University, C.D. DEWHURST, Institut Laue-Langevin, France, L. DEBEER-SCHMITT, K. LITTRELL, Oak Ridge National Laboratory, J. KARPINSKI, EPFL, Switzerland, N.D. ZHIGADLO, ETH, Switzerland — Small-angle neutron scattering (SANS) studies of the vortex lattice (VL) in the type-II superconductor  $\text{MgB}_2$  have revealed an unprecedented degree of metastability that is demonstrably not due to vortex pinning, [C. Rastovski *et al.*, Phys. Rev. Lett. 111, 107002 (2013)]. The VL can be driven to the GS through successive application of an AC magnetic field. Here we report on detailed studies of the transition kinetics and structure of the VL domains. Stroboscopic studies of the transition revealed a stretched exponential decrease of the metastable volume fraction as a function of the number of applied AC cycles, with subtle differences depending on whether the AC field is oriented parallel or perpendicular to the DC field used to create the VL. We speculate the slower transition kinetics for the transverse AC field may be due to vortex cutting. Spatial studies include scanning SANS measurements showing the VL domain distribution within the  $\text{MgB}_2$  single crystal as well as measurements of VL correlation lengths.

**9:00AM E25.00006 Enhancement of long-range correlations in a 2D vortex lattice by an incommensurate 1D disorder potential**<sup>1</sup>, I. GUILLAMON, S. VIEIRA, H. SUDEROW, Universidad Autonoma de Madrid, Spain, R. CORDOBA, J. SESE, J.M. DE TERESA, R. IBARRA, Instituto de Nanociencia de Aragon, Spain — In two dimensional (2D) systems, theory has proposed that random disorder destroys long range correlations driving a transition to a glassy state. Here, I will discuss new insights into this issue obtained through the direct visualization of the critical behaviour of a 2D superconducting vortex lattice formed in a thin film with a smooth 1D thickness modulation [1]. Using scanning tunneling microscopy at 0.1K, we have tracked the modification in the 2D vortex arrangements induced by the 1D thickness modulation while increasing the vortex density by three orders of magnitude. Upon increasing the field, we observed a two-step order-disorder transition in the 2D vortex lattice mediated by the appearance of dislocations and disclinations and accompanied by an increase in the local vortex density fluctuations. Through a detailed analysis of correlation functions, we find that the transition is driven by the incommensurate 1D thickness modulation. We calculate the critical points and exponents and find that they are well above theoretical expectation for random disorder. Our results show that long range 1D correlations in random potentials enhance the stability range of the ordered phase in a 2D vortex lattice. [1] I. Guillamon et al., Nature Physics 10, 851856 (2014)

**9:12AM E25.00007 Study of vortex states and dynamics in mesoscopic superconducting samples with MFM**, GREGORY POLSHYN, TYLER NAIBERT, VICTOR CHUA, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign — Vortex states in superconducting (SC) structures, their dynamics and ways to manipulate them are topics of great interest. We report a new method of magnetic force microscopy (MFM) that allows the study of vortex states in mesoscopic SC samples. For the case of a SC ring, which is biased to a half-integer flux quantum, the flux modulation through the ring caused by the motion of the magnetic tip drives the ring between two consecutive fluxoid states. The corresponding current switching in the ring produces strong position-dependent forces on the cantilever. In the regime where the frequency of the thermally activated jumps between fluxoid states is close to the frequency of the cantilever, large changes in the cantilever frequency and dissipation are observed. This effect may be understood as a stochastic resonance (SR) process. These changes in the cantilevers mechanical properties are used to image the barrier energies between fluxoid states. Additionally, SR imaging of the barrier energies are used to study the effect of the locally applied magnetic field from the MFM tip on the barrier heights. We report the results of measurements for Al rings. Further, the same imaging technique can be applied to more sophisticated SC structures such as arrays of Josephson junctions.

**9:24AM E25.00008 History Dependence of the Vortex Lattice Rotation in the B-phase of  $\text{UPt}_3$  with  $\mathbf{H} \parallel \mathbf{c}^1$** , K.E. AVERS, Northwestern Univ, M.R. ESKILDSEN, Notre Dame University, W.P. HALPERIN, W.J. GANNON, Northwestern Univ, J.L. GAVILANO, G. NAGY, U. GASSER, Paul Scherrer Institute — The unconventional superconductor  $\text{UPt}_3$  is widely believed to be a triplet superconductor, where the low temperature superconducting B-phase is a chiral state. We have performed small angle neutron scattering (SANS) from the vortex lattice (VL) in  $\text{UPt}_3$  at the Paul Scherrer Institute with the magnetic field parallel to the hexagonal *c*-axis in the 0.5 T to 0.9 T range. The diffraction pattern of the VL rotates away from a high symmetry direction producing two domains of different orientation. Our field dependent measurements show a subtle magnetic field history dependence of this orientation; VLs prepared with the magnetic field parallel or anti-parallel with respect to the angular momentum from the circulating screening currents show different field-history dependence. These results suggest a coupling of a chiral superconducting order parameter with the applied magnetic field.

<sup>1</sup>US DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Awards DE-FG02-10ER46783 (University of Notre Dame; neutron scattering) and DE-FG02-05ER46248 (Northwestern University; crystal growth, characterization, neutron

**9:36AM E25.00009 Vortex matter in superconductors: solid or gas?** , VLADIMIR KOZHEVNIKOV, Tulsa Community College, ANNE-MARIE VALENTE-FELICIANO, Thomas Jefferson National Lab, PETER CURRAN, University of Bath, GUNTHER RICHTER, Max-Planck-Institut for Intelligent Systems, HAOLIANG LIU, ALEXANDER VOLODIN, Solid State Physics and Magnetism Section, KU Leuven, SIMON BENDING, University of Bath, CHRIS VAN HAESENDONCK, Solid State Physics and Magnetism Section, KU Leuven — We will report on results of our recent study of the equilibrium magnetic properties of the mixed state in type-II superconductors performed with high purity bulk and film niobium samples in parallel and perpendicular magnetic fields using dc magnetometry and scanning Hall-probe microscopy. Equilibrium magnetization data for the perpendicular geometry were obtained for the first time. It was found that none of the existing theories is consistent with these new data. To address this problem a theoretical model is developed and verified experimentally. The new model describes the magnetic properties of the mixed state in an averaged limit, i.e. without detailing the samples' magnetic structure and therefore ignoring interactions between the structural units (vortices). Nevertheless, it is quantitatively consistent with the data obtained in a perpendicular field. At low values of the Ginzburg-Landau parameter, the model converts to that of Peierls and London for the intermediate state in type-I superconductors, valid in the limit of non-interacting normal domains. We will show that description of the vortex matter in type-II superconductors in terms of a 2D gas is more appropriate than the frequently used crystal- and glass-like scenarios.

**9:48AM E25.00010 Orientational Ordering, Buckling, and Dynamic Transitions for Vortices Interacting with a Periodic Quasi-One Dimensional Substrate** , MINH QUAN LE THIEN, DANIELLE MCDERMOTT, Department of Physics, Wabash College, Crawfordsville, Indiana 47933 USA, CYNTHIA OLSON REICHHARDT, CHARLES REICHHARDT, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545 USA — We examine the statics and dynamics of vortices in the presence of a periodic quasi-one dimensional substrate, focusing on the limit where the vortex lattice constant is smaller than the substrate lattice period. As a function of the substrate strength and filling factor, within the pinned state we observe a series of order-disorder transitions associated with buckling phenomena in which the number of vortex rows that fit between neighboring substrate maxima increases. These transitions coincide with steps in the depinning threshold, jumps in the density of topological defects, and changes in the structure factor. For weaker substrate strengths we find that the vortices retain triangular ordering but can show changes in the orientation of the triangular lattice with respect to the substrate. Under an applied drive the system exhibits a rich variety of distinct dynamical phases, including plastic flow, a density-modulated moving crystal, and moving floating solid phases. We also discuss how these results are related to recent experiments by I. Guilamon et al, Nature Physics 10, 751 (2014), for vortices interacting on quasi-one-dimensional periodic modulated substrates.

**10:00AM E25.00011 The dynamics and pinning of single vortices in type-II superconductors investigated using a scanning SQUID-on-tip microscope** , LIOR EMBON, YONATHAN ANAHORY, ALEX SUHOV, DORRI HALBERTAL, JO CUPPENS, ANTON YAKOVENKO, AVIRAM URI, YURI MYASOEDOV, MICHAEL RAPPAPORT, Weizmann Institute of Science, MARTIN HUBER, University of Colorado Denver, ALEX GUREVICH, Old Dominion University, ELI ZELDOV, Weizmann Institute of Science — The electromagnetic properties of superconductors, particularly their ability to carry non-dissipative currents, are governed by the dynamics of quantized magnetic vortices and their pinning due to material defects. Despite recent advances in the understanding of the complex physics of vortex matter, the behavior of vortices driven by current through a potential created in an actual material is still not well understood, mostly due to the scarcity of adequate experimental tools. Using a novel scanning SQUID-on-tip microscope we have investigated the controlled dynamics of vortices in Pb films with sub-Angstrom sensitivity to vortex displacement. Using the ability to trace vortex trajectories on nanometer scales, we measured, for the first time, the fundamental dependence of the elementary pinning force of multiple defects on the vortex displacement, revealing a far more complex behavior than has previously been recognized. Our results indicate the importance of thermal fluctuations even at 4.2 K, and of the vital role of small and seemingly unimportant ripples in the pinning potential. These give new insights into the mechanisms of magnetic relaxation and electromagnetic response of superconductors.

**10:12AM E25.00012 Dissipative vortex dynamics in overdamped superconducting arrays** , MALCOLM DURKIN, IAN MONDRAGON-SHEM, University of Illinois at Urbana-Champaign, SERENA ELEY, Los Alamos National Laboratory, TAYLOR HUGHES, NADYA MASON, University of Illinois at Urbana-Champaign — We study 2D superconductor-normal-superconductor (SNS) arrays consisting of regularly spaced Nb islands on Au films, measuring the current-driven voltage response. SNS arrays provide a highly tunable platform for studying classical vortex behavior and we are able to access a number of vortex regimes, including edge pinning and site pinning regimes at low fields and commensurate vortex lattice behavior at higher fillings. Focusing on the low vortex filling regime, we study the current driven transition from pinned vortices to flux flow, finding that the differential resistance peak predicted by current driven vortex models is absent in our arrays. While the absence of a differential resistance peak is typically associated with finite temperature effects, this explanation is not consistent with our data. Instead, we find that the dynamic behavior of our system is consistent with the presence of time delayed dissipative forces in an overdamped array.

**10:24AM E25.00013 ABSTRACT WITHDRAWN —**

**10:36AM E25.00014 <sup>93</sup>Nb NMR investigation of vortex- glass transition in layered NbSe<sub>2</sub><sup>1</sup>** , DOUGLAS WILSON, GARIMA SARASWAT, National High Magnetic Field Laboratory, PARASHARAM SHIRAGE, Indian Institute of Technology, PHILIP KUHNS, MICHAEL J. R. HOCH, ARNEIL REYES, National High Magnetic Field Laboratory — We report a detailed low temperature investigation of vortex glass transition in layered superconducting compound NbSe<sub>2</sub> using <sup>93</sup>Nb NMR at fields below H<sub>c2</sub>. Preliminary measurements show that spin-lattice relaxation rate 1/T<sub>1</sub> demonstrates a classic Korringa behavior 1/T<sub>1</sub> ~ T above the superconducting transition T<sub>c</sub>, consistent with previous measurements on this compound. However, for field H perpendicular to the layers, we observed that 1/T<sub>1</sub> exhibits an anomalous plateau between T<sub>c</sub> (H = 0) and T<sub>c</sub>(H) and a suppression of the superconducting enhancement expected below T<sub>c</sub>. Instead, a power law behavior, 1/T<sub>1</sub> ~ T<sup>1.2</sup> below T<sub>c</sub> down to 360mK was observed which suggests a strong anisotropy in the low energy excitations. However, the possibility of enhancement in 1/T<sub>1</sub> due to vortex fluctuations which competes with electronic mechanisms cannot be excluded. The implications of these results with regards to vortex-glass transition will be discussed.

<sup>1</sup>This work was performed at the National High Magnetic Field Laboratory, which is supported by NSF DMR-1157490 and the State of Florida.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**

**Session E27 DCMP: Heavy Fermion Superconductors** 326 - Paula Giraldo Gallow, Florida State University

**8:00AM E27.00001 Tuning the electronic state in  $\text{CeCu}_2\text{Si}_2$ :  $\text{Si} \rightarrow \text{P}$  substitution**, YOU LAI, SCOTT SAUNDERS, ANDREW GALLAGHER, KUAN WEN CHEN, SHENGZHI ZHANG, LUCAS NELSON, DAVID GRAF, FUMITAKE KAMETANI, ARKADY SHEKHTER, RYAN BAUMBACH, FSU-NHMFL — The chemical substitution series  $\text{CeCu}_2\text{Si}_{2-x}\text{Ge}_x$  hosts two distinct superconducting regions that are accessed under applied pressure. The first of these surrounds an antiferromagnetic quantum critical point, while the second does not appear to be associated with the zero-temperature collapse a line of phase transitions. It has been speculated that the second superconducting dome encompasses a quantum phase transition that is associated with a Ce  $4f$ -electron valence collapse, but this has yet to be established. We report a study of the chemical substitution series  $\text{CeCu}_2\text{Si}_{2-x}\text{P}_x$  for  $x \leq 0.2$ , which may expose a new dimension for investigation of quantum valence transitions. This ligand site tuning strategy has the advantage that it changes the number of  $s/p$  electrons without strongly modifying other important variables such as the strength of Coulomb, spin orbit, crystal electric field interactions, and the hybridization between  $f$ - and conduction electrons. We find that the superconductivity is rapidly suppressed and is replaced by strengthening antiferromagnetism with increasing  $x$ . An unexpected additional hysteretic phase transition (V) appears at temperatures below the antiferromagnetic ordering temperature for  $x \geq 0.13$ , which shows several characteristics of Ce valence physics. We will discuss this  $T-x$  phase diagram and consider implications for understanding the proposed valence instability region of  $\text{CeCu}_2\text{Si}_{2-x}\text{Ge}_x$  alloys at high pressure.

**8:12AM E27.00002 Evidence for fully-gapped superconductivity in heavy-fermion  $\text{CeCu}_2\text{Si}_2$** , Y. KASAHARA, D. TERAZAWA, T. YAMASHITA, T. ONISHI, Y. TOKIWA, T. TERASHIMA, Y. MATSUDA, Kyoto Univ., T. TAKENAKA, Y. MIZUKAMI, T. SHIBAUCHI, Univ. of Tokyo, J. WILCOX, C. PUTZKE, A. CARRINGTON, Univ. of Bristol, S. KITAKA, T. SAKAKIBARA, ISSP, Univ. of Tokyo, H. S. JEEVAN, S. SEIRO, C. GEIBEL, Max Planck Institute, Y. HAGA, JAEA — The discovery of superconductivity in heavy-fermion  $\text{CeCu}_2\text{Si}_2$  in 1979 has opened a new playground for unconventional superconductivity in strongly-correlated systems. However, even in this archetypal heavy-fermion superconductor, the symmetry and the structure of the superconducting gap, which are intimately related to the pairing mechanism, are still elusive. Here, to investigate the low-energy quasiparticle excitations in the superconducting state of  $\text{CeCu}_2\text{Si}_2$  ( $T_c = 0.6$  K), we performed specific heat, thermal conductivity, and penetration depth measurements down to 60 mK. We found that specific heat and penetration depth exhibit exponential  $T$ -dependence at low  $T$ . Moreover, thermal conductivity has no residual  $T$ -linear term and shows little  $H$ -dependence. These behavior are in marked contrast to nodal superconductors. From the data taken with different experimental configurations, the detailed superconducting gap structure will be discussed.

**8:24AM E27.00003 Thermal expansion and magnetostriction under extreme conditions of an archetypal heavy fermion system.**<sup>1</sup>, AUDREY GROCKOWIAK, DAVID GRAF, WILLIAM CONIGLIO, National High Magnetic Field Laboratory, TAKAO EBIHARA, Shizuoka University, TIMOTHY MURPHY, STANLEY TOZER, National High Magnetic Field Laboratory, TALLAHASSEE TEAM, PR EBIHARA COLLABORATION — Several dilatometry techniques [1] have been developed and used for low temperature and high magnetic field measurements, but do not permit the use of high pressures. Following the experimental development of R.Daou[2], we successfully coupled Fiber Bragg Gratings (FBG) with pressure cells enabling us to map the magnetic field-pressure-temperature phase space of various systems. FBG measurements permit us to achieve a resolution of  $\Delta L/L \approx 3.10^{-7}$  making it a very sensitive technique. Piston-cylinder cells developed at the NHMFL permit us to reach a pressure of 3 GPa, and their compact size allows them to be used in highly constrained sample volume, giving us the ability to do high pressure dilatometry studies in pulsed and dc high magnetic field facility at temperatures as low as 25 mK. Along with the setup we will present our results on the high pressure, high magnetic field dilatometry of  $\text{CeCu}_2\text{Ge}_2$ . [1] Schmiedeshoff, G., Review of Scientific Instruments, 77(12) (2006) [2] Daou, R., Review of Scientific Instruments, 81(3) (2010)

<sup>1</sup>Part of this work was funded by the US DoE NNSA SSAA DE-NA0001979, and performed at the National High Magnetic Field Laboratory, which is supported by National Science Foundation Cooperative Agreement No. DMR-1157490 and the State of Florida.

**8:36AM E27.00004 Optical Kerr Measurements of  $\text{PrOs}_4\text{Sb}_{12}$** , E. M. LEVENSON-FALK, Stanford University, M. BRIAN MAPLE, UC San Diego, YUJI AOKI, Tokyo Metropolitan University, AHARON KAPITULNIK, Stanford University — By probing the symmetries of a superconducting order parameter, it is possible to gain insight into the microscopic physics underlying superconductivity. This approach is especially important for unconventional superconductors, such as heavy fermion materials, where the pairing mechanisms are poorly understood. Time reversal symmetry breaking plays a large role in many heavy fermion systems, due to their strong magnetic interactions; however, TRS is an especially difficult symmetry to probe. Using a zero-loop-area Sagnac interferometer, we measure the polar Kerr effect in materials and thus extract information about TRSB via the optical conductivity. We present measurements of the polar Kerr effect in the multi-phase heavy fermion material  $\text{PrOs}_4\text{Sb}_{12}$ , and discuss applications to other materials.

**8:48AM E27.00005 Superconducting gap symmetry in  $\text{Pr}_{1-x}\text{Ce}_x\text{Pt}_4\text{Ge}_{12}$  studied through specific heat and resistivity measurements**<sup>1</sup>, R. B. ADHIKARI, Y. P. SINGH, S. ZHANG, Kent State University, K. HUANG, D. YAZICI, I. JEON, M. B. MAPLE, University of California, San Diego, M. DZERO, C. C. ALMASAN, Kent State University — We present results of a systematic study of polycrystalline samples of  $\text{Pr}_{1-x}\text{Ce}_x\text{Pt}_4\text{Ge}_{12}$  ( $0 \leq x \leq 0.2$ ) through low-temperature specific heat and electrical resistivity measurements, which allow us to explore the nature of the superconducting gap symmetry and its evolution with Ce concentration  $x$ . As reported earlier, Ce substitution on the Pr site suppresses monotonically the superconducting (SC) transition temperature  $T_c$ : a small Ce concentration of  $x = 0.14$  suppresses  $T_c$  from 7.8 K in the parent compound to 0.6 K. This study points toward a two-band SC gap scenario for the parent compound, in which the larger gap is nodeless, whereas the smaller gap is nodal. While the larger gap remains nodeless irrespective of the amount of Ce substitution, a rather dramatic effect of Ce substitution is seen in the evolution of the smaller gap: a small amount of Ce substitution ( $x < 0.04$ ) increases the value of this gap, while for  $x > 0.04$ , the data suggest that the nodal character of this gap disappears and both SC order parameters become nodeless. We will discuss our findings in the context of other recent results on this series of filled skutterudite compounds.

<sup>1</sup>This work has been supported by the US NSF (Grant Nos. DMR-1506547 and DMR-1505826) at KSU and by the US DOE (Grant No. DE-FG02-04-ER46105) and US NSF (Grant No. DMR-1206553) at UCSD.

**9:00AM E27.00006 Heavy fermion superconductivity under strong orbital fluctuations in  $\text{PrV}_2\text{Al}_{20}$** , YOSUKE MATSUMOTO, MASAKI TSUJIMOTO, TAKAHIRO TOMITA, AKITO SAKAI, SATORU NAKATSUJI, ISSP, Univ. of Tokyo — Novel quantum phases formed in the vicinity of a magnetic quantum critical point (QCP) have been studied extensively in  $4f$  based intermetallics. On the other hand, it is an interesting open question what types of ground state emerges in the vicinity of a QCP of orbital orderings if the  $f$  electrons' orbital degrees of freedom strongly hybridize with conduction electrons. In order to study this, it is important to choose a material with purely orbital degrees of freedom in the ground state. In addition, the material should be clean and the hybridization should be large. Recent our studies have revealed that  $\text{PrTi}_2\text{Al}_{20}$  ( $T = \text{Ti, V}$ ) are ideal systems. Both systems have the nonmagnetic cubic  $\Gamma_3$  crystal electric field doublet. In addition, the hybridization is strong as is evident in many physical properties. We found that both exhibit heavy fermion superconductivity inside the multipole ordering phases. Especially, in the case of  $\text{PrV}_2\text{Al}_{20}$ , the effective mass is highly enhanced ( $m^*/m_0 \sim 140$ ) even at ambient pressure, revealing even stronger hybridization. This observation indicates the first realization of the novel superconductivity arising from the orbital fluctuation of the  $f$  electrons at ambient pressure, suggesting a proximity to an orbital QCP.

### 9:12AM E27.00007 Superconducting Pairing Correlations near a Kondo-destruction Quantum Critical Point in Cluster Impurity Models

ANG CAI, Rice University, JEDEDIAH PIXLEY, University of Maryland, QIMIAO SI, Rice University — Heavy fermion metals represent a canonical system to study superconductivity driven by quantum criticality. We are particularly motivated by the properties of  $\text{CeRhIn}_5$ , which shows the characteristic features of a Kondo destruction quantum critical point (QCP) in its normal state, and has one of the highest  $T_c$ 's among the heavy fermion superconductors. As a first step to study this problem within a cluster-EDMFT approach [1], we analyze a four-site Anderson impurity model with the antiferromagnetic spin component of the cluster coupled to a sub-Ohmic bosonic bath. We find a QCP that belongs to the same universality class as the single-site Bose-Fermi Anderson model. Together with previous work on a two-site model [2], our result suggests that the Kondo destruction QCP is robust as cluster size increases. More importantly, we are able to calculate the  $d$ -wave pairing susceptibility, which we find to be enhanced near the QCP. Using this model as the effective cluster model of the periodic Anderson model, we are also able to study the superconducting pairing near the Kondo-destruction QCP of the lattice model; preliminary results will be presented. [1] J. H. Pixley, A. Cai, Q. Si, Phys. Rev. B 91, 125127 [2] J. H. Pixley, L. Deng, K. Ingersent, Q. Si, Phys. Rev. B 91, 201109

### 9:24AM E27.00008 Visualization of Ce atoms and surface-induced magnetism in $\text{CeCoIn}_5$

YASUO YOSHIDA, HOWON KIM, The institute for solid state physics, The University of Tokyo, CHI-CHENG LEE, HSIN LIN, Graphene Research Centre, National University of Singapore, YOSHINORI HAGA, NAOYUKI TATEIWA, Advanced Science Research Center, Japan Atomic Energy Agency, ZACHARY FISK, Department of Physics and Astronomy, University of California, Irvine, YUKIO HASEGAWA, The institute for solid state physics, The University of Tokyo —  $\text{CeCoIn}_5$  is known as a heavy fermion compound naturally born at the quantum critical point having an unconventional  $d$ -wave superconducting phase at low temperatures. Recently, several STM works on a cleaved surface of this compound reported visualization of emerging heavy fermion bands and consistency of the bulk superconducting properties reported previously. However, reported STM images in those works only visualized In atoms on the Ce-In plane even though the Ce-In plane contains Ce and In atoms. By performing precise low-temperature STM measurements on  $\text{CeCoIn}_5$ , we successfully visualize Ce atoms on the Ce-In plane and, in addition, surface-induced staggered dumbbell-shaped order on the Co plane. This ordered structure locally has  $C_{2v}$  symmetry but retaining  $C_4$  symmetry. This structure coexists with the superconductivity, and is robust against temperatures ( $>T_c$ ) and an external magnetic field ( $>H_{c2}$ ). In the talk, we will discuss the origin of the peculiar ordered structure based on our experimental observations together with first principles calculations.

### 9:36AM E27.00009 Mapping Dimensionality and Directionality of Electronic Behavior in $\text{CeCoIn}_5$ : the Normal State

ANDRAS GYENIS, BENJAMIN E. FELDMAN, MALLIKA T. RANDERIA, GABRIEL A. PETERSON, Princeton University, PEGOR AYNAJIAN, Binghamton University, ERIC D. BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — Materials made from alternating layers of different constituents can exhibit dramatic variability in their electronic properties depending on which layer is probed. This is evident in the heavy fermion compound  $\text{CeCoIn}_5$ , where scanning tunneling microscopy (STM) has revealed preferential coupling to either light or heavy electron states depending on the surface termination. Here we report STM measurements of  $\text{CeCoIn}_5$  cleaved perpendicular to its basal plane that clearly shows the quasi-two-dimensional nature of the electronic behavior on a single (100) surface. We observe atomic scale modulation of tunneling into the light and heavy electron bands in the  $c$ -axis direction, with no variation visible along the basal planes in the  $b$ -axis direction. In addition, conductance maps reveal preferential scattering along the two-dimensional basal planes. Our measurements highlight the reduced effective dimensionality of electronic states in  $\text{CeCoIn}_5$ , and underscore the potential insight that can be gained by imaging layered materials perpendicular to their  $c$ -axis.

### 9:48AM E27.00010 Mapping Dimensionality and Directionality of Electronic Behavior in $\text{CeCoIn}_5$ : the Superconducting State

BENJAMIN E. FELDMAN, ANDRAS GYENIS, MALLIKA T. RANDERIA, GABRIEL A. PETERSON, Princeton University, PEGOR AYNAJIAN, Binghamton University, ERIC D. BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — Unconventional superconductors often exhibit anisotropic physical properties that arise from the directional dependence of their order parameters. A prime example is  $\text{CeCoIn}_5$ , a heavy fermion  $d$ -wave superconductor with a rich low-temperature phase diagram consisting of competing and coexisting magnetic and superconducting orders. Here we present dilution refrigerator scanning tunneling microscopy of  $\text{CeCoIn}_5$  cleaved perpendicular to its basal plane. We study superconductivity on the (100) surface, whose normal vector points along the antinode of the superconducting energy gap. The gap magnitude is similar to that observed in the basal plane, with a key difference: it does not exhibit any suppression near step edges. Application of a magnetic field along the [100] direction leads to the formation of anisotropic vortices, and the vortex lattice undergoes a transition at high field before the superconducting state gives way to a pseudogap phase. Our measurements illustrate the directional dependence of the superconducting properties in  $\text{CeCoIn}_5$ , and more generally, demonstrate the utility of imaging  $d$ -wave superconductors along their nodal and antinodal directions.

### 10:00AM E27.00011 Zero-field magnetism in Nd-doped $\text{CeRhIn}_5$ under pressure<sup>1</sup>

PRISCILA ROSA, Los Alamos National Laboratory, AARON OOSTRA, University of California at Irvine, YONGKANG LUO, NICHOLAS WAKEHAM, FILIP RONNING, ERIC BAUER, Los Alamos National Laboratory, ZACHARY FISK, University of California at Irvine, JOE THOMPSON, Los Alamos National Laboratory — Unconventional superconductivity is often found in heavy fermion compounds close to a magnetic instability. Although magnetism and superconductivity may coexist when  $T_N > T_c$ , evidence for magnetism is usually suddenly lost when  $T_N < T_c$ . Here we study the heavy-fermion compound  $\text{Ce}_{0.95}\text{Nd}_{0.05}\text{RhIn}_5$  under pressure by means of electrical resistivity and AC calorimetry measurements. Our results show that, even at zero applied magnetic field, Nd substitution unveils a hidden magnetic instability below the superconducting dome. We examine the similarities and differences between our results and those on Nd-doped  $\text{CeCoIn}_5$  as well as pure  $\text{CeRhIn}_5$  under applied field and pressure. We discuss our results in light of recent calculations that include  $d$ -wave superconductivity and underlying magnetic correlations.

### 10:12AM E27.00012 Hybrid heavy-fermion superlattices of $\text{CeCoIn}_5/\text{CeRhIn}_5$

MASAHIRO NARITSUKA, TOMOHIRO ISHII, RINTARO TODA, SHIGERU KASAHARA, YUICHI KASAHARA, YOSHI TOKIWA, TAKAHITO TERASHIMA, YUJI MATSUDA, Kyoto University — Interplay between superconductivity and magnetism continues to provide central topics in condensed matter physics. Among others,  $\text{CeTIn}_5$  ( $T = \text{Co, Rh}$ ) compounds offer one of the suitable platforms for the study of this important issue —  $\text{CeCoIn}_5$  undergoes superconducting transition at  $T_c = 2.3$  K while  $\text{CeRhIn}_5$  orders antiferromagnetically below  $T_N = 3.8$  K at ambient pressure. An intriguing issue concerns coexistence of superconductivity and antiferromagnetism which could be realized at an artificial interface of different materials, but it is not clear how the two different states are affected each other at the interface. Here, by using atomic layer-by-layer molecular beam epitaxy, we fabricate superconducting-antiferromagnetic hybrid superlattices consisting of alternating layers of  $\text{CeCoIn}_5$  and  $\text{CeRhIn}_5$ . Transport measurements confirm the presence of both superconducting and antiferromagnetic phases. The coexistence of superconductivity and antiferromagnetism in a hybrid system is discussed based on the proximity effect at the interface.

**10:24AM E27.00013 Switching of the Spin-Density-Wave in CeCoIn<sub>5</sub> probed by Thermal Conductivity<sup>1</sup>**, DUK Y. KIM, SHI-ZENG LIN, FRANZISKA WEICKERT, ERIC D. BAUER, FILIP RONNING, JOE D. THOMPSON, ROMAN MOVSHOVICH, Los Alamos National Laboratory — Unconventional superconductor CeCoIn<sub>5</sub> orders magnetically in a spin-density-wave (SDW) in the low-temperature and high-field corner of the superconducting phase. Recent neutron scattering experiment revealed that the single-domain SDW's ordering vector  $Q$  depends strongly on the direction of the magnetic field, switching sharply as the field is rotated through the anti-nodal direction. This switching may be manifestation of a pair-density-wave (PDW)  $p$ -wave order parameter, which develops in addition to the well-established  $d$ -wave order parameter due to the SDW formation. We have investigated the hypersensitivity of the magnetic domain with a thermal conductivity measurement. The heat current ( $J$ ) was applied along the [110] direction such that the  $Q$  vector is either perpendicular or parallel to  $J$ , depending on the magnetic field direction. A discontinuous change of the thermal conductivity was observed when the magnetic field is rotated around the [100] direction within  $0.2^\circ$ . The thermal conductivity with the  $Q$  parallel to the heat current ( $J||Q$ ) is approximately 15% larger than that with the  $Q$  perpendicular to the heat current ( $J\perp Q$ ). This result is consistent with additional gapping of the nodal quasiparticle by the  $p$ -wave PDW coupled to SDW.

<sup>1</sup>Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering.

**10:36AM E27.00014 Entanglement and exotic superfluidity in one-dimensional spin-imbalanced lattices<sup>1</sup>**, VIVIAN FRANÇA, Institute of Chemistry, São Paulo State University — The exotic coexistence of superfluidity and magnetism has been investigated theoretical and experimentally since decades. Among the several ideas and models to describe exotic superconductors the so-called Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase stands out. In strongly correlated systems at low temperatures the FFLO state might emerges by the presence of external magnetic fields or by internal polarization as produced by spin-imbalanced populations. Although the FFLO papers are in their 50th birthday and state-of-the-art experiments have been addressed this matter, there have been no unequivocal observations of FFLO superconductivity. We investigate the FFLO superfluid regime in one-dimensional fermionic lattices from a quantum information theory perspective: studying the properties of entanglement. We find that entanglement is non-monotonic with the polarization whenever the lattice is predicted to be an exotic superfluid. We thus propose a simple model for the spin-flip channels involved in the process. Our model is found to allow a very good description of exotic superfluids, while beyond the FFLO regime it reveals a breaking pairs avalanche. Our findings are supported by both density functional theory and density matrix renormalization group calculations.

**10:48AM E27.00015 Microscopic investigation of electronic inhomogeneity induced by substitutions in quantum critical CeCoIn<sub>5</sub>.**, FILIP RONNING, Los Alamos National Lab, HIRONORI SAKAI, Japanese Atomic Energy Agency, JIANXIN ZHU, NICHOLAS WAKEHAM, HIROSHI YASUOKA, Los Alamos National Lab, YO TOKUNAGA, SHIN KAMBE, Japanese Atomic Energy Agency, ERIC BAUER, JOE THOMPSON, Los Alamos National Lab — In Cd-doped CeCoIn<sub>5</sub> magnetic order can be suppressed by pressure giving rise to a dome of superconductivity surrounding a quantum critical point (QCP). However, the typical non-Fermi liquid (NFL) signatures expected at this QCP are absent. In contrast, in Sn-doped CeRhIn<sub>5</sub>, pressure also suppresses magnetism giving rise to a dome of superconductivity, but in this case, the NFL signatures ARE observed at the QCP. We presents results using nuclear quadrupole resonance to probe microscopically the response of the prototypical quantum-critical metal CeCoIn<sub>5</sub> to substitutions of small amounts of Sn and Cd for In. These substituents induce very different local electronic environments as observed by site dependent spin lattice relaxation rates  $1/T_1$ . Cd-doped samples generate a much more inhomogeneous spin environment than observed in Sn-doped samples. This difference naturally explains the presence and absence of NFL signatures at the respective QCPs mentioned above. The effects found here illustrate the need for care in general when interpreting NFL properties determined by macroscopic measurements achieved by chemical substitutions.

## Tuesday, March 15, 2016 8:00AM - 11:00AM – Session E28 DMP: Topological Superconductivity 327 - Abhay Pasupathy, Columbia University

**8:00AM E28.00001 Emergent surface superconductivity in a 3D topological insulator.<sup>1</sup>**, LIA KRUSIN-ELBAUM, Department of Physics, The City College of New York CUNY — Surfaces of three-dimensional topological insulators have emerged as one of the most remarkable states of condensed quantum matter where exotic charge and spin phases of Dirac particles could form. This work reports on novel mesoscopic superconductivity in the topological insulator Sb<sub>2</sub>Te<sub>3</sub> with transition to zero resistance induced through a minor tuning of growth chemistry that depletes bulk conduction channels [1]. The depletion shifts Fermi energy towards the Dirac point as witnessed by a factor of 300 reduction of bulk carrier density and by the largest carrier mobility ( $>25,000\text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ ) found in any topological material of this class. Direct evidence from transport, the unprecedentedly large diamagnetic screening, and the presence of  $\sim 25\text{ meV}$  gaps detected by scanning tunneling spectroscopy reveal the superconducting condensate to emerge first in surface puddles at unexpectedly high temperature of  $\sim 50\text{ K}$ , with the onset of global phase coherence at  $\sim 9\text{ K}$ . The unconventional spin response of Sb<sub>2</sub>Te<sub>3</sub> [2] and the presence of subsurface 2DEG quantum well states arising from charge transfer to the surface [3] are likely to play a role in the emergent superconducting state. The rich structure of this state lends itself to manipulation via growth conditions and the material parameters such as Fermi velocity and mean free path. [1] Emergent surface superconductivity in the topological insulator Sb<sub>2</sub>Te<sub>3</sub>, L. Zhao, H. Deng, I. Korzhovska, J. Secor, M. Begliarbekov, Z. Chen, E. Andrade, E. Rosenthal, A. Pasupathy, V. Oganessian, and Lia Krusin-Elbaum, *Nature Comm.* **6**, 8279 (2015); DOI:10.1038/ncomms9279. [2] Singular robust room-temperature spin response from topological Dirac fermions, L. Zhao, H. Deng, I. Korzhovska, Z. Chen, M. Konczykowski, A. Hruban, V. Oganessian and Lia Krusin-Elbaum, *Nature Mat.* **13**, 580 (2014); DOI: 10.1038/nmat3962. **8:36AM E28.00002 Superconducting Proximity Effect in the Weyl Semimetal WTe<sub>2</sub> and MoTe<sub>2</sub>**, WUDI WANG, MINHAO LIU, Department of Physics, Princeton University, Princeton, NJ 08544, QUINN GIBSON, R. J. CAVA, Department of Chemistry, Princeton University, Princeton, NJ 08544, N. P. ONG, Department of Physics, Princeton University, Princeton, NJ 08544 — WTe<sub>2</sub> and MoTe<sub>2</sub> are predicted to have type-II Weyl nodes and many novel transport properties have been studied. We investigated the transport of cooper pairs and Andreev reflection in Weyl semimetals by proximitizing WTe<sub>2</sub> and MoTe<sub>2</sub> nanoflakes with superconducting pads (Nb and Al). We have fabricated superconductor-nanoflakes-superconductor structure with different length. Supercurrent were observed in both materials with junction length up to 700nm. We conducted dc IV curve measurements and got exotic Fraunhofer patterns. We also measured the current-phase relation with a radio frequency-based CPR measurement technique.

**8:48AM E28.00003 Superconducting proximity effect and the Fermi velocity in the surface-state of  $\text{SmB}_6$  thin films<sup>1</sup>**, SEUNGHUN LEE, XIAOHANG ZHANG, RICHARD L. GREENE, ICHIRO TAKEUCHI, CNAM, MSE, and Physics, University of Maryland —  $\text{SmB}_6$  recently has been predicted to be topological Kondo insulator. Here, we investigate the Fermi velocity ( $v_F$ ) of  $\text{SmB}_6$  using transport measurements and a study on the superconducting proximity effect, independently. In the transport measurement,  $\text{SmB}_6$  thin films show thickness-independent transport characteristics at low temperatures, which is a strong evidence for the presence of the surface conducting channel as well as the insulating bulk state as the nature of Kondo insulator. We estimate the thickness of the surface-state to be  $\approx 7$  nm and the  $v_F$  to be  $\sim 10^5$  m/s. In order to carry out the proximity effect investigation, we fabricated superconducting Nb/ $\text{SmB}_6$  bilayers *in-situ*. We performed Usadel fitting to the variation of critical temperatures of the Nb layers due to the proximity effect. Interestingly, only the fitting regarding a 2D surface model yielded the consistent value of the  $v_F$  with the value obtained from the transport measurement as well as the reported value from the quantum oscillation measurement. These results indicate that  $\text{SmB}_6$  has a true 2D surface-channel responsible for the observed proximity effect.

**9:00AM E28.00004 Probing the Superconducting Proximity Effect of Topological Insulator  $\text{Bi}_2\text{Se}_3$  Using Scanning Tunneling Microscopy**, IAN DAYTON, NICHOLAS SEDLMAYR, VICTOR RAMIREZ, Michigan State University Department of Physics and Astronomy, THOMAS CHASAPIS, Northwestern University Department of Chemistry, REZA LOLOEE, Michigan State University Department of Physics and Astronomy, ALEX LEVCHENKO, University of Wisconsin-Madison Department of Physics, MERCOURI KANATZIDIS, Northwestern University Department of Chemistry, STUART TESSMER, Michigan State University Department of Physics and Astronomy — Placing a 3D topological insulator (TI) in proximity to an s-wave superconductor is theoretically predicted to induce 2D p-wave superconductivity into the topologically protected surface state (TSS). In this talk, we will present cryogenic scanning tunneling microscopy measurements of a large  $\text{Bi}_2\text{Se}_3$  crystal with nanometer scale islands of PbBi deposited on the surface. Local density of states measurements are consistent with p-wave superconductivity in the top  $\text{Bi}_2\text{Se}_3$  quintuple layer, with coherence length of  $540 \pm 50$  nm in the direction parallel to the layer. We see indications of a reverse proximity effect as well, where the TSS from the TI leaks back into local density of states measured on the superconducting islands. The density of states curves also exhibit structure which we interpret as McMillan-Rowell oscillations due to Andreev confinement perpendicular to the layer.

**9:12AM E28.00005 Experimental consequences of candidate pairings for superconducting topological insulators.**, LEI HAO, Department of Physics and Texas Center for Superconductivity, University of Houston, TING-KUO LEE, Institute of Physics, Academia Sinica, WEI-FENG TSAI, Department of Physics, National Sun Yat-sen University, JUN WANG, Department of Physics, Southeast University, CHIN-SEN TING, Department of Physics and Texas Center for Superconductivity, University of Houston — Genuine pairing symmetry of the superconducting topological insulators, including  $\text{Cu}_x\text{Bi}_2\text{Se}_3$ ,  $\text{Bi}_2\text{Se}_3$ , and  $\text{Bi}_2\text{Te}_3$ , are under debate. In this work, we make an extensive comparison on the experimental consequences of several candidate pairings. The physical quantities studied include the surface spectral functions, the surface local density of states, and the electronic thermal conductivities. Apparent differences in the results are found and can be used to identify the actual pairing symmetry. In particular, for model and parameters used in this work which are obtained by fitting first-principles calculations, we get interesting new results such as a segmental flat band of surface Andreev bound states for a spin-singlet pairing. A combination of several experimental techniques should be able to identify the genuine pairing symmetry.

**9:24AM E28.00006 Stability of Majorana vortex bound states on the surface of superconducting topological insulators**, JUNYI ZHANG, Department of Physics, Princeton University, JENNIFER CANO, TITUS NEUPERT, PCTS, Princeton University — Fu and Kane showed that superconductivity induced on the surface of a 3D topological insulator results in isolated Majorana bound states that appear in the cores of vortices. Many efforts to realize this idea are based on proximity-induced superconducting order in a heterostructure. Recently, superconductivity has been observed in  $\text{PbTaSe}_2$ , which has the band topology of a topological insulator with Dirac cone surface states. Hence, it nourishes the vision of realizing the Fu and Kane proposal in a stoichiometric material without the need for doping or fabricating heterostructures. Motivated by this possibility, we give a comprehensive analysis of stability and localization properties of the vortex Majorana modes in such a topological superconducting material. In particular, we address the experimentally relevant questions regarding (i) the energy separation between the vortex bound and excited states, (ii) the dependence of the hybridization between Majorana modes from opposite surfaces on the thickness of a thin-film sample, (iii) the influence of the bulk superconducting pockets on the Majorana states.

**9:36AM E28.00007 Magnetic Ordering In Superconducting Nb-doped  $\text{Bi}_2\text{Se}_3$** , PAUL CORBAE, BENJAMIN LAWSON, GANG LI, FAN YU, TOMOYA ASABA, COLIN TINSMAN, Univ of Michigan - Ann Arbor, YUSHENG QUI, YEW SAN HOR, Missouri University of Science and Technology, LU LI, Univ of Michigan - Ann Arbor — Coexistence of superconductivity and magnetic order has been suggested by early studies of topological superconductor candidate, niobium doped  $\text{Bi}_2\text{Se}_3$ . In order to elucidate the interesting physics of this coexistence, we performed highly sensitive torque magnetometry to study the materials magnetization. We observed a bump feature in the magnetization around 8 Tesla in both the superconducting and non-superconducting samples. This is distinct from the paramagnetic torque response of the parent compound,  $\text{Bi}_2\text{Se}_3$ , suggesting some interesting magnetic order in Nb-doped  $\text{Bi}_2\text{Se}_3$ .

**9:48AM E28.00008 Multi-orbits observed in superconducting Nb-doped  $\text{Bi}_2\text{Se}_3$** , BENJAMIN LAWSON, PAUL CORBAE, GANG LI, FAN YU, TOMOYA ASABA, COLIN TINSMAN, Univ of Michigan - Ann Arbor, YUNSHENG QIU, YEW SAN HOR, Missouri University of Science and Technology, LU LI, Univ of Michigan - Ann Arbor — Recently discovered superconducting niobium doped  $\text{Bi}_2\text{Se}_3$  shows promise to realize new physical phenomenon including the coexistence of superconductivity and magnetic ordering and possibly topological superconductivity. To understand the new physics showcased in this system, a detailed knowledge of the electronic structure is needed. We present the first observation of quantum oscillations in the magnetization (the de Haas-van Alphen effect) of Nb-doped  $\text{Bi}_2\text{Se}_3$ . In the fully superconducting crystal, two distinct orbits are observed, in sharp contrast to  $\text{Bi}_2\text{Se}_3$ , Cu-doped  $\text{Bi}_2\text{Se}_3$ , and Sr-doped  $\text{Bi}_2\text{Se}_3$ . The multiple frequencies observed in our quantum oscillations, combined with our electrical transport studies, indicate the multi-orbit nature of the electronic state of Nb-doped  $\text{Bi}_2\text{Se}_3$ .

**10:00AM E28.00009 Lattice melting and surface Topological order in 3D Time reversal invariant topological superconductor**, YIZHI YOU, KITP — In this talk, we start from the eight copies of 3D Time reversal invariant topological superconductor on a crystal. By proliferating and condensing the disclinations, we can therefore restore the spatial rotation symmetry of the lattice crystal. During the procedure of lattice melting, the fermion acquires a  $\pi$  Berry Phase when winding around the  $2\pi$  disclination and therefore the fermions get confined when disclination loop proliferates. After the disclination condensed, we obtained a 3D bosonic SPT phase with by  $T$  and spatial rotation symmetry. In addition, we investigate the surface state of this Bosonic SPT. If we break the  $T$  symmetry on the surface, the 8 majorana cones are gapped and the  $2\pi$  disclination has semion statistics. To obtain a  $T$  and rotation invariant gapped surface state, we first turn on Fulde-Ferrell superfluid order of the surface to gap the surface fermion and then condensed the vortex/disclination of the superfluid to restore the  $T$  and rotation symmetry. The disclination dipole and vortex exhibit fractional statistics and therefore vortex condensation and lattice melting give rise to new surface topological order.

**10:12AM E28.00010 Topological Superconductivity in Dirac Semimetals** , MASATOSHI SATO, Kyoto Univ, SHINGO KOBAYASHI, Nagoya Univ — Dirac semimetals host bulk band-touching Dirac points and a surface Fermi loop. We develop a theory of superconducting Dirac semimetals. Establishing a relation between the Dirac points and the surface Fermi loop, we clarify how the nontrivial topology of Dirac semimetals affects their superconducting state. We note that the unique orbital texture of Dirac points and a structural phase transition of the crystal favor symmetry-protected topological superconductivity with a quartet of surface Majorana fermions. We suggest the possible application of our theory to recently discovered superconducting states in  $\text{Cd}_3\text{As}_2$ .

**10:24AM E28.00011 Superconducting states of topological surface states in  $\beta\text{-PdBi}_2$  investigated by STM/STS** , KATSUYA IWAYA, RIKEN-CEMS, KENJIRO OKAWA, Tokyo Institute of Technology, TETSUO HANAGURI, YUHKI KOHSAKA, TADASHI MACHIDA, RIKEN-CEMS, TAKAO SASAGAWA, Tokyo Institute of Technology — We investigate superconducting (SC) states of topological surface states in  $\beta\text{-PdBi}_2$  using very low temperature STM. Characteristic quasiparticle interference patterns strongly support the existence of the spin-polarized surface states at the Fermi level in the normal state. A fully-opened SC gap well described by the conventional BCS model is observed, indicating the SC gap opening at the spin-polarized Fermi surfaces. Considering a possible mixing of odd- and even parity orbital functions in  $C_{4v}$  group symmetry lowered from  $D_{4h}$  near the surface, we suggest that the SC gap consists of the mixture of  $s$ - and  $p$ -wave SC gap functions in the two-dimensional state.

**10:36AM E28.00012 Superconductivity in Weyl metals** , GRIGORY BEDNIK, ANTON BURKOV, University of Waterloo, ALEXANDER ZYUZIN, University of Basel — We report on a study of intrinsic superconductivity in a Weyl metal. We show that two distinct superconducting states are possible in this system in principle: a zero-momentum pairing BCS state, with point nodes in the gap function; and a finite-momentum FFLO-like state, with a full nodeless gap. We find that, in an inversion-symmetric Weyl metal the odd-parity BCS state has a lower energy than the FFLO state, despite the nodes in the gap. The FFLO state, on the other hand, may have a lower energy in a noncentrosymmetric Weyl metal, in which Weyl nodes of opposite chirality have different energy. We also discuss the anomalous Hall effect in a superconducting Weyl metal and show that it is not affected by the presence of superconductivity at low enough energies, i.e. when the Fermi surfaces is close enough to the nodes.

**10:48AM E28.00013 Topological nodal Cooper pairing in doped Weyl metals<sup>1</sup>** , YI LI, F. D. M. HALDANE, Princeton University — We generalize the concept of Berry connection of the single-electron band structure to the two-particle Cooper pair states between two Fermi surfaces with opposite Chern numbers. Because of underlying Fermi surface topology, the pairing Berry phase acquires non-trivial monopole structure. Consequently, pairing gap functions have the topologically-protected nodal structure as vortices in the momentum space with the total vorticity solely determined by the monopole charge  $q_p$ . The pairing nodes behave as the Weyl-Majorana points of the Bogoliubov-de Gennes pairing Hamiltonian. Their relation with the connection patterns of the surface modes from the Weyl band structure and the Majorana surface modes inside the pairing gap is also discussed. Under the approximation of spherical Fermi surfaces, the pairing symmetry are represented by monopole harmonic functions. The lowest possible pairing channel carries angular momentum number  $j=|q_p|$ , and the corresponding gap functions are holomorphic or anti-holomorphic functions on Fermi surfaces.

## Tuesday, March 15, 2016 8:00AM - 11:00AM —

Session E29 DCMP: Majorana Fermions 328 - Sergey Frolov, University of Pittsburgh

**8:00AM E29.00001 Spinon Majorana fermion** , RUI WANG, HONG-YAN LU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA, BAIGENG WANG, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China, CHIN-SEN TING, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA — A new realization of Majorana fermions is proposed in the frustrated magnets via the topological proximity effect. Specifically, we consider the interface between a topological insulator and a frustrated magnetic material. Using the renormalization group-based mean-field theory, and calculating the self-energy correction due to the topological insulator, we find that the spin texture and the spin-momentum locking of the Dirac cone will be inherited by the spinons in the nearby frustrated magnets. This leads to a particular topological state of matter that supports the Majorana excitation. Unlike the conventional ones, these Majorana fermions are the composite states of spinons and anti-spinons, rather than electrons and holes. They can also participate in the transport of spinons, resulting in nontrivial spin current, while the charge current is completely frozen.

**8:12AM E29.00002 Chiral Majorana Interference in Quantum Anomalous Hall-Superconductor Junctions** , BIAO LIAN, JING WANG, SHOUCHENG ZHANG, Stanford University — We study the interference of the edge chiral Majorana fermions in junctions of quantum anomalous Hall (QAH) insulators and superconductors (SCs). We show the two chiral Majorana fermions on a QAH edge in contact with an SC generically have a momentum difference  $\Delta k$  that depends on the chemical potentials of both the QAH insulator and the SC. Due to the spacial interference induced by  $\Delta k$ , the longitudinal conductance of normal SC/QAH junctions exhibits an oscillation with respect to the edge lengths and the chemical potentials, which can be measured in transport experiments. Further, we show for QAH/chiral topological SC junctions where there is only one edge chiral Majorana fermion, the dynamical fluctuation of the SC phase yields a geometrical correction to the longitudinal conductance usually derived.

**8:24AM E29.00003 Majorana Fermions at the End of Topological Insulator Nanoribbon** , XIONGJUN LIU, YUQIN CHEN, Peking Univ — Majorana zero modes can exist at the end of a 1D  $p$ -wave SC. 1D semiconductor nanowire approximated a  $s$ -wave superconductor is a famous one of those proposals. In which, strong Zeeman field is required to have a large topological region, but unfortunately suppresses superconducting pairing and makes the system more sensitive to disorder. Here we propose a Nanoribbon system made of 2D topological insulator where finite size effect due to the narrow width between two edges plays an important role. A ferromagnetic insulator and an  $s$ -wave superconductor are attached at each edge, respectively. We introduce a low energy effective model to investigate the superconducting phase diagram. And, the disorder effect is studied analytically by using the self-consistent Born approximation (SCBA). Furthermore, realistic numerical calculation is carried out with a tight-binding model. We demonstrate that, strong Zeeman field generates a large topological region, and at the same time enhances superconducting pairing and makes the system more immune to disorder.

**8:36AM E29.00004 Molecular Andreev bound states and Majorana modes in a double dot system**<sup>1</sup>, EDSON VERNEK, JOELSON F. SILVA, Federal University of Uberlândia — Nanostructured systems such as quantum dots (QD) connected to superconductors have attracted a lot of attention in the recent years. One of the well known phenomena in such a system is the formation of a pair of bound states called Andreev bound states (ABS)<sup>2</sup>. Recently, it has been shown that when a QD is coupled to a topological superconductor wire, a Majorana bound state (MBS) leaks from the end of the wire into the dot<sup>3</sup>. The character of these bound states is much richer in structures like molecules and is far from being completely understood. In this work we study a system composed by a two inter-connected QDs in which one of them is coupled to a normal superconductor and to a normal lead while the other is coupled to a topological superconductor and to a distinct normal metallic lead. We show that in the atomic limit (for small interdot coupling), one of the dots has a pair of ABS whereas the other has a single MBS. More interestingly, in the molecular regime (large inter-dot coupling) we observe a localized Majorana mode coexisting with a delocalized molecular ABS.

**8:48AM E29.00005 Coupled wire model of symmetric Majorana surfaces of topological superconductors I: 4-fermion gapping interactions**, SHARMISTHA SAHOO, ZHAO ZHANG, JEFFREY TEO, Univ of Virginia — Time reversal symmetric topological superconductors in three spatial dimensions carry gapless surface Majorana fermions. They are robust against any time reversal symmetric single-body perturbation weaker than the bulk energy gap. We mimic the massless surface Majorana's by coupled wire models in two spatial dimensions. We introduce explicit many-body interwire interactions that preserve time reversal symmetry and give energy gaps to all low energy degrees of freedom. The gapping 4-fermion interactions are constructed by interwire Kac-Moody current backscattering and rely on the fractionalization or conformal embedding of the Majorana wires.

**9:00AM E29.00006 Coupled wire model of symmetric Majorana surfaces of topological superconductors II: 32-fold periodic topological orders**, ZHAO ZHANG, SHARMISTHA SAHOO, JEFFREY TEO, University of Virginia — We mimic the massless surface Majorana's of topological superconductors by coupled wire models in two spatial dimensions, and introduce many-body gapping interactions that preserve time reversal symmetry. Coupling with a  $Z_2$  gauge theory, the symmetric gapped surface generically carries a non-trivial  $G_N$  topological order, where  $N$  is the number of Majorana species and  $G_N$  is some  $SO(r)_1$  or  $SO(3)_3$ -like topological state. These form a 32-fold periodic class  $G_N \cong G_{N+32}$ , and a  $Z_{32}$  relative tensor product structure  $G_{N_1} \otimes_b G_{N_2} \cong G_{N_1+N_2}$  by anyon condensation. We present the anyon structures of these topological states, and understand the topological orders through bulk-boundary correspondence and the Wilson structures on a torus geometry.

**9:12AM E29.00007 Topological Massive Dirac Edge Modes and Long-Range Superconducting Hamiltonians**, OSCAR VIYUELA, Universidad Complutense de Madrid, DAVIDE VODOLA, GUIDO PUPILLO, Universite de Strasbourg and CNRS, MIGUEL ANGEL MARTIN-DELGADO, Universidad Complutense de Madrid — We discover novel topological effects in the one-dimensional Kitaev chain modified by long-range Hamiltonian deformations in the hopping and pairing terms. This class of models display symmetry-protected topological order measured by the Berry phase of the ground state and the winding number of the Hamiltonians. For exponentially-decaying hopping amplitudes, the topological sector can be significantly augmented as the penetration length increases, something experimentally achievable. For power-law decaying superconducting pairings, the massless Majorana modes at the edges get paired together into a massive non-local Dirac fermion localised at both edges of the chain: a new topological quasiparticle that we call topological massive Dirac fermion. This topological phase has fractional topological numbers as a consequence of the long-range couplings. Possible applications to current experimental setups and topological quantum computation are also discussed.

**9:24AM E29.00008 Local and non-local conductance of one-dimensional topological superconductor with Majorana bound states**, ZHI-QIANG BAO, FAN ZHANG, The University of Texas at Dallas — A one-dimensional topological superconductor has a full pairing gap in the bulk and Majorana bound states on the boundary. It is well known that the existence of Majorana bound states enables a quantized resonant local Andreev reflection. Here we find that non-local topological signatures can also be induced by the Majorana bound states in a simple setup, even though the bulk is fully gapped. The non-local conductance, which can even be quantized, depends crucially on the symmetries, the topological index, and the mesoscopic properties of the bulk. Coulomb interactions can further drive the hybrid system into a novel phase, which can be understood by a set of renormalization-group flow equations.

**9:36AM E29.00009 Phase diagrams and transport signatures of Luttinger liquid - Majorana Kramers pair junction.**<sup>1</sup>, ERIKAS GAIDAMAUSKAS, Niels Bohr Institute, University of Copenhagen, DONG E. LIU, Microsoft Research Station Q, YOUNGHYUN KIM, UC Santa Barbara, JENS PAASKE, KARSTEN FLENSBERG, Niels Bohr Institute, University of Copenhagen, ROMAN M. LUTCHYN, Microsoft Research Station Q — Majorana Kramers pairs appearing at the ends of a time reversal invariant topological superconductor lead to a quantized conductance of  $4e^2/2h$  due to perfect Andreev reflection. We study the stability of Andreev reflection fixed point with respect to electron-electron interactions present in the nanowire and calculate the phase diagram for the system. We find that the low energy properties are determined by local or crossed Andreev reflection fixed points. We analyze transport properties of the junction at these fixed points.

<sup>1</sup>Phase diagrams and transport signatures of Luttinger liquid - Majorana Kramers pair junction

**9:48AM E29.00010 A New Infinite-Randomness Fixed Point in an Interacting Majorana Chain**, S VIJAY, LIANG FU, Massachusetts Inst of Tech-MIT — We perform a real-space renormalization group (RG) study of an interacting chain of Majorana fermions with strong randomness. Our theory naturally describes the interacting, disordered edge of a weak topological superconductor in the BDI symmetry class of fermion topological phases. Our RG scheme reveals a new infinite-randomness fixed-point, governed by flow equations for the probability distribution of couplings. A numerical implementation of our real-space RG yields critical exponents governing susceptibilities and correlation functions near the fixed-point.

**10:00AM E29.00011 Topological Phases of Inhomogeneous Superconductivity**, SILAS HOFFMAN, JELENA KLINOVAJA, DANIEL LOSS, University of Basel — We theoretically consider the effect of a spatially periodic modulation of the superconducting order parameter on the formation of Majorana fermions induced by a one-dimensional system with magnetic impurities brought into close proximity to an  $s$ -wave superconductor. When the magnetic exchange energy is larger than the inter-impurity electron hopping we model the effective system as a chain of coupled Shiba states. While in the opposite regime, the effective system is accurately described by a quantum wire model. Upon including a spatially modulated superconducting pairing, we find, for sufficiently large magnetic exchange energy, the system is able to support a single pair of Majorana fermions with one Majorana fermion on the left end of the system and one on the right end. When the modulation of superconductivity is large compared to the magnetic exchange energy, the Shiba chain returns to a trivially gapped regime while the quantum wire enters a new topological phase capable of supporting two pairs of Majorana fermions.

10:12AM E29.00012 ABSTRACT WITHDRAWN —

**10:24AM E29.00013 Kramers pair of Majoranas in contact with a Luttinger Liquid**, DMITRY PIKULIN, University of British Columbia, YASHAR KOMIJANI, University of British Columbia and Rutgers University, IAN AFFLECK, University of British Columbia — I will discuss the signatures of the Kramers pair of Majorana coupled to a quantum wire. I will start from the non-interacting case, showing perfect Andreev process at zero energy — either intrachannel, or interchannel. I will show that turning on the interactions will make one of the Andreev process stable, and another unstable. I will discuss the stability diagram of the fixed points as a function of interactions strength and show that strong enough interactions lead to a non-trivial fixed point.

**10:36AM E29.00014 Superconductor disorder and strong proximity coupling effects in Majorana nanowires<sup>1</sup>**, WILLIAM COLE, JAY SAU, CMTc and JQI, University of Maryland, College Park — Topological superconductivity induced by proximity to a conventional superconductor is only robust against moderate disorder in the parent superconductor, and only when the energy scale of the interface coupling is much smaller than the parent gap. I present detailed calculations of proximity-induced superconductivity in one-dimensional, spin-orbit coupled, semiconductor nanowires when the parent superconductor disorder and interface coupling exceed this limit. This parameter regime is characterized by unique spectroscopic signatures on both sides of the external field tuned topological phase transition.

**10:48AM E29.00015 Disorder-induced topological transitions in multichannel Majorana wires<sup>1</sup>**, INANC ADAGIDELI, BARIS PEKERTEN, AYKUT TEKER, Sabanci University, MICHAEL WIMMER, Delft University of Technology, OZGUR BOZAT, Sabanci University — In this work, we investigate the effect of disorder on the topological properties of multichannel superconductor nanowires. While the standard expectation is that the spectral gap is closed and opened at transitions changing the topological property of the ground state, we show that the closing and opening of a *transport* gap can also cause topological transitions, even in the presence of (localized) states at both sides of the transition. Such transport gaps, induced by disorder, can thus change the topological index, driving a topologically trivial wire into a nontrivial state. We focus on nanowires exhibiting *p*-wave superconductivity as well as Rashba semiconductor nanowires in proximity to a conventional superconductor, and obtain analytical formulas for topological transitions in these wires, valid for generic realizations of disorder, generalizing earlier results. Full tight-binding simulations show excellent agreement with our analytical results without any fitting parameters.

**Session E30 DMP: Topological and Correlation Effects in Oxide Heterostructures** 329 - James Rondinelli, Northwestern University

**8:00AM E30.00001 Design of Mott and topological phases on buckled 3d-oxide honeycomb lattices<sup>1</sup>**, ROSSITZA PENTCHEVA, University Duisburg-Essen — The honeycomb lattice, as realized e.g. in graphene, has rendered a robust platform for innovative science and potential applications. A much richer generalization of this lattice arises in (111)-oriented bilayers of perovskites, adding the complexity of the strongly correlated, multiorbital nature of electrons in transition metal oxides. Based on first principles calculations with an on-site Coulomb repulsion, here we provide trends in the evolution of ground states versus band filling in (111)-oriented  $(\text{LaXO}_3)_2/(\text{LaAlO}_3)_4$  superlattices, with *X* spanning the entire 3d transition metal series. The competition between local quasi-cubic and global triangular symmetry triggers unanticipated broken symmetry phases, with mechanisms ranging from Jahn-Teller distortion, to charge-, spin-, and orbital-ordering.  $\text{LaMnO}_3$  and  $\text{LaCoO}_3$  bilayers, where spin-orbit coupling opens a sizable gap in the Dirac-point Fermi surface, emerge as much desired oxide-based Chern insulators, the latter displaying a gap capable of supporting room-temperature applications [1] Further realizations of the honeycomb lattice and geometry patterns beyond the perovskite structure will be addressed. [1] D. Doennig, S. Baidya, W.E. Pickett and R. Pentcheva, arXiv: 1510.09177.

**8:36AM E30.00002 Topological magnetic phase in  $\text{LaMnO}_3$  (111) bilayer**, YAKUI WENG, XIN HUANG, Southeast University, YUGUI YAO, Beijing Institute of Technology, SHUAI DONG, Southeast University — Candidates for correlated topological insulators, originated from the spin-orbit coupling as well as Hubbard type correlation, are expected in the (111) bilayer of perovskite-structural transition-metal oxides. Based on the first-principles calculation and tight-binding model, the electronic structure of a  $\text{LaMnO}_3$  (111) bilayer sandwiched in  $\text{LaScO}_3$  barriers has been investigated. For the ideal undistorted perovskite structure, the Fermi energy of  $\text{LaMnO}_3$  (111) bilayer just stays at the Dirac point, rendering a semi-metal (graphene-like) which is also a half-metal (different from graphene nor previous studied  $\text{LaNiO}_3$  (111) bilayer). The Dirac cone can be opened by the spin-orbit coupling, giving rise to nontrivial topological bands corresponding to the (quantized) anomalous Hall effect. For the realistic orthorhombic distorted lattice, the Dirac point moves with increasing Hubbard repulsion (or equivalent Jahn-Teller distortion). Finally, a Mott gap opens, establishing a phase boundary between the Mott insulator and topological magnetic insulator. Our calculation finds that the gap opened by spin-orbit coupling is much smaller in the orthorhombic distorted lattice ( $\sim 1.7$  meV) than the undistorted one ( $\sim 11$  meV).

**8:48AM E30.00003 Electronic structure of two dimensional electron gases at the (111) - surface of  $\text{KTaO}_3$  and  $\text{SrTiO}_3$ <sup>1</sup>**, FLAVIO BRUNO, S. MCKEOWN WALKER, A. DE LA TORRE, S. RICCO, A. TAMAI, University of Geneva (Switzerland), Z. WANG, M. SHI, Swiss Light Source, PSI (Switzerland), T. K. KIM, M. HOESCH, Diamond Light Source (United Kingdom), M.S. BAHRAMY, University of Tokyo (Japan), P. D. C. KING, University of St Andrews (United Kingdom), F. BAUMBERGER, University of Geneva (Switzerland) — Doping the band insulators  $\text{KTaO}_3$  (KTO) and  $\text{SrTiO}_3$  (STO) by chemical substitution or by the creation of oxygen defects induces metallicity and even superconductivity at exceptionally low carrier densities. A promising strongly correlated model system emerged when it was discovered that a 2D electron gas (2DEG) can be stabilized in KTO by field effect, and in STO by interfacing with other oxides. These materials also support a similar 2DEG formed by an electron accumulation layer screening positively charged oxygen vacancy defects that are created in the surface by irradiating the samples with photons of appropriate energy. [Adv. Mat. 27, 3894 (2015)] Here, we will report on direct measurements of the 2DEG band structure stabilized on the (111) – surface of KTO and STO using high resolution angle-resolved photoemission (ARPES) [Phys. Rev. Lett. 113, 177601 (2014)]. The differences and similarities between the electronic structure of these two systems in terms of the strong and weak spin orbit coupling found in KTO and STO respectively will be discussed.

**9:00AM E30.00004 Nitride Multilayers as a Platform for Parallel Two-Dimensional Electron-Hole Gases: MgO/ScN(111)** , ANTIA S. BOTANA, Argonne National Lab, VICTOR PARDO, Universidade de Santiago de Compostela, WARREN E. PICKETT, University of California Davis — At interfaces between insulating oxides  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$ , a two dimensional electron gas has been observed and well studied, while the predicted hole gas has not been realized due to the strong tendency of holes in O-2p orbitals to localize. Here we propose, via ab initio calculations, an unexplored class of materials for the realization of parallel two dimensional (2D), two carrier (electron+hole) gases: nitride-oxide heterostructures, with (111)-oriented ScN and MgO as the specific example. Beyond a critical thickness of five ScN layers, this interface hosts spatially separated conducting Sc-3d electrons and N-2p holes, each confined to about two atomic layers— the transition metal nitride provides both gases. A guiding concept is that the  $\text{N}^{3-}$  anion should promote robust two carrier 2D hole conduction compared to that of  $\text{O}^{2-}$ : metal mononitrides are mostly metallic and even superconducting while most metal monoxides are insulating. Our results, provide guidance for new exploration, both experimental and theoretical, on nitride-based conducting gases that should promote study of long sought exotic states viz. new excitonic phases and distinct, nanoscale parallel superconducting nanolayers<sup>[1]</sup>.

**9:12AM E30.00005 Low temperature transport at the {111}  $\text{LaAlO}_3/\text{SrTiO}_3$  interface.**<sup>1</sup> , S. DAVIS, Applied Physics Program, Northwestern University, V. CHANDRASEKHAR, Department of Physics and Astronomy, Northwestern University, Z. HUANG, K. HAN, ARIANDO ., T. VENKATESAN, Department of Physics, National University of Singapore — For the last ten years the interface between epitaxially grown {001}  $\text{LaAlO}_3$  (LAO) and  $\text{SrTiO}_3$  (STO) has provided a rich playground for exotic physics, including a gate-tuned metal to insulator transition, a gate-tuned superconductor-insulator transition, and the coexistence of 2-D superconductivity and magnetism. Recently the interfaces in other orientations of LAO-STO, namely the {110} and {111} orientations, have received increased attention after they were shown to become conducting. The {111} interface is particularly interesting due to its potential for topological effects as well as its complex Fermi surface. Here we present the results of low temperature electrical transport studies along two crystal directions of a {111} LAO-STO interface grown in intermediate oxygen partial pressures via PLD. More specifically we measure the longitudinal resistance as well as the transverse (Hall) resistance to elucidate the difference between the {111} and {001} LAO/STO interfaces.

**9:24AM E30.00006 Anisotropic superconducting properties of nanowires at the  $\text{LaAlO}_3/\text{SrTiO}_3$  (110) interface**<sup>1</sup> , MENGCHEN HUANG, ANIL ANNADI, Univ of Pittsburgh, KALON GOPINADHAN, THIRU-MALAI VENKATESAN, ARIANDO ARIANDO, National University of Singapore, GUANGLEI CHENG, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Quasi-1D nanowires are created using conductive AFM (c-AFM) lithography<sup>2</sup> at the  $\text{LaAlO}_3/\text{SrTiO}_3$  (110) interface along the (001) and (110) crystallographic directions. The superconducting properties of nanowires were investigated under transport measurements with respect to the crystallography and orbital hierarchy. We observe anisotropic superconductivity where the upper critical magnetic field along the (001) and (110) directions are markedly different with a superconducting dome that is shifted for the two orientations as a function of gate voltages. The superconducting dome shift can be explained by anisotropic band structures along the two different directions combined with the Lifshitz transition<sup>3</sup>.

**9:36AM E30.00007 Heteroepitaxially lifting Dirac degeneracy in topological semimetallic perovskite  $\text{SrIrO}_3$**  , JIAN LIU, University of Tennessee - Knoxville — Crystal symmetry-breaking and time-reversal symmetry breaking in epitaxial thin films and heterostructures of the topological semimetallic perovskite  $\text{SrIrO}_3$  were investigated by experimental growth, characterizations and theoretical calculations. Structure refinement on ultrathin films and first-principles calculations show that the symmetry-protected Dirac line nodes in the topological semimetallic perovskite  $\text{SrIrO}_3$  can be lifted simply by applying epitaxial constraints. In particular, the Dirac nodal ring is found to be gapped in epitaxial film structure where the n-glide symmetry of the bulk Pbnm space group is removed while the mirror symmetry is preserved. Our symmetry-breaking analysis shows that the n-glide operation protects the nodal ring and the b-glide operation provides additional protection for a pair of high-symmetry Dirac points of the nodal ring. These symmetry operations can be selectively broken by different epitaxially strained structures, leading to different semimetallic band crossing. Time-reversal symmetry is further investigated under epitaxial confinement by ferromagnetic  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ . The resulted control over the magnetic anisotropy and spin-orbit coupling will be discussed. The results highlight the vital role of symmetry in spin-orbit-coupled correlated oxides.

**9:48AM E30.00008 Tunneling Spectroscopy of Strongly Correlated Electron Liquids in  $\text{SrTiO}_3$**  , PATRICK MARSHALL, EVGENY MIKHEEV, SANTOSH RAGHAVAN, SUSANNE STEMMER, University of California, Santa Barbara — Tunneling spectroscopy is used to probe the electronic structure of the two-dimensional electron liquid confined in  $\text{RTiO}_3/\text{SrTiO}_3/\text{RTiO}_3$  quantum wells ( $R = \text{Gd, Sm}$ ). The conductance spectra of metallic quantum wells exhibit power law behavior at high energies, reflecting the influence of disorder on the density of states. At low energies a pseudogap is observed in quantum wells containing 5 SrO layers and fewer, coinciding with the quantum phase transition in this system. As the quantum well thickness is reduced the DOS around the Fermi level vanishes in quantum wells embedded in  $\text{GdTiO}_3$ , consistent with the metal-insulator transition occurring at thicknesses of 2 SrO layers and fewer. In  $\text{SmTiO}_3$ -embedded quantum wells the metallic state persists down to the lowest thickness and temperature, with the emergence of coherence peaks indicating the onset of an ordered phase in the itinerant state with possible density wave order. The results shed light on the interplay of disorder, electron-electron interactions, and electron-lattice coupling in strongly correlated systems.

**10:00AM E30.00009 Internal Charge Transfer and Quasi-Two Dimensional Electron Gases at  $\text{NdTiO}_3/\text{SrTiO}_3$  interfaces**<sup>1</sup> , PENG XU, Univ of Minnesota - Twin Cities, TIMOTHY C. DROUBAY, Pacific Northwest National Laboratory, JONG SEOK JEONG, K. ANDRE MKHOYAN, Univ of Minnesota - Twin Cities, PETER V. SUSHKO, SCOTT A. CHAMBERS, Pacific Northwest National Laboratory, BHARAT JALAN, Univ of Minnesota - Twin Cities — Two-dimensional (2D) ultra-high carrier densities are of considerable current research interest for novel plasmonic and high charge-gain devices. However, the highest 2D electron density obtained is thus far limited to  $3 \times 10^{14} \text{ cm}^{-2}$  (electron/unit cell/interface) at  $\text{GdTiO}_3/\text{SrTiO}_3$  interfaces, and is typically an order of magnitude lower at  $\text{LaAlO}_3/\text{SrTiO}_3$  interfaces. In this work, we will present detailed study that carrier densities much higher than expected based on resolution of the polar discontinuity at perovskite oxide heterojunctions can be achieved via band engineering and internal charge<sup>[1]</sup>. The  $\text{SrTiO}_3(8 \text{ u.c.})/\text{NdTiO}_3(2 \text{ u.c.})/\text{SrTiO}_3(8 \text{ u.c.})/\text{LSAT}(001)$  heterostructure shows the expected electronic reconstruction behavior starting at  $t = 2 \text{ u.c.}$ , but then exhibits a higher carrier density regime at  $t \geq 6 \text{ u.c.}$  due to additional charge transfer from band alignment. Combining DFT modeling and experiments using x-ray photoelectron spectroscopy, scanning transmission electron microscopy, electron energy loss spectroscopy, energy dispersive x-ray spectroscopy and electronic transport measurements, we will discuss the origin of these carriers, dimensionality and transport mechanisms. [1] Peng Xu, et al. Advanced Material Interface (2015), in press.

**10:12AM E30.00010 One-dimensional Electron Gases at Oxide Interfaces<sup>1</sup>**, YANWEI CAO, Department of Physics, University of Arkansas, Fayetteville, AR 72701, USA, ZHICHENG ZHONG, Institute for Theoretical and Astrophysics, University of Wurzburg, Am Hubland 9704, Wurzburg, Germany, P. SHAFER, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, XIAORAN LIU, M. KAREEV, S. MIDDEY, D. MEYERS, Department of Physics, University of Arkansas, Fayetteville, AR 72701, USA, E. ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, JAK CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, AR 72701, USA — Emergence of two-dimensional electron gases (2DEG) at the oxide interfaces of two dissimilar insulators is a remarkable manifestation of interface engineering. With continuously reduced dimensionality, it arises an interesting question: could one-dimensional electron gases (1DEG) be designed at oxide interfaces? So far there is no report on this. Here, we report on the formation of 1DEG at the carefully engineered titanate heterostructures. Combined resonant soft X-ray linear dichroism with electrical transport and the first-principles calculations have confirmed the formation of 1DEG driven by the interfacial symmetry breaking. Our findings provide a route to engineer new electronic and magnetic states.

**10:24AM E30.00011 Controlled Confinement of Half-metallic 2D Electron Gas in BaTiO<sub>3</sub>/Ba<sub>2</sub>FeReO<sub>6</sub>/BaTiO<sub>3</sub> Heterostructures: A First-principles Study<sup>1</sup>**, TANUSRI SAHA-DASGUPTA, S.N.Bose National Centre for Basic Sciences, Kolkata, SANTU BAIDYA, University of Duisburg-Essen, Duisburg, UMESH WAGHMARE, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore, ARUN PARAMAKANTI, Canadian Institute for Advanced Research, Toronto, Ontario — Using density functional theory calculations, we establish that the half-metallicity of bulk Ba<sub>2</sub>FeReO<sub>6</sub> survives down to 1 nm thickness in BaTiO<sub>3</sub>/Ba<sub>2</sub>FeReO<sub>6</sub>/BaTiO<sub>3</sub> heterostructures grown along the (001) and (111) directions. The confinement of the two-dimensional (2D) electron gas in this quantum well structure arises from the suppressed hybridization between Re/Fe *d* states and unoccupied Ti *d* states, and it is further strengthened by polar fields for the (111) direction. This mechanism, distinct from the polar catastrophe, leads to an order of magnitude stronger confinement of the 2D electron gas than that at the LaAlO<sub>3</sub>/SrTiO<sub>3</sub> interface. We further show low-energy bands of (111) heterostructure display nontrivial topological character. Our work opens up the possibility of realizing ultra-thin spintronic devices.

**10:36AM E30.00012 Electronic and magnetic phenomena at the interface of LaAlO<sub>3</sub> and Ru-doped SrTiO<sub>3</sub>**, MATTHEW GRAY, TED SANDERS, Stanford University, CATHERINE JENKINS, PADRIAC SHAFER, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, YURI SUZUKI, Stanford University — The emergence of a quasi-two dimensional electron gas with hints of magnetic order at the interface between bulk diamagnetic, band gap insulators LaAlO<sub>3</sub> (LAO) and SrTiO<sub>3</sub> (STO) has led to intensive research of this interface. We doped magnetic, isovalent Ru onto the Ti site of the STO side of the interface. 0-10 nm of SrTi<sub>0.98</sub>Ru<sub>0.02</sub>O<sub>3</sub> were deposited on TiO<sub>2</sub> terminated (001) STO single-crystal substrates and then capped with 1-17 nm of LAO. Insertion of more than 7 unit cells of Ru-doped STO at the interface suppresses metallic conductivity with a surprisingly sharp metal-insulator transition. A similar metal-insulator transition is observed when a homoepitaxial STO film is grown before LAO deposition. X-ray Magnetic Circular Dichroism indicated no magnetic ordering of Ti down to 10 K, and electric transport was indistinguishable from that of undoped LAO/STO interfaces. Together our results indicate that ferromagnetism is not intrinsic to the interface, magnetic Ru dopants are not significant sources of scattering, and that cation vacancy formation alone cannot explain the insulating behavior observed in thick homoepitaxial LAO/STO/STO trilayers.

**10:48AM E30.00013 The Superconducting Phase Diagram of LaAlO<sub>3</sub>/SrTiO<sub>3</sub> Interfaces**, STEFANO GARIGLIO, ALEXANDRE FTE, DANFENG LI, WEI LIU, MARGHERITA BOSELLI, DQMP, Univ of Geneva, MARC GABAY, LPS, Univ Paris-Sud, JEAN-MARC TRISCONI, DQMP, Univ of Geneva — The discovery of a two-dimensional electron liquid (2DEL), formed at the interface between the two band insulators LaAlO<sub>3</sub> (LAO) and SrTiO<sub>3</sub> (STO), has generated significant interest. The 2DEL has indeed intriguing electronic properties including superconductivity and spin-orbit interaction which can be tuned both by field-effect. In this talk I will discuss in detail the superconducting phase diagram revealed by field-effect experiments and the consequences of the electric field on the conducting layer extension. I will then compare the superconducting behaviour of this 2D system with the 3D one of doped STO crystals.

Session E31 DCP: Advances in Density Functional Theory III 331 - Neepa Maitra, Hunter College-CUNY

**8:00AM E31.00001 Orbitals and orbital energies in DFT and TDDFT**, EVERT JAN BAERENDS, Vrije Universiteit Amsterdam — The status and meaning of orbitals and orbital energies in the Kohn-Sham one-electron model of DFT has been controversial, in contrast to Hartree-Fock orbitals and orbital energies. We will argue the opposite: the exact Kohn-Sham orbitals of DFT are "better" than HF orbitals and their orbital energies are much closer to ionization energies than HF orbital energies are. This follows from the relation between the KS potential and the wavefunction, which can be cast in the form  $v_s = v_{c,kin} + v_H + v_{xc}^{hole} + v^{resp}$ <sup>1</sup>, where each term depends on the KS orbitals and the wavefunction (the one- or two-particle density matrices). The response potential

$$v^{resp}(r) = \sum_j \frac{|d_j(r)|^2}{\rho(r)} I_j - \sum_i^H \frac{|\psi_{s,i}(r)|^2}{\rho(r)} (-\epsilon_i) \quad (1)$$

( $d_j$  is the Dyson orbital corresponding to ion state  $\Psi_j^{N-1}$ ,  $\psi_{s,i}$  is a Kohn-Sham orbital) enables the connection between ionization energies  $I_i$  and orbital energies  $\epsilon_i$  to be made<sup>2</sup>. For virtual orbitals and orbital energies similar statements can be made: the shapes and energies of the (exact) KS orbitals are much more realistic than those of the Hartree-Fock model or hybrid functionals<sup>3</sup>. The HOMO-LUMO gap in molecules is very close to the optical gap, and very different from the fundamental gap. In solids the situation is very different, which is the well-known "KS gap problem". Again the response potential  $v^{resp}$  (a good approximation to it) helps to solve this problem, affording a straightforward correction method of the KS gap to the fundamental gap<sup>4</sup>.

**8:36AM E31.00002 Revealing Open Quantum Systems with Subsystem DFT**, ALISA KRISHTAL, MICHELE PAVANELLO, Rutgers University - Newark — The traditional quantum chemical methods, wave function or density based, are designed to solve for a closed system, where the Hamiltonian contains all relevant interactions. The closed system is, however, not realistic, as in real life the system is embedded in an environment with which it interacts to some degree. Including the description of the environment at the full quantum mechanical level leads to the Open Quantum Systems (OQS) theory: the only theory which can describe non-Markovian dynamics between the system and the environment. By allowing the flow of information in both directions phenomena such as quantum entanglement, relevant for the design of quantum computers, become available. While most OQS theories rely on the density matrix to describe the system-bath interaction, time-dependent subsystem DFT[1,2] allows to approach the problem using the electron density. Through Dyson-like equations connecting the density-density response kernels of the OQS and its environment, the extent to which non-Markovian dynamics is present can be revealed. We illustrate this for the process of excitation energy transfer in coupled chromophores embedded in explicit solvent. [1] M. Pavanello, *J. Chem. Phys.* 138, 204118 (2013). [2] A. Krishtal et al. *J. Chem Phys.* 142, 154116 (2015).

**8:48AM E31.00003 An Open Source Embedding Code for the Condensed Phase**, ALESSANDRO GENOVA, Rutgers University - Newark, DAVIDE CERESOLI, CNR, ISTM, ALISA KRISHTAL, Rutgers University - Newark, OLIVIERO ANDREUSSI, EPFL, ROBERT DISTASIO, Cornell University, MICHELE PAVANELLO, Rutgers University - Newark — Work from our group [1,2] as well as others [3,4] has shown that for many systems such as molecular aggregates, liquids, and complex layered materials, subsystem Density-Functional Theory (DFT) is capable of immensely reducing the computational cost while providing a better and more intuitive insight into the underlying physics. We developed a massively parallel implementation of Subsystem DFT for the condensed phase [1] into the open-source Quantum ESPRESSO software package. In this talk, we will discuss how we: (1) implemented such a flexible parallel framework aiming at the optimal load balancing; (2) simplified the solution of the electronic structure problem by allowing a fragment specific sampling of the first Brillouin Zone [2]; (3) achieve enormous speedups by solving the electronic structure of each fragment in a unit cell smaller than the supersystem simulation cell, effectively introducing a fragment specific basis set, with no deterioration of the fully periodic simulation. As of March 14, 2016, the code has been released and is available to the public. [1] A. Genova et al., *JCP* 2014, 141, 174101 [2] A. Genova et al., *JPCM* 2015, Accepted [3] S. Lubert, *JCP* 2014, 141, 234110 [4] C. Jacob, et al., *WIREs* 2014, 4, 325

**9:00AM E31.00004 Scaling properties of the kinetic energy density of atoms – towards an orbital-free meta-GGA.**, ANTONIO CANCIO, JEREMY REDD, Ball State University — The scaling properties of atoms, combining periodicity with gradual increase in density, make a fruitful probe of relationships in density functional theory, and have driven advances in understanding the exchange and correlation energy. Although focus is normally upon the properties of integrated energies, insights can be generated from studying energy density functions as well. We visualize the behavior of the positive-definite kinetic energy density (KED) in closed-shell atoms, in comparison to invariant quantities based upon the gradient and Laplacian of the density. The latter are potential variables for constructing orbital-free functionals for the KE and can be used for analyzing the electronic structure of atoms and molecules. We notice a striking fit of the KED within the core of any atom to a gradient expansion model using both the gradient and the Laplacian, but one different from that derived from first principles for a slowly-varying electron gas. Correlated with this feature, we notice unexpected structure to the KED near the nucleus that cannot be explained simply by the von Weizsäcker model, as is often presumed. These unexpected features provide potential insights for developing better orbital-free meta-GGA models for the kinetic energy.

**9:12AM E31.00005 On the transferability of a parametrized kinetic functional for orbital-free density functional theory calculations**, ALEXANDER KARPENKO, LEONARDO ESPINOSA LEAL, MIGUEL CARO, JOUKO LEHTOMAKI, OLGA LOPEZ-ACEVEDO, Aalto Univ — Because of issues with accuracy and transferability of existing orbital-free (OF) density functionals, OF functional development remains an active research area. Due to numerical difficulties, all-electron self-consistent assessment of OF functionals is limited. Using the projector augmented wave method we compute OFDFT all-electron values<sup>1</sup> and we evaluate the performance of a parametrized OF functional for atoms and molecules. We combine the parametrized Thomas-Fermi-Weizsäcker (TF-W) kinetic model  $\lambda$  and  $\gamma$  for the fractions of Weizsäcker and TF functionals, respectively, with LDA for atoms<sup>2</sup>. We found that one-to-one relation between  $\lambda$  and  $\gamma$  values defines a region in parameter space that allows the atomic energies and eigenvalues to be approximated with a small average error with respect to the Kohn-Sham values. The optimum values is however different for every property and for every atom. Recently, these results have been combined to test parameter transferability from atoms to molecules<sup>3</sup> and we expect will help for further systematic improvement of OF density functionals.

**9:24AM E31.00006 Exact Expressions for Exchange-Correlation Potentials** , VIKTOR STAROVEROV, Department of Chemistry, The University of Western Ontario, London, Ontario N6A 5B7 — The Baerends and Staroverov groups have devised various exact expressions for the exchange-correlation potential in terms of wave-function and Kohn–Sham ingredients. We show that all these expressions can be obtained as special cases of one general approach. One particular expression derived by us involves at most the two-electron reduced density matrix and is ideally suited for practical calculations of exchange-correlation potentials from many-electron wave functions, as demonstrated by numerical examples. Interesting identities emerging from our derivation are also presented and discussed.

**10:00AM E31.00007 Stringent test for non-additive, non-interacting, kinetic energy functionals** , KAILI JIANG, JONATHAN NAFZIGER, Department of Physics and Astronomy, Purdue University, ADAM WASSERMAN, Department of Chemistry, Purdue University — Partition Density Functional Theory (PDFT) provides an ideal framework for testing and developing new approximations to the non-additive and non-interacting kinetic energy functional ( $T_s^{nadd}[\{n_\alpha\}]$ ), understood as a functional of the set of fragment ground-state densities. We present our progress on both of these fronts: (1) Systematic comparison of the performance of various existing approximations to  $T_s^{nadd}[\{n_\alpha\}]$ ; and (2) Development of new approximations. We find that a re-parametrization of the GGA enhancement factor employed for the construction of  $T_s^{nadd}[\{n_\alpha\}]$  through the conjointness conjecture captures essential features of the functional derivatives of  $T_s^{nadd}[\{n_\alpha\}]$ . A physically-motivated two-orbital approximation for  $T_s^{nadd}[\{n_\alpha\}]$  is shown to outperform most other approximations for the case of He<sub>2</sub>, and an intriguing one-parameter formula makes this approximation accurate for all noble-gas diatomics.

**10:12AM E31.00008 Partition Theory for Periodic and Semi-Infinite Systems** , KELSIE NIFFENEGGER, ADAM WASSERMAN, Purdue University — Standard approximations to the exchange-correlation (XC) functional of Kohn-Sham Density-Functional Theory are insufficiently accurate to describe charge transfer at metal-atom interfaces and other systems requiring proper treatment of fractional electron charges. The root of the problem is connected to the lack of derivative discontinuities in the approximate XC functionals at integer numbers of electrons. Partition Theory (PT) is a promising, formally exact method to correct this issue. We study the simplest model for an atom adsorbed at a metal surface: A one-dimensional step potential separated a fixed distance from an attractive well that admits only one bound state when isolated. The semi-infinite metal is populated with non-interacting electrons up to the Fermi energy. We derive the PT-equations for this problem and indicate how the associated partition potential can be calculated. PT is also a promising method for improving the computational scaling of other large and/or periodic systems. We study the partition potential for periodic 1-D chains of identical attractive wells and comment on the uniqueness of the partition potential when going from finite to periodic systems.

**10:24AM E31.00009 Petascale orbital-free density functional theory enabled by small-box techniques** , MOHAN CHEN, MAE, Princeton University, Princeton, NJ, 08544, USA, XIANG-WEI JIANG, Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China, HOULONG ZHUANG, MAE, Princeton University, NJ, 08544, USA, LIN-WANG WANG, Materials Science Division, LBNL, CA, 94720, USA, EMILY CARTER, MAE, Program in Applied and Computational Mathematics, and the Andlinger Center for Energy and the Environment, Princeton University, NJ, 08544, USA — Orbital-free density functional theory (OFDFT) is a quantum-mechanics-based method that utilizes electron density as its sole variable. The main computational cost in OFDFT is use of the ubiquitous fast Fourier transform (FFT), which is mainly used to evaluate the kinetic energy density functional (KEDF) and electron-electron Coulomb interaction terms. We design and implement a small-box FFT (SBFFT) algorithm to overcome the parallelization limitations of traditional FFT algorithms. In addition, a real-space truncation of the non-local Wang-Teter KEDF kernel is proposed. The scalability of SBFFT is demonstrated by efficiently simulating one full optimization step (electron density, forces, and stresses) of 1,024,000 lithium (Li) atoms on up to 131,072 cores. Other tests include calculations of physical properties of different phases of bulk Li, geometry optimizations of nanocrystalline Li, and molecular dynamics simulations of liquid Li samples. All of the tests yield excellent accuracy compared to the original OFDFT calculations, suggesting that the OFDFT-SBFFT algorithm opens the door to first-principles simulations of materials containing millions of atoms.

**10:36AM E31.00010 Degenerate Open Shell Density Perturbation Theory** , MARK PALENIK, BRETT DUNLAP, Naval Research Lab — The density perturbation theory (DPT) methodology we have developed applies the Hohenberg-Kohn theorem to perturbations in density functional theory. At each order, the energy is directly minimized with respect to the density at all lower orders. The difference between the perturbed and unperturbed densities is expanded in terms of a finite number of basis functions, and a single matrix inversion in this space reduces the complexity of the problem to that of non-interacting perturbation theory. For open-shell systems with symmetry, however, the situation becomes more complex. Typically, the perturbation will break the symmetry leading to a zeroth-order shift in the Kohn-Sham potential. Because the symmetry breaking is independent of the strength of the perturbation, the mapping from the initial to the perturbed KS potential is discontinuous and techniques from perturbation theory for noninteracting particles fail. We describe a rigorous formulation of DPT for use in systems that display an initial degeneracy, such as atoms and Fe<sub>55</sub>Cp\*<sub>12</sub> clusters and present initial calculations on these systems.

**Session E32 DCP GERA: Emerging Nanomaterials for Solar Energy Conversion II** 332 - Arthur Nozik, NREL

**8:00AM E32.00001 The engineering of quantum dots for efficient solar energy capture<sup>1</sup>** , JEFFREY PIETRYGA, Los Alamos National Laboratory — Over the past decade, exciting advances have been made in the use of semiconductor nanocrystal quantum dots (QDs) for capture of solar energy, including efficient and inexpensive solar cells based on simple, single-component lead chalcogenide QDs. Such devices take advantage of key advantages offered by QDs, including the ability to control bandgap with particle size, and to alter carrier concentrations using surface modification. Remaining essentially untapped, however, is the much larger potential offered by heterostructured QDs to exhibit new functionality that will enable truly unprecedented device performance. In this talk, I will present recent results from our efforts in application-inspired band-structure engineering of heterostructured QDs. Specifically, I will examine how the selective combination of semiconductor materials in a simple core/shell geometry can result in QDs with radically altered properties optimized for use in applications such as carrier-multiplication-enhanced solar cells, and highly efficient luminescent solar concentrators. I will use these examples to demonstrate the general ability of solution-synthesized nanomaterials to contribute to the overall goal of efficient solar energy capture and conversion in a variety of roles.

**8:36AM E32.00002 Are quantum dots spiky balls?** , JAMES SHEPHERD, NADAV GEVA, TROY VAN VOORHIS, Massachusetts Institute of Technology — We here propose an alternative view to the spiky ball picture of passivated quantum dots. By studying the realistic surface morphology of a dot using atomistic molecular dynamics simulations, paying particular attention to the ligand structure, we find that the ligand shell thickness is substantially reduced by van der Waals packing. This affects the ability of the dot ligands to interdigitate. This is discussed in terms of the available experimental data for the superstructure of quantum dot layers, and related back to the electronic properties of quantum dots.

**8:48AM E32.00003 TBA** , ART NOZIK, National Renewable Energy Laboratory — No abstract available.

**9:24AM E32.00004 Photocatalytic Water-Splitting Characteristic of Electric Reduced Black TiO<sub>2</sub> Nanorods<sup>1</sup>**, JONG-WON YUN, Department of Physics and Energy, Univ. of Ulsan, KI YEON RYU, SUNHO KIM, SE-JUNG JANG, Department of Physics, Univ. of Ulsan, YONG SOO KIM, Department of Physics and Energy, Univ. of Ulsan — In various reduction methods of TiO<sub>2</sub>, the electric reduction could apply to anodized TiO<sub>2</sub> nanotube. However, it is not suitable to reduce TiO<sub>2</sub> nanorods(NRs) grown on fluorine doped tin oxide (FTO) substrate using hydrothermal method, because those are easily peeled off due to lattice mismatching between FTO and TiO<sub>2</sub> NRs. In this talk, we will demonstrate electric reduced-black TiO<sub>2</sub> NRs with strong adhesion on FTO substrate for an effective visible photocatalyst. To fabricate the reduced-black TiO<sub>2</sub> NRs, we firstly deposited TiO<sub>2</sub> seed layer on FTO glass using RF-sputtering for mitigating the exfoliation, then grow TiO<sub>2</sub> NRs with hydrothermal method. Finally, TiO<sub>2</sub> NRs were reduced with electric bias. The final reduced-black TiO<sub>2</sub> NRs exhibit a higher photocurrent density, 0.9 mA/cm<sup>2</sup> in comparison with pure-TiO<sub>2</sub> NRs. This result indicates that our reduced-black TiO<sub>2</sub> NRs has lower bandgap with modified valence band position and enhance the surface reactivity with oxygen defect generation.

**9:36AM E32.00005 TBA**, XIAOGANG PENG, Zhejiang University — No abstract available.

**10:12AM E32.00006 High Pressure Synthesis of Rhombohedral Delafossite Structured  $\alpha$ -AgGaO<sub>2</sub>**, MEYSAM AKHTAR, Department of Physics, University of Louisville, MADHU MENON, Center for Computational Sciences, University of Kentucky, MAHENDRA SUNKARA, Conn Center for Renewable Energy Research, University of Louisville, GAMINI SUMANASEKERA, Department of Physics, University of Louisville, ANDRIY DURYGIN, Center for the Study of Matter at Extreme Conditions, Florida International University, JACEK JASINSKI, Conn Center for Renewable Energy Research, University of Louisville — In this work, we demonstrate for the first time the high pressure synthesis of  $\alpha$ -AgGaO<sub>2</sub> via a solid state reaction of Ag<sub>2</sub>O and Ga<sub>2</sub>O<sub>3</sub>. Synthesis experiments were carried out at pressures and temperatures up to 10 GPa and 600 C, respectively, using a resistively-heated diamond anvil cell. Electron diffraction confirmed the rhombohedral delafossite crystal structure of the synthesized AgGaO<sub>2</sub> and its corresponding lattice parameters of  $a = 2.99$  Å and  $c = 18.43$  Å. The vibrational modes analysis was also conducted using a combination of ab initio density functional theory (DFT) and Raman spectroscopy. This analysis yielded good agreement between the calculated Raman-active modes and experimental Raman data. Finally, the application of the GGA +  $U$  formalism-based on DFT to calculate the electronic band structure of  $\alpha$ -AgGaO<sub>2</sub> provided a more realistic theoretical band gap value than those reported previously.

**10:24AM E32.00007 Competitive Adsorption of Carbon Dioxide/Methane in Coal: First-Principles Quantum Mechanical Investigations<sup>1</sup>**, YINGDI LIU, SANWU WANG, Univ of Tulsa — Sequestration of CO<sub>2</sub> into geological formations has been suggested to mitigate the effect of the increasing of the atmospheric CO<sub>2</sub> concentration on global warming. Coalbeds are investigated as one of the attractive storage sites since the cost of CO<sub>2</sub> sequestration can be offset by the enhanced coalbed methane (ECBM) recovery. Extensive experimental studies have been performed for the competitive adsorption of CO<sub>2</sub>/CH<sub>4</sub> into coalbeds. However, the atomic-level understanding for the interaction between the adsorbate (CO<sub>2</sub>/CH<sub>4</sub>) and the adsorbent (coal) has not been fully explored. We report first-principles density-functional calculations for the competitive adsorption between CO<sub>2</sub>/CH<sub>4</sub> in the coal network. In particular, we report results of atomic structures, bonding characteristics, energetics, as well as electronic structures of the CO<sub>2</sub>/CH<sub>4</sub>-coal systems.

<sup>1</sup>This research used the supercomputer resources at NERSC, of XSEDE, at TACC, and at the Tandy Supercomputing Center.

**10:36AM E32.00008 Gentlest Ascent Dynamics for Calculating First Excited State and Exploring Energy Landscape of Kohn-Sham Density Functionals**, CHEN LI, JIANFENG LU, WEITAO YANG, Duke University — We develop the gentlest ascent dynamics (GAD) for Kohn-Sham density functional theory to search for the index-1 saddle points (i.e., the stationary points with one and only one energy descending direction) on the energy landscape of the Kohn-Sham density functionals. These stationary solutions correspond to excited states in the ground state functionals. As shown by various examples, the first excited states of many chemical systems are given by these index-1 saddle points. Our novel approach provides an alternative, more robust way to obtain these excited states, compared with the widely used  $\Delta$ SCF approach. The method can be easily generalized to target higher index saddle points. Our results also reveal the physical interest and relevance of studying the Kohn-Sham energy landscape.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**

**Session E33 DPOLY: Polymer Glass Formation and Stability** 336 - Connie Roth, Emory University

**8:00AM E33.00001 DPOLY SESSION BREAK —**

**8:36AM E33.00002 Theoretical Insights from Facile Microsecond Simulation of the Glass Transition<sup>1</sup>**, JUI-HSIANG HUNG, TARAK PATRA, DAVID SIMMONS, Univ of Akron — Despite more than half a century of research, the fundamental nature of the glass transition remains one of the major open questions in polymer science and condensed matter physics. Molecular dynamics simulations have provided key insights into this problem, but their ability to firmly establish the underlying nature of glass formation have been limited by the extreme computational difficulty of directly probing the deeply supercooled regime most relevant to this process. Here we describe a new protocol for simulation of the glass transition enabling facile access to in-equilibrium segmental relaxation times approaching and exceeding one microsecond — well into the deeply supercooled regime of most glass-forming liquids. Coupled with a well-validated strategy for extrapolation to experimental timescales, this approach provides vastly improved prediction of experimental glass transition temperatures. Here we combine data acquired through this protocol for the deeply supercooled regime of polymeric, inorganic, organic, and metallic glass formers to robustly test several theories of glass formation and identify microscopic phenomenological features shared across all classes of glass-forming liquid in the deeply supercooled regime.

<sup>1</sup>We acknowledge the W. M. Keck Foundation for financial support of this research

**8:48AM E33.00003 Will it form a stable glass? How the stability of vapor deposited glasses depends on molecular structure**, MICHAEL TYLINSKI, MADELEINE BEASLEY, Univ of Wisconsin, Madison, YEONG ZEN CHUA, CHRISTOPH SCHICK, University of Rostock, Germany, MARK EDIGER, Univ of Wisconsin, Madison — Over the past nine years physical vapor deposition has been used to prepare molecular glasses with exceptional properties. When heated, transformation of these highly stable glasses takes orders of magnitude longer than the transformation of liquid-cooled glasses. Until recently, it appeared that most organic molecules could form stable glasses when vapor deposited. We test the generality of stable glass formation by vapor-depositing a wide range of small organic molecules, including hydroxyl, carbonyl, phosphate, aromatic, and aliphatic functional groups. When prepared under conditions expected to yield highly stable glasses, we observe glasses with a wide range of kinetic stabilities, depending on the functional groups in the molecule. In general, alcohols and molecules with long aliphatic chains do not form highly stable glasses while aromatic molecules do. We also test the hypothesis that the surface mobility during deposition determines if a molecule is able to create highly stable glasses.

**9:00AM E33.00004 Kinetics of Dewetting of Ultra-Thin Films of Organic Glasses**, ZAHRA FAKHRAAI, YUE ZHANG, ROBERT RIGGLEMAN, University of Pennsylvania — Physical vapor deposition (PVD) is widely used in manufacturing ultra-thin layers of amorphous organic solids. It is generally assumed that the properties of these ultra-thin films are the same as bulk dynamics. In this work, we demonstrate that these films exhibit a sharp transition from glassy solid to liquid-like behavior with thickness below 30 nm. This liquid-like behavior persists even at temperatures well below the glass transition temperature,  $T_g$ , where bulk properties suggest that the film should be vitrified. The enhanced dynamics in these films can produce large scale morphological features during PVD and lead to dewetting instability in films held at temperatures as low as  $T_g - 35$  K. We measure an effective viscosity of organic glass films by monitoring the dewetting kinetics. These measurements combined with cooling rate-dependent  $T_g$  measurements show that the apparent activation barrier for rearrangement decreases sharply in films thinner than 30 nm. These observations suggest long-range facilitation of dynamics induced by the free surface. These observations can help understand correlated dynamics in glassy systems and elucidate the processes that lead to the formation of exceptionally stable glasses.

**9:12AM E33.00005 Dynamics of Vapor-Deposited Polymer Glasses from Simulation<sup>1</sup>**, WENGANG ZHANG, FRANCIS STARR, Wesleyan University, JACK DOUGLAS, National Institute of Standards and Technology — We use molecular dynamics simulations to mimic the physical vapor deposition of glassy polymer films. Like experiments, the deposition results in "ultrastable glasses" that have lower energies, and greater kinetic stability than ordinary glasses. It has been suggested that these ultrastable glasses may be equivalent to very highly aged ordinary glasses. To explore this possibility, we contrast both the structure and dynamics of deposited and ordinary glasses. Our modeling indicates that the deposited polymer glass is structurally distinct from the ordinary glass due to anisotropy of chain packing. If the deposited glasses correspond to highly aged ordinary glasses, we would expect vastly larger relaxation times for the deposited glass. Instead, we find that relaxation times of the vapor-deposited glass are nearly the same as that of the ordinary glass. These findings do not support the view that vapor-deposited glassy polymer films are equivalent to highly-aged ordinary glassy polymer films. We further study the dynamical heterogeneity of highly out-of-equilibrium polymer films.

**9:24AM E33.00006 Molecular Orientation in Two Component Vapor-Deposited Glasses: Effect of Substrate Temperature and Molecular Shape**, CHARLES POWELL, Department of Chemistry, University of Wisconsin-Madison, JING JIANG, Department of Polymer Science and Engineering, School of Chemistry and Chemical Engineering, Nanjing University, DIANE WALTERS, MARK EDIGER, Department of Chemistry, University of Wisconsin-Madison — Vapor-deposited glasses are widely investigated for use in organic electronics including the emitting layers of OLED devices. These materials, while macroscopically homogenous, have anisotropic packing and molecular orientation. By controlling this orientation, outcoupling efficiency can be increased by aligning the transition dipole moment of the light-emitting molecules parallel to the substrate. Light-emitting molecules are typically dispersed in a host matrix, as such, it is imperative to understand molecular orientation in two-component systems. In this study we examine two-component vapor-deposited films and the orientations of the constituent molecules using spectroscopic ellipsometry, UV-vis and IR spectroscopy. The role of temperature, composition and molecular shape as it effects molecular orientation is examined for mixtures of DSA-Ph in Alq<sub>3</sub> and in TPD. Deposition temperature relative to the glass transition temperature of the two-component mixture is the primary controlling factor for molecular orientation. In mixtures of DSA-Ph in Alq<sub>3</sub>, the linear DSA-Ph has a horizontal orientation at low temperatures and slight vertical orientation maximized at  $0.96T_{g,mixture}$ , analogous to one-component films.

**9:36AM E33.00007 Measuring Surface Diffusion of Organic Glasses Using Tobacco Mosaic Virus as Probe Nanoparticles<sup>1</sup>**, YUE ZHANG, RICHARD POTTER, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania — Recent studies have shown that diffusion on the surface of organic glasses can be many orders of magnitude faster than bulk diffusion, with lower activation barrier. Developing new probes that can readily measure the diffusion at the surface of an organic glass can help study the effect of chemical structure and molecule's size on the enhanced surface diffusion. In this study, surface diffusion coefficient of molecular glass (TPD) is measured using tobacco mosaic virus (TMV) as probe particles. TMV is placed on the surface of bulk TPD films. The evolution of the meniscus formed around TMV, driven by curvature gradient, is probed at various temperatures. TMV has a well-defined cylindrical shape, with a large aspect ratio (18 nm wide, 300 nm long). As such, the shape of the meniscus around the center of TMV is semi-one dimensional. Based on the self-similarity nature of surface diffusion flow in one dimension, the surface diffusion coefficient and its temperature dependence are measured. It is found that the surface diffusion is greatly enhanced and has weak temperature dependence compared to bulk counterpart, consistent with previous studies, showing that TMV probes serve as an efficient method of measuring surface diffusion.

**9:48AM E33.00008 Relationship between Fragility and  $T_g$  Changes on Confinement for Three Cyanurates**, EVELYN LOPEZ, SINDEE L. SIMON, Texas Tech University — The glass transition temperature ( $T_g$ ) is known to deviate from the bulk when subjected to both thin film and nanopore confinement. Previous work from our laboratory has analyzed the effect of nanopore confinement on the  $T_g$  of three materials: a cyanurate trimer, an uncrosslinked polycyanurate, and a polycyanurate network. The results showed that the  $T_g$ s of the three materials decreased under confinement and that with increasing molecular weight and molecular stiffness, the  $T_g$  depression increased. However, recent studies have pointed to fragility, and not stiffness, as a key factor in determining how the materials  $T_g$  will be affected by confinement, with fragile polymers showing greater confinement effects. In this work, we analyze the effect of both nanopore and thin film confinement on  $T_g$  and calculate the fragilities of the three materials to determine the relationship between the two properties. Fragility is calculated from the dependence of  $T_g$  on the cooling rate, with a fast-scanning calorimeter used to extend the range of cooling rates.

**10:00AM E33.00009 Liquid and Glassy Specific Volume Variations in Thin Supported Polystyrene Films**, XINRU HUANG, CONNIE ROTH, Emory University — Studies of density or specific volume in thin films have been previously studied as a possible means of understanding changes in the glass transition temperature  $T_g(h)$  with decreasing film thickness. In the late 1990s, studies reported no change in the glassy, room temperature density of thin films outside of the plus or minus 1 percent experimental error, while more recent studies have claimed large 25-30 percent increases in film density below about 40 nm. In addition, recent theoretical efforts have suggested that  $T_g(h)$  decreases may be associated with small less than 1 percent increases in specific volume of the equilibrium liquid-line. We use ellipsometry to investigate variations in the liquid and glassy specific volume lines for polystyrene films supported on silicon. We observe small, reproducible increases in specific volume of 0.4 plus or minus 0.2 percent for both the liquid and glassy regimes that are uncorrelated with the observed  $T_g(h)$  decrease. Below 20-30 nm, we also observe what appears to be large increases in density that we attribute to breakdown of the assumptions used to derive the Lorentz-Lorenz formula.

**10:12AM E33.00010 Polymer thin films as a route to access low energy glassy states**, DANIELE CANGIALOSI, CSIC, VIRGINIE M BOUCHER, None, ANGEL ALEGRIA, JUAN COLMENERO, UPV — We investigate the enthalpy recovery in the glassy state of stacked polystyrene films with thickness 30 nm. We first show how the equilibrium dynamics and thermodynamics of such films is mainly bulk-like. When studying enthalpy recovery, we find two mechanisms of equilibration: one showing up below 348 K, that is, the films  $T_g$ ; and the second active below 308 K. The latter mechanism appear to have low activation energy and, as a result, gives rise to dramatic decrease of the fictive temperature  $T_f$  within relatively short aging times. This allows to achieve low energy glasses, in particular approaching the Kauzmann temperature ( $T_k$ ), that is, the temperature at which the entropy of the glass equals that of the crystal. The implications of our results are discussed.

**10:24AM E33.00011 Are polymers glassier upon confinement?**, SIMONE NAPOLITANO, JEAN SPIECE, DANIEL E. MARTINEZ-TONG, MICHELE SFERRAZZA, Universite' Libre de Bruxelles (ULB), AURORA NOGALES, Instituto de Estructura de la Materia, CSIC Madrid — Glass forming systems are characterized by a stability against crystallization upon heating and by the easiness with which their liquid phase can be transformed into a solid lacking of long-range order upon cooling (glass forming ability). Here, we discuss on the the thickness dependence of the thermal phase transition temperatures of poly(L-lactide acid) thin films supported onto solid substrates [1]. The determination of the glass transition ( $T_g$ ), cold crystallization ( $T_{CC}$ ) and melting ( $T_m$ ) temperatures down to a thickness of 6 nm via ellipsometry, permitted us to build up parameters describing glass stability and glass forming ability. We observed a strong influence of the film thickness on the latter, while the former is not affected by 1D confinement. Remarkably, the increase in  $T_g/T_m$  ratio, a parameter related to glass forming ability, is not accompanied by an increase in  $T_{CC}-T_g$ , as observed on the contrary, in bulk metallic glasses. We explained this peculiar behavior of soft matter in confinement considering the impact of irreversible adsorption on local free volume content [2]. [1] J. Spiece et al. Soft Matter, 2015,11, 6179-6186 [2] Non-equilibrium Phenomena in Confined Soft Matter, S Napolitano (ed.) Springer, 2015

**10:36AM E33.00012 ENGINEERING THE CRYSTALLINE MORPHOLOGY OF POLYMER THIN FILMS VIA PHYSICAL VAPOR DEPOSITION**, HYUNCHEOL JEONG, CRAIG ARNOLD, RODNEY PRIESTLEY, Princeton University — Thin-film growth via physical vapor deposition (PVD) has been successfully exploited for the delicate control of film structure for molecular and atomic systems. The application of such a high-energetic process to polymeric film growth has been challenged by chemical degradation. However, recent development of Matrix Assisted Pulsed Laser Evaporation (MAPLE) technique opened up a way to deposit a variety of macromolecules in a PVD manner. Here, employing MAPLE technique to the growth of semicrystalline polymer thin films, we show the engineering of crystalline film morphology can be achieved via manipulation of substrate temperature. This is accomplished by exploiting temperature effect on crystallization kinetics of polymers. During the slow film growth crystallization can either be permitted or suppressed, and crystal thickness can be tuned via temperature modulation. In addition, we report that the crystallinity of polymer thin films may be significantly altered with deposition temperature in MAPLE processing. We expect that this ability to manipulate crystallization kinetics during polymeric film growth will open the possibility to engineer structure in thin film polymeric-based devices in ways that are difficult by other means.

**10:48AM E33.00013 Comparing the Bending Stiffness Measurements of Brittle Paper<sup>1</sup>**, ANDREA HALL, MOLLY MCGATH, PATRICIA MCGUIGGAN, Johns Hopkins University — It has been estimated that one third of the paper materials in libraries are too brittle to handle. A typical paper sheet is comprised of semi-rigid cellulose fibers that are more than ten times longer than the sheet thickness and can be considered a two dimensional random fiber network. The main pathways of degradation, acid-catalyzed hydrolysis and oxidation, cause depolymerization of the cellulose chains and breaking of the intrafiber bonds. Conventional mechanical measurements of aged paper are destructive and often too severe to understand the true extent of deterioration. By comparing the roll test, folding endurance tests, tensile tests and stiffness tests of naturally aged papers with varying amounts of brittleness, we intend to show the limits of each test and relate the state of the paper degradation to the mechanical test results.

**8:00AM E34.00001 Fabric variables in dense sheared suspensions**, FARHANG RADJAI, UMI CNRS-MIT, MIT Energy Initiative, Cambridge, MA / LMGC, University of Montpellier, France, LHAASSAN AMARSID, LMGC, University of Montpellier, France, JEAN-YVES DELENNE, IATE, INRA, University of Montpellier, France — The rheology of granular flows and dense suspensions can be described in terms of their effective shear and bulk viscosities as a function of packing fraction. Using stress partition and equivalence between frictional and viscous descriptions in the dense state, we show that the effective viscosities can be expressed in terms of the force-network anisotropy. This is supported by our extensive DEM-LBM simulations for a broad range of inertial and viscous parameters.

**8:36AM E34.00002 Jammed granular cones affect frictional resistive forces at the onset of intrusion<sup>1</sup>**, JEFFREY AGUILAR, School of Mechanical Engineering, Georgia Institute of Technology, DANIEL GOLDMAN, School of Physics, Georgia Institute of Technology — Characterizing the functional form of granular resistive forces has allowed for analysis of the locomotion of animals and robots on and within dry granular media. Resistive force theory (RFT) has been an effective tool in predicting these forces for various locomotive gaits within the "frictional fluid" regime, where intrusions are sufficiently slow such that granular inertial effects are negligible. These forces have been typically described by a linear dependence to submersion depth. However, recent experiments on robotic jumping [Aguilar & Goldman, Nature Physics, 2015] have revealed the importance of considering the nonlinear effects at the onset of intrusion to accurately predict robot kinematics. Particle image velocimetry (PIV) analysis of sidewall grain flow during foot intrusion reveals a jammed granular cone that develops beneath the foot at the onset of intrusion. A geometric model of cone development combined with empirical RFT forces on angled conical surfaces was able to predict the non-linear force trajectory vs. depth for experimental intrusions of various foot sizes, suggesting that intruders experience non-linear frictional forces according to the shape of the granular jamming fronts that form at the onset of movement.

**8:48AM E34.00003 Jammed Clusters and Non-locality in Dense Granular Flows** , PRASHIDHA KHAREL, PIERRE ROGNON<sup>1</sup>, University of Sydney — We investigate the micro-mechanisms underpinning dense granular flow behaviour from a series of DEM simulations of pure shear flows of dry grains. We observe the development of transient clusters of jammed particles within the flow. Typical size of such clusters is found to scale with the inertial number with a power law that is similar to the scaling of shear-rate profile relaxation lengths observed previously<sup>2</sup>. Based on the simple argument that transient clusters of size  $\ell$  exist in the dense flow regime, the formulation of steady state condition for non-homogeneous shear flow results in a general non-local relation, which is similar in form to the non-local relation conjectured for soft glassy flows<sup>3</sup>. These findings suggest the formation of jammed clusters to be the key micro-mechanism underpinning non-local behaviour in dense granular flows.

**9:00AM E34.00004 Velocity profiles and rheology of a granular bed sheared by a fluid flow**<sup>1</sup> , BENJAMIN ALLEN, ARSHAD KUDROLI, Clark University — We discuss an experimental investigation of motion of a granular bed driven by a laminar fluid flow as a function of applied shear rate. This is a model system to investigate a variety of examples where such a situation arises including wind blowing over sand, sediment transport in rivers, slurries, and turbidity currents. We have developed an experimental apparatus which allows examination of the fluid as well as the grain dynamics both at the surface as well as deep into the bed under steady state conditions with refractive index matching technique. This allows us to obtain both the applied local shear stress by the fluid as well as the local strain rate inside the bed. We find that the granular flux as a function of depth decays exponentially into the bed. Further, the velocity profile is observed to exhibit a crossover from a regime where particles are fully suspended to where there is bed load transport. We will discuss the observed velocity and density profiles in light of various models of granular suspensions.

**9:12AM E34.00005 Modeling Shear Banding in Amorphous Solids, from Atomistic to Continuum**<sup>1</sup> , DARIUS ALIX-WILLIAMS, MICHAEL FALK, Johns Hopkins University — Molecular dynamics simulations of strain localization are carried out using different materials systems and interatomic potentials including CuZr modeled via the embedded-atom method (EAM), amorphous Si modeled using Stillinger-Weber (SW) and a binary Lennard-Jones (LJ) system. Quench schedules and strain rates are varied. Different systems exhibit marked similarities in plastic behavior. Systematic differences between systems are analyzed in the context of Shear Transformation Zone (STZ) theory in the effort to develop a generalized constitutive framework for plasticity in glasses. Effective temperature inferred from the potential energy is explored as a local coarse-grained measure of the degree of disorder.

<sup>1</sup>This research is supported by National Science Foundation award 1408685.

**9:24AM E34.00006 Identifying shear transformation zones in amorphous solids via a virtual strain method** , MICHAEL FALK, Johns Hopkins University, SYLVAIN PATINET, ESPCI, Paris, France — One outstanding problem in the mechanical response of amorphous solids is the identification of flow defect sites, so called shear transformation zones (STZs), a priori in the structure. Many methods have been utilized in order to predict local STZ sites including short-range order, soft-mode analysis and machine learning. Here we directly probe local regions of the material via shear in order to detect nearby saddle points that can result in transformations. This non-perturbative method gives excellent correlation with global shear of the system. It also provides a means to cross-correlate the existence of such local transition pathways with other proposed diagnostics such as the soft-spot method of Manning and Liu. We use the information gained by this method to consider the coarse-graining necessary to connect atomistic methods to continuum theories.

**9:36AM E34.00007 Stick-slip instabilities in sheared granular flow: The role of friction and acoustic vibrations** , CHARLES K. C. LIEOU, Los Alamos National Laboratory and University of California, Santa Barbara, AHMED E. ELBANNA, University of Illinois at Urbana-Champaign, JAMES S. LANGER, JEAN M. CARLSON, University of California, Santa Barbara — We propose a theory of shear flow in dense granular materials. A key ingredient of the theory is an effective temperature that determines how the material responds to external driving forces such as shear stresses and vibrations. We show that, within our model, friction between grains produces stick-slip behavior at intermediate shear rates, even if the material is rate strengthening at larger rates. In addition, externally generated acoustic vibrations alter the stick-slip amplitude, or suppress stick-slip altogether, depending on the pressure and shear rate. We construct a phase diagram that indicates the parameter regimes for which stick-slip occurs in the presence and absence of acoustic vibrations of a fixed amplitude and frequency. These results connect the microscopic physics to macroscopic dynamics and thus produce useful information about a variety of granular phenomena, including rupture and slip along earthquake faults, the remote triggering of instabilities, and the control of friction in material processing.

**9:48AM E34.00008 A microstructural description of shear thickening in dense suspensions.** , ABHINENDRA SINGH, Levich Institute, City College of New York, ROMAIN MARI, DAMTP, University of Cambridge, RYOHEI SETO, Mathematical Soft Matter Unit, Okinawa Institute of Science and Technology, JEFF MORRIS, MORTON DENN, Chemical Engineering Department, City College of New York — The mechanism of shear thickening in dense suspensions has been recently linked to a transition from a lubricated “frictionless” to an unlubricated “frictional” rheology. Recent particle simulations have been successful to quantitatively reproduce both the continuous and discontinuous shear thickening as observed experimentally. However, a microstructural description of these suspensions is still lacking, which would aid in understanding and predicting the flow behavior of shear thickening suspensions. To tackle this challenging issue, we explore various microscopic properties, like the inter-particle force distribution, the particle motion correlations, and the anisotropy (in both contact and force network). Further, we also attempt to link the observed rheological behavior observed at the macro scale to mean displacement and fluctuations at the particle scale.

**10:00AM E34.00009 Deformation in Metallic Glass: Connecting Atoms to Continua**<sup>1</sup> , ADAM R. HINKLE<sup>2</sup>, MICHAEL L. FALK, Johns Hopkins University, CHRIS H. RYCROFT, Harvard University, MICHAEL D. SHIELDS, Johns Hopkins University — Metallic glasses like other amorphous solids experience strain localization as the primary mode of failure. However, the development of continuum constitutive laws which provide a quantitative description of disorder and mechanical deformation remains an open challenge. Recent progress has shown the necessity of accurately capturing fluctuations in material structure, in particular the statistical changes in potential energy of the atomic constituents during the non-equilibrium process of applied shear. Here we directly cross-compare molecular dynamics shear simulations of a ZrCu glass with continuum shear transformation zone (STZ) theory representations. We present preliminary results for a methodology to coarse-grain detailed molecular dynamics data with the goal of initializing a continuum representation in the STZ theory.

**10:12AM E34.00010 Size effects and internal length scales in the elasticity of random fiber networks.** , CATALIN PICU, Rensselaer Polytechnic Institute, KAMEL BERKACHE, EPSTA Alger, Algeria, ALI SHAHSAVARI, Rensselaer Polytechnic Institute, JEAN-FRANCOIS GANGHOFFER, Universite de Lorraine, Nancy, France — Random fiber networks are the structural element of many biological and man-made materials, including connective tissue, various consumer products and packaging materials. In all cases of practical interest the scale at which the material is used and the scale of the fiber diameter or the mean segment length of the network are separated by several orders of magnitude. This precludes solving boundary value problems defined on the scale of the application while resolving every fiber in the system, and mandates the development of continuum equivalent models. To this end, we study the intrinsic geometric and mechanical length scales of the network and the size effect associated with them. We consider both Cauchy and micropolar continuum models and calibrate them based on the discrete network behavior. We develop a method to predict the characteristic length scales of the problem and the minimum size of a representative element of the network based on network structural parameters and on fiber properties.

**10:24AM E34.00011 Is the microscopic stress computed from molecular simulations in mechanical equilibrium?** , ALEJANDRO TORRES-SANCHEZ, Universitat Politcnica de Catalunya, JUAN M. VANEGAS, Sandia National Laboratories, MARINO ARROYO, Universitat Politcnica de Catalunya — The microscopic stress field connects atomistic simulations with the mechanics of materials at the nano-scale through statistical mechanics. However, its definition remains ambiguous. In a recent work [1,2] we showed that this is not only a theoretical problem, but rather that it greatly affects local stress calculations from molecular simulations. We find that popular definitions of the local stress, which are continuously being employed to understand the mechanics of various systems at the nanoscale, violate the continuum statements of mechanical equilibrium. We exemplify these facts in local stress calculations of defective graphene, lipid bilayers, and fibrous proteins. Furthermore, we propose [1,3] a new physical and sound definition of the microscopic stress that satisfies the continuum equations of balance, irrespective of the many-body nature of the inter-atomic potential. Thus, our proposal provides an unambiguous link between discrete-particle models and continuum mechanics at the nanoscale. [1] Torres-Sanchez, A; Vanegas, J. M.; Arroyo, M.; Phys. Rev. Lett. 114, 258102 (2015). [2] Vanegas, J. M.; Torres-Sanchez, A; Arroyo, M.; J. Chem. Theor. Comput., 10 (2), 691702 (2014). [3] Torres-Sanchez, A; Vanegas, J. M.; Arroyo, M.; Submitted to J. Mech. Phys. Solid

**10:36AM E34.00012 Extending two-phase theories of soft composite solids to the non-dilute regime<sup>1</sup>** , FRANCESCO MANCARELLA, Nordic Institute of Theoretical Physics (NORDITA), ROBERT STYLE, University of Oxford, JOHN WETT-LAUFER, Yale University and Nordic Institute of Theoretical Physics (NORDITA) — Composite materials are ubiquitous in the natural environment and in engineered materials and hence capture the interest of a wide audience. Eshelby's 1957 theory treats the interaction of macroscopic stress fields with isolated inclusions within an elastic solid, and it has been widely used to treat the mechanics of composite materials. However, due to its neglect of interface stress, which is a particularly key effect in soft materials, the theory breaks down whenever the typical inclusion size  $R$  is of order or less than the elastocapillary lengthscale  $L$ . In this regime, under external stress, the effect of inclusion shape becomes strongly size-dependent. Here, we develop two new non-dilute theories, estimate the elastic moduli of composites comprised of an isotropic, compressible, linear-elastic compliant solid hosting a non-dilute spatially-random distribution of identical liquid droplets. The composite stiffness depends on a single dimensionless parameter  $L/R$ , and we find significant elastic moduli corrections for inclusions sizes  $R$  as large as  $100 L$ . By generalizing the exact theory recently developed for the corresponding dilute case, we find that when  $R < 3L/2$  ( $R = 3L/2$ ) liquid inclusions stiffen (cloak the far-field signature of) of the host solid.

**10:48AM E34.00013 Continuum modeling of dense granular flow down heaps** , DAVID HENANN, DAREN LIU, Brown University — Dense, dry granular flows display many manifestations of grain-size dependence, or nonlocality, in which the finite-size of grains has an observable impact on flow phenomenology. Such behaviors make the formulation of an accurate continuum model for dense granular flow particularly difficult, since local continuum models are not equipped to describe size-effects. One example of grain-size dependence is seen when avalanches occur on a granular heap – a situation which is frequently encountered in industry, as in rotating drums, as well as in nature, such as in landslides. In this case, flow separates into a thin, quickly flowing surface layer and a slowly creeping bulk. While existing local granular flow models are capable of capturing aspects of the flowing surface layer, they fail to even predict the existence of creeping flow beneath, much less being able to quantitatively describe the flow fields. Recently, we have proposed a new, scale-dependent continuum model – the nonlocal granular fluidity (NGF) model – that successfully predicted steady, slow granular flow fields, including grain-size-dependent shear-band widths in a variety of flow configurations. In this talk, we extend our model to the rapid flow regime and show that the model is capable of quantitatively predicting all aspects of gravity-driven heap flow. In particular, the model predicts the coexistence of a rapidly flowing, rate-dependent top surface layer and a rate-independent, slowly creeping bulk – a feature which is beyond local continuum approaches.

**8:00AM E35.00001 A non-classical phase diagram for virus-bacterial co-evolution mediated by CRISPR.** , PU HAN, MICHAEL DEEM, Rice University — CRISPR is a newly discovered prokaryotic immune system. Bacteria and archaea with this system incorporate genetic material from invading viruses into their genomes, providing protection against future infection by similar viruses. Due to the cost of CRISPR, bacteria can lose the acquired immunity. We will show an intriguing phase diagram of the virus extinction probability, which when the rate of losing the acquired immunity is small, is more complex than that of the classic predator-prey model. As the CRISPR incorporates genetic material, viruses are under pressure to evolve to escape the recognition by CRISPR, and this co-evolution leads to a non-trivial phase structure that cannot be explained by the classical predator-prey model.

**8:12AM E35.00002 Bacterial Invasion Dynamics in Zebrafish Gut Microbial Communities** , SAVANNAH LOGAN, MATTHEW JEMIELITA, Department of Physics, University of Oregon, TRAVIS WILES, Institute of Molecular Biology, University of Oregon, BRANDON SCHLOMANN, Department of Physics, University of Oregon, BRIAN HAMMER, School of Biology, Georgia Institute of Technology, KAREN GUILLEMIN, Institute of Molecular Biology, University of Oregon, RAGHUVeer PARTHASARATHY, Department of Physics, University of Oregon — Microbial communities residing in the vertebrate intestine play an important role in host development and health. These communities must be in part shaped by interactions between microbial species as they compete for resources in a physically constrained system. To better understand these interactions, we use light sheet microscopy and zebrafish as a model organism to image established gut microbial communities as they are invaded by robustly-colonizing challengers. We demonstrate that features of the challenger, including motility and spatial distribution, impact success in invasion and in outcompeting the original community. We also show that physical characteristics of the host, such as the motility of the gut, play important roles in mediating inter-species competition. Finally, we examine the influence of the contact-dependent type VI secretion system (T6SS), which is used by specific bacteria to cause cell lysis by injecting toxic effector proteins into competitors. Our findings provide insights into the determinants of microbial success in the complex ecosystems found in the gut.

**8:24AM E35.00003 Multiple Cancer Cell Population Dynamics in a Complex Ecology** , KE-CHIH LIN, Princeton University, GONZALO TARGA, KENNETH PIENTA, Johns Hopkins Medical Institute, JAMES STURM, ROBERT AUSTIN, Princeton University — We have developed a technology for study of complex ecology cancer population dynamics. The technology includes complex drug gradients, full bright field/dark field/fluorescence imaging of areas of several square millimeters and thin gas-permeable membranes which allow single cell extraction and analysis. We will present results of studies of prostate cancer cell dynamics.

**8:36AM E35.00004 Migration in asymmetric, random environments** , MICHAEL DEEM, DONG WANG, Rice University — Migration is a key mechanism for expansion of communities. As a population migrates, it experiences a changing environment. In heterogeneous environments, rapid adaption is key to the evolutionary success of the population. In the case of human migration, environmental heterogeneity is naturally asymmetric in the North-South and East-West directions. We here consider migration in random, asymmetric, modularly correlated environments. Knowledge about the environment determines the fitness of each individual. We find that the speed of migration is proportional to the inverse of environmental change, and in particular we find that North-South migration rates are lower than East-West migration rates. Fast communication within the population of pieces of knowledge between individuals, similar to horizontal gene transfer in genetic systems, can help to spread beneficial knowledge among individuals. We show that increased modularity of the relation between knowledge and fitness enhances the rate of evolution. We investigate the relation between optimal information exchange rate and modularity of the dependence of fitness on knowledge. These results for the dependence of migration rate on heterogeneity, asymmetry, and modularity are consistent with existing archaeological facts.

**8:48AM E35.00005 Velocity locking and pulsed invasions of fragmented habitats with seasonal growth** , KIRILL KOROLEV, CHING-HAO WANG, Boston University — From crystal growth to epidemics, spatial spreading is a common mechanism of change in nature. Typically, spreading results from two processes: growth and dispersal in ecology or chemical reactions and diffusion in physics. These two processes combine to produce a reaction-diffusion wave, an invasion front advancing at a constant velocity. We show that the properties of these waves are remarkably different depending whether space and time are continuous, as they are for a chemical reaction, or discrete, as they are for a pest invading a patchy habitat in seasonal climates. For discrete space and time, we report a new type of expansions with velocities that can lock into specific values and become insensitive to changes in dispersal and growth, i.e. the dependence of the velocity on model parameters exhibits plateaus or pauses. As a result, the evolution and response to perturbations in locked expansions can be markedly different compared to the expectations based on continuous models. The phenomenon of velocity locking requires cooperative growth and does not occur when per capita growth rate decline monotonically with population density. We obtain both numerical and analytical results describing highly non-analytic properties of locked expansions.

**9:00AM E35.00006 Spatial organization of cooperation.** , NICOLAS DESPRAT, LPS - Ecole Normale Supérieure (Paris) — The structure of the environment spatially confines bacteria inside groups where they live and evolve with their siblings. This population structure may not only select for individual abilities but also for group properties that would eventually enhance the fitness of the colony. In poor media, we might think that maximizing the contact with the environment would maximize the fitness of individual cells. However, we will show that the microcolony of *P. aeruginosa* adapts its morphogenesis to maximize cell-cell contacts rather than cell-environment interactions when iron becomes scarce in the environment. In this case, reducing the surface of exchange with the environment allows to limit the loss of secreted molecules required to efficiently fetch extracellular iron at very low concentration.

**9:36AM E35.00007 Non-equilibrium relaxation in a two-dimensional stochastic lattice Lotka-Volterra model<sup>1</sup>** , SHENG CHEN, UWE C. TÄUBER, Department of Physics, Virginia Tech — We employ Monte Carlo simulations to study a stochastic Lotka-Volterra model on a two-dimensional square lattice with periodic boundary conditions. There are stable states when the predators and prey coexist. If the local prey carrying capacity is finite, there emerges an extinction threshold for the predator population at a critical value of the predation rate. We investigate the non-equilibrium relaxation of the predator density in the vicinity of this critical point. The expected power law dependence between the relaxation time and predation rate is observed (critical slowing down). The numerically determined associated critical exponents are in accord with the directed percolation universality class. Following a sudden predation rate change to its critical value, one observes critical aging for the predator density autocorrelation function with a universal scaling exponent. This aging scaling signature of the absorbing state phase transition emerges at significantly earlier times than stationary critical power laws, and could thus serve as an advanced indicator of the population's proximity to its extinction threshold.

**9:48AM E35.00008 The effects of sudden changes in environmental conditions on the non-equilibrium relaxation of ecological systems<sup>1</sup>** , SHADI ESMAEILI, MICHEL PLEIMLING, Virginia Tech — We study the responses of predator-prey systems to temporary changes in environmental conditions. Such changes can cause a variation in species' predatory preferences which in our model appears as a perturbation in a many-species system. The type of perturbation that we consider in this study is a sudden change in the interaction scheme. We focus on systems evolving on a two-dimensional lattice and discuss the way the systems transition from one steady state to another. Using Monte Carlo simulations we monitor these transitions via the space-time correlation function and the derived correlation length.

<sup>1</sup>This work is supported by the US National Science Foundation through grant DMR-1205309.

**10:00AM E35.00009 Effect of flow and active mixing on bacterial growth in a colon-like geometry** , JONAS CREMER, IGOR SEGOTA, MARKUS ARNOLDINI, ALEX GROISMAN, TERENCE HWA, Department of Physics, U.C. San Diego — The large intestine harbors bacteria from hundreds of species, with bacterial densities reaching up to  $10^{12}$  cells per gram. Many different factors influence bacterial growth dynamics and thus bacterial density and microbiota composition. One dominant force is flow which can in principle lead to a washout of bacteria from the proximal colon. Active mixing by contractions of the colonic wall together with bacterial growth might counteract such flow-forces and allow high bacterial densities to occur. As a step towards understanding bacterial growth in the presence of mixing and flow, we constructed an in-vitro setup where controlled wall-deformations of a channel emulate contractions. We investigate growth along the channel under a steady nutrient inflow. In the limits of no or very frequent contractions, the device behaves like a plug-flow reactor and a chemostat respectively. Depending on mixing and flow, we observe varying spatial gradients in bacterial density along the channel. Active mixing by deformations of the channel wall is shown to be crucial in maintaining a steady-state bacterial population in the presence of flow. The growth-dynamics is quantitatively captured by a simple mathematical model, with the effect of mixing described by an effective diffusion term.

**10:12AM E35.00010 Predicting community composition from pairwise interactions**, JONATHAN FRIEDMAN, Physics, MIT, LOGAN HIGGINS, Microbiology, MIT, JEFF GORE, Physics, MIT — The ability to predict the structure of complex, multispecies communities is crucial for understanding the impact of species extinction and invasion on natural communities, as well as for engineering novel, synthetic communities. Communities are often modeled using phenomenological models, such as the classical generalized Lotka-Volterra (gLV) model. While a lot of our intuition comes from such models, their predictive power has rarely been tested experimentally. To directly assess the predictive power of this approach, we constructed synthetic communities comprised of up to 8 soil bacteria. We measured the outcome of competition between all species pairs, and used these measurements to predict the composition of communities composed of more than 2 species. The pairwise competitions resulted in a diverse set of outcomes, including coexistence, exclusion, and bistability, and displayed evidence for both interference and facilitation. Most pair outcomes could be captured by the gLV framework, and the composition of multispecies communities could be predicted for communities composed solely of such pairs. Our results demonstrate the predictive ability and utility of simple phenomenology, which enables accurate predictions in the absence of mechanistic details.

**10:24AM E35.00011 A field-theoretic approach to the May-Leonard cyclic population dynamics model**, SHANNON SERRAO, UWE TÄUBER, Virginia Tech — Spatially extended stochastic population dynamics models with cyclic predation interactions display intriguing time evolution and spontaneous structure formation. We study a version of the May-Leonard cyclic competition model in  $d$  dimensions with diffusive particle propagation. We use the second-quantized Doi-Peliti formalism and ensuing coherent-state path integral representation to construct its continuum representation and explore its collective dynamics. Expanding the resulting action about the mean-field species concentrations enables us to compute the diagonalized harmonic propagators and hence 'masses', i.e., relaxation rates and eigenfrequencies of the fundamental modes. Furthermore, operating near the Hopf bifurcation point, we identify the validity range for the necessary time scale separation that allows us to project out the purely relaxing eigenmode. The remaining oscillating fields obey the complex Ginzburg-Landau equation, which is consistent with spiral pattern formation.

**10:36AM E35.00012 Range expansions transition from pulled to pushed waves with increasing cooperativity in an experimental microbial population**, SAURABH GANDHI, EUGENE YURTSEV, Massachusetts Inst of Tech-MIT, KIRILL KOROLEV, Boston University, JEFF GORE, Massachusetts Inst of Tech-MIT — Range expansions are becoming more frequent due to environmental changes and rare long distance dispersal, often facilitated by anthropogenic activities. Simple models in theoretical ecology explain many emergent properties of range expansions, such as a constant expansion velocity, in terms of organism-level properties such as growth and dispersal rates. Testing these quantitative predictions in natural populations is difficult because of large environmental variability. Here, we used a controlled microbial model system to study range expansions of populations with and without intra-specific cooperativity. For non-cooperative growth, the expansion dynamics were dominated by population growth at the low-density front, which pulled the expansion forward. We found these expansions to be in close quantitative agreement with the classical theory of pulled waves by Fisher and Skellam, suitably adapted to our experimental system. However, as cooperativity increased, the expansions transitioned to being pushed, i.e. controlled by growth in the bulk as well as in the front. Although both pulled and pushed waves expand at a constant velocity and appear otherwise similar, their distinct dynamics leads to very different evolutionary consequences. Given the prevalence of cooperative growth in nature, understanding the effects of cooperativity is essential to managing invading species and understanding their evolution.

**10:48AM E35.00013 Selection of Cooperation in Spatially Structured Populations**, HYUNMO YANG, Ulsan National Institute of Science and Technology, CHEOL-MIN GHIM, Biomedical Engineering, Ulsan National Institute of Science and Technology — The social dilemma games give rise to an emergence of cooperation in which altruistic individuals survive the natural selection at higher rate than random chance. We try to extend our understanding of this spatial reciprocity by including the impact of degree-degree correlation on the propensity toward prosocial behaviour in an otherwise well-mixed population. In a stochastic death-birth process with weak selection, we find that the disassortative degree mixing, or negative correlation between the degrees of neighbouring nodes significantly promotes the fixation of cooperators whereas the assortative mixing acts to suppress it. This is consistent with the fact that the spatial heterogeneity weakens the average tendency of a population to cooperate, which we describe in a unified scheme of the effective isothermality in coarse-grained networks. We also discuss the individual-level incentives that indirectly foster restructuring the social networks toward the more cooperative topologies.

**Session E36 GSOF: Colloids: Assembly, Mechanics and Techniques** 339 - Daniel Blair, Georgetown University

**8:00AM E36.00001 Fluid to solid transition of hard regular polygons**, JOSHUA ANDERSON, Univ of Michigan - Ann Arbor, MICHAEL ENGEL, JAMES ANTONAGLIA, ANDRES MILLAN, SHARON GLOTZER, University of Michigan — We perform simulations of hard regular polygons and determine the nature of the fluid to solid transition. Hard disks have a first order phase transition from fluid to hexatic and a continuous transition from hexatic to solid [1,2]. Hard polygons have shape and an additional degree of freedom. Directional entropic forces cause the polygons to attract edge to edge, which alters the phase transition. Polygons with enough edges have phase behavior similar to hard disks, with the density of the transition shifted lower. Polygons with few edges show a range of different behaviors. We develop and use HPMC [3] to run these simulations on the Titan supercomputer at the OLCF. HPMC is a scalable GPU-accelerated hard particle Monte Carlo simulation engine built on top of HOOMD-blue. Rrgang, S. C. Glotzer, arxiv:1509.04692

**8:12AM E36.00002 Shape Sensitive Assembly and Colloidal Superball Phase Transitions**, VISHAL SONI, University of Chicago, LAURA ROSSI, DOUGLAS J. ASHTON, Utrecht University, DAVID J. PINE, New York University, ALBERT P. PHILIPSE, Utrecht University, PAUL M. CHAIKIN, New York University, MARJOLEIN DIJKSTRA, Utrecht University, STEFANO SACANNA, New York University, WILLIAM T. M. IRVINE, University of Chicago — Guiding the self-assembly of materials by controlling the shape of the individual particle constituents is a powerful approach to material design. In particular the assembly of colloidal particles driven by depletants is a versatile playground for investigating this potential. We find that colloidal superballs may assemble into distinct phases that depend on both their shape and the size of the depletants. By using a mixture of depletants, one of which is size-tunable, we can explore reversible transitions between these phases.

**8:24AM E36.00003 Heaps of Shapes: Flow-Stabilized Solids with Non-Spherical Colloids**, SCOTT LINDAUER, North Carolina State University, C. WYATT SHIELDS IV, GABRIEL P. LOPEZ, Duke University, KAREN E. DANIELS, ROBERT RIEHN, North Carolina State University — Flow-stabilized solids are a class of fragile matter that are formed when a dense suspension of hard colloids is accumulated against a semipermeable barrier. We build a microfluidic device to confine Brownian particles in a quasi-2D channel; a controlled flow rate above a critical value forms flow-stabilized solids against the barrier. We extend prior work on submicron spherical particles, to particles of size 2-5 microns, and of various shapes: circular, rectangular, hexagonal, and triangular prisms. We perform experiments on these flow-stabilized solids to observe the angle of repose, packing fraction, and orientational order as a function of flow rate. We vary the flow rate quasi-statically in order to conduct the experiment at steady state. We find a critical flow rate below which no pile forms. In general, particles with less-circular shape form more stable heaps.

**8:36AM E36.00004 Digital Alchemy for Materials Design: Colloids and Beyond**, GREG VAN ANDERS, DAPHNE KLOTSAS, ANDREW KARAS, PAUL DODD, SHARON GLOTZER, University of Michigan — Starting with the early alchemists, a holy grail of science has been to make desired materials by manipulating basic building blocks. Building blocks that show promise for assembling new complex materials can be synthesized at the nanoscale with attributes that would astonish the ancient alchemists in their versatility. However, this versatility means that connecting building-block attributes to bulk structure is both necessary for rationally engineering materials and difficult because building block attributes can be altered in many ways. We show how to exploit the malleability of colloidal nanoparticle elements to quantitatively link building-block attributes to bulk structure through a statistical thermodynamic framework we term digital alchemy. We use this framework to optimize building blocks for a given target structure and to determine which building-block attributes are most important to control for self-assembly, through a set of novel thermodynamic response functions. We thereby establish direct links between the attributes of colloidal building blocks and the bulk structures they form. Moreover, our results give concrete solutions to the more general conceptual challenge of optimizing emergent behaviors in nature and can be applied to other types of matter.

**8:48AM E36.00005 Shaping Crystal-Crystal Phase Transitions**, XIYU DU, GREG VAN ANDERS, JULIA DSHE-MUCHADSE, SHARON GLOTZER, Univ of Michigan - Ann Arbor — Previous computational and experimental studies have shown self-assembled structure depends strongly on building block shape. New synthesis techniques have led to building blocks with reconfigurable shape and it has been demonstrated that building block reconfiguration can induce bulk structural reconfiguration. However, we do not understand systematically how this transition happens as a function of building block shape. Using a recently developed digital alchemy[1] framework, we study the thermodynamics of shape-driven crystal-crystal transitions. We find examples of shape-driven bulk reconfiguration that are accompanied by first-order phase transitions, and bulk reconfiguration that occurs without any thermodynamic phase transition. Our results suggest that for well-chosen shapes and structures, there exist facile means of bulk reconfiguration, and that shape-driven bulk reconfiguration provides a viable mechanism for developing functional materials. [1] G. van Anders, D. Klotsa, A. S. Karas, P. M. Dodd, and S. C. Glotzer, ACS Nano, 9, 9542 (2015).

**9:00AM E36.00006 Discontinuous Shear Thickening using Boundary Stress Microscopy**, VIKRAM RATHEE, DANIEL BLAIR, JEFFERY URBACH, Georgetown Univ — The microscopic picture of particle chain formation in discontinuous shear thickening suspensions remains unclear. In order to identify the role of localized stresses arising from particle chains we have applied the technique of Boundary Stress Microscopy to shear thickening suspension. By imaging deformations of an elastic boundary of the sheared suspension, we observe the appearance of localized forces on elastic substrate above critical stress value. These forces possibly arise from particles forming local network under shear. At the onset of thickening, we observe a change in first normal stress difference from negative to positive, inferring frictional contacts. However, the localized forces are only evident when the viscosity increases by an order of magnitude.

**9:12AM E36.00007 Viscosity of Sheared Helical filament Suspensions**, MATTHEW SARTUCCI, JEFF URBACH, DAN BLAIR, Georgetown University, WALTER SCHWENGER, Brandeis University — The viscosity of suspensions can be dramatically affected by high aspect ratio particles. Understanding these systems provides insight into key biological functions and can be manipulated for many technological applications. In this talk, the viscosity as a function of shear rate of suspensions of helical filaments is compared to that of suspensions of straight rod-like filaments. Our goal is to determine the impact of filament geometry on low volume fraction colloidal suspensions in order to identify strategies for altering viscosity with minimal volume fraction. In this research, the detached flagella of the bacteria *Salmonella Typhimurium* are used as a model system of helical filaments and compared to mutated straight flagella of the *Salmonella*. We compare rheological measurements of the suspension viscosity in response to shear flow and use a combination of the rheology and fluorescence microscopy to identify the microstructural changes responsible for the observed rheological response.

**9:24AM E36.00008 Holographic Characterization of Imperfect Spheres**, MARK HANNEL, CHRISTINE MIDDLETON, DAVID GRIER, New York University — Holographic snapshots of colloidal spheres can be fit to Lorenz-Mie theory, yielding the radius, refractive index and position of individual colloids in situ. This procedure assumes that the scatterer is a uniformly dense ideal sphere. Via experimentation and simulation, we demonstrate that small deviations from ideal sphericity produce palatable errors (approximately 1%) in our estimation of the particle's physical properties.

**9:36AM E36.00009 Thermo-responsive cross-linked liquid crystal bowl-shaped colloids<sup>1</sup>**, WEI-SHAO WEI, University of Pennsylvania, Department of Physics and Astronomy, YU XIA, SHU YANG, University of Pennsylvania, Department of Materials Science and Engineering, A. G. YODH, University of Pennsylvania, Department of Physics and Astronomy — In this work we create and investigate cross-linked bowl-shaped nematic liquid crystal (NLC) colloidal particles. Janus colloids are first formed via solvent-induced phase separation in emulsions consisting of NLC monomers and isotropic polymers. This scheme enables us to realize different particle morphologies such as bowl-shape by fine-tuning the confinement of NLCs within the droplets, e.g. by varying the size of droplets, the volume ratio between NLC and polymer, and the type/concentration of surfactants in aqueous background phase. The NLC compartment is composed of RM82 (1,4-Bis-[4-(6-acryloyloxyhexyloxy)benzoyloxy]-2-methylbenzene) monomers, which are then photocrosslinked by dithiol groups to form nematic liquid crystal elastomer. Finally, we remove the polymer parts of Janus colloids to obtain the target structures, which are temperature sensitive due to change of elasticity and molecular alignment of NLC near the isotropic to nematic phase transition temperature. We will explore novel mechanical and optical properties from the thermo-responsive structures as well as their applications, such as biomimic swimming behaviors and adjustable lensing effects.

**9:48AM E36.00010 Simulating Electrophoresis with Discrete Charge and Drag<sup>1</sup>**, AARON J. MOWITZ, THOMAS A. WITTEN, University of Chicago — A charged asymmetric rigid cluster of colloidal particles in saline solution can respond in exotic ways to an electric field: it may spin or move transversely. These distinctive motions arise from the drag force of the neutralizing countercharge surrounding the cluster. Because of this drag, calculating the motion of arbitrary asymmetric objects with nonuniform charge is impractical by conventional methods. Here we present a new method of simulating electrophoresis, in which we replace the continuous object and the surrounding countercharge with discrete point-draggers, called Stokeslets. The balance of forces imposes a linear, self-consistent relation among the drag and Coulomb forces on the Stokeslets, which allows us to easily determine the object's motion via matrix inversion. By explicitly enforcing charge+countercharge neutrality, the simulation recovers the distinctive features of electrophoretic motion to few-percent accuracy using as few as 1000 Stokeslets. In particular, for uniformly charged objects, we observe the characteristic Smoluchowski independence of mobility on object size and shape. We then discuss electrophoretic motion of asymmetric objects, where our simulation method is particularly advantageous.

**10:00AM E36.00011 Dielectrophoresis force of colloidal nanoparticles<sup>1</sup>**, HAO HUANG, Department of Chemical and Biomolecular Engineering, Lehigh University, DANIEL OU-YANG, Department of Physics, Lehigh University — Dielectrophoresis (DEP) is the motion of a polarizable colloidal particle in a nonuniform electric field. The magnitude of the DEP force is known to be proportional to the gradient of  $E^2$ . The DEP force also depends on the relative polarizability of the particle to that of the surrounding medium. Due to its ease of use, DEP has been proposed for a variety of applications to manipulate colloidal particles in a microfluidic setting. However, accurate measurements of the DEP force on colloidal nanoparticles are lacking. A new method is proposed to measure accurately the DEP potential force of colloidal nanoparticles by using confocal fluorescence imaging to determine the density distributions of dilute colloidal nanoparticle in a DEP potential force field. The DEP potential field can be calculated from the particle density distributions since the spatial distribution of the particle number density follows the Boltzmann distribution of the DEP potential energy. The validity of the measured DEP force is tested by examining the force as a function of the E field strength and particle size. The classic MaxwellWagnerOKonski is found to be inadequate to fully describe the frequency dependence of the DEP force.

**10:12AM E36.00012 Extremely Small and Incredibly Fast Microscopy: 1 nm and 10 us dynamics in concentrated colloidal suspensions**, BRIAN LEAHY, MATTHEW BIERBAUM, Cornell Univ, ALEXANDER ALEMI, Disney Research, ITAI COHEN, JAMES SETHNA, Cornell Univ — Recently we developed PERI, a technique for locating colloidal sphere's positions and radii to within 1 nm from ordinary light microscopy images. PERI provides unprecedented access to the physics of colloidal suspensions at small length scales. We use this for high precision measurements of the pair-correlation function  $g(r)$  and colloidal interactions at 1-nm distances. Finally, we couple PERI with high-speed brightfield light microscopy to examine fast dynamics of concentrated suspensions.

**10:24AM E36.00013 Confocal light microscopy at 1 nm: Locating colloids at maximum resolution**, MATTHEW BIERBAUM, BRIAN D. LEAHY, ALEXANDER A. ALEMI, ITAI COHEN, JAMES P. SETHNA, Cornell University — We present PERI, a method to locate colloidal spheres at the information theoretic limit using a generative model for confocal microscope images. Without modification to the microscope we resolve positions and radii to 1 nm, which we verify with experimental data. Employing Monte Carlo techniques, we recover the probability distributions for all particle positions and radii, microscope point spread function, laser intensity fluctuation, scan parameters, and signal to noise ratio in a single fit. Using this technique we explore precision measurements of dense colloidal suspensions including standard quantities such as mean squared displacement and the pair correlation function.

**10:36AM E36.00014 Dissecting diffusive and advective motion in colloidal sedimentation by multi-speckle Ultra-Small-Angle XPCS**, JOHANNES MLLER, THEYENCHERI NARAYANAN, ESRF - The European Synchrotron — In colloidal suspensions internal or external fields can induce directed motions of particles in addition to Brownian diffusion. Here, gradients in temperature or chemical potential, shear flow as well as gravity can act as an external field. Examples for internal motions can be found in synthetic self-propelling particles and microorganisms, generally coined as active matter. We present multi-speckle X-ray photon correlation spectroscopy measurements in the Ultra-Small-Angle scattering range which probes an expanded length scale comparable to DLS and optical microscopy. To demonstrate the advanced capabilities, we show measurements probing the motions within a settling suspension of sub-micron sized silica particles. A global fitting procedure has been applied to separate the diffusive and advective contributions to the particle dynamics. With this, macroscopic parameters such as the sedimentation velocity can be probed on a microscopic level in highly opaque and concentrated systems, which are in general difficult to access for optical investigations. This procedure may prove its value for investigating various kinds of non-equilibrium systems.

**10:48AM E36.00015 Enthalpy versus Entropy: the Thermodynamic Origin of Hard Particle Ordering<sup>1</sup>**, MITCHELL ANTHAMATTEN, SHAW CHEN, JANE OU, JEFFREY WEINFELD, University of Rochester, DEPARTMENT OF CHEMICAL ENGINEERING TEAM — The topic of hard particle ordering transitions is important in the development of molecular to mesoscale materials with potential applications in biomedicine, catalysis, optoelectronics, and renewable energy. The first step toward deterministic materials design rests on understanding the thermodynamic nature of ordering transitions involving two phases in equilibrium. We apply classical thermodynamics to show that (i) first-order, hard particle ordering transitions are forbidden at constant volume; and that (ii) hard-particle ordering is driven by a loss in enthalpy through volume reduction that outweighs a concomitant entropy loss upon ordering. The traditional approach considers minimization of Helmholtz energy, at constant volume, whereas the current study exclusively focuses on equilibrium phase transitions and, therefore, targets minimization of Gibbs energy at constant pressure. The Gibbs energy platform offers physically intuitive interpretations consistent with existing computation and experiments. The prevalent idea of entropy-driven ordering at constant V is restricted to transitions from non-equilibrium initial states that have yet to be properly defined for quantification.

**Session E37 GSOFD DPOLY: Self and Directed Assembly (Equilibrium and Non-Equilibrium)**

340 - Kazem Edmond, Oxford University

**8:00AM E37.00001 Phase Behavior of Thermodynamically Small Clusters of Colloidal Particles**, RAGHURAM THYAGARAJAN, DIMITRIOS MAROUDAS, DAVID FORD, Univ of Mass - Amherst — The self-assembly of finite clusters of colloidal particles into crystalline objects is a topic of technological interest, as a route to produce photonic crystals and other metamaterials. Such assembly problems also are fundamentally interesting because they involve thermodynamically small systems, with number of particles between 10 and 1000 that is far below the bulk limit. In contrast to bulk systems, these colloidal assemblies exhibit phase coexistence over a finite range of physical conditions. Here, we report the results of a computational study of phase behavior of small colloidal clusters interacting via the Asakura-Oosawa depletion pair potential. We conducted Monte Carlo simulations for various levels of the osmotic pressure that controls the strength of the interparticle interactions, using potential energy histograms to identify distinct phases. Over a narrow but finite range of the osmotic pressure, we find bimodal distributions in the potential energy space that are indicative of coexistence between fluid-like and crystalline configurations. We also report systematic quantitative comparisons of the phase behavior observed here with results from a Fokker-Planck order-parameter approach.

### 8:12AM E37.00002 Two-dimensional self-assembly of DNA-functionalized gold nanoparticles<sup>1</sup>

, WENJIE WANG, HONGHU ZHANG, NOAH HAGEN, Ames Laboratory and Iowa State University, IVAN KUZMENKO, Argonne National Laboratory, MUFIT AKINC, ALEX TRAVESSET, SURYA MALLAPRAGADA, DAVID VAKNIN, Ames Laboratory and Iowa State University — 2D superlattices of nanoparticles (NPs) are promising candidates for nano-devices. It is still challenging to develop a simple yet efficient protocol to assemble NPs in a controlled manner. Here, we report on formation of 2D Gibbs monolayers of single-stranded DNA-coated gold nanoparticles (ssDNA-AuNPs) at the air-water interface by manipulation of salts contents. MgCl<sub>2</sub> and CaCl<sub>2</sub> in solutions facilitate the accumulation of the non-complementary ssDNA-AuNPs on aqueous surfaces. Grazing-incidence small-angle X-ray scattering (GISAXS) and X-ray reflectivity show that the surface AuNPs assembly forms a mono-particle layer and undergoes a transformation from short-range to long-range (hexagonal) order above a threshold of [MgCl<sub>2</sub>] or [CaCl<sub>2</sub>]. For solutions that include two kinds of ssDNA-AuNPs with complementary base-pairing, the surface AuNPs form a thicker film and only in-plane short-range order is observed. By using other salts (NaCl or LaCl<sub>3</sub>) at concentrations of similar ionic strength to those of MgCl<sub>2</sub> or CaCl<sub>2</sub>, we find that surface adsorbed NPs lack any orders. X-ray fluorescence measurements provide direct evidence of surface enrichment of AuNPs and divalent ions (Ca<sup>2+</sup>).

### 8:24AM E37.00003 Novel liquid crystal phase transition of linear defects in an epitaxial layer of DNA-nanoparticle superlattices<sup>1</sup>

, SAIJIE PAN, NIELS BOON, MONICA OLVERA DE LA CRUZ, Northwestern Univ — We use Monte Carlo simulations and mean-field theory to study a lattice model system in which DNA-coated nanoparticles form an epitaxial layer onto a patterned bcc (100) template. If nanoparticles only attach to the so-called “center” sites, each of which is the center of a unit cell in the square lattice template, it would result in a perfect bcc epitaxial layer. However, defects arise due to attachment to “edge” sites and “corner” sites. In simulation, we show that edge-binding defects prefer to form linear clusters in horizontal and vertical directions. These linear defects can undergo a second-order isotropic-nematic phase transition in some regimes. A mean-field approach is introduced to provide theoretical descriptions for the system in each of the phases and predict the critical phase transition conditions. Striking agreement is observed between the theory and simulation.

### 8:36AM E37.00004 Transformations and Reconstructions of DNA-directed colloidal crystals

, JOHN CROCKER, YIFAN WANG, IAN JENKINS, TALID SINNO, University of Pennsylvania — DNA is a versatile tool for directing the equilibrium self-assembly of nanoscopic and microscopic objects, but also for subsequently transforming them into new structures. In experiment, at high densities of long grafted DNA strands, and temperatures where the binding is reversible, these systems readily form colloidal crystals and colloidal clusters having a range of symmetries. For interactions that favor alloying between two differently-sized colloidal species, our experimental observations compare favorably to a simulation framework that predicts the equilibrium phase behavior, growth kinetics and solid-solid transitions. Overall, we find that this system recapitulates both ionic crystals and noble-metal alloys. We will discuss the crystallography of the alloy structures formed as well as the interesting Martensitic-type transformations and super-lattice reconstructions they undergo.

### 8:48AM E37.00005 Bioinspired Composites with Spatial and Orientational Control of Reinforcement<sup>1</sup>

, AHMET DEMIROERS, ANDRE STUDART, ETH Zurich, COMPLEX MATERIALS TEAM — Living organisms combine soft and hard components to fabricate composite materials with out-standing mechanical properties. The optimum design and assembly of the anisotropic components reinforce the material in specific directions against multidirectional external loads. Although nature does it quite readily, it is still a challenge for material scientists to control the orientation and position of the colloidal components in a matrix. Here, we use external electric and magnetic fields to achieve positional and orientational control over colloid-polymer composites to fabricate mechanically robust materials to capture some of the essential features of natural systems. We first investigated the assembly of spherical micron-sized colloids using dielectrophoresis, as these particles provided an easily accessible and instructive length scale for performing initial experiments. We used dielectrophoresis for spatial control of reinforcing anisotropic components and magnetic fields to provide control over the orientation of these reinforcing constituents. The obtained composites with different orientational and spatial reinforcement showed enhanced mechanical properties, such as wear resistance, which exhibits similarities to tooth enamel.

### 9:00AM E37.00006 Harmonic and Anharmonic Free Energies in Superlattices of Soft Particle Systems<sup>1</sup>

, ALEX TRAVESSET, Iowa State Univ and Ames lab, CARLES CALERO, Center for Polymer Studies and Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, MA 02215, USA, CHRIS KNOROWSKI, Iowa State Univ and Ames lab — Many problems in self and directed assembly rely on the rigorous calculation of free energies. In systems of nanoparticles with capping ligands, for example, superlattices are found in closely competing structures, such as hcp/fcc, cubic/hexagonal diamond or those isomorphic between MgCu<sub>2</sub> and MgZn<sub>2</sub>. With this motivation, we investigate a general method to calculate free energy of crystalline solids by considering the harmonic approximation and quasistatically switching the anharmonic contribution. The advantage of the method is that the harmonic approximation provides an already very accurate estimate of the free energy, and therefore the anharmonic term is numerically very small and can be determined to very high accuracy. We further show that the anharmonic contribution to the free energy satisfies a number of exact inequalities that place constraints on its magnitude and allows approximate but fast and accurate estimates. We apply it to Lennard Jones systems where we demonstrate that hcp is the equilibrium phase at low temperature and pressure and obtain the coexistence curve with the fcc phase, which exhibits reentrant behavior and binary systems that model nanoparticle superlattices with hydrocarbon capping ligand.

<sup>1</sup>The research was performed at the Ames Laboratory, which is operated for the US DOE by Iowa State University under contract number DE-AC02-07CH11358

### 9:12AM E37.00007 Designing self-assembling 3D structures of microcapsules

, LIKE LI, HENRY SHUM, OLEG SHKLYAEV, VICTOR YASHIN, ANNA BALAZS, University of Pittsburgh — Self-assembly of complex, three-dimensional structures is commonly achieved by biological cells but difficult to realize in synthetic systems with micron-scale or larger components. Some previous modeling studies have considered only the planar self-assembly of microcapsules on a substrate. In this work, nanoparticles released from the capsules bind to the substrate and to the shells of nearby capsules. The non-uniform nanoparticle deposition on a capsule's surface leads to adhesion gradients, which drive the capsules to effectively “climb” on top of one another and self-organize in the vertical direction. We determine conditions that favor this structural organization. In particular, we study how the vertical structuring depends on the background fluid flow, the topography of the microcapsules and the underlying surface, the capsule-capsule interaction and that between the capsules and the substrate. The findings can provide design rules for the autonomous creation of novel nanocomposites, where the layers are formed from nanoparticle-containing and nanoparticle-decorated microcapsules.

**9:24AM E37.00008 Stripes or Checkerboards: Distinguishing Patterns of Self-Assembled Water Drops to Chiral Structures**, LAURA ADAMS, Harvard, SAM OCKO, Stanford University, DAVID WEITZ, Harvard — A robust route for the biased production of single-handed chiral structures has been found in generating non-spherical, multi-component double emulsions, drops within drops, using glass microfluidic devices. Driving the minimization of surface energy are capillary forces that cause linear chains of encapsulated water drops to self-assemble into three-dimensional configurations with a well-defined preference to one type of handedness; thus, breaking left-right symmetry. In two dimensions, the encapsulated drops form patterns of stripes or checkerboards that are captured with a high speed camera. We quantify the dynamics of the evolving structures by measuring the second moment of the mass distribution and their growth and evolution rates. These new self-assembled soft structures are highly stable and open the door for a wide range of exotic configurations.

**9:36AM E37.00009 Bias-free simulation of diffusion-limited aggregation on a square lattice**, YEN LEE LOH, Univ of North Dakota — We identify sources of systematic error in traditional simulations of the Witten-Sander model of diffusion-limited aggregation (DLA) on a square lattice. Based on semi-analytic solutions of the walk-to-line and walk-to-square first-passage problems, we develop an algorithm that reduces the simulation bias to below  $10^{-12}$ . We grow clusters of  $10^8$  particles on  $65536 \times 65536$  lattices. We verify that lattice DLA clusters inevitably grow into anisotropic shapes, dictated by the anisotropy of the aggregation process. We verify that the fractal dimension evolves from the continuum DLA value,  $D = 1.71$ , for small disk-shaped clusters, towards Kesten's bound of  $D = 3/2$  for highly anisotropic clusters with long protruding arms.

**9:48AM E37.00010 The role of symmetry for the orientational ordering of hard regular polygons**, WENBO SHEN, Department of Physics, University of Michigan - Ann Arbor, MICHAEL ENGEL, JOSHUA A. ANDERSON, Department of Chemical Engineering, University of Michigan - Ann Arbor, JAMES A. ANTONAGLIA, Department of Physics, University of Michigan - Ann Arbor, SHARON C. GLOTZER, Department of Chemical Engineering, University of Michigan - Ann Arbor, GLOTZER GROUP TEAM — Understanding the relationship between particle shape and structure is critical for targeted self-assembly. Hard particles, whose phase behavior is governed by geometry alone, spontaneously order when compressed to high enough packing density. Different routes of ordering have been suggested: a direct transition from fluid to crystal as well as the appearance of an intermediate liquid crystalline or a rotator phase. Here, we investigate a family of hard shapes in two dimensions that interpolate from highly anisotropy to highly circular. For this purpose, we determine the phase behavior of hard regular polygons from triangles to dodecagons at densities comprising the development of orientational order. In particular, we focus on the role of particle symmetry on rotational motion and the appearance of rotator phases.

**10:00AM E37.00011 Shape Allophiles Improve Entropic Assembly<sup>1</sup>**, ERIC HARPER, RYAN MARSON, JOSHUA ANDERSON, GREG VAN ANDERS, SHARON GLOTZER, Univ of Michigan - Ann Arbor — We investigate a class of “shape allophiles” that fit together like puzzle pieces as a method to access and stabilize desired structures by controlling directional entropic forces. Squares are cut into rectangular halves, which are shaped in an allophilic manner with the goal of re-assembling the squares while self-assembling the square lattice. We examine the assembly characteristics of this system via the potential of mean force and torque, and the fraction of particles that entropically bind. We generalize our findings and apply them to self-assemble triangles into a square lattice via allophilic shaping. Through these studies we show how shape allophiles can be useful in assembling and stabilizing desired phases with appropriate allophilic design. [1] Harper, et. al., Soft Matter, 2015, 11, 7250-7256. DOI: 10.1039/C5SM90160J. This work was featured on the cover of Soft Matter 07 October, 2015.

**10:12AM E37.00012 Molecular Dynamics Investigation of the Products of Alkoxysilane Condensation: Bulk Gels and Surface Coatings**, ROLAND FALLER, JOSHUA DEETZ, UC Davis — We characterize silica gels and organo-silicon surface coatings using reactive molecular dynamics simulations. To model the chemical reactions, we use a reactive force field (ReaxFF) which we have optimized in a novel parallelized semi-automatic way to model hydrolysis and condensation reactions. The morphologies of silica gels obtained from tetra- and tri-alkoxysilanes are determined by allowing the system to condense while simultaneously removing water and replacing it with precursor solution. It is found that the gels obtained from trialkoxysilanes are more loosely bonded, and that the chemistry of the headgroup is important to the gel morphology. We furthermore simulated the chemisorption of alkoxysilanes with organic headgroups to hydroxylated silica surfaces. We observe a competition between alkoxysilanes condensing with themselves or with the silica surface.

**10:24AM E37.00013 Multiscale Self-Assembly of Quantum-Dots into an Anisotropic Three-Dimensional Random Network**, SERIM ILDAY, Bilkent University & METU, FATIH ILDAY, Bilkent University, RENE HBNER, Helmholtz-Zentrum Dresden-Rossendorf, TY PROSA, ISABELLE MARTIN, CAMECA Instruments Inc, GIZEM NOGAY, METU, ISMAIL KABACELIK, Akdeniz University, ZOLTAN MICS, MISCHA BONN, DMITRY TURCHINOVICH, Max Planck Institute for Polymer Research, HANDE STNEL, METU, DANIELE TOFFOLI, Università di Trieste, DAVID FRIEDRICH, BERND SCHMIDT, KARL-HEINZ HEINIG, Helmholtz-Zentrum Dresden-Rossendorf, RASIT TURAN, METU — Multiscale self-assembly is ubiquitous in nature but its deliberate use to synthesise multifunctional materials remains rare, partly due to the notoriously difficult problem of controlling topology from atomic to macroscopic scales to obtain properties by design. Here, we demonstrate an anisotropic random network of silicon quantum-dots that hierarchically self-assembles from the atomic to the microscopic scales: First, quantum-dots form, to subsequently interconnect without inflating their diameters to form a random network. This network then grows in a preferential direction to form undulated and branching nanowire-like structures. This specific topology allows simultaneous good electrical conduction and a tuneable bandgap. These scale-dependent features were previously thought to be mutually exclusive. Furthermore, we show that the topology is designed and self-assembled following an inherently modular, material-independent methodology, so that the approach is applicable to achieve programmable properties in other materials.

**10:36AM E37.00014 Experimental Investigations of Ionic Self-Assembly of Silica Nanoparticles**, GILLENHAAL BECK, SABIN NISHIMYUMUKIZA, MOHAMMAD ABUDAYYEH, REBECCA MELKERSON, ESTEVAN HALL-MEJIA, IRINA MAZILU, DAN MAZILU, Washington & Lee University — We present a novel experimental method for determining the rate at which anionic silica nanoparticles in a colloidal suspension are adsorbed to a cationic polymer on a glass substrate. This method allows us to study particle self-assembly at time scales under one tenth of a second, two orders of magnitude smaller than previously reported in literature. We compare our experimental findings with a class of stochastic models for cooperative sequential adsorption of particles.

**10:48AM E37.00015 Programmable concatenation of conductively linked gold nanorods using molecular assembly and femtosecond irradiation**, JAKE FONTANA, STEVE FLOM, JAWAD NACIRI, BANAHALLI RATNA, Naval Research Laboratory — The ability to tune the resonant frequency in plasmonic nanostructures is fundamental to developing novel optical properties and ensuing materials. Recent theoretical insights show that the plasmon resonance can be exquisitely controlled through the conductive concatenation of plasmonic nanoparticles. Furthermore these charge transfer systems may mimic complex and hard to build nanostructures[1]. Here we experimentally demonstrate a directed molecular assembly approach to controllably concatenate gold nanorods end to end into discrete linear structures, bridged with gold nanojunctions, using femtosecond laser light. By utilizing high throughput and nanometer resolution this approach offers a pragmatic assembly strategy for charge transfer plasmonic systems. [1] J. Fontana and B. R. Ratna, Applied Physics Letters **105** (2014)

**8:00AM E38.00001 Statistical Mechanics and Hydrodynamics of Self-Propelled Hard Disks**, BENJAMIN HANCOCK, APARNA BASKARAN, Brandeis University — Active particle fluids have constant energy production and dissipation at the level of its constituent particles. Yet, despite its out-of-equilibrium nature, analogies have been drawn between the steady state behavior of active fluids and their passive fluid counterparts. While most of the studies have been phenomenological or numerical, in this talk we present a first systematic derivation of the statistical mechanics and hydrodynamics of self propelled hard disks in particular we focus on two results. First, a dynamical instability signaling the onset of phase separation and cluster formation is derived and compared to existing phenomenological and kinetic estimates. Second, a leading order contribution to the pressure due to particle interactions is derived and compared with simulations of active brownian particles.

**8:12AM E38.00002 Reversible Ratchet Effects and Structural Ordering for Self-Propelled Disks on Quasi-One Dimensional Asymmetric Substrates**, DANIELLE MCDERMOTT, Wabash College, CYNTHIA REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory, Theoretical Division — When a particle is placed in an asymmetric periodic potential and an ac driving force is applied, it is possible to produce a net dc flow through a ratchet effect. When the particles are active, a net dc particle flow can arise even in the absence of external driving, creating an active ratchet effect as has been observed for bacteria in funnel geometries. Here we examine a 2D assembly of self-propelled disks interacting with an asymmetric 1D substrate. We find that at low density, with few particle collisions, this system exhibits a robust ratchet effect in which the particles undergo a net drift in the easy direction of the substrate asymmetry. At higher densities where particle-particle interactions become important, a reversed ratchet effect can arise with the net flow of particles in the hard direction. These reversals occur due to the formation of commensurate chain-like structures of disks. When there are two or more chains of particles in a one substrate well, the effective substrate potential is inverted. This reversible active ratchet effect could be used to separate different species of particles, cause the shepherding of passive particles, or control the migration of micro-organisms, and should be general to a wide class of self driven interacting particle systems.

**8:24AM E38.00003 Melting a crystal of self-propelled particles**, CHRISTOPHER OLSON, MICHAEL MULLER, LEE WALSH, NARAYANAN MENON, Univ. of Massachusetts Amherst — We experimentally study the kinetics of melting a two-dimensional non-cohesive crystal of hard, square-shaped millimeter-scale particles. Interactions between the square particles have four-fold rotational symmetry, but particles are designed with features such that when vibrated their predominant motion is polar along one body axis. We prepare the initial crystalline state with varying orientations of the particle polarity relative to the symmetry axes of the crystal. We then study the melting of this crystal when vertical vibrations are turned on. Orientational and translational order are initially strongly coupled, and during melting translational order is lost before orientational order. The spatial distribution of order parameters and the time scale for melting kinetics is strongly affected by compatibility between the polarity and the crystal axes in the initial condition.

**8:36AM E38.00004 Magnetic properties of self propelled particles**, MELISSA FERRARI, MICHELLE DRISCOLL, New York University, JEREMIE PALACCI, University of California, San Diego, STEFANO SACANNA, DAVID PINE, PAUL CHAIKIN, New York University — We study a class of synthetic light-activated colloidal swimmers which self propel osmotically/phoretically close to a surface and self organize into dynamic clusters. Swimming is activated by a photocatalytic hematite cube exposed from the colloidal surface. Hematite is a canted antiferromagnet, with a permanent magnetic moment; the magnetic moment is oriented in a discrete number of directions relative to the exposed hematite face. The permanent moment allows us to orient and direct the swimmers motion with an applied magnetic field, and different field configurations allow for a large range of directed motion. Furthermore, the various orientations of the magnetic moment give rise to distinct species of swimmers, which can simultaneously undergo clockwise and counterclockwise orbits in a rotating magnetic field.

**8:48AM E38.00005 Guiding catalytically active particles with chemically patterned surfaces**, WILLIAM USPAL, MIHAIL POPESCU, SIEGFRIED DIETRICH, MYKOLA TASINKEVYCH, Max-Planck-Institut für Intelligente Systeme and IV. Institut für Theoretische Physik, Universität Stuttgart — Catalytically active Janus particles in solution create gradients in the chemical composition of the solution along their surfaces, as well as along any nearby container walls. The former leads to self-phoresis, while the latter gives rise to chemi-osmosis, providing an additional contribution to self-motility. Chemi-osmosis strongly depends on the molecular interactions between the diffusing chemical species and the wall. We show analytically, using an approximate “point-particle” approach, that by chemically patterning a planar substrate (e.g., by adsorbing two different materials) one can direct the motion of Janus particles: the induced chemi-osmotic flows can cause particles to either “dock” at a chemical step between the two materials, or to follow a chemical stripe. These theoretical predictions are confirmed by full numerical calculations. Generically, docking occurs for particles which tend to move away from their catalytic caps, while stripe-following occurs in the opposite case. Our analysis reveals the physical mechanisms governing this behavior.

**9:00AM E38.00006 3-d Brownian dynamics simulations of the smallest units of an active biological material**, JUTTA LUETTNER-STRAHMANN, NABINA PAUDYAL, MARAL ADELI KOUDEHI, Department of Physics, The University of Akron — Motor proteins generate stress in a cytoskeletal network by walking on one strand of the network while being attached to another one. A protein walker in contact with two elements of the network may be considered the smallest unit of an active biological material. In vitro experiments, mathematical modeling and computer simulations have provided important insights into active matter on large and on very small length and time scales. However, it is still difficult to model the effects of local environment and interactions at intermediate scales. Recently, we developed a coarse-grained, three-dimensional model for a motor protein transporting cargo by walking on a substrate. In this work, we simulate a tethered motor protein pulling a substrate with elastic response. As the walker progresses, the retarding force due to the substrate tension increases until contact fails. We present simulation results for the effect of motor-protein activity on the tension in the substrate and the effect of the retarding force on the processivity of the molecular motor.

**9:12AM E38.00007 Smarticles: smart, active granular matter<sup>1</sup>**, WILL SAVOIE, Georgia Tech, ARMAN PAZOUKI, DAN NEGRUT, U. Wisconsin-Madison, DANIEL GOLDMAN, Georgia Tech — We investigate a granular medium composed of smart, active particles, or “smarticles”. Previously, we discovered that ensembles of “u”-shaped particles exhibited geometrically-induced cohesion by mechanically entangling via particle interpenetration [Gravish et al, PRL, 2012]; the strength and/or extent of entanglement could be varied by changing particle level entanglement by changes in arm-to-base length of the u-particle. Since changing this parameter on demand is inconvenient, we develop a power-autonomous programmable robot composed of two motors and three links with an on-board microcontroller. This smarticle can be activated to change its configuration (specified by its two joint angles) through audio communication. To complement these experiments, since study large ensembles of smarticles is cost and labor prohibitive, we also develop a simulated smarticle in the Chrono multibody simulation environment. We systematically study ensemble cohesiveness and compaction as a function of shape changes of the smarticles. We find that suitable activation of smarticles allows ensembles to become cohesive to “grip” rigid objects and lose cohesion to release on command.

**9:24AM E38.00008 Active Brownian particles near straight or curved walls: Pressure and boundary layers<sup>1</sup>**, AYHAN DUZGUN, JONATHAN SELINGER, Kent State Univ - Kent — Unlike equilibrium systems, active matter is not governed by the conventional laws of thermodynamics. Through a series of Langevin dynamics simulations and analytic calculations, we explore how systems cross over from equilibrium to active behavior as the activity is increased. In particular, we calculate the profiles of density and orientational order near straight or circular walls, and show the characteristic width of the boundary layers. We find a simple relationship between the enhancements of density and pressure near a wall. Based on these results, we determine how the pressure depends on wall curvature, and hence make approximate analytic predictions for the motion of curved tracers, as well as the rectification of active particles around small openings in confined geometries.

**9:36AM E38.00009 Active particles on curved surfaces**, YAOUE FILY, APARNA BASKARAN, MICHAEL HAGAN, Brandeis University — Active systems have proved to be very sensitive to the geometry of their environment. This is often achieved by spending significant time at the boundary, probing its shape by gliding along it. I will discuss coarse graining the microscopic dynamics of self-propelled particles on a general curved surface to predict the way the density profile on the surface depends on its geometry. Beyond confined active particles, this formalism is a natural starting point to study objects that cannot leave the boundary at all, such as cells crawling on a curved substrate, animals running on uneven ground, or active colloids trapped at an interface.

**9:48AM E38.00010 Edge states in confined active fluids**, ANTON SOUSLOV, VINCENZO VITELLI, Leiden University — Recently, topologically protected edge modes have been proposed and realized in both mechanical and acoustic metamaterials. In one class of such metamaterials, Time-Reversal Symmetry is broken, and, to achieve this TRS breaking in mechanical and acoustic systems, an external energy input must be used. For example, motors provide a driving force that uses energy and, thus, explicitly break TRS. As a result, motors have been used as an essential component in the design of topological metamaterials. By contrast, we explore the design of topological metamaterials that use a class of far-from-equilibrium liquids, called polar active liquids, that spontaneously break TRS. We thus envision the confinement of a polar active liquid to a prescribed geometry in order to realize topological order with broken time-reversal symmetry. We address the design of the requisite geometries, for example a regular honeycomb lattice composed of annular channels, in which the active liquid may be confined. We also consider the physical character of the active liquid that, when introduced into the prescribed geometry, will spontaneously form the flow pattern of a metamaterial with topologically protected edge states. Finally, we comment on potential experimental realizations of such metamaterials.

**10:00AM E38.00011 Effect of micro-stirring on enzymatic reaction kinetics inside a biomimetic container**, IREP GOZEN, VIVA HOROWITZ, ZACHARY CHAMBERS, VINOTHAN MANOHARAN, Harvard University — The intracellular environment is dynamic, influenced by the motion of active machinery such as cytoskeleton filaments and molecular motors. To understand whether and how such activity affects the rates of diffusion-limited reactions, we construct a model system consisting of a phospholipid vesicle encapsulating a small number of micro- or nanoparticles, the active motion of which can be induced by chemical or magnetic cues. We aim to determine a relation between active motion of particles and rates of enzymatic reactions in the confined volume. Our findings might illuminate how active motion influences cytoplasmic reaction dynamics, or may have played a role in protocell genetics.

**10:12AM E38.00012 Correlated Rotational Noise in Active Brownian Systems**, CALEB WAGNER, APARNA BASKARAN, Brandeis Univ — We consider a system of self-propelled particles in a viscous medium for which the angle parametrizing the direction of particle propulsion is subject to correlated noise. The physics involved in the correlated noise is explored by deriving a modified Smoluchowski equation that governs the evolution of the probability distribution for particle positions and orientations. More precisely, given noise correlations that decay exponentially in time with decay constant  $\nu$ , we give the modified Smoluchowski equation as a perturbative expansion in  $\nu$ . While the physical origins of correlated noise may be diverse, we give one interpretation of the resulting dynamics in terms of inertial effects that are absent from the usual overdamped description of self-propelled particles in a viscous medium.

**10:24AM E38.00013 ABSTRACT WITHDRAWN —**

**10:36AM E38.00014 Dancing the night away: Improving the persistence of locomotion on the micron scale**, EMILY W. GEHRELS, W. BENJAMIN ROGERS, Harvard University, ZORANA ZERAVCIC, The Rockefeller University, VINOTHAN N. MANOHARAN, Harvard University — In recent years a range of nano and microscale walkers (motors that are able to move along a preformed track) have been developed. Many of these walkers bind to their tracks using a single binding site at each station along the track. A disadvantage of these systems is that any failure involving a single site becoming unbound leads to the walker falling off of the track and locomotion being prematurely terminated. For this reason, it has been difficult to develop a motor that can reliably take more than a few sequential steps. We present an experimental system of DNA-functionalized colloidal particles which exhibit directed motion along patterned substrates in response to temperature cycling. Many DNA bridges form between each pair of interacting particles, adding redundancy to the binding at each station to realize a system that should be able to consistently take many steps. We take advantage of toehold exchange in the design of the DNA sequences that mediate the colloidal interactions to produce broadened, flat, or even re-entrant binding and unbinding transitions between the particles and substrate. Using this new freedom of design, we devise systems where, by thermal ratcheting, we can externally control the direction of motion and sequence of steps of the colloidal motor.

**8:36AM E39.00002 Superdiffusive cell motility on 2D substrates modeled as a persistent Levy walk** , GIUSEPPE PASSUCCI, MEGAN E. BRASCH, Syracuse University, NICHOLAS O. DEAKIN, CHRISTOPHER E. TURNER, SUNY Upstate Medical University, JAMES H. HENDERSON, M. LISA MANNING, Syracuse University — Cell motility is an essential part of many biological processes such as morphogenesis, wound healing and tumorigenesis. We quantified cell motility by tracking mouse fibroblast and human breast carcinoma nuclei to construct cell trajectories. The mean-squared displacement of these trajectories reveals that cell motion is super diffusive, where displacements scale faster than  $t^{1/2}$  in all directions. Existing self-propelled particle (SPP) models that do not explicitly incorporate ensemble heterogeneity are unable to predict this super-diffusive behavior. Therefore we developed a run-and-tumble SPP model with Levy distributed run times that captures observed super-diffusive behavior in the mean-squared displacement as well as scaling collapse exponents of displacement probability distributions which match those of mouse fibroblast and human breast carcinoma cell trajectories. We additionally introduced small fluctuations in particle orientation during runs, which generates a crossover from super-diffusive to diffusive dynamics at a very long times. This timescale can be extracted in experiments from the velocity auto-correlation function, allowing us to explicitly test this model prediction.

**8:48AM E39.00003 Modelling Rho GTPase biochemistry to predict collective cell migration** , BRIAN MERCHANT, JAMES FENG, Univ British Columbia — The collective migration of cells, due to individual cell polarization and intercellular contact inhibition of locomotion, features prominently in embryogenesis and metastatic cancers. Existing methods for modelling collectively migrating cells tend to rely either on highly abstracted agent-based models, or on continuum approximations of the group. Both of these frameworks represent intercellular interactions such as contact inhibition of locomotion as hard-coded rules defining model cells. In contrast, we present a vertex-dynamics framework which predicts polarization and contact inhibition of locomotion naturally from an underlying model of Rho GTPase biochemistry and cortical mechanics. We simulate the interaction between many such model cells, and study how modulating Rho GTPases affects migratory characteristics of the group, in the context of long-distance collective migration of neural crest cells during embryogenesis.

**9:00AM E39.00004 Two distinct actin networks mediate traction oscillations to confer mechanosensitivity of focal adhesions** , ZHANGHAN WU, Natl Inst of Health - NIH, SERGEY PLOTNIKOV, Univ of Toronto, CLARE WATERMAN, JIAN LIU, Natl Inst of Health - NIH — Cells sense the mechanical stiffness of their extracellular matrix (ECM) by exerting traction force through focal adhesions (FAs), which are integrin-based protein assemblies. Strikingly, FA-mediated traction forces oscillate in time and space and govern durotaxis – the tendency of most cell types to migrate toward stiffer ECM. The underlying mechanism of this intriguing oscillation of FA traction force is unknown. Combining theory and experiment, we develop a model of FA growth, which integrates coordinated contributions of a branched actin network and stress fibers in the process. We show that retrograde flux of branched actin network contributes to a traction peak near the FA distal tip and that stress fiber-mediated actomyosin contractility generates a second traction peak near the FA center. Formin-mediated stress fiber elongation negatively feeds back with actomyosin contractility, resulting in the central traction peak oscillation. This underpins observed spatio-temporal patterns of the FA traction, and broadens the ECM stiffness range, over which FAs could accurately adapt with traction force generation. Our findings shed light on the fundamental mechanism of FA mechanosensing and hence durotaxis.

**9:12AM E39.00005 Cell Shapes and Traction Forces Determine Stress in Motile Confluent Tissue** , XINGBO YANG, Northwestern University, DAPENG BI, Rockefeller University, MICHAEL CZAJKOWSKI, LISA MANNING, CRISTINA MARCHETTI, Syracuse University — Collective cell migration is a highly regulated process involved in wound healing, cancer metastasis and morphogenesis. The understanding of the regulatory mechanism requires the study of mechanical interactions among cells that coordinate their active motion. To this end, we develop a method that determines cellular forces and tissue stresses from experimentally accessible cell shapes and traction forces. This approach allows us for the first time to calculate membrane tensions and hydrostatic pressures at a cellular level in collective migrating cell layers out of equilibrium. It helps us understand the mechanical origin of tissue stresses as previous inferred using Traction Force Microscopy (TFM). We test this approach on a new model of motile confluent tissue, which we term Self-propelled Voronoi Model (SPV) that incorporates cell elasticity, contractility and motility. With the model, we explore the mechanical properties of confluent motile tissue as a function of cell activities and cell shapes in various geometries.

**9:24AM E39.00006 Elastic mismatch enhances cell motility** , YONY BRESLER, BENOIT PALMIERI, MARTIN GRANT, McGill University — In recent years, the study of physics phenomena in cancer has drawn considerable attention. In cancer metastasis, a soft cancer cell leaves the tumor, and must pass through the endothelium before reaching the bloodstream. Using a phase-field model we have shown [1] that the elasticity mismatch between cells alone is sufficient to enhance the motility of the softer cancer cell by means of bursty migration, in agreement with experiment [2]. We will present further characterization of these behaviour, as well as new possible applications for this model. [1] Palmieri, B. et al. Sci. Rep. 5, 11745; [2] Lee, M. et al. Biophys. J 102, 2731 (2012).

**9:36AM E39.00007 Two interacting active dimers on a rigid track** , DAVID MAYETT, Syracuse University, MOUMITA DAS, Rochester Institute of Technology, J. M. SCHWARZ, Syracuse University — Cell migration in morphogenesis and cancer metastasis typically involves an interplay between different cell types. The rules governing such interplay remain largely unknown; however, a recent experiment studying the interaction between neural crest (NC) cells and placodal cells reveals an example of such rules. The study found that NC cells chase the placodal cells by chemotaxis, while placodal cells run away from NC cells when contacted by them. Motivated by this observation, we construct and study a minimal one-dimensional cell-cell model comprised of two cells with each cell represented by two-beads-connected-by-an-active spring. The active spring for each moving cell models the stress fibers with their myosin-driven contractility (and alpha-actinin extensibility), while the friction coefficients of the beads describe the catch/slip bond behavior of the integrins in focal adhesions. We also include a dynamic contact interaction between the two cells to decipher the chase-and-run dynamics observed in the experiment. We then use our model to construct a "phase diagram" consisting of chase-and-run behavior, clumping (of the two cells) with repolarization behavior and clumping with no repolarization behavior that can be qualitatively compared to experiments.

**9:48AM E39.00008 Traction force and tension fluctuations in growing axons** , JEFFREY URBACH, JAMIE POLACKWICH, DANIEL KOCH, RYAN MCALLISTER, Georgetown University, HERBERT GELLER, NHLBI, NIH — Actively generated mechanical forces play a central role in axon growth and guidance during nervous system development. We describe the dynamics of traction stresses from growth cones of actively advancing axons from postnatal rat DRG neurons. By tracking the movement of the growth cone and analyzing the traction stresses in a co-moving reference frame, we show that there is a clear and consistent average stress field underlying the complex spatial stresses present at any one time. The average stress field has strong maxima on the sides of the growth cone, directed inward toward the growth cone neck. This pattern represents a contractile stress contained within the growth cone, and a net force that is balanced by the axon tension. In addition, using high time-resolution measurements, we show that the stress field is composed of fluctuating local stress peaks, with a population of peaks whose lifetime distribution follows an exponential decay, and a small number of very long-lived peaks. We also find that the tension appears to vary randomly over short time scales, roughly consistent with the lifetime of the stress peaks, suggesting that the tension fluctuations originate from stochastic adhesion dynamics.

**10:00AM E39.00009 Multiscale Modeling of Cell Interaction in Angiogenesis: From the Micro- to Macro-scale**, SAMARA PILLAY, PHILIP MAINI, HELEN BYRNE, University of Oxford — Solid tumors require a supply of nutrients to grow in size. To this end, tumors induce the growth of new blood vessels from existing vasculature through the process of angiogenesis. In this work, we use a discrete agent-based approach to model the behavior of individual endothelial cells during angiogenesis. We incorporate crowding effects through volume exclusion, motility of cells through biased random walks, and include birth and death processes. We use the transition probabilities associated with the discrete models to determine collective cell behavior, in terms of partial differential equations, using a Markov chain and master equation framework. We find that the cell-level dynamics gives rise to a migrating cell front in the form of a traveling wave on the macro-scale. The behavior of this front depends on the cell interactions that are included and the extent to which volume exclusion is taken into account in the discrete micro-scale model. We also find that well-established continuum models of angiogenesis cannot distinguish between certain types of cell behavior on the micro-scale. This may impact drug development strategies based on these models.

**10:12AM E39.00010 Cellular Polarization and Contractility in Collective Cell Migration<sup>1</sup>**, KAZAGE J CHRISTOPHE UTUJE, Syracuse University, JACOB NOTBOHM, University of Wisconsin-Madison, SHILADITYA BANERJEE, University of Chicago, BOMI GWEON, Hanyang University, HWANSEOK JANG, YONGDOO PARK, Korea University, JENNIFER SHIN, KAIST, JAMES P. BUTLER, JEFFREY J. FREDBERG, Harvard T.H. Chan School of Public Health, M. CRISTINA MARCHETTI, Syracuse University — Collective cell migration drives many biological processes such as metastasis, morphogenesis and wound healing. These coordinated motions are driven by active forces. The physical nature of these forces and the mechanisms by which they generate collective cell migration are still not fully understood. We have developed a minimum physical model of a cell monolayer as an elastic continuum whose deformation field is coupled to two internal degrees of freedom: the concentration of a chemical signal, controlling cell contractility, and the polarization field controlling the direction of local cell motion. By combining theory with experiments, we show that these two internal variables account for the sloshing waves and the systematic deviations of the direction of cell polarization from that of local cell velocity observed in confined cell monolayers.

**10:24AM E39.00011 Analysis of Shape Dynamics and Actin Polymerization of Collectively Migrating Streams of Cells**, CHENLU WANG, Biophysics Program, University of Maryland, College Park, CAROLE A. PARENT, LCMB, National Cancer Institute, National Institutes of Health, WOLFGANG LOSERT, Department of Physics, University of Maryland, College Park — We use Principal Component Analysis (PCA) to investigate cell-cell coupling during collective cell migration of Dictyostelium discoideum, and explore the underlying mechanisms that regulate the coupling. From PCA of the cell boundary motion obtained from time-lapse images of multicellular streams, we find that cells in streams exhibit more localized anterior protrusions than individually migrating cells. We also find that traveling protrusion waves along cell boundaries connect from cell to cell with high correlation. Further analysis of actin polymerization indicates that actin polymerization is significantly enhanced at the leading edge of cells at cell-cell contacts. The coupling of waves disappears when reducing F-actin polymerization with Latrunculin A.

**10:36AM E39.00012 Connecting single cell to collective cell behavior in a unified theoretical framework**, MISHEL GEORGE, FRANCESCO BULLO, OTGER CAMPÀS, University of California - Santa Barbara — Collective cell behavior is an essential part of tissue and organ morphogenesis during embryonic development, as well as of various disease processes, such as cancer. In contrast to many *in vitro* studies of collective cell migration, most cases of *in vivo* collective cell migration involve rather small groups of cells, with large sheets of migrating cells being less common. The vast majority of theoretical descriptions of collective cell behavior focus on large numbers of cells, but fail to accurately capture the dynamics of small groups of cells. Here we introduce a low-dimensional theoretical description that successfully captures single cell migration, cell collisions, collective dynamics in small groups of cells, and force propagation during sheet expansion, all within a common theoretical framework. Our description is derived from first principles and also includes key phenomenological aspects of cell migration that control the dynamics of traction forces. Among other results, we explain the counter-intuitive observations that pairs of cells repel each other upon collision while they behave in a coordinated manner within larger clusters.

**10:48AM E39.00013 Emergence of oligarchy in collective cell migration.**, LINUS SCHUMACHER, PHILIP MAINI, RUTH BAKER, University of Oxford — Identifying the principles of collective cell migration has the potential to help prevent birth defects, improve regenerative therapies and develop model systems for cancer metastasis. In collaboration with experimental biologists, we use computational simulations of a hybrid model, comprising individual-based stochastic cell movement coupled to a reaction-diffusion equation for a chemoattractant, to explore the role of cell specialisation in the guidance of collective cell migration. In the neural crest, an important migratory cell population in vertebrate embryo development, we present evidence that just a few cells are guiding group migration in a cell-induced chemoattractant gradient that determines the switch between “leader” and “follower” behaviour in individual cells. This leads us to more generally consider under what conditions cell specialisation might become advantageous for collective migration. Alternatively, individual cell responses to locally different microenvironmental conditions could create the (artefactual) appearance of heterogeneity in a population of otherwise identical cellular agents. We explore these questions using a self-propelled particle model as a minimal description for collective cell migration in two and three dimensions.

**Tuesday, March 15, 2016 8:00AM - 11:00AM –**

**Session E40 GSNP GPC: Leo Kadanoff Session I** 343 - Sidney Nagel, University of Chicago

**8:00AM E40.00001 Droplet formation and neck rupture in granular streams and dense suspensions**, HEINRICH JAEGER, University of Chicago — When a pendant drop of liquid breaks off, the final stages of neck formation before the singular event of separation are well described by a power law with an exponent that characterizes the liquid. Specifically, a linear decrease of the neck width with time to breakup implies a highly viscous liquid, while sublinear behavior with exponent 2/3 signals the inviscid limit. It therefore has come as a complete surprise that droplet neck formation in dry granular streams as well as concentrated suspensions, both systems with high apparent viscosity, exhibits the same scaling as the inviscid case. I will discuss some of the experimental evidence for this behavior and attempt an explanation that explicitly considers an aspect unique to the presence of the particles: the feedback between the ability of a (nearly) jammed state to deform and the Gaussian curvature introduced by the neck

**8:12AM E40.00002 Particle Laden Flows from Theory to Experiment<sup>1</sup>**, ANDREA BERTOZZI, Univ of California - Los Angeles — Leo Kadanoff inspired a generation of collaboration across the boundaries of applied mathematics, theoretical physics, engineering, and experimental physics. His influence is seen in laboratories, classrooms, PhD theses, and even undergraduate research across the world. In this talk I review a body of research at UCLA spanning the past ten years in which we have worked to understand the basic physics of particle laden flow by comparing experiments with mathematical models. The project was inspired by some initial experiments and models developed by A. Hosoi's group at MIT. We derive and analyze systems of conservation laws with rich behavior that includes multiple shocks, rarefactions, and singular shocks - and study these along side laboratory experiments. Our work includes both basic physics problems and industrial applications such as spiral separators used in the mining industry.

<sup>1</sup>Supported by NSF grants DMS-1312543 and DMS-1045536

**8:24AM E40.00003 Surface tension models for particle laden thin films<sup>1</sup>**, JEFFREY WONG, LI WANG, ANDREA BERTOZZI, Univ of California - Los Angeles — We study viscous slurries on an incline, for which particles migrate in a fluid due to a combination of gravity-induced settling and shear-induced migration. The lubrication model for the bulk of the fluid is a hyperbolic system of conservation laws for the film height and particle concentration which exhibits interesting behavior, including singular shock solutions corresponding to accumulation of particles at the front. The addition of surface tension to the model produces a capillary ridge that is affected by the particle accumulation and in two dimensions leads to fingering instabilities. We compare this model to experimental results.

<sup>1</sup>This work is supported by NSF grants DMS-1312543 and DMS-1045536.

**8:36AM E40.00004 Plastic flow of polycrystalline materials**, JAMES LANGER<sup>1</sup>, University of California, Santa Barbara — Leo Kadanoff had a long interest in fluid flows, especially fingering instabilities. This interest was one example of his insatiable curiosity about simple, fundamentally important, and often multidisciplinary phenomena. Here is an example of another class of such phenomena that I had hoped to show him this year. The experts in polycrystalline solid mechanics have insisted for decades that their central problem – dislocation-mediated strain hardening – is intrinsically unsolvable. I think they're wrong. My colleagues and I have made progress recently in theories of both amorphous and polycrystalline plasticity by introducing an effective disorder temperature as a dynamical variable in our equations of motion. In this way, we have been able to describe how the densities of flow defects or dislocations evolve in response to external forcing, and thus to develop theories that promise to become as predictive, and full of surprises, as the laws of fluid flow.

<sup>1</sup>For Kadanoff session

**8:48AM E40.00005 Scaling theory of the jamming transition<sup>1</sup>**, ANDREA LIU, University of Pennsylvania, Department of Physics and Astronomy, CARL GOODRICH, SEAS, Harvard University, JAMES SETHNA, Cornell University, Department of Physics, SIDNEY NAGEL, University of Chicago, James Franck Institute — The concept of jamming was first introduced at the University of Chicago by Sid Nagel and Tom Witten. By now we know that there is a zero-temperature critical jamming transition that marks the onset of rigidity in packings of soft repulsive spheres. In contrast to the perfect fcc crystal state, which is the maximally stable state for such systems, the jammed state is only marginally stable mechanically, and thus represents an opposite extreme to the perfect crystal. This marginal stability gives rise to power law scalings and diverging length scales at the transition. Here I will discuss recent developments that put the jamming transition in the same place that the Ising transition was when Leo Kadanoff introduced the ideas of coarse-graining and rescaling into critical phenomena.

**9:00AM E40.00006 Thermal Boundary Layer Equation for Turbulent Rayleigh-Bénard Convection<sup>1</sup>**, EMILY SC CHING, Department of Physics, The Chinese University of Hong Kong, OLGA SHISHKINA, Max Planck Institute for Dynamics and Self-Organization, SUSANNE HORN, Department of Mathematics, Imperial College, SEBASTIAN WAGNER, Max Planck Institute for Dynamics and Self-Organization — Turbulent Rayleigh-Bénard convection, consisting of a fluid confined between two horizontal plates, heated from below and cooled from above, is a paradigm system for studying turbulent thermal convection, which is ubiquitous in nature. In turbulent Rayleigh-Bénard convection, there are viscous boundary layers near all rigid walls and two thermal boundary layers, one above the bottom plate and one below the top plate. The classical Prandtl-Blasius-Pohlhausen theory has often been used to describe the mean velocity and temperature boundary layer profiles but systematic deviations are known to exist. These deviations are due to turbulent fluctuations. In this talk, we report a new thermal boundary layer equation for turbulent Rayleigh-Bénard convection derived for Prandtl number (Pr) greater than 1, which takes into account the effects of turbulent fluctuations by using the idea of an eddy thermal diffusivity. Solving this equation, we have obtained two analytical mean temperature profiles for  $Pr \sim 1$  and  $Pr \gg 1$ . These two theoretical predictions are shown to be in excellent agreement with the results of our direct numerical simulations for  $Pr=4.38$  (water) and  $Pr=2547.9$  (glycerol).

**9:12AM E40.00007 Leo Kadanoff's legacy for turbulent thermal convection**, DETLEF LOHSE<sup>1</sup>, University of Twente — Rayleigh-Bénard (RB) convection the buoyancy-driven flow of a fluid heated from below and cooled from above is a classical problem in fluid dynamics. It played a crucial role in the development of stability theory in hydrodynamics (Rayleigh, Chandrasekhar) and had been paradigmatic in pattern formation and in the study of spatial-temporal chaos (Ahlers, Libchaber, and many other). It was Leo Kadanoff and his associates in Chicago who, in the 1980s and 1990s, propagated the RB system as paradigmatic for the *physics* of fully developed turbulence and contributed tremendously to today's understanding of thermally driven turbulence. He and his experimental coworkers (Libchaber et al.) revealed the importance of the thermal plumes and the large-scale wind, and elucidated the interplay between thermal boundary layers and bulk. His scaling analysis laid the basis for our present understanding of turbulent convection, which I will review in this talk, highlighting Leo's trailblazing contributions.

**9:24AM E40.00008 Control and large deformations of marginal disordered structures**, ARVIND MURUGAN, MATTHEW PINSON, University of Chicago, ELIZABETH CHEN, Harvard University — Designed deformations, such as origami patterns, provide a way to make easily controlled mechanical metamaterials with tailored responses to external forces. We focus on an often overlooked regime of origami - non-linear deformations of large disordered origami patterns with no symmetries. We find that practical questions of control in origami have counterintuitive answers, because of intimate connections to spin glasses and neural networks. For example, 1 degree of freedom origami structures are actually difficult to control about the flat state with a single actuator; the actuator is thrown off by an exponential number of 'red herring' zero modes for small deformations, all but one of which disappear at larger deformations. Conversely, structures with multiple programmed motions are much easier to control than expected - in fact, they are as easy to control as a dedicated single-motion structure if the number of programmed motions is below a threshold ('memory capacity').

**9:36AM E40.00009 Planarity of Force Tilings in Jammed Packings of Disks<sup>1</sup>**, KABIR RAMOLA, BULBUL CHAKRABORTY, Brandeis University — We propose a new order parameter for load induced jamming transitions in disk packings based on the planarity of force tilings. Contact forces between disks in mechanical equilibrium can be arranged in a dual space to form a network (tiling) represented by a set of vertices and edges  $\mathcal{G} = (V, E)$ . A Delaunay triangulation of these vertices then forms a related network  $\mathcal{G}_D = (V, E_D)$ . We define a planarity order parameter  $\psi$  as the overlap of these two graphs  $\psi = \langle \mathcal{G}_D | \mathcal{G} \rangle$ . We use this parameter to characterize jamming transitions in two dimensional granular systems. We find clear signatures of the existence of non-planar and planar phases as a function of external load. We study this behaviour using simulation data of frictionless soft disks and experimental data of frictional disk packings.

**9:48AM E40.00010 Consolidation by lubrication at sedimentary jamming fronts**, DOUGLAS DURIAN, CARLOS ORTIZ, TED BRZINSKI, University of Pennsylvania — We formulate a nonlinear partial differential equation to describe changes in packing fraction for sedimenting particles at low Reynolds number. It is based on two key fluid-mediated forces. One is the viscous interaction of a particle with the surrounding suspension, which causes the settling speed to decrease with increasing packing fraction according to a hindered settling function; we constrain its form by a comprehensive data compilation. The other ingredient is a lubrication force that resists change in separation between neighboring particles; it diverges at contact and hence captures the accumulation of a close-packed sediment. These forces, plus gravity and mass conservation, lead to a new "sedimentation equation" that we propose for the evolution of packing fraction versus position and time. Asymptotic and numerical solutions are presented, and compared with experiment, for the shape of the stationary jamming front between sediment and suspension that moves upwards at constant shape and speed.

**10:00AM E40.00011 What are the microscopic origins of shear jamming?**<sup>1</sup>, BOB BEHRINGER, DONG WANG, Duke University, JIE REN, Merck & Co., JONATHAN BARES, Duke University, BULBUL CHAKRABORTY, Brandeis University, LENKA KOVALCINOVA, LOU KONDIC, NJIT — Granular materials can jam by shear: shear strain applied to a stress-free state in a packing fraction range  $\phi_S < \phi < \phi_J$ , leads to mechanically stable (jammed) anisotropic states (Bi et al. Nature, 2011).  $\phi_J$  is the lowest  $\phi$  for which an isotropic state is jammed, and shear jamming ceases below  $\phi_S$ . The process of shear jamming involves the formation of strong force networks that are initially highly anisotropic 'force chains', then become more isotropic with increasing shear. The mechanisms that lead to shear jamming are also presumably similar to those that lead to Reynolds dilatancy. What microscopic processes can account for shear jamming? Force chains, roughly linear sequences of particles experiencing average or above forces are not stable by themselves. Hence, force chain particles must form additional 'non-chain' contacts. Here, we propose micro-scale structures and their response to shear that serve as a basis to understand the formation of stable force networks and shear jamming. We identify these structures in experimental and numerical data, and track their response to shear.

**10:12AM E40.00012 Itokawa: a case for ballistic segregation**<sup>1</sup>, TROY SHINBROT, Rutgers University, TAPAN SABAWULA, Okinawa Institute for Science and Technology, THEO SIU, MIGUEL VIVAR LAZO, Rutgers University, PINAKI CHAKRABORTY, Okinawa Institute for Science and Technology — Recent photographs of the asteroid Itokawa have revealed strong separation between regions populated almost entirely by small pebbles and other regions consisting only of larger boulders. This size separation has been attributed to the Brazil Nut Effect (BNE), however we point out here that the BNE depends on conditions such as isotropic gravity, parallel sidewalls and periodic vertical shaking that are wholly absent on asteroids. On the other hand, surface areas of boulders and pebbles appear to be comparable on Itokawa, and in this situation it follows that the asteroid must have suffered many orders of magnitude more collisions with pebbles than with boulders. We observe that a pebble will tend to bounce off of a boulder but will sink into a sea of similar pebbles, and so we predict that seas of pebbles must grow on such asteroids. We carry out experiments and simulations to evaluate this and related predictions, and we demonstrate that this new mechanism of segregation based on simple counting of grains can produce the strong separation of sizes reported.

**10:24AM E40.00013 A trans-phase granular continuum relation and its use in simulation**, KEN KAMRIN, SACHITH DUNATUNGA, HESAM ASKARI, MIT — The ability to model a large granular system as a continuum would offer tremendous benefits in computation time compared to discrete particle methods. However, two infamous problems arise in the pursuit of this vision: (i) the constitutive relation for granular materials is still unclear and hotly debated, and (ii) a model and corresponding numerical method must wear "many hats" as, in general circumstances, it must be able to capture and accurately represent the material as it crosses through its collisional, dense-flowing, and solid-like states. Here we present a minimal trans-phase model, merging an elastic response beneath a fictional yield criterion, a  $\mu(I)$  rheology for liquid-like flow above the static yield criterion, and a disconnection rule to model separation of the grains into a low-temperature gas. We simulate our model with a meshless method (in high strain/mixing cases) and the finite-element method. It is able to match experimental data in many geometries, including collapsing columns, impact on granular beds, draining silos, and granular drag problems.

**10:36AM E40.00014 A Hierarchy of Dynamic Equilibria and a View of a Fly's Equilibrium Reflex**, Z. JANE WANG<sup>1</sup>, Cornell University — Understanding structures within a structure is a topic that has fascinated Leo throughout his life, and we are now benefiting from his fundamental insights when we think about living organisms. A living organism is far from statistical equilibrium and it does not have a single critical parameter. Nevertheless, each organism has a hierarchical structure within itself. Recently, asking how often a fly must sense its orientation in order to balance in air has led us to suggest one of the fly's 17 steering muscles, the first basalar muscle, is responsible for maintaining flight stability. Here I suggest that the chain of events associated with flight equilibrium reflex can be viewed as a succession of local linear transformation about a set of dynamic equilibria[1]. Each of the functionally different parts, the sensors, motor neurons, muscles, wing-hinges, flapping wings, and the thorax, operates near its own dynamic equilibrium, often close to the boundary between stability and instability. Locomotion rises as an organism responds to a small perturbation from these equilibria. [1] ZJ Wang, Ann. Rev. Cond. Matter Physics, Vol 7, 2016

**10:48AM E40.00015 The life of vortex knots and the flow of helicity**, WILLIAM IRVINE, University of Chicago — What happens if you take a vortex loop - akin to a smoke ring in air - and tie it into a knot or a link? The knottiness (Helicity) of a fluid is a conserved quantity in many idealized situations (such as Euler fluids) offering the potential for fundamental insights into fluid flow. In real fluids, progress has been hindered by lack of accessible experimental systems. I will tell of how to make a vortex knot and link in water, in the wave function of a superfluid (on a computer) and of what happens thence, with an emphasis on universal aspects of the dynamics and the flow of helicity.

**8:00AM E41.00001 An objective function for Hebbian self-limiting synaptic plasticity rules**, CLAUDIUS GROS, SAMUEL ECKMANN, RODRIGO ECHEVESTE, Institute for Theoretical Physics, Goethe University Frankfurt — Objective functions, formulated in terms of information theoretical measures with respect to the input and output probability distributions, provide a useful framework for the formulation of guiding principles for information processing systems, such as neural networks. In the present work, a guiding principle for neural plasticity is formulated in terms of an objective function expressed as the Fisher information with respect to an operator that we denote as the synaptic flux <sup>1</sup>. By minimization of this objective function, we obtain Hebbian self-limiting synaptic plasticity rules, avoiding unbounded weight growth. Furthermore, we show how the rules are selective to directions of maximal negative excess kurtosis, making them suitable for independent component analysis. As an application, the non-linear bars problem <sup>2</sup> is studied, in which each neuron is presented with a non-linear superposition of horizontal and vertical bars. We show that, under the here presented rules, the neurons are able to find the independent components of the input.

**8:24AM E41.00003 The role of symmetry in the regulation of brain dynamics.**, EVELYN TANG, CHAD GIUSTI, University of Pennsylvania, MATTHEW CIESLAK, SCOTT GRAFTON, University of California, Santa Barbara, DANIELLE BASSETT, University of Pennsylvania — Synchronous neural processes regulate a wide range of behaviors from attention to learning. Yet structural constraints on these processes are far from understood. We draw on new theoretical links between structural symmetries and the control of synchronous function, to offer a reconceptualization of the relationships between brain structure and function in human and non-human primates. By classifying 3-node motifs in macaque connectivity data, we find the most prevalent motifs can theoretically ensure a diversity of function including strict synchrony as well as control to arbitrary states. The least prevalent motifs are theoretically controllable to arbitrary states, which may not be desirable in a biological system. In humans, regions with high topological similarity of connections (a continuous notion related to symmetry) are most commonly found in fronto-parietal systems, which may account for their critical role in cognitive control. Collectively, our work underscores the role of symmetry and topological similarity in regulating dynamics of brain function.

**8:36AM E41.00004 Synchronization in a non-uniform network of excitatory spiking neurons.**, RODRIGO ECHEVESTE, CLAUDIUS GROS, Institute for Theoretical Physics, Goethe University Frankfurt — Spontaneous synchronization of pulse coupled elements is ubiquitous in nature and seems to be of vital importance for life <sup>1</sup>. Networks of pacemaker cells in the heart <sup>2</sup>, extended populations of southeast asian fireflies <sup>3</sup>, and neuronal oscillations in cortical networks <sup>4</sup>, are examples of this. In the present work, a rich repertoire of dynamical states with different degrees of synchronization are found in a network of excitatory-only spiking neurons connected in a non-uniform fashion. In particular, uncorrelated and partially correlated states are found without the need for inhibitory neurons or external currents. The phase transitions between these states, as well the robustness, stability, and response of the network to external stimulus are studied.

**8:48AM E41.00005 Information Transmission and Anderson Localization in two-dimensional networks of firing-rate neurons**<sup>1</sup>, JOSEPH NATALE, GEORGE HENTSCHEL, Emory Univ — Firing-rate networks offer a coarse model of signal propagation in the brain. Here we analyze sparse, 2D planar firing-rate networks with no synapses beyond a certain cutoff distance. Additionally, we impose Dale's Principle to ensure that each neuron makes only or inhibitory outgoing connections. Using spectral methods, we find that the number of neurons participating in excitations of the network becomes insignificant whenever the connectivity cutoff is tuned to a value near or below the average interneuron separation. Further, neural activations exceeding a certain threshold stay confined to a small region of space. This behavior is an instance of Anderson localization, a disorder-induced phase transition by which an information channel is rendered unable to transmit signals. We discuss several potential implications of localization for both local and long-range computation in the brain.

**9:00AM E41.00006 Controlling chaos in balanced neural circuits with input spike trains**, RAINER ENGELKEN, FRED WOLF, MPI for Dynamics and Self-Organization, Goettingen, Germany, BCCN Gttingen, Germany, University of Goettingen, Germany — The cerebral cortex can be seen as a system of neural circuits driving each other with spike trains. Here we study how the statistics of these spike trains affects chaos in balanced target circuits. Earlier studies of chaos in balanced neural circuits either used a fixed input [van Vreeswijk, Sompolinsky 1996, Monteforte, Wolf 2010] or white noise [Lajoie et al. 2014]. We study dynamical stability of balanced networks driven by input spike trains with variable statistics. The analytically obtained Jacobian enables us to calculate the complete Lyapunov spectrum. We solved the dynamics in event-based simulations and calculated Lyapunov spectra, entropy production rate and attractor dimension. We vary correlations, irregularity, coupling strength and spike rate of the input and action potential onset rapidness of recurrent neurons. We generally find a suppression of chaos by input spike trains. This is strengthened by bursty and correlated input spike trains and increased action potential onset rapidness. We find a link between response reliability and the Lyapunov spectrum. Our study extends findings in chaotic rate models [Molgedey et al. 1992] to spiking neuron models and opens a novel avenue to study the role of projections in shaping the dynamics of large neural circuits.

**9:12AM E41.00007 Simulation of dendritic growth reveals necessary and sufficient parameters to describe the shapes of dendritic trees.** , OLIVIER TROTTIER, SUJOY GANGULY, HUGO BOWNE-ANDERSON, Yale University, XIN LIANG, Tsinghua University, JONATHON HOWARD, Yale University — For the last 120 years, the development of neuronal shapes has been of great interest to the scientific community. Over the last 30 years, significant work has been done on the molecular processes responsible for dendritic development. In our ongoing research, we use the class IV sensory neurons of the *Drosophila melanogaster* larva as a model system to understand the growth of dendritic arbors. Our main goal is to elucidate the mechanisms that the neuron uses to determine the shape of its dendritic tree. We have observed the development of the class IV neuron's dendritic tree in the larval stage and have concluded that morphogenesis is defined by 3 distinct processes: 1) branch growth, 2) branching and 3) branch retraction. As the first step towards understanding dendritic growth, we have implemented these three processes in a computational model. Our simulations are able to reproduce the branch length distribution, number of branches and fractal dimension of the class IV neurons for a small range of parameters.

**9:24AM E41.00008 Partial Synchronization in Pulse-Coupled Oscillator Networks I: Theory<sup>1</sup>** , JAN ENGELBRECHT, BOLUN CHEN, RENATO MIROLLO, Boston College — We study  $N$  identical integrate and fire model neurons coupled in an all to all network through  $\alpha$ -function pulses, weighted by a parameter  $K$ . Studies of the dynamics of this system often focus on the stability of the fully synchronous and the fully asynchronous splay states, that naturally depend on the sign of  $K$ , i.e. excitation vs inhibition. We find that for finite  $N$  there is a rich set of other partially synchronized attractors, such as  $(N - 1, 1)$  fixed states and partially synchronized splay states. Our framework exploits the neutrality of the dynamics for  $K = 0$  which allows us to implement a dimensional reduction strategy that replaces the discrete pulses with a continuous flow, with the sign of  $K$  determining the flow direction. This framework naturally incorporates a hierarchy of partially synchronized subspaces in which the new states lie. For  $N = 2, 3, 4$ , we completely describe the sequence of bifurcations and the stability of all fixed points and limit cycles.

<sup>1</sup>Work Supported by NSF DMS 1413020

**9:36AM E41.00009 Partial Synchronization in Pulse-Coupled Oscillator Networks II: A Numerical Study<sup>1</sup>** , BOLUN CHEN, JAN R. ENGELBRECHT, RENATO MIROLLO, Boston College — We use high-precision numerical simulations, to compute the dynamics of  $N$  identical integrate and fire model neurons coupled in an all-to-all network through  $\alpha$ -function pulses. In particular, we determine the discrete evolution of the state of our system from spike to spike. In addition to traditional fully synchronous and splay states, we exhibit multiple competing partially synchronized ordered states, which are fixed points and limit cycles in the phase space. Close examinations reveal the bifurcations among different states. By varying the parameters, we map out the phase diagram of stable fixed points. Our results illustrate the power of dimensional reduction in complex dynamical systems, and shed light on the collective behaviors of neural networks.

<sup>1</sup>Work supported by NSF DMS 1413020.

**9:48AM E41.00010 Critical behavior of large maximally informative neural populations<sup>1</sup>** , JOHN BERKOWITZ, Univ of California - San Diego, TATYANA SHARPEE, Computational Neurobiology Laboratory, Salk Institute for Biological Studies, La Jolla, CA; Department of Physics, University of California, San Diego — We consider maximally informative encoding of scalar signals by neural populations. In a small time window, neural responses are binary, with spiking probability that follows a sigmoidal tuning curve. The width of the tuning curve represents effective noise in neural transmission. Previous analyses of this problem for relatively small numbers of neurons with identical noise parameters indicated the presence of multiple bifurcations that occurred with decreasing noise value. For very high noise values, maximal information is achieved when all neurons have the same threshold values. With decreasing noise, the threshold values split into two or more groups via a series of bifurcations, until finally each neuron has a different threshold. Analyzing this problem in the large  $N$  limit, we found instead that there is a single phase transition from redundant coding to coding based on distributed thresholds. The order parameter of this transition is the threshold standard deviation across the population; differences in noise parameter from the mean are analogous to local magnetic fields. Near the bifurcation point, information transmitted follows a Landau expansion. We use this expansion to quantify the scaling of the order parameter with noise and effective magnetic field.

**10:00AM E41.00011 Spike frequency adaptation is a possible mechanism for control of attractor preference in auto-associative neural networks.<sup>1</sup>** , JAMES ROACH, LEONARD SANDER, MICHAL ZOCHOWSKI, Univ of Michigan - Ann Arbor — Auto-associative memory is the ability to retrieve a pattern from a small fraction of the pattern and is an important function of neural networks. Within this context, memories that are stored within the synaptic strengths of networks act as dynamical attractors for network firing patterns. In networks with many encoded memories, some attractors will be stronger than others. This presents the problem of how networks switch between attractors depending on the situation. We suggest that regulation of neuronal spike-frequency adaptation (SFA) provides a universal mechanism for network-wide attractor selectivity. Here we demonstrate in a Hopfield type attractor network that neurons minimal SFA will reliably activate in the pattern corresponding to a local attractor and that a moderate increase in SFA leads to the network to converge to the strongest attractor state. Furthermore, we show that on long time scales SFA allows for temporal sequences of activation to emerge. Finally, using a model of cholinergic modulation within the cortex we argue that dynamic regulation of attractor preference by SFA could be critical for the role of acetylcholine in attention or for arousal states in general.

**10:12AM E41.00012 On the Emergent Properties of Recurrent Neural Networks at Criticality** , YAHYA KARIMIPANAH, ZHENGYU MA, RALF WESSEL, Washington University in St. Louis — Irregular spiking is a widespread phenomenon in neuronal activities in vivo. In addition, it has been shown that the firing rate variability decreases after the onset of external stimuli. Since these are known as two universal features of cortical activity, it is natural to ask whether there is a universal mechanism underlying such phenomena. Independently, there has been mounting evidence that superficial layers of cortex operate near a second-order phase transition (critical point), which is manifested in the form of scale free activity. However, despite the strong evidence for such a criticality hypothesis, it is still very little known on how it can be leveraged to facilitate neural coding. As the decline in response variability is regarded as an essential mechanism to enhance coding efficiency, we asked whether the criticality hypothesis could bridge between scale free activity and other ubiquitous features of cortical activity. Using a simple binary probabilistic model, we show that irregular spiking and decline in response variability, both arise as emergent properties of a recurrent network poised at criticality. Our results provide us with a unified explanation for the ubiquity of these two features, without a need to exploit any further mechanism.

**10:24AM E41.00013 Computing with scale-invariant neural representations<sup>1</sup>**, MARC HOWARD, KARTHIK SHANKAR, Boston Univ — The Weber-Fechner law is perhaps the oldest quantitative relationship in psychology. Consider the problem of the brain representing a function  $f(x)$ . Different neurons have receptive fields that support different parts of the range, such that the  $i$ th neuron has a receptive field at  $x_i$ . Weber-Fechner scaling refers to the finding that the width of the receptive field scales with  $x_i$  as does the difference between the centers of adjacent receptive fields. Weber-Fechner scaling is exponentially resource-conserving. Neurophysiological evidence suggests that neural representations obey Weber-Fechner scaling in the visual system and perhaps other systems as well. We describe an optimality constraint that is solved by Weber-Fechner scaling, providing an information-theoretic rationale for this principle of neural coding. Weber-Fechner scaling can be generated within a mathematical framework using the Laplace transform. Within this framework, simple computations such as translation, correlation and cross-correlation can be accomplished. This framework can in principle be extended to provide a general computational language for brain-inspired cognitive computation on scale-invariant representations.

**10:48AM E41.00015 Physics of Intrinsic and Extrinsic Factors that Cause the Onset of the Deadliest Illness of Mankind and are Important for Diagnostics and Treatment**, ARJUN SAXENA, retired — One of the most important topic of research in the field of Physics of Behavior is the deadliest illness of mankind which is the group of illnesses called mental illnesses. They are getting attention increasingly worldwide by the medical communities and their respective governments, because of the following fact. It is now well established that these illnesses cause more loss of human lives, destruction of families, businesses and overall economy than all the other illnesses combined. The purpose of this paper is to identify and provide solutions to two fundamental issues of such illnesses which still remain as problems. One is the stigma associated with them because of their name “mental”. The patients are regarded as less than normal because their illness is only “mental” in origin. The second is that it is still not widely recognized that they are caused by medical problems in their “brain” which afflict their “mind”. This paper explains this and gives an improved 3-D model using the physics of intrinsic and extrinsic factors of both “brain” and “mind”. It leads to an important new name, “BAMI” (Brain and Mind Illness), which eliminates the stigma and gives quantitative parameters to diagnose the illness and monitor medicines to treat such illnesses.

**8:36AM E42.00002 Broader Understanding of Multiple Component Dynamic Processes in Miscible Polymer/Polymer Blends**, RAVI SHARMA, HENGXI YANG, PETER GREEN, University of Michigan — Utilizing two different experimental techniques, isothermal frequency sweeps and isochronal temperature sweeps, in broadband dielectric spectroscopy can allow for the identification of multiple processes derived from the same relaxation mechanism in certain polymer/polymer blends. A study of poly(vinyl methyl ether) (PVME) in bulk, miscible blends with polystyrene (PS) gives evidence of two separate relaxation processes associated exclusively with the segmental dynamics of PVME; the  $\alpha_0$  process from the temperature sweep, related to average segmental dynamics, and the  $\alpha'$  process from the frequency sweep, related to relaxations confined within “frozen” domains. The appearance of multiple processes is driven by compositional heterogeneity, mainly chain connectivity and concentration fluctuation effects. Analysis of the breadth and intensity of the dielectric loss curves gives insight into the structure and thermodynamics of the blend, which in turn can explain temperature and composition dependent dynamic trends. These results are contrasted with other miscible blend systems, polyisoprene (PI)/poly(4-tert-butylstyrene) (P4tBS) and polyisoprene (PI)/polyvinyl ether (PVE).

**8:48AM E42.00003 Thermal and Mechanical Properties of Poly(methyl methacrylate)/Poly(vinylidene fluoride-r-hexafluoro propylene) Blends<sup>1</sup>**, STEVEN LEE, Materials Science and Engineering, MAEVE CONWAY<sup>2</sup>, Mechanical, Aerospace and Nuclear Engineering, DENIZ RENDE, Center for Materials, Devices and Integrated Systems, RAHMI OZISIK, Materials Science and Engineering; Rensselaer Polytechnic Institute — Poly(vinylidene fluoride), PVDF, is a highly crystalline and rigid polymer, and is used in many applications where chemical inertness, resistance to various solvents and environmental degradation are required. Copolymerization of PVDF with hexafluoropropylene (HFP) tends to decrease the amount of crystallinity, thereby, resulting in a more flexible polymer, which provides new applications for PVDF. Various studies were undertaken to investigate the structure and properties of miscible blends of PVDF and poly(methyl methacrylate), PMMA; however, no studies were performed on the blends of P(VDFHFP) random copolymers and PMMA. In the current study, we investigate the miscibility, and thermal and mechanical properties of P(VDFHFP)/PMMA blends via differential scanning calorimetry, thermogravimetric analysis, and nanoindentation. Results indicate that increasing PMMA concentration leads to decreased crystallinity and shifting of the crystallization onset temperature during cooling to lower values.

**9:00AM E42.00004 Engineering thermal conductivity in polymer blends<sup>1</sup>**, VAHID RASHIDI, ELEANOR COYLE, JOHN KIEFFER, KEVIN PIPE, Univ of Michigan - Ann Arbor — Weak inter-chain bonding in polymers is believed to be a bottleneck for both thermal conductivity and mechanical strength. Most polymers have low thermal conductivity (~0.1 W/mK), hindering their performance in applications for which thermal management is critical (e.g., electronics packaging). In this work, we use computational methods to study how hydrogen bonding between polymer chains as well as water content can be used to engineer thermal transport in bulk polymers. We examine how changes in the number of hydrogen bonds, chain elongation, density, and vibrational density of states correlate with changes in thermal conductivity for polymer blends composed of different relative constituent fractions. We also consider the effects of bond strength, tacticity, and polymer chain mass. For certain blend fractions, we observe large increases in thermal conductivity, and we analyze these increases in terms of modifications to chain chemistry (e.g., inter-chain bonding) and chain morphology (e.g., chain alignment and radius of gyration). We observe that increasing the number of hydrogen bonds in the system results in better packing as well as better chain alignment and elongation that contribute to enhanced thermal conductivity.

**9:12AM E42.00005 Field-theoretic study on colloidal interaction in solutions of adsorbing homopolymers** , WEI LI, KRIS DELANEY, GLENN FREDRICKSON, Univ of California - Santa Barbara — Using self-consistent field theory, we study the free polymer induced (FPI) interaction between colloidal particles in a homopolymer solution. In the colloid limit, the Derjaguin approximation can be applied to relate the potential of mean force between two spherical objects to that between two parallel plates. A field-theoretic model is formulated in the grand canonical ensemble to compute the potential of mean force for the system consisting of two solid plates with polymer solution confined in between. The relationship between polymer-colloid affinity and FPI interaction is investigated through simulations. Three distinct regimes, including depletion interaction, steric repulsion and bridging interaction, are identified. A transition through these interaction regimes with increasing polymer-colloid affinity is shown as a consequence of competing entropic and enthalpic effects. We also study the impact of varying the degree of polymerization of the homopolymer, the solvent quality and the polymer concentration on the FPI interaction.

**9:24AM E42.00006 Entanglement Length in Miscible Blends of *cis*-Polyisoprene and Poly(*p*tert-butylstyrene)** , HIROSHI WATANABE, YUMI MATSUMIYA, Inst. Chem. Res., Kyoto Univ. — In miscible polymer blends, the entanglement length is common for the components, but its changes with the composition  $w$  remain unclear. For this problem, this study analyzed viscoelastic data for miscible blends of *cis*-polyisoprene (PI) and poly(*p*tert-butylstyrene) (PtBS), considering the basic feature that the local relaxation is determined only by  $w_{PI}$ . On the basis of this feature, a series of unentangled low- $M$  PI/PtBS blends having various  $M$  and a given  $w_{PI}$  were utilized as references for well-entangled high- $M$  PI/PtBS blends having the same  $w_{PI}$ , and the modulus data of the references were subtracted from the high- $M$  blend data. For an optimally chosen reference, the storage modulus  $G'_e$  of the high- $M$  blends obtained after the subtraction exhibited a clear entanglement plateau  $G'_N$  and the corresponding  $G''_e$  decreased in proportion to  $1/\omega$  at high frequencies  $\omega$ . Thus, the onset of entanglement relaxation was detected. The  $G'_N$  values were well described by a linear mixing rule of the entanglement length with the number fraction of Kuhn segments of the components being utilized as the averaging weight. This result, not explained by a mean-field picture of entanglement, is discussed in relation to local packing of bulky PtBS chains and skinny PI chains.

**9:36AM E42.00007 Effect of twist-orientation on mechanical properties of self-reinforced poly(lactic acid) screws in simulated body environment** , MASATO SAKAGUCHI, SATOSHI KOBAYASHI, tokyo metropolitan university, COMPOSITE ENGINEERING LAB TEAM — Poly(lactic acid) (PLA) attracts much attention as a typical biodegradable polymer, and has been applied as a bone fixation device. As one of the methods to improve mechanical properties of PLA bone fixation device, orientations of molecular chains have been investigated. However, conventional uniaxial drawing could not improve mechanical properties along the other loading direction than the drawing direction, such as torsion. In this study, screw is treated as a bone fixation device. In order to improve torsional strength of a bioabsorbable PLA screw, twist-orientation method has been developed. PLA screw is prepared through a series of routes including extrusion molding, extrusion drawing, twist-orientation and forging. This screw was immersed in the phosphate buffer solution for 0, 8, 16 and 24 weeks, then shear strength, orientation function, crystallinity and molecular weight were measured. As a result, twist-orientation improves the initial torsional strength of PLA screw without the decrease in initial shear strength. In addition, the shear strength on twist-oriented screw is equivalent that of non-twist oriented screw during immersion until 24 weeks. This result shown that the twist-orientation does not decrease shear strength after immersion.

**9:48AM E42.00008 PVC-OH Functionalized SWCNT Nanocomposites** , ANDRES SALGADO, ROBERT JONES, SAMANTHA RAMIREZ, IBRAHIM ELAMIN, JAMES HINTHORNE, MIRCEA CHIPARA, University of Texas Rio Grande Valley — Nanocomposites of polyvinylchloride loaded with various amounts of OH functionalized Single Walled Carbon Nanotubes (SWCNT-OH) have been obtained by melt mixing using a Haake Rheomixer. The polymeric matrix has been loaded by various amount of SWCNT-OH ranging between 0 and 15 % wt. The as obtained nanocomposites have been measured by Raman spectroscopy using a InVia Renishaw spectrometer. The Raman lines have been deconvoluted into a superposition of extended Breit-Wigner-Fano line shapes. The effect of nanofiller concentration on the stress transfer from the polymeric matrix to SWCNTs has been analyzed and the Radial Breathing Mode was investigated. Differential Scanning Calorimetry revealed modest shifts of the melting and crystallization temperatures upon loading with SWCNT-OH. Additional information has been obtained by X-Ray measurements. The as obtained nanocomposites have not a very good thermal stability due to the thermally induced dehydrochlorination process. The thermogravimetric data are analyzed in detail and related to Raman results. Preliminary data on the thermal stability of these nanocomposites are reported.

**10:00AM E42.00009 Bottlebrush Polymer Additives for Binary Polymer Blends** , HUI ZHEN MAH, PANTEA AFZALI, HANH PHAN, University of Houston, LUQING QI, STACY PESEK, RAFAEL VERDUZCO, Rice University, GILA STEIN, University of Houston — Bottlebrush polymers are highly branched polymers that have been used in applications such as self-assembling photonics, drug delivery and stimuli-responsive surface coatings. However, they have not been widely studied as compatibilizers for polymer blends. In this study, bottlebrush polymers with poly(styrene-*r*-methyl methacrylate) side chains were used as additives for thin film blends of polystyrene (PS) and poly(methyl methacrylate) (PMMA). The blends were heated above the glass transition temperature to drive phase separation, and the resulting morphology was characterized with atomic force microscopy and optical microscopy. Outcomes were compared with PS/PMMA blends that contain conventional compatibilizers such as linear random copolymers of poly(styrene-*r*-methyl methacrylate) and diblock PS-PMMA copolymers. The bottlebrush additive accumulates at the PS/PMMA interface and drives the formation of vesicle-like droplets that assemble into longer chains. The continuity of the chains depends on the blend composition, where a network structure is achieved close to the critical composition. This unusual microstructure was not observed with the other additives, and may be a consequence of preferential wetting of the bottlebrush by the PS phase.

**10:12AM E42.00010 Molecular Dynamics Simulations of Nanoparticles Coated with Charged Polymers** , CHENGYUAN WEN, SHENGFENG CHENG, Virginia Polytechnic Institute and State University — Polymer coating is frequently used to stabilize colloidal and nano-sized particles. We employ molecular dynamics simulations to study nanoparticles coated with polymer chains that contain ionizable groups. In a polar solvent, the chains become charged with counterions dissociated. In the computational model, we treat the solvent as a uniform dielectric background and use the bead-spring model for the polymer chains. Counterions are explicitly included as mobile beads. The nanoparticle is modeled as a layer of sites uniformly distributed on a spherical surface with a certain fraction of sites serving as the tether points of the grafted polymer brush. We vary the grafting density and calculate the distribution of polymer beads and counterions around the nanoparticle. Our results indicate that charged chains adopt extended conformations because of their mutual repulsions. We further study the interactions between two polymer-coated nanoparticles and obtain the potential of mean force. We also find an interesting transition of a confined single layer of such polymer-coated nanoparticles into two layers when the confinement is removed. Results show that the brush-brush contact has a nonuniform distribution and the nanoparticles tend to form dipole-like structures.

**10:24AM E42.00011 Raman Investigations of PVDF-BaTiO<sub>3</sub> Nanocomposites** , JULIO CANTU, Univ of Texas, Rio Grande Valley, CRISTIAN CHIPARA, PULLICKEL AJAYAN, Rice University, JAMES HINTHORNE, MIRCEA CHIPARA, Univ of Texas, Rio Grande Valley — BaTiO<sub>3</sub> nanoparticles (from Nanostructured & Amorphous Materials, Inc.) were dispersed within PVDF powder (from Sigma Aldrich) by melt mixing using a Haake Rheomix with two counter rotating screws. The mixing consisted of 3 segments first at 190 °C and 60 rotations per minute (rpm) for 30 minutes, second at 210 °C and 80 rpm for 15 minutes, and the last at 180 °C and 60 rpm for 30 minutes. Nanocomposites containing various fractions of nanofiller, ranging from 0 to 15 % wt. have been prepared. Raman investigations on the as obtained nanocomposites have been performed by using a Renishaw InVia spectrometer operating at 532 and 785 cm<sup>-1</sup>. Complementary Wide Angle X-Ray Scattering measurements on the same samples revealed that the as obtained nanocomposites have a dominant beta phase and provided additional information about the size of polymeric crystallites. The effect of the nanofiller on the Raman lines of the PVDF are analyzed in detail. The Raman spectra have been deconvoluted assuming a superposition distorted Lorentzian line shape. The changes of the Raman spectrum parameters (position, amplitude, width, and asymmetry factors) due to the loading with BaTiO<sub>3</sub> is discussed.

**10:36AM E42.00012 Coarse-grained explicit solvent simulation of the translational and rotational diffusion of a spherical particle in a polymer solution**, VICTOR PRYAMITSYN, Northwestern University, VENKAT GANESAN, University of Texas at Austin — We use an extension of DPD model to address the dynamical properties of a colloid particle in an unentangled semi-dilute polymer solution. Solvent and monomers are represented as DPD particles. The colloid particle is represented as a larger DPD particle with the rotational degrees of freedom and tangential component of the dissipative and random DPD interactions with the solvent and monomers. This allows us to model a finite slip length boundary condition at the particle fluid interface and study translational  $D_t$  and rotational  $D_r$  diffusivities of a spherical particle. For zero polymer concentration our results agree with the Stokes-Einstein (SE) theory. For dilute and semi-dilute polymer solutions we have found that polymer dynamic follow the Zimm model in a dilute regime and the Rouse model at high polymer concentration. For particles smaller than the polymer  $R_g$  observed  $D_t$  is much higher than SE prediction for  $R > R_g$  SE prediction recovers. We have found that increase of  $D_r$  relative to SE is rather correlated to the  $\frac{R}{R_g}$  ratio than  $\frac{R}{\xi}$ , where  $\xi$  is the thickness of a depletion shell around the particle.  $D_r$  is very sensitive to the slip length at the particle fluid interface and insensitive to  $\frac{R}{R_g}$ .

**10:48AM E42.00013 Characterization of the crosslinking reaction in high performance phenolic resins**, JIGNESHKUMAR PATEL, GUO XIANG ZOU, SHAW LING HSU, university of massachusetts, UNIVERSITY OF MASSACHUSETTS/POLYMER SCIENCE & ENGINEERING TEAM — In this study, a combination of thermal analysis, infrared spectroscopy (near and mid) in conjunction with low field NMR, was used to characterize the crosslinking reaction involving phenol formaldehyde resin and a crosslinking agent, Hexamethylenetetramine (HMTA). The strong hydrogen bonds in the resin and the completely crystalline HMTA ( $T_m = 280$  C) severely hamper the crosslinking process. Yet the addition of a small amount of plasticizer can induce a highly efficient crosslinking reaction to achieve the desired mechanical properties needed in a number of high performance organic-inorganic composites. The infrared spectroscopy clarifies the dissolution process of the crystalline crosslinker and the specific interactions needed to achieve miscibility of the reactants. The thermal analysis enabled us to follow the changing mobility of the system as a function of temperature. The low field NMR with the T1 inverse recovery technique allowed us to monitor the crosslinking process directly. For the first time, it is now possible to identify the functionality of the plasticizer and correlate the crosslinked structure achieved to the macroscopic performance needed for high performance organic-inorganic composites.

**Session E43 GSNP GSOF: Jamming and the Glass Transition I** 346 - Ray Orbach

**8:00AM E43.00001 ABSTRACT WITHDRAWN —**

**8:12AM E43.00002 Jamming for a system of granular crosses<sup>1</sup>**, ZEGAN SHANG, Duke University, HU ZHENG, Hohai University, DONG WANG, JONATHAN BARES, ROBERT BEHRINGER, Duke University — A disordered stress-free granular packing can be turned into a rigid structure, which is called jammed state, by increasing the density of particles per unit volume or by applying shear deformation. The jamming behavior of systems made of 2D circular discs have been investigated in detail, but very little is known about the special geometry particles, particularly non-convex particles like crosses. Here, we perform an experimental study on the jamming of a system of quasi-2D granular crosses. In the present experiments, we measure the pressure, and coordinate number evolution of a 2D packing of photo-elastic cross discs. This talk will present results from a simple shear experiment for stresses and for the order parameter associated with the cross orientation and its correlation.

**8:24AM E43.00003 Experimental studies of contact networks in jammed colloidal systems**, ERU KYEYUNE-NYOMBI, LANE GILCHRIST, HERNN MAKSE, City College of New York — Recent theoretical advances in the statistical mechanics of jamming have provided a new outlook for thermodynamically characterizing packings of granular matter. Packing density, spatial ordering metrics, and the number of inter-particle contacts are a few fundamental parameters used in various theoretical models. However, experimental measurements of inter-particle forces have been illusive. Here, fluorescent molecular probes are used to identify inter-particle contacts in high resolution confocal images of jammed colloidal systems.

**8:36AM E43.00004 Experimental Study of Athermal Elastic Network Mechanics**, JONATHAN MICHEL, PETER YUNKER, Georgia Institute of Technology — Recently, significant theoretical effort has been directed towards understanding the mechanics of networks. Elastic networks are of inherent fundamental interest <sup>1</sup> and serve as useful analogs for describing other physical systems. Recent applications include modeling of collagen <sup>2</sup> and descriptions of jamming in granular media and glass formation <sup>3</sup>. I propose to discuss ongoing experimental efforts to study mechanical properties of elastic networks, such as Young's modulus and ultimate strength, in the athermal limit. I will begin with the simple case of regular, isostatic crystalline lattices and proceed to studies of random, connected elastic networks of varying bond number for a given number of lattice sites, including both isostatic and sub-isostatic networks.

**8:48AM E43.00005 Interparticle contact networks of granular packings below jamming**, BHASKAR SEN GUPTA, THIBAUT BERTRAND, COREY S. O'HERN, Yale University, MARK D. SHATTUCK, City College of New York — We employ computer simulations to investigate the structural properties of interparticle contact networks in granular packings of bidisperse disks below jamming onset at which the system becomes solid-like. We show that the properties of the contact networks are highly sensitive to changes in the packing-generation protocol and its numerical implementation. Thus, we formulate an analytical method to implement steepest descent of hard, athermal particles undergoing isotropic compression, which allows us to calculate the number of contacts as a function of packing fraction. These results represent an important first step in developing a theoretical description of shear- and compression-induced jamming in frictional granular media.

**9:00AM E43.00006 Contact breaking in frictionless granular packings<sup>1</sup>**, QIKAI WU, THIBAUT BERTRAND, COREY O'HERN, Yale University, MARK SHATTUCK, City College of the City University of New York — We numerically study the breaking of interparticle contact networks in static granular packings of frictionless bidisperse disks that are subjected to vibrations. The packings are created using an isotropic compression protocol at different values of the total potential energy per particle  $E_p$ . We first add displacements along a single vibrational mode  $i$  of the dynamical matrix to a given packing and calculate the minimum amplitude  $A_i$  of the perturbation at which the first interparticle contact breaks. We then identify the minimum amplitude  $A_{\min}$  over all perturbations along each mode and study the distribution of  $A_{\min}$  from an ensemble of packings at each  $E_p$ . We then study two-, three-, and multi-mode excitations and determine the dependence of  $A_{\min}$  on the number of modes that are included in the perturbation.

**9:12AM E43.00007 Echoes of the glass transition in athermal soft spheres** , PETER MORSE, ERIC CORWIN, University of Oregon — The glass transition and the athermal jamming transition are both transitions from one disordered state to another marked by a sudden increase in rigidity. Before the onset of rigidity, thermal hard spheres and athermal soft spheres both share the same configuration space. Is there a signature of the glass transition in the topology of the allowed configuration space, and is this same signature present for athermal spheres? I will answer these questions by introducing the concept of local rigidity, and in doing so, I will demonstrate the existence of a pre-jamming phase transition precisely at the glass transition density.

**9:24AM E43.00008 Structural Signatures of the glass transition** , CHI ZHANG, Department of Physics, Université de Fribourg, CH-1700 Fribourg, Switzerland., NICOLETTA GNAN, EMANUELA ZACCARELLI, CNR-ISC, UOS Sapienza, P.le A. Moro 2, Roma I-00185, Italy. Dipartimento di Fisica, Sapienza Università di Roma, P.le A. Moro 2, Roma I-00185, Ital, FRANK SCHEFFOLD, Department of Physics, Université de Fribourg, CH-1700 Fribourg, Switzerland. — The nature of colloidal glasses and the glass transition remains a topic of scientific interest. Scientists often focus on the study of dynamical properties since major structural changes have not been found to date in the vicinity of the glass transition. In this work we study both structural and dynamic signatures of the glass and jamming transition. Confocal microscopy measurements and molecular dynamic simulations are conducted on buoyancy and index matched microscale emulsion droplets with polydispersity of 12%, where crystallization is avoided. We find that the glass transition of such system is associated with detailed structural signatures on both global and local scales. At the global level, the peak amplitude of the radial distribution function shows a nonmonotonic evolution around a volume fraction of 59%. At the individual particle level, some local parameters such as the configuration of the nearest neighbors and the locally favoured structures also evolve differently across a volume fraction of about 59% whereas the jamming transition is clearly observed at higher densities 64.2%. Our results reveal clear structural signatures of the glass transition, which could help the further understanding of the underlying physical mechanism leading to dynamical arrest.

**9:36AM E43.00009 Casimir forces in systems near jamming<sup>1</sup>** , JUSTIN BURTON, JUAN-JOSÉ LIÉTOR-SANTOS, Department of Physics, Emory University — Casimir forces arise when long-ranged fluctuations are geometrically confined between two surfaces. In most cases these fluctuations are quantum or thermal in nature, such as those near a classical critical point, yet this is not a requirement. The  $T = 0$  jamming transition in frictionless, granular systems shares many properties with classical critical points, such as a diverging correlation length, although it has recently been identified as a unique example of a random first-order transition (RFOT). Here we show the existence of Casimir forces between two pinned particles immersed in systems near the frictionless jamming transition. We observe two components to the total force: a short-ranged, depletion force and a long-ranged, repulsive Casimir force. The Casimir force dominates when the pinned particles are much larger than the ambient jammed particles. In this case, we find that particles with the largest forces have the least number of contacts, and that these particles are clustered between the pinned particles, giving rise to a repulsive force which is independent of system preparation and inter-particle potential.

<sup>1</sup>We acknowledge support from NSF DMR-1455086

**9:48AM E43.00010 Rearrangements in Sheared Disordered Solids: Low and High Pressure Regimes** , SVEN WIJTMANS, Syracuse University, MERLIJN VAN DEEN, MARTIN VAN HECKE, Universiteit Leiden, M. LISA MANNING, Syracuse University — We study contact changes and rearrangements in quasistatic shear of disordered jammed packings at a range of pressures. We distinguish rearrangements where particle positions are discontinuous, leading to energy and stress discontinuities, from more frequent network events where contacts change but particle positions remain continuous. Moreover, we introduce two distinct protocols to unambiguously distinguish line reversible, loop reversible and irreversible events. The prevalence and spatial extension of five distinct event types (there are no loop reversible network events) evidence two distinct regimes: a low pressure regime dominated by irreversible extended events and a high pressure regime dominated by reversible localized ones. These trends indicate a crossover in the qualitative nature of plastic behavior in disordered solids near and far from jamming.

**10:00AM E43.00011 ABSTRACT WITHDRAWN —**

**10:12AM E43.00012 Rheological Transition of Sheared Frictionless Disks with Rotational Motion<sup>1</sup>** , PETER OLSSON, Ume University, STEVE TEITEL, University of Rochester — We consider the massive Durian bubble model for sheared bidisperse disks, but modified so as to include the rotational motion of particles due to dissipative collisional torques. In such a model, particles possess a viscous tangential dissipation, though no elastic tangential friction. As the packing fraction is increased, we find a discontinuous transition from Bagnoldian to Newtonian rheology, at a packing fraction that lies below the jamming transition. At this transition we find a region of coexisting shear bands of Bagnoldian and Newtonian rheology, and suggestions of discontinuous shear thickening upon increasing the shear strain rate.

<sup>1</sup>This work has been supported by NSF Grant No. DMR-1205800.

**10:24AM E43.00013 Critical Scaling of Bagnold Rheology at the Jamming Transition of Frictionless Disks<sup>1</sup>** , STEPHEN TEITEL, University of Rochester, DANIEL VÅGBERG, Delft Univ of Tech, PETER OLSSON, Umeå University — We simulate shear-driven, frictionless, bidisperse disks in two dimensions, as a function of applied shear strain rate and packing fraction, for a model with a normal viscous dissipation that results in Bagnoldian rheology for all control parameters. Carrying out a critical scaling analysis of the pressure and shear stress near the jamming transition we find values of the critical exponents that disagree with theoretical predictions of Otsuki and Hayakawa[1] but are closer to more recent theoretical results by DeGiuli et al[2], as well as earlier simulations by Peyneau and Roux[3]. We find that it is essential to include leading corrections-to-scaling to arrive at self-consistent results.

**10:48AM E43.00015 Increasing the maximally random jammed density with electric field to reduce the fat level in chocolate**, R. TAO<sup>1</sup>, H. TANG, Temple Univ — Chocolate is one of the most popular food types and flavors in the world. Unfortunately, at present, chocolate products contain too much fat, leading to obesity. For example, a typical molding chocolate has various fat up to 40% in total and chocolate for covering ice cream has fat 50 -60%. Especially, as children are the leading chocolate consumers, reducing the fat level in chocolate products to make them healthier is important and urgent. While this issue was called into attention and elaborated in articles and books decades ago and led to some patent applications, no actual solution was found unfortunately. Why is reducing fat in chocolate so difficult? What is the underlying physical mechanism? We have found that this issue is deeply related to the basic science of soft matters, especially to their viscosity and maximally random jammed (MRJ) density  $\varphi_x$ . All chocolate productions are handling liquid chocolate, a suspension with cocoa solid particles in melted fat, mainly cocoa butter. The fat level cannot be lower than  $1-\varphi_x$  in order to have liquid chocolate to flow. Here we show that that with application of an electric field to liquid chocolate, we can aggregate the suspended particles into prolate spheroids. This microstructure change reduces liquid chocolate's viscosity along the flow direction and increases its MRJ density significantly. Hence the fat level in chocolate can be effectively reduced. We are looking forward to a new class of healthier and tasteful chocolate coming to the market soon.

**8:36AM E44.00002 Entanglement verification with detection efficiency mismatch**, YANBAO ZHANG, NORBERT LÜTKENHAUS, Institute for Quantum Computing & Department of Physics and Astronomy, University of Waterloo — Entanglement is a necessary condition for secure quantum key distribution (QKD). When there is an efficiency mismatch between various detectors used in the QKD system, it is still an open problem how to verify entanglement. Here we present a method to address this problem, given that the detection efficiency mismatch is characterized and known. The method works without assuming an upper bound on the number of photons going to each threshold detector. Our results suggest that the efficiency mismatch affects the ability to verify entanglement: the larger the efficiency mismatch is, the smaller the set of entangled states that can be verified becomes. When there is no mismatch, our method can verify entanglement even if the method based on squashing maps [PRL 101, 093601 (2008)] fails.

**8:48AM E44.00003 Machine Learning for Quantum Metrology and Quantum Control<sup>1</sup>**, BARRY SANDERS<sup>2</sup>, EHSAN ZAHEDINEJAD, PANTITA PALITTAPONGARNPIM, University of Calgary — Generating quantum metrological procedures and quantum gate designs, subject to constraints such as temporal or particle-number bounds or limits on the number of control parameters, are typically hard computationally. Although greedy machine learning algorithms are ubiquitous for tackling these problems, the severe constraints listed above limit the efficacy of such approaches. Our aim is to devise heuristic machine learning techniques to generate tractable procedures for adaptive quantum metrology and quantum gate design. In particular we have modified differential evolution to generate adaptive interferometric-phase quantum metrology procedures for up to 100 photons including loss and noise, and we have generated policies for designing single-shot high-fidelity three-qubit gates in superconducting circuits by avoided level crossings. Although quantum metrology and quantum control are regarded as disparate, we have developed a unified framework for these two subjects, and this unification enables us to transfer insights and breakthroughs from one of the topics to the other.

**9:00AM E44.00004 Ultimate precision limit and optimal probe states for quantum metrology**, HAIDONG YUAN, Chinese Univ of Hong Kong, CHI-HANG FRED FUNG, Huawei, Hong Kong Science Park — An important task in science and technology is to find out the highest achievable precision in measuring and estimating parameters of interest with given resources, and design schemes to reach it. Quantum metrology, which exploits quantum mechanical effects to achieve high precision, has gained increasing attention in recent years. Here we present a general framework for quantum metrology which relates the ultimate precision limit directly to the underlying dynamics, this framework provides efficient methods for computing the ultimate precision limit and optimal probe states. We further demonstrate the power of the framework by deriving a sufficient condition on when ancillary systems are not useful for improving the precision limit.

**9:12AM E44.00005 Improving the precision of weak measurement by nonclassical states**, SHENG-SHI PANG, University of Rochester, TODD A. BRUN, University of Southern California — Weak value amplification is a useful protocol to amplify tiny physical effects by postselecting the system in a weak measurement. However, there has been controversy over its precision advantage in parameter estimation recently, since it discards unselected results of the postselection measurement on the system, which may take away useful information. While it is now clear that retaining failed postselections can yield more Fisher information than discarding them, the advantage of postselection measurement itself still remains to be clarified. If a weak measurement with postselection measurement cannot not produce higher precision than without postselection measurement, it would be meaningless to discuss the use of postselection results. In this work, we address this problem by studying the optimal signal-to-noise ratio (SNR) of postselected weak measurement. We find a surprising result that when the probe is initially prepared in a proper squeezed coherent state, the postselected weak measurement can give a higher SNR than the standard weak measurement, while such an advantage vanishes when the probe is prepared in a normal coherent state. This suggests that raising the precision of weak measurement by postselection calls for the presence of nonclassicality in the probe state.

**9:24AM E44.00006 Robust Calibration of a Universal Single-Qubit Gate-Set via Robust Phase Estimation**, SHELBY KIMMEL, University of Maryland, QUICS, GUANG HAO LOW, THEODORE J. YODER, Massachusetts Institute of Technology — An important step in building a quantum computer is calibrating experimentally implemented quantum gates to produce operations that are close to ideal unitaries. The calibration step involves estimating the systematic errors in gates and then using controls to correct the implementation. Quantum process tomography is a standard technique for estimating these errors, but is both time consuming, (when one only wants to learn a few key parameters), and is usually inaccurate without resources like perfect state preparation and measurement, which might not be available. With the goal of efficiently and accurately estimating specific errors using minimal resources, we develop a parameter estimation technique, which can gauge key systematic parameters (specifically, amplitude and off-resonance errors) in a universal single-qubit gate-set with provable robustness and efficiency. In particular, our estimates achieve the optimal efficiency, Heisenberg scaling, and do so without entanglement and entirely within a single-qubit Hilbert space. Our main theorem making this possible is a robust version of the phase estimation procedure of Higgins et al. [B. L. Higgins et al., New J. Phys. 11 073023 (2009)].

**9:36AM E44.00007 Numerical Analysis of Robust Phase Estimation** , KENNETH RUDINGER, Center for Computing Research, Sandia National Laboratories, SHELBY KIMMEL, QuICS, University of Maryland — Robust phase estimation (RPE) is a new technique for estimating rotation angles and axes of single-qubit operations, steps necessary for developing useful quantum gates [arXiv:1502.02677]. As RPE only diagnoses a few parameters of a set of gate operations while at the same time achieving Heisenberg scaling, it requires relatively few resources compared to traditional tomographic procedures. In this talk, we present numerical simulations of RPE that show both Heisenberg scaling and robustness against state preparation and measurement errors, while also demonstrating numerical bounds on the procedure's efficacy. We additionally compare RPE to gate set tomography (GST), another Heisenberg-limited tomographic procedure. While GST provides a full gate set description, it is more resource-intensive than RPE, leading to potential tradeoffs between the procedures. We explore these tradeoffs and numerically establish criteria to guide experimentalists in deciding when to use RPE or GST to characterize their gate sets.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**9:48AM E44.00008 Formal Computer Validation of the Quantum Phase Estimation Algorithm<sup>1</sup>** , WAYNE WITZEL, KENNETH RUDINGER, Sandia National Laboratories, Albuquerque, NM, MOHAN SAROVAR, Sandia National Laboratories, Livermore, CA, ROBERT CARR, University of New Mexico — While peer review and scientific consensus provide some assurance to the validity of ideas, people do make mistakes that can slip through the cracks. A plethora of formal methods tools exist and are in use in a variety of settings where high assurance is demanded. Existing tools, however, require a great deal of expertise and lack versatility, demanding a non-trivial translation between a high-level description of a problem and the formal system. Our software, called Prove-It, allows a nearly direct translation between human-recognizable formulations and the underlying formal system. While Prove-It is not designed for particularly efficient automation, a primary goal of other formal methods tools, it is extremely flexible in following a desired line of reasoning (proof structure). This approach is particularly valuable for validating proofs that are already known. We will demonstrate a validation of the Quantum Phase Estimation Algorithm using Prove-It. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:00AM E44.00009 Efficient Bayesian Phase Estimation** , NATHAN WIEBE, Microsoft Research, CHRISTOPHER GRANADE, University of Sydney — We provide a new efficient adaptive algorithm for performing phase estimation that does not require that the user infer the bits of the eigenphase in reverse order; rather it directly infers the phase and estimates the uncertainty in the phase directly from experimental data. Our method is highly flexible, recovers from failures, and can be run in the presence of substantial decoherence and other experimental imperfections and is as fast or faster than existing algorithms.

**10:12AM E44.00010 Bounding quantum gate error rate based on reported average fidelity** , YUVAL SANDERS, JOEL WALLMAN, Univ of Waterloo, BARRY SANDERS, Univ of Calgary — Remarkable experimental advances in quantum computing are exemplified by recent announcements of impressive average gate fidelities exceeding 99.9% for single-qubit gates and 99% for two-qubit gates. Although these high numbers engender optimism that fault-tolerant quantum computing is within reach, the connection of average gate fidelity with fault-tolerance requirements is not direct. Here we use reported average gate fidelity to determine an upper bound on the quantum-gate error rate, which is the appropriate metric for assessing progress towards fault-tolerant quantum computation, and we demonstrate that this bound is asymptotically tight for general noise. Although this bound is unlikely to be saturated by experimental noise, we demonstrate using explicit examples that the bound indicates a realistic deviation between the true error rate and the reported average fidelity. We introduce the Pauli-distance as a measure of this deviation, and we show that knowledge of the Pauli-distance enables tighter estimates of the error rate of quantum gates.

**10:24AM E44.00011 Percolation bounds for decoding thresholds with correlated erasures in quantum LDPC codes<sup>1</sup>** , KATHLEEN HAMILTON, None, LEONID PRYADKO, University of California, Riverside — Correlations between errors can dramatically affect decoding thresholds, in some cases eliminating the threshold altogether. We analyze the existence of a threshold for quantum low-density parity-check (LDPC) codes in the case of correlated erasures. When erasures are positively correlated, the corresponding multi-variate Bernoulli distribution can be modeled in terms of cluster errors, where qubits in clusters of various size can be marked all at once. In a code family with distance scaling as a power law of the code length, erasures can be always corrected below percolation on a qubit adjacency graph associated with the code. We bound this correlated percolation transition by weighted (uncorrelated) percolation on a specially constructed cluster connectivity graph, and apply our recent results [1] to construct several bounds for the latter.

**10:36AM E44.00012 Robustness and performance scaling of quantum information processors with respect to gate removal and defects** , YUNSEONG NAM, REINHOLD BLÜMEL, Wesleyan Univ — A single logical gate, when removed from a classical computer, can completely destroy its information processing capability. For a quantum processor, the story is quite different. We find that the processing capability of a quantum information processor is robust with respect to the removal of a large number of quantum logical gates. In fact, even when most of the quantum processor's gates are removed, quantum processors, such as the universally applicable quantum Fourier transform or the quantum adder, work with satisfactory performance. In this talk, we present our numerical and analytical results detailing the performance scaling of quantum processors with respect to gate pruning operations. We also present the performance scaling of pruned quantum processors subjected to gate defects in the remaining gates.

**10:48AM E44.00013 Assessing the performance of quantum repeaters for all phase-insensitive Gaussian bosonic channels** , KENNETH GOODENOUGH, DAVID ELKOUSS, STEPHANIE WEHNER, Delft Univ of Tech, QUTECH TEAM — One of the most sought-after goals in experimental quantum communication is the implementation of a quantum repeater. Quantum repeaters can be assessed by comparing their performance with the quantum- and private capacity of a direct transmission, assisted by unlimited classical two-way communication. Calculating these quantities is hard to compute however, motivating the search for upper bounds on these capacities. Takeoka, Guha and Wilde found the squashed entanglement of a quantum channel to be an upper bound on these capacities. In general it is hard to find the exact value of the squashed entanglement of a quantum channel, but clever, sub-optimal squashing maps still allow one to upper bound this quantity, and thus also the corresponding capacities. We follow this approach to upper bound the capacity of some specific channels, where in particular we extend the analysis of Takeoka et al. on the pure-loss channel to the general case of any Gaussian bosonic channel with equal noise in each quadrature. This bound is of practical importance, since it allows one to benchmark the implementation of quantum repeaters in quantum key distribution networks for a large class of channels.

**Session E45 GQI DAMOP: Hybrid Quantum Systems I** 348 - Mark Dykman, Michigan State University

**8:00AM E45.00001 Charge dynamics and spin blockade in a hybrid double quantum dot in silicon**<sup>1</sup>, ANASUA CHATTERJEE, MATIAS URDAMPILLETA, CHEUK CHI LO, JOHN MANSIR, London Centre for Nanotechnology, University College London, SYLVAIN BARRAUD, CEA-LETI, ANDREAS BETZ, M. FERNANDO GONZALEZ-ZALBA, Hitachi Cambridge Laboratory, JOHN J. L. MORTON, London Centre for Nanotechnology, University College London — Hybrid architectures combining donor atoms and quantum dots in silicon can take advantage of fast gate voltage based spin manipulations to form a hybrid singlet-triplet qubit, with access to the quantum memory offered by the nuclear spin of the donor via the hyperfine interaction. Additionally, spin buses using quantum dot chains could mediate the transfer of quantum information between long-lived donor spins. We present an approach to a novel hybrid double quantum dot by coupling a donor to an artificial atom in a CMOS-compatible nanotransistor. Using gate-based RF-reflectometry, we probe the charge stability of the system and its quantum capacitance. Through microwave spectroscopy, we find a tunnel coupling of 2.7GHz and characterize the charge dynamics, revealing a charge  $T_1$  of 100ns. We also show spin blockade at the interdot transition and investigate the spin dynamics, opening up the possibility to operate this coupled system as a singlet-triplet qubit and to coherently transfer spin information between the quantum dot and the donor electron and nucleus.

**8:12AM E45.00002 Controlling spin relaxation with a cavity**, AUDREY BIENFAIT, SPEC, CEA-Saclay, JARRYD PLA, University College of London, YUIMARU KUBO, SPEC, CEA-Saclay, XIN ZHOU, Institute of Electronics, Microelectronics, and Nanotechnology, MICHAEL STERN, University of Bar Ilan, CHEUK LO, University College of London, CHRISTOPHER WEIS, THOMAS SCHENKEL, Lawrence Berkeley National Laboratory, DENIS VION, DANIEL ESTEVE, SPEC, CEA-Saclay, JOHN MORTON, University College of London, PATRICE BERTET, SPEC, CEA-Saclay — Spontaneous emission of radiation is one of the fundamental relaxation mechanisms for a quantum system. For spins, however, it is negligible compared to non-radiative relaxation processes due to their weak coupling to the electromagnetic field. In 1946, Purcell realized [1] that spontaneous emission is strongly enhanced when the quantum system is placed in a resonant cavity - an effect now used to control the lifetime of systems with an electrical dipole [2]. Here, by coupling donor spins in silicon to a high quality factor superconducting microwave cavity of small mode volume, we reach the regime where spontaneous emission constitutes the dominant spin relaxation channel [3]. The relaxation rate is increased by three orders of magnitude when the spins are tuned to the cavity resonance, showing it can be engineered and controlled on-demand. Our results provide a novel way to initialize any spin into its ground state, with applications in magnetic resonance and quantum information processing. They also show for the first time an alteration of spin dynamics by quantum fluctuations, a step towards the coherent magnetic coupling of a spin to microwave photons. [1] E. M. Purcell, Phys. Rev. 1946, 69, 681. [2] P. Goy et al., PRL. 50, 1983. [3] A. Bienfait et al., arxiv :1508.06148

**8:24AM E45.00003 Coupling a Small Ensemble of Electrons on Helium to a Superconducting Circuit**, GE YANG, GERWIN KOOLSTRA, University of Chicago, DAVID CZAPLEWSKI, LEONIDAS OCOLA, Argonne National Laboratory Center for Nanoscale Materials, DAVID I. SCHUSTER, University of Chicago — Electrons on helium is a unique two-dimensional electron gas system formed at the interface of a quantum liquid (superfluid helium) and vacuum. If single electrons on helium can be isolated, the motional and spin states could form the building blocks for hybrid quantum computing [1,2]. Here we first review the strong coupling between a large electron ensemble and a microwave resonator [3]. Then we will describe methods to isolate small mesoscopic ensembles with less than 100 electrons in a micron-sized trap at the end of a quarter wavelength microwave cavity. Finally we will discuss the effect of helium fluctuations on the coherence of the hybrid circuit. [1] S. Lyon, Phys. Rev. A. 74, 5 (2006) [2] D.I. Schuster, et al. Phys. Rev. Lett. 105, 040503 (2010) [3] Ge Yang, et al., arXiv:1508.04847(2015)

**8:36AM E45.00004 Magnetic resonance at the quantum limit**, PATRICE BERTET, CEA Saclay — The detection and characterization of paramagnetic species by electron-spin resonance (ESR) spectroscopy has numerous applications in chemistry, biology, and materials science [1]. Most ESR spectrometers rely on the inductive detection of the small microwave signals emitted by the spins during their Larmor precession into a microwave resonator in which they are embedded. Using the tools offered by circuit Quantum Electrodynamics (QED), namely high quality factor superconducting micro-resonators and Josephson parametric amplifiers that operate at the quantum limit when cooled at 20mK [2], we report an increase of the sensitivity of inductively detected ESR by 4 orders of magnitude over the state-of-the-art, enabling the detection of 1700 Bismuth donor spins in silicon with a signal-to-noise ratio of 1 in a single echo [3]. We also demonstrate that the energy relaxation time of the spins is limited by spontaneous emission of microwave photons into the measurement line via the resonator [4], which opens the way to on-demand spin initialization via the Purcell effect. These results constitute a first step towards circuit QED experiments with magnetically coupled individual spins. [1] A. Schweiger and G. Jeschke, Principles of Pulse Electron Magnetic Resonance (Oxford University Press, 2001) [2] X. Zhou et al., Physical Review B 89, 214517 (2014). [3] A. Bienfait et al., arxiv :1507.06831 [4] A. Bienfait et al., arxiv :1508.06148

**9:12AM E45.00005 Hybrid Quantum Information Processing with Superconducting Circuits and Rydberg Atoms**, MATTHEW BECK, JOSHUA ISAACS, DONALD BOOTH, MARK SAFFMAN, ROBERT MCDERMOTT, University of Wisconsin - Madison — Hybrid approaches to quantum information processing exploit the strengths of disparate quantum technologies to realize performance that exceeds what can be reached with any single technology on its own. Here we describe steps toward realization of a hybrid superconducting circuit Rydberg atom quantum architecture that will marry a fast, high-fidelity superconducting quantum processor with a long-lived quantum memory based on trapped Rydberg atoms. The key challenge is development of a high-fidelity microwave photon Rydberg atom interface. We have designed superconducting thin-film microwave resonators that allow trapping of single Rydberg atoms at a voltage antinode, where coupling to the zero-point fields of the resonator is strongest. We discuss the dependence of resonator quality factor and achievable coupling factor on device geometry. Finally, we present preliminary results of experiments to couple Rydberg atoms and superconducting linear resonators in a custom liquid helium cryostat.

**9:24AM E45.00006 Photon-mediated interactions: a scalable tool to create and sustain entangled states of N atoms**, CAMILLE ARON, Laboratoire de Physique Thorique, cole Normale Suprieure, CNRS, Paris, France and Instituut voor Theoretische Fysica, KU Leuven, Leuven, Belgium, MANAS KULKARNI, New York City College of Technology, City University of New York, HAKAN TURECI, Princeton University — We propose and study the use of photon-mediated interactions for the generation of steady-state entanglement between N atoms that are separated by arbitrary distances. Through the judicious use of coherent drives and the placement of the atoms in a network of Cavity QED systems, a balance between their unitary and dissipative dynamics can be precisely engineered to stabilize a long-range correlated state of qubits in the steady state. We discuss the general theory behind such a scheme, and present an example of how it can be used to drive a register of N atoms to a generalized W-state, and the entanglement sustained indefinitely. The achievable steady-state fidelities for entanglement and its scaling with the number of qubits are discussed for presently existing superconducting quantum circuits. While the protocol is primarily discussed for a superconducting circuit architecture, it is ideally realized in any Cavity QED platform that permits controllable delivery of coherent electromagnetic radiation to specified locations.

**9:36AM E45.00007 Spin-cavity longitudinal coupling for two-qubit gates and measurement**, RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740 — We have studied the possibility of longitudinal coupling of various encoded quantum dot spin-qubits to a microwave resonator via modulation of voltage gates. A dynamical coupling of tens of MHz can be achieved. We investigate specific procedures for entangling gates using accumulated geometrics phases and calculate possible gate times and fidelities. Implications for qubit readout and continuous quantum monitoring are also considered.

**9:48AM E45.00008 Magnetization detecting electron paramagnetic resonance spectroscopy using a dc-SQUID directly coupled to an electron spin ensemble<sup>1</sup>**, HIRAKU TOIDA, YUICHIRO MATSUZAKI, KOSUKE KAKUYANAGI, XIAOBO ZHU<sup>2</sup>, WILLIAM MUNRO, NTT Basic Research Laboratories, KAE NEMOTO, National Institute of Informatics, HIROSHI YAMAGUCHI, SHIRO SAITO, NTT Basic Research Laboratories — Electron parametric resonance (EPR) spectroscopy is one of the most widely-used tool to characterize materials containing unpaired electrons. In the case of conventional EPR spectrometers, the resonance is detected as a change of microwave transmittance of a cavity. In our method, on the other hand, magnetization of the sample induced by the resonance is detected by a direct current superconducting quantum interference device (dc-SQUID) magnetometer, which is bonded to the sample. Here, we report detection of electron spin polarization and EPR spectroscopy using a micrometer-sized dc-SQUID magnetometer. We measure temperature and in-plane magnetic field dependence of spin polarization ratio and it has good agreement to the hyperbolic tangent law. We also successfully demonstrate EPR spectroscopy by applying a continuous microwave signal to the sample with a on-chip microstrip. We estimate the sensing volume and the minimum distinguishable number of electron spins to be  $\sim 10^{-10} \text{ cm}^3$  ( $\sim 0.1 \text{ pl}$ ) and  $\sim 10^6$ , respectively. This result paves the way towards realizing highly sensitive EPR spectroscopy in nanometer-sized area.

**10:00AM E45.00009 Coupling nanoscale spin ensembles to a SQUID embedded in superconducting circuits<sup>1</sup>**, C. EICHLER, J. R. PETTA, Department of Physics, Princeton University — Electron spin resonance is a ubiquitous phenomenon used for the characterization of paramagnetic materials and to coherently control electron spins as carriers of quantum information. The coupling strength between spins and RF magnetic fields can be increased by using microwave frequency resonators, realized either as 3D cavities or in planar geometries. Here, we study microwave resonators embedding a superconducting quantum interference device (SQUID), which couples to nearby electron spins of phosphorus donors in silicon. We compare different SQUID and resonator geometries aiming at enhanced spin sensitivity. We also study the coupled system in a sideband regime where the Zeeman energy is nonresonant with the cavity frequency, allowing for operation at lower DC magnetic fields.

**10:12AM E45.00010 Angular dependant micro-ESR characterization of a locally doped  $\text{Gd}^{3+}:\text{Al}_2\text{O}_3$  hybrid system for quantum applications**, I. S. WISBY, NPL, UK & Royal Holloway, UK, S.E. DE GRAAF, NPL, UK, R. GWILLIAM, ATI, University of Surrey, UK, A. ADAMYAN, Chalmers University of Technology, S. E. KUBATKIN, Chalmers University of Technology, Sweden, P. J. MEESON, Royal Holloway, UK, A. YA. TZALENCHUK, NPL, UK & Royal Holloway, UK, T. LINDSTROM, NPL, UK — Rare-earth doped crystals interfaced with superconducting quantum circuitry are an attractive platform for quantum memory and transducer applications. Here we present a detailed characterization of a locally implanted  $\text{Gd}^{3+}$  in  $\text{Al}_2\text{O}_3$  system coupled to a superconducting micro-resonator, by performing angular dependent micro-electron-spin-resonance (micro-ESR) measurements at mK temperatures. The device is fabricated using a hard  $\text{Si}_3\text{N}_4$  mask to facilitate a local ion-implantation technique for precision control of the dopant location. The technique is found not to degrade the internal quality factor of the resonators which remains above  $10^5$  (1). We find the measured angular dependence of the micro-ESR spectra to be in excellent agreement with the modelled Hamiltonian, supporting the conclusion that the dopant ions are successfully integrated into their relevant lattice sites whilst maintaining crystalline symmetries. Furthermore, we observe clear contributions from individual microwave field components of our micro-resonator, emphasising the need for controllable local implantation. 1) Wisby et al. Appl. Phys. Lett. **105**, 102601 (2014)

**10:24AM E45.00011 Strong Coupling of a Donor Spin Ensemble to a Volume Microwave Resonator**, BRENDON ROSE, ALEXEI TYRYSKIN, STEPHEN LYON, Princeton University — We achieve the strong coupling regime between an ensemble of phosphorus donor spins (5e13 total donors) in highly enriched 28-Si (50 ppm 29-Si) and a standard dielectric resonator. Spins were polarized beyond Boltzmann equilibrium to a combined electron and nuclear polarization of 120 percent using spin selective optical excitation of the no-phonon bound exciton transition. We observed a spin ensemble-resonator splitting of 580 kHz (2g) in a cavity with a Q factor of 75,000 ( $\kappa \ll \gamma \approx 120 \text{ kHz}$  where  $\kappa$  and  $\gamma$  are the external and internal resonator loss rates respectively). The spin ensemble has a long dephasing time (9  $\mu\text{s}$ ) providing a wide window for viewing the time evolution of the coupled spin ensemble-cavity system described by the Tavis-Cummings model. The free induction decay shows repeated collapses and revivals revealing a coherent and complete exchange of excitations between the superradiant state of the spin ensemble and the cavity (about 10 cycles are resolved). This exchange can be viewed as a swap of information between a long lived spin ensemble memory qubit ( $T_2 \approx 2 \text{ ms}$ ) and a cavity

**10:36AM E45.00012 Suppressing gate errors through extra ions coupled to a cavity in frequency-domain quantum computation using rare-earth-ion-doped crystal**, SATOSHI NAKAMURA, HAYATO GOTO, MAMIKO KUJIRAKA, KOUICHI ICHIMURA, Corporate RD Center, Toshiba Corporation, QUANTUM COMPUTER TEAM — The rare-earth-ion-doped crystals, such as  $\text{Pr}^{3+}:\text{Y}_2\text{SiO}_5$ , are promising materials for scalable quantum computers, because the crystals contain a large number of ions which have long coherence time. The frequency-domain quantum computation (FDQC) enables us to employ individual ions coupled to a common cavity mode as qubits by identifying with their transition frequencies. In the FDQC, operation lights with detuning interact with transitions which are not intended to operate, because ions are irradiated regardless of their positions. This crosstalk causes serious errors of the quantum gates in the FDQC. When resonance conditions between eigenenergies of the whole system and transition-frequency differences among ions are satisfied, the gate errors increase. Ions for qubits must have transitions avoiding the conditions for high-fidelity gate. However, when a large number of ions are employed as qubits, it is difficult to avoid the conditions because of many combinations of eigenenergies and transitions. We propose new implementation using extra ions to control the resonance conditions, and show the effect of the extra ions by a numerical simulation. Our implementation is useful to realize a scalable quantum computer using rare-earth-ion-doped crystal based on the FDQC.

**10:48AM E45.00013 Magneto-transport studies of a few hole GaAs double quantum dot in tilted magnetic fields.**, SERGEI STUDENIKIN, ALEX BOGAN, National Research Council of Canada, LISA TRACY, Sandia National Laboratories, LOUIS GAUDREAU, ANDY SACHRAJDA, MAREK KORKUSINSKI, National Research Council of Canada, JOHN RENO, TERRY HARGETT, Sandia National Laboratories — Compared to equivalent electron devices, single-hole spins interact weakly with lattice nuclear spins leading to extended quantum coherence times. This makes p-type Quantum Dots (QD) particularly attractive for practical quantum devices such as qubit circuits, quantum repeaters, quantum sensors etc. where long coherence time is required. Another property of holes is the possibility to tune their g-factor as a result of the strong anisotropy of the valance band. Hole g-factors can be conveniently tuned *in situ* from a large value to almost zero by tilting the magnetic field relative to the 2D hole gas surface normal. [1] In this work we explore high-bias magneto-transport properties of a p-type double quantum dot (DQD) device fabricated from a GaAs/AlGaAs heterostructures using lateral split-gate technology.[2] A charge detection technique is used to monitor number of holes and tune the p-DQD in a single hole regime around (1,1) and (2,0) occupation states where Pauli spin-blockaded transport is expected. Four states are identified in quantizing magnetic fields within the high-bias current stripe – three-fold triplet and a singlet which allows determining effective heavy hole g-factor as a function of the tilt angle from 90 to 0 degrees. [1] G. Ares et al., Phys.Rev. Lett. **110**, .046602 (2013); [2] L. A. Tracy,et al., App. Phys. Lett. **104**, 123101 (2014).

**Session E46 GIMS: Advances in Scanning Probe Microscopy II: High Frequencies and Optical Techniques** 311 - Fabian Natterer, IBM Almaden Research Center

**8:00AM E46.00001 Towards microwave imaging of single two-level defects in dielectric materials**, SEBASTIAN DE GRAAF, National Physical Laboratory, Teddington, United Kingdom, ANDREY DANILOV, Chalmers University of Technology, Department of Microtechnology and Nanoscience, Gothenburg, Sweden, ALEXANDER TZALENCHUK, National Physical Laboratory, Teddington, United Kingdom, SERGEY KUBATKIN, Chalmers University of Technology, Department of Microtechnology and Nanoscience, Gothenburg, Sweden — Two-level fluctuators (TLF) are a major source of decoherence in quantum devices and significant effort is invested towards better understanding and eliminating these types of material defects. Here we propose that a near-field scanning microwave microscope (NSMM) can be used to image individual two-level defects on the nano-scale, provided that such a microscope operates in the right regime [1]. Not only would such a coherent NSMM be able to obtain nano-scale spatial distributions of defects and their locations within dielectric materials, it would also be able to determine the relative orientation of the TLF dipole with respect to the dielectric crystal, giving vital information about the nature of the TLF. We theoretically describe the operation and capabilities of a coherent NSMM and show that individual defects can be imaged in dielectric materials with low enough loss tangent, such as sapphire and silicon dioxide, relevant for solid state quantum technologies. We describe the requirements for constructing such an NSMM and report on our recent progress in setting up this technology [2]. [1] S. E. de Graaf, et al., Sci. Rep., in press (2015). [2] S. E. de Graaf, et al., Rev. Sci. Instrum. 84, 023706 (2013).

**8:12AM E46.00002 Advances in imaging and quantification of electrical properties at the nanoscale using Scanning Microwave Impedance Microscopy (sMIM)**<sup>1</sup>, STUART FRIEDMAN, FRED STANKE, YONGLIANG YANG, OSKAR AMSTER, PrimeNano, Inc — Scanning Microwave Impedance Microscopy (sMIM) is a mode for Atomic Force Microscopy (AFM) enabling imaging of unique contrast mechanisms and measurement of local permittivity and conductivity at the 10s of nm length scale. sMIM has been applied to a variety of systems including nanotubes, nanowires, 2D materials, photovoltaics and semiconductor devices. Early results were largely semi-quantitative. This talk will focus on techniques for extracting quantitative physical parameters such as permittivity, conductivity, doping concentrations and thin film properties from sMIM data. Particular attention will be paid to non-linear materials where sMIM has been used to acquire nano-scale capacitance-voltage curves. These curves can be used to identify the dopant type (n vs p) and doping level in doped semiconductors, both bulk samples and devices.

**8:24AM E46.00003 Magnetic resonance force detection using a membrane resonator**, NICOLAS SCOZZARO, WILLIAM RUCHOTZKE, AMANDA BELDING, JEREMY CARDELLINO, ERICK BLOMBERG, BRENDAN MCCULLIAN, VIDYA BHALLAMUDI, DENIS PELEKHOV, P. CHRIS HAMMEL, Ohio State University - Columbus — Silicon nitride ( $\text{Si}_3\text{N}_4$ ) membranes are commercially-available, versatile structures that have a variety of applications. Although most commonly used as the support structure for transmission electron microscopy (TEM) studies, membranes are also ultrasensitive high-frequency mechanical oscillators. The sensitivity stems from the high quality factor  $Q \sim 10^6$ , which has led to applications in sensitive quantum optomechanical experiments. The high sensitivity also opens the door to ultrasensitive force detection applications. We report force detection of electron spin magnetic resonance at 300 K using a  $\text{Si}_3\text{N}_4$  membrane with a force sensitivity of 4 fN/ $\sqrt{\text{Hz}}$ , and a potential low temperature sensitivity of 25 aN/ $\sqrt{\text{Hz}}$ . Given membranes' sensitivity, robust construction, large surface area and low cost,  $\text{SiN}$  membranes can potentially serve as the central component of a compact room-temperature ESR and NMR instrument that has superior spatial resolution to conventional NMR.

**8:36AM E46.00004 Dipolar Decoupling in Magnetic Resonance Force Microscopy using Optical Control Pulses**, WILLIAM ROSE, University of Illinois at Urbana-Champaign, HOLGER HAAS, University of Waterloo, RAFFI BUDAKIAN, University of Illinois at Urbana-Champaign — We present data showing how a modified gradient ascent pulse engineering method can be used to design nuclear magnetic resonance pulses that perform a single unitary transformation over a large range of maximum Rabi field strengths ( $B_1$ ), while decoupling the secular dipolar interactions between spins. We designed dipolar-decoupling  $\pi$ -pulses that perform well over spins feeling maximum  $B_1$  fields from 131 – 274 G. By combining these  $\pi$ -pulses into a simple multiple pulse sequence, with fields produced by a silver microwire, we have increased  $T_2^*$  in a polystyrene sample attached to the tip of a silicon nanowire from 11  $\mu\text{s}$  to  $\sim 250\text{ms}$ . This dipolar decoupling could be used to improve the spatial resolution of nano-MRI experiments and to allow spectroscopy of chemical shifts in nanoscale samples.

**8:48AM E46.00005 Force-Detected Magnetic Resonance Imaging in Micron-Scale Liquids**, AIMEE SIXTA, Department of Physics, The University of Texas at Austin, Austin, TX 78712 USA, SOPHIA BOGAT, DIEGO WRIGHT, SHIRIN MOZAFFARI, DANIEL TENNANT, JEREMY PASTER, JOHN MARKERT, Department of Physics, The University of Texas at Austin — We report our efforts in the development of Nuclear Magnetic Resonance Force Microscopy (NMRFM) for the study of biological materials in liquid media at the micron scale. Our probe contains microfluidic samples sealed in thin-walled (few m) quartz tubes, with a micro-oscillator sensor nearby in vacuum to maintain its high mechanical resonance quality factor. An initial demonstration utilizes a permalloy magnet on the oscillator tip, which provides a resonant slice of thickness 0.5 m and an area of diameter 10m; these first measurements aim to demonstrate a single-shot measurement of the longitudinal relaxation time  $T_1$  in aqueous solutions of  $\text{Cu}_2\text{SO}_4$ . We also aim to implement a sawtooth 2 $\pi$  cyclic inversion of the nuclear spins, a detection scheme that effectively eliminates common measurement artifacts. At the micron scale, both spin diffusion and physical diffusion in liquids tend to blur images in conventional magnetic resonance imaging (MRI); we aim to exploit the local nature of the NMRFM probe to obtain higher resolution dynamical images, with the ultimate goal of imaging within individual biological cells.

**9:00AM E46.00006 Time-Resolved SQUID Sensor with a Nyquist Frequency up to 25 GHz**, Z. CUI, Stanford Institute for Materials and Energy Sciences, Y. H. WANG, Stanford University, P. KRATZ, Stanford Institute for Materials and Energy Sciences, A. J. ROSENBERG, Stanford University, C. A. WATSON, I. SOCHNIKOV, Stanford Institute for Materials and Energy Sciences, Y.-K.-K. FUNG, G. GIBSON, IBM Watson Research Center, J. R. KIRTLEY, Stanford Institute for Materials and Energy Sciences, M. B. KETCHEN, OcteVue, K. A. MOLER, Stanford Institute for Materials and Energy Sciences — We demonstrate a time-resolved scanning Superconducting Quantum Interference Device (SQUID) sensor with an expected maximum sampling rate of 50 GHz. The time-resolved SQUID sampler is operated by a pump-probe pulse sequence and will be particularly useful in studying high-frequency magnetic devices and the transient behavior of magnetic materials. The high sampling rate is achieved through a Josephson-interferometry technique developed at IBM[1][2]. We tested our sampler with flux signals of order 10  $m\Phi_0$  (where  $\Phi_0$  is the magnetic flux quantum), which corresponds to 25 million Bohr magnetons located 1 micron directly below the pickup loop. Operating in this regime, our sampler will have much higher sensitivity than bulk sensors like conventional SQUIDS and much larger spatial scanning range than single-spin sensors like NV centers. The SQUID sampler will thus be well-suited to characterize individual mesoscopic samples as well as bulk samples with mesoscopic features. [1]S. M. Faris, APL 36, 1005 (1980). [2]J. R. Kirtley, et al., "Advanced sensors for scanning SQUID microscopy", Superconductive Electronics Conference (ISEC 2013), invited paper F2.

**9:12AM E46.00007 Toward single atom qubits on a surface: Pump-probe spectroscopy and electrically-driven spin resonance**, WILLIAM PAUL, IBM Research - Almaden — We will discuss the characterization of spin dynamics by pump-probe spectroscopy and the use of gigahertz-frequency electric fields to drive spin resonance of a Fe atom on a MgO/Ag(001) surface. In the spirit of this session, the technical challenges in applying a precise voltage to the tip sample junction across a wide radio-frequency bandwidth will be described. The energy relaxation time,  $T_1$ , of single spins on surfaces can be measured by spin-polarized pump-probe STM (scanning tunneling microscopy) [1]. To date, the relaxation times reported for Fe-Cu dimers on Cu<sub>2</sub>N insulating films have been of the order  $\sim 100$  ns [1]. A three-order-of-magnitude enhancement of lifetime, to  $\sim 200$   $\mu$ s, was recently demonstrated for Co on a single-monolayer of MgO [2]. Here, we report on the tailoring of the  $T_1$  lifetime of single Fe atoms on single- and multi-layer MgO films grown on Ag(001). Next, we demonstrate electron spin resonance of an individual single Fe atom, driven by a gigahertz-frequency electric field applied across the tip-sample junction, and detected by a spin-polarized tunneling current. The principle parameters of the spin resonance experiment, namely the phase coherence time  $T_2$  and the Rabi rate, are characterized for Fe atoms adsorbed to the monolayer MgO film. [1] Loth et al., Science 329, 1628 (2010) [2] Rau and Baumann et al., Science 344, 988 (2014) [3] Baumann and Paul et al., Science 350, 417 (2015)

**9:48AM E46.00008 Cantilever detection of electron spin resonance in the terahertz region**, HIDEYUKI TAKAHASHI, Organization of Advanced Science and Technology, Kobe University, EIJI OHMICHII, Graduate School of Science, Kobe University, HITOSHI OHTA, Molecular Photoscience Research Center, Kobe University — Electron spin resonance (ESR) is used in a wide range of research areas. Most commercially available spectrometers operate at the X-band ( $\sim 10$  GHz). However, high-frequency ESR ( $>100$  GHz) has many advantages, such as the high spectral resolution, the ESR detection beyond the zero-field splitting etc. We report the cantilever detection of electron spin resonance in the terahertz region. This technique mechanically detects ESR as a change in magnetic torque that acts on the cantilever, while the conventional method, such as the cavity perturbation and the transmission method, directly measures the absorption of electromagnetic wave power. Backward wave oscillators (BWO) were used as THz-wave sources. Despite the small sample mass ( $m = 4$   $\mu$ g) and low power output of the BWO ( $P < 4$  mW above 1 THz), we observed ESR absorption of Co Tutton salt,  $\text{Co}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ , in frequencies of up to 1.1 THz. Spin sensitivity was estimated to be the order of  $10^{11}$ - $10^{12}$  spins/gauss above 1 THz. This technique will not only broaden the scope of ESR spectroscopy application but also lead to high-spectral-resolution ESR imaging. [1]H. Takahashi, E. Ohmichi and H. Ohta, Appl. Phys. Lett. **107**, 182405 (2015).

**10:00AM E46.00009 Ultrafast nano-imaging of the photoinduced phase transition dynamics in  $\text{VO}_2$** , SVEN A. DOENGES, OMAR KHATIB, BRIAN T. O'CALLAHAN, Department of Physics, Department of Chemistry, and JILA, University of Colorado, Boulder, CO 80309, JOANNA M. ATKIN, Department of Chemistry, University of North Carolina, Chapel Hill, NC 27514, JAE HYUNG PARK, DAVID H. COBDEN, Department of Physics, University of Washington, Seattle, WA 98195, MARKUS B. RASCHKE, Department of Physics, Department of Chemistry, and JILA, University of Colorado, Boulder, CO 80309 — Many quantum phase transitions in correlated matter exhibit spatial inhomogeneities with expected yet unexplored effects on the associated ultrafast dynamics. Here we demonstrate the combination of ultrafast non-degenerate pump-probe spectroscopy with scattering scanning near-field optical microscopy (s-SNOM) for ultrafast nano-imaging. In a femtosecond near-field non-degenerate near-IR (NIR) pump and mid-IR (MIR) probe experiment, we study the photoinduced insulator-to-metal (IMT) transition in nominally homogeneous  $\text{VO}_2$  micro-crystals using far-from equilibrium excitation. We observe spatial heterogeneity on 50-100 nm length scales in the fluence dependent IMT dynamics, ranging from sub-100 fs to 1 ps. With pump fluences as high as nominally 10 mJ/cm<sup>2</sup> we can reach distinct excitation and saturation regimes. These results suggest a large sensitivity of the IMT with respect to local variations in strain, doping, or defects difficult to discern microscopically.

**10:12AM E46.00010 Nanoscale dynamics of the Insulator-to-Metal transition in  $\text{VO}_2$** , AARON STERNBACH, University of California, San Diego — We have improved upon the technique of time resolved scanning near-field optical microscopy to study the development of inhomogeneous phase transitions in the time domain with 20 nanometer spatial resolution and 100 femtosecond temporal resolution. In our present work, we study Vanadium Dioxide ( $\text{VO}_2$ ), which is a canonical correlated electron system that exhibits an insulator-to-metal transition (IMT) above room temperature. We observe inhomogeneous dynamics that are related to mesoscopic strain variations. Our measurement resolves the dynamical evolution of the IMT on length scales that are short compared with the typical sizes of metallic domains in  $\text{VO}_2$ . By using Near-Infrared radiation, measured on a pulse-to-pulse basis, we are able to achieve an unprecedented Signal-to-Noise ratio. Our advances pave a pathway to study a wide range of systems with inhomogeneities properties on the nanoscale with high sensitivity, nanoscopic spatial, and ultrafast temporal resolution.

**10:24AM E46.00011 s-SNOM based IR and THz spectroscopy for nanoscale material characterization**, TOBIAS GOKUS, ANDREAS HUBER, ADRIAN CERNESCU, neaspec GmbH — Scattering-type Scanning Near-field Optical Microscopy (s-SNOM) allows to overcome the diffraction limit of conventional light microscopy enabling optical measurements at a spatial resolution of 10nm. s-SNOM employs an externally-illuminated sharp metallic AFM tip to create a nanoscale hot-spot at its apex. The optical tip-sample near-field interaction is determined by the local dielectric properties (refractive index) of the sample and detection of the elastically tip-scattered light yields nanoscale resolved near-field images simultaneous to topography. Development of a dedicated Fourier-transform detection module for analyzing light scattered from the tip which is illuminated by a broadband laser source enables IR spectroscopy of complex polymer nanostructures. Applications presented further demonstrate characterization of embedded structural phases in biominerals (bone), organic semiconductors or functional semiconductor nanostructures. Furthermore, by extending the concept of broadband-s-SNOM spectroscopy to the THz-spectral range, we demonstrate optical near-field imaging and spectroscopy at THz-frequencies (0.5-2.5 THz) by coupling the free space beam of a dedicated THz-TDS to the s-SNOM system.

**10:36AM E46.00012 Novel combination of near-field s-SNOM microscopy with peak-force tapping for nano-chemical and nano-mechanical material characterization with sub-20 nm spatial resolution**, MARTIN WAGNER, Bruker Nano Surfaces, Santa Barbara, KARINA CARNEIRO, STEFAN HABELITZ, UC San Francisco, THOMAS MUELLER, BNS, BNS TEAM, UCSF TEAM — Heterogeneity in material systems requires methods for nanoscale chemical identification. Scattering scanning near-field microscopy (s-SNOM) is chemically sensitive in the infrared fingerprint region while providing down to 10 nm spatial resolution. This technique detects material specific tip-scattering in an atomic force microscope. Here, we present the first combination of s-SNOM with peak-force tapping (PFT), a valuable AFM technique that allows precise force control between tip and sample down to 10s of pN. The latter is essential for imaging fragile samples, but allows also quantitative extraction of nano-mechanical properties, e.g. the modulus. PFT can further be complemented by KPFM or conductive AFM for nano-electrical mapping, allowing access to nanoscale optical, mechanical and electrical information in a single instrument. We will address several questions ranging from graphene plasmonics to material distributions in polymers. We highlight a biological application where dental amelogenin protein was studied via s-SNOM to learn about its self-assembly into nanoribbons. At the same time PFT allows to track crystallization to distinguish protein from apatite crystals for which amelogenin is supposed to act as a template.

**10:48AM E46.00013 Towards optically-integrated scanning tunneling microscopy studies of defects in semiconductors**, ANNE BENJAMIN, EVAN LANG, KEVIN WERNER, ENAM CHOWDHURY, JAY GUPTA, Ohio State Univ - Columbus — As electronic devices approach the nanoscale, their function is increasingly dependent on the local environment of individual defects. We are developing a combination of optical illumination and scanning tunneling microscopy techniques to study how the properties of individual defects depend on aspects of the local environment, such surface or defect proximity, applied electric fields, and illumination. Here we present studies of individual Zn and Er impurities in GaAs(110).

We use controlled motion of the STM tip during voltage sweeps to resolve previously hidden in-gap states of Zn acceptors and probe Zn further from the surface than previously accessible. We discovered two classes of Zn acceptors, one with defect states that did not shift with tip-induced band bending (TIBB), and one with states that do. Similar behavior was observed for above-gap illumination, consistent with the surface photovoltage effect (SPV). For Er on GaAs(110), we discovered three different adsorption states sharing two different sites. We found defect states near the conduction band edge, which shifted with TIBB as well as IR illumination resonant with the Er f-shell transitions.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**  
**Session E47 DCMF: Surfaces and Interfaces of Complex Oxides 312 -**

**8:00AM E47.00001 Controlling the electronic properties of  $\text{Er}_2\text{O}_3$  thin film by oxygen vacancies**, AARON WANG, ANDREW YOST, VIVEK JAIN, QILIN DAI, JINKE TANG, TEYU CHIEN, University of Wyoming — With a high dielectric constant and wide bandgap,  $\text{Er}_2\text{O}_3$  is suitable for applications in electronic and optical devices. It is known that in many oxide materials, oxygen vacancy concentration plays a decisive role in engineering the properties of the oxides. To address the oxygen vacancy concentration effects on the properties of  $\text{Er}_2\text{O}_3$ , here we present Scanning Tunneling Microscopy and Spectroscopy (STM/S) and X-Ray Diffraction (XRD) studies of the  $\text{Er}_2\text{O}_3$  thin film made by Pulsed Laser Deposition (PLD). XRD shows  $\text{Er}_2\text{O}_3$  thin film deposited at 700°C in high vacuum (HV) (sample 1) has broader peaks compared to that of the one deposited at room temperature (RT) in HV followed by 400°C annealing in air (sample 2). This indicates that, for sample 1, the loss of long range periodicity in crystal structure is mainly due to oxygen vacancies. Moreover, a relatively rough surface with 2 to 5 nm nanoclusters were observed in sample 1 by STM; while sample 2 is too resistive for STM measurements. In addition, Scanning Tunneling Spectroscopy (STS) analysis for sample 1 revealed the bandgap as well as features in the conduction band which may be related to the oxygen vacancies.

**8:12AM E47.00002 Effect of  $\text{LaInO}_3$  layer thickness on the conductance enhancement at the  $\text{LaInO}_3/\text{Ba}_{1-x}\text{La}_x\text{SnO}_3$  polar interface**, CHULKWON PARK, USEONG KIM, JUYEON SHIN, YOUNG MO KIM, YOUJUNG KIM, KOOKRIN CHAR, Seoul National University — We have recently reported on the high performance thin film transistors based on La-doped  $\text{BaSnO}_3$  (BLSO), which has high electron mobility and thermal stability, with  $\text{LaInO}_3$  (LIO) gate dielectric [1, 2]. During the course of this research we have observed  $10^4$  times enhancement of the sheet conductance of BLSO channel layer, which implies formation of 2DEG, after the interface formation with LIO. Detailed further study revealed that the La concentration in the BLSO channel layer critically affects the enhancement of sheet conductance on the LIO/BSO interface [3]. We investigated the LIO thickness dependence on the conductance of LIO/BSO interface and will discuss the origin of this phenomenon in terms of the intrinsic interface polarization in the LIO layer. This understanding is the first step towards the device application of the perovskite oxide heterostructures and may potentially lead to new interface states. [1] H. J. Kim, U. Kim *et al.*, Appl. Phys. Express **5**, 061102 (2012). [2] U. Kim *et al.*, APL Mat. **3**, 036101 (2015). [3] U. Kim *et al.*, preprint.

**8:24AM E47.00003 Optical properties of  $\text{CuFeO}_2$  and  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  highly epitaxial thin films**<sup>1</sup>, A. L. CABRERA, R. A. WHEATLEY, S. ROJAS<sup>2</sup>, Instituto de Fisica, Pontificia Universidad Catolica de Chile, T. JOSHI, P. BORISOV<sup>3</sup>, D. LEDERMAN, Department of Physics and Astronomy, West Virginia University, Morgantown — Delafossite thin films of 20 and 200 nm  $\text{CuFeO}_2$  and 52 nm  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  were grown by Pulsed Laser Deposition (PLD) on  $\text{Al}_2\text{O}_3$  (0001) substrates. High epitaxial quality of the films was verified by the techniques of X-Ray Diffraction and Raman spectroscopy. Optical transmission and reflection spectroscopies were performed on the films under vacuum and in  $\text{CO}_2$  controlled atmosphere, respectively. Tauc plots based on transmission data yielded direct optical band gap at 2.4 eV, 2.8eV and 3.1eV and indirect band gap at 0.9 eV and 1.3 eV for  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  ( $x=0.25$ ) and the direct band gap at 1.9eV, 3.1eV and the indirect band gap at 1.1eV for the  $\text{CuFeO}_2$  films.

**8:36AM E47.00004 Comparative study of water and carbon dioxide adsorption on  $\text{CuFeO}_2$  and  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  highly epitaxial thin films**<sup>1</sup>, S. ROJAS<sup>2</sup>, Instituto de Fisica, Pontificia Universidad Catolica de Chile, T. JOSHI, P. BORISOV<sup>3</sup>, D. LEDERMAN, Department of Physics and Astronomy, West Virginia University, Morgantown, A. L. CABRERA, Instituto de Fisica, Pontificia Universidad Catolica de Chile — Thermal programmed desorption (TPD) of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  from a 200 nm thick  $\text{CuFeO}_2$  and 52 nm thick  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  delafossite surfaces was performed in a Ultra-high vacuum (UHV) chamber. The thin films with epitaxial quality were grown by Pulsed Laser Deposition (PLD) on  $\text{Al}_2\text{O}_3$  (0001) substrates. The adsorption / desorption of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  process was also monitored with X-ray Photoelectron Spectroscopy (XPS) and Auger Electron Spectroscopy (AES). Our results revealed that carbon dioxide is preferentially chemisorbed by  $\text{CuFe}_{1-x}\text{Ga}_x\text{O}_2$  over water and we observed the opposite behavior with regard to chemisorption of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  over  $\text{CuFeO}_2$ . Hydroxyls and metal carbonates were formed on the surface due to the chemisorption of  $\text{H}_2\text{O}$  and  $\text{CO}_2$ . Arrhenius plots for  $\text{CO}_2$  and  $\text{H}_2\text{O}$  desorption were done and activation energy for desorption were obtained.

**8:48AM E47.00005 Crystallographic orientation dependence of electronic properties at  $\text{LaAlO}_3/\text{SrTiO}_3$  interfaces**, NEIL CAMPBELL, MARK RZCHOWSKI, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, USA, SANGWOO RYU, HYUNGWOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin, Madison, Wisconsin 53706, USA — The two-dimensional electron liquid (2DEL) formed at the interface between perovskite oxides  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$  has been found to show many interesting properties, including ones that depend on the electronic and structural properties of the interface. Most research has investigated the (001) orientation, where the crystal structure is square in the plane. Changing the crystallographic orientation can change the polarization mismatch and shift energies and occupations of the orbitals near the Fermi surface. This affects the 2DEL in many ways, particularly by changing the spatial extent and profile of the charge density. The interplay between interlayer hopping integrals and orbital energy shifts make the 2DELs in different orientations behave differently in response to gating. The interface plane defines a symmetry-breaking direction for the  $d$  orbitals and electrostatic potential, causing splitting of Ti  $d$  bands, affecting band occupation and mass near the interface. Heterostructures grown on (111)  $\text{SrTiO}_3$ , have similar Ti  $d$  orbital energies since they all have lobes crossing the interface, while in (001), the  $d_{xy}$ , and  $d_{x^2-y^2}$  orbitals do not have such lobes. We present temperature-dependent Hall and magnetotransport data probing these orientational differences.

**9:00AM E47.00006 Thickness Dependence of Electrical and Structural Properties of Tensile Strained Calcium Manganese Oxide Thin Films<sup>1</sup>**, CACIE HART, ZOEY WARECKI<sup>2</sup>, ADEEL CHAUDHRY, NATALIE FERRONE, DAVID HOUSTON, BRIDGET LAWSON, GRACE YONG, RAJESWARI KOLAGANI, Towson University — We have investigated the properties of  $\text{CaMnO}_{3-\delta}$  thin films epitaxially grown by pulsed laser deposition on lattice mismatched substrates, (100) $\text{LaAlO}_3$  and (100) $\text{SrTiO}_3$ , leading to a tensile strain of  $\sim 4\%$  and 1.5% respectively. For our films these substrates, thickness dependence of the properties is characteristically different from what has been previously observed in thin films of hole-doped manganites. We observe that the resistivity decreases significantly as the film thickness decreases. The decrease in resistivity is more pronounced in the films on (100) $\text{SrTiO}_3$  with the larger lattice mismatch, the resistivity of the thinnest films being about 3 orders of magnitude lower than the of bulk  $\text{CaMnO}_3$ . Thickness dependence of the lattice constants also show deviations from the behavior expected from strain relaxation. These results suggest a coupling between tensile strain and oxygen deficiency consistent with predictions from models based on density functional theory calculations. Our results are relevant for potential catalytic applications of  $\text{CaMnO}_{3-\delta}$  thin films.

**9:12AM E47.00007 Role of lanthanum aluminate composition in interface formation with strontium titanate**, ABDUL RUMAIZ, National Synchrotron Light Source II, Brookhaven National Laboratory, CONAN WEILAND, National Institute of Standards and Technology, GEORGE STERBINSKY, Advanced Photon Source, Argonne National Laboratory, C. STEPHEN HELLBERG, Center for Computational Materials Science, Naval Research Laboratory, JOSEPH WOICK, National Institute of Standards and Technology, SHAOBO ZHU, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University — While  $\text{LaAlO}_3$  (LAO) and  $\text{SrTiO}_3$  (STO) are both insulators, the interface between the two materials is conductive when the LAO is above a critical thickness and the STO is  $\text{TiO}_2$ -terminated; the origin of this conductivity is widely debated. It has also been demonstrated that the conductive interface depends on the composition of the LAO film: conductive interfaces were only found to occur for  $\text{La:Al} < 0.97$ . Hard x-ray photoelectron spectroscopy has been performed on ten unit cell thick Al-rich ( $\text{La:Al} = 0.9$ ), stoichiometric ( $\text{La:Al} = 1$ ), and La-rich ( $\text{La:Al} = 1.1$ ) LAO films deposited on STO to elucidate the role of LAO composition in the interfacial structure. A small built-in potential was observed in the Al-rich film compared to the stoichiometric and La-rich films, as determined from valence-band broadening. The stoichiometric and La-rich films were also found to have La-enrichment at the interface, while the Al-rich film did not. These results combined with first-principles calculations demonstrate the role that defects in the LAO film play in the LAO/STO interfacial structure.

**9:24AM E47.00008 Metallic interface in non- $\text{SrTiO}_3$  based titanate superlattice<sup>1</sup>**, XIAORAN LIU, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA, D. CHOUDHURY, Department of Physics, Indian Institute of Technology, Kharagpur 721302, India, YANWEI CAO, M. KAREEV, S. MIDDEY, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, Arkansas 72701, USA, UNIVERSITY OF ARKANSAS TEAM, INDIAN INSTITUTE OF TECHNOLOGY TEAM — We report on the fabrication of all perovskite Mott insulator/band insulator  $\text{YTiO}_3/\text{CaTiO}_3$  superlattices by pulsed laser deposition. The combination of *in-situ* reflection high energy electron diffraction, X-ray diffraction and X-ray reflectivity confirms the high quality of the films grown in a layer-by-layer mode. Electrical transport measurements reveal that a non- $\text{SrTiO}_3$  based two-dimensional electron gas system has formed at the  $\text{YTiO}_3/\text{CaTiO}_3$  interface. These studies offer another route in the pursuit of complex oxide two-dimensional electron gas systems which allows to obtain greater insights into the exotic many-body phenomena at such interfaces.

**9:36AM E47.00009 The Effect of Polarization on Local Electronic Structure in Ferroelectric Nano-Domains in  $\text{BaTiO}_3$** , ERIE MORALES, Univ of Pennsylvania, CARLOS PEREZ, DAWN BONNELL, University of Pennsylvania, MSE TEAM — Novel ferroelectric  $\text{BaTiO}_3$  applications ranging from sensors to nanogenerators require a detailed understanding of atomic interactions at surfaces. Single crystals provide a platform that allows the exploitation of surface physical and chemical properties that can be readily transferred to other ABO<sub>3</sub> perovskites. The processes that result in the atomic and electronic structures of surfaces in tandem with polarization of domains are necessary steps towards understanding  $\text{BaTiO}_3$ . Here we treat  $\text{BaTiO}_3$  surface using sputtering-annealing cycles that yield the (6x1) reconstruction. We demonstrate that it is possible to pole a thin  $\text{BaTiO}_3$  single crystal in ultra high vacuum using scanning tunneling microscopy (STM). We determine that we can prepare  $\text{BaTiO}_3$  using *in-situ* annealing that allows us to control the size of poled region to 40nm. We pole in constant-current mode in STM by applying a bias of less than 10 V between tip and sample for 100ms. STM and scanning tunneling spectroscopy characterization allow us to map topography and local density of states, respectively. For a given unique pulse, the poled domains show a fluctuating electronic occupation of conduction bands and shifting of valence band. We will also discuss the effect of polarization on molecular adsorption.

**9:48AM E47.00010 Effect of the undoped  $\text{BaSnO}_3$  space layer on the high mobility  $\text{LaInO}_3/\text{Ba}_{1-x}\text{La}_x\text{SnO}_3$  polar interface**, JUYEON SHIN, CHULKWON PARK, YOUNG MO KIM, YOUJUNG KIM, KOOKRIN CHAR, Seoul national university — We have recently reported on the sheet conductance enhancement at the interface between two band insulators:  $\text{LaInO}_3$  (LIO) and  $\text{BaSnO}_3$  (BSO) [1, 2]. The advantages of the two-dimensional electron gas-like (2DEG) state at the LIO/ $\text{Ba}_{1-x}\text{La}_x\text{SnO}_3$  (BLSO) polar interface are its stability, the controllability of the local carrier concentration, and the high electron mobility of BLSO [3]. The origin of enhanced conductance at the interface is still under investigation, but the doping level of BSO is a critical parameter for the polar charge contribution. [2] We have investigated a new structure using an undoped BSO space layer at the LIO/BLSO interface. On one hand, this new structure will improve the mobility of the LIO/BLSO structure by reducing La impurity scattering. On the other hand, through this new structure we can answer the issues related with La diffusion at the LIO/BLSO polar interface and trace the origin of the 2DEG-like charge. This new modified structure of the LIO/BSO polar interface looks promising for higher electron mobility devices. [1] U. Kim *et al.*, APL Mat. 3, 036101 (2015). [2] U. Kim *et al.*, preprint. [3] H. J. Kim, U. Kim *et al.*, Appl. Phys. Express 5, 061102 (2012).

**10:00AM E47.00011 Electronic Structure of Epitaxial Thin Films of the Transparent Conducting Oxide La:BaSnO<sub>3</sub> Measured By In-Situ Angle-Resolved Photoemission Spectroscopy**, EDWARD LOCHOCKI, HANJONG PAIK, Cornell University, MASAKI UCHIDA, University of Tokyo, DARRELL SCHLOM, KYLE SHEN, Cornell University — Lanthanum-doped barium stannate (La:BaSnO<sub>3</sub>) is a transparent conducting oxide where single crystals have exhibited unusually high mobility and oxygen stability. Here we present in-situ angle-resolved photoemission (ARPES) measurements of La:BaSnO<sub>3</sub> epitaxial films that were co-deposited onto lattice-matched rare-earth scandate substrates by molecular-beam epitaxy (MBE). Density functional theory (DFT) calculations agree well with the observed valence bands and predict a parabolic conduction band. However, the features observed near the Fermi energy ( $E_F$ ) are non-dispersive yet localized in momentum space. This unusual appearance may be the result of quasi-localized charge carriers or out-of-plane momentum broadening. Over long measurement periods, we also observe changes to the valence band and near- $E_F$  feature that bear a strong resemblance to the beam-induced two-dimensional electron gases previously reported in SrTiO<sub>3</sub> and KTaO<sub>3</sub>. The origin of these unexpected phenomena and their relationship to the structural and transport properties of these films will be discussed.

**10:12AM E47.00012 Band gap formation in La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> (LSMO) thin films measured by reflectivity/absorption and ultrafast spectroscopy**, GUERAU CABRERA, ROBBYN TRAPPEN, West Virginia University, YING-HAO CHU, National Chiao Tung University, MIKEL HOLCOMB, West Virginia University — Thin film La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> (LSMO) is a prime candidate for highly spin-polarized magnetic-tunnel-junction memories. Due to its magnetic properties, it is also a good candidate for applications utilizing electrical control of magnetism when grown adjacent to a ferroelectric layer such as Pb(Zr/Ti)O<sub>3</sub> (PZT). Recently, Wu and others have seen the emergence of a band gap (about 1eV) in LSMO thin films, when grown adjacent to PZT. Currently, it is understood that LSMO is a half-metal, with a pseudo-gap due to a low density of states (DOS) near the Fermi level. The transition from pseudo-gap to band gap is not yet fully understood. It is therefore our aim to investigate the formation of this band gap through optical reflectivity/absorption and ultrafast carrier dynamics for a variety of thicknesses ranging from a few nanometers to thicker films (about 100 nm).

**10:24AM E47.00013 Interfacial stability of ultrathin film magnetite (Fe<sub>3</sub>O<sub>4</sub>) in ozone assisted MBE deposition**, HAWOONG HONG, JONGJIN KIM, Argonne National Laboratory, XINYUE FANG, University of Illinois at Urbana-Champaign, SEUNGBUM HONG, Argonne National Laboratory, TAI C. CHIANG, University of Illinois at Urbana-Champaign — Iron oxide films were grown on sapphire (0001) surfaces using nominally 100% ozone. Both of monolayer-wise deposition and continuous deposition were tried to find the structures of the films at the start of the film formation. The studies utilized x-ray scattering with synchrotron radiation from the Advanced Photon Source. Consideration of substrate and film structures predicts Fe<sub>2</sub>O<sub>3</sub>(0001) (hematite) film formation. However, in both of the deposition modes, the initial films formed as magnetite Fe<sub>3</sub>O<sub>4</sub>(111). As the film growth progresses, hematite (Fe<sub>2</sub>O<sub>3</sub>(0001)) appears. At the later stage, the magnetite disappears and the whole film turned to hematite. Real time and static x-ray diffraction results show the same result. Possibility of the oxidation limited transformation should be excluded. Other possible cause of this reverse stability will be discussed.

**10:36AM E47.00014 Effects of strain, electric field and correlations on the resistance noise in epitaxial NdNiO<sub>3</sub> films<sup>1</sup>**, G. SAMBANDAMURTHY, ALI ALSAQQA, SUJAY SINGH, State Univ of NY - Buffalo, SRIMANTA MIDDEY, MICHAEL KAREEV, JAK CHAKHALIAN, University of Arkansas - Fayetteville — Rare earth nickelates are strongly correlated materials that exhibit metal-insulator and Neel transitions as a function of temperature. The nature of the transport mechanisms in individual phases (paramagnetic metal, paramagnetic insulator and antiferromagnetic insulator) is an active area of research. We use low frequency (1 mHz < f < 10 Hz) resistance noise spectroscopy to probe the phases and the transitions between them in ultrathin epitaxial films of NdNiO<sub>3</sub> grown on substrates that introduce different strains. While the transport behavior and the transition temperatures are greatly affected by the strain, the noise behavior across the transitions is found to be similar. In the low temperature antiferromagnetic phase, an intriguing switching between two distinct ground states is observed pointing to a subtle competition in the energy landscape. The noise magnitude as a function of electric field in submicron devices will also be presented.

**10:48AM E47.00015 Quantitative measurements and modeling of electronic and atomic surface structure in epitaxial LaNiO<sub>3</sub> thin films by ARPES, LEED-I(V), and DFT+DMFT**, JACOB RUF, ELIZABETH NOWADNICK, Cornell University, HYOWON PARK, Columbia University, PHILIP KING, Cornell University, ANDREW MILLIS, Columbia University, DARRELL SCHLOM, KYLE SHEN, Cornell University — Careful exploration of the phase space available for artificially engineering emergent electronic properties in epitaxial thin films and superlattices of transition-metal oxides requires close feedback between materials synthesis, experimental characterization of both electronic and atomic structures, and modeling based on advanced computational methods. Here we apply this general strategy to the perovskite rare-earth nickelate LaNiO<sub>3</sub>, using molecular-beam epitaxy to synthesize thin films, performing *in situ* angle-resolved photoemission spectroscopy (ARPES) and low-energy electron diffraction (LEED) measurements, and comparing our results with the predictions of density functional theory plus dynamical mean-field theory (DFT+DMFT). Our study establishes LaNiO<sub>3</sub> as a moderately correlated metal in which the quasiparticle mass enhancement can be modeled with quantitative accuracy by DFT+DMFT. Finally, in view of efforts to produce  $e_g$  orbital polarization in nickelate heterostructures as a means of mimicking single-band cuprate-like physics, we discuss the extent to which our ARPES and LEED results suggest that such effects are intrinsically present at film surfaces due to the existence of polar distortions, as reported by coherent Bragg rod analysis of surface x-ray diffraction.

**Session E48 GQI: Quantum Error Correction in Superconducting Qubits** 349 - Austin Fowler, Google, Inc.

**8:00AM E48.00001 Increasing error resilience in superconducting qubits based on symmetries and parametric protocols<sup>1</sup>**, DAVID SCHUSTER<sup>2</sup>, University of Chicago — The field of superconducting quantum computing has seen remarkable advances in the past decade, and is getting closer to realizing logical qubits partially stabilized by error correction. However, achieving full scalability necessary to build a universal quantum computer remains a significant challenge which calls for new ideas to make superconducting qubits even more resilient with respect to external noise and fabrication imperfections. Past breakthroughs in this direction include circuit QED enabled measurement and long-range interactions; reliably long coherence times in transmon qubits; and additional coherence improvements by the use of 3D cavities. Here we review previous work on topological protection in superconducting circuit networks, and report on new efforts, in experiment and theory, to increase autonomous error protection of superconducting qubits by harnessing symmetry properties of circuit Hamiltonians and employing parametric processes for robust manipulation and storage of quantum information.

**8:36AM E48.00002 Engineering stabilizer measurements in circuit QED: I<sup>1</sup>** , KEVIN CHOU, JACOB BLUMOFF, M. REAGOR, C. AXLINE, R. BRIERLEY, Yale University, S. NIGG, University of Basel, P. REINHOLD, R. HEERES, C. WANG, K. SLIWA, A. NARLA, Yale University, M. HATRIDGE, University of Pittsburgh, L. JIANG, M. H. DEVORET, S. M. GIRVIN, R. J. SCHOEKOPF, Yale University — Quantum error correction based on stabilizer codes has emerged as an attractive approach towards building a practical quantum information processor. One requirement for such a device is the ability to perform hardware efficient measurements on registers of qubits. We demonstrate a new protocol to realize such multi-qubit measurements. A key feature of our approach is that it enables arbitrary stabilizer measurements to be selected in software, and requires a relatively small number of buses, ancillae, and control lines. This allows for a minimally complex sample realizing a simple dispersive hamiltonian while maintaining a high degree of decoupling between our fixed-tuned qubits. We experimentally implement these measurements in 3D circuit QED using transmon qubits coupled to a common bus resonator. In this first of two talks, we introduce our 3D cQED system and describe the protocol for measuring n-qubit parities of a three qubit register.

<sup>1</sup>We acknowledge funding from ARO

**8:48AM E48.00003 Engineering stabilizer measurements in circuit QED: II<sup>1</sup>** , JACOB BLUMOFF, KEVIN CHOU, M REAGOR, C AXLINE, R BRIERLY, Yale University, S NIGG, University of Basel, P REINHOLD, R HEERES, C WANG, K SLIWA, A NARLA, Yale University, M HATRIDGE, University of Pittsburgh, L JIANG, M H DEVORET, S M GIRVIN, R J SCHOEKOPF, Yale University — Quantum error correction based on stabilizer codes has emerged as an attractive approach towards building a practical quantum information processor. One requirement for such a device is the ability to perform hardware efficient measurements on registers of qubits. We demonstrate a new protocol to realize such multi-qubit measurements. A key feature of our approach is that it enables arbitrary stabilizer measurements to be selected in software, and requires a relatively small number of buses, ancillae, and control lines. This allows for a minimally complex sample realizing a simple dispersive hamiltonian while maintaining a high degree of decoupling between our fixed-tuned qubits. We experimentally implement these measurements in 3D circuit QED using transmon qubits coupled to a common bus resonator. In the second of two talks, we present a full characterization of the algorithm describing the outcome dependent projections via quantum process tomography.

**9:00AM E48.00004 Weight-4 Parity Checks on a Surface Code Sublattice with Superconducting Qubits<sup>1</sup>** , MAIKA TAKITA, ANTONIO CORCOLES, EASWAR MAGESAN, NICHOLAS BRONN, JARED HERTZBERG, JAY GAMBETTA, MATTHIAS STEFFEN, JERRY CHOW, IBM T.J. Watson Research Center — We present a superconducting qubit quantum processor design amenable to the surface code architecture. In such architecture, parity checks on the data qubits, performed by measuring their X- and Z- syndrome qubits, constitute a critical aspect. Here we show fidelities and outcomes of X- and Z-parity measurements done on a syndrome qubit in a full plaquette consisting of one syndrome qubit coupled via bus resonators to four code qubits. Parities are measured after four code qubits are prepared into sixteen initial states in each basis. Results show strong dependence on ZZ between qubits on the same bus resonators.

**9:12AM E48.00005 Active resonator reset in the non-linear regime of circuit QED to improve multi-round quantum parity checks<sup>1</sup>** , CORNELIS CHRISTIAAN BULTINK, M.A. ROL, X. FU, B.C.S. DIKKEN, J.C. DE STERKE, R.F.L. VERMEULEN, R.N. SCHOUTEN, A. BRUNO, K.L.M. BERTELS, L. DICARLO, QuTech, Delft University of Technology — Reliable quantum parity measurements are essential for fault-tolerant quantum computing. In quantum processors based on circuit QED, the fidelity and speed of multi-round quantum parity checks using an ancillary qubit can be compromised by photons remaining in the readout resonator post measurement, leading to ancilla dephasing and gate errors. The challenge of quickly depleting photons is biggest when maximizing the single-shot readout fidelity involves strong pulses turning the resonators non-linear. We experimentally demonstrate the numerical optimization of counter pulses for fast photon depletion in this non-analytic regime. We compare two methods, one using digital feedback and another running open loop. We assess both methods by minimizing the average number of rounds to ancilla measurement error.

<sup>1</sup>We acknowledge funding from the EU FP7 project SCALEQIT, FOM, and an ERC Synergy Grant.

**9:24AM E48.00006 Demonstration of quantum superiority in learning parity with noise with superconducting qubits<sup>1</sup>** , DIEGO RISTÈ, MARCUS DA SILVA, COLM RYAN, Raytheon BBN Technologies, ANDREW CROSS, JOHN SMOLIN, JAY GAMBETTA, JERRY CHOW, IBM T.J. Watson Research Center, BLAKE JOHNSON, Raytheon BBN Technologies — A problem in machine learning is to identify the function programmed in an unknown device, or oracle, having only access to its output. In particular, a parity function computes the parity of a subset of a bit register. We implement an oracle executing parity functions in a five-qubit superconducting processor and compare the performance of a classical and a quantum learner. The classical learner reads the output of multiple oracle calls and uses the results to infer the hidden function. In addition to querying the oracle, the quantum learner can apply coherent rotations on the output register before the readout. We show that, given a target success probability, the quantum approach outperforms the classical one in the number of queries needed. Moreover, this gap increases with readout noise and with the size of the qubit register. This result shows that quantum advantage can already emerge in current systems with a few, noisy qubits.

<sup>1</sup>We acknowledge support from IARPA under contract W911NF-10-1-0324.

**9:36AM E48.00007 A Very Small Logical Qubit** , ELIOT KAPIT, Tulane University — Superconducting qubits are among the most promising platforms for building a quantum computer. However, individual qubit coherence times are not far past the scalability threshold for quantum error correction, meaning that millions of physical devices would be required to construct a useful quantum computer. Consequently, further increases in coherence time are very desirable. In this letter, we blueprint a simple circuit consisting of two transmon qubits and two additional lossy qubits or resonators, which is passively protected against all single qubit quantum error channels through a combination of continuous driving and engineered dissipation. Photon losses are rapidly corrected through two-photon drive fields implemented with driven SQUID couplings, and dephasing from random potential fluctuations is heavily suppressed by the drive fields used to implement the multi-qubit Hamiltonian. Comparing our theoretical model to published noise estimates from recent experiments on flux and transmon qubits, we find that logical state coherence could be improved by a factor of forty or more compared to the individual qubit  $T_1$  and  $T_2$  using this technique.

**9:48AM E48.00008 Scalable in-situ qubit calibration during repetitive error detection**, J. KELLY, R. BARENDSE, A. FOWLER, J. MUTUS, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, A. DUNSWORTH, UC Santa Barbara, E. JEFFREY, E. LUCERO, A. MEGRANT, M. NEELEY, Google, Santa Barbara, C. NEILL, P.J.J. O'MALLEY, UC Santa Barbara, P. ROUSHAN, D. SANK, Google, Santa Barbara, C. QUINTANA, A. VAINSENER, J. WENNER, UC Santa Barbara, T. WHITE, Google, Santa Barbara, J.M. MARTINIS, University of California and Google, Santa Barbara — A quantum computer protects a quantum state from the environment through the careful manipulations of thousands or millions of physical qubits. However, operating such quantities of qubits at the necessary level of precision is an open challenge, as optimal control parameters can vary between qubits and drift in time. We present a method to optimize physical qubit parameters while error detection is running using a nine qubit system performing the bit-flip repetition code. We demonstrate how gate optimization can be parallelized in a large-scale qubit array and show that the presented method can be used to simultaneously compensate for independent or correlated qubit parameter drifts. Our method is  $O(1)$  scalable to systems of arbitrary size, providing a path towards controlling the large numbers of qubits needed for a fault-tolerant quantum computer.

**10:00AM E48.00009 Tracking errors of a logical qubit comprised of superpositions of cat states in a superconducting resonator**, A. PETRENKO, N. OFEK, R. HEERES, P. REINHOLD, Y. LIU, Z. LEGHTAS, B. VLASTAKIS, L. FRUNZIO, LIANG JIANG, Yale University Department of Applied Physics, M. MIRRAHIMI, INRIA Paris-Rocquencourt, M.H. DEVORET, R.J. SCHOELKOPF, Yale University Department of Applied Physics — QEC schemes involve redundantly encoding a qubit into a larger space of states that has symmetry properties that allow one to measure error syndromes. Traditional approaches involve encodings that employ large numbers of physical qubits, enhancing decay rates significantly and requiring considerable hardware overhead to realize. A hardware-efficient proposal [1,2], which we term the cat code, sheds much of this complexity by encoding a qubit in superpositions of cat states in a superconducting resonator, which has one dominant error syndrome: single photon loss. As these cat states are eigenstates of photon number parity, the loss of a photon changes the parity without corrupting the encoded information. In a superconducting cQED architecture, we demonstrate that we track these errors in real-time with repeated single shot parity measurements and map their occurrence onto applications of a unitary rotation of an arbitrary encoded state in the logical space. Our results illustrate the utility of long-lived resonators in the context of a full QEC system by highlighting the advantages of employing the cat code to suppress decoherence. [1]Leghtas et.al. PRL 111 120501 2013 [2]Mirrahipi et.al. NJP 16 045014 2014

**10:12AM E48.00010 Stabilizing the phase of superpositions of cat states in a cavity using real-time feedback**, N. OFEK<sup>1</sup>, A. PETRENKO, R. HEERES, P. REINHOLD, Y. LIU, Z. LEGHTAS, B. VLASTAKIS, L. FRUNZIO, LIANG JIANG, Yale University, Department of Applied Physics, M. MIRRAHIMI, INRIA Paris-Rocquencourt, M.H. DEVORET, R.J. SCHOELKOPF, Yale University, Department of Applied Physics — In a superconducting cQED architecture, a hardware efficient quantum error correction (QEC) scheme exists, called the cat code [1,2], which maps a qubit onto superpositions of cat states in a superconducting resonator, by mapping the occurrence of errors, or single photon jumps, onto unitary rotations of the encoded state. By tracking the parity of the encoded state, we can count the number of photon jumps and are able to apply a correcting unitary transformation. However, the situation is complicated by the fact that photon jumps do not commute with the deterministic anharmonic time evolution of a resonator state, or Kerr, inherited by the resonator from its coupling to a Josephson junction. As predicted in [1], a field in the resonator will inherit an overall phase  $\theta = KT$  in  $IQ$  space each time a photon jumps that is proportional to the Kerr  $K$  and the time  $T$  at which the jump occurs. Here I will present how we can track the errors in real time, take them into account together with the time they occur and make it possible to stabilize the qubit information. [1]Leghtas et.al. PRL 111 120501 2013 [2]Mirrahipi et.al. NJP 16 045014 2014

<sup>1</sup>Please place my talk right after the talk of Andrei Petrenko.

**10:24AM E48.00011 Encoding quantum information in a stabilized manifold of a superconducting cavity**<sup>1</sup>, S. TOUZARD, Z. LEGHTAS, S.O. MUNDHADA, C. AXLINE, M. REAGOR, K. CHOU, J. BLUMOFF, K.M. SLIWA, S. SHANKAR, L. FRUNZIO, R.J. SCHOELKOPF, Department of Applied Physics, Yale University, M. MIRRAHIMI, Department of Applied Physics, Yale University and INRIA Paris Rocquencourt, M.H. DEVORET, Department of Applied Physics, Yale University — In a superconducting Josephson circuit architecture, we activate a multi-photon process between two modes by applying microwave drives at specific frequencies. This creates a pairwise exchange of photons between a high-Q cavity and the environment. The resulting open dynamical system develops a two-dimensional quasi-energy ground state manifold. Can we encode, protect and manipulate quantum information in this manifold? We experimentally investigate the convergence and escape rates in and out of this confined subspace. Finally, using quantum Zeno dynamics, we aim to perform gates which maintain the state in the protected manifold at all times.

**10:36AM E48.00012 Simulation of an arbitrary quantum channel with minimal ancillary resource**, CHAO SHEN, KYUNGJOO NOH, VICTOR V. ALBERT, MICHEL H. DEVORET, ROBERT J. SCHOELKOPF, STEVEN M. GIRVIN, LIANG JIANG, Yale University — We discuss an explicit and efficient construction of quantum circuits that can simulate an arbitrary given quantum channel acting on a d-level quantum system, with the minimal quantum ancillary resource—a qubit and its QND readout. The elementary operations required are unitary evolutions and single qubit projective measurement. We further show that this technique opens up exciting new possibilities in the field of quantum control, quantum simulation, quantum error correction, and quantum state discrimination. Our proposal can be implemented on platforms such as a superconducting transmon qubit inside a microwave cavity.

**10:48AM E48.00013 Quantum Parameter Estimation in Continuous Measurement-Based Quantum Control**, LUIS CORTEZ-GONZALEZ, Universidad Autonoma de Nuevo Leon, ANDREW N. JORDAN, University of Rochester — We consider continuous measurement as a quantum tracking and control method for superconducting quantum systems. In experiments with superconducting qubits information about the quantum state of the system is extracted in the form of a noisy analog voltage signal reflected from a coupled readout resonator. Every element of the measurement sequence describes a weak measurement that provides uncertain information about the quantum state of the qubit. In this talk we describe how the information contained in the continuous readout signal is used to estimate unknown parameters of the system as well as the most probable state evolution to produce the observed measurement record. We will theoretically compare a variety of estimation techniques including Maximum Likelihood methods and Bayesian hypothesis testing among others.

**Session E51 DMP FIAP: Dopants and Defects in Semiconductors: Theory** Hilton Baltimore Holiday Ballroom 2 - Adam Gali, Hungarian Academy of Sciences and Budapest University of Technology and Economics

**8:00AM E51.00001 Beyond Graphene: Electronic and Mechanical Properties of Defective 2-D Materials<sup>1</sup>**, HUMBERTO TERRONES, Rensselaer Polytechnic Institute — One of the challenges in the production of 2-D materials is the synthesis of defect free systems which can achieve the desired properties for novel applications. However, the reality so far indicates that we need to deal with defective systems and understand their main features in order to perform defect engineering in such a way that we can engineer a new material. In this talk I discuss first, the introduction of defects in a hierarchic way starting from 2-D graphene to form giant Schwarzites or graphene foams, which also can exhibit further defects, thus we can have several levels of defectiveness. In this context, it will be shown that giant Schwarzites, depending on their symmetry, can exhibit Dirac-Fermion behavior and further, possess protected topological states as shown by other authors. Regarding the mechanical properties of these systems, it is possible to tune the Poisson Ratio by the addition of defects, thus shedding light to the explanation of the almost zero Poisson ratios in experimentally obtained graphene foams. Second, the idea of Haecelites, a planar sp<sup>2</sup> graphene-like structure with heptagons and pentagons, can be extended to transition metal dichalcogenides (TMDs) with square and octagonal-like defects, finding semi-metallic behaviors with Dirac-Fermions, and even topological insulating properties.

**8:36AM E51.00002 Scalable, Composable Operators for Defect Analysis and Design**, ROSE WEISBURGH, PETER CHUNG, University of Maryland — Defect structures in semiconductors can profoundly affect electronic properties through electron-phonon interactions. Knowledge of the changes to phonon properties induced by defects is vital for understanding phonon effects on electronic behavior. Defects can cause the dominant phonon peaks in the spectrum to split and shift resulting in carriers that can scatter in energy levels not foreseen in the bulk. We have developed a novel mathematical and computational framework for estimating the phonon spectra in the harmonic approximation for lattices containing arbitrary defect structures. Linear operators are used to calculate defective phonon spectra directly from the spectrum of a pristine reference lattice. The primary benefit is that the full eigensolve must only be performed once for the reference defect-free crystal. The operators can be adjusted to vary the defect concentration, defective mass ratio, and/or defective potential subsequently without having to re-evaluate the eigensystem. In the talk, we will present the theory behind our methodology and initial results about the sensitivity of electro-thermal properties of semiconductors to various point defects.

**8:48AM E51.00003 First principle study of the role of oxygen non-stoichiometry in the structure and properties of amorphous InO and InGaO.<sup>1</sup>**, RABI KHANAL, JULIA MEDVEDEVA, Missouri S&T — Ab-initio molecular dynamics liquid-quench simulations of amorphous In-O and In-Ga-O are performed to investigate the structural, electronic and optical properties of these oxides. A new approach is developed to study the formation of oxygen defects in the amorphous oxides and their role in carrier generation and transport. First, the effect of oxygen non-stoichiometry on the local structure (i.e., the average Metal-Oxygen bond length and coordination) as well as on the long-range structural characteristics (i.e., the average M-M distance and the M-O-M angle) is discussed. The latter determines how the MO polyhedra are connected into a continuous network. Presence of Ga has a significant effect on the long-range structural correlations in non-stoichiometric structures. Further, the structural properties of oxygen defects as well as their effect on the electronic band structure is investigated. The results reveal charge accumulation on metal-metal bond(s) near the Fermi level suggesting the existence of two types of oxygen defect. Finally, strongly localized states near the valence band maximum originate from O<sub>2</sub> bonds and from charge imbalance associated with low coordinated oxygen atom surrounded by highly coordinated metal atoms.

**9:00AM E51.00004 Polarization effects in silver delafossite systems**, GIHAN PANAPITIYA, JAMES P. LEWIS, West Virginia Univ — Delafossites are a promising class of materials which has applications in catalysis and optoelectronic devices. Even though much work has been carried out on the cuprate family of delafossites, little is known about the structural and electronic properties of its silver counterpart. In this work, we present a computational study for two delafossite oxides of the form  $AgB_{1-x}Fe_xO_2$  (For B = Al, Ga). A large number of structures are studied by varying the Fe alloying percentage(x) from 0 to 5 and by choosing the impurity sites randomly. We find that the local structural changes occurring at the vicinity of Fe atoms in these two systems have opposite trends with regard to the O-O distance. The reason for this difference in the trends is identified as the polarization effects on the inter-atomic distances caused by the displacements in O atoms resulting from the incorporation of Fe in sites, previously occupied by either Al or Ga. We believe that these effects are mediated by the differences in the atomic radii of Fe, Al and Ga. Higher alloying levels coupled with nearest neighbor Fe atoms can intensify these distortions in the structure creating deformations in the O-Ag-O bonds, which are directly related to the formation of the conduction band edge in these systems.

**9:12AM E51.00005 Discriminating a deep defect from shallow acceptors in supercell calculations: gallium antisite in GaAs**, PETER SCHULTZ, Sandia National Laboratories — To make reliable first principles predictions of defect energies in semiconductors, it is crucial to discriminate between effective-mass-like defects—for which existing supercell methods fail—and deep defects—for which density functional theory calculations can yield reliable predictions of defect energy levels. The gallium antisite  $Ga_{As}$  is often associated with the 78/203 meV shallow double acceptor in Ga-rich gallium arsenide. Within a framework of level occupation patterns, analyses of structure and spin stabilization can be used within a supercell approach to distinguish localized deep defect states from shallow acceptors such as  $B_{As}$ . This systematic analysis determines that the gallium antisite is inconsistent with a shallow state, and cannot be the 78/203 shallow double acceptor. The properties of the Ga antisite in GaAs are described, predicting that the Ga antisite is a deep double acceptor and has two donor states, one of which might be accidentally shallow. — Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Company, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**9:24AM E51.00006 *Ab Initio* Modeling of Transition-Metal Impurities in MgO<sup>1</sup>**, SERGEY V. LEVCHENKO, SEBASTIAN ALARCON VILLASECA, ALIAKSEI MAZHEIKA, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE — Fe- and Ni-doped MgO are promising materials for the catalytic conversion of methane and CO<sub>2</sub>. However, theoretical studies of these materials are scarce. The self-interaction error (SIE) in approximate DFT leads to an incorrect description of the electron localization and hybridization between *d* states of Ni or Fe and the oxide electronic bands. Replacing a fraction  $\alpha$  of the (semi-)local exchange by the exact exchange reduces the SIE, but  $\alpha$  remains a parameter depending on the target property. We explore the dependence of the formation energies of Ni<sub>Mg</sub> and Fe<sub>Mg</sub> substitutional defects in MgO on  $\alpha$  in the Heyd-Scuseria-Ernzerhof hybrid functional (HSE), and compare the results to CCSD(T) embedded-cluster calculations. For Ni<sub>Mg</sub> defects HSE( $\alpha$  = 0.3) reproduces CCSD(T) formation energies and CO adsorption energies on Ni<sub>Mg</sub>. However,  $\alpha$  = 0.48 is needed in the case of Fe<sub>Mg</sub>. For both Ni<sub>Mg</sub> and Fe<sub>Mg</sub>,  $\alpha$  = 0.44-0.50 satisfies best the exact DFT condition that the HOMO does not depend on occupation. Contrary to PBE and HSE06, HSE( $\alpha$   $\approx$  0.5) reproduces the experimentally observed  $O_h \rightarrow D_{4h}$  (oblate) Jahn-Teller distortion for Fe<sub>Mg</sub>.

**9:36AM E51.00007 Phase Transformations upon Doping in Tungsten Trioxide<sup>1</sup>**, WENNIE WANG, Univ of California - Santa Barbara, ANDERSON JANOTTI<sup>2</sup>, University of Delaware, CHRIS G. VAN DE WALLE, Univ of California - Santa Barbara — Tungsten trioxide (WO<sub>3</sub>) is an emerging semiconductor material, with a growing number of applications in Li-ion batteries, photocatalysis, gas sensors and electrochromic devices. As an electrochromic material, WO<sub>3</sub> turns from transparent to blue upon doping with monovalent species. Due to it having an empty A-site in the ABO<sub>3</sub> perovskite structure, high doping concentrations are possible through intercalation. Tungsten trioxide has been experimentally shown to transform from the ground-state monoclinic symmetry to cubic symmetry with increasing monovalent doping [1]. We use first-principles calculations to understand this transformation. Our calculations show that the addition of electrons to the conduction band is a primary driver of the phase transformation. We quantify the energetics and structural aspects of this transformation using density functional theory, allowing us to elucidate the mechanism. Comparison with experiment, role of the dopant species, and implications of structural changes for device applications will be discussed. [1] Q. Zhong, J. Dahn, K. Colbow. *Phys. Rev. B* **46** 2554 (1992).

**9:48AM E51.00008 Electronic structure of intrinsic defects in non-stoichiometric amorphous In-Ga-Zn-O semiconductors**, WOO HYUN HAN, KEE JOO CHANG, Korea Adv Inst of Sci & Tech — Amorphous oxide semiconductors, such as amorphous In-Ga-Zn-O (a-IGZO), have attracted much attention because of their use as a channel material in thin-film transistors (TFTs). Despite many advantages such as flexibility, transparency, and high electron mobility, a-IGZO based TFTs suffer from defects which cause the instability of threshold voltage under negative bias illumination stress (NBIS) as well as positive bias stress (PBS). Recently, we have proposed that O-vacancy and O-interstitial defects are responsible for the NBIS and PBS instabilities, respectively. In the previous studies, O-related defects were intentionally introduced in stoichiometric a-IGZO. Since the composition ratio is likely to be deviated from the ideal stoichiometry during fabrication, it is important to understand the electronic structure of non-stoichiometric a-IGZO. Here we perform density functional calculations to investigate the electronic structure of O-related defects in various a-IGZO systems with non-stoichiometric chemical compositions, which are generated through melt-and-quench molecular dynamics simulations. We consider both O-abundant and O-deficient samples and discuss the role of intrinsic defects in the device instability.

**10:00AM E51.00009 Efficient n-type doping of MoO<sub>3</sub><sup>1</sup>**, HARTWIN PEELAERS, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — MoO<sub>3</sub> is a layered material that has shown great promise as a transparent contact to organic photovoltaics and organic light-emitting diodes. It also exhibits photo- and electrochromic properties, and can be used as catalyst or sensor material. Due to its capability to reversibly accommodate Li it can be used in Li batteries. Despite these interesting properties, remarkably little is known about the properties of native defects and the possibilities of controlling the properties by intentional doping. We have used advanced hybrid functional calculations within density functional theory to investigate efficient doping strategies for this material. In particular, we explored the role of native defects in the conductivity of this material. To control the n-type conductivity and to obtain a larger amount of free carriers, intentional dopants can be used. We show that substitutional Re (on a Mo site) is a shallow donor. In contrast, substitutional doping with Mn, which also has one additional electron compared to Mo, leads to compensating behavior. Halogen impurities on the O site also act as shallow donors.

**10:12AM E51.00010 The Role of Interface Defects on Phase Selection in ZnO/MgO Core/Shell Nanowires<sup>1</sup>**, DOMINIC CRITCHLOW, Austin Peay State University, Vanderbilt University, ZHINENG LI, Stony Brook University, Vanderbilt University, XIAO SHEN, CLAIRE MARVINNEY, YEVGENIY PUZYREV, LIDA PAN, JAMES MCBRIDE, RICHARD HAGLUND, SOKRATES PANTELIDES, Vanderbilt University — ZnO nanowires, coated with MgO, have potential for optical devices. The optical properties of the ZnO/MgO core-shell structures depend on the properties of the interface. Both epitaxial interface with wurtzite MgO on ZnO and non-epitaxial interface with rocksalt MgO have been observed. Differences in MgO interface structure poses questions to what type of defects must be present to achieve these different crystal structures. Density functional theory calculations are carried out to explore the role of surface oxygen vacancies and the step edges. The results from DFT calculations show that oxygen vacancies have no effect on the crystal structure. On the other hand, the calculations show that the step edges make rocksalt MgO structure more favorable. TEM images taken on the ZnO nanowires that has rocksalt MgO coating revealed steps in the ZnO Nanowire, confirming the theoretical prediction.

**10:24AM E51.00011 Structure of self-assembled Mn atom chains on Si(001)**, RENAN VILLARREAL, MARIA LONGOBARDI, SIGRUN A. KOESTER, Department of Quantum Matter Physics, University of Geneva, Geneva, CH-1211, Switzerland, CHRISTOPHER J. KIRKHAM, Division of Precision Science and Technology and Applied Physics, Graduate School of Engineering, Osaka University, 2-1, Yamada-oka, Suita, Japan, DAVID BOWLER, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, London WC1E 6BT, United Kingdom, CHRISTOPH RENNER, Department of Quantum Matter Physics, University of Geneva, Geneva, CH-1211, Switzerland — Mn has been found to self-assemble into atomic chains running perpendicular to the surface dimer reconstruction on Si(001). They differ from other atomic chains by a striking asymmetric appearance in filled state scanning tunneling microscopy (STM) images. This has prompted complicated structural models involving up to three Mn atoms per chain unit. Combining STM, atomic force microscopy and density functional theory we find that a simple necklace-like chain of single Mn atoms reproduces all their prominent features, including their asymmetry not captured by current models. The upshot is a remarkably simpler structure for modelling the electronic and magnetic properties of Mn atom chains on Si(001).

**10:36AM E51.00012 Electronic structures in SiC/SiO<sub>2</sub> interface from first-principles calculation -Roles of peculiar electron states floating in internal space-**, YU-ICHIRO MATSUSHITA, The University of Tokyo, MAURO BOERO, The University of Strasbourg, ATSUSHI OSHIYAMA, The University of Tokyo — Silicon carbide (SiC) is a promising material for power electronic devices. We have reported that the wavefunction at the conduction-band minimum (CBM) of SiC “floats in internal space with continuum-state character” [1]. By considering the floating nature of the CBM, drastic energy-level changes of CBM observed in SiC polytypes can be explained naturally [2]. Moreover, we have clarified that floating nature of CBM varies the effective masses in SiC. In this study, we have investigated how the electronic structure of CBM is modified in SiC/SiO<sub>2</sub> interfaces, where the internal space is severely deformed, and how the floating electron state affects the material properties. We have found that we can realize 1 dimensional electron channels in the interface, and that the effective masses of CBM strongly depend on the interface structures. [1] Y. i. Matsushita, S. Furuya, and A. Oshiyama, PRL, 108, 246404 (2012). [2] Y. i. Matsushita, and A. Oshiyama, PRL 112 136403 (2014).

**10:48AM E51.00013 Ab initio study of the effect of vacancies on the thermal conductivity**, NAKIB PROTIK, Boston College, JESUS CARRETE, NATALIO MINGO, LITEN, CEA-Grenoble, NEBIL KATCHO, CIC EnergiGUNE, DAVID BROIDO, Boston College — Point defects and vacancies in particular can have a profound impact on phonon thermal transport. Examples are seen in diamond [1] and cubic boron arsenide [2, 3] where large C and As vacancy concentrations give much lower thermal conductivity than expected [2, 3]. Here, we calculate the phonon-vacancy scattering rates using an *ab initio* Green's function approach [1], which treats the scattering to all orders in contrast to standard perturbation theory approaches. The lattice thermal conductivity,  $\kappa$ , is calculated from first principles by solving the Boltzmann transport equation for phonons, with interatomic force constants determined using density functional theory. The reduction in  $\kappa$  with vacancy defect density is assessed. The phonon-vacancy scattering can show significant differences using the Green's function method compared to what would be predicted from the perturbative Born approximation, consistent with previous findings for diamond [1]. Lett. 106, 074105 (2015).

## Tuesday, March 15, 2016 8:00AM - 10:12AM – Session E52 GERA FIAP: Physics of Batteries I Hilton Baltimore Holiday Ballroom 3 -

**8:00AM E52.00001 Diffusion and possible freezing phases of Li-ions in  $\text{LiFePO}_4$** <sup>1</sup>, YUEN YIU, Ames Laboratory, Iowa State University, RASMUS TOFT-PETERSEN, Helmholtz-Zentrum Berlin, GEORG EHLERS, Oak Ridge National Laboratory, DAVID VAKNIN, Ames Laboratory, Iowa State University — Elastic and inelastic neutron scattering studies of  $\text{LiFePO}_4$  single crystal reveal new Li-ion diffusion properties relevant to its function as Li-battery materials. In the past decade there has been broad interest in  $\text{LiFePO}_4$  and its related compounds, largely due to the applications of these materials as cathodes in Li- batteries. This is owing to these materials' high charge-discharge ability and conductivity, both of which are by virtue of the Li-ions' high mobility. In this talk, we present our findings on the temperature and directional dependence of Li-ions' diffusion in  $\text{LiFePO}_4$ .  $\text{LiFePO}_4$  adopts the olivine structure at room temperature (Space group: *Pnma*), which contains channels along principal crystalline directions that allow Li-ion motion. Elastic neutron scattering reveals lowering of symmetry from the *Pnma* structure below room temperature, which can be interpreted as the freezing of Li-ions, and can be subsequently linked to the reported decrease in Li-ion conductivity. Inelastic neutron scattering, in the 35K to 720K temperature range, shows temperature dependence, as well as anisotropy (i.e. along 0K0 versus 00L) of Li-ion diffusion.

<sup>1</sup>Ames Laboratory is supported by U.S. DOE, BES, DMSE, under contract DE-AC02-07CH11358. Spallation Neutron Source of Oak Ridge National Laboratory is sponsored by U.S. DOE, BES, SUFD.

**8:12AM E52.00002 Structural Properties and Electrochemical Performance of ZnO Nanosheets Grown Directly on Al substrate by Chemical Bath Deposition Techniques**, AHMED AL-ASADI, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL 62901, United States, ROBERTO FERRERA, Department of Chemistry and Biochemistry, Southern Illinois University Carbondale, Carbondale, IL, 62901, United States, LUKE HENLEY, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL 62901, United States, NESTOR LOPEZ, VICTOR CAROZO, ZHONG LIN, MAURICIO TERRONES, Department of Physics and Center for 2-Dimensional and Layered Materials, The Pennsylvania State University, University Park, PA 16802, United State, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL 62901, United States — We will report on the synthesis & electrochemical characterization of 2-dimensional zinc oxide grown directly on Al substrate by a simple chemical bath deposition method at low temperature (below 100°C). Detail structural characterizations of the synthesized ZnO sheets will be presented and discussed. The electrochemical performances of electrochemical double layer capacitors (EDLC) on electrodes fabricated using these materials were evaluated using cyclic voltammetry, galvanostatic charge-discharge, and electrochemical impedance spectroscopy using various electrolytes. We found that high specific capacitance values (greater than 300 F/g) could be achieved using an aqueous electrolyte. The aforementioned results indicates the possibly for using 2-D ZnO architectures fabricated by this simple and cost efficient technique for future electrochemical energy storage devices.

**8:24AM E52.00003 In situ analysis of capacity fade in thin-film anodes for high performance Li-ion all-solid-state batteries**, MARINA S. LEITE, CHEN GONG, Department of Materials Science and Eng., Institute for Research in Electronics and Applied Physics, Univ. of Maryland, College Park, Maryland 20742, DMITRY RUZMETOV, Sensors and Electron Devices Directorate, US Army Research Laboratory, Adelphi, Maryland, Material Measurement Laboratory, NIST, Gaithersburg Maryland, A. ALEC TALIN, Sandia National Laboratories, Livermore, California 94550 — There is still a pressing need to understand how the solid-interfaces in Li-ion all-solid-batteries form, including their chemical composition and electrical characteristics. In order to resolve the origin of the degradation mechanism in Al anodes, we combine in situ scanning electron microscopy in ultra-high vacuum with electrochemical cycling, in addition to ex situ characterization of the morphological, chemical, and electrical changes of the Al anodes upon lithiation. An AlLi alloy capped by a stable Al-Li-O is formed on the top surface of the anode, trapping Li, which results in the capacity fade, from 48.0 to 41.5  $\mu\text{Ah}/\text{cm}^2$  in two cycles [1]. The addition of a Cu capping layer is insufficient to prevent the device degradation because of the fast Li diffusion within Al. Yet, Si present extremely stable cycling: >92% of capacity retention after 100 cycles, with average Coulombic efficiency of 98% [2]. Our in situ measurements represent a new platform for probing the real-time degradation of electrodes in all-solid-state batteries for energy storage devices. [1] M.S. Leite et al., J. Mater. Chem. A, 2, 20552 (2014). i-Cover. [2] C. Gong et al., ACS Appl. Mater. Interfaces, 2015. DOI: 10.1021/acsami.5b07058

**8:36AM E52.00004 Non-Destructive Measurement of *in-operando* Lithium Concentration in Batteries via X-Ray Compton Scattering**, HASNAIN HAFIZ, Northeastern U., K. SUZUKI, Gunma U., B. BARBIELLINI, Northeastern U., Y. ORIKASA, Kyoto U., S. KAPRZYK, Northeastern U. and AGH U. of Sc. and Tech., M. ITOU, JASRI, K. YAMAMOTO, Kyoto U., Y. J. WANG, Northeastern U. and LBNL, Y. UCHIMOTO, Kyoto U., A. BANSIL, Northeastern U., Y. SAKURAI, JASRI, H. SAKURAI, Gunma U. — Non-destructive determination of lithium distribution in a working battery is key for addressing both efficiency and safety issues. Although various techniques have been developed to map the lithium distribution in electrodes, these methods are mostly applicable to test cells. Here we propose the use of high-energy x-ray Compton scattering spectroscopy to measure the local lithium concentration in closed electrochemical cells. A combination of experimental measurements and parallel first-principles computations is used to show that the shape parameter *S* of the Compton profile is linearly proportional to lithium concentration and thus provides a viable descriptor for this important quantity. The merits and applicability of our method are demonstrated with illustrative examples of  $\text{Li}_x\text{Mn}_2\text{O}_4$  cathodes and a working commercial lithium coin battery CR2032.

**8:48AM E52.00005 In-Situ AFM Investigation of Solid Electrolyte Interphase Formation and Failure Mechanisms in Lithium-Ion Batteries.** , THOMAS MUELLER, Bruker Nano Surfaces, RAVI KUMAR, ANTON TOKRANOV, Brown University, School of Engineering, TEDDY HUANG, CHUNZENG LI, Bruker Nano Surfaces, XINGCHENG XIAO, General Motors Global RD Center, BRIAN SHELDON, Brown University, School of Engineering — The formation and evolution of the solid electrolyte interphase (SEI) is critical for lifetime and performance of lithium-ion batteries (LIBs), particularly for LIBs with high energy density materials such as silicon. Si has almost ten times theoretical specific capacity vs graphite, but its volume changes during cycling (up to 400%) put enormous strains on the SEI layer, resulting in continuous capacity loss. In this study we report in situ atomic force microscopy (AFM) investigation on the formation and failure mechanisms of SEI layer using patterned Si island structures. Due to the shear lag effect, patterned Si islands go through lateral expansion and contraction, putting the SEI layer in tension and compression during lithiation and delithiation, respectively. Experimentally, we performed the studies in a glovebox with <1 ppm O<sub>2</sub> and H<sub>2</sub>O, using PeakForce Tapping to image the extremely fragile SEI layer. We show for the first time the in operando cracking of SEI layer. To understand the mechanics of the SEI layer, the critical strain for cracking was derived from a progression of the AFM images. Our studies provide new insight into SEI formation, evolution and its mechanical response, and offer guidance to tailor passivation layers for optimal performance.

**9:00AM E52.00006 Why LiFePO<sub>4</sub> is a safe battery electrode: Coulomb repulsion induced electron-state reshuffling upon lithiation** , YUNG JUI WANG, Northeastern Univ. (NU) and ALS, LBNL, XIAOSONG LIU, ALS, LBNL, B. BARBIELLINI, HASNAIN HAFIZ, SUSMITA BASAK, NU, JUN LIU, THOMAS RICHARDSON, EETD, LBNL, GUOJIUN SHU, FANGCHENG CHOU, National Taiwan Univ., TSU-CHIEN WENG, DENNIS NORDLUND, DIMOSTHENIS SOKARAS, SLAC, B. MORITZ, T. P. DEVEREAUX, Stanford Univ. and SLAC, RUIMIN QIAO, YI-DE CHUANG, ALS, LBNL, ARUN BANSIL, NU, ZAHID HUSSAIN, WANLI YANG, ALS, LBNL — We performed systematic experimental and theoretical studies based on soft X-ray emission, absorption, and hard X-ray Raman spectroscopy of Li<sub>x</sub>FePO<sub>4</sub>. The results show a non-rigid electron-state reconfiguration of both the occupied and unoccupied Fe-3d and O-2p states during the (de)lithiation process. The critical 3d electron state configurations are consistent with the calculations based on MBJGGA+U framework, which improves the overall lineshape prediction compared with the conventionally used GGA+U method. The combined experimental and theoretical studies show that the non-rigid electron state reshuffling guarantees the stability of oxygen during the redox reaction throughout the charge and discharge process of LiFePO<sub>4</sub> electrodes, leading to the intrinsic safe performance of the electrodes. Work supported by the US DOE.

**9:12AM E52.00007 An experimental and computational investigation of structural dependence of catalytic properties of Pt-Ru nanoparticles<sup>1</sup>** , BINAY PRASAI, Central Michigan University — An approach to determining the 3D atomic structure of metallic nanoparticles (NPs) in fine detail is described and exemplified on Pt–Ru alloy NPs of importance to the development of devices for clean energy conversion such as fuel cells. NPs are characterized structurally by total scattering experiments involving high-energy synchrotron X-ray diffraction coupled to atomic pair distribution functions (PDFs) analysis. 3D structure models are built by molecular dynamics simulations and further refined against the experimental PDF data by reverse Monte Carlo simulations and analyzed in terms of structural characteristics. Structural characteristics of activated NPs and data for their catalytic activity are compared side by side and strong evidence found that electronic effects, indicated by significant changes in Pt–Pt and Ru–Ru metal bond lengths at NP surface, and practically unrecognized so far atomic ensemble effects, indicated by distinct stacking of atomic layers near NP surface and prevalence of particular configurations of Pt and Ru atoms in these layers, contribute to the observed enhancement of the catalytic activity of Pt<sub>x</sub>Ru<sub>100–x</sub> alloy NPs at  $x \sim 50$ .

**9:24AM E52.00008 Detailed characterization of lithium diffusion mechanisms in crystalline silicon using the kinetic Activation-Relaxation Technique.** , MICKAL TROCHET, OSCAR ANTONIO RESTREPO GUTIERREZ, NORMAND MOUSSEAU, Universit de Montral — Silicon displays a potential for high-capacity anode material for lithium-ion batteries as it can absorb large quantities of this metal. Yet, very little is understood about the evolution of diffusion mechanisms and migration barriers as the concentration of lithium increases. Until now, for example, simulations studies were limited by the time scale over which diffusion takes place. Here, we use the kinetic activation relaxation technique (kART[1]), an unbiased off-lattice Monte Carlo method with on-the fly catalog building, coupled with the ReaxFF forcefield to follow diffusion of Li in c–Si over timescale of seconds and more at room temperature, obtaining detailed information about the whole set of possible diffusion mechanisms as the local environment evolves. We first present a detailed characterization of Li diffusion in the presence of 1 to 3 impurities and then show the evolution of systems with a higher concentration of solute as Li aggregate. These results provide a first detailed picture of the onset of Li aggregating into this high-capacity material, as it modifies the structure through local rearrangements and long-range elastic deformations, crucial information for the development of the next generation of high-capacity anode. \pard\pard[1] M. Trochet *et al.*, “Diffusion of point defects in crystalline silicon using the kinetic activation-relaxation technique method,” *Phys. Rev. B*, vol. 91, no. 22, p. 224106, 2015.

**9:36AM E52.00009 Gold Nanoparticles-Enhanced Proton Exchange Membrane (PEM) Fuel Cell** , HONGFEI LI, CHENG PAN, Stony Brook University, PING LIU, YIMEI ZHU, RADOSLAV ADZIC, Brookhaven National Laboratory, MIRIAM RAFAILOVICH, Stony Brook University — Proton exchange membrane fuel cells have drawn great attention and been taken as a promising alternated energy source. One of the reasons hamper the wider application of PEM fuel cell is the catalytic poison effect from the impurity of the gas flow. Haruta has predicted that gold nanoparticles that are platelet shaped and have direct contact with the metal oxide substrate to be the perfect catalysts of the CO oxidation, yet the synthesis method is difficult to apply in the Fuel Cell. In our approach, thiol-functionalized gold nanoparticles were synthesized through two-phase method developed by Brust *et al.* We deposit these Au particles with stepped surface directly onto the Nafion membrane in the PEM fuel cell by Langmuir–Blodgett method, resulting in over 50% enhancement of the efficiency of the fuel cell. DFT calculations were conducted to understand the theory of this kind of enhancement. The results indicated that only when the particles were in direct surface contact with the membrane, where AuNPs attached at the end of the Nafion side chains, it could reduce the energy barrier for the CO oxidation that could happen at T<300K.

**9:48AM E52.00010 One pot electrochemical synthesis of polymer/CNT/metal nanoparticles for fuel cell applications.** , LAKSHMAN VENTRAPRAGADA, JINGYI ZHU, MEHMET KARAKAYA, RAMAKRISHNA PODILA, APPARAO RAO, Clemson University, CLEMSON NANOMATERIALS CENTER TEAM — Carbon nanotubes (CNTs) have become a key player in the design of materials for energy applications. They gained their popularity in industrial and scientific research due to their unique properties like excellent conductivity, high surface area, etc. Here we used chemical vapor deposition (CVD) to synthesize two types of CNTs namely, helically coiled CNTs and vertically aligned CNTs. These CNTs were subsequently used to make composites with conducting polymers and metal nanoparticles. One pot electrochemical synthesis was designed to electropolymerize aniline, pyrrole etc. on the surface of the electrode with simultaneous deposition of platinum and gold metal nanoparticles, and CNTs in the polymer matrix. The as synthesized composite materials were characterized with scanning electron microscope for surface morphology and spectroscopic techniques like Raman, UV-Vis for functionality. These were used to study electrocatalytic oxidation of methanol and ethanol for alkaline fuel cell applications. Electrodes fabricated from these composites not only showed good kinetics but also exhibited excellent stability. Uniqueness of this composite lies in its simple two step synthesis and it doesn't involve any surfactants unlike conventional chemical synthesis routes.

**10:00AM E52.00011 Energy storage mechanism for hybrid battery** , JUN FENG, NATASHA CHERNOVA, FREDRICK OMENYA, ALOK RASTOGI, STANLEY WHITTINGHAM, Binghamton University — Many devices require both high energy and high power density, and lithium ion batteries and super-capacitors cannot separately always meet the requirements. In this work, we study the operating mechanism of a hybrid battery, which combines the best properties of batteries and supercapacitors. We analyze the lithium ion storage mechanism using XRD, Raman, TEM and electrochemical measurements. The model system studied combines a non-intercalating carbon black anode with a  $\text{LiFePO}_4$  cathode. At 50% state of charge, XRD data for  $\text{LiFePO}_4$  cathode material shows a mixture of  $\text{LiFePO}_4$  and  $\text{FePO}_4$ , indicating battery reaction. On the other hand, the activated carbon remains structurally unchanged. We also discuss the impact of a range of activated carbon/  $\text{LiFePO}_4$  (AC/LFP) ratios. From cyclic voltammetry and charge/discharge results, the system exhibits battery-domain characteristics when the AC/ LFP ratio is below one, but showing more supercapacitor-domain traits when the ratio is higher. Besides, the systems have higher rate capacity at AC/LFP ratio around four as compared to one. This research is supported by NSF under Award Number 1318202.

**Session E53 FGSA: The Future of Physics: Crossing Disciplines and Collaborating** Hilton Baltimore Holiday Ballroom 4 - Krista Freeman, Carnegie Mellon University

**8:00AM E53.00001 Cross Discipline Training to Reach the Mountain Top of Your Career** , RENEE HORTON, NASA Michoud Assembly Facility — No abstract available.

**8:36AM E53.00002 Random walks along the squishy boundary of physics and engineering** , ROBERT LEHENY, Johns Hopkins University — Many of the key problems and systems of interest in soft matter physics are similarly a focus for other fields, such as chemical engineering and biomedical engineering, making the area inherently highly interdisciplinary. Although soft matter physicists and engineers share topics of interest, the reasons for their interest are of course not identical, and when brought together through collaboration, these varied perspectives can help enrich the science. In my talk, I will illustrate this point with some specific examples from projects from my research background, particularly in the area of interfacial rheology. I will also try to offer some advice on how young scientists can position themselves to contribute in an environment where cross-disciplinary interactions are increasingly important.

**9:12AM E53.00003 Collaborating Across Borders** , AMY FLATTEN, American Physical Society, Director of International Affairs — Physicists transcend national boundaries, ethnic differences, and scientific disciplines to address globally shared problems and questions. This talk will highlight how scientists have collaborated across borders – both geographic and scientific – to achieve ground-breaking discoveries through international scientific cooperation. The speaker also will address how international collaborations will be even more crucial for addressing future challenges faced by the physics community, such as building large-scale research facilities, strengthening scientific capacity in developing countries, fostering "science for diplomacy" in times of political tensions and other critical issues.

**9:48AM E53.00004 Panel Discussion –**

**8:00AM E54.00001 Study of microwave reflection in the regime of the radiation-induced magnetoresistance oscillations in the high mobility GaAs/AlGaAs 2D electron system<sup>1</sup>** , ANNIKA KRIISA, H-C. LIU, R. L. SAMARAWEEERA, Georgia State University, Atlanta, GA 30303, M. S. HEIMBECK, Army Aviation & Missile RD & E Center, Redstone Arsenal, Huntsville, AL 35898, H. O. EVERITT, Army Aviation & Missile RD & E Center, Redstone Arsenal, Huntsville, AL 35898 and Dept. of Physics, Duke University, Durham, NC 27708, W. WEGSCHEIDER, ETH-Zurich, 8093 Zurich, Switzerland, R. G. MANI, Georgia State University, Atlanta, GA 30303 — Microwave-induced zero-resistance-states in the photo-excited GaAs/AlGaAs system evolve from the minima of microwave photo-excited quarter-cycle shifted magnetoresistance oscillations. Such magnetoresistance oscillations are known to exhibit nodes at cyclotron resonance ( $hf = \hbar\omega_c$ ) and cyclotron resonance harmonics ( $hf = n\hbar\omega_c$ ). Further, the effective mass extracted from the radiation-induced magnetoresistance oscillations is known to differ from the canonical effective mass ratio for electrons in the GaAs/AlGaAs system.[1] In an effort to reconcile this difference, we have looked for cyclotron resonance in the microwave reflection from the high mobility 2DES and attempted to correlate the observations with observed oscillatory magnetoresistance over the  $30 \leq f \leq 330$  GHz band. The results of such a study will be reported here. [1] R. G. Mani et al., Phys. Rev. Lett. 92, 146801 (2004).

<sup>1</sup>DOE-BES, Mat'l. Sci. & Eng. Div., DE-SC0001762; ARO W911NF-14-2-0076; ARO W911NF-15-1-0433

**8:12AM E54.00002 Frequency-dependence of the linear-polarization-angle phase-shift in the microwave radiation-induced magnetoresistance oscillations** , HAN-CHUN LIU, RASANGA SAMARAWEEERA, Georgia State Univ, WERNER WEGSCHEIDER, ETH-Zurich, Zurich, Switzerland , RAMESH MANI, Georgia State Univ — High-mobility GaAs/AlGaAs heterojunctions subjected to microwave photoexcitation in the perpendicular magnetic field configuration exhibit -cycle phase-shifted oscillatory magnetoresistance and zero-resistance states at low magnetic fields or high filling factors [1]. Recent studies showed that the amplitude of oscillatory magnetoresistance is polarization-angle sensitive and can be described by a fitting formula,  $R_{xx}(\theta) = A \cos 2(\theta - \theta_0)$  with diagonal resistance,  $R_{xx}$ , polarization angle  $\theta$ , and the extracted phase shift,  $\theta_0$ . Previous works have demonstrated that  $\theta_0$  is frequency-dependent by investigating some specific frequencies [2,3]. Here, we examine the continuous variation of  $\theta_0$  with frequency over the bands, 36-40 GHz and 45-49 GHz. Surprisingly, the results indicate dissimilar  $\theta_0$  variation within the two frequency bands. A comparison of  $\theta_0(f)$  with the microwave polarization reported by an in-situ polarization sensor suggests that the frequency variation of  $\theta_0$  might be caused by two different mechanisms in the two examined bands. [1] R. G. Mani et al., Nature 420, 646 (2002). [2] A. N. Ramanayaka et al., Phys. Rev. B 85, 205315 (2012). [3] Han-Chun Liu et al., J. Appl. Phys. 117, 064306 (2015)

**8:24AM E54.00003 Microwave radiation-induced magnetoresistance oscillations in the high mobility GaAs/AlGaAs system under bichromatic excitation**, BINUKA GUNAWARDANA, HAN-CHUN LIU, RASANAGA SAMARAWEEA, Georgia State Univ, WERNER WEGSCHEIDER, ETH Zurich, RAMESH MANI, Georgia State Univ — Bichromatic microwave excitation has been used in atomic physics, for example, to destabilize the populations distribution of cold atoms.[1] In semiconductor physics, bichromatic excitation of the high mobility 2D electron system is thought to provide evidence for current domains in the regime of the microwave radiation-induced zero-resistance states[2-4]. We examined radiation-induced magneto-resistance oscillations under bichromatic excitation over the  $30 < f < 100$  GHz band to obtain a better understanding of the lineshape observed in the dual excitation experiment of the high mobility GaAs/AlGaAs 2D electron system. Thus, we photo-excited the GaAs/AlGaAs Hall bar specimen at liquid helium with one microwave source at a fixed, relatively high frequency and a second microwave source at several lower frequencies corresponding to various frequency ratios. The microwave intensity due to both sources were also changed systematically to study the evolution of the oscillatory magnetoresistance lineshape. Here, we report the results of this study which aims to examine superposition- or lack thereof- in the lineshape observed in the bichromatic experiment. [1]A. Buchleitner, L. Sirko and H. Walther Europhysics Lett. 16, 35 (1991). [2] R. G. Mani et al., Nature, 420, 646 (2002) [3] M. A. Zudov et al., Phys. Rev. Lett. 96, 236804 (2004). [4] X. L. Lei and S. Y. Liu, Appl. Phys. Lett. 89, 182117 (2006).

**8:36AM E54.00004 Analysis of bell-shape negative giant-magnetoresistance in high mobility GaAs/AlGaAs 2D electron systems using multi-conduction model.**, RASANGA SAMARAWEEA, HAN-CHUN LIU, Georgia State University, WERNER WEGSCHEIDER, ETH Zurich, RAMESH MANI, Georgia State University — Recent advancements in the growth techniques of the GaAs/AlGaAs two dimensional electron system (2DES) routinely yield high quality heterostructures with enhanced physical and electrical properties, including devices with 2D electron mobilities well above  $10^7$  cm<sup>2</sup>/Vs. These improvements have opened new pathways to study interesting physical phenomena associated with the 2D electron system. Negative giant-magnetoresistance (GMR) is one such phenomenon which can be observed in the high mobility 2DES. However, the negative GMR in the GaAs/AlGaAs 2DES is still not fully understood. In this contribution, we present an experimental study of the bell-shape negative GMR in high mobility GaAs/AlGaAs devices and quantitatively analyze the results utilizing the multi-conduction model [1]. The multi-conduction model includes interesting physical characteristics such as negative diagonal conductivity, non-vanishing off-diagonal conductivity, etc. The aim of the study is to examine GMR over a wider experimental parameter space and determine whether the multi-conduction model serves to describe the experimental results. [1] R. G. Mani, A. Kriisa, and W. Wegscheider, Sci. Rep. 3, 2747 (2013).

**8:48AM E54.00005 Microwave polarization angle study of the radiation-induced magnetoresistance oscillations in the GaAs/AlGaAs 2D electron system under dc current bias**<sup>1</sup>, MUHAMMAD-ZAHIR IQBAL, HAN-CHUN LIU, Georgia State University, Atlanta, GA 30303, MARTIN S. HEIMBECK, Army Aviation & Missile RDE Center, Redstone Arsenal, Huntsville, AL 35898, HENRY O. EVERITT, Army Aviation & Missile RDE Center, Redstone Arsenal, Huntsville, AL 35898 and Dept. of Physics, Duke University, Durham, NC 27708, WERNER WEGSCHEIDER, ETH-Zurich, 8093 Zurich, Switzerland, RAMESH G. MANI, Georgia State University, Atlanta, GA 30303 — Microwave-induced magnetoresistance oscillations followed by the vanishing resistance states are a prime representation of non-equilibrium transport phenomena in two-dimensional electron systems (2DES). The effect of a dc current bias on the nonlinear response of 2DES with microwave polarization angle under magnetic field is a subject of interest. Here, we have studied the effect of various dc current bias on microwave radiation-induced magnetoresistance oscillations in a high mobility 2DES. Further, we systematically investigate the effect of the microwave polarization angle on the magneto-resistance oscillations at two different frequencies 152.78 GHz and 185.76 GHz. This study aims to better understand the effects of both dc current and microwave polarization angle in the GaAs/AlGaAs system, both of which modify the observed magneto-transport properties

<sup>1</sup>DOE-BES, Mat'l. Sci. & Eng. Div., DE-SC0001762; ARO W911NF-14-2-0076; ARO W911NF-15-1-0433

**9:00AM E54.00006 Microwave Reflection Spectroscopy of a Two-Dimensional Electron Gas**, JIE ZHANG, RUIYUAN LIU, LINGJIE DU, RUI-RUI DU, Rice University, LOREN PFEIFFER, KEN WEST, Princeton University — Cyclotron resonance (CR) is a standard method to determine the carrier effective mass in two-dimensional electron systems, typically by measuring/analyzing the absorption or transmission signal. Here we report a microwave spectrometer utilizing the reflection signal. In our experiment setup based on a top-loading helium3 cryostat and a superconducting solenoid, the microwave (up to 40GHz) is sent down via a coax cable to the sample surface, and the reflection signal is then collected by the same cable and fed upward to a directional coupler, and being detected. We demonstrate the applicability of the spectrometer by measuring the CR of high-mobility electrons or holes in GaAs/AlGaAs quantum wells. The construction of spectrometer, preliminary data, and brief discussions will be presented. The work at Rice was supported by Welch Foundation grant C-1682.

**9:12AM E54.00007 Response of Plasmonic Terahertz Detectors to Modulated Signals**, SERGEY RUDIN, GREG RUPPER, MEREDITH REED, U.S. Army Research Laboratory, MICHAEL SHUR, Rensselaer Polytechnic Institute — We present theoretical study of the response of two-dimensional gated electron gas to an amplitude modulated signals with carrier frequency in the terahertz range. Our model is based on complete hydrodynamic equations, and includes effects of viscosity, pressure gradients and thermal transport in the conduction channel of a high electron mobility semiconductor transistor. The modulation response was evaluated as a function of modulation frequency for a range of mobility values in different semiconductor materials. Maximum modulation frequency was evaluated as a function of channel mobility, with typical values in the subterahertz range of frequencies. Our analysis shows that short channel field effect transistors operating in the plasmonic regime meets the requirements for applications as terahertz detectors and modulators in high-speed wireless communication circuits.

**9:24AM E54.00008 Infrared magneto-transmission studies of the 2DEGs in (CdMn)Te and CdTe Quantum wells**<sup>1</sup>, IMTIAZ TANVEER, University at Buffalo, SUNY, MACIEJ WIATER, GRZEGORZ KARCZEWSKI, TOMASZ WÓJTOWICZ, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland, B.D. MCCOMBE, University at Buffalo, SUNY — We are probing quantum hall ferromagnetism (QHF) in the 2DEG of Modulation-doped quantum wells (QWs) in the (CdMn)Te/(CdMg)Te (with 1.5% Mn) heterostructure system by THz cyclotron resonance. Samples with CdTe QWs are also studied. Both structures have the same QW width (30 nm), very similar electron densities in the wells  $\sim 3.0 \times 10^{11}$  cm<sup>-2</sup> and mobilities of 450,000 (CdTe) and 66,000 cm<sup>2</sup>/Vs ((CdMn)Te) at 1.6 K. The electron effective masses ( $m^*/m_0$ ) from cyclotron resonance measurements at 5K are  $0.110 \pm 0.001$  for CdTe and  $0.114 \pm 0.003$  for (CdMn)Te. Linear fits to the resonance positions in frequency vs. field give small non-zero intercepts which may result from small non-parabolicity or bound magneto-plasmon effects. The FWHM linewidths from Lorentzian fits of the transmission minima are  $\sim 2$  cm<sup>-1</sup>(CdTe) and  $\sim 8$  cm<sup>-1</sup>((CdMn)Te). Our present focus is on detailed studies of the CR positions and linewidths in the magnetic field region around the cusp-like behavior in the  $R_{xx}$  oscillations, which indicates the presence of the QHF state. The field position of this state is tuned via electron density in the QWs varied incrementally by a photon-dose method with an in-situ green LED.

**9:36AM E54.00009 Coherent coupling of magneto-excitons probed by two-dimensional Fourier transform spectroscopy<sup>1</sup>**, JAGANNATH PAUL, CUNMING LIU, University of South Florida, STEPHEN MCGILL, National High Magnetic Field Lab, Florida State University, DAVID HILTON, University of Alabama at Birmingham, DENIS KARAISKAJ, University of South Florida — We present the coherent two dimensional Fourier Transform (2DFT) spectra of magneto-excitons in undoped GaAs quantum wells at high magnetic field up to 10 Tesla. The 2DFT data reveal strong coherent coupling between resonances and line shapes which are strikingly different from the zero field spectra. 2DFT spectra measured using co-linear and co-circular polarizations at low temperatures will be discussed.

<sup>1</sup>The work at USF and UAB was supported by the National Science Foundation under grant number DMR-1409473. The work at NHMFL, Florida State University was supported by the National Science Foundation under grant numbers DMR-1157490 and DMR-1229217.

**9:48AM E54.00010 Observation of a Bound Exciton Transition in Ion-Beam Synthesized  $\beta$ -FeSi<sub>2</sub>**, A. GLEN BIRDWELL, FRANK J. CROWNE, TERRANCE P. O'REGAN, U.S. Army Research Laboratory, Adelphi, Maryland 20783, USA — Photoreflectance studies of  $\beta$ -FeSi<sub>2</sub> have revealed the presences of strong (direct) optical transitions together with several interesting lower-energy spectral features, including indirect gap excitonic transitions. In this presentation, we focus on one of these features made observable at low temperatures and located a few meV below the first direct gap. We attribute the origin of this feature to a transition that takes place on a bound exciton-ionized acceptor complex. Our observations of this transition together with results of our previous photoreflectance analysis lead us to identify it as the fundamental mechanism for the 1.5  $\mu$ m light emission in  $\beta$ -FeSi<sub>2</sub>. This result provides deeper insight into the light emission properties of  $\beta$ -FeSi<sub>2</sub>.

**10:00AM E54.00011 Langevin Bimolecular Recombination Kinetics of a Layered Exciton–Trion Gas**, FRANK CROWNE, ANTHONY BIRDWELL, Army Research Laboratory — The use of rate equations to describe various many-body kinetic processes in highly photoexcited layered semiconductors is discussed. In these systems, pairs of electrons and holes generated by photons from an external laser combine to form a multicomponent plasma whose time evolution is governed by gas dynamics and various recombination processes. At high levels of illumination this leads to a variety of secondary components in addition to neutral excitons, notably the so-called trions, which consist of exciton–electron and exciton–hole bound states. Although the recombination is modeled as bimolecular for all pairs of carrier species, the structure of the rate terms is sensitive to the dimensionality of the system due to the Langevin nature of encounters between carriers. It is demonstrated that charge neutrality does not apply to individual carrier species, e.g., electron and hole densities need not be equal in the presence of trions. In order to track the full time evolution from laser initiation to steady state, the system of rate equations is simulated numerically.

**10:12AM E54.00012 Magneto-transport properties of PbSe single crystals**, NAWREEN ANAND, University of Florida, CATALIN MARTIN, Ramapo College of NJ, Mahwah, NJ, GENDA GU, Brookhaven National Lab, Upton, NY, DAVID TANNER, University of Florida — PbSe is a low-gap semiconductor with excellent infrared photodetection properties. Here we report our high magnetic field and low temperature electrical properties measurement performed on a moderately doped PbSe single crystals with p-type bulk carrier density of around  $110^{18} \text{ cm}^{-3}$ . Longitudinal resistance ( $R_{xx}$ ) and Hall resistance ( $R_{xy}$ ) were simultaneously measured between 0 T and 18 T, and at temperatures between 0.8 K and 25 K, show quantum oscillations above 6 T. The quantum oscillation frequency is  $\sim 15 \text{ T}$ , giving an estimate for the carrier density of each L pocket in the BZ participating in these oscillations. The effective mass of the free carriers is estimated from the temperature dependence of oscillation amplitudes. Measurements as the magnetic fields is rotated reveal the magneto-transport properties of a 3D-like fermi surface. Dingle temperature and free carrier scattering rate has been estimated and compared to optical measurements. Optical measurements also show a low frequency phonon mode around  $45 \text{ cm}^{-1}$  and bandgap of around 0.2 eV along with other interband electronic transitions.

**10:24AM E54.00013 Colossal figure of merit of transparent conducting nano-ribbon networks**, JINWEI GAO, QIANG PENG, SONGRU LI, BING HAN, QIKUN RONG, XUBING LU, GUOFU ZHOU, South China Normal University, Guangzhou, China, JUN-MING LIU, Nanjing University, Nanjing, China, QIANMING WANG, South China Normal University, Guangzhou, China, ZHIFENG REN, University of Houston, Houston, USA, KRZYSZTOF KEMPA, Boston College — An inexpensive, simultaneously transparent and conducting metallic nano-ribbon network can be obtained by exploiting the self-cracking property of the egg-white film, subsequently used as a sacrificial mask for metal sputtering. The process results in a network of metallic nano-ribbons ideally suited for electroplating. Due to large inter-ribbon distance, an even 100-fold increase in the ribbon thickness has a negligible effect on the network transparency. Here we demonstrate this effect by developing a network with a colossal, by far the highest reported figure of merit of over 25000. This network can be used as an ultimate window electrode for solar cells, as well as LEDs.

**10:36AM E54.00014 Gate Tunable InSb Quantum Well Structures grown on GaSb (001)**, MIHIR PENDHARKAR, ANTHONY MCFADDEN, BORZOYEH SHOJAEI, JOON SUE LEE, CHRIS PALMSTROM, Univ of California - Santa Barbara — Study of quantum well structures with InSb channels is of special interest to the field of spintronics and quantum computing due to the strong spin orbit coupling and large g-factor of InSb. Gate control of InSb quantum wells is a necessary component in construction of an InSb based Spin-Field Effect Transistor. In this work, InSb quantum well structures have been grown on lattice mismatched GaSb substrates by Molecular Beam Epitaxy. Magneto-transport measurements at low temperatures have been used to investigate the influence of gate voltage on electron mobility and density. A conventional metal top gate, separated from the III-V structure with an Atomic Layer Deposited insulating dielectric, has been used. Use of the conducting GaSb substrate as a potential, bottom gate electrode has also been investigated. Surface morphology of as-grown films has been studied using Atomic Force Microscopy.

**10:48AM E54.00015 Reconciling Particle-Beam and Optical Stopping-Power Measurements in Silicon<sup>1</sup>**, WILLIAM KARSTENS, St. Michael's College, E. J. SHILES, Retired, DAVID Y SMITH, University of Vermont and Argonne National laboratory — A swift, charged particle passing through matter loses energy to electronic excitations via the electro-magnetic transients experienced by atoms along its path. Bethe related this process to the matter's frequency-dependent dielectric function  $\epsilon(\hbar\omega)$  through the energy-loss function,  $\text{Im}[-1/\epsilon(\hbar\omega)]$ . The matter's response may be summarized by a single parameter, the mean excitation energy, or  $I$  value, that combines the optical excitation spectrum and excitation probability. Formally,  $\ln I$  is the mean of  $\ln \hbar\omega$  weighted by the energy-loss function. This provides an independent optical check on particle energy-loss experiments. However, a persistent disagreement is found for silicon: direct particle-beam studies yield  $173.5 < I < 176 \text{ eV}$ , but a fit to the stopping-power of 36 elements suggests 165 eV. An independent determination from optical data in 1986 gave 174 eV supporting the higher values. However, recent x-ray measurements disclosed short comings in the 1986 optical data: 1. Measurements by Ershov and Lukirskii underestimated the L-edge strength, and 2. A power-law extrapolation overestimated the K-edge strength. We have updated these data and find  $I = 162 \text{ eV}$ , suggesting that silicon's recommended  $I$  value should be reconsidered. While this 5% change in  $I$  value changes the stopping power by only 1%, it is significant for precision measurements with Si detectors.

**Tuesday, March 15, 2016 8:00AM - 11:00AM —**  
**Session E55 DBIO: Delbruck Prize Session** Hilton Baltimore Holiday Ballroom 6 - Steven D. Schwartz, University of Arizona

**8:00AM E55.00001 Precision Measurement in Biology** , STEPHEN QUAKE, Stanford University and Howard Hughes Medical Institute — Is biology a quantitative science like physics? I will discuss the role of precision measurement in both physics and biology, and argue that in fact both fields can be tied together by the use and consequences of precision measurement. The elementary quanta of biology are twofold: the macromolecule and the cell. Cells are the fundamental unit of life, and macromolecules are the fundamental elements of the cell. I will describe how precision measurements have been used to explore the basic properties of these quanta, and more generally how the quest for higher precision almost inevitably leads to the development of new technologies, which in turn catalyze further scientific discovery. In the 21st century, there are no remaining experimental barriers to biology becoming a truly quantitative and mathematical science.

**8:36AM E55.00002 Dynamics of DNA in vitro and in vivo** , JENS-CHRISTIAN MEINERS, University of Michigan — While the structure of DNA has reached iconic status, its dynamics are equally important for its biological function. The thermal fluctuations of DNA gives rise to fundamental properties, such as its entropic elasticity, and enable many biological functions like the formation of regulatory DNA-protein complexes. More recently, evidence is emerging that active, ATP-hydrolysis driven processes also contribute to the motion of DNA in vivo. These active processes can enhance the efficiency of self-assembly processes involving DNA quite substantially. In a living cell, on the other hand, the motion of the DNA is severely constrained by numerous topological barriers, like supercoiling and protein binding, which in turn can locally enhance, but globally restrict the formation of regulatory DNA-protein complexes. In my talk I will review the dynamics of DNA and the interplay between thermal fluctuations, active processes, and topological constraints in the context of in-vitro experiments with optical tweezers, and in-vivo studies of the bacterial chromosome using fluorescence techniques, and interpret the results in the framework of statistical mechanics and polymer physics.

**9:12AM E55.00003 Dissecting human cerebral organoids and fetal neocortex using single-cell RNAseq.** , BARBARA TREUTLEIN, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany; Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany — Cerebral organoids – three-dimensional cultures of human cerebral tissue derived from pluripotent stem cells – have emerged as models of human cortical development. However, the extent to which in vitro organoid systems recapitulate neural progenitor cell proliferation and neuronal differentiation programs observed in vivo remains unclear. Here we use single-cell RNA sequencing (scRNA-seq) to dissect and compare cell composition and progenitor-to-neuron lineage relationships in human cerebral organoids and fetal neocortex. Covariation network analysis using the fetal neocortex data reveals known and novel interactions among genes central to neural progenitor proliferation and neuronal differentiation. In the organoid, we detect diverse progenitors and differentiated cell types of neuronal and mesenchymal lineages, and identify cells that derived from regions resembling the fetal neocortex. We find that these organoid cortical cells use gene expression programs remarkably similar to those of the fetal tissue in order to organize into cerebral cortex-like regions. Our comparison of in vivo and in vitro cortical single cell transcriptomes illuminates the genetic features underlying human cortical development that can be studied in organoid cultures.

**9:48AM E55.00004 Monitoring of organ transplants through genomic analyses of circulating cell-free DNA.** , IWIJN DE VLAMINCK, Cornell University — Solid-organ transplantation is the preferred treatment for patients with end-stage organ diseases, but complications due to infection and acute rejection undermine its long-term benefits. While clinicians strive to carefully monitor transplant patients, diagnostic options are currently limited. My colleagues and I in the lab of Stephen Quake have found that a combination of next-generation sequencing with a phenomenon called circulating cell-free DNA enables non-invasive diagnosis of both infection and rejection in transplantation. A substantial amount of small fragments of cell-free DNA circulate in blood that are the debris of dead cells. We discovered that donor specific DNA is released in circulation during injury to the transplant organ and we show that the proportion of donor DNA in plasma is predictive of acute rejection in heart and lung transplantation. We profiled viral and bacterial DNA sequences in plasma of transplant patients and discovered that the relative representation of different viruses and bacteria is informative of immunosuppression. This discovery suggested a novel biological measure of a person's immune strength, a finding that we have more recently confirmed via B-cell repertoire sequencing. Lastly, our studies highlight applications of shotgun sequencing of cell-free DNA in the broad, hypothesis free diagnosis of infection.

**10:24AM E55.00005 Accurate and High-Coverage Immune Repertoire Sequencing Reveals Characteristics of Antibody Repertoire Diversification in Young Children with Malaria** , NING JIANG, None — Accurately measuring the immune repertoire sequence composition, diversity, and abundance is important in studying repertoire response in infections, vaccinations, and cancer immunology. Using molecular identifiers (MIDs) to tag mRNA molecules is an effective method in improving the accuracy of immune repertoire sequencing (IR-seq). However, it is still difficult to use IR-seq on small amount of clinical samples to achieve a high coverage of the repertoire diversities. This is especially challenging in studying infections and vaccinations where B cell subpopulations with fewer cells, such as memory B cells or plasmablasts, are often of great interest to study somatic mutation patterns and diversity changes. Here, we describe an approach of IR-seq based on the use of MIDs in combination with a clustering method that can reveal more than 80% of the antibody diversity in a sample and can be applied to as few as 1,000 B cells. We applied this to study the antibody repertoires of young children before and during an acute malaria infection. We discovered unexpectedly high levels of somatic hypermutation (SHM) in infants and revealed characteristics of antibody repertoire development in young children that would have a profound impact on immunization in children.

**Tuesday, March 15, 2016 11:15AM - 1:39PM –**

**Session F1 DCMP GSNP: Pattern Formation** Ballroom I - Sidney Nagel, University of Chicago

**11:15AM F1.00001 Fingers, toes and tongues: the anatomy of interfacial instabilities in viscous fluids** , IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology — The invasion of one fluid into another of higher viscosity is unstable and produces complex patterns in a quasi-two dimensional geometry. This viscous-fingering instability, a bedrock of our understanding of pattern formation, has been characterized by a most-unstable wavelength that sets the characteristic *width* of the fingers. We have shown that a second, previously overlooked, parameter governs the *length* of the fingers and characterizes the dominant global features of the patterns. Because interfacial tension suppresses short-wavelength fluctuations, its elimination would suggest an instability producing highly ramified singular structures. Our experimental investigations using miscible fluids show the opposite behavior – the interface becomes more stable even as the stabilizing effect of interfacial tension is removed. This is accompanied by slender structures, tongues, that form in the narrow thickness of the fluid. Among the rich variety of global patterns that emerge is a regime of blunt structures, “toes”, that exhibit the unusual features characteristic of proportionate growth. This type of pattern formation, while quite common in mammalian biology, was hitherto unknown in physical systems.

**11:51AM F1.00002 Pattern formation with proportionate growth<sup>1</sup>** , DEEPAK DHAR, Tata Institute of Fundamental Research, Mumbai — It is a common observation that as baby animals grow, different body parts grow approximately at same rate. This property, called proportionate growth is remarkable in that it is not encountered easily outside biology. The models of growth that have been studied in Physics so far, e.g diffusion -limited aggregation, surface deposition, growth of crystals from melt etc. involve only growth at the surface, with the inner structure remaining frozen. Interestingly, patterns formed in growing sandpiles provide a very wide variety of patterns that show proportionate growth. One finds patterns with different features, with sharply defined boundaries. In particular, even with very simple rules, one can produce patterns that show striking resemblance to those seen in nature. We can characterize the asymptotic pattern exactly in some special cases. I will discuss in particular the patterns grown on noisy backgrounds.

<sup>1</sup>supported by J. C. Bose fellowship from DST ( India)

**12:27PM F1.00003 Patterns in Active Nematics** , JULIA M YEOMANS, University of Oxford — Active systems, from bacterial suspensions to cellular monolayers, are continuously driven out of equilibrium by local injection of energy from their constituent elements and exhibit turbulent-like, chaotic patterns. We describe how active systems can be stabilised by tuning a physical feature of the system, friction. We demonstrate how the crossover between wet active systems, whose behaviour is dominated by hydrodynamics, and dry active matter where any flow is screened, can be achieved by using friction as a control parameter and demonstrate vortex ordering at the wet-dry crossover. We show that the self organisation of vortices into lattices is accompanied by the spatial ordering of topological defects leading to active crystal-like structures. The emergence of vortex lattices which leads to the positional ordering of topological defects may be a useful step towards the design and control of active materials.

**1:03PM F1.00004 Instabilities and pattern formation on the pore scale<sup>1</sup>** , ANNE JUEL, University of Manchester — What links a babys first breath to adhesive debonding, enhanced oil recovery, or even drop-on-demand devices? All these processes involve moving or expanding bubbles displacing fluid in a confined space, bounded by either rigid or elastic walls. In this talk, we show how spatial confinement may either induce or suppress interfacial instabilities and pattern formation in such flows. We demonstrate that a simple change in the bounding geometry can radically alter the behaviour of a fluid-displacing air finger both in rigid and elastic vessels. A rich array of propagation modes, including steady and oscillatory fingers, is uncovered when air displaces oil from axially uniform tubes that have local variations in flow resistance within their cross-sections. Moreover, we show that the experimentally observed states can all be captured by a two-dimensional depth-averaged model for bubble propagation through wide channels. Viscous fingering in Hele-Shaw cells is a classical and widely studied fluid-mechanical instability: when air is injected into the narrow, liquid-filled gap between parallel rigid plates, the axisymmetrically expanding air-liquid interface tends to be unstable to non-axisymmetric disturbances. We show how the introduction of wall elasticity (via the replacement of the upper bounding plate by an elastic membrane) can weaken or even suppress the fingering instability by allowing changes in cell confinement through the flow-induced deflection of the boundary. The presence of a deformable boundary also makes the system prone to additional solid-mechanical instabilities, and these wrinkling instabilities can in turn enhance viscous fingering.

**Tuesday, March 15, 2016 11:15AM - 2:15PM –**  
**Session F2 DCMP DAMOP: Topology and Localization in Floquet Systems** Ballroom II - Shivaji  
Sondhi, Princeton

**11:15AM F2.00001 Floquet States: Anomalous topological phases and steady state engineering** , GIL REFAEL, Caltech — Periodically driven quantum systems provide a novel and versatile platform for realizing topological phenomena. In my talk I'll provide a brief introduction to the Floquet path to topological behavior. Next, I will concentrate on a remarkable Floquet state that has no static analog: A 2d system which has chiral edge states, alongside fully localized bulk orbitals. This unique situation serves as the basis for a new topologically-protected non-equilibrium transport phenomenon: quantized non-adiabatic charge pumping. We identify the bulk topological invariant that characterizes this new phase, which we dub the 'anomalous Floquet Anderson Insulator'. In the second part of my talk, I will discuss recent results on stabilizing desired steady states in periodically driven fermionic semiconducting systems using bosonic and fermionic bath engineering.

**11:51AM F2.00002 When do Floquet systems fail to heat?** , ANUSHYA CHANDRAN, Perimeter Institute — Periodically driven quantum systems do not have a conserved energy. Thus, statistical mechanical lore holds that if they thermalize, it must be to infinite temperature. I will first show this holds in undriven systems that satisfy the eigenstate thermalization hypothesis. I will then present two counter-examples to infinite temperature heating. The first is the bosonic O(N) model at infinite N, in which the steady states are paramagnetic and have non-trivial correlations. The second is the Clifford circuit model, which can fail to heat depending on the choice of circuit elements. The resulting steady states can then be localized or delocalized but not ergodic. Such models shed light on the nature of interacting Floquet localization.

**12:27PM F2.00003 Floquet thermodynamics—nature of ensembles and order under periodic driving** , ACHILLEAS LAZARIDES, Max Planck Institute for the Physics of Complex Systems, Dresden — We study the long-time behaviour of many-body Floquet systems—closed quantum systems under temporally periodic driving, arguably the simplest deviation from equilibrium. We begin by showing that generically such interacting systems heat up and discuss the microscopic mechanism by which this happens. We then discuss two ways to prevent this: integrability and disorder. In the integrable case, a "periodic Gibbs ensemble" may be derived by maximising the entropy and shown to exactly describe the long-time steady state, while in the interacting disordered (many-body localised, or MBL) case, we identify the regime under which driving does not delocalise the system. We conclude by discussing the nontrivial steady-states achieved in interacting Floquet systems.

**1:03PM F2.00004 Floquet engineering with ultracold fermions: From Haldane's model of topological bands to spin-dependent lattices** , MICHAEL MESSER, ETH Zurich — Periodically driving a system of ultracold fermionic atoms in an optical lattice allows for implementing a large variety of effective Hamiltonians through Floquet engineering. Using this concept we realize the Haldane model which is a fundamental example of a Hamiltonian exhibiting topologically distinct phases of matter. By loading non-interacting degenerate fermions in a periodically modulated honeycomb lattice we can implement and characterize the topological band structure. We explore the resulting Berry-curvatures of the lowest band and map out topological phase transitions connecting distinct regimes. Such a technique may be extended to also address internal degrees of freedom. By periodically modulating a magnetic field gradient we tune the relative amplitude and sign of the tunneling for different internal states. Thereby we experimentally realize spin-dependent effective Hamiltonians where one state can be pinned to the lattice, while the other remains itinerant. For each spin state, the differing band structure can be characterized either by measuring the expansion of an atomic cloud in the lattice, or by a measurement of the effective mass through dipole oscillations. Furthermore we use the tunability of ultracold atoms to investigate the role of interactions.

**1:39PM F2.00005 Localization effects in periodically driven many-body systems<sup>1</sup>**, FRANOIS HUVE-NEERS, CEREMADE, Universit Paris Dauphine — In this talk, I will discuss the emergence of quasi, or sometimes strictly, conserved quantities in periodically driven many-body quantum systems. In the particular case of a many-body localized Hamiltonian, characterized by a full set of local integral of motions (LIOMs), I will show that the driven system itself admits a full set of strictly conserved LIOMs, if the driving frequency is high enough. Moreover, I will show that the ideas developed in the context of driven systems can be generalized to describe the emergence of pre-thermal behavior in a wide class of both closed and driven systems.

**Tuesday, March 15, 2016 11:15AM - 2:15PM —**

**Session F3 GMAG DCMP: Superconducting Spintronics** Ballroom III - Hans Nembach, National Institute of Standards and Technology

**11:15AM F3.00001 The road to superconducting spintronics<sup>1</sup>**, MATTHIAS ESCHRIG, Royal Holloway, University of London — Energy efficient computing has become a major challenge, with the increasing importance of large data centres across the world, which already today have a power consumption comparable to that of Spain, with steeply increasing trend. Superconducting computing is progressively becoming an alternative for large-scale applications, with the costs for cooling being largely outweighed by the gain in energy efficiency. The combination of superconductivity and spintronics - "superspintronics" - has the potential and flexibility to develop into such a green technology. This young field is based on the observation that new phenomena emerge at interfaces between superconducting and other, competing, phases. The past 15 years have seen a series of pivotal predictions and experimental discoveries relating to the interplay between superconductivity and ferromagnetism. The building blocks of superspintronics are equal-spin Cooper pairs, which are generated at the interface between superconducting and a ferromagnetic materials in the presence of non-collinear magnetism. Such novel, spin-polarised Cooper pairs carry spin-supercurrents in ferromagnets and thus contribute to spin-transport and spin-control. Geometric Berry phases appear during the singlet-triplet conversion process in structures with non-coplanar magnetisation, enhancing functionality of devices, and non-locality introduced by superconducting order leads to long-range effects. With the successful generation and control of equal-spin Cooper pairs the hitherto notorious incompatibility of superconductivity and ferromagnetism has been not only overcome, but turned synergistic. I will discuss these developments and their extraordinary potential. I also will present open questions posed by recent experiments and point out implications for theory.

<sup>1</sup>This work is supported by the Engineering and Physical Science Research Council (EPSRC Grant No. EP/J010618/1).

**11:51AM F3.00002 Nanoscale memory elements based on the superconductor-ferromagnet proximity effect and spin-transfer torque magnetization switching**, BURM BAEK, NIST - Boulder — Superconducting-ferromagnetic hybrid devices have potential for a practical memory technology compatible with superconducting logic circuits and may help realize energy-efficient, high-performance superconducting computers. We have developed Josephson junction devices with pseudo-spin-valve barriers <sup>1</sup>. We observed changes in Josephson critical current depending on the magnetization state of the barrier (parallel or anti-parallel) through the superconductor-ferromagnet proximity effect. This effect persists to nanoscale devices in contrast to the remanent field effect. In nanopillar devices <sup>2</sup>, the magnetization states of the pseudo-spin-valve barriers could also be switched with applied bias currents at 4 K, which is consistent with the spin-transfer torque effect in analogous room-temperature spin valve devices. These results demonstrate devices that combine major superconducting and spintronic effects for scalable read and write of memory states, respectively. Further challenges and proposals towards practical devices will also be discussed. In collaboration with: William Rippard, NIST Boulder, Matthew Pufall, NIST Boulder, Stephen Russek, NIST-Boulder, Michael Schneider, NIST Boulder, Samuel Benz, NIST Boulder, Horst Rogalla, NIST-Boulder, Paul Dresselhaus, NIST - Boulder

**12:27PM F3.00003 Spin-polarized superconductivity for spintronics<sup>1</sup>**, JASON ROBINSON, Cambridge University — The feasibility of superconducting spintronics depends on the spin sensitivity of ferromagnets to the spin of equal-spin triplet Cooper pairs (1). Such pairs are generated at superconductor(S) / ferromagnet(F) interfaces in which certain forms of magnetic inhomogeneity (2,3) are present. In this talk I will introduce the topic of the triplet proximity effect in S-F heterostructures and will discuss my group's recent progress, which includes: spin-selectivity of triplet Cooper pairs in F-S-F superconducting spin-valves (4) and evidence for the formation of a spin-polarized superconducting densities of state in an s-wave superconductor proximity coupled to a magnetically inhomogeneous antiferromagnet (5).

**1:03PM F3.00004 Quasiparticle-mediated spin Hall effect in a superconductor**, TARO WAKAMURA, Univ of Paris - Sud 11 CNRS — Superconductivity often brings novel phenomena to spintronics. According to theoretical predictions, superconductivity may enhance the spin Hall effect (SHE) due to the increase in the resistance of superconducting quasiparticles which mediate spin transport in superconductors. In this work, we show a first experimental observation of quasiparticle-mediated SHE in a superconducting NbN, which exhibits an enormous enhancement below the superconducting critical temperature ( $T_C = 10$  K). We fabricated a lateral device structure composed of Py (NiFe) and NbN wires bridged by a nonmagnetic Cu wire. A pure spin current is generated in the Cu bridge by a spin injection current ( $I$ ) between the Py and the Cu, and absorbed into the NbN wire. The absorbed spin currents are converted into charge currents via the inverse SHE, thereby generating the inverse SH voltage ( $V_{ISHE}$ ). When NbN is in the normal state at 20 K ( $>T_C$ ), inverse SH signals  $\Delta R_{ISHE}$  ( $R_{ISHE} \equiv V_{ISHE}/I$ ) are independent of  $I$ . However, at 3 K ( $<T_C$ ), as  $I$  decreases  $\Delta R_{ISHE}$  dramatically increases, and when  $I = 0.01 \mu A$ , the signal becomes more than 2000 times greater than that in the normal state. Our experimental demonstration shows a great potentiality of superconductors for spintronics and its future applications.

**1:39PM F3.00005 Cryogenic Memories based on Spin-Singlet and Spin-Triplet Ferromagnetic Josephson Junctions<sup>1</sup>**, ERIC GINGRICH, Northrop Grumman Corporation — The last several decades have seen an explosion in the use and size of computers for scientific applications. The US Department of Energy has set an ExaScale computing goal for high performance computing that is projected to be unattainable by current CMOS computing designs [1]. This has led to a renewed interest in superconducting computing as a means of beating these projections. One of the primary requirements of this thrust is the development of an efficient cryogenic memory. Estimates of power consumption of early Rapid Single Flux Quantum (RSFQ) memory designs are on the order of MW, far too steep for any real application [1]. Therefore, other memory concepts are required. S/F/S Josephson Junctions, a class of device in which two superconductors (S) are separated by one or more ferromagnetic layers (F) has shown promise as a memory element. Several different systems have been proposed utilizing either the spin-singlet or spin-triplet superconducting states [2]. This talk will discuss the concepts underpinning these devices, and the recent work done to demonstrate their feasibility. **11:15AM F4.00001 Topology Matters: Structure and dynamics of ring polymers**, DIETER RICHTER, JCNS at Forschungszentrum Jlich, 52425 Jlich Germany — In this talk I present recent experimental advances addressing the structure and dynamics of rings. I focus mainly on neutron scattering results that reveal experimental insight on a molecular scale. Structural investigations characterizing rings as compact objects in the melts are put into theoretical context. In contrast to the plateau regime common for all other high molecular weight polymer systems, the dynamic modulus of pure ring systems is characterized by a power law decay, while the viscosity displays a much weaker molecular weight dependence as a corresponding linear melt. The dynamics of ring melts is uniquely addressed by neutron spin-echo spectroscopy. The sub-diffusive center of mass motion at short times agrees well with simulation as well as theoretical concepts. In the internal dynamics the basic length scale of the ring molecule, the loop size, manifests itself clearly. The experiments reveal strong evidence for loop motions and call for further theoretical work describing them. Finally, small fractions of ring molecules in linear melts turn out to be very sensitive probes in order to scrutinize the dynamics of the host with the potential to reveal fundamental aspects of the dynamics of branched polymer systems. \pardReview Letters 131, 168302 (2014)Review Letters 115, 148302 (2015)Matter 11, DOI: 10.1039/C5SM01994J (2015)

**11:51AM F4.00002 From chromosome crumpling to the interacting randomly branched polymers**, RALF EVERAERS, Laboratoire de Physique, ENS de Lyon — The conformational statistics of ring polymers in melts or dense solutions is strongly affected by their quenched microscopic topological state. The effect is particularly strong for non-concatenated unknotted rings, which are known to crumple and segregate and which have been implicated as models for the generic behavior of interphase chromosomes. In [1] we have used a computationally efficient multi-scale approach to identify the subtle physics underlying their behavior, where we combine massive Molecular Dynamics simulations on the fiber level with Monte Carlo simulations of a wide range of lattice models for the large scale structure. This allowed us to show that ring melts can be *quantitatively* mapped to coarse-grained melts of *interacting* randomly branched primitive paths. To elucidate the behavior of interacting branched polymers, we use a combination of scaling arguments and computer simulations[2]. The simulations are carried out for different statistical ensembles: ideal randomly branching polymers, melts of interacting randomly branching polymers, and self-avoiding trees with annealed and quenched connectivities. In all cases, we perform a detailed analysis of the tree connectivities and conformations. We find that the scaling behaviour of average properties is very well described by the Flory theory of Gutin et al. [Macromolecules 26, 1293 (1993)]. A detailed study of the corresponding distribution functions allows us to propose a coherent framework of the behavior of interacting trees, including generalised Fisher-Pincus relationships and the detailed analysis of contacts statistics. **12:27PM F4.00003 Self-Similar Conformations and Dynamics of Non-Concatenated Entangled Ring Polymers<sup>1</sup>**, TING GE, University of North Carolina at Chapel Hill — A scaling model of self-similar conformations and dynamics of non-concatenated entangled ring polymers is developed. Topological constraints force these ring polymers into compact conformations with fractal dimension  $D=3$  that we call fractal loopy globules (FLGs). This result is based on the conjecture that the overlap parameter of loops on all length scales is equal to the Kavassalis-Noolandi number 10-20. The dynamics of entangled rings is self-similar, and proceeds as loops of increasing sizes are rearranged progressively at their respective diffusion times. The topological constraints associated with smaller rearranged loops affect the dynamics of larger loops by increasing the effective friction coefficient, but have no influence on the tubes confining larger loops. Therefore, the tube diameter defined as the average spacing between relevant topological constraints increases with time, leading to "tube dilation". Analysis of the primitive paths in molecular dynamics (MD) simulations suggests complete tube dilation with the tube diameter on the order of the time-dependent characteristic loop size. A characteristic loop at time  $t$  is defined as a ring section that has diffused a distance of its size during time  $t$ . We derive dynamic scaling exponents in terms of fractal dimensions of an entangled ring and the underlying primitive path and a parameter characterizing the extent of tube dilation. The results reproduce the predictions of different dynamic models of a single non-concatenated entangled ring. We demonstrate that traditional generalization of single-ring models to multi-ring dynamics is not self-consistent and develop a FLG model with self-consistent multi-ring dynamics and complete tube dilation. Various dynamic scaling exponents predicted by the self-consistent FLG model are consistent with recent computer simulations and experiments. We also perform MD simulations of nanoparticle (NP) diffusion in melts of non-concatenated entangled ring polymers. NPs larger than the undiluted tube diameter undergo power-law sub-diffusion in entangled rings in contrast to strong suppression in entangled linear chains. This result demonstrates that there is no long-lived confining tube in entangled ring polymers, which agrees with complete tube dilation in the self-consistent FLG model.

### 1:03PM F4.00004 Polymer Crystallization under Confinement , GEORGE FLOUDAS, University of Ioannina —

Recent efforts indicated that polymer crystallization under confinement can be substantially different from the bulk. This can have important technological applications for the design of polymeric nanofibers with tunable mechanical strength, processability and optical clarity. However, the question of *how, why and when* polymers crystallize under confinement is not fully answered. Important studies of polymer crystallization confined to droplets and within the spherical nanodomains of block copolymers emphasized the interplay between heterogeneous and homogeneous nucleation. Herein we report on recent studies<sup>1–5</sup> of polymer crystallization under hard confinement provided by model self-ordered AAO nanopores. Important open questions here are on the type of nucleation (homogeneous vs. heterogeneous), the size of critical nucleus, the crystal orientation and the possibility to control the overall crystallinity. Providing answers to these questions is of technological relevance for the understanding of nanocomposites containing semicrystalline polymers. [1] H. Duran, M. Steinhart, H.-J. Butt, G. ### 1:39PM F4.00005 Rheology of Rings: Current Status and Future Challenges<sup>1</sup> , GREGORY MCKENNA,

Texas Tech Univ — Understanding the dynamics of circular or ring-like polymers has been a subject of investigation since the 1980s and is one which remains an area that is not fully understood [1–5]. Part of the reason for this is the difficulty of making synthetic rings of sufficient size to establish the nature of the entanglement dynamics, if entanglements even exist in these materials. Furthermore, there is now strong evidence that small amounts of linear impurities can impact the dynamics. Hence, one of the major challenges to our understanding of ring dynamics is to make large molecular weight rings of sufficient purity that the dynamics of the rings themselves can be determined. In the present work the current state of understanding of the dynamics of rings is outlined and current work from our group of collaborators [6] to make extremely large circular polymers using Echeverria Coli as a route to make pure rings (circular DNA) in sufficient quantity and size to determine the dynamics of these materials will be shown. First results of ring dynamics in dilute solution are presented and new results on concentrated and entangled solutions will be discussed. Remaining challenges will be elucidated. [1] J. Session F5 GMAG DCMP FIAP: Spin Transport in Semiconductors 301 - Pengke Li, University of Maryland, College Park

### 11:15AM F5.00001 Spin-orbit fields at semiconductor interfaces<sup>1</sup> , MARTIN GMITRA, University of Regensburg

— Solids without space inversion symmetry exhibit spin-orbit fields, which are emerging manifestations of spin-orbit coupling of the underlying atomic structure. Primary examples of spatially asymmetric systems are interfaces, which are omnipresent in electronic devices. As the device dimensions scale down, interfaces imprint their symmetries into the transport channel by proximity effects. Proximity spin-orbit fields already play important roles in anisotropic magnetoresistance of ultrathin structures such as Fe/GaAs [1], in the physics of Majorana fermions [2,3] and Andreev reflection [4] of semiconductor/superconductor junctions, in Skyrmin textures [5] in ferromagnets, or in spin-orbit torques [6]. It is thus of vital interest to gain qualitative insight and realistic quantitative description of the interfacial spin-orbit fields for various materials hybrid settings. We have proposed a methodology to extract spin-orbit fields, both their magnitudes and directions, and applied it to investigate Fe/GaAs junctions [7]. Only at low momenta the traditional description of the fields in terms of linear Rashba and Dresselhaus works. At generic momenta the fields exhibit what we call butterfly patterns, conforming to the interfacial symmetry. Remarkably, the spin-orbit fields depend rather strongly on the magnetization orientation. We will also discuss our recent results on the spin-orbit coupling in zinc-blende and wurtzite semiconductor nanostructures.

### 11:51AM F5.00002 Realization of an all-electric spin transistor using quantum point contacts

, TSE-MING CHEN, POJEN CHUANG, SHENG-CHIN HO, National Cheng Kung University, LUKE SMITH, FRANCOIS SFIGAKIS, University of Cambridge, MICHAEL PEPPER, University College London, CHIN-HUNG CHEN, JU-CHUN FAN, National Cheng Kung University, JONATHAN GRIFFITHS, IAN FARRER, HARVEY BEERE, GEB JONES, DAVE RITCHIE, University of Cambridge — The spin field effect transistor envisioned by Datta and Das opens a gateway to spin information processing. Although the coherent manipulation of electron spins in semiconductors is now possible, the realization of a functional spin field effect transistor for information processing has yet to be achieved, owing to several fundamental challenges such as the low spin-injection efficiency due to resistance mismatch, spin relaxation, and the spread of spin precession angles. Alternative spin transistor designs have therefore been proposed, but these differ from the field effect transistor concept and require the use of optical or magnetic elements, which pose difficulties for the incorporation into integrated circuits. Here, we present an all-electric all-semiconductor spin field effect transistor, in which these obstacles are overcome by employing two quantum point contacts as spin injectors and detectors. Distinct engineering architectures of spin-orbit coupling are exploited for the quantum point contacts and the central semiconductor channel to achieve complete control of the electron spins—spin injection, manipulation, and detection—in a purely electrical manner. Such a device is compatible with large-scale integration and hold promise for future spintronic devices for information processing. Ref: P. Chuang *et al.*, *Nat. Nanotechnol.* *10*, 35 (2015).

### 12:03PM F5.00003 Current-induced spin polarization in InGaAs epilayers with varying doping densities , MARTA LUENGO-KOVAC, SIMON HUANG, DAVIDE DEL GAUDIO, JORDAN OCCENA, RACHEL GOLDMAN, VANESSA SIH, Univ of Michigan - Ann Arbor —

Current-induced spin polarization (CISP) is a phenomena in which an applied electric field produces a bulk spin polarization in the plane of the sample. As this is thought to arise from the spin-orbit coupling, it was originally predicted that the magnitude of CISP should be proportional to the spin-orbit (SO) splitting [1]. However, crystal axis-dependent measurements of the CISP and SO fields showed a negative differential relationship between these two quantities [2]. To develop a phenomenological understanding of the factors affecting the magnitude of CISP, we performed measurements on three In<sub>0.025</sub>Ga<sub>0.975</sub>As epilayers, Si-doped at 0.67, 9.6, and 14.1 × 10<sup>17</sup> cm<sup>-3</sup>. We will discuss the effects of the doping density and electron mobility on the magnitudes of the SO fields and CISP. [1] V. Edelstein, *Solid State Commun.* **73**, 233 (1990). [2] Norman, B. M., *et al.*, *Phys. Rev. Lett.* **112**, 056601 (2014).

**12:15PM F5.00004 Effective spin Hall properties of a mixture of materials with and without spin-orbit coupling: Tailoring the effective spin-diffusion length<sup>1</sup>**, YUE ZHANG, MEGAN PRESTGARD, ASHUTOSH TIWARI, MIKHAIL RAIKH, Univ of Utah — We study theoretically the effective spin Hall properties of a composite consisting of two materials with and without spin-orbit (SO) coupling. In particular, we assume that SO material represents a system of grains of radius,  $a$ , and density,  $n$ , in a matrix with no SO. We calculate the effective spin Hall angle,  $\theta_{eff}^{SH}$ , and the effective spin diffusion length,  $\lambda_{eff}$ , of the mixture. Our main qualitative finding is that, if the bare spin diffusion length,  $\lambda$ , is much smaller than  $a$ , then  $\lambda_{eff}$  is strongly *enhanced*, well beyond  $\lambda/(na^3)^{1/2}$ , which can be expected from purely “geometrical” consideration. The physical origin of this additional enhancement is that, with small diffusion length,  $\lambda \ll a$ , the spin current mostly flows *around the grain* without suffering much loss. We also demonstrate that the voltage, created by a spin current, is sensitive to a very weak magnetic field directed along the spin current, and even reverses sign in a certain domain of fields. The origin of this sensitivity is that the spin precession, caused by magnetic field, takes place outside the grains where SO is absent.

**12:27PM F5.00005 Spin relaxation via exchange with donor impurity-bound electrons<sup>1</sup>**, IAN APPELBAUM, Univ of Maryland-College Park — In the Bir-Aronov-Pikus depolarization process affecting conduction electrons in p-type cubic semiconductors, spin relaxation is driven by exchange with short-lived valence band hole states. We have identified an analogous spin relaxation mechanism in nominally undoped silicon at low temperatures, when many electrons are bound to dilute dopant ion potentials. Inelastic scattering with externally injected conduction electrons accelerated by electric fields can excite transitions into highly spin-orbit-mixed bound excited states, driving strong spin relaxation of the conduction electrons via exchange interaction. We reveal the consequences of this spin depolarization mechanism both below and above the impact ionization threshold, where conventional charge and spin transport are restored.

**1:03PM F5.00006 Electrical spin injection and detection in Si nanowires with axial doping gradient**, KONSTANTINOS KOUNTOURIOTIS, JORGE BARREDA, TIM KEIPER, MEI ZHANG, PENG XIONG, Florida State Univ — Due to the technological importance and potential long spin coherence time in silicon, there have been significant recent efforts to realize spin injection, coherent transport, and electrical spin detection in Si nanowires (NWs). The nature of the electronic transport at the interface and its resistance are crucial factors in realizing efficient spin injection/detection between a ferromagnet (FM) and a semiconductor (SC). In this work, we examine the effects on electrical spin injection and detection by FM/SC interfaces with well-defined Schottky barriers in Si NW devices. The Si NWs are synthesized via a vapor-liquid-solid method using silane and phosphine precursor gases for the growth and doping respectively, which results in a graded phosphorus doping profile along the length of the NW. The Si NWs are dispersed on a  $p^+-Si/SiO_2/SiN_x$  substrate, and a series of CoFe electrodes are defined along a Si NW with electron beam lithography and magnetron sputtering after the removal of the native oxide by HF treatment. As a consequence of the doping gradient, the FM electrodes form Ohmic and Schottky barrier contacts of varying heights along the length of a single NW. Two-terminal local and four-terminal non-local spin-valve measurements are performed to probe spin accumulation and transport at different FM contacts, enabling a study of the dependence of the spin signals on the Schottky barrier height and interface resistance on a single device. \*Work supported by NSF grant DMR-1308613.

**1:15PM F5.00007 Room-temperature operation of Si spin MOSFET with high on/off spin signal ratio**, MASASHI SHIRAISHI, Department of Electronic Science and Engineering, Kyoto University, HAYATO KOIKE, Technology HQ, TDK Corporation, TAKAYUKI TAHARA, Department of Electronic Science and Engineering, Kyoto University, TOMOYUKI SASAKI, MAKOTO KAMENO, Technology HQ, TDK Corporation, YUICHIRO ANDO, Department of Electronic Science and Engineering, Kyoto University, KAZUHIRO TANAKA, SHINJI MIWA, YOSHISHIGE SUZUKI, Graduate School of Engineering Science, Osaka University — Si spintronics is now one of the pivotal fields in semiconductor spintronics. After the first report on successful propagation of pure spin current in Si, much effort has been paid for realization of Si spin metal-oxide-semiconductor field-effect transistor (MOSFET), since Si spin MOSFETs allow constructing reconfigurable logic circuits with ultra-low energy consumption. Our group achieved the first operation of Si spin MOSFET at room temperature by using non-degenerate n-type Si [1]. However, the remaining issue to be solved was low on/off ratio of spin signals. In this presentation, we report on our experimental demonstration of Si spin MOSFET with high on/off ratio of spin signals. The on/off ratio is greater than  $10^3$ , whereas on/off ratio in a conventional MOSFET operation is ca.  $10^5$ . More importantly, the gate voltage dependence of the spin signals and the MOSFET signals are in good agreement [2]. This achievement can pave the way to a practical application of Si spin MOSFETs. References: [1] T. Sasaki, M. Shiraishi et al., Phys. Rev. Applied 2, 034005 (2014). [2] T. Tahara, M. Shiraishi et al., Appl. Phys. Express, in press (selected as Spotlight Paper).

**1:27PM F5.00008 Electronic measurement of strain effects on spin transport in silicon<sup>1</sup>**, LAN QING, HOLLY TINKEY, IAN APPELBAUM, Center for Nanophysics and Advanced Materials and Department of Physics, University of Maryland, College Park, Maryland 20742 — Spin transport in silicon is limited by the Elliott-Yafet spin relaxation mechanism, which is driven by scattering between degenerate conduction band valleys. Mechanical strain along a valley axis partially breaks this degeneracy, and will ultimately quench intervalley spin relaxation for transitions between states on orthogonal axes. Using a custom-designed and constructed strain probe, we study the effects of uniaxial compressive strain along the  $\langle 100 \rangle$  direction on ballistic tunnel junction devices used to inject spin-polarized electrons into silicon. The effects of strain-induced valley splitting will be presented and compared to our theoretical model.

<sup>1</sup>This work is supported by the Office of Naval Research under Contract No. N000141410317, the National Science Foundation under Contract No. ECCS-1231855, the Defense Threat Reduction Agency under Contract No. HDTRA1-13-1-0013, and the Maryland NanoCenter.

**1:39PM F5.00009 Three-terminal experiments on epitaxial Si/MgO tunnel junctions**, JULIANE LAURER, MAREEN SCHAEFER, MATTHIAS KRONSEDER, MICHAELA TROTTMANN, MARKUS HAERTINGER, JOSEF ZWECK, CHRISTIAN H. BACK, DIETER WEISS, MARIUSZ CIORGA, DOMINIQUE BOUGEARD, Institut fuer Experimentelle und Angewandte Physik, Universitaet Regensburg, Germany — In the field of spin injection into semiconductors, experiments in a three-terminal (3T) Hanle geometry are widely used to determine spin life times and spin diffusion lengths. However, as charge and spin current are not separated in the 3T geometry, it is yet unclear how reliable 3T experiments are to reveal spin-related quantities of the semiconductor channel. In particular, the impact of defect states in the tunnel barrier or at its interfaces on measured 3T Hanle-like signals has intensely been discussed recently. In our contribution, we compare 3T experiments on entirely MBE-grown epitaxial Si/MgO/Fe/Au and Si/MgO/Au, i.e. ferromagnetic and nonmagnetic tunnel junctions. Both sample types show a similar Lorentzian signal comparable to those obtained by the Hanle effect of a precessing and dephasing spin ensemble. In contrast to the ferromagnetic sample, the resistance of the nonmagnetic sample increases for increasing external magnetic field. We discuss the dependence of the signal on bias, temperature and orientation of the external magnetic field, taking into account the high crystalline quality of our epitaxial tunnel junctions with atomically sharp interfaces.

**1:51PM F5.00010 Spin Transport and Precession in Epitaxial BaTiO<sub>3</sub>/Ge Heterostructures**, YICHEN JIA, CRISTINA VISANI, LIOR KORNBLUM, ERIC JIN, CHARLES AHN, FRED WALKER, Yale University — Spintronics has opened up new possibilities to leverage the spin degree of freedom in electronic devices. Spin injection from ferromagnets into semiconductors has been realized by inserting a thin tunnel barrier layer, which adjusts the conductivity mismatch. However, limited functionality in conventional tunnel barriers hinders the control and manipulation of spin. Here we report the spin injection and detection in p-type Germanium (p-Ge) through a functional BaTiO<sub>3</sub> (BTO) tunnel barrier. Epitaxial BTO thin films are grown on p-Ge by molecular beam epitaxy (MBE), followed by electron beam pattern generation (EBPG) to fabricate multi-terminal spin devices. Spin accumulation is demonstrated using the Hanle technique, where the spin signal shows a non-monotonic temperature dependence. Using this temperature dependence, we investigate the dominant spin damping pathways in each temperature regime. Furthermore, we discuss the possibility of manipulating spin transport using the BTO layer, which would allow one to integrate the unique functionalities of complex oxides with semiconductor spintronics devices.

**Tuesday, March 15, 2016 11:15AM - 2:03PM –**  
**Session F6 GMAG DMP: Iridates II** 302 - Ilija Zeljkovic, Boston College

**11:15AM F6.00001 The role of correlations in the low energy electronic structure of lightly electron doped Sr<sub>2</sub>IrO<sub>4</sub> and Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub>.**, ALBERTO DE LA TORRE, FLAVIO BRUNO, ZHIMING WANG, ANNA TAMAI, CHRISTOPHE BERTHOD, DIDIER JACCARD, University of Geneva, ALASKA SUBEDI, Max Planck - Hamburg, ANTOINE GEORGES, Ecole Polytechnique, CNRS, ROBIN PERRY, University College London, FELIX BAUMBERGER, University of Geneva — We characterized the emergence of exotic electronic ground states in lightly electron doped (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>2</sub>IrO<sub>4</sub> and (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> by ARPES. In the single layer iridate, a large Fermi surface with nodal coherent spectral weight and antinodal pseudogap emerges, concomitantly with the collapse of the Mott gap, upon doping [1]. On the other hand, in Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> a small non-gapped Fermi surface with coherent quasiparticles, together with a reduction of the correlated gap throughout the entire Brillouin Zone is observed when doping above the insulator to metal transition [2]. By comparing the electronic structure of these two materials, we provide evidence that the interplay between spin-orbit and electron-electron correlations ( $U$ ) in (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>2</sub>IrO<sub>4</sub> and (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> is rather different: while in Sr<sub>2</sub>IrO<sub>4</sub> this interplay results in a pseudospin-1/2 single band Mott insulator with a phenomenology very similar to that of cuprates, in Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub>  $U$  enhances the bilayer splitting gap to originate a ground state resembling that of a correlated semiconductor. [1] A. de la Torre et al, PRL 115, 176402 (2015); [2] A. de la Torre et al, PRL 113, 256402 (2014)

**11:27AM F6.00002 Electrically tunable transport in antiferromagnetic Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub><sup>1</sup>**, HEIDI SEINIGE, CHENG WANG, The University of Texas at Austin, GANG CAO, University of Kentucky, JIANSHI-S. ZHOU, JOHN B. GOODENOUGH, MAXIM TSOI, The University of Texas at Austin — Recently we demonstrated experimentally the existence of interconnections between magnetic state and transport currents in antiferromagnetic (AFM) Mott insulator Sr<sub>2</sub>IrO<sub>4</sub>. We found a very large anisotropic magnetoresistance [1] and demonstrated a reversible resistive switching driven by high-density currents/high electric fields [2]. These results support the feasibility of AFM spintronics, where antiferromagnets are used in place of ferromagnets, however a low Néel temperature of this material (240 K) questions any practical applications. Here we present a comparative electrical transport study of its sister compound Sr<sub>2</sub>IrO<sub>4</sub> which has a higher transition temperature (285 K). Similar to the case of Sr<sub>2</sub>IrO<sub>4</sub>, we find a continuous reduction in the resistivity of Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> as a function of increasing electrical bias and abrupt reversible changes above a threshold bias current. We explain these results by a reduction of activation energy associated with a field-driven lattice distortion. [1] C. Wang et al., Phys. Rev. X 4, 041034 (2014); [2] C. Wang et al, PRB 92, 115136 (2015).

<sup>1</sup>This work was supported in part by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA, and by NSF grants DMR-1207577, DMR-1265162, and DMR-1122603.

**11:39AM F6.00003 Magnetic excitations and lattice distortions in highly-doped (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub>**, TOM HOGAN, University of California Santa Barbara, MARY UPTON, Argonne National Laboratory, XIAOPING WANG, Oak Ridge National Laboratory, STEPHEN WILSON, University of California Santa Barbara — (Sr<sub>1-x</sub>La<sub>x</sub>)<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> has been shown to undergo a first-order phase transition from a localized antiferromagnetic insulating state to a correlated metal. We discuss the further characterization of these correlations by examining the excitation spectra of a highly-doped sample. These reveal evidence of a dispersive feature associated with an over-damped magnon mode, similar to the behavior of the undoped parent compound, as well as a higher energy excitation. The nature of the lattice distortion brought on by La-doping will also be discussed.

**11:51AM F6.00004 Nature of the magnetic correlations in photo-doped and chemically-doped spin-orbit Mott insulator Sr<sub>2</sub>IrO<sub>4</sub><sup>1</sup>**, MARK P. M. DEAN, Brookhaven National Laboratory — In the iridates, competition between spin-orbit coupling, crystal field, and electronic correlation has lead to the observation of several novel states. Particularly notable is the spin-orbit Mott insulating state in Sr<sub>2</sub>IrO<sub>4</sub> which has close analogies to the high temperature superconducting cuprates. This talk will describe the nature of the magnetic correlations in Sr<sub>2</sub>IrO<sub>4</sub> and how the magnetic correlations can be modified by two different doping schemes. I will first describe doping via photo-excitation in which we use femtosecond infrared pulses to excite carriers across the Mott gap. After excitation, we probe the resulting magnetic state as a function of time delay using the first implementation of magnetic resonant inelastic X-ray scattering at a free electron laser. We find that the non-equilibrium state 2 ps after the excitation has strongly suppressed long-range magnetic order, but hosts photo-carriers that induce strong, non-thermal magnetic correlations. The magnetism recovers its two-dimensional in-plane Néel correlations on a timescale of a few ps, while the three-dimensional long range magnetic order is restored over a far longer, fluence-dependent timescale of a few 100 ps. In the second part of the talk I will describe chemical doping via Ir-Ru substitution. In this situation, we find that with increased Ru concentration, the dispersive magnetic excitations in the parent compound become almost momentum-independent, opening a magnetic gap > 150 meV. We attribute this gap to the combined effects of disorder and Ir-Ru interactions.

**12:27PM F6.00005 Jahn-Teller effect in systems with strong on-site spin-orbit coupling**, EKATERINA PLOTNIKOVA, Leibniz Institute for Solid State and Materials Research Dresden, Germany, MARIA DAGHOFER, University of Stuttgart, Germany, JEROEN VAN DEN BRINK, Leibniz Institute for Solid State and Materials Research Dresden, Germany, KRZYSZTOF WOHLFELD, Stanford University and SLAC National Accelerator Laboratory, USA and University of Warsaw, Poland — When strong spin-orbit coupling removes orbital degeneracy, it would at the same time appear to render the Jahn-Teller mechanism ineffective. We discuss such a situation, the  $t_{2g}$  manifold of iridates, and show that, while the Jahn-Teller effect does indeed not affect the  $j = 1/2$  antiferromagnetically ordered ground state, it leads to distinctive signatures in the  $j = 3/2$  spin-orbit exciton. It allows for a hopping of the spin-orbit exciton between the nearest neighbor sites without producing defects in the  $j = 1/2$  antiferromagnet. This arises because the lattice-driven Jahn-Teller mechanism only couples to the orbital degree of freedom, but is not sensitive to the phase of the wave function that defines isospin  $j_z$ . This contrasts sharply with purely electronic propagation, which conserves isospin, and presence of Jahn-Teller coupling can explain some of the peculiar features of measured resonant inelastic x-ray scattering spectra of Sr<sub>2</sub>IrO<sub>4</sub>.

**12:39PM F6.00006 Unveiling the Origin of the Basal-plane Antiferromagnetism in the  $J_{\text{eff}}=1/2$  Mott Insulator  $\text{Ba}_2\text{IrO}_4$ : A Density Functional and Model Hamiltonian Study**, YUSHENG HOU, HONGJUN XIANG, XINGAO GONG, Fudan University, KEY LABORATORY OF COMPUTATIONAL PHYSICAL SCIENCES (MINISTRY OF EDUCATION) COLLABORATION — Based on the density functional theory and our new model Hamiltonian, we have studied the basal-plane antiferromagnetism in the novel  $J_{\text{eff}}=1/2$  Mott insulator  $\text{Ba}_2\text{IrO}_4$ . By comparing the magnetic properties of the bulk  $\text{Ba}_2\text{IrO}_4$  with those of the single-layer  $\text{Ba}_2\text{IrO}_4$ , we demonstrate unambiguously that the basal-plane antiferromagnetism is caused by the intralayer magnetic interactions rather than by the previously proposed interlayer ones. In order to reveal the origin of the basal-plane antiferromagnetism, we propose a new model Hamiltonian by adding the single ion anisotropy and pseudo-quadrupole interactions into the general bilinear pseudo-spin Hamiltonian. The obtained magnetic interaction parameters indicate that the single ion anisotropy and pseudo-quadrupole interactions are unexpectedly strong. Systematical Monte Carlo simulations demonstrate that the basal-plane antiferromagnetism is caused by the isotropic Heisenberg, bond-dependent Kitaev and pseudo-quadrupole interactions. Our results show for the first time that the single ion anisotropy and pseudo-quadrupole interaction can play significant roles in establishing the exotic magnetism in the  $J_{\text{eff}}=1/2$  Mott insulator.

**12:51PM F6.00007 Frustration in square lattice of Iridium  $J_{\text{eff}}=1/2$  moments at high pressure<sup>1</sup>**, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, GILBERTO FABBRI, Brookhaven National Laboratory, JONG WOO KIM, JUNG HO KIM, Advanced Photon Source, Argonne National Laboratory, BUMJOON KIM, Max Planck Institute for Solid State Research, GANG CAO, University of Kentucky, VIKTOR STRUZHNIKIN, Geophysical Laboratory, Carnegie Institution of Washington — We study the evolution of magnetic order in the weakly ferromagnetic, insulator  $\text{Sr}_2\text{IrO}_4$  under applied pressure using x-ray resonant magnetic scattering and x-ray magnetic circular dichroism techniques in the diamond anvil cell. The weak inter-layer coupling is readily tunable with pressure giving rise to a change in magnetic structure followed by coexisting and competing magnetic phases with different inter-layer coupling. Application of moderate magnetic fields stabilizes one of the magnetic phases. Higher pressures drive the system into a magnetically disordered state, possibly a quantum paramagnetic state. We discuss the results in the context of a J1-J2 model where the increasing strength of next-nearest-neighbor exchange coupling with pressure leads to frustration of in-plane interactions

**1:03PM F6.00008 Effect of longer-range lattice anisotropy on the electronic structure and magnetism of spin-orbit-coupled  $5d$  transition-metal oxides**, NIKOLAY BOGDANOV<sup>1</sup>, VAMSHI KATUKURI<sup>2</sup>, JUDIT ROMHÁNYI<sup>3</sup>, Institute for Theoretical Solid State Physics, IFW Dresden, Germany, VIKTOR YUSHANKHAI, Joint Institute for Nuclear Research, Dubna, Russia, VLADISLAV KATAEV, BERNDT BÜCHNER, Institute for Solid State Research, IFW Dresden, Germany, JEROEN VAN DEN BRINK, LIVIU HOZOI, Institute for Theoretical Solid State Physics, IFW Dresden, Germany — Our detailed quantum chemistry calculations provide magnetic  $g$  factors and exchange interactions for the quasi two-dimensional iridates  $\text{Sr}_2\text{IrO}_4$  and  $\text{Ba}_2\text{IrO}_4$ . While canonical ligand-field considerations predict  $g_{||}$ -factors  $< 2$  for the positive tetragonal distortions present in  $\text{Sr}_2\text{IrO}_4$ , we find  $g_{||} > 2$ . This implies that the  $d$  levels in  $\text{Sr}_2\text{IrO}_4$  are inverted with respect to the ordering deduced from the local ligand distortions, whereas we find them in  $\text{Ba}_2\text{IrO}_4$  to be instead normally ordered. Electron spin resonance measurements confirm the level inversion in  $\text{Sr}_2\text{IrO}_4$ . This  $d$ -level switching is driven by the specific ionic charge distribution within adjacent  $\text{IrO}_2$  and  $\text{SrO}$  layers. Since polar discontinuities and the associated complications do not arise for such layers, our results highlight the tetravalent  $d$ -metal 214 oxides as ideal platforms to explore  $d$ -level reconstruction and engineering in the context of oxide heterostructures.

**1:15PM F6.00009 Influence of isovalent doping of  $\text{Ca}^{2+}$  on the Spin orbit Mott insulator  $\text{Sr}_2\text{IrO}_4$** , XIANG CHEN, Boston Coll, STEPHEN WILSON, UCSB, WILSON GROUP TEAM — Here we investigate the influence of isoelectronic doping into the spin-orbit Mott materials  $\text{Sr}_2\text{IrO}_4$ . Specifically, we explore the influence of isovalent Ca substitution as a perturbation to the  $J_{\text{eff}}=1/2$  Mott ground state by combined transport, bulk magnetization, and scattering measurements. The evolution of the lattice geometry/structure-type as well as the electronic phase behavior will be presented as  $\text{Ca}^{2+}$  is substituted on the  $\text{Sr}^{2+}$  site.

**1:27PM F6.00010 Crystal growth and intrinsic magnetic behavior of  $\text{Sr}_2\text{IrO}_4$** , NAKHEON SUNG, H. GRETTARSSON, D. PROEPPER, J. PORRAS, M. LE TACON, A. V. BORIS, B. KEIMER, B. J. KIM, Max Planck Institute for Solid State Research — We report on the growth of stoichiometric  $\text{Sr}_2\text{IrO}_4$  single crystals, which allow us to unveil their intrinsic magnetic properties. The effect of different growth conditions has been investigated for crystals grown by the flux method. We find that the magnetic response depends very sensitively on the details of the growth conditions. We assess the defect concentration based on magnetization, X-ray diffraction, Raman scattering, and optical conductivity measurements. We find that samples with a low concentration of electronically active defects show much reduced in-gap spectral weight in the optical conductivity and a pronounced two-magnon peak in the Raman scattering spectrum. A prolonged exposure at high temperature during the growth leads to higher defect concentration likely due to creation of oxygen vacancies. We further demonstrate a systematic intergrowth of  $\text{Sr}_2\text{IrO}_4$  and  $\text{Sr}_3\text{Ir}_2\text{O}_7$  phases by varying the growth temperature. Our results thus emphasize that revealing the intrinsic magnetic properties of  $\text{Sr}_2\text{IrO}_4$  and related materials requires a scrupulous control of the crystal growth process.

**1:39PM F6.00011 Magnetic Properties comparison of 3D Kitaev candidate materials beta and gamma  $\text{Li}_2\text{IrO}_3$** , RAMON RUIZ, Univ of California - Berkeley, NICHOLAS BREZNAY COLLABORATION, ALEX FRANO COLLABORATION, TONI HELM COLLABORATION, JAMES ANALYTIS COLLABORATION — Honeycomb iridates have been the focus of substantial interest due to the strong magnetic frustration that arises from their edge-shared bonding environment, which favors a strongly anisotropic Ising-like exchange between bonds. In materials with edge-shared  $\text{IrO}_6$  octahedra, spin-anisotropy of the exchange between neighboring effective spin-1/2 states is enhanced by the interference of the two exchange paths across the planar Ir-O-Ir bond. In the honeycomb lattice, such an interaction couples different orthogonal spin components for the three nearest neighbors; no single exchange direction can be simultaneously satisfied, leading to strong frustration which can be described by the Kitaev-model. We have recently synthesized two new structures that retain the same bonding environment as the honeycomb lattice, and extend this physics to three-dimensions. In this work, we compare the magnetic properties of these two novel structures, presenting evidences that their high temperature behavior can be explained by geometric  $g$ -factor constraints while the low temperature anisotropy and degeneracy of the ground state suggest the presence of spin anisotropic exchange.

**1:51PM F6.00012 The Mott Insulating Nature of  $\text{Na}_2\text{IrO}_3$  : DFT+DMFT Study** , MINJAE KIM, CPHT, Ecole Polytechnique & College de France, BEOM HYUN KIM, RIKEN, Saitama, B. I. MIN, Pohang University of Science and Technology — We have investigated the insulating nature of  $\text{Na}_2\text{IrO}_3$ , employing both the density-functional theory (DFT) and the combination of the DFT and the dynamical mean-field theory (DFT+DMFT). We have obtained the paramagnetic (PM) insulating state even above the Neel temperature ( $T_N$ ), which reveals that  $\text{Na}_2\text{IrO}_3$  is a Mott-type insulator. The photoemission spectrum is well described by the density of states from the DFT+DMFT in this PM insulating state. However, the analysis of optical conductivity suggests that the non-local correlation effect is also important in  $\text{Na}_2\text{IrO}_3$ . We have also found sizable redistribution of both charge and spin densities upon cooling below  $T_N$  which suggests that  $\text{Na}_2\text{IrO}_3$  is not a standard Mott insulator having rigid charge density. Therefore, despite the Mott-type insulating state of  $\text{Na}_2\text{IrO}_3$ , the itineracy and the non-local correlation are important as well in describing its electronic and magnetic properties due to the extended nature of Ir 5d state.

**11:15AM F7.00001 Making Physics Fun: The 2015 Science Outreach Catalyst Kit** , SHAUNA LEFEBVRE, Union College, HANNAH PELL, Lebanon Valley College — The Society of Physics Students is dedicated to performing outreach events to get the general public excited about physics. The SPS National Office established the Science Outreach Catalyst Kit program in 2001 to aid SPS chapters at colleges all around the world in their efforts to bring physics education to students of all ages. Each year SPS produces twenty-five SOCKs in conjunction with the National Institute of Standards and Technology to give to SPS chapters on a first come, first serve basis. I spent my time at the SPS offices this summer helping to develop the 2015 SOCK. We designed activities that help students from elementary to high school explore basic acoustics with everyday materials like cups, straws, string, balloons, and rubber bands. In this presentation I will discuss why we chose to include the activities we did and the process of making this years SOCK a reality.

**11:27AM F7.00002 Optimization of the Diode-Pumped Solid State Nd:YLF Amplifier Chain for the 263 nm Drive Laser at the FAST Facility<sup>1</sup>** , JULIE M. GILLIS, THEODORE A. CORCOVILOS, Dept. of Physics, Duquesne University, Pittsburgh, PA, DEAN R. EDSTROM JR., JINHAO RUAN, JAMES K. SANTUCCI, Accelerator Division, Fermi National Accelerator Laboratory, Batavia, IL — The RF photoinjector of the 50 MeV superconducting electron linear accelerator at the Fermilab Accelerator Science and Technology (FAST) Facility is driven by a phase-locked laser system. The neodymium-doped yttrium-lithium fluoride (Nd:YLF) seed laser provides short (3 ps) infrared (1053 nm) pulses to an amplifier chain before conversion to ultraviolet (263 nm) through two frequency-doubling BBO crystals. The amplification section consists of seven diode-pumped solid state (DPSS) amplifiers, which increase the pulse energy of the seed laser using optically end-pumped Nd:YLF crystals. To maximize the total gain of the amplifier chain, each stage must be properly tuned with optimized optics, alignment, and laser beam characterization. In this paper we report on one of the single-pass amplifier improvements to achieve a consistent gain of 4.83 with stabilized output pulse trains for up to 1500 seed pulses. The final ultraviolet pulses imaged onto the  $\text{Cs}_2\text{Te}$  photocathode of the RF electron gun have been doubled in energy to 10.2  $\mu\text{J}$  per pulse as a result of these alterations.

**11:39AM F7.00003 Alpha Background Rejection in Bolometer Detectors** , NICHOLAS DEPORZIO, Northeastern Univ, CUORE COLLABORATION — This study presents the modification of bolometer detectors used in particle searches to veto or otherwise reject alpha radiation background and the statistical advantages of doing so. Several techniques are presented in detail – plastic film scintillator vetoes, metallic film ionization vetoes, and Cherenkov radiation vetoes. Plastic scintillator films are cooled to bolometer temperatures and bombarded with 1.4MeV to 6.0MeV alpha particles representative of documented detector background. Quantum dot based liquid scintillator is similarly bombarded to produce a background induced scintillation light. Photomultipliers detect this scintillation light and produce a veto signal. Layered metallic films of a primary metal, dielectric, and secondary metal, such as gold-polyethylene-gold films, are cooled to milli-kelvin temperatures and biased to produce a current signal veto when incident 1.4MeV to 6.0MeV alpha particles ionize conduction paths through the film. Calibration of veto signal to background energy is presented. These findings are extrapolated to quantify the statistical impact of such modifications to bolometer searches. Effects of these techniques on experiment duration and signal-background ratio are discussed.

**11:51AM F7.00004 All-Optical Helicity Dependent Spin Switching in a Many-Spin System<sup>1</sup>** , TANNER LATTA, G. P. ZHANG, Indiana State University — All-optical helicity dependent magnetic switching (AOS) is achieved through using an ultrafast laser pulse to manipulate and switch the spin of an electron from one direction to another. This process happens in a short amount of femtoseconds after the laser pulse is introduced. All-optical helicity dependent magnetic switching (AOS) does not fall to the assistance of any external magnetic field. Linearly polarized light, as well as right and left circularly polarized light are used to manipulate the spin of the electrons. Ferrimagnetic, rather than ferromagnetic, materials are more suitable to create conditions in which AOS are viable due to the orientation of the spins within this material. In the following study we show and conclude that AOS is possible with the use of left and right circularly polarized laser pulses. All-optical helicity dependent magnetic switching has many applications in magnetic recording technology or magnetic memory devices.

<sup>1</sup>DE-FG02-06ER46304

**12:03PM F7.00005 Rapid Adiabatic Passage in a Rb gas with intense Frequency Chirped Laser Light** , BRIAN KAUFMAN, TANNER GROGAN, TRACY PALTOO, MATTHEW WRIGHT, Adelphi Univ — We will discuss our progress toward using intense frequency chirped laser light to control the excitation of atoms in a room-temperature gas cell. We illuminate  $^{87}\text{Rb}$  atoms with a 1 GHz in 8 ns frequency chirped pulse of laser light covering the  $5S_{1/2} F=1 \rightarrow 5P_{3/2}$  and explore the saturation behavior as intensity increases. We estimate that we are exciting over 90% of the atoms over 1 mm<sup>2</sup>.

**12:15PM F7.00006 Magnetic Second Harmonic Generation Imaging** , CARINA BELVIN, Department of Physics, Wellesley College, CHANGMIN LEE, Department of Physics, MIT, FERHAT KATMIS, Francis Bitter Magnet Lab and Department of Physics, MIT, PABLO JARILLO-HERRERO, Department of Physics, MIT, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab and Department of Physics, MIT, NUH GEDIK, Department of Physics, MIT — Second harmonic generation is an effective probe of lattice, electronic, and magnetic symmetries of crystals where inversion symmetry is broken. In particular, magnetic second harmonic generation (MSHG) can be used to measure the magnetism induced at surfaces and interfaces of centrosymmetric materials. Imaging this MSHG signal can provide spatial information about the magnetic domains and domain boundaries that form at these interfaces. We have constructed an MSHG imaging setup using a femtosecond Ti:sapphire laser system and a highly sensitive CCD camera. Our setup can potentially be used to investigate magnetic domains and domain wall boundaries in magnetic topological insulator systems, such as  $\text{EuS}/\text{Bi}_2\text{Se}_3$  heterostructures.

**12:27PM F7.00007 High Q-factor Surface Plasmon-Polariton Resonance in a Plasmonic Perfect Absorber in the Terahertz Regime**, J ROBINSON, K BHATTARAI, S SILVA, J ZHOU, Univ of South Florida — Perfect absorption of light has become one of the exotic properties of plasmonic metamaterials which are popular due to the variety of feasible applications, particularly using them as a chemical/bio sensor. We present the plasmonic perfect absorber that exhibits strong surface plasmon-polariton (SPP) resonance. Due to the Fabry-Perot cavity effect, the SPP resonance is significantly sharpened and the Q-factor reaches 63.1. Correspondingly, the electric field of the surface wave is largely enhanced. Furthermore, we have shown numerically that the absorption peak is independent of the incident angle. The high Q-factor and enhanced surface wave are beneficial to increase the performances of the sensor and detector devices, especially in the THz regime, where such properties are hard to achieve by natural materials.

**12:39PM F7.00008 Figures and First Years: Examining first-year Calculus I student ability to incorporate figures into technical reports**, NATHAN ANTONACCI, MICHAEL ROGERS, THOMAS PFAFF, Ithaca Coll — This three-year study focused on first-year Calculus I students and their abilities to incorporate figures into technical reports. Students were handed guidelines as part of their Multidisciplinary Sustainability Education Module meant to aid them in crafting effective figures. Figure-specific questionnaires were added in the class to gain insight into the quantitative literacy skills students possessed both before starting their course and after its completion. Reviews of the figures in 78 technical reports written by 106 students showed repeated failure to refer to figures in discussion sections and use them in evidence-based arguments. Analysis of quantitative literacy skills revealed that the students could both read and interpret figures, suggesting that issues with literacy were not the main contributor to the sub-par graphs.

**12:51PM F7.00009 Simulating Entanglement Dynamics of Singlet-Triplet Qubits Coupled to a Classical Transmission Line Resonator**, MICHAEL WOLFE, JASON KESTNER, Department of Physics, UMBC — Electrons confined in lateral quantum dots are promising candidates for scalable quantum bits. Particularly, singlet-triplet qubits can entangle electrostatically and offer long coherence times due to their weak interactions with the environment. However, fast two-qubit operations are challenging. We examine the dynamics of singlet triplet qubits capacitively coupled to a classical transmission line resonator driven near resonance. We numerically simulate the dynamics of the von Neumann entanglement entropy and investigate parameters of the coupling element that optimizes the operation time for the qubit.

**1:03PM F7.00010 Simulation of weak anchoring effects on nematic liquid crystal hemispheres**, SEAN GILLEN<sup>1</sup>, DAVID A.T. SOMERS<sup>2</sup>, JEREMY N. MUNDAY<sup>3</sup>, University of Maryland, College Park — The free energy of a nematic liquid crystal droplet depends on an interplay between elastic and surface interactions. When the two contributions are of similar magnitude, there exists a transition of the nematic structure of the droplet. Because the two contributions scale differently with length scales, this transition is visible as a function of the size of the droplet. We carry out numerical simulations to explore the use of this transition in measuring surface anchoring energies. This technique could help elucidate alignment forces on liquid crystals, such as those caused by rubbed surfaces, electric fields, or even the Casimir torque.

## **Tuesday, March 15, 2016 11:15AM - 2:15PM – Session F8 DCMP DMP: Superconductivity: Novel Superconductors 304 -**

**11:15AM F8.00001 Molecular orbital polarization in Na<sub>2</sub>Ti<sub>2</sub>Sb<sub>2</sub>O: a scenario to metal-to-metal phase transition without spontaneous symmetry breaking**, HEUNG-SIK KIM, HAE-YOUNG KEE, Univ of Toronto — We suggest a scenario of partial Fermi surface (FS) gapping related to metal-to-metal phase transition without a spontaneous symmetry breaking. This theory is applied to Na<sub>2</sub>Ti<sub>2</sub>Sb<sub>2</sub>O, where the density polarization of spin-orbital entangled molecular orbitals occurs due to spin-orbit coupling. This is further enhanced by electronic correlations of Ti d-orbitals. Sharp increase of the polarization happens above a critical electronic interaction strength which then gaps out a part of FS made of d-orbitals, while the rest of FS associated with Sb p-orbitals remain almost intact. Experimental implications to test our proposal are also discussed.

**11:27AM F8.00002 Pressure dependence of the magnetic ground states in MnP<sup>1</sup>**, SACHITH DISANAYAKE, MASAAKI MATSUDA, QCMD, Oak Ridge National Laboratory, J.-G. CHENG, Chinese Academy of Sciences, China, F. YE, S. CHI, QCMD, Oak Ridge National Laboratory, J. MA, H. D. ZHOU, University of Tennessee, J.-Q. YAN, MSTD, Oak Ridge National Laboratory, S. KASAMATSU, O. SUGINO, T. KATO, K. MATSUBAYASHI, T. OKADA, Y. UWATOKO, ISSP, University of Tokyo — The newly discovered superconductor MnP shows a ferromagnetic order below  $T_C \approx 290$  K followed by a helical order below  $T_s \approx 50$  K in ambient pressure. An antiferromagnetic order is suggested in the vicinity of the pressure induced superconducting phase. We have performed single crystal neutron diffraction experiments to determine the magnetic structure under pressure. Both  $T_C$  and  $T_s$  are gradually suppressed with increasing pressure and the helical order disappears at 1.2 GPa. At intermediate pressures of 1.8 and 2.0 GPa, the ferromagnetic order first develops and is gradually suppressed below a characteristic temperature. At 4 GPa no magnetic signal was observed down to 3.5 K. Our results suggested that the new magnetic phase in the vicinity of the superconducting phase is in a short-ranged magnetic state due to frustration or in an itinerant magnetic state, where the itinerant small Mn moments are weakly interacting.

<sup>1</sup>This research at ORNLs HFIR and SNS was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

**11:39AM F8.00003 Chemical pressure effect on dynamic spin properties in CrAs<sup>1</sup>**, M. MATSUDA, M. B. STONE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, J.-G. CHENG, W. WU, F. LIN, J. L. LUO, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, J.-Q. YAN, Material Science and Technology Division, Oak Ridge National Laboratory and University of Tennessee, Knoxville, K. MATSUBAYASHI, Y. UWATOKO, Institute for Solid State Physics, University of Tokyo — CrAs is an antiferromagnetic metal, which shows a helical spin structure accompanied by an abrupt lattice expansion at  $T_N \sim 260$  K in ambient pressure. With applying pressure, the magnetic transition is suppressed and superconductivity appears with a maximum transition temperature of  $\sim 2$  K. Since Cr has the spin degree of freedom, elucidating the magnetic contribution to the superconductivity is crucial to understand the pairing mechanism. However, inelastic neutron scattering (INS) measurement under high pressure is challenging due to sample space limitation. Therefore, we studied chemical pressure effect by substituting As by P, which is found to be almost the same as the external pressure. We performed INS experiments in undoped and P-doped CrAs using powder samples. The results in the P-doped CrAs clearly indicate that the antiferromagnetic fluctuations still remain above the critical P content, where the long range magnetic order is suppressed, suggesting a coupling between the magnetism and the superconductivity.

**11:51AM F8.00004 Reversal of the Upper Critical Field Anisotropy and Spin-Locked Superconductivity in K<sub>2</sub>Cr<sub>3</sub>As<sub>3</sub>**, FEDOR F. BALAKIREV, Los Alamos National Laboratory, TAI KONG, Ames Laboratory, Iowa State University, MARCELO JAIME, ROSS D. MCDONALD, CHARLES H. MIELKE, Los Alamos National Laboratory, ALEXANDER GUREVICH, Old Dominion University, PAUL C. CANFIELD, SERGEY L. BUD'KO, Ames Laboratory, Iowa State University — We report the first measurements of the anisotropic upper critical field  $H_{c2}(T)$  for K<sub>2</sub>Cr<sub>3</sub>As<sub>3</sub> single crystals up to 60 T and  $T > 0.6$  K.  $H_{c2}(T)$  was determined via resistivity and proximity detector oscillator techniques. Our results show that the upper critical field parallel to the Cr chains,  $H_{c2\parallel}$ , exhibits a paramagnetically-limited behavior, whereas no evidence of paramagnetic pair breaking was observed with field perpendicular to the Cr chains. As a result, the curves  $H_{c2\perp}(T)$  and  $H_{c2\parallel}(T)$  cross at  $T \sim 4$  K, so that the anisotropy parameter  $\gamma(T) = H_{c2\perp} / H_{c2\parallel}$  increases from  $\gamma \sim 0.35$  near  $T_c$  to  $\gamma \sim 1.7$  at 0.6 K. This behavior of  $H_{c2}(T)$  is inconsistent with triplet superconductivity but suggests a form of singlet superconductivity with the electron spins locked onto the direction of Cr chains.

**12:03PM F8.00005 Material Specific Rational Design of A<sub>1</sub>B<sub>2</sub>C<sub>3</sub>O<sub>7</sub> High-T<sub>c</sub> Superconductors without Copper [A, B, C = Cations]**, O'PAUL ISIKAKU-IRONKWE, MICHAEL J. SCHAFFER, RTS Design Technologies, San Diego CA 92101 — Soon after the discovery of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> with  $T_c = 93$  K, a similar structured system with Ag replacing Cu was discovered with a  $T_c = 50$  K. Also, the discovery of Ba<sub>0.6</sub>K<sub>0.4</sub>BiO<sub>3</sub> with  $T_c = 30$  K indicated that Cu was not indispensable for high temperature superconductivity (HTSC). Latter, the discoveries of the Pnictide and Chalcogenide high-T<sub>c</sub> superconductors confirmed those earlier experimental indications. Using our recently developed Material Specific Characterization Dataset (MSCD) model for analysis and design of superconductors, we have computed many designs that satisfy the MSCD characteristics of YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> as a design model. Our design recognizes the valence state characteristics that make YBa<sub>2</sub>Cu<sub>3</sub>O<sub>6.8</sub> a semiconductor, while YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> is a superconductor. Here we present ten material specific rational design examples of potential A<sub>1</sub>B<sub>2</sub>C<sub>3</sub>O<sub>7</sub> HTSCs without Cu, using the YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> design model. This MSCD design model opens the possibility for search and discovery of high-T<sub>c</sub> oxide superconductor systems without copper.

**12:15PM F8.00006 Microscopic Origin of the Neutron Spin Resonance in Heavy Fermion Superconductor Ce<sub>1-x</sub>Y<sub>b</sub>xCoIn<sub>5</sub>**, YU SONG, Rice University, JOHN VAN DYKE, University of Illinois at Chicago, I. K. LUM, B. D. WHITE, University of California, San Diego, L. SHU, Fudan University, SOOYOUNG JANG, University of California, San Diego, A SCHNEIDEWIND, PETR CERMAK, Julich Center for Neutron Science, Y. QIU, NIST center for neutron scattering, M. B. MAPLE, University of California, San Diego, DIRK K. MORR, University of Illinois at Chicago, PENGCHENG DAI, Rice University — We have systematically studied the evolution of the neutron resonance mode in Ce<sub>1-x</sub>Y<sub>b</sub>xCoIn<sub>5</sub> ( $x = 0, 0.05, 0.3$ ) with neutron scattering. We uncover clear dispersive feature of the mode and show that it is quite robust to disorder due to doping. Our results suggest that the resonance in Ce<sub>1-x</sub>Y<sub>b</sub>xCoIn<sub>5</sub> is a paramagnon reminiscent of spin waves in CeRhIn<sub>5</sub>.

**12:27PM F8.00007 Consistency of measured phase boundaries of the FFLO superconducting phase for different materials and types of probes**, CHARLES AGOSTA, Clark University, NATHANAEL FORTUNE, Smith College, SCOTT HANNAHS, JU-HYUN PARK, National High Magnetic Field Laboratory, JOHN SCHLEUTER, Argonne National Laboratory, LUCY LIANG, SHUYAO GAO, Smith College, LOGAN BISHOP-VAN HORN, MAX NEWMAN, Clark University, SHUYAO GU, Smith College, LUCY LIANG — New magnetocaloric and specific heat measurements of the high field superconducting state in the organic superconductor  $\kappa$ -(BEDT-TTF)<sub>2</sub>Cu(NCS)<sub>2</sub> are compared to rf penetration depth, magnetic torque, and NMR measurements. The position of the phase lines separating the uniform superconducting state with the FFLO state and the normal state are mostly in good agreement with each other. The order of the phase transitions can only be determined from the calorimetric measurements and will be compared to theory. Results from other organic superconductors show that there is universal behavior. As an example, the distance between the lower and upper magnetic field phase line containing the FFLO state is proportional to the upper critical field. The position of the lower phase line, the Clogston Chandrasakar paramagnetic limit, will be compared to semi empirical calculations based on the specific heat for five different superconductors.

**12:39PM F8.00008 Magnetocaloric Evidence for FFLO Superconductivity in  $\kappa$ -(BEDT-TTF)<sub>2</sub>Cu(NCS)<sub>2</sub><sup>1</sup>**, NATHANAEL FORTUNE, Smith College, CHARLES AGOSTA, Clark University, SCOTT HANNAHS, JU-HYUN PARK, National High Magnetic Field Laboratory, SHUYAO GU, LUCY LIANG, Smith College, JOHN SCHLEUTER, Argonne National Laboratory — We present new magnetocaloric and calorimetric measurements of the high field superconducting state in the layered structure superconductor  $\kappa$ -(BEDT-TTF)<sub>2</sub>Cu(NCS)<sub>2</sub>. The strongly field-orientation dependent phase transition between the low field superconducting state and high field superconducting states is first order and is nearly temperature independent, occurring at the Clogston-Chandrasakar paramagnetic limit  $H_p$ . Magnetocaloric measurements  $dT/dH$  as a function of magnetic field reveal that the system becomes strongly paramagnetic at the cross over from the low field to high field state. At lower temperatures, we are able to resolve small changes at the phase boundary due to the absorption/release of latent heat when increasing/decreasing field, indicating that the high field state is higher entropy than the low field state. These results provide strong new evidence for the formation of paramagnetic spin domains within an inhomogeneous FFLO superconducting state. They also allow us to rule out alternative explanations involving the formation of spin density waves within a homogenous superconducting state.

**12:51PM F8.00009 Charge fluctuations and superconductivity in organic conductors: the case of  $\beta''$ -(BEDT-TTF) $_2$ SF $_5$ CH $_2$ CF $_2$ SO $_3$** , GEORGIOS KOUTROULAKIS, Univ of California - Los Angeles, H. KUHNE, Hochfeld-Magnetlabor Dresden, H.-H. WANG, Univ of California - Los Angeles, J. A. SCHLUETER, Argonne National Laboratory, J. WOSNITZA, Hochfeld-Magnetlabor Dresden, S. E. BROWN, Univ of California - Los Angeles — Superconductivity in most organic charge transfer salts is considered magnetically mediated, in part due to the proximity to antiferromagnetic ground states, as well as the preponderance of spin fluctuations in their normal state. An alternative proposal is based on mediation by charge fluctuations, close to collapsed charge-ordered insulating states. The all-organic salt  $\beta''$ -(BEDT-TTF) $_2$ SF $_5$ CH $_2$ CF $_2$ SO $_3$ , which undergoes a superconducting transition at  $T_C=4.5$ K, has been suggested as a candidate material for the realization of charge-fluctuation pairing. Here, we report on a detailed  $^{13}\text{C}$  NMR study examining the normal and superconducting states of this material, and we discuss the results in the context of the proposal for charge-fluctuation driven superconductivity.

**1:03PM F8.00010 Superconducting Properties of a Nanoparticle Assembly of the Organic Conductor (TMTSF) $_2$ ClO $_4$** , LAUREL WINTER, Los Alamos National Laboratory, National High Magnetic Field Laboratory (NHMFL), EDEN STEVEN, JAMES BROOKS, SHERMAN BENJAMIN, Florida State University, NHMFL FL, JU-HYUN PARK, NHMFL FL, DOMINIQUE DE CARO, CHRISTOPHER FAULMANN, LYDIE VALADE, KANE JACOB, IMANE CHTIOUI, CNRS, University of Toulouse, BELEN BALLESTEROS, JORDI FRAXEDAS, ICN2, CSIC Barcelona — While the study of thin-film and nanoparticle geometries on semiconductor devices, type-I elemental superconductors, and even single-molecular magnet materials have been explored, progress on thin-film and nanoparticle organic superconductors — in particular charge-transfer organic salts — has remained elusive. Recent refinements of synthesis conditions have produced nanoparticles of the Bechgaard salt (TMTSF) $_2$ ClO $_4$ . High resolution TEM studies have determined these nanoparticles are approximately 3-5 nm in size, which form nanoparticle clusters that are on average 34 nm in size<sup>1</sup>. In order to investigate the properties of these nanoparticles, randomly oriented assemblies were studied in magnetic fields up to 16 T, using a high sensitivity inductive method in a dilution refrigerator, the results of which show that the ground-state properties of the nanoparticle assembly compares favorably with the bulk-single-crystal material<sup>2</sup>. <sup>1</sup> D. de Caro *et al.*, *Eur. J. Inorg. Chem.*, **2014**, 4010 (2014). <sup>2</sup> L. E. Winter *et al.*, *Phys. Rev. B.*, **91**, 035437 (2015).

**1:15PM F8.00011 Realization of insulating state and superconductivity in Rashba semiconductor BiTeCl**, JIANJUN YING, VIKTOR STRUZHUKIN, ALEXANDER GONCHAROV, HO-KWANG MAO, Carnegie Inst of Washington, FEI CHEN, XIAN-HUI CHEN, University of Science and Technology of China, ALEXANDER GAVRILIUK, Russian Academy of Sciences, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research — Measurements of the resistivity, Hall coefficient, and Raman spectroscopy are performed on a Rashba semiconductor BiTeCl single crystal at high pressures up to 50 GPa. We find that applying pressure first induces the theoretically predicted insulating state followed by a superconducting phase with the insulating normal state. Upon heavy compression, another different superconducting phase is entered with the metallic normal state. The dome-like evolution of the superconducting transition temperature with pressure is obtained with the crossover from the electron to hole carriers across the boundary of the two superconducting phases. These findings imply the possible realization of topological state of the insulating and superconducting phases in this material.

**1:27PM F8.00012 MgB $_2$  Ultrathin Films Fabricated by Hybrid Physical Chemical Vapor Deposition and Subsequent Ion Milling.**, NARENDRA ACHARYA, MATTHAEUS WOLAK, TENG TAN, Temple University, DANIEL CUNNANE, BORIS KARASIK, Jet Propulsion Laboratory, XIAOXING XI, Temple University — Hot electron bolometer (HEB) mixers are a great tool for measuring high-resolution spectroscopy at Terahertz frequencies. MgB $_2$  offers a higher critical temperature (39 K) compared to commonly used Nb and NbN and boasts a shorter intrinsic electron-phonon relaxation time, giving rise to a broader intermediate frequency (IF) bandwidth. We have fabricated high quality ultrathin MgB $_2$  films using hybrid physical-chemical vapor deposition (HPCVD) and employing ion milling to achieve thickness down to 2 nm. The thinnest achieved films show high  $T_c$  of 28 K with residual resistivity below 28  $\Omega\text{cm}$  and high critical current  $J_c$  of  $1 \times 10^6$  A/cm $^2$  at 20 K. As a result of the employed low angle ion milling process, the films remain well connected even after being thinned down since the initial thick films offer a better connectivity than as-grown thin films. The established process offers a way to realize MgB $_2$  based HEB mixers of extremely low thickness and therefore small local oscillator power requirements and increased IF bandwidth.

**1:39PM F8.00013 Epitaxial growth of MgB $_2$  films at ambient temperature**, HIROAKI SHISHIDO, TAKUYA YOSHIDA, TAKATOSHI NAKAGAMI, TAKEKAZU ISHIDA, Department of Physics and Electronics, Graduate School of Engineering, Osaka Prefecture University — We grew crystalline MgB $_2$  thin films using molecular beam epitaxy at a low substrate temperature of 110 °C under an ultrahigh vacuum of about  $10^{-6}$  Pa. MgB $_2$  thin films were deposited on the (001) surface of a 4H-SiC substrate with an epitaxial Mg buffer layer. The epitaxial growth was confirmed by X-ray diffraction measurements. MgB $_2$  thin films show a sharp superconducting transition at 27.2 K, with a relatively narrow superconducting transition width  $\Delta T_c = 0.9$  K. The growth temperature was lower than any in prior reports on superconducting MgB $_2$  thin films. The presence of the epitaxial Mg buffer layer is crucial for reducing the epitaxial temperature.

**1:51PM F8.00014 Unconventional superconductivity in half-Heusler semimetals<sup>1</sup>**, PHILIP BRYDON<sup>2</sup>, Department of Physics, University of Otago, LIMIN WANG, Center for Nanophysics and Advanced Materials, University of Maryland, MICHAEL WEINERT, DANIEL AGTERBERG, Department of Physics, University of Wisconsin, Milwaukee — We consider the superconductivity of the topological half-Heusler semimetals YPtBi and LuPtBi, where pairing occurs between  $j = 3/2$  quasiparticles. This permits Cooper pairs with quintet or septet total angular momentum, in addition to singlet and triplet states. Purely on-site interactions can generate unconventional (quintet) time-reversal symmetry-breaking states with topologically nontrivial point or line nodes. Furthermore, due to the broken inversion symmetry in these materials, the usual  $s$ -wave singlet state can mix with a  $p$ -wave septet state, also with topologically stable line-nodes.

**2:03PM F8.00015 Superfluid Density and Flux-Flow Resistivity Measurements of Multiple-Band Superconductor  $\beta$ -PdBi $_2$** , TATSUNORI OKADA, YOSHINORI IMAI, ATSUTAKA MAEDA, University of Tokyo —  $\beta$ -PdBi $_2$  ( $T_c^{\text{max}} = 5.4$  K) is a newcomer of the multiple-band superconductors, revealed by the specific heat and the upper critical field measurements [1], and the angle-resolved photoemission spectroscopy [2]. In addition, authors of ref. [2] observed the spin-polarized band dispersion and proposed that  $\beta$ -PdBi $_2$  is a candidate of topological superconductor. However, there is less information on superconducting properties so far. In order to clarify the superconducting gap function, we measured the temperature ( $T$ ) and magnetic field ( $B$ ) dependence of microwave complex conductivity of  $\beta$ -PdBi $_2$  single crystals. We found that the superfluid density exhibits the thermally activated  $T$  dependence, manifesting the absence of nodes in the superconducting gaps. We also found that the flux-flow resistivity increased with  $B$  with downward-convex shape. Based on some theories, we considered that such a behavior originated from the backflow of supercurrents around vortices reflecting rather small Ginzburg-Landau parameter ( $\kappa \simeq 5$ ). **Session F11 DMP: Nematicity in Fe-based Superconductors 307 - Anna Boehmer, Ames Laboratory**

**11:15AM F11.00001 Ising nematic quantum critical point in a metal: a Monte Carlo study<sup>1</sup>**

, SAMUEL LEDERER, Massachusetts Inst of Tech-MIT — The Ising nematic quantum critical point (QCP) associated with the zero temperature transition from a symmetric to a nematic *metal* is an exemplar of metallic quantum criticality. We have carried out a minus sign-free quantum Monte Carlo study of this QCP for a two dimensional lattice model with sizes up to  $24 \times 24$  sites. The system remains non-superconducting down to the lowest accessible temperatures. The results exhibit critical scaling behavior over the accessible ranges of temperature, (imaginary) time, and distance. This scaling behavior has remarkable similarities with recently measured properties of the Fe-based superconductors proximate to their putative nematic QCP.

**11:51AM F11.00002 NMR evidence for inhomogeneous nematic fluctuations in**

**BaFe<sub>2</sub>(As<sub>1-x</sub>P<sub>x</sub>)<sub>2</sub>**, ADAM P. DIOGUARDI, Los Alamos National Laboratory, TANAT KISSIKOV, CHING-HAN LIN, KENT R. SHIRER, MATTHEW M. LAWSON, University of California Davis, Department of Physics, HANS-JOACHIM GRAFE, IFW Dresden, Institute for Solid State Research, Dresden, Germany, JIUN-HAW CHU, IAN R. FISHER, Department of Applied Physics and Geballe Laboratory for Advanced Materials, Stanford University, & Stanford Institute of Energy and Materials Science, RAFAEL M. FERNANDES, School of Physics and Astronomy, University of Minnesota, Minneapolis, NICHOLAS J. CURRO, University of California Davis, Department of Physics — We present evidence for nuclear spin-lattice relaxation driven by glassy nematic fluctuations in isovalent P-doped BaFe<sub>2</sub>As<sub>2</sub> single crystals. Both the <sup>75</sup>As and <sup>31</sup>P sites exhibit stretched-exponential relaxation similar to the electron-doped systems. By comparing the hyperfine fields and the relaxation rates at these sites we find that the As relaxation cannot be explained solely in terms of magnetic spin fluctuations. We demonstrate that nematic fluctuations couple to the As nuclear quadrupolar moment and can explain the excess relaxation. These results suggest that glassy nematic dynamics are a universal phenomenon in the iron-based superconductors.

**12:03PM F11.00003 Measuring Nematic Susceptibilities from the Elastoresistivity Tensor<sup>1</sup>**

A. T. HRISTOV, M. C. SHAPIRO, Stanford University, PATRICK HLOBIL, Karlsruher Institut für Technologie, AKASH MAHARAJ, JIUN-HAW CHU, IAN FISHER, Stanford University — The elastoresistivity tensor  $m_{ijkl}$  relates changes in resistivity to the strain on a material. As a fourth-rank tensor, it contains considerably more information about the material than the simpler (second-rank) resistivity tensor; in particular, certain elastoresistivity coefficients can be related to thermodynamic susceptibilities and serve as a direct probe of symmetry breaking at a phase transition. The aim of this talk is twofold. First, we enumerate how symmetry both constrains the structure of the elastoresistivity tensor into an easy-to-understand form and connects tensor elements to thermodynamic susceptibilities. In the process, we generalize previous studies of elastoresistivity to include the effects of magnetic field. Second, we describe an approach to measuring quantities in the elastoresistivity tensor with a novel transverse measurement, which is immune to relative strain offsets. These techniques are then applied to BaFe<sub>2</sub>As<sub>2</sub> in a proof of principle measurement.

**12:15PM F11.00004 Origin of the in-plane resistivity anisotropy of the iron pnictides: scattering rate or plasma frequency?<sup>1</sup>**

, MICHAEL SCHTTT, Univ of Minn - Minneapolis, JRG SCHMALIAN, Institute for Theoretical Condensed Matter Physics, Karlsruhe Institute of Technology, 76128 Karlsruhe, Germany, RAFAEL FERNANDES, Univ of Minn - Minneapolis — The prime experimental tool to probe the electronic nematic phase in the iron pnictides is the in-plane resistivity anisotropy, which can arise from an anisotropic scattering rate and/or an anisotropic plasma frequency. To shed light on its origin, we investigate the impact of spin fluctuations on the anisotropic ac conductivity of the iron pnictides. We show that two mechanisms contribute to the ac conductivity anisotropy. On the one hand, the inelastic scattering by spin fluctuations directly introduces an anisotropic scattering rate. On the other hand, the same inelastic scattering causes the renormalization of the Fermi velocity at the hot spots. Interestingly, while both mechanisms affect the ac conductivity anisotropy, only the first causes an anisotropy in the dc limit. In contrast, the second mechanism effectively renormalizes both the plasma frequency and the scattering rate. The latter effect opposes the anisotropy induced by the direct scattering of electrons, effectively reducing the observable scattering rate anisotropy. Our results agree qualitatively with recent experiments in detwinned iron pnictides and show the unavoidable entanglement between the scattering rate anisotropy and the plasma frequency anisotropy that arises from spin fluctuations.

**12:27PM F11.00005 Nematic Crossover in BaFe<sub>2</sub>As<sub>2</sub> under Uniaxial Stress**

, XIAO REN<sup>1</sup>, LIAN DUAN, YUWEN HU, JIARUI LI, Peking University, Beijing 100871, China, RUI ZHANG, Rice University, Houston, Texas 77005, USA, HUIQIAN LUO, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, PENGCHENG DAI, Rice University, Houston, Texas 77005, USA, YUAN LI<sup>2</sup>, Peking University, Beijing 100871, China — The nature of the nematic order in iron-based superconductors has invoked intense research interest. A substantial portion of experimental attempts on resolving this issue required the use of single-domain samples produced under external stress. Here we use Raman scattering, a technique that can detect spontaneous point-group symmetry breaking without resorting to single-domain samples, to study BaFe<sub>2</sub>As<sub>2</sub>, the parent compound of the 122 Fe-based superconductors. We show that an applied compression along the Fe-Fe direction, which is commonly used to produce untwinned orthorhombic samples, changes the structural phase transition at temperature T<sub>s</sub> into a crossover that spans a considerable temperature range above T<sub>s</sub>. Even in crystals that are not subject to any applied force, a distribution of substantial residual stress remains, which may explain phenomena that are seemingly indicative of symmetry breaking above T<sub>s</sub>. Our results are consistent with an onset of spontaneous nematicity only below T<sub>s</sub>.

**12:39PM F11.00006 Neutron scattering in detwinned  $\text{SrFe}_2\text{As}_2$  single crystals**, LI ZHANG, China Jiliang University/Rice University, YU SONG, YU LI, RUI ZHANG, WEIYI WANG, HAORAN MAN, PENGCHENG DAI, Rice University — **Abstract:** Large  $\text{SrFe}_2\text{As}_2$  single crystals (2cm) were grown with self-flux method. The basic sample characterizations were described by XRD, MPMS and PPMS. Orthorhombic  $a$  along horizontal orientation and  $b$  along vertical orientation were determined by X-ray Laue diffraction. The crystals were cut into rectangular pieces along the  $[1,1,0]$  and  $[1,-1,0]$  directions by high precision wire saw. The device for sample detwinning was made of 6061 aluminum alloy with low neutron incoherent scattering cross section. Uniaxial pressure can be applied by a spring along orthorhombic  $[0,1,0]$  direction by tuning the screw in one end. The pressure can be calculated by the known elasticity coefficient ( $k = 10.5 \text{ N/mm}$ ) and the compression of the spring ( $\Delta x$ ) [1]. Our neutron scattering experiments were carried out using the MAPS at the ISIS in England. Low Energy (such as  $E_i=80\text{meV}$ ) with different temperatures, especially around ( $T_N = T_S = 193 \text{ K}$ ) is done in the time-of-flight experiment[2]. It is interesting to find out the pressure induced spin excitation anisotropy. After careful analysis, we conclude that resistivity and spin excitation anisotropies are likely intimately connected. The results also compared with similar experiment in parent  $\text{BaFe}_2\text{As}_2$  in Murlin at the ISIS. **Keywords:** neutron scattering, detwin,  $\text{SrFe}_2\text{As}_2$ , single crystals Figure 1, Large  $\text{SrFe}_2\text{As}_2$  single crystals grown with self-flux method. **12:51PM F11.00007 Nematic fluctuations and acoustic phonon in the Raman response of iron-based superconductors**<sup>1</sup>, M. KHODAS, University of Iowa, W.-L. ZHANG, Chinese Academy of Sci (CAS), G. BLUMBERG, Rutgers University, Piscataway, New Jersey 08854, USA, P. RICHARD, H. DING, Chinese Academy of Sci (CAS), ATHENA S. SEFAT, Oak Ridge National Laboratory — Nematicity is a generic feature in the under- and optimally-doped iron-based superconductors. Raman and shear modulus studies indicate a critical behavior of the xy symmetry susceptibility towards an extrapolated temperature  $\theta$  defining a hidden critical point tens of degrees below the structural transition  $T_S$ . It was proposed that Raman scattering is insensitive to the orthorhombic lattice deformation and a strong electron-phonon (ep) coupling could possibly lift the nematic transition from  $\theta$  to  $T_S$ , while the ep coupling strength remains unknown. Here we report a very low frequency phonon mode associated with an orthorhombic lattice deformation near  $T_S$  contributing to the xy symmetry Raman response. We propose an ep coupling model to describe the Raman response and establish the connection of Raman susceptibility and elastic shear modulus. The ep coupling strength deduced from the Raman response is insufficient to lift  $T_S$  by 60 K above  $\theta$ , suggesting that the structural phase transition at  $T_S$  and the hidden phase transition at  $\theta$  have different origins.

**1:03PM F11.00008 Electronic Raman study of superconducting  $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$** <sup>1</sup>, SHANGFEI WU, GIRSH BLUMBERG, Rutgers Univ, PIERRE RICHARD, HONG DING, IOP,CAS, HAIHU WEN, Nanjing Univ — We use electronic Raman scattering to probe the superconductivity gap structure and collective modes in under-doped and optimally-doped  $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ . In the under-doped samples, we observe a sharp superconducting coherence peak at  $60 \text{ cm}^{-1}$  in the XY ( $B_{2g}$ ) geometry below  $T_c$ , which is consistent with the gap value determined by ARPES on the outer hole Fermi surface pocket <sup>2</sup>. The Raman spectrum shows a threshold at approximately  $30 \text{ cm}^{-1}$  followed by the superconducting coherence peak with a low-energy tail. We identify a peak at around  $95 \text{ cm}^{-1}$  between 13 K and 22 K in the same geometry in the orthorhombic phase below  $T_c$ , which becomes broader and weaker upon heating. A sharp and symmetric mode at  $120 \text{ cm}^{-1}$  is also observed in the optimally-doped samples in the same geometry. These collective modes have similar energy scale with the neutron spin resonance mode, the kink observed by ARPES and the bosonic mode observed by STM <sup>3</sup>, indicating that they have intimate relationship with superconductivity in the iron pnictides.

**1:15PM F11.00009 Numerical Study of Iron-Based Superconductors and Nematic Order**, HARRISON RUIZ, MARTIN CLAASSEN, YAO WANG, CHUNJING JIA, BRIAN MORITZ, THOMAS DEVEREAUX, SIMES, SLAC National Accelerator Laboratory/Stanford University — We perform an exact diagonalization study of the multi-orbital Hubbard model including coupling to lattice degrees of freedom. The single-particle spectral function, dynamical spin, charge, and Raman response are studied to examine a spin nematic phase due to a biquadratic exchange coupling.

**1:27PM F11.00010 The realization of nematic order in iron-pnictide superconductors**, HONG-YI CHEN, CHUNG-PIN CHOU, National Taiwan Normal University, C. S. TING, University of Houston — The interplay between the nematicity and superconductivity in iron-pnictide is studied with a proposed magnetic configuration in a microscopic model. The spin-driven order in the nematic state has been found in a small area in the electron-doped regime. In the nematic state, in the normal state, the broken degeneracy of the orbitals  $d_{xz}$  and  $d_{yz}$  causes the elliptic Fermi surface. In the state where the nematicity coexists with the superconductivity, an orthorhombic magnetic fluctuations appears and its Fourier transformation shows two uneven pairs of peaks at  $(\pm\pi, 0)$  and  $(0, \pm\pi)$ . Finally, two modulated stripe SDW perpendicularly intertwined each other and makes the charge density and the spatial distribution of the LDOS reflecting a  $d_{x^2-y^2}$ -symmetry form factor.

**1:39PM F11.00011 Spin-Driven Nematic Instability in Realistic Microscopic Models: Application to Iron-Based Superconductors**, MORTEN HOLM CHRISTENSEN, Niels Bohr Institute, University of Copenhagen and School of Physics and Astronomy, University of Minnesota, JIAN KANG, School of Physics and Astronomy, University of Minnesota, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, RAFAEL M. FERNANDES, School of Physics and Astronomy, University of Minnesota — Electronic nematicity due to the partial melting of density waves is a prevalent phenomenon in the field of high temperature superconductivity. In contrast to usual electronic instabilities, such as magnetic and charge order, this fluctuation-driven order cannot be captured by the standard RPA method. By including fluctuations beyond RPA, we derive the orbitally-resolved nematic susceptibility of a generic multi-orbital Hubbard model, thus putting it on equal footing with other electronic susceptibilities of weakly and moderately interacting systems. Application to iron-based superconductors reveals that the  $d_{xy}$ -orbital plays a primary role in promoting a nematic transition preempting the magnetic transition. It furthermore demonstrates the importance of high-energy magnetic fluctuations in stabilizing nematic order in the absence of magnetic order. Finally, we show that the RPA ferro-orbital susceptibility shows no divergence on its own, providing strong evidence for a magnetic mechanism for nematicity.

**1:51PM F11.00012 Effect of Orbital Nematicity on Superconductivity in the Iron Pnictides and Chalcogenides**, ANDRIY NEVIDOMSKYY, Rice University, RONG YU, Renmin University of China — Orbital ordering leading to the observed nematic phase in the iron-based superconductors has been firmly established in a variety of experiments. It is therefore important to investigate the effect of the orbital order on the superconductivity. To this end, we have performed strong-coupling calculation within the slave-boson approach to the multiorbital  $t$ - $J_1$ - $J_2$  models for the iron-based superconductors. We report the phase diagram as a function of both electron/hole doping and the orbital ordering strength. We find that the amplitude of the otherwise dominant  $A_{1g}$  ( $s\pm$ ) pairing channel diminishes as the strength of orbital ordering is increased, yielding to the  $B_{1g}$  ( $d_{x^2-y^2}$ ) pairing channel. This effect is especially pronounced in the electron-doped case, with the  $d$ -wave pairing stabilized by the realistic values of the orbital splitting  $\sim 50$  meV. While the  $d$ -wave pairing has not been conclusively observed in the iron-based superconductors, the competition between the  $s$ - and  $d$ -wave pairing found in the calculations may have ramifications for FeSe,  $\text{KFe}_2\text{As}_2$  and  $\text{K}_x\text{Fe}_{2-y}\text{Se}_2$ .

**2:03PM F11.00013 Possible surface nematic order in iron pnictides<sup>1</sup>**, KOK WEE SONG, ALEXEI KOSHELEV, Argonne National Laboratory — Nematic fluctuations play important role in the physics of the iron-based superconductors. Indications for weak precursor nematic transition has been found in the compound  $\text{BaAs}_{2-x}\text{P}_x\text{Fe}_2$ [1]. However, high-resolution specific-heat measurements did not reveal any bulk transition[2]. To resolve this controversy, we consider the possibility of the surface nematic transition preceding the bulk transition. We consider the simplest model of two interacting quasi-two-dimensional electronic bands and explore the free-surface effects on the nematic order. We found that three-dimensional effects suppress the bulk nematic order and therefore this order is enhanced near the surface.

**11:51AM F12.00002 Prototypes for the dynamics underlying precipitation and temperature extremes<sup>1</sup>**, J DAVID NEELIN, UCLA — Projecting changes in precipitation and temperature extreme events can be aided by a deeper understanding of the dynamics underlying such variations. For precipitation, this is closely connected to the interaction of fast, small-scale motions with variability of large-scale climate. Simple prototype models from the physics and applied math literature can point to analysis methods, connections among related quantities, and hypotheses for the dynamics, especially when the prototype models can be derived from climate-model equations. An overview will be provided including recent work with a number of collaborators. For distributions of precipitation-related variables, prototypes including Fokker-Planck solutions and first-passage problems for variations across an onset threshold yield insights into the form of present-day observed distributions and predictions for the form of the global warming change to evaluate in climate models. In distributions of water vapor and temperature, the widespread occurrence of non-Gaussian tails is likely explained in part by prototypes for tracer advection across a maintained gradient. The shape of these tails can have substantial implications for regional changes in probabilities of precipitation and temperature extremes with large-scale warming.

**1:39PM F12.00005 Aerosols, Clouds, and Precipitation as Scale Interactions in the Climate System and Controls on Climate Change**, LEO DONNER, Geophysical Fluid Dynamics Laboratory/NOAA — Clouds are major regulators of atmospheric energy flows. Their character depends on atmospheric composition, dynamics, and thermodynamic state. Clouds can assume organized structures whose scales are planetary, while processes important for determining basic properties occur on the scale of microns. The range of processes, scales, and interactions among them has precluded the development of concise theories for the role of clouds in climate, and limitations in modeling clouds in complex climate models remain among the key uncertainties in understanding and projecting climate change. The distribution function of vertical velocities (updraft speeds) in clouds is an important control on climate forcing by clouds and possibly a strong correlate with climate sensitivity. (Climate forcing refers to the change in Earth's energy balance as atmospheric composition changes, in particular, due to human activity. Climate sensitivity is defined here as the equilibrium change in globally averaged annual surface temperature as a result of doubled carbon dioxide.) Vertical velocities are central because they determine the thermodynamic environment governing phase changes of water, with both equilibrium and non-equilibrium phenomena important. The spatial and temporal spectra of relevant vertical velocities includes scales both numerically resolved by climate models and below their resolution limit. The latter implies a requirement to parameterize these smaller scale motions in models. The scale dependence of vertical velocities and emerging observational constraints on their distribution provide new opportunities for representing aerosols, clouds, and precipitation in climate models. Success in doing so could provide important breakthroughs in understanding both climate forcing and sensitivity.

**Session F13 DCOMP DAMOP: New Developments in the Study of Inhomogeneous Strongly Correlated Quantum Systems 309** - Mark Jarrell, Louisiana State University

**11:15AM F13.00001 New theoretical tools for quantum glasses, with and without quenched disorder**, LOUK RADEMAKER, Univ of California - Santa Barbara — Even though most solid materials are disordered or glasslike, our understanding of such non-equilibrium phases of matter is meager. Our task is thus to develop new tools to understand the nature of quantum glasses. These can be characterized into two classes: with or without quenched disorder. Interacting spin or electron models with quenched disorder are known to exhibit many-body localization (MBL). We discuss a new method based on a Hilbert-space preserving RG scheme to find the integrals of motion for an interacting system. We used this approach to numerically study MBL phases and the corresponding transition.

On the other hand, we discuss the possibility of self-generated electron glassiness in the absence of quenched disorder. Such structural quantum glasses, requiring geometric frustration and long-range interactions, are in many ways similar to the quenched disorder glasses. We will discuss the soft gap in the density of states, which is now related to short-range frozen density correlations. Using both numerical and analytic arguments we find Arrhenius-type slow relaxation and stretched exponential behavior.

**11:51AM F13.00002 Quench and Transport Dynamics in Disordered Atomic Hubbard Lattices<sup>1</sup>**, BRIAN DEMARCO, Univ of Illinois - Urbana — I will give an overview of our experiments using ultracold atom gases trapped in optical lattices to probe transport, dynamics, and relaxation in disordered Hubbard models. By introducing disorder to naturally clean optical lattices using focused optical speckle, we realize variants of the disordered Bose- and Fermi-Hubbard models. In these systems, the distribution of Hubbard parameters is fully known, and the ratio of characteristic energy scales is completely tunable. I will discuss two measurements. In the first, we observe localization via transport measurements in the metallic regime of the Fermi-Hubbard model. We observe three phenomena consistent with many-body localization: localization at non-zero temperature, localization across a range of temperatures, and interaction-induced delocalization. These measurements show agreement with a mean-field theory in a limited parameter regime. In a separate experiment using bosonic atoms, we measure excitations following a quantum quench of disorder. Via comparison to state-of-the-art quantum Monte Carlo calculations that capture all aspects of the experiments—including all the particles—we show that the onset of excitations corresponds to the superfluid-Bose-glass transition. I will discuss how this behavior is reminiscent of the quantum Kibble-Zurek effect.

**12:27PM F13.00003 The role of weak interactions on the mobility-edge of strongly disordered electron systems<sup>1</sup>**, CHINEDU EKUMA, Naval Research Lab, Washington D.C. — New insights into the nature of the mobility edge of a weakly correlated, disordered Anderson spectra will be presented within the typical medium dynamical cluster approximation (TMDCA). The TMDCA systematically incorporates non-local spatial correlations (beyond the single-site approximations) treating the disorder to all orders and the interacting, non-local cluster self-energy up to second order in the perturbation expansion of the interactions,  $U$ . An arbitrary small interaction is found to lead to an exponential fast crossover of the sharp mobility edge that separates the localized and extended states in the non-interacting regime below the critical disorder strength  $W_c^{U=0}$  whenever the chemical potential of the non-interacting typical density of states is below the mobility edge energy. This smearing of the mobility edge is ascribed to the inelastic scattering due to  $U$ . However, as the chemical potential,  $\mu$  approaches the smeared edge, reduction of the phase space for scattering by  $U$  causes the edge to once again become sharp. A concomitant soft-pseudogap is found at energy,  $\omega = 0$  independent of filling, which is linear rather than quadratic in  $\omega$ , due to the lack of momentum conservation. The method is demonstrated on realistic low-dimensional structures.

**1:03PM F13.00004 Precise finite-temperature properties of disordered strongly-correlated electronic systems**, EHSAN KHATAMI, San Jose State University — The interplay between disorder and electronic interactions in quantum many-body systems is not well understood. Experiments with ultracold atoms on optical lattices hold a great promise for exploring the different competing phases that arise in these systems by simulating disordered quantum lattice models in the presence of interactions. However, these experiments often rely on precise and approximate-free results from numerical calculations for various static and dynamic properties of these models in order to characterize the experimental systems. In this talk, I will present recently obtained data for the thermodynamic properties and magnetic correlations of the disordered three-dimensional Hubbard model using the determinant quantum Monte Carlo. I will also discuss new techniques within the numerical linked-cluster expansions that allow for fast and precise calculation of finite-temperature properties of disordered systems in the thermodynamic limit.

**1:39PM F13.00005 Properties of dirty bosons in disordered optical lattices**, USHNISH RAY, Princeton University — Disorder is ubiquitous in nature and its presence can lead to fascinating phenomena such as Anderson localization, Griffiths mechanisms and glassiness. These types of behavior have profound consequences on low temperature ordered phases that are difficult to study, particularly due to lack of controllable disorder. Recent advances in ultra-cold atomic systems have made it possible to make significant progress in overcoming such challenges – making direct comparisons with large scale Quantum Monte-Carlo techniques a possibility. I will talk about the disordered Bose-Hubbard model and the equilibrium properties of the domains that arise in trapped systems. I will show how they correspond to phases and explore the consequences of finite temperature and strong correlations. These aspects will be used to explain the observations of experimental measurements. In particular, I will highlight results of a recent collaborative enterprise that show excellent agreement between theory and experiment.

Session F14 FEd: Integration of Research and Teaching Excellence: Cottrell Scholars 310 - Richard Wiener, Research Corp

**11:15AM F14.00001 From Particle Physics to Education: The Role of Tinkering**, MATS SELEN, Univ of Illinois - Urbana — The love of tinkering is perhaps the single most universal trait among scientists. From designing an experiment to building a computer application to solving a differential equation, the cycle of "observe - explain - test - revise" is at the root of the scientific creative process. Driven by the love of tinkering, we have developed a small low-cost wireless lab system with the goal of putting real scientific instrumentation in the hands of anyone with a desire to innovate and explore. I will describe how this came about and how it has changed our view of introductory physics labs at the University of Illinois.

**11:51AM F14.00002 Excellence and Diversity in Physics, and the Quest for Other Worlds**, KEIVAN STASSUN, Vanderbilt Univ — A major concern for American competitiveness today is the full engagement of US citizens in the STEM enterprise. Of particular concern is the ongoing under-representation of African Americans, Hispanic Americans, and Native Americans, who comprise 35% of the US college-age population but only 2% of physical science PhDs awarded in the US. Since 2004, with initial funding from an NSF CAREER grant and then from a Research Corp Cottrell Scholar award, the Fisk-Vanderbilt Masters-to-PhD Bridge Program has attracted 98 students, 79 of them under-represented minorities, 50% of them women, and with a PhD retention rate of 90%. Fisk has become the top producer of Black U.S. recipients of the master's degree in physics, and Vanderbilt has become the top research university to award the PhD to under-represented minorities in physics, astronomy, and materials science. Among the many "firsts" of the program are: the first member of the Sioux Nation to earn an advanced physics degree, the first Native Hawaiian woman to receive the prestigious NSF Graduate Research Fellowship, the first African American to receive NASA's top Hubble Postdoctoral Fellowship, and the first African American woman to publish an astronomy paper as first author in the prestigious journal Nature. Indeed, this latter example represents the groundbreaking discovery that the sizes and ages of stars—and therefore the sizes and ages and compositions of the planets that orbit those stars—can be measured directly and accurately via the "flicker" of the stars' light. This discovery has transformed the ability of astronomers to understand the physical nature of the exoplanets that are now being found by the thousands around distant stars.

**12:27PM F14.00003 Undergraduate research: A win-win for both students and faculty**<sup>1</sup>, TOM SOLOMON, Bucknell University — Undergraduate students benefit significantly from opportunities to do research with faculty, both at predominately undergraduate institutions (PUIs) and also at major Research I universities. If done well, these research opportunities can also benefit the faculty mentor, especially at PUIs with heavy teaching loads. In fact, the experience works best for the student if it also benefits the faculty. In this talk, I will discuss my experiences working with undergraduate research students, some of whom have been as productive as advanced graduate students. I will discuss situations where things have worked very well for everyone concerned, as well as some mistakes that I made in the past that resulted in bad research experiences. This discussion will be provided in the context of an experimental program in nonlinear dynamics, a field that is well-suited to participation by undergraduates.

**1:03PM F14.00004 Interdisciplinary biophysics major with a comprehensive research-based capstone**, RAE ANDERSON, University of San Diego — No abstract available.

**1:39PM F14.00005 Untypical Undergraduate Research: Player Motion Analysis in Sports**, DINAH LOERKE, University of Denver — There is significant concern about the degree of attrition in STEM disciplines from the start of K-12 through to the end of higher education, and the analysis of the 'leaky pipeline' from the various institutions has identified a critical decline - which may be as high as 60 percent - between the fraction of students who identify as having an interest in a science or engineering major at the start of college/university, and the fraction of students who ultimately graduate with a STEM degree. It has been shown that this decline is even more dramatic for women and underrepresented minorities (Blickenstaff 2005, Metcalf 2010). One intervention which has been proven to be effective for retention of potential STEM students is early research experience, particularly if it facilitates the students' integration into a STEM learning community (Graham et al. 2013, Toven-Lindsey et al. 2015). In other words, to retain students in STEM majors, we would like to encourage them to 'think of themselves as scientists', and simultaneously promote supportive peer networks. The University of Denver (DU) already has a strong undergraduate research program. However, while the current program provides valuable training for many students, it likely comes too late to be effective for student retention in STEM, because it primarily serves older students who have already finished the basic coursework in their discipline; within physics, we know that the introductory physics courses already serve as gatekeeper courses that cause many gifted but 'non-typical' students to lose interest in pursuing a STEM major (Tobias 1990). To address this issue, my lab is developing a small research spinoff program in which we apply spatiotemporal motion analysis to the motion trajectories of players in sports, using video recordings of DU Pioneer hockey games. This project aims to fulfill a dual purpose: The research is framed in a way that we think is attractive and accessible for beginning students who have not yet finished the basic physics course sequence, and we hope to use it to attract untypical and retain undecided students in physics. Secondly, since mathematical techniques for trajectory analysis are independent of scale, we hope to harness the creativity and analytical intuition of undergraduates to simultaneously benefit our core biophysical research program.

**11:15AM F15.00001 Stable bound states of like charges on top of graphene in magnetic field**<sup>1</sup>, SERGEY SLIZOVSKIY, Loughborough University — We show theoretically that in the external magnetic field like charges on top of graphene monolayer may be mutually attracted to form thermodynamically stable macro-molecules. For this to happen graphene needs to be in Quantum Hall plateau state with local chemical potential being between the Landau levels. Graphene electron(s) gets localized in the middle between charges and provides overscreening of Coulomb repulsion between the charges. The size of the resulting macro-molecules is of the order of the magnetic length ( $\sim 10$  nm for magnetic field 10 T). The possible stable macro-molecules that unit charges can form on graphene in magnetic field are classified. The binding survives significant temperatures, exceeding mobility barriers for many ionically bond impurities. The influence of possible lattice-scale effects of valley-mixing are discussed. Tuning the doping of graphene or the magnetic field, the binding of impurities can be turned on and off and the macro-molecule size may be tuned. This opens the perspective to nanoscopic manipulation of ions on graphene by using magnetic field and gating.

**11:27AM F15.00002 Ab initio study of magnetic single layer MPX<sub>3</sub> metal-phosphorous-trichalcogenides**, BHEEMA LINGAM CHITTARI, EUYHEON HWANG, Sungkyunkwan University, JEIL JUNG, University of Seoul, ALLAN H. MACDONALD, The University of Texas at Austin — We analyze the electronic structure of two dimensional (2D) MPX<sub>3</sub> (M = V, Cr, Mn, Fe, Co, Ni, Cu, Zn, and X = S, Se, Te) transition metal thiophosphates, viewing them as single layer van der Waals materials that can exhibit magnetic order. Our ab initio calculations for MPX<sub>3</sub> single layer compounds predict both semiconducting phases with variable band gap sizes and metallic phases, and an intimate interplay between magnetic order and the presence of a gap. A systematic trend of decreasing band gaps in antiferromagnetic states is observed as the chalcogen atoms S, Se, and Te change from smaller to larger atomic number, Ferromagnetic, antiferromagnetic, and nonmagnetic phases, and lattice constant changes accompanied by distortions in crystal symmetry, occur as the metal atom is varied. The sensitive interdependence between magnetic, structural, and electronic properties suggests the important potential of this class of 2D magnetic van der Waals materials for strain and field-effect carrier tunable spintronics.

**11:39AM F15.00003 Anisotropic optical properties of few-layer transition metal dichalcogenide  $\text{ReS}_2$** , ZHENGLU LI, TING CAO, FELIPE H. DA JORNADA, MENG WU, STEVEN G. LOUIE, Physics Department, UC Berkeley and Lawrence Berkeley National Lab — We present first-principles (DFT, GW and GW-BSE) calculations of the electronic and optical properties of few-layer rhenium disulfide ( $\text{ReS}_2$ ). Monolayer  $\text{ReS}_2$  shows strong many-electron effects with a fundamental quasiparticle band gap of 2.38 eV based on  $G_0W_0$  calculation and a large exciton binding energy of 690 meV based on solving the Bethe-Salpeter equation. Highly anisotropic linear-polarized optical absorptions are revealed for few-layer and bulk  $\text{ReS}_2$ . The band gap shows a decreasing trend with the optical polarization direction near the absorption edge gradually rotating from around 67 degree in the monolayer to 85 degree in the bulk, referencing to the Re-chain. Our calculations are consistent with recent experimental data and theoretical studies, and provide a systematic understanding of the electronic and optical properties in few-layer  $\text{ReS}_2$ . This work was supported by National Science Foundation Grant No. DMR15-1508412 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility.

**11:51AM F15.00004 Anisotropy in the optical properties of bulk and layered transition metal dichalcogenide  $\text{ReS}_2$** , SUVADIP DAS, NIHAR PRADHAN, CARLOS GARCIA, DANIEL RHODES, STEPHEN MCGILL, LUIS BALICAS, EFSTRATIOS MANOUSAKIS, National High Magnetic Field Lab. & Dept. Physics, Florida State Univ. — Unlike most transition metal dichalcogenides,  $\text{ReS}_2$  in the distorted  $1T'$  phase, is a direct gap semiconductor. We measured the temperature dependent photoluminescence in both bulk and layered  $\text{ReS}_2$  and examined the evolution of the peaks with the number of layers. We obtained strong signatures of optical anisotropy in the absorption spectroscopy and photocurrent response which makes this material a potential candidate for optoelectronic applications. Many body calculations including electron-hole interactions as implemented in the GW+BSE approach, agrees with the strong anisotropy in the optical properties of bulk and monolayer  $\text{ReS}_2$ . A shift in the excitonic peaks by about 0.8 eV introduced by solving the Bethe-Salpeter equation indicates strong contribution from excitonic bound states in this transition metal dichalcogenide.

**12:03PM F15.00005 First-principles Study of Temperature Dependence of Energy Gap in 2D Materials<sup>1</sup>**, YUNING WU, XIAOGUANG ZHANG, Department of Physics and Quantum Theory Project, University of Florida — We use a first-principles method to study the temperature dependence of energy gap in 2D semiconductors, including monolayer  $\text{MoS}_2$  and  $\text{MoSe}_2$ , etc, due to the effect of phonons on the band structure. The phonon vibrations are modeled by a set of frozen-phonon configurations, in which atomic displacements are determined by the Bose-Einstein distribution of the phonon modes. The electronic structure is calculated for each configuration, and the energy gap is extracted from configurational statistics. Calculated temperature dependence of energy gap agrees with the photoluminescence experiments [1] in terms of both the values of the band gap as well as the line shapes. [1] S. Tongay *et al.*, Nano Lett. 12, 5576, (2012)

<sup>1</sup>This work is supported by NSF grant 1508898

**12:15PM F15.00006 Ab initio studies of excitations in monolayer black phosphorus<sup>1</sup>**, TOBIAS FRANK, MARCIN KURPAS, MARTIN GMITRA, University of Regensburg, RENE DERIAN, IVAN STICH, Inst. of Physics, Slovak Academy of Sciences, JAROSLAV FABIAN, University of Regensburg — Monolayer black phosphorus, or phosphorene, represents an ideal system to study many-body electron-electron and electron-hole interactions due to its strong anisotropy driven 1d electronic nature. In particular, the size of the fundamental band gap value and excitonic binding energies remain unresolved given the different gap values of 1.6 to 2.4 eV [1] obtained by many-body GW calculations. We present our contribution to this issue studying excitations in phosphorene employing quantum monte carlo (QMC) calculations. We show the evolution of finite size effects of the fundamental and optical gap, with respect to relatively large supercell sizes in the theoretical framework of diffusion monte carlo (DMC) explicitly including electronic correlations. Our studies point to a significant influence of electron correlation on the fundamental gap as well as to a strong anisotropic nature of the excitonic state. Furthermore we address the question of a multiconfigurational ground state in monolayer black phosphorus. [1] A. N. Rudenko, Shengjun Yuan, and M. I. Katsnelson, Phys. Rev. B 92 085419 (2015)

<sup>1</sup>This work is supported by the DFG GRK 1570, SFB 689, and European Union Seventh Framework Programme under Grant Agreement No. 604391 Graphene Flagship.

**12:27PM F15.00007 Prediction of two-dimensional van der Waals ferroelectric materials**, WENJUN DING, JIANBAO ZHU, University of Science and Technology of China, YANFEI GAO, University of Tennessee, DI XIAO, Carnegie Mellon University, YI GU, Washington State University, ZHENYU ZHANG, WENGUANG ZHU, University of Science and Technology of China — Based on density functional theory calculations, we discover a class of two-dimensional van der Waals ferroelectric materials with spontaneous out-of-plane electric polarization, and the orientation of the electric polarization can be reversed by a seemingly lateral shift of a single atomic layer. We further find that the electronic structures of a bilayer of such two-dimensional ferroelectric materials can be switched to be either semiconducting or metallic, depending on their relative orientations of the electric polarization. This finding expands the family of the two-dimensional materials with ferroelectricity and offers new opportunities to tune the properties of van der Waals heterostructures for practical device applications.

**12:39PM F15.00008 Giant piezoelectricity of monolayer group IV monochalcogenides.**, RUIXIANG FEI, Department of Physics, Washington University, WENBIN LI, Research Laboratory of Electronics, Massachusetts Institute of Technology, JU LI, Department of Nuclear Science and Engineering and Department of Materials Science and Engineering, Massachusetts Institute of Technology, LI YANG, Department of Physics, Washington University — We predict enormous, anisotropic piezoelectric effects in intrinsic monolayer group IV monochalcogenides ( $\text{MX}$ ,  $\text{M}=\text{Sn}$  or  $\text{Ge}$ ,  $\text{X}=\text{Se}$  or  $\text{S}$ ), including  $\text{SnSe}$ ,  $\text{SnS}$ ,  $\text{GeSe}$ , and  $\text{GeS}$ . Using first-principle simulations based on the modern theory of polarization, we find that their piezoelectric coefficients are about one to two orders of magnitude larger than those of other 2D materials, such as  $\text{MoS}_2$  and  $\text{GaSe}$ , and bulk quartz and  $\text{AlN}$  which are widely used in industry. This enhancement is a result of the unique “puckered”  $\text{C}_{2v}$  symmetry and electronic structure of monolayer group IV monochalcogenides. Given the achieved experimental advances in the fabrication of monolayers, their flexible character, and ability to withstand enormous strain, these 2D structures with giant piezoelectric effects may be promising for a broad range of applications such as nano-sized sensors, piezotronics, and energy harvesting in portable electronic devices.

**12:51PM F15.00009 ABSTRACT WITHDRAWN —**

**1:03PM F15.00010 Structural variability and electronic properties of bulk and monolayer Si<sub>2</sub>Te<sub>3</sub>**<sup>1</sup>, COREY COMBS, University of Tennessee Knoxville Department of Materials Science and Engineering, Vanderbilt University Department of Physics and Astronomy, XIAO SHEN, Vanderbilt University Department of Physics and Astronomy, University of Memphis Department of Physics and Materials Science, YEVGENIY PUZYREV, LIDA PAN, Vanderbilt University Department of Physics and Astronomy, SOKRATES PANTELIDES, Vanderbilt University Department of Physics and Astronomy, Oak Ridge National Laboratory Materials Science and Technology Division — Silicon telluride, a layered material recently experimentally made to a few atomic layer-thick (1) has intriguing variations of optical and electronic properties, associated with the flexibility of its structure. In Si<sub>2</sub>Te<sub>3</sub>, the Te atoms form a hexagonal close packed structure, while Si atoms form Si-Si dimers and fill 2/3 of the allowed sites. There are 4 possible orientations of the Si-Si dimers, 3 in-plane directions 60 degrees to each other and one out-of-plane direction perpendicular to 2D plane. X-ray and electron diffraction data on bulk Si<sub>2</sub>Te<sub>3</sub> suggested that 1/4 of the dimers are vertical while the other 3/4 of the dimers are randomly oriented horizontally. We performed density functional calculations to show that both bulk and monolayer Si<sub>2</sub>Te<sub>3</sub> exhibit large variations in properties, resulting from reorientation of silicon dimers. These variations are up to 5 percent in lattice constant and up to 40 percent in electron band gap. Transition of Si<sub>2</sub>Te<sub>3</sub> from bulk to monolayer configuration also shows an increase in the band gap and lattice constant. We show that these properties are, in principle, controllable by temperature and strain, making Si<sub>2</sub>Te<sub>3</sub> a promising candidate as optomechanical and optoelectronic material. (1) Keuleyan, S. et al. *Nano Lett.* 2015, 15 (4), 2285-2290.

**1:15PM F15.00011 Effect of functionalization on the electronic and atomic properties of layered MXenes**, KURT FREDRICKSON, Stanford University, ALEKSANDRA VOJVODIC, SLAC National Accelerator Laboratory, JENS NRSKOV, Stanford University — MXenes (M = Transition Metal, X = C or N) are a promising family of materials that have been recently manufactured from MAX phases. MXenes have already been shown as promising candidates for use in lithium ion batteries, supercapacitors, and fuel cells (1). MXenes consist of M<sub>1-x</sub>X<sub>2-x</sub>(x-1), two-dimensional sheets weakly bound by van der Waals forces. However, due to the selective removal of the A ion to manufacture MXenes, they are highly reactive, with a wide variety of possible functional groups. Previous studies have shown that the electronic properties of MXene single sheets are highly dependent on their functionalization, but so far there are few studies on the effect of functionalization of the bulk phase of MXene, which consists of many layers of MXenes bound together. In this talk, we will illustrate the effect of functionalization of bulk MXenes by H, H<sub>2</sub>, OH, and O for Mo<sub>2</sub>C and Ti<sub>2</sub>C. We will also show the effect of applied potential on the functionalization of Mo<sub>2</sub>C and Ti<sub>2</sub>C. Finally, we will compare our results with experimental measurements. (1) M. Naguib, V.D. Mochalin, M.W. Barsoum and Y. Gogotsi, *Adv. Mater.* 26, 992 (2014).

**1:27PM F15.00012 Single layer lead iodide: computational exploration of structural, electronic and optical properties, strain induced band modulation and the role of spin-orbital-coupling**, MEI ZHOU, WENHUI DUAN, Department of Physics and State Key Laboratory of Low-dimensional Quantum Physics, Tsinghua University, Beijing 100084, China, YING CHEN, Institute for Frontier Materials, Deakin University, Waurn Ponds, VIC 3216, Australia, AIJUN DU, School of Chemistry, Physics and Mechanical Engineering, Queensland University of Technology, Brisbane, QLD 4001, Australia — Graphitic like layered materials exhibit intriguing electronic structures and the search for new types of two-dimensional (2D) monolayer materials is of great interest for developing novel nano-devices. By using density functional theory method, we investigate the structure, stability, electronic and optical properties of monolayer lead iodide (PbI<sub>2</sub>). The stability of PbI<sub>2</sub> monolayer is first confirmed by phonon dispersion calculation. Compared to the calculation using generalized gradient approximation, screened hybrid functional and spin-orbit coupling effects can predicts an accurate band gap (2.63 eV). The biaxial strain can tune its band gap size in a wide range from 1 eV to 3 eV, which can be understood by the strain induced uniformly change of electric field between Pb and I atomic layer. The calculated imaginary part of the dielectric function of 2D graphene/PbI<sub>2</sub> van der Waals type hetero-structure shows significant red shift of absorption edge compared to that of a pure monolayer PbI<sub>2</sub>. Our findings highlight a new interesting 2D material with potential applications in nanoelectronics and optoelectronics.

**1:39PM F15.00013 Two-dimensional silicon and carbon monochalcogenides with the structure of phosphorene**, DARIO ROCCA, ALI ABOUD, SÉBASTIEN LEBÈGUE, Université de Lorraine and CNRS, Nancy (France), GANAPATHY VAITHEESWARAN, University of Hyderabad, Hyderabad (India) — Phosphorene has recently attracted interest for applications in transistors and photodetectors. Inspired by this material we carried out an ab initio study to predict new binary materials with a structure similar to phosphorene. Specifically, carbon or silicon atoms and chalcogen atoms (up to Te) were combined to form a phosphorene-like monolayer. The structure of these new compounds was then optimized and the dynamical stability of the structures was demonstrated by computing phonon dispersion curves. A series of materials were found to be stable: CS, CSe, CTe, SiO, SiS, SiSe, and SiTe. Electronic properties such as band gaps and effective masses were computed at the density functional theory level. By using the accurate HSE hybrid functional it was found that these materials span a broad range of bandgaps, going from the 2.1 eV of SiS to the 0.55 eV of SiTe. The effective masses were also computed; similarly to phosphorene, a strong anisotropy was found when comparing the zigzag and armchair directions. The variety of electronic properties found for these systems will contribute to broaden the technological applicability of two dimensional materials.

**1:51PM F15.00014 Electron counting and a large family of two-dimensional semiconductors**, MAOSHENG MIAO, Department of Chemistry and Biochemistry, California State University Northridge, JORGE BOTANA, Beijing Computational Science Research Center, EVA ZUREK, Department of Chemistry, University at Buffalo, JINGYAO LIU, Institute of Theoretical Chemistry, Jilin University, WEN YANG, Beijing Computational Science Research Center — Two-dimensional semiconductors (2DSC) are currently the focus of many studies, thanks to their novel and superior transport properties that may greatly influence future electronic devices. The potential applications of 2DSCs range from low-dimensional electronics, topological insulators and valleytronics all the way to novel photolysis. However, compared with the conventional semiconductors that are comprised of main group elements and cover a large range of band gaps and lattice constants, the choice of 2D materials is very limited. In this work, we propose and demonstrate a large family of 2DSCs, all adopting the same structure and consisting of only main group elements. Using advanced density functional calculations, we demonstrate the attainability of these materials, and show that they cover a large range of lattice constants, band gaps and band edge states, making them good candidate materials for heterojunctions. This family of two dimensional materials may be instrumental in the fabrication of 2DSC devices that may rival the currently employed 3D semiconductors.

**2:03PM F15.00015 Highly anisotropic Dirac fermions in square graphynes**, LIZHI ZHANG, Univ of Electronic Sci & Tech / University of Utah, ZHENGFEI WANG, University of Science and Technology of China, JIANSHENG RAO, ZIHENG LI, WULIN HUANG, ZHIMING WANG, Univ of Electronic Sci & Tech, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, FENG LIU, University of Utah — Recently, there have been intense search of new 2D materials, and one especially appealing class of 2D materials is the all-carbon allotropes of Dirac materials. Here, we predict a new family of 2D carbon allotropes, square graphynes (S-graphynes) that exhibit highly anisotropic Dirac Fermions, using first-principle calculations within density functional theory. The equal-energy contour of their 3D band structure shows a crescent shape, and the Dirac crescent has varying Fermi velocities from 0.6 10<sup>5</sup> to 7.2 10<sup>5</sup> m/s along different k directions. Near the Fermi level, the Dirac crescent can be nicely expressed by an extended 2D Dirac model Hamiltonian. Furthermore, tight-binding band fitting reveals that the Dirac crescent originates from the next-nearest-neighbor interactions between C atoms. Our findings enrich the Dirac physics founded in other 2D Dirac systems, and offer a new design mechanism for creating Dirac band by tuning the interaction range. We envision that the highly anisotropic Dirac crescent may be exploited in all-carbon-based electronic devices for manipulating anisotropic electron propagation.

**Tuesday, March 15, 2016 11:15AM - 2:15PM –**

**Session F16 DMP: Exciton Dynamics in 2D Semiconductors** 315 - Xiaobo Yin, University of Colorado, Boulder

**11:15AM F16.00001 Interlayer Exciton Lifetimes in MoSe<sub>2</sub>/WSe<sub>2</sub> Heterostructures**, KYLE SEYLER, No Company Provided, PASQUAL RIVERA, University of Washington, HONGYI YU, University of Hong Kong, JOHN SCHABILEY, University of Washington, JIAQIANG YAN, DAVID MANDRUS, University of Tennessee, Oak Ridge National Lab, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington — Semiconductor heterostructures of two-dimensional (2D) transition-metal dichalcogenides (TMDs) have emerged as an exciting new platform for novel device engineering and physics. A fundamental question for the field is how the strong Coulomb interactions, electronic structure, and underlying valley physics affect the optoelectronic response. While researchers have made significant progress in understanding intralayer exciton dynamics in monolayer TMDs, there is comparatively little understanding of the interlayer excitons that form in their heterostructures. In this talk, we will report on time-resolved photoluminescence experiments of interlayer excitons in MoSe<sub>2</sub>/WSe<sub>2</sub> vertical heterostructures, which show wide tunability with gate and variability with emission energy. We will also discuss the underlying mechanisms for this behavior and show how it can be utilized to generate long-lived valley excitons.

**11:27AM F16.00002 Coupled spin-valley-dynamics in single-layer transition metal dichalcogenides**, GERD PLECHINGER, PHILIPP NAGLER, CHRISTIAN SCHÜLLER, TOBIAS KORN, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, D-93040 Regensburg, Germany — Single layers of transition metal dichalcogenides (TMDCs) like MoS<sub>2</sub> and WS<sub>2</sub> can be produced by simple mechanical exfoliation. Offering a direct bandgap at the K-points in the Brillouin zone, they represent a promising semiconductor material for flexible and transparent optoelectronic applications. Due to inversion symmetry breaking together with strong spin-orbit-interaction, the valley and spin degrees of freedom are coupled in monolayer TMDCs. Via circularly polarized optical excitation, an efficient polarization of the  $K^+$  or the  $K^-$  valley can be generated. Here, we investigate the dynamics of these coupled spin-valley polarizations in monolayer MoS<sub>2</sub> and WS<sub>2</sub> by means of photoluminescence spectroscopy and time-resolved Kerr rotation (TRKR). The results indicate a maximum achievable spin-valley-lifetime in these materials exceeding one nanosecond at low temperatures. Furthermore, we extract the dependence of the spin-valley lifetime on temperature. By varying the excitation energy, we reveal the excitonic resonances as well as the spin-polarized bandstructure around the K valleys common to monolayer TMDCs.

**11:39AM F16.00003 Measurements of ultrafast luminescence dynamics in transition metal dichalcogenide monolayers**, CEDRIC ROBERT, GANG WANG, DELPHINE LAGARDE, ANDREA BALOCCHI, THIERRY AMAND, PIERRE RENUCCI, FABIAN CADIZ, BERNHARD URBASZEK, XAVIER MARIE, CNRS/INSA Toulouse — We report time resolved photoluminescence (PL) measurements using a synchro-scan streak camera system with sub-ps time resolution, the fastest detector currently available for PL. The strong electron-hole Coulomb interaction in monolayer (ML) transition metal dichalcogenides results in excitons with high binding energies and oscillator strength. Therefore very short intrinsic radiative lifetimes can be expected. Here measurements with few ps time resolution are crucial. In our experiment we excite the ML sample with a fs laser pulse in a cryostat (T=4300 K). In the model system ML MoSe<sub>2</sub> we can separate spectrally the neutral and the charged exciton and perform detailed time-resolved PL studies on each complex. For the neutral exciton we resolve a PL emission time as short as 2ps, previous measurements were limited by the detector time-resolution. This short time depends on the experimental conditions such as temperature and applied external fields. We will discuss the different competing relaxation and recombination mechanisms, such as the intrinsic radiative recombination, the escape from the light cone through phonon scattering, the interplay between bright and dark exciton states and the possible transfer from the neutral to the charged exciton at lower energy.

**11:51AM F16.00004 Exciton Dynamics on Suspended and Substrate-supported MoS<sub>2</sub> and WS<sub>2</sub> Monolayers.**<sup>1</sup>, CHAO XU, YILING YU, YIFEI YU, ANDY BARRETTE, LINYOU CAO, KENAN GUNDOGDU, North Carolina State University, KENAN GUNDOGDU TEAM, LINYOU CAO TEAM — MoS<sub>2</sub> and WS<sub>2</sub> monolayers are promising atomic-scale platform for novel light emission devices, however, despite perfect surface passivation and strong exciton binding energy, their luminescence efficiencies are very low. Here, through the observation of exciton dynamics by ultrafast transient reflection, we revealed that the substrate can affect the exciton dynamics on MoS<sub>2</sub> and WS<sub>2</sub> monolayers, by facilitating the non-radiative recombination pathways, thus reducing the luminescence efficiency. Furthermore, strong many-body interactions such as exciton-exciton annihilation, are enhanced on suspended MoS<sub>2</sub> and WS<sub>2</sub> monolayers, whereas the defects in substrates may efficiently quench excitons thus mitigate those effects.

**12:03PM F16.00005 Observation of excitonic Floquet states in a monolayer transition metal dichalcogenide**, EDBERT J. SIE, XI LING, MIT, YI-HSIEN LEE, NTHU Taiwan, LIANG FU, JING KONG, NUH GEDIK, MIT — Quantum systems that are driven by a time-periodic potential can form a series of new states that are called the Floquet states. In solids, the realization of Floquet states is rare and fascinating because it contains novel features that could be hybridized to create a new phase of matter. To date, such observation is limited to a recent experiment on a topological insulator (Y. H. Wang et al., Science 342, 453 (2013)). In this talk, we will show the observation of Floquet states from the excitons in a monolayer transition metal dichalcogenide that is performed using ultrafast optical spectroscopy. We will discuss the generation mechanism of these Floquet states as well as the significance of these observations.

**12:15PM F16.00006 Optical polarization and intervalley scattering in single layers of MoS<sub>2</sub> and MoSe<sub>2</sub>**<sup>1</sup>, BEREND JONKER, Naval Research Laboratory, GEORGE KIOSEOGLU, University of Crete, AUBREY HANBICKI, MARC CURRIE, ADAM FRIEDMAN, Naval Research Laboratory, NRL / U. CRETE COLLABORATION, NRL / U. CRETE COLLABORATION — We probe the valley population dynamics in MoSe<sub>2</sub> and MoS<sub>2</sub> by selectively populating the K and K' valleys with circularly polarized light while systematically varying the laser excitation energy. For both systems, the difference in the excitation energy and photoluminescence emission energy,  $dE = E_{\text{pump}} - E_{\text{PL}}$ , governs the depopulation of carriers in each valley. Adding more energy above a distinct threshold characteristic of the longitudinal acoustic (LA) phonon for each material enables inter-valley scattering and produces a sharp decrease in the observed circular polarization. LA phonons in these two systems have different energies (30 meV for MoS<sub>2</sub> and 19 meV for MoSe<sub>2</sub>), and we show that the threshold for the excess energy required to initiate the depolarization process clearly reflects the material specific phonon energy. In addition, our results show that independent of how many carriers are excited, i.e. whether you create neutral or charged excitons, the scattering process is the same. We find that the key parameter for the depolarization process is the extra kinetic energy of the exciton — depolarization is due to intervalley scattering that begins to occur when the exciton energy exceeds a threshold corresponding to twice the LA phonon energy.

**12:27PM F16.00007 Coherent Exciton Dynamics in Atomically Thin Semiconductors**, XIAOQIN (ELAINE) LI, Univ of Texas, Austin — The near band-edge optical response of an emerging class of semiconductors, known as the transitional metal dichalcogenides (TMDs), is dominated by tightly-bound excitons and charged excitons (i.e. trions). A fundamental property of these quasiparticles (excitons and trions) is quantum decoherence time, which reflects irreversible quantum dissipation arising from system (excitons and trions) and bath (vacuum and other quasiparticles) interactions and determines the timescale during which excitons can be coherently manipulated. Dephasing time is also equivalent to the intrinsic homogeneous linewidth of exciton resonance. In addition, excitons in TMDs are localized at the corners of the Brillouin zone and provide a convenient way to optically manipulate the valley degree of freedom, which may act as a useful information carrier analogous to electronic charge or spin. Direct measurement of valley coherence time is challenging because it corresponds to a non-radiative coherence between two degenerate states. Using ultrafast multi-dimensional optical spectroscopy, we investigate the intrinsic homogeneous linewidth of excitons, exciton valley coherence as well as coupling between excitons and trions. Our studies reveal coherent electronic dynamics on the order of  $\sim 100$  fs in monolayer TMDs. We gratefully acknowledge financial support from NSF, AFOSR, and the Welch Foundation.

**1:03PM F16.00008 Ultrafast Manipulation of the Valley Coherence in Monolayer WSe<sub>2</sub>**, ZILIANG YE, DEZHENG SUN, TONY HEINZ, Departments of Applied Physics and Photon Science, Stanford University — The valley degree of freedom in solids has been proposed as a pseudospin carrier for the future quantum electronics. Valley polarization has been created in transition metal dichalcogenide monolayers using circularly polarized light and the existence of coherence in the valley exciton pseudospin has been experimentally demonstrated<sup>1</sup>. The degeneracy of the valley degeneracy has recently been lifted both by the application of magnetic fields and dynamically by the optical Stark effect with circularly polarized light<sup>2–3</sup>. Here we demonstrate the all-optical manipulation of valley exciton coherence, i.e., of the valley exciton pseudospin, by the optical Stark effect. Using below-bandgap circularly polarized light, we rotate the valley exciton pseudospin on the femtosecond time scale. Both the direction and speed of the rotation can be optically controlled by tuning the dynamic phase of excitons in opposite valleys. In addition, by varying the time delay between the excitation and control pulses, we probe the lifetime of the intervalley coherence in monolayer WSe<sub>2</sub>.

**1:15PM F16.00009 Probing ultrafast valley dynamics in 2D semiconductors via time-resolved Kerr rotation**, JIANI HUANG, THANG HOANG, Department of Physics and Center for Metamaterials and Integrated Plasmonics, Duke University, TIAN MING, JING KONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, MAIKEN MIKKELSEN, Department of Physics and Department of Electrical and Computer Engineering, Duke University — Monolayer transition metal dichalcogenides (TMDs) offer a tantalizing platform for controlling spin and valley degrees of freedom, enabling future optoelectronic devices with enhanced and novel functionalities. Here, we experimentally probe the valley dynamics in monolayer MoS<sub>2</sub> and WSe<sub>2</sub> using time-resolved Kerr rotation (TRKR) from  $T = 10$  K to 300 K. This pump-probe technique offers sub-picosecond temporal resolution, providing insight into ultrafast valley dynamics inaccessible by polarized and time-resolved photoluminescence spectroscopy. Bi-exponential decay dynamics were observed for both materials at low temperatures. Strong long-range exchange interactions between the K valleys led to a rapid exciton valley depolarization time ( $< 10$  ps), while the valley polarization of the trion and defect states decays within several tens of ps. Moreover, spatial distributions of the TRKR amplitude across monolayer flakes indicated weaker valley polarizations near the edges of MoS<sub>2</sub>, which is likely associated with the Mo- or S-zigzag terminations at the boundaries. These temporal and spatial TRKR measurements reveal insight into the complex dynamics of valley excitonic states in monolayer TMDs.

**1:27PM F16.00010 Intervalley double resonance processes in MoS<sub>2</sub>**, YUANXI WANG, Pennsylvania State University, BRUNO CARVALHO, LEANDRO MALARD, CRISTIANO FANTINI, Universidade Federal de Minas Gerais, VINCENT CRESPI, Pennsylvania State University, MARCOS PIMENTA, Universidade Federal de Minas Gerais — Intervalley scattering plays a significant role in electronic energy dissipation in semiconductors. We investigate the intervalley scattering of monolayer and few-layer MoS<sub>2</sub>, by combining density functional theory calculations and resonant Raman spectroscopy probed by up to 20 laser excitation energies. We observe that two Raman peaks within  $420\text{--}460\text{ cm}^{-1}$  are dispersive over a small range of laser energy, a clear signature of second-order processes involving intervalley scattering. Both modes involve LA and TA phonons at or near the K point. A third Raman peak at  $466\text{ cm}^{-1}$  shows a strong intensity dependence on the layer number and is assigned 2LA(M). Our results invalidate previous Raman peak assignment proposals and open up a better understanding of double resonance processes in transition metal dichalcogenides.

**1:39PM F16.00011 Interlayer Interaction Effects and Spin-Pseudospin Transfer in 2D MoSe<sub>2</sub>-WSe<sub>2</sub> Heterostructures**<sup>1</sup>, JOHN SCHABLEY, PASQUAL RIVERA, KYLE SEYLER, University of Washington, HONGYI YU, University of Hong Kong, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory, University of Tennessee, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington — Heterostructures composed of MoSe<sub>2</sub>-WSe<sub>2</sub> monolayer semiconductors host spatially indirect interlayer excitons, which are bound states of an electron in the MoSe<sub>2</sub> layer and a hole in the WSe<sub>2</sub> layer. Interlayer excitons are observable in photoluminescence experiments as a low energy peak whose spectral position is consistent with the predicted type-II band alignment. The electron and hole which form the interlayer exciton are localized in momentum space valleys that occur at the (K and -K) corners of the Brillouin zone. To probe this interlayer valley physics, we perform two color pump-probe measurements to investigate the interactions between intralayer excitons in the heterostructure, resonantly pumping excitons in one layer and probing excitons in the other layer. We observe evidence of interlayer interaction effects in the nonlinear differential reflection spectra. Polarization dependent spectroscopy reveals evidence of interlayer spin-valley pseudospin transfer.

<sup>1</sup>We gratefully acknowledge support from the DOE, NSF, Cottrell Scholar Award, Croucher Foundation, and RGC of Hong Kong.

**1:51PM F16.00012 The role of collective motion in the ultrafast charge transfer in van der Waals heterostructures.**, HAN WANG, Rensselaer Polytechnic Institute, JUNHYEOK BANG, Spin Engineering Physics Team, Korea Basic Science Institute (KBSI), YIYANG SUN, Rensselaer Polytechnic Institute, LIANGBO LIANG, Oak Ridge National Laboratory, DAMIEN WEST, VINCENT MEUNIER, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — The success of van der Waals (vdW) heterostructures made of graphene, metal dichalcogenides, and other layered materials, hinges on the understanding of charge transfer across the interface as the foundation for new device concepts and applications. In contrast to conventional heterostructures, where a strong interfacial coupling is essential to charge transfer, recent experimental findings indicate that vdW heterostructures can exhibit ultra-fast charge transfer despite the weak binding of these heterostructures. Using time-dependent density functional theory molecular dynamics, we find that the collective motion of excitons at the interface lead to plasma oscillations associated with optical excitation. Furthermore, instability of these oscillations explain the rapid charge transfer across the interface and are shown to be a general feature of vdW heterostructures provided they have a critical minimum dipole coupling. Application to the MoS<sub>2</sub>/WS<sub>2</sub> heterostructure yields good agreement with experiment, indicating near complete charge transfer within a timescale of 100 fs.

**2:03PM F16.00013 Layer- and Frequency-dependent Second-harmonic Generation from GaSe Atomic Crystals<sup>1</sup>**, YANHAO TANG, JOHN A. MCGUIRE, CHIH WEI LAI, Department of Physics and Astronomy, Michigan State University, KRISHNA C. MANDAL, Department of Electrical Engineering, University of South Carolina — GaSe is a layered semiconductor with an indirect bandgap at about 2.0 eV only ~20 meV below the direct bandgap at room temperature. Atomically thin GaSe crystals are expected to exhibit an increasing bandgap. This can be probed through the strong nonlinear optical response of GaSe. We report optical second-harmonic generation (SHG) in reflection from GaSe atomic crystals of 1 to > 100 layers on a Si substrate with a 90 nm SiO<sub>2</sub> layer. Room-temperature measurements were performed with fundamental photon energies of 0.85 to 1.4 eV as well as at 1.58 eV. By accounting for multilayer interference, the layer-dependent SHG intensity data are fit to obtain the magnitude of the second-order nonlinear optical susceptibility,  $\chi^{(2)}$ . For samples thicker than ~7 layers, we find  $|\chi^{(2)}| = 80 \pm 18$  pm/V, consistent with reported values for bulk GaSe. For samples  $\leq 6$  layers,  $|\chi^{(2)}|$  is reduced compared to that in thicker samples and shows a minimum in trilayer samples. The frequency-dependence of the SHG response suggests that this reduction of  $|\chi^{(2)}|$  in the few-layer region is due to increase of the direct bandgap.

**11:15AM F17.00001 hBN/graphene heterostructures for spectroscopy studies in normal and superconducting regime**, RICCARDO PISONI, Massachusetts Institute of Technology/Politecnico di Milano, JOEL I-JAN WANG, Massachusetts Institute of Technology/Harvard School of Engineering and Applied Sciences, LANDRY BRETHERAU, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS), Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Tunneling spectroscopy is a powerful tool to study the electronic properties of materials, as it has the capability of probing the electronic density of states at energies away from the Fermi level. Though local probes, such as scanning tunneling spectroscopy (STS), are widely used to elucidate the novel electronic properties of graphene, planar (2-D to 2-D) tunneling is also desirable for its capability to probe the global behavior of a 2-D electronic system. To study the intrinsic properties of the material via tunneling, one must employ a proper tunneling barrier and minimize the local doping introduced by the tunneling. Here we present a fabrication technique involving ultra thin hexagonal Boron Nitride (hBN) as both a tunneling barrier and an encapsulation overlayer to protect the 2-D Van der Waals material under study. In particular we focus on the fabrication of ultra thin hBN/graphene/hBN Van der Waals heterostructures that allows us to perform tunneling spectroscopy in graphene in normal and superconducting regime.

**11:27AM F17.00002 New Method of fabricating high-mobility graphene/LaAlO<sub>3</sub>/SrTiO<sub>3</sub> nanostructures<sup>1</sup>**, SHIVENDRA TRIPATHI, GIRIRAJ JNAWALI, LU CHEN, MENGCHENG HUANG, JEN-FENG HSU, BRIAN D'URSO, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Graphene and LaAlO<sub>3</sub>/SrTiO<sub>3</sub> (LAO/STO) are both two-dimensional electronic systems with a fascinating range of properties. The coupling between these two 2DEGs has the potential to produce various novel phenomena and create new functionalities. Successful integration of these two systems must overcome a number of technical challenges. Graphene-complex-oxide (GCO) heterostructures are created using Hyflon AD (2,2,4-trifluoro-5 trifluoromethoxy-1,3 dioxole) as a support layer for transferring and patterning CVD graphene on LAO/STO. This approach has advantages over more traditional methods that use Poly(Methyl Methacrylate) (PPMA) to transfer CVD graphene in that the Hyflon is easier to remove from the oxide surface after processing. To test the quality of GCO heterostructures, a graphene Hall bar structure is created. The quantum Hall regime can routinely be reached in the graphene layer, while preserving the ability of the LAO/STO to be patterned using AFM lithography. This approach opens up the possibility for the exploration of a wide range of GCO devices.

**11:39AM F17.00003 Tunneling Spectroscopy of Andreev states in Graphene**, LANDRY BRETHERAU, Massachusetts Institute of Technology (MIT), USA, JOEL I-JAN WANG, Massachusetts Institute of Technology (MIT), USA / Harvard University (USA), RICCARDO PISONI, Massachusetts Institute of Technology (MIT), USA / Politecnico di Milano (Italy), KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS), Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology (MIT), USA — Although not intrinsically superconducting, graphene (G) can inherit electronic properties of a superconductor (S) placed in good contact with it. This proximity effect originates from the formation in the graphene of entangled electron-hole states, the Andreev states. In an S-G-S geometry, the Andreev states energies depend on the difference between the order parameter phases of the two superconductors. Such a phenomenon is usually probed by measuring the dissipationless Josephson supercurrent carried by Andreev states. Here instead, we have performed a direct tunneling spectroscopy of graphene connected to two superconducting electrodes, in a SQUID geometry that enables us to vary the phase difference. The measured energy spectra are consistent with a continuum of Andreev bound states modulating with phase with energies smaller than the superconducting gap. Interestingly, out of gap modulation is also observed and can be interpreted as Andreev scattering states. Additionally, we discuss how these phenomena evolve as a function of graphene normal DOS, which is tuned by a back-gate electrode.

**11:51AM F17.00004 Specular Interband Andreev Reflections in Graphene**, KONSTANTIN B. EFETOV, Ruhr-Universitaet Bochum, DMITRI EFETOV, Massachusetts Institute of Technology, LEI WANG, Columbia University, GIL-HO LEE, Harvard University, JIA SHUANG, ROBERT CAVA, Princeton University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS Japan, JAMES HONE, CORY DEAN, Columbia University, PHILIP KIM, Harvard University — Electrons incident from a normal metal onto a superconductor are reflected back as holes – a process called Andreev reflection. In a normal metal where the Fermi energy is much larger than a typical superconducting gap, the reflected hole retraces the path taken by the incident electron. In graphene with ultra- low disorder, however, the Fermi energy can be tuned to be smaller than the superconducting gap. In this unusual limit, the holes are expected to be reflected specularly at the superconductor-graphene interface due to the onset of interband Andreev processes, where the effective mass of the reflected holes change sign. Here we present measurements of gate modulated Andreev reflections across the low disorder van der Waals interface formed between graphene and the superconducting NbSe<sub>2</sub>. We find that the conductance across the graphene/superconductor interface exhibits a characteristic suppression when the Fermi energy is tuned to values smaller than the superconducting gap, a hallmark for the transition between intraband retro and interband specular- Andreev reflections.

**12:03PM F17.00005 Spin superconductivity and ac-Josephson effect in Graphene system under strong magnetic field**, HAIWEN LIU, International Center for Quantum Materials and School of Physics, Peking University, Beijing 100871, China, HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China, QING-FENG SUN, X. C. XIE, International Center for Quantum Materials and School of Physics, Peking University, Beijing 100871, China, COLLABORATIVE INNOVATION CENTER OF QUANTUM MATTER, BEIJING, CHINA COLLABORATION — We study the spin superconductivity in Graphene system under strong magnetic field. From the microscopically Gor'kov method combined with the Aharonov-Casher effect, we derive the effective Landau-Ginzburg free energy and analyze the time evolution of order parameter, which is confirmed to be the off-diagonal long range order. Meanwhile, we compare the ground state of spin superconductivity to the canted-antiferromagnetic state, and demonstrate the equivalence between these two states. Moreover, we give out the pseudo-field flux quantization condition of spin supercurrent, and propose an experimental measurable ac-Josephson effect of spin superconductivity in this system.

**12:15PM F17.00006 Ballistic and diffusive regimes in current-phase relations of graphene SNS heterojunctions**, PHILIP KRATZ, Stanford University, FRANCOIS AMET, Duke University, CHRISTOPHER WATSON, Stanford University, KATHRYN MOLEK, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, CHUNG KE, Duke University, Durham, IVAN BORZENETS, University of Tokyo, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, RUSSELL DEACON, (CEMS), RIKEN, MICHIOHISA YAMAMOTO, University of Tokyo, YURIY BOMZE, Duke University, SEIGO TARUCHA, University of Tokyo, GLEB FINKELSTEIN, Duke University — Current-phase relations (CPRs) are an indirect measurement of the energy distribution of phase-coherent modes in Josephson junctions through the spectral supercurrent near equilibrium, probing low-energy excitations not accessible by transport. We report on planned experimental measurements of the CPRs of gated, high-mobility ( $10^5 \text{ cm}^2/\text{Vs}$ ) single-layer graphene SNS heterojunctions in ring geometries with superconducting MoRe alloy contacts, inductively read out with a scanning superconducting quantum interference device (SQUID) magnetometer. The graphene layers are encapsulated on both sides with hexagonal-BN (h-BN). We will address the CPR dependence on experimentally tunable parameters (temperature, carrier density, and channel length), and possible crossovers between the ballistic and diffusive regimes.

**12:27PM F17.00007 The role of double  $\text{TiO}_2$  layers at the interface of  $\text{FeSe}/\text{SrTiO}_3$  superconductors**, KE ZOU, Department of Applied Physics and Center for Research on Interface Structures and Phenomena (CRISP), Yale University, New Haven CT 06520, USA — The marked enhancement of the superconducting critical temperature for FeSe grown on  $\text{SrTiO}_3$  (STO) is a notable recent discovery in the field of high temperature superconductivity. A complete understanding of the mechanism for this enhancement has not been elucidated and is thought to be due to how the electronic structure is modified by the interface. We determine the surface reconstruction of  $\text{SrTiO}_3$  that is used to achieve superconducting FeSe films in experiments. In particular, we observe the existence of a double  $\text{TiO}_2$  layer and identify the symmetry of the reconstruction at the  $\text{FeSe}/\text{SrTiO}_3$  interface. The double  $\text{TiO}_2$  layer plays two important roles. First, it facilitates epitaxial growth of FeSe films. Second, *ab initio* calculations reveal that electron transfer to the FeSe is enhanced by the double layer termination more strongly than by other surface structures of  $\text{SrTiO}_3$ . The enhanced electron transfer suppresses the hole pocket near the  $\Gamma$  point, leading to a band structure characteristic of superconducting samples. The characterization of the interface structure presented here is a key step towards understanding the electronic properties of this novel superconductor.

**1:03PM F17.00008 Josephson Coupling in  $\text{Nb}/\text{SmB}_6/\text{Nb}$  Junctions<sup>1</sup>**, XIAOHANG ZHANG, SEUNGHUN LEE, CNAM, MSE, and Physics, University of Maryland, College Park, JASPER DRISKO, JOHN CUMINGS, MSE, University of Maryland, College Park, RICHARD GREENE, CNAM and Physics, University of Maryland, College Park, ICHIRO TAKEUCHI, CNAM, MSE, and Physics, University of Maryland, College Park — Josephson coupling of superconductors through a topological surface has attracted considerable attention because it may provide device applications of topological insulators with implications for Majorana fermions. However, the results of previous Josephson junction studies on topological insulators have not been fully understood due to complications arising from the conducting bulk and the non-pristine nature of the surfaces/interfaces of the topological insulator materials used. In this work,  $\text{SmB}_6$  thin films with a highly insulating bulk were adopted to minimize the influence of the bulk carriers while in-situ deposition of Nb film on  $\text{SmB}_6$  surface was used to ensure the interface quality. The bilayer structure was then patterned into  $\text{Nb}/\text{SmB}_6/\text{Nb}$  lateral junctions by e-beam lithography and ion milling. The Nb electrodes in our junctions had a typical width of  $\sim 1 \mu\text{m}$  and the gap between the two Nb electrodes was varied from 50 nm to 200 nm. A critical current up to 40  $\mu\text{A}$  has been observed in junctions with a gap around 50 nm at 2.0 K. In this talk, I will discuss the implication of our results to the desired Josephson coupling through topological surface states.

**1:15PM F17.00009 Conductivity Modulation in a gated Normal-CDW-Normal configuration<sup>1</sup>**, SAUMYA BISWAS, ROGER LAKE, Univ of California - Riverside — There is considerable interest in switching by exploiting a voltage controlled phase transition, and one such phase is the charge density wave phase that occurs in a number of quasi one dimensional and two dimensional transition metal dichalcogenides. Voltage controlled switching of the charge density wave transition in  $1\text{T-TaS}_2$  has recently been demonstrated. We consider a transistor geometry with normal metal contacts and a channel of CDW material. The interaction is modeled with a negative U Hubbard term. Normal-CDW-temperature-U phase diagrams show the regime of the CDW in the ideal lattice. The wavelength of the CDW in the transistor channel is determined by both the conditions of Fermi surface nesting and also the condition of commensurability with the channel length between the two normal leads. Moving the Fermi level of the channel first results in phase boundaries within the CDW as the conditions of commensurability and Fermi surface nesting become incompatible. Moving the Fermi level from half filling by few tens of meV causes a collapsing of the CDW gap and an effective CDW-normal transition, leaving vestiges of the CDW in the channel. The transition is accompanied by one to two orders of magnitude increase in the conductivity.

**1:27PM F17.00010 Probing the Interaction of Graphene and Correlated Electron Systems by STM and Magnetotransport<sup>1</sup>**, MICHAEL ALTVATER, MARC REYNAUD, ADITYA SRIPAL, ALICE HUANG, GUOHONG LI, EVA Y. ANDREI, Rutgers University, Department of Physics and Astronomy, RUI ZHAO, JOSHUA ROBINSON, Pennsylvania State University, Materials Science and Engineering, Center for Two-Dimensional and Layered Materials — Since the discovery of 2D materials including graphene and TMDs, many have been shown to exhibit a wide variety of properties including correlated electronic phases, metal-insulator transitions, and highly tunable material properties leading to a rapid increase in research interest. Recent advances in nanostructure fabrication allow us to further study the interaction of these materials by creating heterostructures, layered devices made from low dimensional materials. In this work, we investigate the interaction of Dirac electrons in graphene with the charge density wave formed in  $1\text{T-TaS}_2$ , a van der Waals stacked TMD exhibiting a number of electronic phases including a high temperature metallic phase, several charge density wave phases, a Mott insulating phase, and superconductivity with the addition of pressure or dopants. Using STM, STS, and magnetotransport, we probe the effects of graphene on the phase transition properties of the CDW in  $\text{TaS}_2$  as well as the effect of the highly correlated substrate on the electronic spectrum in graphene. Our work will provide insight into the effects of correlated physics in heterostructures and how we might take advantage of these effects to produce novel devices and applications.

**1:39PM F17.00011 Dimensionality effect on the charge density wave and superconductivity of molecular beam epitaxy grown monolayer NbSe<sub>2</sub>**, HYEJIN RYU, YI ZHANG, ZAHID HUSSAIN, SUNG-KWAN MO, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, Z.-X. SHEN, Geballe Laboratory for Advanced Materials, Departments of Physics and Applied Physics, Stanford University, Stanford, California 94305, USA, MIGUEL M. UGEDA, AARON J. BRADLEY, SEITA ONISHI, YI CHEN, WEI RUAN, CLAUDIA OJEDA-ARISTIZABAL, MARK T. EDMONDS, HSIN-ZON TSAI, ALEXANDER RISS, DUNGHAI LEE, ALEX ZETTL, MICHAEL F. CROMMIE, Department of Physics, University of California at Berkeley, Berkeley, California 94720, USA — Transition metal dichalcogenides are ideal compounds to investigate dimensionality effect since the weak coupling between layers enables to study single-layer material which removes interlayer interactions and introduces quantum confinement. We investigate dimensionality effect of NbSe<sub>2</sub> in which the bulk phase shows charge density wave (CDW) ( $T_{CDW} = 33$  K) and superconductivity ( $T_c = 7.2$  K). We report electronic band structure of MBE grown monolayer NbSe<sub>2</sub> measured by Angle-resolved photoemission spectroscopy compared with bulk. We find the number of bands crossing the Fermi energy reduces from three (bulk) to one (monolayer). Based on the significant suppression of superconducting  $T_c = 0.65$  K with robust CDW in monolayer NbSe<sub>2</sub>, our results imply the band remained at the Fermi level in monolayer NbSe<sub>2</sub> may play a crucial role in CDW formation and the disappeared bands are possibly in charge of superconductivity.

**1:51PM F17.00012 Reversible Semiconducting-to-Metallic Phase Transition in Chemical Vapor Deposition Grown Monolayer WSe<sub>2</sub> and Applications for Devices**, YUQIANG MA, BILU LIU, ANYI ZHANG, LIANG CHEN, MOHAMMAD FATHI, CHENFEI SHEN, AHMAD ABBAS, MINGYUAN GE, MATTHEW MECKLENBURG, CHONGWU ZHOU, Univ of Southern California, USC NANOLAB TEAM<sup>1</sup> — Two-dimensional (2D) semiconducting monolayer transition metal dichalcogenides (TMDCs) have stimulated lots of interest because they are direct bandgap materials that have reasonably good mobility values. However, contact between most metals and semiconducting TMDCs like 2H phase WSe<sub>2</sub> is highly resistive, thus degrading the performance of field effect transistors (FETs) fabricated with WSe<sub>2</sub> as active channel materials. We applied a phase engineering method to chemical vapor deposition (CVD) grown monolayer 2H-WSe<sub>2</sub> and demonstrated semiconducting-to-metallic phase transition in atomically thin WSe<sub>2</sub>. We have also shown that metallic phase WSe<sub>2</sub> can be converted back to semiconducting phase, demonstrating the reversibility of this phase transition. In addition, we fabricated FETs based on these CVD-grown WSe<sub>2</sub> flakes with phase-engineered metallic 1T-WSe<sub>2</sub> as contact regions and intact semiconducting 2H-WSe<sub>2</sub> as active channel materials. The device performance is substantially improved with metallic phase source/drain electrodes, showing on/off current ratios of  $10^7$  and mobilities up to  $66 \text{ cm}^2/\text{Vs}$  for monolayer WSe<sub>2</sub>.

**2:03PM F17.00013 Metal to insulator quantum-phase transition in few-layered ReS<sub>2</sub>**<sup>1</sup>, NIHAR PRADHAN, NHMFL, Tallahassee, FL-32310, USA, AMBER MCCREARY, Dept. of Physics, Penn State University, PA 16802, USA, DANIEL RHODES, ZHENGUANG LU, DMITRY SMIRNOV, EFSTRATIOS MANOUSAKIS, NHMFL, Tallahassee, FL-32310, USA, SIMIN FENG, Dept. of Physics, Penn State University, PA 16802, USA, RAJU NAMBURU, MADAN DUBEY, U.S. Army Research Laboratory, Adelphi, MD 20783, USA, ANGELA HIGHT WALKER, NIST, Gaithersburg, MD 20899, USA, HUMBERTO TERRONES, Dept. of Physics, RPI, NY 12180, USA, MAURICIO TERRONES, Dept. of Physics, Penn State University, PA 16802, USA, VLADIMIR DOBROSAVLJEVIC, LUIS BALICAS, NHMFL, Tallahassee, FL-32310, USA — ReS<sub>2</sub> a layer-independent direct band-gap semiconductor of 1.5 eV implies a potential for its use in optoelectronic applications. Here, we present an overall evaluation of transport and anisotropic Raman of few-layered ReS<sub>2</sub> FET. ReS<sub>2</sub> exfoliated on SiO<sub>2</sub> behaves as an *n*-type semiconductor with an intrinsic carrier mobility surpassing  $\mu_i \sim 30 \text{ cm}^2/\text{Vs}$  at  $T = 300$  K which increases up to  $\sim 350 \text{ cm}^2/\text{Vs}$  at 2 K. Semiconducting behavior is observed at low electron densities *n*, but at high values of *n* the resistivity decreases by a factor  $>7$  upon cooling to 2 K and displays a metallic  $T^2$ -dependence. The electric-field induced metallic state observed in MoS<sub>2</sub> was recently claimed to result from a percolation type of transition. Instead, through a scaling analysis of the conductivity as a function of *T* and *n*, we find that the metallic state of ReS<sub>2</sub> results from a second-order metal to insulator transition driven by electronic correlations.

**Session F18 GMAG DMP: Frustrated Magnetism: Pyrochlore and Spin Ice** 317 - Kate Ross, Colorado State University

**11:15AM F18.00001 Diffuse neutron scattering of Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> revisited**, MIKAEL TWENGSTRÖM, KTH, Sweden, MARTIN RUMINY, PSI, Switzerland, JUAN CARLOS ANDRESEN, KTH, Sweden, MAREK BARTKOWIAK, PSI, Switzerland, SEAN GIBLIN, Cardiff University, UK, STEVEN T. BRAMWELL, UCL, UK, MICHEL J. P. GINGRAS, University of Waterloo & CIFAR, Canada, TOM FENNELL, PSI, Switzerland, PATRIK HENELIUS, KTH, Sweden — Neutron scattering is a sensitive probe of correlations in condensed matter physics, and measurements of spin correlations by diffuse neutron scattering is one of the foremost methods of constraining the Hamiltonian of spin ice materials such as Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. Recent investigations of spin ices have highlighted the possibility of very slow equilibration at low temperature and/or structural defects in samples, effects which were not taken into account in the original parametrizations of the Hamiltonian. Hence, we have in this study performed a new set of diffuse magnetic neutron scattering experiments on an oxygen-annealed single crystal of the spin ice <sup>162</sup>Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. Compensation coils and an in-situ AC-susceptometer were used to control the zero magnetic field at the sample position as well as determining the thermal equilibrium of the magnetic spins respectively. In addition, we performed large-scale Monte Carlo simulations as to make a statistical fit of the dipolar spin ice model to the measured structure factor in the temperature range [0.65, 2] K, where the spin ice physics starts to develop. This will enable a most carefully controlled determination of the Hamiltonian of Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>.

**11:27AM F18.00002 Radio-frequency magnetic susceptibility of spin ice crystals Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> using tunnel diode resonator**, SERAFIM TEKNOWIJOYO, KYUIL CHO, MAKARIY A. TANATAR, RUSLAN PROZOROV, Ames Laboratory and Iowa State University, ROBERT J. CAVA, JASON W. KRIZAN, Princeton University, AMES LABORATORY AND IOWA STATE UNIVERSITY TEAM, PRINCETON UNIVERSITY COLLABORATION — Spin ice compound, Dy<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>, has shown complex frequency - dependent magnetic behavior at low temperatures. While the DC measurements show conventional paramagnetic behavior, finite frequency susceptibility shows two regimes, - complex kagomé ice behavior at around 2 K and spin collective behavior above 10 K, depending on the frequency. Conventional AC susceptibility is limited to frequencies in a kHz range, but to get an insight into the possible Arrhenius activated behavior and characteristic relaxation times, higher frequencies are desired. We used self-oscillating tunnel-diode resonator (TDR) to probe magnetic susceptibility at 14.6 MHz, in the presence of a DC magnetic field and down to 50 mK. We found an unusual non-monotonic field dependence of the lower transition temperature, most likely associated with different spin configurations in a kagomé ice and an activated behavior of the upper transition, which has now shifted to 50 K range. This work was supported by the U.S. DOE BES MSED and was performed at the Ames Laboratory, Iowa State University under contract DE-AC02-07CH11358. The work at Princeton university was supported by DOE BES grant number DE-FG02-08ER46544.

**11:39AM F18.00003 Possible observation of photon excitations in the quantum spin-ice  $\text{Pr}_2\text{Zr}_2\text{O}_7$** , YOSHIFUMI TOKIWA, TAKUYA YAMASHITA, DAIKI TERAZAWA, TAKAHITO TERASHIMA, Kyoto University, KENTA KIMURA, Osaka University, MARIO HALIM, SATORU NAKATSUJI, University of Tokyo, YUJI MATSUDA, Kyoto University — It has been theoretically shown that the ground state of spin-ice system with quantum fluctuations can be quantum spin liquid, where new elementary excitations, photon, emerge [1]. In the rare-earth pyrochlore,  $\text{Pr}_2\text{Zr}_2\text{O}_7$ , which contains spin-ice correlations with significant quantum fluctuations, the absence of magnetic ordering even at very low temperature suggests formation of quantum spin liquid state [2]. In order to examine the emergence of new exotic excitations, we have performed low-temperature thermal conductivity ( $\kappa$ ) measurements of  $\text{Pr}_2\text{Zr}_2\text{O}_7$ . Interestingly, our data of  $\kappa/T$  shows a steep increase with decreasing temperature below 0.2K. Since the monopole density is negligibly small at such low temperature, the steep increase possibly indicates emergence of new elementary excitations. Anomalous magnetic-field dependence of  $\kappa/T$  observed below 0.2K further supports this possibility. [1] M. Hermele et al., Phys. Rev. B 69, 064404 (2004). [2] K. Kimura et al., Nature Commun. 4, 1934 (2013).

**11:51AM F18.00004 Thermal transport measurements of spin ice materials<sup>1</sup>**, WILLIAM TOEWS, JENNIFER REID, RAFAEL NADAS, University of Waterloo, STEFAN KYCIA, University of Guelph, TIMOTHY MUNSIE, McMaster University, HANNA DABKOWSKA, BRUCE GAULIN, McMaster University, Brockhouse Institute for Materials Research, ROBERT HILL, University of Waterloo — Extensive thermal conductivity measurements have been conducted on several rare-earth titanate materials. We report the consequences of crystalline quality and magnetic impurities on the mobility and dynamics of delocalized magnetic excitations. Detailed x-ray diffraction measurements have also been conducted on these samples to accurately characterize the sample quality. Differences between the various materials measured are also discussed.

<sup>1</sup>This research was supported by NSERC of Canada.

**12:03PM F18.00005 Atomic Structure Study of the Quantum Spin-ice Pyrochlore  $\text{Yb}_2\text{Ti}_2\text{O}_7$** , ALI MOSTAED, GEETHA BALAKRISHNAN, MARTIN LEES, RICHARD BEANLAND, Department of Physics, University of Warwick, MICROSCOPY TEAM, SUPERCONDUCTIVITY AND MAGNETISM TEAM — The quantum spin-ice candidate  $\text{Yb}_2\text{Ti}_2\text{O}_7$  (YTO) lies on the boundary between a number of competing magnetic ground states. Features in the low-temperature specific heat capacity are found to vary in sharpness and temperature depending on materials processing. It has been suggested that these changes in the magnetic ground state could be influenced by several factors, including the degree of cation stuffing, changes in oxygen occupancy and/or vacancies. In the present work, the structures of three different YTO samples, grown by the optical floating zone technique and that exhibit quite different heat capacity behaviour, have been studied by annular dark field scanning transmission microscopy (ADF-STEM). We show that the detailed intensity distribution around the visible atomic columns is sensitive to the presence of nearby atoms of low atomic number (in this case oxygen), even though they are not directly visible in the images. To the best of our knowledge, this is the first time that oxygen columns with a distance of ~30 pm have been distinguished in ADF-STEM images. Furthermore, by comparing atomic columns with different configurations of nearby oxygen atoms, we are able to distinguish between the different YTO samples. Finally, the ADF data for the crystal that exhibits no specific heat anomaly shows signs of the substitution of Yb atoms on Ti sites, supporting the view that the magnetic ground state of YTO is extremely sensitive to disorder.

**12:15PM F18.00006 Impact of Stoichiometry of  $\text{Yb}_{2+x}\text{Ti}_{2-x}\text{O}_{7-x/2}$  on its Structure and Physical Properties<sup>1</sup>**, KATHRYN ARPINO, BENJAMIN TRUMP, TYREL MCQUEEN, COLLIN BROHOLM, SEYED KOOHPAYEH, Johns Hopkins Univ — The rare-earth pyrochlores ( $R_2\text{M}_2\text{O}_7$ ) are topic of intense study in the field of magnetism as an ideal host for geometric frustration including spin-liquid and spin-ice behaviour. Specifically,  $R_2\text{Ti}_2\text{O}_7$  has proved a rich playground: compounds  $R = \text{Ho}$  and  $\text{Dy}$  are classical spin ices,  $R = \text{Tb}$  has been shown to be a spin liquid at low temperatures, and  $R = \text{Yb}$  is a candidate quantum spin ice. This system is attractive for the large anisotropic magnetic properties of rare earth ions,  $\text{Ti}^{4+}$ 's lack of magnetic moment which isolates the magnetic ordering of  $R^{3+}$ , and the comparative ease of making single crystals via the floating zone technique. This talk will present the structure and physical properties of a  $\text{Yb}_{2+x}\text{Ti}_{2-x}\text{O}_{7-x/2}$  series including both the pure and stuffed samples. The series shows a dramatic change in the low-temperature (50-200 mK) specific heat signature upon doping away from the pure compound. Understanding the magnetic and physical properties of the off-stoichiometric series sheds light both on the magnetic ordering of the ideal spin ice candidate compound as well as aids in evaluating the quality and stoichiometry of a measured sample. In this vein, proper single-crystal growth conditions in order to ensure single crystals of appropriate stoichiometry will also be discussed.

**12:27PM F18.00007 Magnetic monopole condensation transition out of quantum spin ice: application to  $\text{Pr}_2\text{Ir}_2\text{O}_7$  and  $\text{Yb}_2\text{Ti}_2\text{O}_7$** , GANG CHEN<sup>1</sup>, State Key Laboratory of Surface Physics, Fudan Univ; Perimeter Institute for Theoretical Physics — We study the proximate magnetic orders and the related quantum phase transition out of quantum spin ice (QSI). We apply the electromagnetic duality of the compact quantum electrodynamics to analyze the condensation of the magnetic monopoles for QSI. The monopole condensation transition represents a unconventional quantum criticality with unusual scaling laws. The magnetic monopole condensation leads to the magnetic states that belong to the 2-in 2-out spin ice manifold and generically have an enlarged magnetic unit cell. We demonstrate that the antiferromagnetic state with the ordering wavevector  $\mathbf{Q} = 2\pi(001)$  is proximate to QSI while the ferromagnetic state with the ordering wavevector  $\mathbf{Q} = (000)$  is not proximate to QSI. This implies that if there exists a direct transition from QSI to the ferromagnetic state, the transition must be strongly first order. We apply the theory to the puzzling experiments on two pyrochlore systems  $\text{Pr}_2\text{Ir}_2\text{O}_7$  and  $\text{Yb}_2\text{Ti}_2\text{O}_7$ .

<sup>1</sup>chgsgt@gmail.com

**12:39PM F18.00008 How quantum are classical spin ices?<sup>1</sup>**, MICHEL J P GINGRAS, JEFFREY G RAU, Univ of Waterloo — The pyrochlore spin ice compounds  $\text{Dy}_2\text{Ti}_2\text{O}_7$  and  $\text{Ho}_2\text{Ti}_2\text{O}_7$  are well described by classical Ising models down to low temperatures. Given the empirical success of this description, the question of the importance of quantum effects in these materials has been mostly ignored. We argue that the common wisdom that the strictly Ising moments of non-interacting  $\text{Dy}^{3+}$  and  $\text{Ho}^{3+}$  ions imply Ising interactions is too naive and that a more complex argument is needed to explain the close agreement between the classical Ising model theory and experiments. By considering a microscopic picture of the interactions in rare-earth oxides, we show that the high-rank multipolar interactions needed to induce quantum effects in these two materials are generated only very weakly by superexchange. Using this framework, we formulate an estimate of the scale of quantum effects in  $\text{Dy}_2\text{Ti}_2\text{O}_7$  and  $\text{Ho}_2\text{Ti}_2\text{O}_7$ , finding it to be well below experimentally relevant temperatures.

**12:51PM F18.00009 Disorder-Induced Quantum Spin Liquid in Spin Ice Pyrochlores**, LUCILE SAVARY, Massachusetts Institute of Technology, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — We discuss disorder in spin ice materials, and in particular in compounds with non-Kramers magnetic ions. We show that in the minimal relevant model, disorder succeeds in inducing a long-range entangled Coulombic quantum spin liquid phase. The phase diagram also contains an analog of the Mott glass state, envisioned in dirty boson systems with particle-hole symmetry. We discuss the relevance of our results to the material  $\text{Pr}_2\text{Zr}_2\text{O}_7$ , and how these ideas might be applied to convert a classical spin ice to a quantum one.

**1:03PM F18.00010 Low-temperature Spin-Ice State of Quantum Heisenberg Magnets on Pyrochlore Lattice**, YUAN HUANG, KUN CHEN, University of Massachusetts, Amherst; University of Science and Technology of China, YOUJIN DENG, University of Science and Technology of China; University of Massachusetts, Amherst, NIKOLAY PROKOF'EV, BORIS SVISTUNOV, University of Massachusetts, Amherst; Russian Research Center "Kurchatov Institute" — We establish that the isotropic spin-1/2 Heisenberg antiferromagnet on pyrochlore lattice enters a spin-ice state at low, but finite, temperature. Our conclusions are based on results of the bold diagrammatic Monte Carlo simulations that demonstrate good convergence of the skeleton series down to temperature  $T = J/6$ . The "smoking gun" identification of the spin-ice state is done through a remarkably accurate microscopic correspondence for static spin-spin correlation function between the quantum Heisenberg and classical Heisenberg/Ising models at all accessible temperatures. In particular, at  $T/J = 1/6$ , the momentum dependence shows a characteristic bow-tie pattern with pinch points. By numerical analytical continuation method, we also obtain the dynamic structure factor at real frequencies, showing a diffusive spinon dynamics at pinch points and spin wave continuum along the nodal lines?

**1:15PM F18.00011 Antiferromagnetic order in the pyrochlores  $\text{R}_2\text{Ge}_2\text{O}_7$  ( $\text{R} = \text{Er}, \text{Yb}$ )**, ZHILING DUN, Univ. of Tennessee, Knoxville, XIANG LI, Beijing National Laboratory for Condensed Matter Physics, RAFAEL FREITAS, EVERTON ARRIGHI, Instituto de Física, Universidade de São Paulo, Brazil, CLARINA CRUZ, Oak Ridge National Laboratory, MINSEONG LEE, EUN SANG CHOI, Florida State University and NHMFL, HUIBO CAO, Oak Ridge National Laboratory, HARLYN SILVERSTEIN, University of Manitoba, CHRIS WIEBE, Florida State University and NHMFL, University of Manitoba, University of Winnipeg, Canadian Institute for Advanced Research, JINGUANG CHEN, Beijing National Laboratory for Condensed Matter Physics, HAIDONG ZHOU, Univ. of Tennessee and NHMFL — Elastic neutron scattering, ac susceptibility, and specific heat experiments on the pyrochlores  $\text{Er}_2\text{Ge}_2\text{O}_7$  and  $\text{Yb}_2\text{Ge}_2\text{O}_7$  show that both systems are antiferromagnetically ordered in the  $\Gamma_5$  manifold. The ground state is a  $\psi_3$  phase for the Er sample and a  $\psi_2$  or  $\psi_3$  phase for the Yb sample, which suggests "Order by Disorder" (ObD) physics. Furthermore, we unify the various magnetic ground states of all known  $\text{R}_2\text{X}_2\text{O}_7$  ( $\text{R} = \text{Er}, \text{Yb}, \text{X} = \text{Sn}, \text{Ti}, \text{Ge}$ ) compounds through the enlarged XY type exchange interaction  $J_{\pm}$  under chemical pressure. The mechanism for this evolution is discussed in terms of the phase diagram proposed in the theoretical study [Wong et al., Phys. Rev. B 88, 144402, (2013)].

**1:27PM F18.00012 Theory for magnetic excitations in quantum spin ice**, SHIGEKI ONODA, Condensed Matter Theory Lab., RIKEN and Quantum Matter Theory Research Team, RIKEN Center for Emergent Matter Science, TRINANJAN DATTA, Dept. of Chemistry and Physics, Georgia Regents Univ. — Magnetic excitations in magnetic rare-earth pyrochlore oxides called quantum spin ice (QSI) systems such as  $\text{Yb}_2\text{Ti}_2\text{O}_7$ ,  $\text{Pr}_2\text{Zr}_2\text{O}_7$ , and  $\text{Tb}_2\text{Ti}_2\text{O}_7$  have attracted great interest for possible observations of the quantum dynamics of spin ice monopoles and emergent photon excitations. However, their spectral properties remain open especially for cases relevant to experimental systems. Here, we develop a theoretical framework that incorporates gauge fluctuations into a modified gauge mean-field approach, so that it reproduces key features of recent quantum Monte-Carlo results on the double broad specific heat in the simplest QSI model and can describe a continuous growth of a coherence in gauge-field correlations on cooling down to Coulomb-phase ground states. Using this new approach, we provide a theory for magnetic neutron-scattering spectra. It is found that spin-flip exchange interactions produce dispersive QSI monopole excitations which create a particle-hole continuum neutron-scattering spectrum. Gauge fluctuations give multi-particle contributions to the spectrum, which will be possibly detected in Higgs phases.

**1:39PM F18.00013 Ubiquitous Magnetic Excitations in the Ytterbium Pyrochlores**, ALANNAH HALLAS, JONATHAN GAUDET, McMaster University, NICHOLAS BUTCH, NIST Center for Neutron Research, MAKOTO TACHIBANA, National Institute for Materials Science, RAFAEL FREITAS, Universidade de São Paulo, CHRIS WIEBE, University of Winnipeg, GRAEME LUKE, BRUCE GAULIN, McMaster University — The ytterbium pyrochlores,  $\text{Yb}_2\text{B}_2\text{O}_7$  ( $\text{B} = \text{Sn}, \text{Ti}, \text{Ge}$ ) are well described in terms of  $S_{\text{eff}} = 1/2$  quantum spins with local XY anisotropy, decorating the cubic pyrochlore lattice and interacting via anisotropic exchange. While structurally only the non-magnetic B-site cation, and hence, primarily the lattice parameter, is changing across the series  $\text{Yb}_2\text{B}_2\text{O}_7$  ( $\text{B} = \text{Sn}, \text{Ti}, \text{Ge}$ ), a range of magnetic behavior is observed. The low temperature magnetism in  $\text{Yb}_2\text{Ti}_2\text{O}_7$  and  $\text{Yb}_2\text{Sn}_2\text{O}_7$  has ferromagnetic character. Conversely,  $\text{Yb}_2\text{Ge}_2\text{O}_7$  displays an antiferromagnetically ordered Neel state at low temperatures. We present a comparative analysis of the spin dynamic properties of these three systems using inelastic neutron scattering. While the static properties of the ytterbium pyrochlores are distinct from one another, we find a ubiquitous character to the spin dynamics. The inelastic scattering for each of these ytterbium pyrochlores show a gapless continuum of spin excitations, that tends to resemble over-damped ferromagnetic spin waves at low Q. Furthermore, the specific heat for each of these materials follows a common form with a broad, high-temperature anomaly followed by a sharp low-temperature anomaly. We find that the dynamic properties correlate strongly with the broad specific heat anomaly but remain unchanged across the sharp, low temperature specific heat anomaly.

**1:51PM F18.00014 Ferromagnetic correlations in  $\text{Yb}_2\text{Ti}_2\text{O}_7$  as revealed by small angle neutron scattering techniques**, CONNOR BUHARIWALLA, QIANLI MA, McMaster University, LISA DEBEER-SCHMITT, Oak Ridge National Lab, HANNA DABKOWSKA, Brockhouse Institute for Materials Research, BRUCE GAULIN, McMaster University — We report low temperature SANS measurements on frustrated  $S_{\text{eff}} = 1/2$  XY pyrochlore magnet  $\text{Yb}_2\text{Ti}_2\text{O}_7$  [1]. The ground state of this material has been proposed as a realization of a quantum spin ice; however, the low temperature phase behaviour has been complicated by sample dependencies believed to be related to weak "stuffing" [2]. Our SANS study focuses on the low Q structure of elastic "rods" of magnetic scattering which extend from  $Q=0$  along the 111 direction. Using a single crystal sample, we characterize the low Q ( $< 0.2\text{\AA}^{-1}$ ) temperature dependence of this structured diffuse scattering intensity to  $T=30\text{mK}$ , passing through the enigmatic heat capacity anomaly near  $T_c=200\text{mK}$ . The temperature dependence of this diffuse scattering near  $Q=0$  is largely consistent with that measured previously near 111 [3]. [1] K.A. Ross et al., Phys. Rev. X 1, 021002 (2011) [2] K.A. Ross et al., Phys. Rev. B 86, 174424 (2012) [3] K.A. Ross et al., Phys. Rev. B 84, 174442 (2011)

**2:03PM F18.00015 Extended spin ice**, JEFFREY G. RAU, MICHEL J. P. GINGRAS, University of Waterloo — We introduce a new classical spin liquid on the pyrochlore lattice which we call 'extended spin ice'. The ground state manifold of this model is extensive and characterized by a set of local rules that extend the conventional 2-in/2-out spin ice condition. This includes the ice states in addition to a complex set of tree structures built from 3-in/1-out, 3-out/1-in and all-in/all-out tetrahedra. Under local dynamics this model freezes heterogeneously at low temperatures into a 'spin slush', with extremely slow relaxation for some spins while other spin clusters fluctuate quickly. In addition to this dynamical heterogeneity, distinctive spherical patterns in the spin correlations serve as a further signature. Possible applications to materials as well the effects of transverse quantum exchange will be discussed.

**Session F19 GMAG DCMP: Kondo Physics, Heavy Fermions, and Quantum Criticality** 318 - Ivelisse Cabrera, NIST

**11:15AM F19.00001 Robust antiferromagnetism in the  $R_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  series: comparison of  $\text{Ce}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  and  $\text{Nd}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$** <sup>1</sup>, SERGEY L. BUD'KO, SCOTT M. SAUNDERS, HALYNA HODOVANETS, PAUL C. CANFIELD, Ames Laboratory/Iowa State University — Recently, remarkably robust and correlated coherence and antiferromagnetism were found in the  $\text{Ce}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  series [H. Hodovanets et al., *PRL* **114**, 236601 (2015)]. Whereas Ce is known to hybridize and its compounds often show a strongly correlated behavior, Nd magnetism is associated with a local moment nature. In this talk, we report new measurements on the  $\text{Ce}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  series that extend the antiferromagnetic and coherence lines even further and then compare the data for  $\text{Ce}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  and the data for a local moment based  $\text{Nd}_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  series to separate effects of Ce - hybridization from the behavior that might be common in the  $R_{1-x}\text{La}_x\text{Cu}_2\text{Ge}_2$  (R=magnetic rare earth) family.

**11:27AM F19.00002 Possible Kondo-Lattice-Enhanced Magnetic Ordering at Anomalously High Temperature in Nd Metal under Extreme Compression**<sup>1</sup>, JAMES S. SCHILLING, JING SONG, VIKAS SONI, JINHYUK LIM, Washington University in St. Louis — Most elemental lanthanides order magnetically at temperatures  $T_o$  well below ambient, the highest being 292 K for Gd. Sufficiently high pressure is expected to destabilize the well localized magnetic  $4f$  state of the heavy lanthanides, leading to increasing influence of Kondo physics on the RKKY interaction. For pressures above 80 GPa,  $T_o$  for Dy and Tb begins to increase dramatically, extrapolating for Dy to a record-high value near 400 K at 160 GPa.<sup>2</sup> This anomalous increase may be an heretofore unrecognized feature of the Kondo lattice state; if so, one would expect  $T_o$  to pass through a maximum and fall rapidly at even higher pressures. A parallel is suggested to the ferromagnet  $\text{CeRh}_3\text{B}_2$  where  $T_o = 115$  K at ambient pressure, a temperature more than 100-times higher than anticipated from simple de Gennes scaling.<sup>3</sup> Here we discuss recent experiments on Nd where anomalous behavior in  $T_o(P)$  is found to occur at lower pressures, perhaps reflecting the fact that Nd's  $4f$  wave function is less localized.

**11:39AM F19.00003 Competition between Kondo and indirect exchange at the edges and bulk of graphene, and 2D materials.**, ANDREW ALLERDT, Northeastern University, GEORGE MARTINS, Oakland University, ADRIAN FEIGUIN, Northeastern University — We study the problem of two magnetic impurities at the surface of graphene, BN,  $\text{MoS}_2$ , phosphorene, silicene and germanene using exact numerical methods. We map the band structure of these materials onto one dimensional tight-binding chains in the same spirit as Wilson's numerical renormalization group. We use the density matrix renormalization group to solve the problem exactly, keeping all the information about the underlying lattice. Competition between Kondo and Ruderman-Kittel-Kasuya-Yosida (RKKY) interactions is non-trivial, due to strong non-perturbative effects. Depending on the presence of a pseudogap, or gap, we identify an important directionality and position dependence of the correlations. We present scenarios and regimes where impurities prefer to form their own Kondo clouds instead of an RKKY singlet state, or remain as uncoupled local moments. In the particular case of graphene, ferromagnetism is only stable at half-filling. In addition, we study the effects of spin-orbit coupling, and the presence of edge states.

**11:51AM F19.00004 Revisiting the Toulouse limit of a Kondo junction**, C.J. BOLECH, NAYANA SHAH, University of Cincinnati — Following the development of a scheme to bosonize and debosonize consistently [1,2], we present in detail the Toulouse-point analytic solution of the two-lead (nonequilibrium) Kondo junction model. The existence and location of the solvable point is not modified, but the calculational methodology and the final expressions for observable quantities change markedly as compared to the previously accepted results.

**12:03PM F19.00005 Magnetic-field tuned ground states of  $\text{CeAuBi}_2$  single crystals**, H. HODOVANETS, T. METZ, H. KIM, Y. NAKAJIMA, K. WANG, J. YONG, S. R. SAHA, J. S. HIGGINS, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park 20742, USA, N. BUTCH, CNAM, UMD, College Park 20742, USA/NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park 20742, USA — We present detailed temperature- and field-dependent data obtained from magnetization, resistivity and heat capacity measurement performed on nearly stoichiometric  $\text{CeAuBi}_2$  single crystals. The compound orders antiferromagnetically at  $\sim 13$  K and shows large magnetic anisotropy at low temperatures with the c-direction being an easy axis. The field-dependent magnetization data at low temperatures reveal the existence of a spin-flop transition for  $\mathbf{H}||\mathbf{c}$  ( $H_c \sim 75$  kOe and  $T=1.8$  K). The zero-field resistivity and heat capacity data show features characteristic of a Ce-based intermetallic with crystal electric field splitting and possible correlated, Kondo lattice effects. The constructed  $T-H$  phase diagram, for the magnetic field applied along the easy, [001], direction shows that the magnetic field required to suppress  $T_N$  is  $\sim 75$  kOe. The possibility of realization of the field-tuned quantum critical point (QCP) in  $\text{CeAuBi}_2$  will be discussed.

**12:15PM F19.00006 Neutron scattering, magnetic, and transport properties of non-centrosymmetric  $\text{ULrSi}_3$ .**, SHANTA SAHA, I-LIN LIU, Center for Nano Physics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742, CRAIG BROWN, NICHOLAS BUTCH, NIST Center for Neutron Research, Gaithersburg, MD 20899, JOHNPIERRE PAGLIONE, Center for Nano Physics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD 20742 — Heavy-fermion superconductivity in the non-centrosymmetric crystal structure has drawn much attention [1]. It is argued that the order parameter contains not only a spin-singlet part, but also an admixture of a spin-triplet state. The compound  $\text{ULrSi}_3$  crystallizes in the non-centrosymmetric  $\text{BaNiSn}_3$  structure which is closely related to the well-known  $\text{ThCr}_2\text{Si}_2$ -type [2]. Preliminary study on polycrystalline  $\text{ULrSi}_3$  shows antiferromagnetic order below Neel temperature  $T_N=42$  K [2]. Its lanthanide analog  $\text{CeIrSi}_3$  shows heavy-fermion superconductivity under pressure [1]. Therefore, further investigation on  $\text{ULrSi}_3$  would be meaningful. We would like to present the results of our investigation on  $\text{ULrSi}_3$  by neutron scattering, magnetic, and transport measurement on poly and single crystals grown by Czochralski method in a tetra-arc-furnace. [1] Onuki et al., J. Phys. Soc. Jpn. **77**, suppl. A 37 (2008). [2] Buffat et al., J. Mag. Mag. Mat. **62**, 53 (1986).

**12:27PM F19.00007 Single to multiparticle excitations in the itinerant helical magnet  $\text{CeRhIn}_5$** , CHRIS STOCK, Univ of Edinburgh, J. A. RODRIGUEZ-RIVERA, NIST and Univ of Maryland, K. SCHMALZL, ILL, E. E. RODRIGUEZ, Univ of Maryland, A. STUNAU, ILL, C. PETROVIC, BNL —  $\text{CeRhIn}_5$  is an itinerant magnet where the  $\text{Ce}^{3+}$  spins order in a simple helical phase. We investigate the spin excitations in this material using triple-axis neutron spectroscopy and observe sharp spin waves at low energies consistent with previous reports and a nearest neighbour exchange of  $\sim 1$  meV [1]. At higher energies, the fluctuations are heavily damped where the single-quasiparticle excitations are replaced by a momentum and energy-broadened continuum constrained by kinematics of energy and momentum conservation [2]. The delicate energy balance between localized and itinerant characters results in the breakdown of the single-quasiparticle picture in  $\text{CeRhIn}_5$ . [1] P. Das et al. Phys. Rev. Lett **113**, 246403 (2014). [2] C Stock et al. Phys. Rev. Lett. **114**, 247005 (2015). [3] T. Park et al. PNAS **105**, 6825 (2008).

**12:39PM F19.00008 Physical properties of the van der Waals bonded ferromagnet  $\text{Fe}_{3-x}\text{GeTe}_2$** , ANDREW MAY, Materials Science and Technology Division, ORNL, STUART CALDER, Quantum Condensed Matter Division, ORNL, CLAUDIA CANTONI, Materials Science and Technology Division, ORNL, HUIBO CAO, Quantum Condensed Matter Division, ORNL, MICHAEL MCGUIRE, Materials Science and Technology Division, ORNL —  $\text{Fe}_3\text{GeTe}_2$  is an itinerant ferromagnetic with a layered structure held together by van der Waals bonds. The material has been synthesized using a flux-growth technique that results in large single crystals suitable for neutron scattering, and its magnetic structure and phase diagram have been investigated. The flux-grown crystals possess a Curie temperature  $T_C \approx 150$  K, which is less than that reported for polycrystalline  $\text{Fe}_3\text{GeTe}_2$  with  $T_C \approx 230$  K. The difference is explained by intrinsic Fe-deficiency in these single crystals. This talk will summarize the physical properties of the flux grown single crystals and a series of polycrystalline samples with varying concentrations of Fe, which reveal how Fe content is correlated to structural parameters and  $T_C$ . In combination with the magnetic properties, Hall effect and thermoelectric data reveal that  $\text{Fe}_{3-x}\text{GeTe}_2$  compounds are multi-carrier type, itinerant ferromagnets. Research supported by the US DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

**12:51PM F19.00009 Complex magnetic phases in non-centrosymmetric heavy fermion  $\text{CeCoGe}_3$** <sup>1</sup>, SHAN WU, Johns Hopkins University, Institute for Quantum Matter, CHRIS STOCK, University of Edinburgh, CEDOMIR PETROVIC, Brookhaven National Laboratory, J.A. RODRIGUEZ-RIVERA, NIST center for Neutron Research, COLLIN BROHOLM, Johns Hopkins University, Institute for Quantum Matter — The non-centrosymmetric nature of the tetragonal heavy fermion system  $\text{CeCoGe}_3$  has attracted much interest in the high pressure superconducting state of the material. We have explored the related ambient pressure magnetism using neutron scattering. There are three successive phase transitions at  $T_{N1} \sim 21$  K,  $T_{N2} \sim 12$  K and  $T_{N3} \sim 8$  K. The upper transition greatly enhances the susceptibility and there are meta-magnetic transitions in the lower T phases. We confirmed the previously determined AFM spin structure for  $T_{N2} < T < T_{N1}$  [1]. At lower T we find a complex commensurate structure that can be described as intertwined antiferromagnetic segments. We also report inelastic magnetic neutron scattering, which is dominated by the periodicity of the chemical cell rather than the magnetic unit cell. [1]M.Smidman, etc. *Phys. Rev. B*, **88**,134416 (2013)

**1:03PM F19.00010 Quantum criticality on ferromagnetic systems: it is not where you think it is!**, VALENTIN TAUFOR, UDHARA KALUARACHCHI, MANH CUONG NGUYEN, STELLA K KIM, XIAO LIN, EUN DEOK MUN, HYUNSOO KIM, YUJI FURUKAWA, CAI ZHUANG WANG, KAI MING HO, SERGEY L BUD'KO, PAUL C CANFIELD, Ames Laboratory / Iowa State University, Ames, IA 50011, USA, ZURAB GUGUCHIA, RUSTEM KHASANOV, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, PIETRO BONFA, ROBERTO DE RENZI, Dipartimento di Fisica e Scienze della Terra, Parco Area delle Scienze 7/A, I-43124 Parma, Italy — When a ferromagnetic-paramagnetic transition is tuned to 0 K by application of pressure in clean systems, the transition becomes of the first order at a tricritical point before disappearing. Instead of having a quantum critical point, i.e. a second order transition at 0 K, there is a quantum phase transition of the first order. The quantum phase transition can be from a ferromagnetic to a paramagnetic phase, or to a spatially modulated phase. We illustrate this case on a new material:  $\text{LaCrGe}_3$ . We will present the temperature-pressure-magnetic field phase diagram of  $\text{LaCrGe}_3$  and show that quantum criticality is avoided by the appearance of a modulated phase. We will also explain how quantum criticality can be re-introduced. Work at Ames Laboratory was supported by US DOE under the Contract No. DE-AC02-07CH11358. Magnetization measurements under pressure were supported by Ames Laboratory's laboratory-directed research and development (LDRD) funding.

**1:15PM F19.00011 Theory of electronic and magnetic properties of weak antiferromagnetic  $\text{TiAu}$** <sup>1</sup>, WEN FONG GOH, WARREN PICKETT, Univ of California - Davis — To date, only a few itinerant magnetic compounds have been found, viz.  $\text{ZrZn}_2$ ,  $\text{TiBe}_2$  and  $\text{Sr}_3\text{In}$ , all comprised of nonmagnetic elements.  $\text{TiAu}$ , a newly synthesized itinerant weak antiferromagnet, orders antiferromagnetically below 36 K. Neutron diffraction reveals an ordered local moment of only  $0.15 \mu_B/\text{Ti}$  at a wave vector  $Q=(0,\pi/b,0)$ . Hole doping, viz.  $\text{Ti}_{1-x}\text{Sc}_x\text{Au}$ , causes the magnetic moment to disappear at a quantum critical point  $x_{SC}=0.13$ . We present results of an extensive study of the electronic and magnetic properties of  $\text{TiAu}$ . DFT calculations reveal van Hove singularities at  $(0,0.45\pi/b,0.49\pi/c)$ , 4 meV above the Fermi level. Several types of analysis will be discussed: fixed spin moment studies and Stoner enhancement; magnetic energies; magnetism versus doping; Fermi surface nesting; corrections for spin fluctuations.

<sup>1</sup>Supported by Grant NSF DMREF DMR 1534719

**1:27PM F19.00012 Quantum Criticality in  $\text{YFe}_2\text{Al}_{10}$** , WILLIAM GANNON, Texas AM University, LIUSUO WU, Oak Ridge National Laboratory, IGOR ZALIZNYAK, Brookhaven National Laboratory, YIMING QIU, JOSE RODRIGUEZ-RIVERA, National Institute of Standards and Technology, MEIGAN ARONSON, Texas AM University — Quantum criticality has been studied in many systems, but there are few systems where observed scaling can be unified with a critical free energy  $F$ , or where the critical exponents form the basis for QC universality classes. We have identified a new layered material  $\text{YFe}_2\text{Al}_{10}$  that shows remarkably strong QC behavior, where the scaling properties of the magnetic susceptibility and specific heat are consistent with the same  $F$ . Recent neutron scattering results paint a remarkable picture of the QC fluctuations in  $\text{YFe}_2\text{Al}_{10}$ . In contrast to classical transitions, where fluctuations are relatively long ranged and inelastic scattering is observed at a magnetic zone center, in  $\text{YFe}_2\text{Al}_{10}$  the scattering is independent of wave vector in the critical plane, indicating that the fluctuations are spatially localized, while out of plane scattering indicates that the interplanar interactions are restricted to nearest neighbors. The dynamical susceptibility  $\chi'' \simeq E^{-2}$ , and is wholly temperature independent, indicating that E/T scaling is present, the signature of QC fluctuations. These results hint that the the criticality in  $\text{YFe}_2\text{Al}_{10}$  is local, which until now has only been found in a few f-electron based compounds.

**1:39PM F19.00013 Quantum criticality in single crystalline  $\text{YFe}_2\text{Al}_{10}$  determined from zero-field and longitudinal-field muon spin relaxation**<sup>1</sup>, KEVIN HUANG, CHENG TAN, JIAN ZHANG, ZHAOFENG DING, Department of Physics, Fudan University, DOUGLAS MACLAUGHLIN, Department of Physics, UC Riverside, OSCAR BERNAL, Department of Physics, CSU Los Angeles, PEI-CHUN HO, Department of Physics, CSU Fresno, LIUSUO WU, MEIGAN ARONSON, Department of Physics, Stony Brook University, LEI SHU, Department of Physics, Fudan University — Muon spin relaxation ( $\mu\text{SR}$ ) measurements were performed on single crystalline  $\text{YFe}_2\text{Al}_{10}$  down to 19 mK and in magnetic fields up to  $\sim 100$  Oe. Zero-field- $\mu\text{SR}$  measurements showed no evidence of magnetic order down to 19 mK, consistent with previous measurements. However, we also find that the depolarization rate  $\Lambda$  is temperature independent above 1 K but increases in an exponential behavior for  $T < 1$  K. Longitudinal-field  $\mu\text{SR}$  measurements also reveals a time-field scaling where  $G(t, H) = G(t/H^\gamma)$ , with  $\gamma = 0.67$ . This is further confirmed from the magnetic field dependence of  $\Lambda$ , which finds  $\Lambda(H) \propto H^{0.67}$  at 19 mK. This is further evidence that single crystalline  $\text{YFe}_2\text{Al}_{10}$  is in close proximity to a ferromagnetic quantum critical point.

<sup>1</sup>The research performed in this study was supported by the National NSF of China under Grant no. 11474060 and STCSM of China (No. 15XD1500200). Work at CSULA funded by NSF/DMR-1105380. Research at CSU-Fresno is supported by NSF DMR-1506677.

**1:51PM F19.00014 Doping-Induced Quantum Critical Point in an Itinerant Antiferromagnet TiAu**, JESSICA SANTIAGO, ETERI SVANIDZE, Rice University, TIGLET BESARA, THEO SIEGRIST, National High Magnetic Field Laboratory, Florida State University, EMILIA MOROSAN, Rice University — The recently discovered itinerant magnet TiAu is the first antiferromagnet composed of non-magnetic constituents. The spin density wave ground state develops below  $T^N \sim 36$  K, about an order of magnitude smaller than in Cr. Achieving a quantum critical point in this material would provide a better understanding of weak itinerant antiferromagnets, while giving long sought-after insights into the effects of spin fluctuations in itinerant electron systems. While the application of pressure increases the ordering temperature  $T^N$ , partial substitution of Ti provides an alternative avenue towards achieving a quantum critical point. The non-Fermi liquid behavior accompanies the quantum phase transition, as evidenced by the divergent specific heat coefficient and linear temperature dependence of the resistivity. The transition is accompanied by enhanced electron-electron correlations as well as strong spin-fluctuations, providing an experimental avenue for the verification of the self-consistent theory of spin fluctuations.

**2:03PM F19.00015 Itinerant magnetism in quantum critical  $\text{YFe}_2\text{Al}_{10}$** , WENHU XU, WEIGUO YIN, ROBERT KONIK, ALEXEI TSVELIK, Brookhaven Natl Lab, GABRIEL KOTLIAR, Rutgers University — The absence of magnetic order and the scaling laws in thermodynamical and transport properties in layered compound  $\text{YFe}_2\text{Al}_{10}$  suggest competition among different types of collective quantum states. Measurements on magnetic susceptibility have demonstrated a Curie-Weiss (CW) behavior with a reduced fluctuating Fe moment of 0.45B and  $T_{CW} \simeq -28\text{K}$ . Using first principle methods, we show that the correlation in  $\text{YFe}_2\text{Al}_{10}$  is moderate and the Fe magnetism is itinerant. Competing ground states include a paramagnetic state, an in-plane antiferromagnetic ordering (G-type) state and an in-plane collinear ordering (C-type) state. Although a bulk ferromagnetic order is not favored in total energy, both the G-type and C-type ground state prefer ferromagnetic inter-layer coupling.

**Tuesday, March 15, 2016 11:15AM - 2:15PM –**  
**Session F20 DCOMP GSCCM DMP: Materials in Extremes: High-pressure Synthesis of New Materials** 319 - Jennifer Ciezak-Jenkins, Army Research Laboratory

**11:15AM F20.00001 Extreme thermodynamic conditions: novel stoichiometries, violations of textbook chemistry, and intriguing possibilities for the synthesis of new materials.**<sup>1</sup>, ELISSAIO STAVROU, Lawrence Livermore National Laboratory — As evidenced by numerous experimental and theoretical studies, application of high pressure can dramatically modify the atomic arrangement and electronic structures of both elements and compounds. However, the great majority of research has been focused on the effect of pressure on compounds with constant stoichiometries (typically those stable under ambient conditions). Recent theoretical predictions, using advanced search algorithms, suggest that composition is another important variable in the search for stable compounds, i.e. that the more stable stoichiometry at elevated pressures is not *a priori* the same as that at ambient pressure. Indeed, thermodynamically stable compounds with novel compositions were theoretically predicted and experimentally verified even in relatively simple chemical systems including: Na-Cl, C-N, Li-H, Na-H, Cs-N, H-N, Na-He, Xe-Fe. These materials are stable due to the formation of novel chemical bonds that are absent, or even forbidden, at ambient conditions. Tuning the composition of the system thus represents another important, but poorly explored approach to the synthesis of novel materials. By varying the stoichiometry one can design novel materials with enhanced properties (e.g. high energy density, hardness, superconductivity etc.), that are metastable at ambient conditions and synthesized at thermodynamic conditions less extreme than that those required for known stoichiometries. Moreover, current outstanding questions, “anomalies” and “paradoxes” in geo- and planetary science (e.g. the Xenon paradox) could be addressed based on the stability of surprising, stoichiometries that challenge our traditional “textbook” picture. In this talk, I will briefly present recent results and highlight the need of close synergy between experimental and theoretical efforts to understand the challenging and complex field of variable stoichiometry under pressure. Finally, possible new routes for the synthesis of novel materials will be discussed.

<sup>1</sup>This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344.

**11:51AM F20.00002 Hydrogen sulfide at high pressure: change in stoichiometry**<sup>1</sup>, ALEXANDER GONCHAROV, SERGEY LOBANOV, Carnegie Inst of Washington, IVAN KRUGLOV, Moscow Institute of Physics and Technology, XIAO-MIAO ZHAO, Carnegie Inst of Washington, XIAO-JIA CHEN, Center for High Pressure Science & Technology Advanced Research (HPStar), Shanghai, China, ARTEM OGANOV, Skolkovo Institute of Science and Technology, Moscow, Russia, ZUZANA KONOPKOVA, DESY Photon Science, D-22607 Hamburg, Germany, VITALI PRAKAPENKA, Center for Advanced Radiation Sources, University of Chicago, Chicago, IL 60637, USA — Hydrogen sulfide ( $\text{H}_2\text{S}$ ) was studied by x-ray synchrotron diffraction (XRD) and Raman spectroscopy up to 144 GPa at 180-295 K. We find that  $\text{H}_2\text{S}$  compound become unstable with respect to formation of new compounds with different composition including pure S,  $\text{H}_3\text{S}$  and  $\text{HS}_2$  depending on the thermodynamic P-T path. These results are supported by our quantum-mechanical variable-composition evolutionary simulations that show the stability of the above mentioned compounds at elevated pressures. The stability of  $\text{H}_3\text{S}$  at high pressures, which we find a strong experimental and theoretical confirmation here, suggests that it is this material which is responsible for high-temperature superconducting properties reported previously.

**12:03PM F20.00003 ABSTRACT WITHDRAWN –**

**12:15PM F20.00004 A possible analog to  $\text{MgB}_2$ : Discovery of a predicted layered LiB via cold compression**<sup>1</sup>, ALEKSEY KOLMOGOROV, SAMAD HAJINAZAR, CHRIS ANGYAL, Binghamton University, VLADIMIR KUZNETZOV, University of Oxford, ANDREW JEPHCOAT, Okayama University — Stoichiometric LiB has been previously predicted [1,2] to be a new synthesizable layered material with electronic and vibrational properties desired for  $\text{MgB}_2$ -type superconductivity. However, previous experiments showed no signs of the proposed compound forming under high pressures. We report on the synthesis of the LiB via cold compression in the diamond anvil cell [3]. Remarkably, the signature powder XRD peak from the new layered compound appeared above 21 GPa and remained visible down to ambient pressure upon sample quenching. Apparent stacking disorder in LiB and a stoichiometry shift in the starting  $\text{LiB}_y$  (from  $y \approx 0.90$  down to  $y \approx 0.75$ ) made material characterization a challenge. *Ab initio* modeling allowed us to establish the pressure-dependent composition of  $\text{LiB}_y$  and predict related stable structures overlooked in previous studies. **12:27PM F20.00005 Discovering new materials and new phenomena with evolutionary algorithms**, ARTEM OGANOV, Skolkovo Institute of Science and Technology — Thanks to powerful evolutionary algorithms, in particular the USPEX method, it is now possible to predict both the stable compounds and their crystal structures at arbitrary conditions, given just the set of chemical elements. Recent developments include major increases of efficiency and extensions to low-dimensional systems and molecular crystals (which allowed large structures to be handled easily, e.g.  $\text{Mg}(\text{BH}_4)_2$  and  $\text{H}_2\text{O}-\text{H}_2$ ) and new techniques called evolutionary metadynamics and Mendelevian search. Some of the results that I will discuss include: 1. Theoretical and experimental evidence for a new partially ionic phase of boron,  $\gamma$ -B and an insulating and optically transparent form of sodium. 2. Predicted stability of “impossible” chemical compounds that become stable under pressure – e.g.  $\text{Na}_3\text{Cl}$ ,  $\text{Na}_2\text{Cl}$ ,  $\text{Na}_3\text{Cl}_2$ ,  $\text{NaCl}_3$ ,  $\text{NaCl}_7$ ,  $\text{Mg}_3\text{O}_2$  and  $\text{MgO}_2$ . 3. Novel surface phases (e.g. boron surface reconstructions). 4. Novel dielectric polymers, and novel permanent magnets confirmed by experiment and ready for applications. 5. Prediction of new ultrahard materials and computational proof that diamond is the hardest possible material.

**1:03PM F20.00006 Structural study of superconducting sulfur hydride under high pressure**<sup>1</sup>, KATSUYA SHIMIZU, MARI EINAGA, MASAFUMI SAKATA, HARUSHIGE NAKAO, Osaka Univ, MIKHAIL EREMETS, ALEXANDER DROZDOV, IVAN TROYAN, MPI Chem, NAOHISA HIRAO, YASUO OHISHI, JASRI/SPRING-8, KYOKUGEN, GRADUATE SCHOOL OF ENGINEERING SCIENCE, OSAKA UNIVERSITY TEAM, MAX PLANCK INSTITUTE FOR CHEMISTRY TEAM, JASRI/SPRING-8 TEAM — Superconductivity exceeding 200 K was recently reported in the highly compressed hydrogen sulfide [1]. The superconductor was found to be synthesized by pressure above 90 GPa under low temperature exceeding 200 K. Here we report our high-pressure structural studies for  $\text{H}_2\text{S}$  and  $\text{D}_2\text{S}$  using a synchrotron x-ray at room temperature and low temperature [2]. The sample at 10 GPa was firstly cooled down to 200 K and compressed up to 150 GPa, then cooled down to 10 K. The resistivity and diffraction patterns were monitored at all procedures. The critical temperature and zero resistivity were confirmed. The x-ray diffraction data in both cells showed good agreement with the theoretically predicted structures [3].

**1:15PM F20.00007 High –Pressure Synthesis and Characterization of Incompressible Titanium Pernitride**<sup>1</sup>, VENKATA BHADRAM, DUCK YOUNG KIM, TIMOTHY STROBEL, Carnegie Institution of Washington — We report the discovery of a new transition-metal pernitride,  $\text{TiN}_2$ , which was synthesized by reacting  $\text{TiN}$  with  $\text{N}_2$  at 73GPa in a laser-heated diamond anvil cell (DAC). Our *in situ* pressure dependent x-ray diffraction studies suggest that  $\text{TiN}_2$  is recoverable at ambient conditions in a crystal structure that contains single bonded nitrogen units ( $\text{N}_2$  dumbbells) embedded in the metal lattice and exhibits high bulk modulus (in the range 360-385 GPa) which is usually observed in superhard materials. We have performed *ab initio* calculations to understand the electronic properties and bonding nature in  $\text{TiN}_2$  and thereby elucidate the origin of incompressible behavior of this material which is rooted in the nearly filled anti-bonding states of the pernitride units. Although, study of transition metal pernitrides has been an active area of research for quite some time, most of the pernitrides synthesized so far are belong to noble metal group. To our knowledge, this is the first experimental report on  $\text{TiN}_2$  which is the only light metal pernitride exhibiting bonding-mechanical property relation that is usually seen in heavy metal pernitrides.

**1:27PM F20.00008 Electride-like phases at extreme compression and elevated temperatures**<sup>1</sup>, STANIMIR BONEV, Lawrence Livermore National Laboratory, JONATHAN DUBOIS, Lawrence Livermore National Laboratory, Livermore, CA 94550 — The transformation of materials into electride-like structures under the application of extreme pressure has attracted a lot of interest recently. Theoretical studies have predicted the existence of low-coordinated crystal phases, where the conduction electrons are localized in the interstitial atomic regions, for a number of elements at high density. Most of these works have been limited to static lattice calculations. The pressures where such transformations are projected to occur are accessible in shock-wave experiments, but at elevated temperatures. In this talk I will discuss the temperature dependence of electride structures, both solids and liquids, as well as the requirements for their accurate simulation.

<sup>1</sup>This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

**1:39PM F20.00009 The effects of hydrogenation and high pressure on  $\alpha$ -tetragonal boron: a first principles study**, NAOKI UEMURA, KOUN SHIRAI, ISIR, Osaka University — It is well known that boron rich crystals are superhard materials.  $\alpha$ -tetragonal ( $\alpha$ -tet) boron is one of the metastable phase in elemental boron crystals under high temperature and high pressure. This phase has a possibility of including some hydrogen atoms due to the experimental process, but it has not yet been shown crystal structures and electronic properties of hydrogenated  $\alpha$ -tet boron. Using first-principles calculations, we theoretically predicted stable structures and investigated the influences from hydrogenation of  $\alpha$ -tet boron and high pressures. According to our calculations, non-bonding states of pure  $\alpha$ -tet boron, which were mostly occupied by  $P_z$  like orbitals coming from interstitial boron atoms in  $\alpha$ -tet boron, were completely vanished by doping some hydrogen atoms and the higher the pressure was, the larger energy gaps between the valence band maximum and the conduction band minimum on  $\alpha$ -tet boron were. These results provide that the deformation potential depended on the pressure is positive, which is basically negative on semiconductors except for diamonds and is an index of the hardness under pressure on semiconductors.

**1:51PM F20.00010 Creation and formation mechanism of new carbon phases constructed by amorphous carbon.**<sup>1</sup>, MINGGUANG YAO, WEN CUI, BINGBING LIU, State Key Laboratory of Superhard Materials, Jilin University — Our recent effort is focusing on the creation of new hard/superhard carbon phases constructed by disordered carbons or amorphous carbon clusters under high pressure. We showed that the pressure-induced amorphous hard carbon clusters from collapsed fullerenes can be used as building blocks (BBs) for constructing novel carbon structures. This new strategy has been verified by compressing a series of intercalated fullerenes, pre-designed by selecting various dopants with special features. We demonstrate that the boundaries of the amorphous BBs are mediated by intercalated dopants and several new superhard materials have been prepared. We also found that the dopant-mediated BBs can be arranged in either ordered or disordered structures, both of which can be hard enough to indent the diamond anvils. The hardening mechanisms of the new phases have also been discussed. For the glassy carbon (GC) constructed by disordered fullerene-like nanosized fragments, we also found that these disordered fragments can bond and the compressed GC transformed into a transparent superhard phase. Such pressure-induced transformation has been discovered to be driven by a novel mechanism (unpublished). By understanding the mechanisms we can clarify the controversial results on glassy carbon reported recently.

**2:03PM F20.00011 First-principles study of MoHn (n=1, 2 and 3) crystal structures under high pressure**, XIAOLEI FENG, JURONG ZHANG, Jilin University, HANYU LIU, Carnegie Institution of Washington, HUI WANG, Jilin University — Hydrogen-rich materials have attracted attention recently, owing to their fascinating chemical bonding and potential high superconducting critical temperatures temperature. Inspired by the recent identification of polyhydrides of d metals and molybdenum hydride molecules with a high H content, we explored the crystal structures of MoHn (n = 1, 2, and 3) under high pressures using particle swarm optimization combined with first-principles electronic structure calculations. Several novel structures of MoH2 and MoH3 are predicted at high pressures. MoH is calculated to be stable at ambient pressure; at  $P > 2.3$  GPa the hexagonal phase of MoH2 becomes stable, and at 24 GPa it transforms into an orthorhombic structure, which remains stable up to 100 GPa. All three stable structures show metallic behavior under pressure. The calculated electronic properties suggest that the d-orbitals of the Mo atoms provide the dominant contribution to the density of states at the Fermi level, which is different from the density of states previously predicted for H-rich materials. The present results offer insights in understanding of chemical and physical properties in hydrogen-rich materials, especially in extreme environments.

**Session F21 GMAG DMP: Molecular Nanomagnets** 320 - Andrew Kent, New York University

**11:15AM F21.00001 Coherent manipulation of quantum spin states in a single molecular nano-magnet**, WOLFGANG WERNSDORFER, Institut Neel, CNRS, Grenoble — The endeavour of quantum electronics is driven by one of the most ambitious technological goals of today's scientists: the realization of an operational quantum computer (<http://quroupe.eu>). We started to address this goal by the new research field of molecular quantum spintronics. The building blocks are magnetic molecules, i.e. well-defined spin qubits. We will discuss this still largely unexplored field and present our first results: For example, using a molecular spin-transistor, we achieved the electronic read-out of the nuclear spin of an individual metal atom embedded in an SMM. We could show very long spin lifetimes ( $>10$  s). Using the hyperfine Stark effect, which transforms electric fields into local effective magnetic fields, we could not only tune the resonance frequency by several MHz, but also perform coherent quantum manipulations on a single nuclear qubit faster than a  $\mu$ s by means of electrical fields only, establishing the individual addressability of identical nuclear qubits. Using three different microwave frequencies, we could implement a simple four-level Grover algorithm. S. Thiele, F. Balestro, R. Ballou, S. Klyatskaya, M. Ruben, W. Wernsdorfer, Science 344, 1135 (2014).

**11:51AM F21.00002 Landau-Zener in a continuously measured molecular spin**, FILIPPO TROIANI, Istituto Nanoscienze, CNR (Italy), MARCO AFFRONTI, Universit di Modena e Reggio Emilia (Italy), STEPHAN THIELE, CLEMENT GODFRIN, FRANCK BALESTRO, WOLFGANG WERNSDORFER, Institut Nel, CNRS (France), SVETLANA KLYATSKAYA, MARIO RUBEN, Karlsruhe Institute of Technology (Germany) — The dynamics of a quantum system driven through an avoided level crossing represents a relevant problem in many physical contexts. Here we present a joint theoretical and experimental investigation of a single-molecule magnet (namely, a terbium double-decker complex) in a three-terminal geometry. The Tb spin is driven through an avoided level crossing by a time-dependent magnetic field, and its dynamics is monitored through a continuous measurement of the conductance. The dependence of the spin-reversal probability on the field sweeping rate presents clear deviations from the Landau-Zener formula, which applies to the case of closed systems. The comparison between direct and inverse Landau-Zener transitions points at the dominance of dephasing, with respect to inelastic incoherent processes. The spin dynamics is simulated within a master equation approach. The observed behaviors are reproduced by assuming that dephasing takes place in the basis of the time-dependent Hamiltonian eigenstates. The spin dephasing is traced back to the continuous measurement of the electron spin, and a fundamental role is played by the finite time resolution of the conductance measurement.

**12:03PM F21.00003 Magnetic hysteresis in a lanthanide molecular magnet dimer system<sup>1</sup>**, JAMES ATKINSON, REBECCA CEBULKA, ENRIQUE DEL BARCO, University of Central Florida, Physics Department, Orlando, FL, USA, OLIVIER ROUBEAU, Instituto de Ciencia de Materiales de Aragn (ICMA), CSIC and Universidad de Zaragoza, Zaragoza, Spain, VERONICA VELASCO, LEO BARRIOS, GUILLLEM AROMI, Universitat de Barcelona, Departament de Quimica Inorganica, Barcelona, Spain — Molecular magnets present a wonderful means for studying the dynamics of spin. Often synthesized as a crystal lattice of identical systems, ensemble measurements enable thorough detailing of the internal degrees of freedom. Here we present the results of characterization performed on a dimer system,  $\text{CeTm}(\text{HL})_2(\text{H}_2\text{L})\text{NO}_3\text{pyH}_2\text{O}$  (L = ligand,  $\text{C}_{45}\text{H}_{31}\text{O}_{15}\text{N}_3$ ), consisting of two lanthanide spins (Cerium and Thulium) with expected local axial anisotropies tilted with respect to each other. Microwave EPR spectroscopy at low temperature reveals hysteresis in observed absorption features, with angle dependence studies indicating the presence of several easy axis orientations. We attempt to understand this system through modelling via a spin Hamiltonian, and to determine the strength and nature of the coupling between the lanthanide centers.

**12:15PM F21.00004 Search for giant magnetic anisotropy in transition-metal dimers on defected hexagonal boron nitride sheet<sup>1</sup>**, JIE LI, State Key Lab. of Surface Physics, Key Lab. of Computational Physical Sciences, and Dept. of Physics, Fudan Univ., HUI WANG, Dept. of Physics and Astronomy, Univ. of California, JUN HU, College of Physics, Optoelectronics and Energy, Soochow Univ., RUQIAN WU, Dept. of Physics and Astronomy, Univ. of California — For a magnetic units at the nanometer scale, one of the most important issues is how to hold thermal fluctuation of its magnetization, i.e., how to enhance its blocking temperature ( $T_{\text{B}}^{\text{B}}\text{s}$ ) to above 300K. Through systematic density functional calculations, the structural stability and magnetic properties of many transition-metal dimers embedded in a defected hexagonal boron nitride monolayer are investigated. We find twelve cases that may have magnetic anisotropy energies (MAEs) larger than 30 meV. In particular, Ir-Ir@Dh-BN has both large MAE ( $\sim 126$  meV) and high structural stability, which makes it a promising candidate of magnetic unit in spintronics and quantum computing devices.

<sup>1</sup>Work at Fudan was supported by the Chinese National Science Foundation (11474056) and National Basic Research Program of China (2015CB921400). Work at UCI was supported by DOE-BES (Grant No. DE-FG02-05ER46237).

**12:27PM F21.00005 Molecular Magnetism in MnTe Clusters<sup>1</sup>**, JIA CHEN, Department of Applied Physics, Columbia University, ARUN NANDURI, BONNIE CHOI, Department of Chemistry, Columbia University, ANDREW MILLIS, Department of Physics, Columbia University, DAVID REICHMAN, XAVIER ROY, Department of Chemistry, Columbia University — Electron correlation in recently synthesized molecular clusters with  $\text{Mn}_4\text{Te}_4$  cores in cubane structures and ligand exteriors are studied experimentally and theoretically. We used density functional theory with on-site Coulomb interactions (DFT+U) to construct effective spin Hamiltonians and estimate the dependence of parameters on choice of ligand. The lack of inversion symmetry combined with the heavy tellurium ions leads to a significant Dzyaloshinskii-Moriya (DM) interaction. Comparison of measurements to the magnetic susceptibility calculated from the spin model is used to validate the results. We also extend this work to more complex clusters with more than one cubanes, where interesting high-spin ground state may occur. It has been measured recently,  $\text{Fe}_8\text{Te}_8$  in dicubane structure has ground state with magnetization of  $12\mu_B$ , which makes it promising candidate for single molecular magnets.

<sup>1</sup>A.J.M. acknowledges support from NSF under contract DMR-1308236. J.C. is supported by the NSF MRSEC program through Columbia in the Center for Precision Assembly of Superstratic and Superatomic Solids under Grant No.DMR-1420634.

**12:39PM F21.00006 Spin-Valve Effect at Organic-Ferromagnetic Interfaces**, NICOLAE ATODIRESEI, VASILE CACIUC, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — The ability to reliably describe the electronic properties of carbon-based materials adsorbed on magnetic surfaces is essential to understand and assist the engineering of functionalities in hybrid organic spintronic devices. Based on the density functional theory, we performed theoretical studies [1-4] to understand how to tailor the magnetic properties of hybrid organic-ferromagnetic interfaces by adsorbing organic materials containing  $\pi$ -electrons onto several magnetic substrates. For such hybrid systems, the magnetic properties like molecular magnetic moments and their spatial orientation, spin-polarization and the magnetic exchange coupling can be specifically tuned by an appropriate choice of the organic material. \*Email: n.atodiresei@fz-juelich.de [1] N. Atodiresei et al., MRS Bulletin 39, 596 (2014). [2] J. Brede et al., Nat. Nanotech. 9, 1018 (2014). [3] K. V. Raman et al., Nature 493, 509 (2013). [4] M. Callsen et al., Phys. Rev. **12:51PM F21.00007 Magnetic dipole-dipole sensing at atomic scale using electron spin resonance STM**, T. CHOI, W. PAUL, IBM Almaden Research, S. ROLF-PISSARCZYK, Max Planck Institute, Germany, A. MACDONALD, U. of British Columbia, Canada, K. YANG, Chinese Academy of Sciences, F.D. NATTERER, EPFL, Switzerland, C.P. LUTZ, A.J. HEINRICH, IBM Almaden Research — Magnetometry having both high magnetic field sensitivity and atomic resolution has been an important goal for applications in diverse fields covering physics, material science, and biomedical science. Recent development of electron spin resonance STM (ESR-STM) promises coherent manipulation of spins and studies on magnetic interaction of artificially built nanostructures, leading toward quantum computation, simulation, and sensors. In ESR-STM experiments, we find that the ESR signal from an Fe atom underneath a STM tip splits into two different frequencies when we position an additional Fe atom nearby. We measure an ESR energy splitting that decays as  $1/r^3$  ( $r$  is the separation of the two Fe atoms), indicating that the atoms are coupled through magnetic dipole-dipole interaction. This energy and distance relation enables us to determine magnetic moments of atoms and molecules on a surface with high precision in energy. Unique and advantageous aspects of ESR-STM are the atom manipulation capabilities, which allow us to build atomically precise nanostructures and examine their interactions. For instance, we construct a dice *cinque* arrangement of five Fe atoms, and probe their interaction and energy degeneracy. We demonstrate the ESR-STM technique can be utilized for quantum magnetic sensors.

**1:03PM F21.00008 ABSTRACT WITHDRAWN —**

**1:15PM F21.00009 Spin blockade effect in single-molecule transistors<sup>1</sup>**, GUANGPU LUO, KYUNGWHA PARK, Virginia Tech, Blacksburg, Virginia — Recently single-molecule transistors consisting of individual single-molecule magnets trapped between electrodes have been experimentally realized and electron transport properties through individual single-molecule magnets have been measured. For a single-molecule magnet the  $(2S+1)$ -fold degeneracy of magnetic levels in a given spin multiplet is lifted even in the absence of external magnetic field, due to the magnetic anisotropy induced by spin-orbit coupling. This anisotropic nature of single-molecule magnets allowed one to discover interesting, unexpected transport properties. A recent theoretical study showed that an Eu-based anisotropic magnetic molecule can switch its magnetic anisotropy between magnetic easy plane and easy axis upon varying the charge state of the molecule. Motivated by this report, we investigate how this switch of magnetic anisotropy influences the electron transport through the molecule, by considering sequential electron tunneling. We calculate current-voltage characteristics by solving the master equation based on the model Hamiltonians. We explore this interesting effect in the absence and presence of external magnetic field.

<sup>1</sup>Funding from NSF DMR-1206354.

**1:27PM F21.00010 Hybrid quantum systems with YBCO coplanar resonators and spin ensembles of organic radicals**, ALBERTO GHIRRI, Istituto Nanoscienze - CNR, Centro S3, via Campi 213/a, 41125 Modena, Italy, CLAUDIO BONIZZONI, Dipartimento FIM, Università di Modena e Reggio E. and Istituto Nanoscienze - CNR, via Campi 213/a, 41125 Modena, Italy, FILIPPO TROIANI, Istituto Nanoscienze - CNR, via Campi 213/a, 41125 Modena, Italy, ANTONIO CASSINESE, CNR-SPIN and Dipartimento di Fisica, Università di Napoli Federico II, 80138 Napoli, Italy, MASSIMILIANO D'ARIENZO, LUCA BEVERINA, Department of Materials Science State University of Milano-Bicocca Via Cozzi 55 I-20125 Milano, Italy, MARCO AFFRONTI, Dipartimento FIM, Università di Modena e Reggio E. and Istituto Nanoscienze - CNR, via Campi 213/a, 41125 Modena, Italy — We have studied the coherent coupling of microwave photons in a superconducting coplanar resonator with a spin ensemble of stable open-shell organic radicals. We fabricated YBCO/sapphire coplanar resonators that show quality factors  $\simeq 3 \cdot 10^4$  at 1.8 K, that remain remarkably stable in high magnetic field applied parallel to the YBCO film [QL (7 T) = 90% QL (0 T)] [1]. Spin ensembles of (3,5-Dichloro-4-pyridyl)bis(2,4,6-trichlorophenyl)methyl organic radical (PyBTM) show sharp EPR linewidth (8 MHz) due to the effect of the exchange narrowing. The frequency of the spin transition is tuned by means of the external magnetic field. We show the achievement of the strong collective coupling with the resonant photons with coupling rates exceeding 90 MHz at 1.8 K. [1] A. Ghirri, C. Bonizzoni, D. Gerace, S. Sanna, A. Cassinese and M. Affronte, Appl. Phys. Lett. 106, 184101 (2015).

**1:39PM F21.00011 First-principles study on magnetism of Ru monolayer under an external electric field**, YUKIE KITAOKA, HIROSHI IMAMURA, AIST, Spintronics Research Center — Electric field control of magnetic properties such as magnetic moment and magnetic anisotropy has been attracted. For the  $4d$  TM films, on the other hand, it was recently reported that the ferromagnetism Pd thin-film is induced by application of an external electric field otherwise Pd thin-film shows paramagnetic [1]. However, little attention has been paid to the magnetism of other  $4d$  TMs. Here, we investigate the magnetism of the free-standing Ru monolayer and that on MgO(001) substrate under an external electric field by using first-principles FLAPW method [2]. We found that the free-standing Ru monolayer is ferromagnet with magnetic moment of  $1.50 \mu_B/\text{atom}$ . The MA energy is 3.45 meV/atom, indicating perpendicular MA, at zero electric field ( $E=0$ ) and increases up to 3.84 meV/atom by application of  $E=1$  (V/Å). The Ru monolayer on MgO(001) substrate is also ferromagnet with magnetic moment of  $0.89 \mu_B/\text{atom}$ . The MA energy is 1.49 meV/atom, indicating perpendicular MA, at  $E=0$  and decreases to 1.33 meV/atom by application of  $E=1$  (V/Å). [1] Y. Sun, J. D. Burton, E. Y. Tsymlal, PRB 81, 064413 (2010). [2] K. Nakamura, T. Ito, A. J. Freeman, L. Zhong, J. Fernandez-de-Castro, PRB, 67, 014420 (2003).

**1:51PM F21.00012 Chemically Controllable Ferromagnetic Graphene for High-Performance Spintronic Devices**, JEONGMIN HONG, UC Berkeley — The spin and charge of the electron when taken together, offer many opportunities for the creation of new information processing and storage devices applications with ultralow power consumption. Chemically controllable growth of large area nanocarbon structures has attracted considerable interests due to their superior properties. If large area nanocarbon could have by-design magnetic properties, multifunctional electronic devices could be built through modulation controlled by external factors such as 1) functionalization onto basal plane of carbon, 2) substrate effects (proximity induced ferromagnetism), and 3) external electric field. We performed soft X-ray measurement techniques using X-ray magnetic circular dichroism (XMCD) and revealed the controllable ferromagnetic properties on graphene structures. The chemically controllable nanomagnet would be an excellent building block for the applications of graphene-based high-performance spintronic devices.

**2:03PM F21.00013 Energy gap of Graphene Nanoflakes: Edge Magnetism and Self-Energy Corrections.** , ROMEO DE COSS GOMEZ, CARLOS MANUEL RAMOS CASTILLO, Departement of applied physics centro de investigacion y de estudios avanzados del instituto politecnico nacional — Previous theoretical works has predicted that graphene nanostructures with zigzag edge exhibit metallic behavior around 6-7 nm, however in such calculations the magnetic nature of zigzag edges was not considered. In this work, the influence of the edge magnetism on the size dependence of energy-gap in hexagonal graphene nanoflakes (GNFs) with zigzag borders is studied by density functional theory calculations. Thus, we found that meanwhile the calculations without spin polarization predicts that the metallic behaviour for GNFs begin at 6 nm deviating from the trend predicted for effective model of Dirac fermions, spin-polarized calculations predicts semiconducting behavior at 6 nm. This result shows clearly that the origin of metallic behaviour predicted at 6 nm in previous works is not related with the well known band-gap problem of Kohn-Sham scheme, but with neglecting spin polarization. Furthermore, to correct the band-gap problem of Kohn-Sham Scheme, we have calculated the size dependence of fundamental energy-gap using the quasiparticle formalism by adding/removing an electron to/from the system.

**11:15AM F22.00001 Hot Electron Dynamics at Semiconductor-Molecule Interfaces: Insights from First-Principles Dynamics Simulation** , YOSUKE KANAI, University of North Carolina at Chapel Hill — Quantum dynamics of excited electrons is fundamental to functionalities of semiconductor-molecule interfaces that are an integral part of various solar energy conversion and opto-electronic technologies. Thus, developing a predictive and quantitative understanding of the electron dynamics at the atomistic level for such complex interfaces is of great interest. In this talk, I will discuss our recent effort on addressing several challenges in understanding how atomistic features such as surface defects influence these electron dynamical processes. We tackle this problem theoretically by employing a first-principles simulation approach that synergistically combine fewest switches surface hopping, many-body perturbation theory, and first-principles molecular dynamics. New findings from the first-principles simulation will be discussed in the context of a larger effort within Solar Fuels EFRC at UNC Chapel Hill. I will also discuss how the results from atomistic theories pose a conceptual challenge when characterizing these interfacial electron processes for these complex interfaces using a simple kinetic model.

**11:51AM F22.00002 Nonadiabatic dynamics with spin-orbit couplings** , GLORIA CAPANO, 2Laboratory of ultrafast spectroscopy, Ecole Polytechnique Fédérale de Lausanne, Lausanne, 1015, Switzerland., FELIPE FRANCO DE CARVALHO, 1Centre Européen de Calcul Atomique et Moléculaire, Lausanne, 1015, Switzerland., IVANO TAVERNELLI, IBM Research Zurich, 8803 Rüschlikon, Switzerland. — In this talk I will present some recent advances in TDDFT-based nonadiabatic dynamics for molecular systems using Tully's surface hopping. In particular, I will describe a method for the efficient simulation of intersystem crossing events, which requires the on-the-fly calculation of spin-orbit coupling matrix elements along the trajectories. This approach will be applied to the study of the photophysics of metal-organic complexes in solution and of different carbon nanostructures including graphene nanoflakes and nanotubes with different wrapping topologies.

**12:03PM F22.00003 Real-time TDDFT simulations of time-resolved core-level spectroscopies in solid state systems.** , SRI CHAITANYA DAS PEMMARAJU, DAVID PRENDERGAST, Lawrence Berkeley National Laboratory, THEORY OF NANOSTRUCTURED MATERIALS FACILITY TEAM — The advent of sub-femtosecond time-resolved core-level spectroscopies based on high harmonic generated XUV pulses has enabled the study of electron dynamics on characteristic femtosecond time-scales. Unambiguous interpretation of these powerful yet complex spectroscopies however requires the development of theoretical algorithms capable of modeling light-matter interaction across a wide energy range spanning both valence and core orbitals. In this context we present a recent implementation of the velocity-gauge formalism of real-time TDDFT [1] within a linear combination of atomic orbital (LCAO) framework, which facilitates efficient numerical treatment of localized semi-core orbitals. Dynamics and spectra obtained from LCAO based simulations are compared to those from a real-space grid implementation [1]. Potential applications are also illustrated by applying the method towards interpreting recent atto-second time-resolved IR-pump XUV-probe spectroscopies investigating sub-cycle excitation dynamics in bulk silicon [2].

**12:15PM F22.00004 Long-range dispersion forces between molecules subject to attosecond pulses from ab initio calculations** , MICAEL OLIVEIRA, Department of Physics, University of Liege, Belgium, KSENIA KOMAROVA-VLADIMIROVA, FRANCOISE REMACLE, Department of Chemistry, University of Liege, Belgium, MATTHIEU VERTRAETE, Department of Physics, University of Liege, Belgium — The London-van der Waals dispersion forces arising from instantaneously induced dipoles in molecules are a key ingredient in a wide range of phenomena in physics, chemistry, and biology. Therefore, the ability to control and manipulate dispersion forces between atoms and molecules is of great importance. Because those dispersion interactions depend crucially on the electronic properties of the molecular systems, a simple route to achieve this would consist in manipulating their electronic states. The recent development of ultra-short optical pulses has given researchers unprecedented control over the electronic degrees of freedom. These pulses, tailored in their frequency and envelope, allow the generation of a strongly out of equilibrium population of electronic states. In this talk we show how the Hamacker constants characterizing the London-van der Waals interaction between two molecules subject to an optical pulse can be calculated using time-dependent density functional theory (TD-DFT) or standard quantum chemistry methods and present several test cases of molecules subjected to IR and UV attosecond pulses.

**12:27PM F22.00005 Nonequilibrium Green's Function approach to time-resolved photoabsorption<sup>1</sup>** , GIANLUCA STEFANUCCI, ENRICO PERFETTO, University of Rome Tor Vergata, ANNA-MAIJA UIMONEN, ROBERT VAN LEEUWEN, University of Jyväskylä — We propose a nonequilibrium Green's function (NEGF) approach to calculate the time-resolved absorption spectrum of nanoscale systems [1]. We can deal with arbitrary shape, intensity, duration and relative delay of the pump and probe fields and include ionization processes as well as hybridization effects due to surfaces. We present numerical simulations of atomic systems using different approximate self-energies and show that electron correlations are pivotal to reproduce important qualitative features. [1] E. Perfetto, A.-M. Uimonen, R. van Leeuwen and G. Stefanucci, Phys. Rev. A 92, 033419 (2015) [2] E. Perfetto, D. Sangalli, A. Marini and G. Stefanucci, Phys. Rev. B, accepted

**12:39PM F22.00006 AB INITIO DYNAMICS OF AN ELECTRON INTERACTING WITH A LATTICE DEFECT**, VSEVOLOD IVANOV, MARCO BERNARDI, California Institute of Technology, Pasadena, California 91125. — We study the scattering process of a charge carrier with a defect in a range of bulk and 2D materials. The scattering potential is obtained using density functional theory, the carrier is represented by a gaussian wavepacket, and the dynamics is carried out with a split-operator technique. Our parallel code can model the electron-defect scattering processes in real space and time, with an electron wavepacket of realistic size (100 - 1000 unit cells) and an accuracy typical of ab initio calculations. We apply our approach to model a carrier scattering with a vacancy in silicon and an impurity in monolayer MoS<sub>2</sub>, obtaining angular dependent scattering cross sections and resonant states.

**12:51PM F22.00007 Real-Time Time-Dependent DFT Study of Electronic Stopping in Semiconductors under Proton Irradiation**, DILLON C. YOST, KYLE G. REEVES, YOSUKE KANAI, University of North Carolina - Chapel Hill — Understanding the detailed mechanisms of how highly energetic charged particles transfer their kinetic energy to electronic excitations in materials has become an important topic in various technologies ranging from nuclear energy applications to integrated circuits for space missions. In this work, we use our new large-scale real-time time-dependent density functional theory simulation [1] to investigate details of the ion-velocity-dependent dynamics of electronic excitations in the electronic stopping process. In particular, we will discuss how point defects in semiconductor materials influence the electronic stopping process under proton irradiation, using silicon carbide (3C-SiC) as a representative material due to its great technological importance. Additionally, we will provide atomistic insights into existing analytical models that are based on the plane-wave Born approximation by examining velocity-dependence of the projectile charge from first-principles simulations. [1] “Quantum Dynamics Simulation of Electrons in Materials on High-Performance Computers” A. Schleife, E. W. Draeger, V. Anisimov, A. A. Correa, Y. Kanai, Computing in Science and Engineering, 16 (5), 54 (2014).

**1:03PM F22.00008 Semiconductors Under Ion Radiation: Ultrafast Electron-Ion Dynamics in Perfect Crystals and the Effect of Defects**, CHENG-WEI LEE, ANDRÉ SCHLEIFE, University of Illinois at Urbana-Champaign — Stability and safety issues have been challenging difficulties for materials and devices under radiation such as solar panels in outer space. On the other hand, radiation can be utilized to modify materials and increase their performance via focused-ion beam patterning at nano-scale. In order to grasp the underlying processes, further understanding of the radiation-material and radiation-defect interactions is required and inevitably involves the electron-ion dynamics that was traditionally hard to capture. By applying Ehrenfest dynamics based on time-dependent density functional theory, we have been able to perform real-time simulation of electron-ion dynamics in MgO and InP/GaP. By simulating a high-energy proton penetrating the material, the energy gain of electronic system can be interpreted as electronic stopping power and the result is compared to existing data. We also study electronic stopping in the vicinity of defects: for both oxygen vacancy in MgO and interface of InP/GaP superlattice, electronic stopping shows strong dependence on the velocity of the proton. To study the energy transfer from electronic system to lattice, simulations of about 100 femto-seconds are performed and we analyze the difference between Ehrenfest and Born-Oppenheimer molecular dynamics.

**1:15PM F22.00009 Role of non-adiabatic carrier dynamics in non-thermal phase transition of Ge-Sb-Te alloy**, JUNHYEOK BANG, Korea Basic Science Institute (KBSI), YIYANG SUN, X.-Q. LIU, Rensselaer Polytechnic Institute (RPI), F. GAO, University of Michigan, S. B. ZHANG, Rensselaer Polytechnic Institute (RPI) — Non-thermal phase transition driven by femtosecond laser irradiation has been explained by the simple static plasma annealing effect: excitation of a large fraction of valence electrons to conduction bands weakens lattices and leads to the structural phase transition in low temperature. Here, by time-dependent density functional theory and molecular dynamics study of Ge-Sb-Te alloys, we find that the energy-dependent dynamics of excited carriers is critical in determining the phase transition mechanism. For low energy carriers electron-phonon scattering becomes a dominant relaxation process, and for high energy carriers electron-electron scattering remains a dominant relaxation process. As a result, we observe significant ionic temperature increase for low energy excitation, which aids phase transition by thermal effect, and non-thermal phase transition for high energy excitation. This provides a new conceptual framework in understanding fundamental phenomenon of the phase transition.

**1:27PM F22.00010 Optimal ultrafast laser pulse-shaping to direct photo-induced phase transitions**, BIN HWANG<sup>1</sup>, JENNI PORTMAN, PHILLIP DUXBURY<sup>2</sup>, Michigan State University — Photo-induced phase transitions (PIPT) in quantum and/or complex materials are the epitome of challenging non-equilibrium many-body phenomena, that also have a wide range of potential applications. We present a computational approach to finding optimal ultrafast laser pulse shapes to control the outcome of pump-probe PIPT experiments. The Krotov approach for optimal control is combined with a Keldysh Green's function calculation to describe experimental outcomes such as photoemission, transient single particle density of states and optical responses. Results for a simple model charge density wave system will be presented.

**1:39PM F22.00011 Multiphysics modeling of non-linear laser-matter interactions for optically active semiconductors**<sup>1</sup>, BRENT KRACZEK, JAROSLAW KANP, US Army Research Laboratory — Development of photonic devices for sensors and communications devices has been significantly enhanced by computational modeling. We present a new computational method for modelling laser propagation in optically-active semiconductors within the paraxial wave approximation (PWA). Light propagation is modeled using the Streamline-upwind/Petrov-Galerkin finite element method (FEM). Material response enters through the non-linear polarization, which serves as the right-hand side of the FEM calculation. Maxwell's equations for classical light propagation within the PWA can be written solely in terms of the electric field, producing a wave equation that is a form of the advection-diffusion-reaction equations (ADREs). This allows adaptation of the computational machinery developed for solving ADREs in fluid dynamics to light-propagation modeling. The non-linear polarization is incorporated using a flexible framework to enable the use of multiple methods for carrier-carrier interactions (e.g. relaxation-time-based or Monte Carlo) to enter through the non-linear polarization, as appropriate to the material type. We demonstrate using a simple carrier-carrier model approximating the response of GaN.

**1:51PM F22.00012 Kinetic Density Functional Theory for Plasmonic Nanostructures**, LUCAS V. BESTEIRO, Ohio University, HUI ZHANG, Rice University, ALEXANDER GOVOROV, Ohio University — We present a quantum kinetic theory of the dynamic response of typical noble metals [1]. The kinetic DFT is derived starting from the master equation of motion for the density matrix, which involves both momentum and energy relaxation processes. Therefore, the quantum system is described by two relaxation parameters, unlike the conventional time-dependent DFT incorporating only one relaxation parameter. This allows us to describe both the absorption of light and the generation of hot plasmonic electrons. The proposed theory can be employed to model and predict a variety of metal and hybrid nanostructures for applications in photocatalysis, sensors, photodetectors, metamaterials, etc. To support this, we show how the formalism can provide insights on several recent experimental results [2-4]. **2:03PM F22.00013 Electrically induced spontaneous emission in open electronic system**, RULIN WANG, Beijing Computational Science Research Center, YU ZHANG, The University of Hong Kong, CHIYUNG YAM, Beijing Computational Science Research Center, COMPUTATION ALGORITHMS DIVISION (CSRC) TEAM, THEORETICAL AND COMPUTATIONAL CHEMISTRY (HKU) COLLABORATION — A quantum mechanical approach is formulated for simulation of electroluminescence process in open electronic system. Based on nonequilibrium Greens function quantum transport equations and combining with photon-electron interaction, this method is used to describe electrically induced spontaneous emission caused by electron-hole recombination. The accuracy and reliability of simulation depends critically on correct description of the electronic band structure and the electron occupancy in the system. In this work, instead of considering electron-hole recombination in discrete states in the previous work, we take continuous states into account to simulate the spontaneous emission in open electronic system, and discover that the polarization of emitted photon is closely related to its propagation direction. Numerical studies have been performed to silicon nanowire-based P-N junction with different bias voltage.

**11:15AM F23.00001 Direct Writing of Metamaterials Using Atomic Calligraphy**<sup>1</sup>, THOMAS STARK, JEREMY REEVES, LAWRENCE BARRETT, RICHARD LALLY, DAVID BISHOP, Boston University — The trend toward creating metamaterials with spectral features at shorter wavelengths demands a concomitant decrease in the minimum feature size. Many fabrication techniques have been developed to meet this challenge, all of which must address competition between resolution and throughput [1]. We fabricate metamaterials using atomic calligraphy, a technique that tackles both the throughput and resolution challenges, and present optical characterization of the metamaterials we fabricate [2]. Atomic calligraphy is a microelectromechanical systems (MEMS) based moveable stencil used to fabricate nanostructures. We increase the throughput of this technique by using many stencils in parallel and work toward further enhancing throughput by using a stage system to step the MEMS and repeat fabrication over large areas. Finally, we characterize the infrared response of the metamaterials that we fabricated. This technology can be used to fabricate metamaterials on a host of substrates, including those that are chemically incompatible with or have topological features that preclude them from use with conventional nanofabrication techniques, such as mechanical scaffolds that enable tuning of the metamaterial spectral response. **11:27AM F23.00002 Graphene-like Networks in the lattice of Ag, Cu and Al metals**, LOURDES SALAMANCA-RIBA, XIAOXIAO GE, ROMAINE ISAACS, HM IFTEKAR JAIM, MANFRED WUTTIG, SERGEY RASHKEEV, MAIJA KUKLJA, LIANBING HU, University of Maryland, COVETICS TEAM TEAM — Graphene-like networks form in the lattice of metals such as silver, copper and aluminum via an electrocharging assisted process. In this process a high current of >80A is applied to the liquid metal containing particles of activated carbon. The resulting material is called M covetic (M=Al, Ag Cu). We have previously reported that this process gives rise to carbon nanostructures with sp<sup>2</sup> bonding embedded in the lattice of the metal. The carbon bonds to the metal as evidenced by Raman scattering and first principles simulation of the phonon density of states. With this process we have observed that graphene nanoribbons form along preferential crystalline directions and form 3D epitaxial structures with Al and Ag hosts. Bulk Cu covetic was used to deposit films by e-beam deposition and PLD. The PLD films contain higher C content and show higher transmittance (~90%) and resistance to oxidation than pure copper films of the same thickness. We compare the electrical and mechanical properties of covetics containing C in the 0 to 10 wt % and the transmittance of Cu covetic films compared to pure Cu films of the same thickness. Supported by ONR grant N000141410042

**11:39AM F23.00003 Patterned Fabrication of Zinc Oxide Nanowire Arrays**<sup>1</sup>, SAHAR KHAN<sup>2</sup>, THOMAS LAMSON<sup>3</sup>, HUIZHONG XU<sup>4</sup>, St. John's University — Zinc oxide nanowires possess desirable mechanical, thermodynamic, electrical, and optical properties. Although the hydrothermal growth process can be applied in tolerable growth conditions, the dimension and density of nanowires has a complex dependence on substrate pre-treatment, precursor concentrations, and growth conditions. Precise control of the geometry and density of nanowires as well as the location of nanowires would allow for the fabrication of useful nanowaveguide devices. In this work, we used electron beam lithography to pattern hole arrays in a polymer layer on gold-coated glass substrates and synthesized zinc oxide nanowires inside these holes. Arrays of nanowires with diameters ranging from 50 nm to 140 nm and various spacings were obtained. The transmission of light through these zinc oxide nanowire arrays in a silver film was also studied.

**11:51AM F23.00004 Effect of Ti adhesive layer on individual gold nanodisk surface plasmon resonance**, DESALEGN TADESSE DEBU, PIJUSH GHOSH, DAVID FRENCH, STEPHEN BAUMAN, JOSEPH B. HERZOG, Univ of Arkansas-Fayetteville — We investigate localized surface plasmon resonance (SPR) of gold nanodisks of various diameter and height fabricated on extremely thin Ti adhesive layers. Dark field scattering measurements reveal significant dependence of SPR in the size nano structures and polarization of the light. Comparisons of peak resonance extracted from spectra using Gaussian fitting of different Ti adhesive layer thickness indicates significant red shifting and damping of the plasmon mode. Experimental results are supported by numerical simulation based on three dimensional finite element time domain analysis. From the simulation and experimental results we quantitatively developed optimized model equation of resonance mode of the nanodisks with respect to adhesive layer thickness and broadening effect of the line shape. Such optimized model is very helpful in guiding targeted nanofabrication such as gold nanodisk antennas or biosensors.

**12:03PM F23.00005 Aluminum Nanowire Arrays via Directed Assembly<sup>1</sup>**, NATHAN T. NESBITT, JUAN M. MERLO, AARON H. ROSE, YITZI M. CALM, LUKE A. D'IMPERIO, DAVE T. COURTNEY, STEVE SHEPARD, KRZYSZTOF KEMPA, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College — Vertically-oriented metal nanowire arrays are rare. Here, freestanding, vertically-oriented, and lithographically-ordered Al nanowire arrays have been fabricated via directed assembly [1]. The fabrication technique is a variation on the preparation of anodized aluminum oxide (AAO) templates, using nanoimprint lithography (NIL) to direct the formation of pores on an Al film and produce Al nanowires. Near-field scanning optical microscope (NSOM) and conventional optical microscope data of a single nanowire lying on glass and illuminated by a laser spot show evidence of surface plasmons propagating along the nanowire. **12:15PM F23.00006 The total scattering atomic pair distribution function: New methodology for nanostructure analysis.**, AHMAD MASADEH, Department of Physics, The University of Jordan — The conventional x-ray diffraction (XRD) methods probe for the presence of long-range order (periodic structure) which are reflected in the Bragg peaks. Local structural deviations or disorder mainly affect the diffuse scattering intensity. In order to obtain structural information about both long-range order and local structure disorder, a technique that takes in account both Bragg and diffuse scattering need to be employed, such as the atomic pair distribution function (PDF) technique. This work introduces a PDF based methodology to quantitatively investigate nanostructure materials in general. The introduced methodology can be applied to extract quantitatively structural information about structure, crystallinity level, core/shell size, nanoparticle size, and inhomogeneous internal strain in the measured nanoparticles. This method is generally applicable to the characterization of the nano-scale solid, many of which may exhibit complex disorder and strain [1,2] (1) Ahmad. S. Masadeh, et al., *Phys. Rev. B* 76, 115413 (2007). (2) Xiaohao Yang, *Ahmad S Masadeh*, *Physical Chemistry Chemical Physics*; 15, 8480 (2013).

**12:27PM F23.00007 In-situ transmission x-ray microscopy study of photon-induced oxidation of silver nanowires**, LE YU, Department of Physics, Bryn Mawr College; School of Electronic Science and Engineering, Nanjing University, China, YUGANG SUN, Center for Nanoscale Materials, Argonne National Laboratory, YUXIN WANG, ZHONGHOU CAI, X-ray Science Division, Advanced Photon Source, Argonne National Laboratory, PING HAN, School of Electronic Science and Engineering, Nanjing University, China, X.M. CHENG, Department of Physics, Bryn Mawr College — Oxidation of metal nanoparticles usually follows a Kirkendall process to transform solid nanoparticles to hollow metal oxide nanoshells. However the morphological trajectory of nanoparticles and the mass diffusion kinetics involved in the nanoscale Kirkendall process are complex. In this presentation we report the use of in-situ transmission x-ray microscopy (TXM) to directly image individual silver nanowires under oxidation atmosphere, which are created from radiolysis of air under illumination of the focused synchrotron x-ray beam. The in-situ results clearly show the morphological transformation from solid silver nanowires to hollow nanotubes in the course of oxidation reaction of silver. Quantitative analysis of the time-resolved TXM images provides unprecedented details on reaction kinetics and mass diffusion kinetics associated with the oxidation process. Work at Bryn Mawr College is supported by NSF grant #1207085. Use of the Advanced Photon Source and the Center for Nanoscale Materials at Argonne National Laboratory was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

**12:39PM F23.00008 Investigation of Carbon incorporation into Al 6061 alloys**, XIAOXIAO GE, LOURDES SALAMANCA RIBA, MANFRED WUTTIG, Univ of Maryland-College Park, COVETICS COLLABORATION — The incorporation of carbon nanostructures into aluminum alloys, such as Al6061 and Al7075, has the potential to further improve the mechanical, electrical and anti-corrosion properties of these alloys. We report on a novel method to incorporate up to 10.0 wt% carbon into the crystal structure of Al 6061 alloys to form a new material "Al Covetics". In this method, a DC current is applied to molten Al metal containing activated carbon particles. The current facilitates ionization of the carbon atoms and their bonding to each other, forming graphic chains and layers along preferential directions of the Al lattice. Raman mapping of the G and D peaks of graphitic carbon was used to confirm the role of the current in ensuring that the carbons remain in the metal by electro-static force and spread into the metal matrix evenly.  $sp^2$  bonding of carbon was found all over the surface in the Covetics. Carbon signals were also observed everywhere in Covetics with Energy Dispersive X-ray Spectroscopy. However, localized carbon signals were detected in samples made with activated carbon but without applying any current. The dependence of the mechanical, electrical and structural properties of Al Covetics on C content from 3 to 10 wt. % will be presented.

**12:51PM F23.00009 Electrical and Optical Characterization of Cobalt Doped Nanostructured ZnO/p-Si Heterojunctions**, AMRIT KAPHE, ECHO ADCOCK SMITH, PARAMESWAR HARI, DANIEL CRUNKLETON, TYLER JOHANNES, TODD OTANICAR, KENNETH ROBERTS, Univ of Tulsa — In this study we investigated electrical and optical properties of heterojunctions made of cobalt doped ZnO nanorods and Boron doped silicon (p-Si). ZnO nanorods were grown on a seed layer of Zn sputtered on p-Si using a chemical bath deposition technique. Cobalt percentage in the ZnO were varied from 0-20%. Scanning Electron Microscope (SEM) images indicate that the diameter of ZnO nanorods increased with higher cobalt doping. Room temperature photoluminescence shows an increase in the defect peak at 550 nm with increasing doping. Band gap was measured using UV-VIS spectroscopy. In addition, we also performed current-voltage (I-V), capacitance-voltage (C-V) measurements on ZnO/p-Si samples under both dark and illumination conditions. I-V characteristics show good rectifying behavior under dark and illumination conditions. The saturation current, diode ideality factor, carrier concentrations, built in potential, and barrier height were calculated from I-V and C-V measurements. We will discuss the implications of the band gap, I-V, and C-V measurements with variations in cobalt doping concentrations in ZnO/p-Si heterojunctions.

**1:03PM F23.00010 One-dimensional Growth of Zinc Crystals on a Liquid Surface<sup>1</sup>**, CHENXI LU, YI CHENG, QIFA PAN, XIANGMING TAO, BO YANG, GAOXIANG YE, Department of Physics, Zhejiang University, Hangzhou 310027, P. R. China, THE LAB OF FILMS ON LIQUID SUBSTRATES TEAM — The catalyst-free growth of nanocrystals on various substrates at room temperature has been a long-standing goal in the development of material science. We report the growth of one-dimensional zinc nanocrystals on silicone oil surfaces by thermal evaporation method at room temperature ( $20 \pm 2$  °C). Uniform zinc nanorods with tunable size can be obtained. The typical length and width of the nanorods are 250-500 nm and 20-40 nm, respectively. The growth mechanism can be attributed to the effect of the liquid substrate and the preferential growth direction of the crystals. This result provides a novel and simple way to fabricate the precursors (zinc crystals) for preparation of Zn-based semiconductors and other metallic crystals on liquid substrates.

<sup>1</sup>The research was funded by the National Natural Science Foundation of China (Grant No. 11374082).

**1:15PM F23.00011 Tracking and Removing Br during the Bottom-Up Synthesis of a Graphene Nanoribbon**, CHRISTOPHER BRONNER, University of California, Berkeley, JONAS BJÖRK, Linköping University, PETRA TEGEDER, Ruprecht-Karls-Universität Heidelberg — Thermally induced, two-step bottom-up synthesis from halogen-substituted molecular precursors adsorbed at metal surfaces is an intriguing concept for obtaining graphene nanoribbons with well-defined edge structure and widths on the nanometer scale. The reaction pathways of the dissociated Br atoms have so far not been in the focus of research although they may very well interfere with the on-surface synthesis. Using temperature-programmed desorption we show that Br leaves the surface as HBr in an associative desorption process during the second reaction step, the cyclodehydrogenation. Density functional theory is employed to compare this process to the competing desorption of molecular hydrogen and furthermore shows that prior to desorption, Br is submerged under the three-dimensional intermediate reaction product, polyanthrylene. Upon exposure of this intermediate co-adsorbate to an atmosphere of molecular hydrogen, Br is removed from the surface but the cyclodehydrogenation step is still feasible which demonstrates that Br does not influence the on-surface synthesis. Generally, the ability to remove Br by providing molecular hydrogen opens an effective way to exclude unfavorable influences of the halogen (e.g. side-products, steric effects) in on-surface coupling reactions.

**1:27PM F23.00012 Synthesis of metal-organic framework films by pore diffusion method.**, NAO-HIRO MURAYAMA, YUKI NISHIMURA, Tottori Univ, HIROSHI KAJIRO, Nippon Steel & Sumitomo Metal Co., SATORU KISHIDA, KENTARO KINOSHITA, Tottori Univ, TIFREC, TEDREC, TOTTORI UNIV TEAM, NIPPON STEEL & SUMITOMO METAL CO. COLLABORATION, TOTTORI INTEGRATED FRONTIER RESEARCH CENTER (TIFREC) COLLABORATION, TOTTORI UNIVERSITY ELECTRONIC DISPLAY RESEARCH CENTER (TEDREC) COLLABORATION — Metal-organic frameworks (MOFs) presents high controllability in designing the nano-scale pore, and this enable molecular storages, catalysts, gas sensors, gas separation membranes, and electronic devices for next-generation. Therefore, a simple method for film synthesis of MOFs compared with conventional methods<sup>[1]</sup> is strongly required. In this paper, we provide pore diffusion method, in which a substrate containing constituent metals of MOF is inserted in solution that includes only linker molecules of MOF. As a result, 2D growth of MOF was effectively enhanced, and the formation of flat and dense MOF films was attained. The growth time,  $t$ , dependence of film thickness,  $d$ , can be expressed by the relation of  $d = A \ln(t+1) + B$ , where A and B are constants. It means that ionized coppers diffuse through the pores of MOFs and the synthesis reaction proceeds at the MOF/solvent interface. We demonstrated the fabrication of a HKUST-1/Cu-TPA hetero structure by synthesizing a Cu-TPA film continuously after the growth of a HKUST-1 film on the CuO<sub>x</sub> substrate. [1] Denise Zacher *et al.*, *Angew. Chem. Int. Ed.* **50**, 176 (2011).

**1:39PM F23.00013 Glancing angle deposited villi-like nanostructures for enhanced chemo-resistive performances<sup>1</sup>**, HI GYU MOON, YOUNGMO JUNG, TAIKJIN LEE, SEOK LEE, Korea Institute of Science and Technology, HYUNG-HO PARK, Yonsei University, CHULKI KIM, CHONG-YUN KANG, Korea Institute of Science and Technology — Metal oxide nanostructures have attracted enormous attention for diverse applications such as solar cells, nanogenerators, nanolasers, optoelectronic devices and chemoresistive sensor. To achieve the enhanced electrical properties for these applications, one-dimensional (1D) metal oxide materials including nanowires, nanorods, nanotubes and nanobelts have been widely studied. However, the use of 1D nanomaterials as chemoresistive sensors is still in the beginning stage in how to integrate them. As an alternative, porous thin films based on 1D metal oxide nanostructures are considered as more desirable configuration due to their simplicity in synthesis, high reproducibility. In this study, we propose facile synthesis and self-assembled villi-like nanofingers (VLNF) WO<sub>3</sub> thin films with large specific surface area on the SiO<sub>2</sub>/Si substrate. Room-temperature glancing angle deposition of WO<sub>3</sub> by a simple controlling in both polar and azimuthal directions resulted in anisotropic nanostructures with large aspect ratio and porous structures with a relative surface area of 350 m<sup>2</sup>/g.

<sup>1</sup>Glancing angle deposited villi-like nanostructures for enhanced chemo-resistive performances

**1:51PM F23.00014 Replace this text with your abstract title.**, YANG LI, Ohio University Argonne National Laboratory, ANDREW DILULLO, BRANDON FISHER, Argonne National Laboratory, SAW-WAI HLA, Argonne National Laboratory & Ohio University — We investigate the interaction of graphene nanoribbon (GNR) with cobalt-porphyrin (Co-TBrPP) molecules using low temperature scanning tunneling microscopy (STM), tunneling spectroscopy, and atomic/molecular manipulation schemes. GNRs are formed by fusing 10,10'-dibromo-9,9'-bianthryl molecules on a Au(111) surface. Due to a weak binding, the Co-TBrPP molecules are mobile on GNR. The lateral manipulation scheme using the STM tip is employed to investigate the diffusion of the molecule on this surface. Guided by the edges of the GNR, the molecules diffuse in one-dimensional paths. We will also discuss the electronic properties of Co-TBrPP on GNR measured by using tunneling spectroscopy and spectroscopic mapping. We acknowledge the support of DOE SISGR grant: DE-FG02-09ER16109.

**11:15AM F24.00001 Theory of light scattering at nanoparticles and optical forces between small particles**, JUAN JOSE SAENZ, Donostia International Physics Center (DIPC) — Appropriate combinations of laser beams can be used to trap and manipulate small particles with optical tweezers as well as to induce significant optical binding forces between particles. Here we review some basic concepts related to the optical forces on small (subwavelength) particles, focusing on the interplay between scattering asymmetry and momentum transfer. These forces are, in general, non-conservative (curl forces) which lead to a number of intriguing predictions regarding the dynamics of nanoparticles. Optical forces between small particles are usually strongly anisotropic depending on the interference landscape of the external fields. This is in contrast with the familiar isotropic van der Waals and, in general, Casimir-Lifshitz interactions between neutral bodies arising from random electromagnetic waves generated by equilibrium quantum and thermal fluctuations. As we will see, artificially created random fluctuating light fields can be used to induce and control dispersion forces between small colloidal particles. Interestingly, for relatively high refractive index semiconductor nanoparticles, the interactions can be tuned from attractive to strongly repulsive when the frequency of the external fluctuating field is tuned near the first magnetic Mie-resonance. Interactions induced by randomly fluctuating light fields open a path towards the control of translational invariant interactions with tuneable strength and range in colloidal systems.

**11:51AM F24.00002 Redox-driven conductance modulation of a single quantum dot in an electrolytic environment<sup>1</sup>**, GIACOMO LOVAT, University of Trieste and Columbia University, BOYEON CHOI, XAVIER ROY, LATHA VENKATARAMAN, Columbia University — Electrons confined in zero-dimensional systems exhibit shape and size-dependent electronic and optical properties of interest for many technological applications. A realization of molecular-scale quantum dots having precise shape and size is provided by the synthesis of atomically defined isostructural metal chalcogenide clusters functionalized with organic connectors, which opens the possibility of wiring up these dots without altering significantly their electronic structure. Here, we characterize the charge transport in single molecule junctions fabricated with Co<sub>6</sub>Se<sub>8</sub> clusters via the scanning tunneling microscope break junction technique. The cluster structure consists of an octahedron of Co atoms concentric with a cube of Se atoms; the electrical connection to the Au leads is provided by aurophilic thiol-terminated ligands attached at the Co sites. We demonstrate that conductance modulation in a cluster junction can be achieved by controlling the charge state of the cluster. The conductance of the oxidized species differs from that of the neutral ones, consistent with the value obtained in a control experiment with chemically oxidized clusters.

**12:03PM F24.00003 First Principles Simulations of Nanoparticle Solids<sup>1</sup>**, ARIN GREENWOOD, Institute for Molecular Engineering, University of Chicago, MÁRTON VÖRÖS, Institute for Molecular Engineering, University of Chicago; Materials Science Division, Argonne National Laboratory, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Nanoparticle solids are gaining popularity as materials for optoelectronic devices such as solar cells [1, 2]. However, there is still much debate regarding the transport regime governing the charge carriers. To date, no comprehensive description of transport mechanisms in nanoparticle solids has been established, and there is a lack of computational studies predicting electron mobilities and transport rates at the *ab initio* level. In order to understand electron transport properties, it is an essential prerequisite to build realistic structural models of nanoparticle solids to use for prediction of electronic structure and eventually transport properties. Here we present *Ab Initio* Molecular Dynamics simulations of lead chalcogenide nanoparticles and surrounding ligands to extract relevant electronic structure properties for charge transport calculations. We tested the validity of recently observed “band-like” transport [3] by assessing the formation of bands and their dependence on nanoparticle surface structure and ligands.

**12:15PM F24.00004 Molecularly-linked gold nanoparticle films across the insulator-to-metal transition: from hopping to strong electron correlations**, MONIQUE TIE, AL-AMIN DHIRANI, Univ of Toronto — Materials which have strong electron-electron interactions are known to display a wide variety of exotic behaviours. We have found that molecularly-linked gold nanoparticle films represent a new class of materials that exhibit correlated electronic behaviours. Most notably, (a) they undergo a percolation insulator-to-metal transition as a function of film thickness, (b) as the system transitions from an insulator to a metal, a previously unobserved zero-bias conductance peak emerges, attributed to electron correlations, and (c) Coulomb effects play an important role in the conductance on both the insulating and metallic sides near the transition. On the insulating side near the transition, we observe hopping transport with significant Coulomb charging barriers (Efros-Shklovskii variable range hopping). On the metallic side, we have found that conductance behaves as a Fermi liquid with disorder mediated electron-electron interactions. Remarkably, in this barely-metallic phase, we have found elastic scattering lengths smaller than inter-atomic Au-Au separation, violating the Ioffe-Regel limit and signalling strong electron-electron interactions. These results show that gold nanoparticle films can serve as a new test bed for studying correlated electrons and illustrate the promise

**12:27PM F24.00005 Towards the Ultimate Limit of Connectivity in Quantum Dots with High Mobility and Clean Gaps**, HUASHAN LI, DAVID ZHITOMIRSKY, SHREYA DAVE, JEFFREY GROSSMAN, Massachusetts Institute of Technology — Colloidal quantum dots (CQDs) are especially promising for commercial electronic and optoelectronic applications, yet there is a considerable lack of fundamental understanding of their electronic structure as they couple within thin films. In this work, we applied a combination of computational and experimental techniques to gain insight into the impact of connectivity in CQD assemblies. High Resolution Transmission Electron Microscopy demonstrates that a range of connectivity between dots in the film is attainable by tuning the CQD size and ligand treatment. These results were complemented by *ab-initio* simulations within the phonon-assisted charge hopping scenario. We find that both the orbital hybridization and interfacial dipole moment can change the electronic structure substantially; thus, control over the interface structure beyond stoichiometry is necessary to eliminate trap states. In addition, carrier mobility has a strong dependence on the type of connectivity (i.e., bridge vs. necking), the connectivity orientation, carrier energy, and defect states. Based on our calculations, we propose a scheme for improved carrier mobility, by necking the dots for the advantage of large electron coupling, followed by excess ligand passivation to recover the wavefunction delocalization.

**12:39PM F24.00006 Metal-Insulator Transition in nanoparticle solids: a kinetic Monte Carlo study<sup>1</sup>**, GERGELY ZIMANYI, LUMAN QU, Physics, UC Davis, Davis, CA 95616, MARTON VOROS, Materials Science Division, Argonne National Laboratory, IL — Nanoparticle (NP) solids recently emerged as a promising platform for high performance electronic/optoelectronic devices, including third generation solar cells, light emitting diodes and field effect transistors. A challenge of NP films is that their charge transport is in the unfavorable hopping/insulating regime. Recent experiments showed that it is possible to tune the NP solids through a Metal-Insulator Transition (MIT) via ligand engineering and ALD matrix infilling. However, the microscopic understanding of this transition is not yet clear. To address this challenge, we developed a Kinetic Monte Carlo transport modeling framework that builds on determining NP parameters from *ab initio*-based calculations of the energy level structures, charging energies and overlaps, and then uses these to compute the hopping mobility across a disordered NP array by the Marcus and Miller-Abrahams mechanisms. We reproduced and explained the observed non-monotonous dependence of the mobility on the NP diameter. Centrally, we extended our platform to be able to capture the MIT. We determined the MIT phase boundary on the (NP-NP overlap - Electron density) plane. We demonstrated that all mobilities fall on a universal scaling curve, allowing us to determine the critical behavior across the MIT.

**12:51PM F24.00007 The effect of oxidation on charge carrier motion in PbS quantum dot thin films studied with Kelvin Probe Microscopy<sup>1</sup>**, LAN PHUONG NGUYEN HOANG, PHEONA WILLIAMS, JASON MOSCATELLO, KATHY AIDALA<sup>2</sup>, Mt Holyoke Coll, AIDALA GROUP TEAM — We developed a technique that uses scanning probe microscopy (SPM) to study the real-time injection and extraction of charge carriers in thin film devices. We investigate the effects of oxidation on thin films of Lead Sulfide (PbS) quantum dots with tetrabutyl-ammonium-iodide (TBAI) ligands in an inverted field effect transistor geometry with gold electrodes. By positioning the SPM tip at an individual location and using Kelvin Probe Force Microscopy (KPFM) to measure the potential over time, we can record how the charge carriers respond to changing the backgate voltage with grounded source and drain electrodes. We see relatively fast screening for negative backgate voltages because holes are quickly injected into the PbS film. The screening is slower for positive gate voltages, because some of these holes are trapped and therefore less mobile. We probe these trapped holes by applying different gate voltages and recording the change in potential at the surface. There are mixed reports about the effect of air exposure on thin films of PbS quantum dots, with initial exposure appearing to be beneficial to device characteristics. We study the change in current, mobility, and charge injection and extraction as measured by KPFM over hours and days of exposure to air.

**1:03PM F24.00008 Effects of electron-phonon interactions on the electron tunneling spectrum of PbS quantum dots**, A. ZIMMERS, H. WANG, E. LHUILLIER, Q. YU, A. MOTTAGHIZADEH, ESPCI-UPMC-CNRS Paris-France, C. ULYSSE, CNRS, Lab Photon & Nanostruct, Marcoussis, France, A. DESCAMPS-MANDINE, B. DUBERTRET, H. AUBIN, ESPCI-UPMC-CNRS Paris-France — We present a tunnel spectroscopy study of single PbS and HgSe quantum dots (QDs) as a function of temperature and gate voltage. The samples are fabricated through high-vacuum projection of the QDs on the chip circuit. For PbS, three distinct signatures of strong electron-phonon coupling are observed in the electron tunneling spectrum (ETS) of these QDs. In the shell-filling regime, the 8x degeneracy of the electronic levels is lifted by the Coulomb interactions and allows the observation of phonon subbands that result from the emission of optical phonons. At low bias, a gap is observed in the ETS that cannot be closed with the gate voltage, which is a distinguishing feature of the Franck-Condon blockade. From the data, a Huang-Rhys factor in the range 5 similar to 1.7-2.5 is obtained. Finally, in the shell-tunneling regime, the optical phonons appear in the inelastic ETS  $d(2)/dV(2)$ . For HgSe, the data show that the inter-band and intra-band gap can be clearly identified in the ETS.

**1:15PM F24.00009 Enhancement of pumped current in quantum dots.**, JUAN PABLO RAMOS, Universidad Tecnica Federico Santa Maria, Valparaíso, Chile, LUIS FOA, Universidad Nacional de Córdoba, Córdoba, Argentina, VICTOR MARCELO APEL, Universidad Catolica del Norte, Antofagasta, Chile, PEDRO ORELLANA, Universidad Tecnica Federico Santa Maria, Valparaíso, Chile — A direct current usually requires the application of a non-zero potential difference between source and drain, but on nanoscale systems (NSS) it is possible to obtain a non-zero current while the potential difference is zero. The effect is known as quantum charge pumping (QCP) and it is due to the interference provided by the existence of a time-dependent potential (TDP). QCP can be generated by a TDP in non-adiabatic limit. An example of this is a system composed by a ring with a dot embedded on it, under the application of an oscillating TDP. By the action of a magnetic field across the system, a pumped current is generated, since time reversal symmetry is broken. Decoherence is crucial, both from a scientific and technological point of view. In NSS it is expected that decoherence, among others things, decreases the QCP amplitude. In this context, we study what is the effect of a bath on the pumped current in our system. We find that for certain values of magnetic flux, the bath-system produce amplification of the pumped current. [1] J. P. Ramos *et al.* J. of appl. Phys. **115**, 124507, (2014). [2] M. Moskalets *et al.* Phys. Rev. B **64**, 201305, (2001).

**1:27PM F24.00010 Strong coupling effects in coherent electron transport in periodic quantum nanostructures**<sup>1</sup>, T. V. SHAHBAZYAN, L. S. PETROSYAN, Jackson State University — We study coherent transport in a system of periodic linear chain of quantum dots placed between two parallel quantum wires. We show that resonant-tunneling conductance between the wires exhibits Rabi splitting of the resonance peak as a function of Fermi energy in the wires. This effect is an electron transport analogue of the Rabi splitting in optical spectra of two interacting systems. The conductance peak splitting originates from anticrossing of Bloch bands in a periodic system caused by strong coupling between electron states in the quantum dot chain and quantum wires. A perpendicular magnetic field, by breaking the system left-right symmetry, gives rise to multiple Bloch band anticrossings leading to the appearance of a fine structure in the conductance lineshape.

**1:39PM F24.00011 How many electrons make a semiconductor nanocrystal film metallic**<sup>1</sup>, KONSTANTIN REICH, TING CHEN, NICOLAAS KRAMER, HAN FU, UWE KORTSHAGEN, BORIS SHKLOVSKII, Univ of Minnesota - Twin Cities — For films of semiconductor nanocrystals to achieve their potential as novel, low-cost electronic materials, a better understanding of their doping to tune their conductivity is required. So far, it not known how many dopants will turn a nanocrystal film from semiconducting to metallic. In bulk semiconductors, the critical concentration  $n_M$  of electrons at the metal-insulator transition is described by the famous Mott criterion:  $n_M a_B^3 \simeq 0.02$ , where  $a_B$  is the effective Bohr radius. We show theoretically that in a dense NC film, where NCs touch each other by small facets, the concentration of electrons  $n_c \gg n_M$  at the metal-insulator transition satisfies the condition:  $n_c \rho^3 \simeq 0.3$ , where  $\rho$  is a radius of contact facets. In the accompanying experiments, we investigate the conduction mechanism in films of phosphorus-doped, ligand-free silicon nanocrystals. At the largest electron concentration achieved in our samples, which is half the predicted  $n_c$ , we find that the localization length of hopping electrons is close to three times the nanocrystals diameter, indicating that the film approaches the metal-insulator transition.

**1:51PM F24.00012 Anomalous hopping conduction in nanocrystalline/amorphous composites and amorphous semiconductor thin films**<sup>1</sup>, JAMES KAKALIOS, KENT BODURTHA<sup>2</sup>, School of Physics and Astronomy, University of Minnesota — Composite nanostructured materials consisting of nanocrystals (nc) embedded within a thin film amorphous matrix can exhibit novel optoelectronic properties. Composite films are synthesized in a dual-chamber co-deposition PECVD system capable of producing nanocrystals of material A and embedding then within a thin film matrix of material B. Electronic conduction in composite thin films of hydrogenated amorphous silicon (a-Si:H) containing nc-germanium or nc-silicon inclusions, as well as in undoped a-Si:H, does not follow an Arrhenius temperature dependence, but rather is better described by an anomalous hopping expression ( $\exp[-(T_0/T)^{3/4}]$ ), as determined from the “reduced activation energy” proposed by Zabdorskii and Shlimak. This temperature dependence has been observed in other thin film resistive materials, such as ultra-thin disordered films of Ag, Bi, Pb and Pd; carbon-black polymer composites; and weakly coupled Au and ZnO quantum dot arrays. There is presently no accepted theoretical understanding of this expression. The concept of a mobility edge, accepted for over four decades, appears to not be necessary to account for charge transport in amorphous semiconductors.

**11:15AM F25.00001 Magnetic Field Reentrant Superconductivity in Aluminum Nanowires\***, TERENCE BRETZ-SULLIVAN, ALLEN GOLDMAN, School of Physics and Astronomy, University of Minnesota — Reentrance to the superconducting state through the application of a magnetic field to quasi-one dimensional superconductors driven resistive by current, is counter to the expected properties of superconductors. It was not until recently that a microscopic mechanism explaining the phenomenon was proposed in which superconductivity and phase slip driven dissipation coexist in a non-equilibrium state.<sup>1</sup> Here we present additional results of magnetic field induced reentrance into the superconducting state in quasi-one-dimensional aluminum nanowires with an in-plane magnetic field both transverse to, and along the wire axis. The reentrant behavior is seen in the magnetic field dependence of the I-V characteristic and resistance vs. temperature, and in the wire's magnetoresistance at 450mK. <sup>1</sup>Y. Chen, Y.-H. Lin, S.D. Snyder, A.M. Goldman and A. Kamenev, Nature Physics **10**, 567-571 (2014). \* This work was supported by DOE Basic Energy Sciences Grant DE-FG02-02ER46004. **11:27AM F25.00002 Andreev bound state at a strongly correlated oxide interface<sup>1</sup>**, GUANGLEI CHENG, MICHELLE TOMCZYK, Univ. of Pittsburgh, ALEXANDRE TACLA, ANDREW DALEY, Univ. of Strathclyde, SHICHENG LU, JOSH VEAZEY, MENGCHEN HUANG, PATRICK IRVIN, Univ. of Pittsburgh, SANGWOO RYU, HYUNGWOO LEE, CHANG-BEOM EOM, Univ. of Wisconsin-Madison, DAVID PEKKER, JEREMY LEVY, Univ. of Pittsburgh — Strongly correlated electrons at oxide interfaces give rise to a set of novel physics phenomena including superconductivity and magnetism. At the  $\text{LaAlO}_3/\text{SrTiO}_3$  (LAO/STO) interface, signatures of strong electron pairing persist even for conditions where superconductivity is suppressed. Meanwhile, an Andreev bound state (ABS) is a single quasiparticle excitation that mediates pair transport in confined superconductor-normal systems. Here we report a transition from pair resonant transport to ABS in sketched single electron transistors at the LAO/STO interface. This transition is consistent with a change of electron-electron interaction from attractive to repulsive, occurring at or near the Lifshitz transition. Such new electronically tunable electron-electron interaction may be useful for quantum simulation and engineering of novel quantum states in oxide materials.

**11:39AM F25.00003 Solitons in chiral p-wave superconductors and their possible link to topological phases in the non-adiabatic regime**, LEONARDO MIRANDA SANTANA, EMIL YUZHABASHYAN, Rutgers University — Solitons occur in non-linear systems where dispersion is counterbalanced by non-linearity and are ubiquitous in integrable systems. Two different types of solitons have been shown to exist in the s-wave BCS model. Normal and anomalous solitons connect unstable stationary states with zero and nonzero superconducting gaps, respectively. For the s-wave model, all the normal multi-solitons have been entirely constructed, but only the single anomalous soliton in the presence of particle-hole symmetry has been obtained. We develop a method to construct all the anomalous multi-solitons without requiring particle-hole symmetry of the initial states. Our method can be extended to the chiral p-wave BCS model, for which we also construct both normal and anomalous solitons. It is well known that the chiral p-wave BCS model describes a topological superconductor. We believe that there should exist many topological invariants encoded in its anomalous multi-solitons, extending the notion of topological phase to the non-adiabatic regime. Out of equilibrium topological superfluids are known to display richer topological phase diagrams than those in equilibrium. We believe that anomalous solitons are likely elementary objects in the characterization of these non-equilibrium topological phases.

**11:51AM F25.00004 Measuring the winding number instability in mesoscopic superconducting rings**, ANTHONY LOLLO, IVANA PETKOVIC, MICHEL DEVORET, LEONID GLAZMAN, JACK HARRIS, Yale University — In equilibrium, a flux-biased superconducting ring occupies a state that is characterized by the integer winding number of its complex order parameter. Transitions between states of differing winding number occur via phase slips of the order parameter. A number of aspects of these phase slips remain poorly understood, including the particular value of flux bias at which the transition occurs, and the particular state into which the system relaxes. We use cantilever torque magnetometry to address these questions by measuring the equilibrium supercurrent in arrays of isolated aluminum rings over a wide range of applied flux and temperature. We fit the measured supercurrent using one-dimensional stationary Ginzburg Landau theory over the entire field range  $-B_{c3} < B < B_{c3}$  and for  $T_c/2 < T < T_c$ . We show that phase slips occur at the critical flux predicted by Ginzburg Landau theory. The value of this critical flux shows the influence of the rings' finite circumference. We find that in all instances the winding number changes by unity; this may be because the dynamics of the switching events are overdamped in these rings.

**12:03PM F25.00005 Thermally activated phase slips from metastable states in mesoscopic superconducting rings**, IVANA PETKOVIC, ANTHONY LOLLO, JACK HARRIS, Yale University — In equilibrium, a flux-biased superconducting ring at low temperature can occupy any of several metastable states. The particular state that the ring occupies depends on the history of the applied flux, as different states are separated from each other by flux-dependent energy barriers. There is a critical value of the applied flux at which a given barrier goes to zero, the state becomes unstable, and the system transition into another state. In recent experiments performed on arrays of rings we showed that this transition occurs close to the critical flux predicted by Ginzburg-Landau theory. Here, we will describe experiments in which we have extended these measurements to an individual ring in order to study the thermal activation of the ring over a barrier that has been tuned close to zero. We measure the statistics of transitions as function of temperature and ramp rate.

**12:15PM F25.00006 Superconducting tunneling on thin film gold nanowires – a platform for searching Majorana fermions<sup>1</sup>**, PENG WEI, PATRICK LEE, JAGADEESH MOODERA, MIT — The metallic surface states of (111)-oriented gold thin film has been theoretically shown to be a superior candidate for Majorana fermions (MF) due to its orders of magnitude stronger spin-orbit coupling compared to semiconductor nanowires.[1] We experimentally demonstrate an ideal platform using heterostructure based nanowires for achieving this, and exploit quantum tunneling to probe the MFs forming at the end of the nanowires. By controlling the material properties of the tunnel barrier, we explore the peculiar behaviors of superconducting gold surface states in both pair tunneling (Josephson like) and quasiparticle tunneling regimes that may hint the signatures of MFs. Additionally, in the mesoscopic 1D gold nanowire superconductor, we observe a new superconducting phase with an energy gap much larger than any of the superconductors in the tunneling device, hinting possible unknown pairing mechanism. Our approach directly demonstrates a crucial step in achieving realistic fault-tolerant quantum computation devices based on non-abelian particles. [1] A. C. Potter and P. A. Lee, Phys Rev B 85, 094516 (2012)

**12:27PM F25.00007 Spins of Andreev states in double quantum dots**, ZHAOEN SU, JUN CHEN, PENG YU, University of Pittsburgh, MOIRA HOCERVAR, Institut Neel CNRS, Grenoble, SEBASTIEN PLISSARD, CNRS, LAAS, Toulouse, France, DIANA CAR, Eindhoven University of Technology, ALEXANDRE TACLA, University of Pittsburgh, ANDREW DALEY, University of Strathclyde, DAVID PEKKER, University of Pittsburgh, ERIK BAKKERS, Eindhoven University of Technology, SERGEY FROLOV, University of Pittsburgh — Andreev (or Shiba) states in coupled double quantum dots is an open field. Here we demonstrate the realization of Andreev states in double quantum dots in an InSb nanowire coupled to two NbTiN superconductors. The magnetic field dependence of the Andreev states has been explored to resolve the spins in different double dot configurations. The experiment helps to understand the interplay between pair correlation, exchange energy and charging energy with a well-controlled system. It also opens the possibility to implement Majorana modes in Kitaev chains made of such dots.

**12:39PM F25.00008 Detection of Majorana Kramers pairs using a quantum point contact<sup>1</sup>**, JIAN LI, Princeton University, WEI PAN, Sandia National Laboratories, B. ANDREI BERNEVIG, Princeton University, ROMAN LUTCHYN, Microsoft Research Station Q — We propose a setup that integrates a quantum point contact (QPC) and a Josephson junction on a quantum spin Hall sample, experimentally realizable in InAs/GaSb quantum wells. The confinement due to both the QPC and the superconductor results in a Kramers pair of Majorana zero-energy bound states when the superconducting phases in the two arms differ by an odd multiple of  $\pi$  across the Josephson junction. We investigate the detection of these Majorana pairs with the integrated QPC, and find a robust switching from normal to Andreev scattering across the edges due to the presence of Majorana Kramers pairs. This transport signature is expected to be exhibited in measurements of differential conductance and/or current cross-correlation at low bias.

**12:51PM F25.00009 Conductance through a proximitized nanowire in the Coulomb blockade regime**, BERNARD VAN HECK, Yale University, ROMAN LUTCHYN, Microsoft Station Q, LEONID GLAZMAN, Yale University — Motivated by recent experiments of the Copenhagen group on InAs nanowires with epitaxial Al [1], we investigate the two-terminal conductance of a strongly proximitized nanowire in the Coulomb blockade regime. We identify the leading electron transport processes at zero applied magnetic field  $B$  as well as at finite fields, suppressing the induced gap  $\Delta_{\text{ind}}(B)$ . In the conventional superconducting phase, the conductance is controlled by the sequential Cooper pair tunneling if  $\Delta_{\text{ind}}(B)$  exceeds the charging energy  $E_c$ , and by the elastic single-electron processes if  $\Delta_{\text{ind}}(B) < E_c$ . The latter mechanism yields smaller values of the linear conductance, and strongly asymmetric Coulomb blockade peaks, which explains the experimental finding in Ref. [1]. We also develop a quantitative theory for the differential conductance and examine its evolution across the topological transition point. [1] A. Higginbotham et al., Nature Physics (2015) doi:10.1038/nphys3461

**1:03PM F25.00010 Time-reversal asymmetry without local moments via directional scalar spin chirality**, PAVAN HOSUR, Stanford Univ — Quantum phases of matter that violate time-reversal symmetry invariably develop local spin or orbital moments in the ground state. Here, a directional scalar spin chiral order (DSSCO) phase is introduced, that disrespects time-reversal symmetry but has no static moments. It can be obtained by melting the spin moments in a magnetically ordered phase but retaining residual broken time-reversal symmetry. Orbital moments are then precluded by the spatial symmetries of the spin rotation symmetric state. Interestingly, polar Kerr effect in the 3D DSSCO has the same symmetries as those observed experimentally in the pseudogap phase of several underdoped cuprates. Finally, it is shown that the DSSCO provides a phenomenological route for reconciling the results of Kerr effect and nuclear magnetic resonance experiments in the cuprates, with charge ordering tendencies — observed in X-ray diffraction studies — playing a crucial role. The so-called "memory effect" in the cuprates can be incorporated into this picture as well.

**1:15PM F25.00011 Reentrant phase coherence in a quasi-one-dimensional superconductor<sup>1</sup>**, DIANE ANSERMET, ALEXANDER P. PETROVIC, SHIKUN HE, Nanyang Technological University, DMITRI CHERNYSHOV, European Synchrotron Radiation Facility, MORITZ HOESCH, Diamond Light Source, DIALA SALLOUM, Lebanese University, PATRICK GOUGEON, MICHEL POTEL, University of Rennes 1, LILIA BOERI, Graz University of Technology, OLE K. ANDERSEN, Max Planck Institute for Solid State Research, CHRISTOS PANAGOPOULOS, Nanyang Technological University — Short coherence lengths characteristic of low-dimensional superconductors are related to high critical fields or temperatures. Fatally, such materials are often sensitive to disorder and suffer from phase fluctuations in the order parameter which diverge with temperature  $T$ , magnetic field  $H$  or current  $I$ . To solve synthesis and fluctuation problems, we propose to build superconductors from inhomogeneous composites of nanofilaments. Single crystals of quasi-one-dimensional  $\text{Na}_{2-\delta}\text{Mo}_6\text{Se}_6$  featuring Na vacancy disorder ( $\delta \sim 0.2$ ) behave as percolative networks of superconducting nanowires. Long range order is established via transverse coupling between individual filaments, yet phase coherence is unstable to fluctuations and localization in the zero- $(T, H, I)$  limit. A region of reentrant phase coherence develops upon raising  $(T, H, I)$  and is attributed to an enhancement of the transverse coupling due to electron delocalization. The observed reentrance in the electronic transport coincides with a peak in the Josephson energy  $E_J$  at non-zero  $(T, H, I)$ .  $\text{Na}_{2-\delta}\text{Mo}_6\text{Se}_6$  is a blueprint for a new generation of low dimensional superconductors with resilience to phase fluctuations at high  $(T, H, I)$ .

**1:27PM F25.00012 Probing Andreev and Majorana States with Voltage Pulses<sup>1</sup>**, JOSEPH WESTON, XAVIER WAIN TAL, CEA, INAC-SPSMS, F-38000 Grenoble, France — We study the effect of time-resolved voltage pulses applied to normal-insulator-superconductor junctions. With the aid of cutting-edge numerical techniques, we see that applying an alternating train of voltage pulses allows us to manipulate the (Andreev) quasi-bound states that form between the insulator and superconductor. When the superconductor is rendered topologically nontrivial, the presence of a Majorana state gives a zero-bias peak (ZBP) in the conductivity of the junction<sup>2</sup>. We show that by applying different amplitudes/frequencies of voltage pulses we can eliminate or recreate the ZBP and hence probe its Majorana character<sup>3</sup>. The persistence of this effect in the presence of finite temperature and moderate disorder is promising for the validation of recent experimental results concerning detection of Majoranas in nanowire-superconductor junctions<sup>4</sup>.

**1:39PM F25.00013 Large variance of  $T_c$  at large length scales in granular mesoscopic Nb islands**, RITA GARRIDO MENACHO, MALCOLM DURKIN, University of Illinois at Urbana-Champaign, SARANG GOPALAKRISHNAN, Harvard University, JIAN-MIN ZUO, NADYA MASON, University of Illinois at Urbana-Champaign — Superconductivity in granular mesoscopic islands, in which the average grain size is smaller than the superconducting coherence length, remains largely unstudied. We performed transport measurements of single Nb islands to study the relation between the critical temperature ( $T_c$ ) and the island diameter. We found that  $T_c$  is largely suppressed at scales much larger than the coherence length of Nb. This can be explained by considering a proximity effect between the grains in the island in which the largest grains define the onset of superconductivity. Following this logic, the grain distribution is proportional to the island area and large  $T_c$  fluctuations are expected as the diameter of the island decreases. We perform a  $T_c$  variance study of large sets of islands at various diameters, and demonstrate an exponential decay relation reaching bulk Nb properties as the island diameter increases.

**1:51PM F25.00014 Quantum interference in a Cooper pair splitter device**, SZABOLCS CSONKA, G. FULOP, Department of Physics, Budapest University of Technology and Economics, F. DOMINGUEZ, A. LÉVY YEYATI, Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, S. D'HOLLOSZY, A. BAUMGARTNER, P. MAKK, C. SCHONENBERGER, Department of Physics, University of Basel, V. A. GUZENKO, Laboratory for Micro- and Nanotechnology, Paul Scherrer Institute, M. H. MADSEN, J. NYGARD, Nano-Science Center, Niels Bohr Institute, University of Copenhagen — Cooper pair splitting (CPS) is a process in which the electrons of naturally occurring spin singlet pairs in a superconductor are spatially separated using two quantum dots. In the present work we investigate the evolution of the conductance correlations in an InAs nanowire based CPS device in the presence of an external magnetic field. In our experiments the gate dependence of the signal that depends on both quantum dots continuously evolves from a slightly asymmetric Lorentzian to a strongly asymmetric Fano-type resonance with increasing B field. Our experiments can be understood in a simple 3 site model, which shows that the nonlocal CPS leads to symmetric line shapes, while the local transport processes can exhibit an asymmetric shape due to quantum interference. These findings demonstrate that the electrons from a Cooper pair splitter can propagate coherently after their emission from the superconductor and how a magnetic field can be used to optimize the performance of a CPS device. In addition CPS devices were developed where the nanowire segments between the two dots were removed, nonlocal measurement on such CPS devices will also be presented.

**Session F26 DCMP DMP: Weyl Semimetal - Theory** 325 - Catalin Martin, Ramapo College of New Jersey

**11:15AM F26.00001 Raman spectroscopy of exfoliated few-layered n-type  $\text{Bi}_2\text{Te}_3$**  , FENGJIAO LIU, MEHMET KARAKAYA, POOJA PUNEET, Clemson Nanomaterials Center, Department of Physics and Astronomy, Clemson University, Clemson, SC USA 29634, RAMAKRISHNA PODILA, Laboratory of Nano-biophysics and COMSET, Clemson Nanomaterials Center, Dept. of Physics & Astronomy, Clemson University, Clemson, SC USA 29634, SRIPARNA BHATTACHARYA, Clemson Nanomaterials Center, Department of Physics and Astronomy, Clemson University, Clemson, SC USA 29634, APPARAO M. RAO, Clemson Nanomaterials Center, Laboratory of Nano-biophysics and COMSET, Dept. of Physics and Astronomy, Clemson University, Clemson, SC USA 29634, CLEMSON NANOMATERIALS CENTER, DEPT. OF PHYSICS & ASTRONOMY, CLEMSON UNIVERSITY, CLEMSON, SC 29634 COLLABORATION, LABORATORY OF NANO-BIOPHYSICS AND COMSET, CLEMSON UNIVERSITY, CLEMSON, SC USA 29634 COLLABORATION — A novel chemical-exfoliation spark-plasma-sintering (CE-SPS) process was applied to enhance the thermoelectric figure of merit and compatibility factor of few-layered n-type  $\text{Bi}_2\text{Te}_3$ . New vibrational modes were observed in the micro-Raman spectra of the few-layered  $\text{Bi}_2\text{Te}_3$  samples, which are absent in the bulk. Here we focus on the emergence of the new intermediate and high-frequency Raman modes and their dependence on the layer thickness. A detailed Raman study probing the origin of these exfoliation induced defect modes will be presented.

**11:27AM F26.00002 Disorder and metal-insulator transitions in Weyl semimetals** , HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China, CHUI-ZHEN CHEN, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, JUNTAO SONG, Department of Physics, Hebei Normal University, Hebei 050024, China, QING-FENG SUN, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, ZIJIANG WANG, Department of Physics, Boston College, Chestnut Hill, Massachusetts 02167, USA, X. C. XIE, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — The Weyl semimetal (WSM) is a newly proposed quantum state of matter. It has Weyl nodes in bulk excitations and Fermi arcs surface states. We study the effects of disorder and localization in WSMs and find three novel phase transitions. (I) Two Weyl nodes near the Brillouin zone boundary can be annihilated pairwise by disorder scattering, resulting in the opening of a topologically nontrivial gap and a transition from a WSM to a three-dimensional (3D) quantum anomalous Hall state. (II) When the two Weyl nodes are well separated in momentum space, the emergent bulk extended states can give rise to a direct transition from a WSM to a 3D diffusive anomalous Hall metal. (III) Two Weyl nodes can emerge near the zone center when an insulating gap closes with increasing disorder, enabling a direct transition from a normal band insulator to a WSM. We determine the phase diagram by numerically computing the localization length and the Hall conductivity, and propose that the novel phase transitions can be realized on a photonic lattice.

**11:39AM F26.00003 Critical exponents at the unconventional disorder-driven transition in a Weyl semimetal** , SERGEY SYZРАНOV, Univ of Colorado - Boulder, PAVEL OSTROVSKY, Max Planck Institute for Solid State Research, Stuttgart, Germany; L. D. Landau Institute for Theoretical Physics RAS, Moscow, Russia, VICTOR GURARIE, LEO RADZIHOVSKY, Univ of Colorado - Boulder — Disordered non-interacting systems in sufficiently high dimensions have been predicted to display a non-Anderson disorder-driven transition that manifests itself in the critical behaviour of the density of states and other physical observables. Recently the critical properties of this transition have been extensively studied for the specific case of Weyl semimetals by means of numerical and renormalisation-group approaches. Despite this, the values of the critical exponents at such a transition in a Weyl semimetal are currently under debate. We present an independent calculation of the critical exponents using a two-loop renormalisation-group approach for Dirac fermions in  $2 + \varepsilon$  dimensions and resolve controversies currently existing in the literature.

**11:51AM F26.00004 Elastic Gauge Fields in Weyl Semimetals<sup>1</sup>** , ALBERTO CORTIJO, YAGO FERREIROS, KARL LANDSTEINER, MARIA ANGELES HERNANDEZ VOZMEDIANO, Consejo Superior de Investigaciones Científicas — We show that, as it happens in graphene, elastic deformations couple to the electronic degrees of freedom as pseudo gauge fields in Weyl semimetals. We derive the form of the elastic gauge fields in a tight-binding model hosting Weyl nodes and see that this vector electron-phonon coupling is chiral, providing an example of axial gauge fields in three dimensions. As an example of the new response functions that arise associated to these elastic gauge fields, we derive a non-zero phonon Hall viscosity for the neutral system at zero temperature. The axial nature of the fields provides a test of the chiral anomaly in high energy with three axial vector couplings.

**12:03PM F26.00005 Quantum oscillations in Weyl semimetals** , JAN BORCHMANN, TAMI PEREG-BARNEA, McGill University — In this work we present recent progress on quantum oscillations of a Weyl semimetal in a slab geometry. Based on semiclassical arguments, it has been conjectured that the Fermi arcs present on the surface of the slab can lead to quantum oscillations with a characteristic dependence on the applied magnetic field as well as the thickness of the slab, which differ from the quantum oscillations in the bulk. To further investigate this we present results from a calculation via a Floquet formalism as well as a lattice quantum treatment of the problem. We present results on the oscillation frequency as well as the phase offset.

**12:15PM F26.00006 Characterization of the Weyl semimetal via the “Fermi arc” of Wannier-Stark ladder** , KUN WOO KIM, WOO-RAM LEE, Korea institute for advanced study, YONG BAEK KIM, University of Toronto, KWON PARK, Korea institute for advanced study — Weyl semimetals have been characterized unequivocally by the Fermi-arc spectrum of the surface states in photoemission experiments. While successful, such a method reveals the topological nature of the Weyl phase in the bulk indirectly via the surface spectrum. In this talk, we propose an alternative method to characterize the Weyl phase via the bulk spectrum of the Wannier-Stark ladder (WSL) emerging under an electric field. Specifically, we show that, for weak-to-moderate strengths of electric field, the WSL exhibits its own “Fermi arc” precisely corresponding to the surface spectrum counterpart, which can be used to characterize the Weyl phase directly in the bulk spectrum.

**12:27PM F26.00007 Phase diagrams of disordered Weyl semimetals** , HASSAN SHAPOURIAN, TAYLOR L. HUGHES, Univ of Illinois - Urbana — Weyl semimetals are gapless quasi-topological materials with a set of isolated nodal points forming their Fermi surface. They manifest their quasi-topological character in a series of topological electromagnetic responses including the anomalous Hall effect. Here we study the effect of disorder on Weyl semimetals while monitoring both their nodal/semi-metallic and topological properties through computations of the localization length and the Hall conductivity. We present detailed phase diagrams of three different lattice tight-binding models and we find that weak disorder preserves the nodal points up to the diffusive limit, but does affect the Hall conductivity. We show that the trend of the Hall conductivity is consistent with an effective picture in which disorder causes the Weyl nodes move within the Brillouin zone along a specific direction that depends deterministically on the properties of the model and the neighboring phases to the Weyl semimetal phase.

**12:39PM F26.00008 Dynamical axion string, screw dislocation in Weyl semimetals and Axion insulators** , YI-ZHI YOU, University of California, Santa Barbara, GIL YOUNG CHO, Korea Advanced Institute of Science and Technology, TAYLOR HUGHES, University of Illinois Urbana- Champaign — We study the interplay between the geometry and axion string resulting from a chiral symmetry breaking in 3D. The chiral symmetry is spontaneously broken by charge density wave (CDW) order parameter nesting two Weyl points, which turns it into an axion insulator. The phase fluctuation of the CDW order parameter acts as a dynamical axion field coupled to electromagnetic field via  $\theta F \wedge F$  term. When the axion insulator is coupled with the background geometry with torsional defects, i.e. screw dislocations, there is a novel interplay between the dislocation and the dynamical axion string. First, we show that the screw dislocation traps an axial charge. This then implies that if an axion string braids with a parallel screw dislocation, there is Berry phase accumulated during the braiding procedure. In addition, the cubic coupling between the axial current and the torsion bilinear shows the Berry phase accumulated by the three-loop braiding procedure, where we braid one dislocation loop around the other dislocation loop where the both are linked by an axion string loop. We also observe a chiral magnetic effect induced by a screw dislocation in the absence of chemical potential imbalance between Weyl points.

**12:51PM F26.00009 Non-Fermi liquid phase and non-Gaussian itinerant quantum criticality of Weyl semimetals<sup>1</sup>**, PALLAB GOSWAMI, University of Maryland, College Park — A Weyl semimetal is a gapless topological phase in three dimensions, for which the touching points between two nondegenerate bands act as monopoles and antimonopoles of Abelian Berry curvature, with monopole strength  $m$ . Such a gapless phase can support  $m$  Fermi arcs as the protected, zero energy surface states. We consider the stability of a generalized Weyl semimetal with  $m > 1$  in the presence of interaction and disorder by employing a renormalization group analysis, which is controlled by the parameter  $\epsilon = (1 - \frac{1}{m})$ . For any  $m > 1$ , we show how the long range Coulomb interaction gives rise to an infra-red stable, non-Fermi liquid phase without any sharp quasiparticle pole. In the presence of sufficiently strong short range interactions, the non-Fermi liquid can transform into a translational symmetry breaking, axionic insulator. We demonstrate that the associated itinerant quantum critical point possesses non-Gaussian scaling properties. We establish the stability of the emergent non-Fermi liquid phase and the itinerant quantum critical point against weak disorder. Finally, we discuss the scaling properties of physical quantities, the fate of the Fermi arcs, and the experimental relevance of our results for some candidate materials.

**1:03PM F26.00010 Detecting monopole charge via quantum interference transport**, XIN DAI, Tsinghua Univ, HAIZHOU LU, South University of Science and Technology China, HONG YAO, Tsinghua Univ — Topological Weyl and double-Weyl semimetals host different monopole charges in momentum space. How to detect the signature of the monopole charges in quantum transport remains a challenging topic. Here, we reveal the connection between the parity of monopole charge in topological semimetals and the quantum-interference correction to the conductivity. We demonstrate that the parity of monopole charge determines the sign of quantum-interference correction, with odd and even parity yielding the weak anti-localization and weak localization effect, respectively. This is attributed to the Berry phase difference between time-reversed trajectories circulating the great circle of the Fermi sphere that encloses the monopole charges. From standard Feynman diagram calculations, we further show that the weak-field magnetoconductivity is proportional to  $\pm\sqrt{B}$  for double-Weyl semimetals and Weyl semimetals, respectively, which could be verified experimentally.

**1:15PM F26.00011 Chirality-dependent Hall Effect in Weyl Semimetals<sup>1</sup>**, SHENGYUAN YANG, Singapore University of Technology and Design, HUI PAN, Beihang University, FAN ZHANG, University of Texas at Dallas — We generalize a semiclassical theory and use the argument of angular momentum conservation to examine the ballistic transport in lightly-doped Weyl semimetals, taking into account various phase-space Berry curvatures. We predict universal transverse shifts of the wave-packet center in transmission and reflection, perpendicular to the direction in which the Fermi energy or velocities change adiabatically. The anomalous shifts are opposite for electrons with different chirality, and can be made imbalanced by breaking inversion symmetry. We discuss how to utilize local gates, strain effects, and circularly polarized lights to generate and probe such a chirality-dependent Hall effect.

**1:27PM F26.00012 Full quantum theory of the chiral anomaly transport in a Weyl semimetal<sup>1</sup>**, WOO-RAM LEE, KWON PARK, Korea Inst for Advanced Study, KIAS TEAM — In relativistic field theory, the chiral anomaly means a violation of the number conservation of chiral fermions. In condensed matter physics, the chiral anomaly can be manifested in a Weyl semimetal as a negative magnetoresistance in the presence of parallel electric and magnetic fields. In this work, we use the Keldysh-Floquet Greens function formalism to develop a full quantum theory of the chiral anomaly transport, which can be valid in a broad range of both electric and magnetic field strengths.

<sup>1</sup>The authors thank KIAS Center for Advanced Computation (CAC) for providing computing resources.

**1:39PM F26.00013 Effect of disorder in three dimensional layered Chern insulator**, SHANG LIU, School of Physics, Peking University, Beijing, 100871, China, TOMI OHTSUKI, Department of Physics, Sophia University, Chiyoda-ku, Tokyo, 102-8554, Japan, RYUICHI SHINDOU, International Center for Quantum Materials, Beijing, 100871, China — Critical nature of quantum phase transition between topological phase and non-topological phase is one of the most fundamental research issues in the studies of topological phases, where a bulk delocalized state is universally observed between distinct phases as a holographic requirement from the stable surface states. In this work, we studied the effects of disorder in a three dimensional layered Chern insulator, which, in the clean limit, is either a Chern insulator or Weyl semimetal (WSM) depending on the strength of an inter-layer coupling. By calculating the localization length with the transfer matrix method and density of states with the kernel polynomial expansion, we found two distinct types of metallic phases between the Anderson insulator and Chern insulator phases; one is a diffusive metallic (DM) phase and the other is a renormalized WSM phase. We showed that the longitudinal conductivity at the zero energy state remains finite not only in the DM phase but also in the renormalized WSM phase, while goes to zero at the semimetal-metal quantum phase transition point. Based on the Einstein relation combined with the self-consistent Born analysis, we also argue the conductivity scaling near the quantum transition point.

**1:51PM F26.00014 The appearance of a switch in orbital texture and the resulting absence of complete spin polarization in a Rashba semiconductor<sup>1</sup>**, QIHANG LIU, XIUWEN ZHANG, ALEX ZUNGER, University of Colorado, Boulder — We consider spin-orbit coupling (SOC) induced spin splitting and spin polarization in nonmagnetic bulk materials lacking inversion symmetry, in which a pair of side-by-side bands that cross at some wavevector  $K$  is formed. We find that (i) even though in the semi-classical single-electron model the two bands manifest complete spin polarization, we find via density functional theory and  $k \cdot p$  modeling that SOC-induced spin splitting in real materials does not necessarily manifest complete spin polarization. (ii) Away from band crossing point  $K$  and looking at the same wavevector, the spin polarization in different branches does not compensate each other. When considering the full pair of spin-split bands this leads to a net spin texture. We explain this unexpected phenomenon and find that the key factor here is the complex interplay between spin and orbital textures entangled by SOC. (iii) In surprising analogy to the surface states of topological insulators (such as  $\text{Bi}_2\text{Se}_3$ ), a bulk Rashba compound (such as  $\text{BiTeI}$ ) also exhibits a switch of in-plane orbital character between radial and tangential orbital at the critical band crossing point  $K$ . These observations provide a different thinking on the fundamental concept of SOC-induced spin polarization, and opens a new route for manipulating spin degree of freedom by the atomic-orbital feature.

**2:03PM F26.00015 Quantum Mechanics of Palladium Nanostructures**, AJIT HIRA, JAMES MCKEOUGH, BRIDGET ORTIZ, JUAN DIAZ, Northern New Mexico College — We continue our interest in the chemisorption of different atomic and molecular species on small clusters of metallic elements, by examining the interactions of  $\text{H}$ ,  $\text{H}_2$ ,  $\text{Li}$  and  $\text{O}$  adsorbates with  $\text{Pd}_n$  clusters ( $n = 2$  thru 20). The study of clusters can reveal the effects of substrate geometry on the behavior of adsorbates. Transition-metal clusters are especially suited for the study of quantum size effects and for formation of metallic states, and are ideal candidates for catalytic processes. Hybrid ab initio methods of quantum chemistry (particularly the DFT-B3LYP model) are used to derive optimal geometries for the clusters of interest. We compare calculated binding energies, bond-lengths, ionization potentials, electron affinities and HOMO-LUMO gaps for the clusters. Of particular interest are the comparisons of binding strengths at the three important types of sites: edge (E), hollow (H), on-top (T), threefold sites and fourfold sites. Effects of crystal symmetries corresponding to the bulk structures are investigated. The capacity of Pd clusters to adsorb H atoms will be compared to Ni clusters. Admixture with Pt atoms will also be considered.

**Session F27 DMP: Carbon Nanotube & Related Materials: Optical & Other Properties 326 -**

Shu-Jen Han, IBM T. J. Watson Research Center

**11:15AM F27.00001 Terahertz Science and Technology of Macroscopically Aligned Carbon Nanotube Films**, JUNICHIRO KONO, Rice Univ — One of the outstanding challenges in nanotechnology is how to assemble individual nano-objects into macroscopic architectures while preserving their extraordinary properties. For example, the one-dimensional character of electrons in individual carbon nanotubes leads to extremely anisotropic transport, optical, and magnetic phenomena, but their macroscopic manifestations have been limited. Here, we describe methods for preparing macroscopic films, sheets, and fibers of highly aligned carbon nanotubes and their applications to basic and applied terahertz studies. Sufficiently thick films act as ideal terahertz polarizers, and appropriately doped films operate as polarization-sensitive, flexible, powerless, and ultra-broadband detectors. Together with recently developed chirality enrichment methods, these developments will ultimately allow us to study dynamic conductivities of interacting one-dimensional electrons in macroscopic single crystals of single-chirality single-wall carbon nanotubes.

**11:51AM F27.00002 Photocurrent generation efficiency of a carbon nanotube pn junction**, DANIEL MCCULLEY, LEE ASPITARTE, ETHAN MINOT, Oregon State University — Carrier multiplication effects can enhance the quantum efficiency of photovoltaic devices. For example, quantum dot solar cells have demonstrated photon-to-electron conversion efficiencies greater than 100% when photon energies exceed twice the band gap. Carbon nanotube photodiodes exhibit carrier multiplication effects (Gabor et al, Science 2009), but the quantum efficiency of such photodiodes has not previously been characterized. We have reproduced the carrier multiplication phenomena in individual CNT pn junctions and investigated the conditions under which it occurs. We will present early results quantifying the internal quantum efficiency of the process.

**12:03PM F27.00003 Excitonic Contribution to Near-Field Enhancements of a Carbon Nanotube Antenna<sup>1</sup>**, BENJAMIN SOFKA, SLAVA V ROTKIN, Lehigh University — Complexes containing rare earth ions (REI) and single-walled carbon nanotubes (SWNT) show promise to be utilized for the optical sensing of biomolecules. We theoretically study the near-field electromagnetic effects in such a system using a propagating polariton model for the SWNT antenna. To be in resonance with the REI transitions that are in the NIR/optical range, excitonic transitions in the SWNT must be included in the model. We calculate measurable field enhancements in the vicinity of the SWNT antenna that lead to an increase of the REI photoluminescence.

**12:15PM F27.00004 Electroluminescence from individual air-suspended carbon nanotubes within split-gate structures<sup>1</sup>**, N. HIGASHIDE, T. UDA, M. YOSHIDA, A. ISHII, Y. K. KATO, The University of Tokyo — Electrically induced light emission from chirality-identified single-walled carbon nanotubes are investigated by utilizing split-gate field-effect devices fabricated on silicon-on-insulator substrates. We begin by etching trenches through the top silicon layer into the buried oxide, and the silicon layer is thermally oxidized for use as local gates [1]. We partially remove the oxide and form gate electrodes, then contacts for nanotubes are deposited on both sides of the trench. Catalyst particles are placed on the contacts, and nanotubes are grown over the trench by chemical vapor deposition. We use photoluminescence microscopy to locate the nanotubes and perform excitation spectroscopy to identify their chirality. Gate-induced photoluminescence quenching is used to confirm carrier doping [2], and electroluminescence intensity is investigated as a function of the split-gate and bias voltages.

**12:27PM F27.00005 Theory of quadruple plasmon in doped carbon nanotubes**, KEN-ICHI SASAKI, NTT Basic Research Laboratories, SHUICHI MURAKAMI, Tokyo Institute of Technology — A single-wall carbon nanotube possesses two different types of plasmons specified by wavenumbers in the azimuthal and axial directions. In this presentation we show that the azimuthal plasmons consist of underdamped oscillations forming electric dipoles inside a nanotube and overdamped oscillations forming magnetic dipoles. These, originating from the surface plasmons of graphene, are of prime importance in the optical properties of doped "metallic" tubes, such as depolarization effect and relaxation of photo-excited carriers. The axial plasmons also consist of underdamped and overdamped oscillations which are inherent in the cylindrical waveguide-structures of nanotubes and relevant to optics and transport. We discuss the exact configurations of the electromagnetic fields in connection with Aharonov-Bohm effect and point out a possibility of the generation of transient energy band gaps in metallic nanotubes.

**12:39PM F27.00006 Electrical Activation of Dark Excitonic States in Carbon Nanotubes<sup>1</sup>**, TAKUSHI UDA, MASAHIRO YOSHIDA, AKIHIRO ISHII, YUICHIRO K. KATO, The University of Tokyo — Electrical activation of optical transitions to parity-forbidden dark excitonic states in individual carbon nanotubes is reported. We examine electric field effects on various excitonic states by simultaneously measuring both photocurrent and photoluminescence. As the applied field increases, we observe an emergence of new absorption peaks in the excitation spectra. From the diameter dependence of the energy separation between the new peaks and the ground state of  $E_{11}$  excitons, we attribute the peaks to the dark excited states which became optically active due to the applied field. A simple field-induced exciton dissociation model is introduced to explain the photocurrent threshold fields, and the edge of the  $E_{11}$  continuum states have been identified using this model.

**12:51PM F27.00007 Multi-Excitonic Emission from Solitary Dopant States of Carbon Nanotubes.** , H. HTOON, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, X. MA, N. F. HARTMANN, L. ADAMSKA, K. A. VELIZHANIN, S. TRETIK, J. K. S. BALDWIN, S. K. DOORN, Los Alamos National Laboratory — Oxygen doping of single wall carbon nanotubes (SWCNTs) has been rapidly emerging as an effective mean for introduction of new functionalities. Recently, through demonstration of fluctuation free, room temperature single photon generation<sup>1</sup>, we established these states as a new type of solid-state two level atom with potentials in quantum information technologies. This study further showed that while some doped tubes were characterized with a near complete photon antibunching, significant numbers of doped tubes exhibit some degree of photon bunching indicating that they emit more than one photon in one excitation cycle. Here in this work, by separating slow and fast photons in the time domain, we show for the first time that the multiple photon emissions originated from higher order multi-exciton states of solitary dopants. We also show that such multi-exciton states can allow emission of photon pairs with efficiency as high as 20-30% of single exciton emission. With this work, we bring out multi-excitonic processes of the solitary dopant states as a new area to be explored for potential applications in lasing, entangled photon generation and carrier multiplication. <sup>1</sup> X. Ma et al., Nature Nanotech. **10**, 671 (2015)

**1:03PM F27.00008 Gate-voltage induced trions in suspended carbon nanotubes<sup>1</sup>** , MASAHIRO YOSHIDA, ALEXANDER POPERT, YUICHIRO K. KATO, The University of Tokyo — We observe trion emission from suspended carbon nanotubes where carriers are introduced electrostatically using field-effect transistor structures [1]. The trion peak emerges below the  $E_{11}$  emission energy at gate voltages that coincide with the onset of bright exciton quenching. By investigating nanotubes with various chiralities, we verify that the energy separation between the bright exciton peak and the trion peak becomes smaller for larger diameter tubes. Trion binding energies that are significantly larger compared to surfactant-wrapped carbon nanotubes are obtained, and the difference is attributed to the reduced dielectric screening in suspended tubes.

**1:15PM F27.00009 New Feature Observed in the Raman Resonance Excitation Profiles of (6,5)-Enriched, Selectively Bundled SWCNTs** , A. R. HIGHT WALKER, J. R. SIMPSON, National Institute of Standards and Technology, O. ROSLYAK, Fordham University, E. HAROZ, H. TELG, J. G. DUQUE, J. J. CROCHET, A. PIRYATINSKI, S. K. DOORN, Los Alamos National Lab — Understanding the photophysics of exciton behavior in single wall carbon nanotube (SWCNT) bundles remains important for opto-electronic device applications. We report resonance Raman spectroscopy (RRS) measurements on (6,5)-enriched SWCNTs, dispersed in aqueous solutions and separated using density gradient ultracentrifugation into fractions of increasing bundling. Near-IR to UV absorption spectroscopy shows a redshift and broadening of the main excitonic transitions with increasing bundling. A continuously tunable dye laser coupled to a triple-grating spectrometer affords measurement of Raman resonance excitation profiles (REPs) over a range of wavelengths covering the (6,5)- $E_{22}$  range (505 to 585) nm. REPs of both the radial breathing mode (RBM) and G-band reveal a redshifting and broadening of the (6,5)  $E_{22}$  transition energy with increasing bundling. Additionally, we observe an unexpected peak in the REP of bundled SWCNTs, which is shifted lower in energy than the main  $E_{22}$  and is anomalously narrow. We compare these observations to a theoretical model that examines the origin of this peak in relation to bundle polarization-enhanced exciton response.

**1:27PM F27.00010 Simulations of resonant Raman response in bundles of semiconductor carbon nanotubes.** , OLEKSIY ROSLYAK, <sup>1</sup>Physics and Engineering Physics Department, Fordham University, Bronx, NY 10458, ANDREI PIRYATINSKI, STEPHEN DOORN, ERIK HAROZ, HAGEN TELG, JUAN DUQUE, JARED CROCHET, Los Alamos Natl Lab, J. R. SIMPSON, A. R. HIGHT WALKER, Engineering Physics Division, NIST, Gaithersburg, MD 20886, LANL COLLABORATION, FORDHAM COLLABORATION, NIST COLLABORATION — This work is motivated by an experimental study of resonant Raman spectroscopy under  $E_{22}$  excitation, which shows a new, sharp feature associated with bundling in (6,5) semiconductor carbon nanotubes. In order to provide an insight into the experimental data, we model Raman excitation spectra using our modified discrete dipole approximation (DDA) method. The calculations account for the exciton states polarized along and across the nanotube axis that are characterized by a small energy splitting. Strong polarization of the nanotubes forming the bundle results in the exciton state mixing whose spectroscopic signatures such as peaks positions, line widths, and depolarization ratio are calculated and compared to the experiment. Furthermore, the effects of the energy and structural disorder, as well as structural defects within the bundle are also examined and compared with the experimental data.

**1:39PM F27.00011 Improvement of polypyrrole nanowire devices by plasmonic space charge generation: high photocurrent and wide spectral response by Ag nanoparticle decoration<sup>1</sup>** , SEUNG-HOON LEE, Department of Physics, Pukyong National University, SEUNG WOO LEE, School of Chemical Engineering, Yeungnam University, JAW-WON JANG<sup>2</sup>, Department of Physics, Pukyong National University — In this study, improvement of the opto-electronic properties of non-single crystallized nanowire devices with space charges generated by localized surface plasmon resonance (LSPR) is demonstrated. The photocurrent and spectral response of single polypyrrole (PPy) nanowire (NW) devices are increased by electrostatically attached Ag nanoparticles (Ag NPs). The photocurrent density is remarkably improved, up to 25.3 times, by the Ag NP decoration onto the PPy NW (PPy<sub>AgNPs</sub> NW) under blue light illumination. In addition, the PPy<sub>AgNPs</sub> NW shows a photocurrent decay time twice that of PPy NW, as well as an improved spectral response of the photocurrent. The improved photocurrent efficiency, decay time, and spectral response resulted from the space charges generated by the LSPR of Ag NPs. Furthermore, the increasing exponent ( $m$ ) of the photocurrent ( $J_{PC} \sim V_m$ ) and finite-differential time domain (FDTD) simulation straightforwardly indicate relatively large plasmonic space charge generation.

**1:51PM F27.00012 Optical Properties of waste derived carbon dots** , PRASHANT SARSWAT, MICHAEL FREE, University of Utah — Carbon dots (CDs) have been extensively examined recently, mainly due to their luminescence and excitation wavelength dependent emission behavior. These dots can be derived from a variety of carbonaceous sources. Some of the possible sources are carbonaceous waste materials. Although it is possible to synthesize CDs using waste and their applications in light source, few steps such as to purification of starting material and removal of other impurities during solvothermal processing can enhance the performance of CDs and associated devices. Our primary results suggest that carbonaceous waste in liquid form is easy to process. In contrast the solid carbonaceous wastes are relatively difficult to process, but their availability is higher. In this regard, a detailed study has been performed to formulate the appropriate processing parameters for best performing CDs.

**2:03PM F27.00013 C<sub>8</sub>-structured carbon quantum dots: Synthesis, blue and green double luminescence, and origins of surface defects**, CHEN XIFANG, ZHANG WENXIA, Department of Physics, Southeast University, Nanjing 211189, PR China, WANG QIANJIN, National Laboratory of Solid State Microstructures and Department of Materials Science and Engineering, Nanjing University, Nanjing 210093, PR China, FAN JIYANG, Department of Physics, Southeast University, Nanjing 211189, PR China — Carbon quantum dots (CQDs) have attracted great attention in the past few years due to their low cytotoxicity, exploited various synthesis methods, unexampled abundance of raw materials on earth, and robust near-infrared to near-UV luminescence. Carbon nanoparticles have applications in biological labeling, delivery of drugs and biological molecules into cells, and light emitting diodes and lasing. CQDs generally exist as nanodiamonds or graphite quantum dots according to previous research reports. In this study, we report the first synthesis of the third-allotrope CQDs through carbonization of sucrose and study their luminescence properties. These CQDs have a body-centered cubic structure and each lattice point is composed of eight atoms which form a sub-cube (so called C<sub>8</sub> crystal structure). High-resolution transmission electron microscopy and X-ray diffraction confirm the C<sub>8</sub> structure of the synthesized carbon nanocrystallites with an average size of 2 nm. The C<sub>8</sub> CQDs exhibit double-band luminescence with two peaks centered at around 432 and 520 nm. The study based on the photoluminescence, UV-Vis absorption, Fourier-transform infrared, and X-ray photoelectron spectroscopies reveals that the green emission originates from the C=O related surface defect.

**Session F28 DMP: Topological Insulator Thin Films** 327 - Matthew Brahlek, Pennsylvania State University

**11:15AM F28.00001 Interfacing Topological Insulators with Ferromagnetism<sup>1</sup>**, ANTHONY RICHARDELLA, Department of Physics, The Pennsylvania State University — In topological insulators, the surface states arise from strong spin-orbit coupling while the degeneracy of the Dirac point is protected by time reversal symmetry. Introducing magnetism in proximity to the surface states breaks this symmetry, destroying the non-trivial Berry phase at the Dirac point and leads to a hedgehog spin texture near the newly opened magnetic gap.<sup>2</sup> This symmetry broken phase leads to a host of unusual physics, such as the quantum anomalous Hall (QAH) effect. In this talk, we discuss the growth by molecular beam epitaxy and characterization of such magnetically interfaced and magnetically doped topological insulators. Such materials often suffer from structural defects and interfacial layers, as well as from degradation during device fabrication.<sup>3</sup> In particular, it is shown that Cr doped (Bi<sub>1-x</sub>Sb<sub>x</sub>)<sub>2</sub>Te<sub>3</sub> can exhibit perfect Hall quantization at low temperatures despite these defects. However, the magnetic ordering of this material was found to be quite unusual, displaying a super-paramagnetic like character, perhaps reflecting this disorder.<sup>4</sup> Such observations highlight the surprising behavior of such broken symmetry phases in topological materials. This work was performed in collaboration with A. Kandala, M. Liu, W. Wang, N.P. Ong, C.-X. Liu, and N. Samarth, in addition to the authors of the references cited.

**11:51AM F28.00002 Structure and transport of topological insulators on epitaxial graphene<sup>1</sup>**, JAMES KALLY, Dept. of Physics, Penn State Univ., DANIELLE REIFSNEYDER HICKEY, Dept. of Chemical Engineering and Materials Science, Univ. of Minnesota, YU-CHUAN LIN, Dept. of Materials Science and Engineering, Penn State Univ., ANTHONY RICHARDELLA, JOON SUE LEE, Dept. of Physics, Penn State Univ., JOSHUA ROBINSON, Dept. of Materials Science and Engineering, Penn. State Univ., K. ANDRE MKHOYAN, Dept. of Chemical Engineering and Materials Science, Univ. of Minnesota, NITIN SAMARTH, Dept. of Physics, Penn State Univ. — Recent advancements in spintronics have shown that a class of materials, topological insulators (TI), can be used as a spin-current generator or detector. Topological insulators have protected surface states with the electrons spin locked to its momentum. To access these surface states, (Bi, Sb)<sub>2</sub>Te<sub>3</sub> can be grown by molecular beam epitaxy to have the Fermi energy near the Dirac point so that transport occurs only through the spin-dependent surface states. Graphene is another 2D material of great interest for spintronics because of its very long spin diffusion length. This is an ideal material to act as a spin channel in devices. The van der Waals nature of the growth exhibited by 2D materials such as (Bi, Sb)<sub>2</sub>Te<sub>3</sub> and graphene allows heterostructures to be formed despite the large lattice mismatch. We explore the structure and transport of (Bi, Sb)<sub>2</sub>Te<sub>3</sub> grown on epitaxial graphene on 6H-SiC substrates for spintronic applications.

**12:03PM F28.00003 Band Bending Inversion in Bi<sub>2</sub>Se<sub>3</sub> Nanostructures**, LOUIS VEYRAT, IFW-Dresden, Institute for Solid State Research, FABRICE IACOVELLA, Laboratoire National des Champs Magnétiques Intenses (LNCMI-EMFL), JOSEPH DUFOULEUR, CHRISTIAN NOWKA, HANNES FUNKE, IFW-Dresden, Institute for Solid State Research, MING YANG, WALTER ESCOFFIER, MICHEL GOIRAN, Laboratoire National des Champs Magnétiques Intenses (LNCMI-EMFL), BARBARA EICHLER, OLIVER G. SCHMIDT, BERND BCHNER, SILKE HAMPEL, ROMAIN GIRAUD, IFW-Dresden, Institute for Solid State Research — Shubnikov-de-Haas oscillations were studied under high magnetic field in Bi<sub>2</sub>Se<sub>3</sub> nanostructures grown by Chemical Vapor Transport, for different bulk carrier densities ranging from  $3 \times 10^{19} \text{ cm}^{-3}$  to  $6 \times 10^{17} \text{ cm}^{-3}$ . The contribution of topological surface states to electrical transport can be identified and separated from bulk carriers and massive two-dimensional electron gas. Band bending is investigated, and a crossover from upward to downward band bending is found at low bulk density, as a result of a competition between bulk and interface doping. These results highlight the need to control electrical doping both in the bulk and at interfaces in order to study only topological surface states[1]. **12:15PM F28.00004 High-mobility surface states and conductance fluctuations in Bismuth Telluro-Sulfide topological insulator devices**, TANUJ TRIVEDI, SUSHANT SONDE, HEMA C. P. MOVVA, SANJAY K. BANERJEE, Microelectronics Research Center, The University of Texas at Austin — Since the experimental discovery of three-dimensional topological insulators (TI), (Bi,Sb)<sub>2</sub>(Se,Te)<sub>3</sub> binary compounds are the principal material systems to explore TI physics. However, transport experiments studying surface-states are complicated by parallel bulk conductivity contribution, which is expected to improve for ternary and quaternary chalcogenide compounds of Bi and Sb. A promising alternative is the Sulfur-based tetradymite with an ideal formula of Bi<sub>2</sub>Te<sub>2</sub>S, which has received little attention. We present van der Waals epitaxial growth and magnetotransport in Bismuth Telluro-Sulfide (BTS) crystalline nanosheets. Gating-enhanced Weak-antilocalization (WAL) and Universal Conductance Fluctuations (UCF) are observed in BTS devices. Empirical modeling of the data shows the existence of two-dimensional surface transport. A three-channel Hall conductivity model is proposed, which is utilized in conjunction with an extended-WAL analysis, showing the presence of a high-mobility surface component and indication for separation of transport channels in BTS devices. Our growth and comprehensive transport experiments demonstrate BTS as a promising candidate TI material.

**12:27PM F28.00005 In Situ Thin Film Growth and Characterization of Topological Dirac Semimetal  $\text{Na}_3\text{Bi}$** <sup>1</sup>, JACK HELLERSTEDT, MARK EDMONDS, CHANG LIU, Monash Centre for Atomically Thin Materials, NAVNEETH RAMAKRISHNAN, NUS Singapore, SHAFFIQUE ADAM, Yale-NUS College, MICHAEL FUHRER, Monash Centre for Atomically Thin Materials — The alkali pnictide  $\text{Na}_3\text{Bi}$  is a three-dimensional Dirac semimetal possessing Dirac-like dispersions in  $k_x$ ,  $k_y$  and  $k_z$ , that has attracted recent interest as a condensed matter system for realizing the chiral anomaly [1]. The high reactivity of sodium makes conventional synthesis and characterization extremely difficult: we circumvent this issue by combining thin film growth with low temperature STM and magnetotransport in one comprehensive UHV system. We have successfully grown  $\text{Na}_3\text{Bi}$  on  $\alpha\text{-Al}_2\text{O}_3$  (0001) substrates, achieving low temperature mobilities in excess of  $3,500 \text{ cm}^2/\text{Vs}$  and carrier densities as low as  $5 \times 10^{12} \text{ cm}^{-2}$ . Perpendicular magnetoresistance up to 1T shows quadratic behavior with weak anti-localization at low field. Quantitative analysis of this data suggests that our samples are in a charge inhomogeneous regime reminiscent of charge puddling in graphene [2]. **12:39PM F28.00006 Epitaxial  $\text{Cd}_3\text{As}_2$  Thin Films Synthesized by Molecular Beam Epitaxy**, TIMO SCHUMANN, MANIK GOYAL, SUSANNE STEMMER, Univ of California - Santa Barbara —  $\text{Cd}_3\text{As}_2$  is a three-dimensional (3D) Dirac semimetal, i.e. it possesses Dirac cones in a 3D bulk state where the band dispersion relation is linear near the Fermi energy.  $\text{Cd}_3\text{As}_2$  has raised considerable interest due to its high electron mobilities in bulk crystals and for novel quantum phenomena, such as chiral anomalies. However, few studies have been performed using thin films of  $\text{Cd}_3\text{As}_2$ . In this presentation, we report on the synthesis of  $\text{Cd}_3\text{As}_2$  thin films by molecular beam epitaxy (MBE). Single phase, epitaxial films were grown on undoped GaSb(111)B substrates with the (112) facet of  $\text{Cd}_3\text{As}_2$  parallel to the GaSb(111) surface. We report on the structural quality and orientation variants in the films. Electrical transport properties indicate electron mobilities exceeding  $6000 \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$ . We discuss the impact of the MBE growth parameters and substrate preparation on the structural and electrical properties of the films.

**12:51PM F28.00007 Asymmetric topological interfaces and charge transfer in epitaxial  $\text{Bi}_2\text{Se}_3$ /II-VI superlattices**, ZHIYI CHEN, The Graduate Center - CUNY, The City College of New York - CUNY, LUKASF ZHAO, INNA KORZHOVSKA, THOR GARCIA, MARIA TAMARGO, LIA KRUSIN-ELBAUM, The City College of New York - CUNY, KYUNGWHA PARK, Virginia Tech. — Access to charge transport through Dirac surface states in topological insulators (TIs) can be challenging due to their intermixing with the bulk or with non-topological subsurface two-dimensional electron gas (2DEG) quantum well states. Formed by bending of bulk electronic bands near the surface, 2DEG states arise via charge transfer to the topological surfaces, so the choice of layers abutting these surfaces is critical. Here we report molecular beam epitaxial growth of  $\text{Bi}_2\text{Se}_3/\text{Zn}_x\text{Cd}_{1-x}\text{Se}$  superlattices that support only one topological surface channel per TI layer. The topological nature of conducting channels is evidenced by  $\pi$ -Berry phase and by the two-dimensional weak antilocalization. Both density functional theory calculations and transport measurements suggest that a single topological Dirac cone per TI layer arises from the asymmetry between the Se-terminated and Zn-terminated interfaces of  $\text{Zn}_x\text{Cd}_{1-x}\text{Se}$  with  $\text{Bi}_2\text{Se}_3$ . Our findings suggest that topological transport could be controlled by adjusting charge transfer from non-topological spacers in hybrid structures. \*Supported by NSF-DMR-1420634, NSF-DMR-1312483, DOD-W911NF-13-1-0159, NSF DMR-1206354 and computer resources from SDSC under DMR060009N and VT ARC

**1:03PM F28.00008 Study of the circular photo-galvanic effect in electrically gated  $(\text{Bi,Sb})_2\text{Te}_3$  thin films**, YU PAN, TIMOTHY PILLSBURY, ANTHONY RICHARDELLA, THOMAS FLANAGAN, NITIN SAMARTH, The Pennsylvania State University — Illumination with circularly polarized light is known to produce a helicity dependent photocurrent in topological insulators such as  $\text{Bi}_2\text{Se}_3$  [Nature Nanotech. 7, 96 (2012)]. Symmetry considerations suggest that this circular photo-galvanic effect (CPGE) arises purely from the surface. However, whether or not the CPGE is directly related to optical excitations from the helical surface states is still under debate. To clarify the origin of the CPGE, we first compare the helicity dependent photocurrent in intrinsic  $(\text{Bi,Sb})_2\text{Te}_3$  to Cr doped  $(\text{Bi,Sb})_2\text{Te}_3$  thin films in which the Dirac surface states are perturbed by magnetic coupling. Secondly, we discuss the tunable CPGE in electrically gated  $(\text{Bi,Sb})_2\text{Te}_3$  thin films excited by optical excitations at different wavelengths. The dependence on the chemical potential and the photon energy of the excitation unveils the origin of the CPGE. Funded by ONR.

**1:15PM F28.00009 Low Temperature Quantum Transport Properties of  $\text{Bi}_2\text{Se}_3$  Topological Insulator Thin Films**<sup>1</sup>, DAVID LEDERMAN<sup>2</sup>, SERCAN BABAKIRAY, PAVEL BORISOV, AMIT KC, YURI GLINKA, West Virginia University —  $\text{Bi}_2\text{Se}_3$  thin films with nominal thickness values of 12, 16, 20 and 25 quintuple layers (QLs) were grown by molecular beam epitaxy (MBE) on  $\text{Al}_2\text{O}_3$  substrates. The magnetoconductance (MC) was analyzed using the two-dimensional Altshuler-Aronov (AA) and Hikami-Larkin-Nagaoka (HLN) mechanisms. Using a simple model where the channels for the bulk and surface states are independent from each other, and assuming that all channels undergo WAL, it was possible to determine the phase coherence length ( $L_\phi$ ) of the carriers of the surface and bulk contributions independently from the MC with the field perpendicular to the surface. The value of  $L_\phi$  for the surface states was independent of thickness, as expected, while  $L_\phi$  for the bulk channel was strongly dependent on film thickness. WAL was also measured with the field applied parallel to the surface, and from the MC data in this configuration, it was possible to obtain values for  $L_\phi$  that were similar to the perpendicular configuration for all samples except for the thinnest sample (12 QL), which may be a result of interactions between the metallic surface states on opposite sides of the film. We will discuss these results in view of other results from the literature.

**1:27PM F28.00010 High quality topological insulator thin films grown by molecular beam epitaxy using  $\text{MoS}_2$  monolayer as buffer layer**, K. H. CHEN, H. Y. LIN, C. Y. WANG, S. R. YANG, J. KWO, Dept. of Physics, Natl Tsing Hua Univ., Hsinchu 30013, Taiwan, C. K. CHENG, M. HONG, Graduate Institute of Applied Physics and Dept. of Physics, National Taiwan Univ., Taipei 10617, Taiwan, X. Q. ZHANG, Y. H. LEE, Dept. of Material Science and Engineering, Natl Tsing Hua Univ., Hsinchu 30013, Taiwan — Topological insulators (TIs), a new state of quantum matter, display a rich variety of physical phenomena. High quality TI films of  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$  have been obtained by van der Waals epitaxy on various substrates. To further reduce the high defect density level common in these films, we have extended the investigation to utilize 2D layered materials of hexagonal symmetry as substrates, such as large area CVD-grown  $\text{MoS}_2$  monolayer. Streaky RHEED patterns were observed during growth. Normal scans of x-ray diffraction indicated that the c-axis of films grown on both  $\text{Al}_2\text{O}_3$ (0001) and  $\text{MoS}_2/\text{Al}_2\text{O}_3$ (0001) were fully strain relaxed with a FWHM varying from 0.01 to 0.03, suggesting a very high degree of crystallinity. Using AFM, we found that size of triangular shaped domains were substantially bigger ( $\sim 1.5\mu\text{m}$ ) than those without  $\text{MoS}_2$  ( $\sim 0.6\mu\text{m}$ ). Furthermore, reduction by  $\sim 16\%$  in carrier concentration and a mobility as high as  $5700 \text{ cm}^2/\text{Vs}$  were observed in our 50nm film with  $\text{MoS}_2$ . Other thickness dependent transport properties such as WAL are underway, along with ARPES study of the electronic structures.

**1:39PM F28.00011 Visualizing virgin magnetic domains of V-doped  $\text{Sb}_2\text{Te}_3$  thin films<sup>1</sup>**, WENBO WANG, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA, CUI-ZU CHANG, JAGADEESH S. MOODERA, Francis Bitter Magnet Lab, Massachusetts Institute of Technology, Cambridge, MA 02139, USA., WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 USA — Quantum anomalous Hall effect (QAHE) was experimentally realized in a ferromagnetic topological insulator Cr-doped  $(\text{Bi,Sb})_2\text{Te}_3$  thin film for the first time[1]. Recently, a more robust QAHE has been observed in V-doped  $(\text{Bi,Sb})_2\text{Te}_3$  thin film, which has a much larger coercive field and higher Curie temperature at the same doping level[2]. However, a mysterious self-magnetization phenomenon was observed in the V-doped  $\text{Sb}_2\text{Te}_3$ , where net magnetization spontaneously develops after zero field cooling. In this talk, we utilize cryogenic magnetic force microscopy (MFM) technique to study the domain states of V doped  $\text{Sb}_2\text{Te}_3$  film under various cooling fields. A zero net magnetization state with equally distributed up and down domains was observed after zero-field cooling. In addition, a small external magnetic field ( $\sim 5$  Oe) is able to significantly polarize the magnetization of the film. Our MFM results are qualitatively consistent with in-situ magnetoresistance measurements. [1] C.-Z. Chang et al., Science 340, 167 (2013). [2] C.-Z. Chang et al., Nature Materials 14, 473477(2015).

**1:51PM F28.00012 Controlling the 2DEG states evolution at a metal/ $\text{Bi}_2\text{X}_3$  ( $\text{X}=\text{Se,Te}$ ) interface**, HAN-JIN NOH, JINWON JEONG, EN-JIN CHO, Department of Physics, Chonnam National University, JOONBUM PARK, JUN SUNG KIM, Department of Physics, Pohang University of Science and Technology, ILYOU KIM, BYEONG-GYU PARK, Pohang Accelerator Laboratory, Pohang University of Science and Technology, HYEONG-DO KIM, Department of Physics and Astronomy, Institute for Basic Science — We have demonstrated that the evolution of the two-dimensional electron gas (2DEG) system at an interface of metal and the model topological insulator (TI)  $\text{Bi}_2\text{X}_3$  ( $\text{X}=\text{Se, Te}$ ) can be controlled by choosing an appropriate kind of metal elements and by applying a low temperature evaporation procedure. In particular, we find that only topological surface states (TSSs) can exist at a  $\text{Mn}/\text{Bi}_2\text{X}_3$  interface, which would be useful for implementing a TI-based device with surface current channels only. The existence of the TSSs alone at the interface was confirmed by angle-resolved photoemission spectroscopy (ARPES). Based on the ARPES and core-level x-ray photoemission spectroscopy measurements, we propose a cation intercalation model to explain our findings.

**2:03PM F28.00013 Characterization of high-quality  $\text{Bi}_2\text{Se}_3$  films grown using a selenium cracker source<sup>1</sup>**, THERESA GINLEY, STEPHANIE LAW, University of Delaware — Topological insulators, including  $\text{Bi}_2\text{Se}_3$ , are becoming increasingly prevalent in research due to their unique electronic properties. These materials exhibit an insulating bulk but conducting surfaces with electron spin-momentum locking. Using Molecular Beam Epitaxy (MBE) it is possible to grow high-quality thin films of  $\text{Bi}_2\text{Se}_3$ . Yet these films have not lived up to their potential, in part due to significant bulk conductivity arising from material defects like selenium vacancies. Current MBE growth methods for  $\text{Bi}_2\text{Se}_3$  use standard selenium sources that evaporate large selenium molecules which must then be cracked into smaller molecules to be incorporated into the film. This process is inefficient and requires very high fluxes of selenium for good quality growths. However, using a selenium cracking source results in the evaporation of monomers and dimers, facilitating incorporation into the film. We will present electrical, structural, and optical measurements demonstrating that the use of a cracker source allows films to be grown using much lower selenium:bismuth flux ratios with good mobility and low carrier density.

**Session F29 DCMP DMP: Novel Topological Phases: Theory** 328 - Bitan Roy, University of Maryland

**11:15AM F29.00001 Chiral topological superconductor and half-integer conductance plateau from quantum anomalous hall plateau transition**, QUAN ZHOU, Stanford Univ, JING WANG, BIAO LIAN, SHOUCHENG ZHANG, Stanford University, ZHANG'S GROUP TEAM — We propose to realize a two-dimensional chiral topological superconducting (TSC) state from the quantum anomalous hall plateau transition in a magnetic topological insulator thin LM through the proximity ECT to a conventional s-wave superconductor. This state has a full pairing gap in the bulk and a single chiral majorana mode at the edge. The optimal condition for realizing such chiral tsc is to have inequivalent superconducting pairing amplitudes on top and bottom surfaces of the doped magnetic topological insulator. We further propose several transport experiments to detect the chiral TSC. One unique signature is that the conductance will be quantized into a half-integer plateau at the coercive eld in this hybrid system. In particular, with the point contact formed by a superconducting junction, the conductance oscillates between  $E_2=2H$  AND  $E_2=H$  with the frequency determined by the voltage across the junction. we close by discussing the feasibility of these experimental proposals.

**11:27AM F29.00002 Bona fide interaction-driven topological phase transition in correlated SPT states**, ZI YANG MENG, Institute of Physics, Chinese Academy of Sciences, YUAN-YAO HE, HAN-QING WU, Department of Physics, Renmin University of China, Beijing 100872, China, YI-ZHUANG YOU, CENKE XU, Department of Physics, University of California, Santa Barbara, California 93106, USA, ZHONG-YI LU, Department of Physics, Renmin University of China, Beijing 100872, China — It is expected the interplay between non-trivial band topology and strong electron correlation will lead to very rich physics. Thus a controlled study of the competition between topology and correlation is of great interest. Here, employing large-scale quantum Monte Carlo simulations, we provide a concrete example of the Kane-Mele-Hubbard model on an AA stacking bilayer honeycomb lattice with inter-layer antiferromagnetic interaction. Our simulation identified several different phases: a quantum spin-Hall insulator (QSH), a xy-plane antiferromagnetic Mott insulator (xy-AFM) and an inter-layer dimer-singlet insulator (dimer-singlet). Most importantly, a bona fide topological phase transition between the QSH and the dimer-singlet insulators, purely driven by the inter-layer antiferromagnetic interaction is found. At the transition, the spin and charge gap of the system close while the single-particle excitations remain gapped, which means that this transition has no mean field analogue and it can be viewed as a transition between bosonic SPT states. At one special point, this transition is described by a  $(2+1)\text{d}$   $\text{O}(4)$  nonlinear sigma model with exact  $\text{SO}(4)$  symmetry, and a topological term at  $\theta=\pi$ . Relevance of this work towards more general interacting SPT states is discussed.

**11:39AM F29.00003 Topological Phases on Non-orientable Surfaces: Twisting by Parity Symmetry**, PAK ON CHAN, ICMT at University of Illinois Urbana-Champaign, CHI YAN TEO, Physics at the University Of Virginia, SHINSEI RYU, ICMT at University of Illinois Urbana-Champaign — We discuss  $(2+1)\text{D}$  topological phases on non-orientable spatial surfaces, such as Möbius strip, real projective plane and Klein bottle, etc., which are obtained by twisting the parent topological phases by their underlying parity symmetries through introducing parity defects. We construct the ground states on arbitrary non-orientable closed manifolds and calculate the ground state degeneracy. Such degeneracy is shown to be robust against continuous deformation of the underlying manifold. We also study the action of the mapping class group on the multiplet of ground states on the Klein bottle. The physical properties of the topological states on non-orientable surfaces are deeply related to the parity symmetric anyons which do not have a notion of orientation in their statistics. For example, the number of ground states on the projective plane equals the root of the number of distinguishable parity symmetric anyons, while the ground state degeneracy on the Klein bottle equals the total number of parity symmetric anyons; In deforming the Klein bottle, the Dehn twist encodes the topological spins whereas the Y-homeomorphism tells the particle-hole relation of the parity symmetric anyons.

**11:51AM F29.00004 Analysis of the Kane-Mele-Kondo lattice at finite temperatures.**<sup>1</sup>, TSUNEYA YOSHIDA, Condensed Matter Theory Laboratory, RIKEN, ROBERT PETERS, Computational Condensed Matter Physics Laboratory, RIKEN, NORIO KAWAKAMI, Department of Physics, Kyoto University — Recently, correlation effects on topological insulators are extensively studied because the interplay of topological properties and electron correlations is expected to induce exotic phenomena. A promising candidate for a topological insulator in heavy-fermion systems is  $\mathrm{SmB}_{6}$  where the Kondo effects play an essential role. In this article, we study the Kane-Mele-Kondo lattice at finite temperatures. By using the dynamical mean-field theory, we obtain a temperature vs. interaction phase diagram (a Doniach phase diagram). Furthermore, we have observed an intriguing crossover behavior induced by the interplay of electron correlations and topologically nontrivial properties. In the bulk system, the spin-Hall conductivity which is proportional to the spin Chern number is zero at low temperatures while the conductivity rapidly increases with increasing temperature. Correspondingly, gapless modes are restored by temperature effects at the edge sites, which are destroyed by the Kondo effect at low temperature.

<sup>1</sup>This work is partly supported by KAKENHI (No. 25400366, and 15H05855). The numerical calculations were performed at the ISSP in the University of Tokyo and on the SR16000 at YITP in Kyoto University.

**12:03PM F29.00005 Bulk Topological Proximity Effect**, TIMOTHY HSIEH, HIROAKI ISHIZUKA, LEON BALENTS, Kavli Institute for Theoretical Physics, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — Existing proximity effects stem from systems with a local order parameter, such as a local magnetic moment or a local superconducting pairing amplitude. Here, we demonstrate that despite lacking a local order parameter, topological phases also may give rise to a proximity effect of a distinctively inverted nature. We focus on a general construction in which a topological phase is extensively coupled to a second system, and we argue that in many cases, the inverse topological order will be induced on the second system. To support our arguments, we rigorously establish this “bulk topological proximity effect” for all gapped free fermion topological phases and representative integrable models of interacting topological phases. We present a terrace construction which illustrates the phenomenological consequences of this proximity effect. Finally, we discuss generalizations beyond our framework, including how intrinsic topological order may also exhibit this effect.

**12:15PM F29.00006 Electrically tunable spin polarization of chiral edge modes in a quantum anomalous Hall insulator**, RUI-XING ZHANG, HSIU-CHUAN HSU, CHAO-XING LIU, Department of Physics, The Pennsylvania State University — In the quantum anomalous Hall effect, chiral edge modes are expected to conduct spin polarized current without dissipation and thus hold great promise for future electronics and spintronics with low energy consumption. However, spin polarization of chiral edge modes has never been established in experiments. In this work, we theoretically study spin polarization of chiral edge modes in the quantum anomalous Hall effect, based on both the effective model and more realistic tight-binding model constructed from the first principles calculations. We find that spin polarization can be manipulated by tuning either a local gate voltage or the Fermi energy. We also propose to extract spin information of chiral edge modes by contacting the quantum anomalous Hall insulator to a ferromagnetic (FM) lead. The establishment of spin polarization of chiral edge modes, as well as the manipulation and detection in a fully electrical manner, will pave the way to the applications of the quantum anomalous Hall effect in spintronics.

**12:27PM F29.00007 Topological invariants in interacting topological insulators: Success and Breakdown**, YUAN-YAO HE, HAN-QING WU, Department of Physics, Renmin University of China, Beijing 100872, China, ZI YANG MENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, ZHONG-YI LU, Department of Physics, Renmin University of China, Beijing 100872, China — The content of this talk is twofold. In the first part, we provide a paradigm of efficient numerical evaluation scheme for topological invariants via zero-frequency single-particle Green's function in quantum Monte Carlo (QMC) simulations. Especially, we introduce a periodization process to overcome the ubiquitous finite-size effect and make use of symmetry properties of the underlying systems to reduce the computational effort. This scheme is tested to be successful on models of interacting topological insulators, where there is single-particle gap closing at the transition. In the second part, we apply the above scheme to wider classes of interacting topological insulators, in which the breakdown of constructing topological invariant via single-particle Green's functions is presented. These systems host novel interaction-driven topological phase transitions without symmetry breaking, and hence fermionic degree of freedom is not involved at the critical point, instead, collective bosonic mode become critical.

**12:39PM F29.00008 Of Bulk and Boundaries: Generalized Transfer Matrices for Tight-Binding Models**<sup>1</sup>, VATSAL DWIVEDI, VICTOR CHUA, Univ of Illinois - Urbana — We construct a generalized transfer matrix corresponding to noninteracting tight-binding lattice models, which can subsequently be used to compute the bulk bands as well as the edge states. Crucially, our formalism works even in cases where the hopping matrix is non-invertible. Following Hatsugai [PRL 71, 3697 (1993)], we explicitly construct the energy Riemann surfaces associated with the band structure for a specific class of systems which includes systems like Chern insulator, Dirac semimetal and graphene. The edge states can then be interpreted as non-contractible loops, with the winding number equal to the bulk Chern number. For these systems, the transfer matrix is symplectic, and hence we also describe the windings associated with the edge states on  $Sp(2, R)$  and interpret the corresponding winding number as a Maslov index. This work is discussed in arXiv preprint arXiv:1510.04279.

**12:51PM F29.00009 Topological Edge States with Zero Hall Conductivity in a Dimerized Hofstadter Model**, ALEXANDER LAU, CARMINE ORTIX, JEROEN VAN DEN BRINK, Institute for Theoretical Solid State Physics, IFW Dresden — The Hofstadter model is one of the most celebrated models for the study of topological properties of matter and allows the study of the quantum Hall effect in a lattice system. Indeed, the Hofstadter Hamiltonian harbors the topological chiral edge states that are responsible for the quantized Hall conductivity. Here, we show that a lattice dimerization in the Hofstadter model opens an energy gap at half-filling. What is more, we demonstrate that even if the ensuing insulator has a Chern number equal to zero, concomitantly a doublet of edge states appear that are pinned to specific momenta. We show that the presence of these states can be understood from the topological properties of lower dimensional cuts of the system, using a mapping of the Hofstadter Hamiltonian to a collection of one-dimensional Aubry-André-Harper (AAH) models. A sub-set of AAH chains in this collection preserve inversion symmetry. This guarantees the presence of topologically protected doublets of end modes to which the edge states are pinned. To explicitly prove the robustness of the emerging edge states, we define and calculate the topological invariant that protects them, which turns out to be an integer invariant for inversion-symmetric AAH models.

**1:03PM F29.00010 Field theory of symmetry protected valence bond solid states in (2+1) dimensions**, AKIHIRO TANAKA, National Institute for Materials Science, Jpn, SHINTARO TAKAYOSHI, Department of Quantum Matter Physics, University of Geneva — With the scope of identifying possible symmetry-protected topological (SPT) states, we revisit the effective field theory description of 2d antiferromagnets in terms of nonlinear sigma models with topological Berry phase terms. We focus on ground states that can be characterized as spatially-uniform valence-bond-solid states residing on a square lattice, which implies that the spin quantum number  $S$  be an even integer. A path integral representation of wave functionals allows us to study the topological properties of the ground state in terms of a field theory defined in a space whose dimensionality is reduced by one, which leads us to an interesting incarnation of the well-known Haldane-gap argument for 1d antiferromagnets. From this, we conclude that the ground state can be an SPT state when  $S = 2 \times \text{odd integer}$ , while for  $S = 2 \times \text{even integer}$  it is topologically trivial. We also discuss how our method generalizes to 1d and 3d antiferromagnets.

**1:15PM F29.00011 First-Order Character and Observable Signatures of Topological Quantum Phase Transitions**, GIORGIO SANGIOVANNI, University of Wuerzburg, Germany, ADRIANO AMARICCI, SISSA Trieste, Italy, JAN CARL BUDICH, University of Innsbruck, Austria, MASSIMO CAPONE, SISSA Trieste, Italy, BJOERN TRAUZETTEL, University of Wuerzburg, Germany — Topological quantum phase transitions are characterized by changes in global topological invariants. These invariants classify many-body systems beyond the conventional paradigm of local order parameters describing spontaneous symmetry breaking. For noninteracting electrons, it is well understood that such transitions are continuous and always accompanied by a gap closing in the energy spectrum, given that the symmetries protecting the topological phase are maintained. Here, we demonstrate that a sufficiently strong electron-electron interaction can fundamentally change the situation: we discover a topological quantum phase transition of first-order character in the genuine thermodynamic sense that occurs without a gap closing. Our theoretical study reveals the existence of a quantum critical endpoint associated with an orbital instability on the transition line between a 2D topological insulator and a trivial band insulator. Remarkably, this phenomenon entails unambiguous signatures related to the orbital occupations that can be detected experimentally. Part of the results presented in this talk have been published in Phys. Rev. Lett. 114, 185701 (2015)

**1:27PM F29.00012 Construction of non-Abelian topological insulators using non-Abelian bosonization**, PO-HAO HUANG, Boston University, JYONG-HAO CHEN, Paul Scherrer Institute, PEDRO GOMES, Universidade de Sao Paulo, TITUS NEUPERT, Princeton University, CHRISTOPHER MUDRY, Paul Scherrer Institute, CLAUDIO CHAMON, Boston University — A way to construct 2D topological insulators and superconductors is to couple an array of wires. The advantage of this construction is that one can use bosonization. Many 2D integer and fractional topological quantum states have been proposed using Abelian bosonization. In this talk we show how to use non-Abelian bosonization to construct non-Abelian topological insulators and superconductors in 2D. With the help of conformal field theory, we construct topological states whose edge states are described by coset theories of the Wess-Zumino-Witten model. In this construction, all the interactions we use to gap the bulk are physical, i.e. tunneling of electrons and current-current interactions.

**1:39PM F29.00013 Constructing parent Hamiltonians for  $SU(N)$  AKLT states - a diagrammatic method**, ABHISHEK ROY, THOMAS QUELLA, Institute of Theoretical Physics, University of Cologne — Over the last decade, there has been increasing experimental interest in alkaline cold atom systems which exhibit  $SU(N)$  symmetry. Theoretical work has shown that a one-dimensional  $SU(N)$  chain can have  $N - 1$  symmetric protected states distinguished by fractionalized boundary spins. We introduce a new method for constructing  $SU(N)$  invariant Hamiltonians for Haldane phases in one dimension. Working at the AKLT point where the ground state is known exactly, we show a universal form of the Hamiltonian for any appropriate choice of physical and boundary spins. We apply our method to the case where the physical spin is in the adjoint representation and obtain a general expression for the Hamiltonian as well the Transfer Matrix for any  $N$ . Finally we comment on the relevance of our results to the generalized Haldane conjecture.

**1:51PM F29.00014 Topological Nonsymmorphic Crystalline Superconductors**, QING-ZE WANG, CHAO-XING LIU, The Pennsylvania State University — Topological superconductors possess a nodeless superconducting gap in the bulk and gapless zero energy modes, known as "Majorana zero modes", at the boundary of a finite system. In this work, we introduce a new class of topological superconductors, which are protected by nonsymmorphic crystalline symmetry and thus dubbed "topological nonsymmorphic crystalline superconductors". We construct an explicit Bogoliubov-de Gennes type of model for this superconducting phase in the D class and show how Majorana zero modes in this model are protected by glide symmetry. Furthermore, we generalize the classification of topological nonsymmorphic crystalline superconductors to the classes with time reversal symmetry, including the DIII and BDI classes, in two dimensions. Our theory provides a guidance to search for new topological superconducting materials with nonsymmorphic crystal structures.

**2:03PM F29.00015 Equivalence of topological insulators and superconductors**, GERARDO ORTIZ, Indiana Univ - Bloomington, EMILIO COBANERA, Dartmouth College — Systems of free fermions are classified by symmetry, space dimensionality, and topological properties described by K-homology. We show that by taking a many-body/Fock space viewpoint it becomes possible to establish equivalences of topological insulators and superconductors in terms of duality transformations [1]. These mappings connect topologically inequivalent systems of fermions, jumping across entries in existent classification tables, because of the phenomenon of symmetry transmutation by which a symmetry and its dual partner have identical algebraic properties but very different physical interpretations and electromagnetic response. Since our analysis extends to interacting fermion systems we also briefly discuss some such applications. To illustrate main concepts we will present dual superconducting partners of paradigmatic models, such as the Haldane Chern insulator as well as a quantum spin Hall effect graphene model. [1] Phys. Rev. B 92, 155125 (2015).

**Session F30 DMP: Orbital and Electronic Transitions in Oxide Heterostructures** 329 - Hyowon Park, University of Illinois, Chicago

**11:15AM F30.00001 Orbital reconstruction through interlayer cation charge imbalance: insights from wave-function-based quantum chemistry calculations**, LIVIU HOZOI, IFW Dresden, Germany — A promising route to engineering the electronic properties of quantum materials and devices rests on the idea of orbital reconstruction in multilayered oxide heterostructures. In this context, we identify and discuss in detail one simple, appealing mechanism for tailoring the sequence of d-electron energy levels: interplanar cation charge imbalance (ICCI) along successive metal-oxygen layers [1,2]. Through interplay with distortions of the ligand cages, it provides a knob for tuning the order of electronic levels in even intrinsically stacked oxides. We analyze in this regard electron spin resonance data for the 214 Sr-iridate oxide compound [1]. While canonical ligand-field theory predicts z-axis g factors smaller than 2 for positive tetragonal distortions as present in Sr214, the experiment indicates values larger than 2. This implies that the iridium d levels are inverted with respect to their normal ordering. State-of-the-art quantum chemistry calculations confirm the level switching in Sr214, whereas we find them to be instead normally ordered in the sister compound Ba214. Given the nonpolar character of the metal-oxygen layers, our findings highlight the tetravalent transition-metal 214 oxides as ideal platforms to explore d-orbital engineering in the context of oxide electronics. The crucial role of internal anisotropic fields related to the environment beyond nearest-neighbor ligands is further highlighted by ab initio quantum chemistry calculations on 3D pyrochlore osmates and iridates [3,4]. **11:51AM F30.00002 Enhancement of conductivity in ultrathin films of  $\text{LaNiO}_3$** , JENNIFER FOWLIE, MARTA GIBERT, SARA CATALANO, JEAN-MARC TRISCONE, University of Geneva — In order to achieve tailor-made properties in oxide heterostructures it is essential to first fully understand the physics of these materials and their behavior when pushing the 2-D limit. That is the principle goal of this work.  $\text{LaNiO}_3$  (LNO), a metal in bulk, has previously been found to be insulating in ultrathin form and this behavior was attributed to the onset of weak, and then strong, localization. A key feature of ultrathin films is that a significant portion of the sample is under the influence of the two "boundaries", these are the interfaces with the substrate and with the vacuum respectively. The effects of both of these boundaries have been studied previously by changing substrate material and with the addition of an encapsulating layer. In this work we show that, for LNO grown on  $\text{LaAlO}_3$  (001) substrates, there is an enhancement of conductivity that occurs on the verge of the ultrathin regime (less than 10 unit cells) and we hypothesize that this stems from a structural distortion imposed at the substrate-film interface.

**12:03PM F30.00003 Metal-insulator transition and emergence of spontaneous polarization in  $(\text{La}_{1-x}\text{Sr}_x\text{MnO}_3)_m/(\text{LaNiO}_3)_n$  superlattices constructed from metallic building blocks<sup>1</sup>**, SAURABH GHOSH, Vanderbilt University, Oak Ridge National Laboratory, USA, ROHAN MISHRA, Washington University in St. Louis, USA, JASON HOFFMAN, ANAND BHATTACHARYA, Argonne National Laboratory, USA, ALBINA Y. BORISEVICH, Oak Ridge National Laboratory, USA, SOKRATES T. PANTELIDES, Vanderbilt University, USA —  $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$  and  $\text{LaNiO}_3$  are metallic oxides. However, short-period superlattices of the form  $(\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3)_m/(\text{LaNiO}_3)_n$  show insulating behavior depending on  $m$  and  $n$ . In particular, the insulating property is robust when  $m = n = 2$  (SL 2/2). Here, using first-principles density functional theory (DFT) and DFT+U (static  $d-d$  Coulomb interaction), we explain the experimental observation and discuss a general mechanism that underlies such metal-insulator transition for different  $m$  and  $n$ . The general mechanism is based on the finding that disproportionation on Ni sites is the key. Further, we predict that insulating SL 2/2 is ferroelectric with large spontaneous polarization. The ferroelectric distortion persists in the cases where the superlattices are metallic, which leads to the possibility of designing a new family of 'polar metals'. Finally, we discuss the origin of such polar distortion and its coupling with the magnetic properties (by considering spin-phonon coupling) of the material.

**12:15PM F30.00004 Polarity and the Metal-Insulator Transition in ultrathin  $\text{LaNiO}_3$  on  $\text{SrTiO}_3$** , J.W. FREELAND, I.C. TUNG, Advanced Photon Source, Argonne National Laboratory, G. LUO, University of Wisconsin, Madison, H. ZHOU, Advanced Photon Source, Argonne National Laboratory, J.H. LEE, Korea Atomic Energy Research Institute, S.H. CHANG, Materials Science Division, Argonne National Laboratory, D. MORGAN, University of Wisconsin, Madison, M.J. BEDZYK, Northwestern University, D.D. FONG, Materials Science Division, Argonne National Laboratory — Dimensionality and strain control of nickelates has been shown as a route for control of interesting electronic and magnetic phases. However, little is known about the evolution of atomic structure in these layered architectures and the interplay with these states. Here we present, a detailed study of lattice structures measured real time during the layer-by-layer growth of  $\text{LaNiO}_3$  on  $\text{SrTiO}_3$ . Using hard X-rays coupled with oxide MBE, we have tracked the lattice structure evolution as a function of depth across the regime where transport shows a clear metal to insulator transition. At the same time X-ray absorption shows the films are closer to  $\text{LaNiO}_{2.5}$  when thin and evolve to  $\text{LaNiO}_3$  by 10 unit cells thickness. Analysis of the structure during growth displays a very complex evolution throughout the film of the lattice parameter and displacement of the B-site from the unit cell center, which theory connects with pathways of compensating the polar mismatch at the surface and interface. Work at the APS, Argonne is supported by the U.S. Department of Energy, Office of Science, and Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

**12:27PM F30.00005 Tailoring the electronic transitions of  $\text{NdNiO}_3$  films through  $(111)_{\text{pc}}$ -oriented interfaces**, SARA CATALANO, University of Geneva, MARTA GIBERT, University of Geneva Switzerland, VALENTINA BISOGNI, SLS PSI Villigen Switzerland, FEIZHOU HE, RONNIE SUTARTO, CLS Saskatoon Canada, MICHEL VIRET, CEA CNRS Saclay France, PAVLO ZUBKO, JEN-NIFER FOWLIE, University of Geneva Switzerland, GEORGE A. SAWATZKY, UBC Vancouver Canada, THORSTEN SCHMITT, SLS PSI Villigen Switzerland, JEAN-MARC TRISCONI, University of Geneva Switzerland — Bulk  $\text{NdNiO}_3$  displays a 1<sup>st</sup> order metal to insulator transition (MIT) that occurs simultaneously with a paramagnetic to antiferromagnetic Néel transition. For  $\text{NdNiO}_3$  epitaxial thin films grown along the  $(001)_{\text{pc}}$  axis, the MIT can be tuned between 0 and 200K through a variety of parameters, such as epitaxial strain or electrostatic carrier doping. Here, we extend the control of the electronic transitions of  $\text{NdNiO}_3$  thin films over an unprecedented temperature range by selecting  $(111)_{\text{pc}}$ -oriented substrates as a template for the growth. We show that  $(111)_{\text{pc}}$   $\text{NdNiO}_3/\text{NdGaO}_3$  heterostructures exhibit a MIT above room temperature, at  $T=335\text{K}$ , and a Néel transition at  $T=230\text{K}$ . By comparing the behavior of  $\text{NdNiO}_3$  layers grown on substrates with different symmetries and lattice parameters, we conclude that the particularly large tuning of the critical temperatures of the system is produced by the specific lattice matching conditions imposed along the  $(111)_{\text{pc}}$  axis of orthorhombic substrates.

**12:39PM F30.00006 Electronic and magnetic structure of ultra-thin film of  $\text{EuNiO}_3$** , SRIMANTA MIDDEY, D. MEYERS, M KAREEV, Department of Physics, University of Arkansas, Fayetteville, AR 72701 USA, J. LIU, Department of Physics and Astronomy, The University of Tennessee, Knoxville, TN 37996, USA, J. W. KIM, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, P. SHAFER, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, P. J. RYAN, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville, AR 72701 USA — In order to uncover the effect of reduced dimensionality on electronic and magnetic structure of rare earth nickelates series, we have investigate ultra thin film of  $\text{EuNiO}_3$  (ENO) using hard and soft resonant x-ray scattering. Despite of such small thickness, it exhibits checker board type charge ordering, and E antiferromagnetic transition highlighting bulk-like electronic and magnetic structure can be retained for highly distorted member of  $\text{RENiO}_3$  family. The presence of charge ordering at room temperature also provides opportunity for their use in novel electric field controlled devices.

**12:51PM F30.00007 Modeling Correlation Effects in Nickelates with Slave Particles<sup>1</sup>**, ALEXANDRU BOGDAN GEORGESCU, Department of Physics and Center for Research on Interface Structures and Phenomena, Yale University, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Physics, Mechanical Engineering and Center for Research on Interface Structures and Phenomena, Yale University — Nickelate interfaces display interesting electronic properties including orbital ordering similar to that of cuprate superconductors and thickness dependent metal-insulator transitions. One-particle band theory calculations do not include dynamic localized correlation effects on the nickel sites and thus often incorrectly predict metallic systems or incorrect ARPES spectra. Building on two previous<sup>1,2</sup> successful slave-particle treatments of local correlations, we present a generalized slave-particle method that includes prior models and allows us to produce new intermediate models<sup>3</sup>. The computational efficiency of these slave-boson methods means that one can readily study correlation effects in complex heterostructures. We show some predictions of these methods for the electronic structure of bulk and thin film nickelates.

**1:03PM F30.00008 Testing for Quantum Criticality in the  $(\text{Nd,L a})\text{NiO}_3$  phase space by Inelastic Tunneling Electron Spectroscopy (IETS)**, ANDREW KLEVITCH, University of Alabama, ANKIT DISA, FRED WALKER, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University, GINA ADAM, Department of Electrical and Computer Engineering, University of California at Santa Barbara, JAMES ALLEN, Department of Physics, University of California, CHARLES AHN, Center for Research on Interface Structures and Phenomena and Department of Applied Physics, Yale University, ADAM HAUSER, University of Alabama — Continuous (2<sup>nd</sup> order)  $T=0\text{K}$  Mott transitions are highly sought after because they are predicted to produce interesting quantum critical phenomena at higher temperatures such as quantum spin liquid states and marginal Fermi behavior. The rare earth nickelate system has generated significant interest for understanding charge and spin ordering phenomena in correlated materials and for potential application in novel switching devices. We will present Inelastic Electron Tunneling Spectroscopy (IETS) measurements from a series of films across the  $(\text{Nd,L a})\text{NiO}_3$  compositional system, yielding the single particle density of states at and across the quantum phase transition. Previous work has shown that pure  $\text{NdNiO}_3$  thin films have a characteristic bandgap, and pure  $\text{LaNiO}_3$  films have a characteristic pseudo-gap, satisfying a major requirement for a quantum critical transition point. Accordingly, our films undergo a metal-to-insulator transition upon cooling for high Nd content, while remaining metallic at all temperatures for high La content.

**1:15PM F30.00009 Suppression of charge and spin order in confined NdNiO<sub>3</sub> layers**, ANKIT DISA, DIVINE KUMAR, ANDREI MALASHEVICH, SOHRAB ISMAIL-BEIGI, FRED WALKER, CHARLES AHN, Yale University — Atomic-layer synthesis allows one to study and control the complex phase behavior correlated systems by controllably modifying dimensionality and interfacial constraints. To this end, the rare-earth nickelates (*R*NiO<sub>3</sub>) embody a remarkable model system, as exhibited by the bulk metal-insulator and paramagnetic-antiferromagnetic ordering transitions, which are sensitive to structural and electronic conditions. We present evidence from transport, x-ray absorption, and resonant x-ray scattering measurements of NdNiO<sub>3</sub>/NdAlO<sub>3</sub> superlattices of a suppression of charge and spin order induced by interfacial confinement. We find that the spectroscopic signatures of charge localization and antiferromagnetic ordering remain for NdNiO<sub>3</sub> layers thicker than a single unit cell. The disappearance of ground state order in single NdNiO<sub>3</sub> layers is attributed to enhanced *e<sub>g</sub>* orbital polarization from the interaction with the NdAlO<sub>3</sub> confining layers. We also observe a crossover region of thickness with no metal-insulator transition but distinct charge and spin ordering temperatures. These findings shed light on the interplay between competing ground states in nickelates and help guide efforts to controlling long-range order in such systems.

**1:27PM F30.00010 Effect of strain on ferroelectric field effect in strongly correlated oxide Sm<sub>0.5</sub>Nd<sub>0.5</sub>NiO<sub>3</sub>**<sup>1</sup>, LE ZHANG, XUEGANG CHEN, H. JEFFREY GARDNER, Dept. of Physics and Astronomy, University of Nebraska Lincoln, MARK A. KOTEN, JEFFREY E. SHIELD, Dept. of Mechanical Engineering, University of Nebraska Lincoln, XIA HONG, Dept. of Physics and Astronomy, University of Nebraska Lincoln — We report the effect of epitaxial strain on the magnitude and retention of the ferroelectric field effect in a prototype FerroFET based on a charge transfer-type Mott insulator, Sm<sub>0.5</sub>Nd<sub>0.5</sub>NiO<sub>3</sub> (SNNO). It has been shown that epitaxial strain can change the transition temperature *T<sub>MI</sub>* in SNNO by more than 100 K, and modify the metal-insulator transition (MIT) characteristic between first-order and second-order. We have fabricated epitaxial PbZr<sub>0.3</sub>Ti<sub>0.7</sub>O<sub>3</sub> (PZT)/3.8–4.3 nm SNNO heterostructures on (001) LaAlO<sub>3</sub> (LAO) and SrTiO<sub>3</sub> (STO) substrates. The magnitude of the field effect modulation can differ by more than one order of magnitude in these two systems, which has been attributed to strain modified MIT characteristic in SNNO. In both systems, we also observe a pronounced relaxation of off state resistance *R<sub>OFF</sub>*, showing a thermally activated behavior with corresponding activation energy of 22 meV (28 meV) for devices on LAO (STO). The time dynamics and thermal response of the retention behavior suggest that strain-induced oxygen vacancies play a critical role in the ferroelectric field effect instability.

**1:39PM F30.00011 Current-voltage profile of a strongly correlated materials heterostructure using non-equilibrium dynamical mean field theory**, KHADIJEH NAJAFI, JAMES FREERICKS, Georgetown university — We investigate the nonlinear electronic transport across a multilayered heterostructure which consists of Mott insulator layers connected to ballistic metal leads on both sides. To create current flow, we turn on an electric field in the leads for a finite period of time and then turn it off and let the system reach the steady state by adding an electric field over the correlated region. We use nonequilibrium dynamical mean-field theory to obtain the current-voltage relation. To do so, we current bias the device, and adjust the voltage profile to ensure current conservation and charge conservation throughout. The calculation ultimately works directly in the steady-state limit.

**1:51PM F30.00012 Photoinducing the hidden M2 phase in VO<sub>2</sub>**<sup>1</sup>, D.A. WALKO, Argonne National Laboratory, R.K. SMITH<sup>2</sup>, Bowling Green State University, HAIDAN WEN, A.D. DICHARA, Argonne National Laboratory, JAEWOO JEONG, MAHENS H. SAMANT, IBM Almaden Research Center, STUART S.P. PARKIN, IBM Almaden Research Center and Max Planck Institute for Microstructure Physics — We used time-resolved x-ray diffraction to study photoinduced structural phase transitions in a 170-nm-thick VO<sub>2</sub> film grown on sapphire (1,0,-1,0). Heating the unstrained film from room temperature induces the well-known phase transition from the monoclinic (M1) phase directly to the high-temperature tetragonal rutile (R) phase. In contrast, upon ultrafast optical excitation, the phase transition depends strongly on the laser intensity. At low fluences, the film is partially transformed into the monoclinic M2 phase, a phase which generally is observed only in doped or strained materials. Above a threshold at higher fluences, a small portion of the film is transformed into the M2 phase, decaying on a time scale of a few nanoseconds, while the majority of the film is transformed into the R phase which can persist for tens of nanoseconds. We further discuss the effects of laser wavelength on the efficiency of producing the M2 phase.

**2:03PM F30.00013 Quantum capacitance in thin film vanadium dioxide metal insulator transition**<sup>1</sup>, ZHE WU, TALBOT KNIGHTON, VINICIO TARQUINI, Department of Physics and Astronomy, Wayne State University, DAVID TORRES, TONGYU WANG, NELSON SEPULVEDA, Electrical and Computer Engineering Department, Michigan State University, JIAN HUANG, Department of Physics and Astronomy, Wayne State University — We present capacitance measurements of the electronic density of states performed in high quality vanadium dioxide (VO<sub>2</sub>) thin films on sapphire (Al<sub>2</sub>O<sub>3</sub>) substrate. These films show the expected metal insulator transition near 60 °C with resistivity changing by 3 orders of magnitude with a hysteresis of 10 °C. To make a capacitive probe, a gate is suspended above the film surface using a flip-chip method with microfabricated supports. The geometric capacitance per-area reached is 40 pF/mm<sup>2</sup>. Such a large capacitance can be significantly modified by electron interaction and band charging/discharging which appear as an extra term known as the quantum capacitance (*C<sub>q</sub>*). An AC signal applied to the gate allows measurement of the changing density of states (DOS) across the MIT. The DOS abruptly increases as the sample is heated through the transition point. Conversely the low temperature drop of *dμ/dn* is consistent with an energy gap opening in the insulating phase. These parameters shed light on the transition mechanism.

**Tuesday, March 15, 2016 11:15AM - 2:15PM –**  
**Session F31 DCMP: Superconductivity: Spectroscopy of Cuprates 331 -**

**11:15AM F31.00001 Ultrafast Gap Dynamics in Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+δ</sub> Studied by High Resolution trARPES**, STEPHEN PARHAM, HAOXIANG LI, JUSTIN WAUGH, XIAOQING ZHOU, THOMAS NUMMY, JUSTIN GRIFFITH, University of Colorado Boulder, Z. XU, J. SCHNEELOCH, R.D. ZHONG, GENDA GU, Brookhaven National Lab, DANIEL DESSAU, University of Colorado Boulder, DESSAU GROUP TEAM, GU GROUP TEAM — We perform time and angle resolved photoemission spectroscopy on optimally doped Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+δ</sub> (BSCCO-2212) using higher energy resolution than previously reported. This technique allows us to observe quasiparticle and gap dynamics directly in the time domain. We find that the quasiparticle decays have a rich momentum and energy dependence, with the general trend of faster decays closer to the antinode and faster decays inside the superconducting gap scale. We can understand this entire landscape by modeling the electrons as following a non-equilibrium, “pseudo”-temperature that controls all electrons in the zone. Using this model, which has zero free parameters, we find excellent agreement with the data.

**11:27AM F31.00002 A Tight Binding Approach to Understanding the Orbital Character of Pb-BSSCO and its Effects on Photoemission Matrix Elements<sup>1</sup>**, THOMAS NUMMY, University of Colorado Boulder, YUE CAO, Brookhaven National Lab, JUSTIN WAUGH, STEPHEN PARHAM, HAOXIANG LI, XIAOQING ZHOU, University of Colorado Boulder, SUNG-KWAN MO, Lawrence Berkeley National Lab, A. MAGREZ, H. BERGER, EPFL Lausanne, DANIEL DESSAU, University of Colorado Boulder — We measure the near Fermi energy electronic structure of Pb-BSSCO using Angle Resolved Photoemission Spectroscopy (ARPES) for various light polarization, incident at a glancing angle. A strong dependence of the photocurrent for a given crystal momentum on the polarization of light is observed. A minimal model tight binding calculation in a basis of local atomic orbitals is then utilized to determine the orbital composition of the single particle wavefunction as a function of crystal momentum in a single CuO<sub>2</sub> plane. Building off of these results, we simulate the relative ARPES photocurrent throughout crystal momentum space in the dipole approximation and compare to our experimental data. These comparisons confirm the presence of changing wavefunction orbital composition throughout the Brillouin zone in Pb-BSSCO.

**11:39AM F31.00003 Phonon modes in cuprates possibly related to the 10 meV ARPES kink<sup>1</sup>**, ADRIAN MERRITT, University of Colorado - Boulder, SEUNG-RYONG PARK, Incheon National University, JOHN-PAUL CASTELLAN, Karlsruhe Institute of Technology, GENDA GU, Brookhaven National Laboratory, DMITRY REZNIK, University of Colorado - Boulder — One of the possible mechanisms of high T<sub>c</sub> superconductivity is Cooper pairing with the help of bosons responsible for kinks in electronic dispersion observed by angle-resolved photoemission (ARPES). Up to now most effort has been devoted to the kinks near 70 meV. More recent ARPES experiments revealed an additional energy scale near 10 meV. Since no magnetic excitations peaked at these energies have been identified, the likeliest candidates appear to be phonons. We recently performed measurements of low-energy phonons in a large single crystal sample of optimally-doped 2212 BSSCO. We measured all phonons below 15 meV. There are many branches, in particular an optic branch disperses from 7 meV from the zone center with an anticrossing with an acoustic branch near h=0.2. In addition, there is evidence for a very low energy branch dispersing through 3-4 meV. I will present these results as well as similar data on LSCO and YBCO. A comparison with recent ultrafast optics experiment detecting lattice modes around 10 meV will also be made.

**11:51AM F31.00004 Power Law Liquid – A Unified Form of Low-Energy Nodal Electronic Interactions in Hole Doped Cuprate Superconductors**, DANIEL DESSAU, TED REBER, XIAOQING ZHOU, NICK PLUMB, STEPHEN PARHAM, JUSTIN WAUGH, YUE CAO, ZHE SUN, HAOXIANG LI, QIANG WANG, Univ of Colorado - Boulder, J.S. WEN, Z.J. XU, GENDA GU, Brookhaven National Labs, Y. YOSHIDA, HIROSHI EIASHI, AIST, Tsukuba, Japan, GERALD ARNOLD, Univ of Colorado - Boulder, UNIVERSITY OF COLORADO, BOULDER TEAM, BROOKHAVEN NATIONAL LABS TEAM, AIST, TSUKUBA, JAPAN TEAM — Based upon detailed ARPES measurements of Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+δ</sub> over a wide range of doping levels, we present a new unifying phenomenology for the non-Fermi liquid normal-state interactions (scattering rates) in the nodal direction. This new phenomenology has a continuously varying power law exponent (hence named a Power Law Liquid or PLL), which with doping varies smoothly from a quadratic Fermi Liquid to a linear Marginal Fermi Liquid and beyond. Using the extracted PLL parameters we can calculate the optics and resistivity over a wide range of doping and normal-state temperature values, with the results closely matching the experimental curves. This agreement includes the presence of the T\* “pseudogap” temperature scale observed in the resistivity curves including the apparent quantum critical point.

**12:03PM F31.00005 ARPES Study of Triple Layer Nickelate R<sub>4</sub>Ni<sub>3</sub>O<sub>10</sub> (R=Pr, La)**, HAOXIANG LI, XIAOQING ZHOU, THOMAS NUMMY, Department of Physics, University of Colorado at Boulder, Boulder, CO 80309, USA, JUNJIE ZHANG, Material Science Division, Argonne National Lab, Argonne, IL 60439, USA, VICTOR PARDO, Departamento de Fisica Aplicada, Universidade de Santiago de Compostela, E-15782 Campus Sur s/n, Santiago de Compostela, Spain, WARREN E. PICKETT, Department of Physics, University of California, Davis, CA, 95616, USA, JOHN F. MITCHELL, Material Science Division, Argonne National Lab, Argonne, IL 60439, USA, DANIEL S. DESSAU, Department of Physics, University of Colorado at Boulder, Boulder, CO 80309, USA — Layered nickelates present a similar crystal and electronic structure to the high-T<sub>c</sub> cuprates. They are potential candidates to host superconductivity, and have demonstrated intriguing anomalies in resistivity, magnetic susceptibility, and specific heat [1-3]. Here we present an ARPES study of the triple layer nickelate R<sub>4</sub>Ni<sub>3</sub>O<sub>10</sub> (R=Pr, La) and compare it with density functional calculations. A large hole pocket centered at the zone corners similar to the cuprates is observed, with additional zone folding due to the structural/magnetic cell doubling. An additional band-like feature is found near the Fermi surface at the gamma point, and shows a different symmetry than that of the hole pocket. These details of the fermiology and their relevance to the properties of these materials will be discussed. [1] Z. Zhang et al. J. Solid State Chem. 117, 236 (1995). [2] M. D. Carvalho et al. J. Appl. Phys. 88, 544 (2000). [3] M. Zinkevich et al. J. Alloys Compd. 438, 92 (2007).

**12:15PM F31.00006 ABSTRACT WITHDRAWN —**

**12:27PM F31.00007 Photodoping of Effects in Underdoped Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+x</sub> Revealed by Time and Angle Resolved Photoemission Spectroscopy<sup>1</sup>**, JONATHAN RAMEAU, Brookhaven Natl Lab, S. FREUTEL, I. AVIGO, M. LIGGES, L. RETTIG<sup>2</sup>, P. ZHOU, University of Duisburg-Essen, J. SCHNEELOCH, R. ZHONG, Z. XU, GENDA GU, PETER JOHNSON, Brookhaven Natl Lab, UWE BOVENSIEPEN, University of Duisburg-Essen — While in the last several years great strides have been made in the use of ultrafast optical excitation to induce non-equilibrium effects in the superconducting state of cuprate high T<sub>c</sub> superconductors, less attention has been paid to what such pump-probe experiments might reveal about the equilibrium properties of these materials, particularly in their normal states. Recently we have investigated the non-equilibrium properties of the normal state of optimally doped Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+x</sub> (T<sub>c</sub> = 91 K) using time and angle resolved photoelectron spectroscopy (tr-ARPES). This effort revealed a pump-induced modification of the nodal mass renormalization at 70 meV as well as a longer-lived photodoping effect. Building on this work, we will present further findings related to the photodoping effect as it is manifested in the normal state of underdoped (T<sub>c</sub> = 50 K) Bi<sub>2</sub>Sr<sub>2</sub>CaCu<sub>2</sub>O<sub>8+x</sub>.

**12:39PM F31.00008 The self-energies and bosonic spectrum of high T<sub>c</sub> cuprate from laser-based ARPES.**, JIN MO BOK, JONG JU BAE, HAN-YONG CHOI, Sungkyunkwan Univ, LI YU, X. J. ZHOU, Institute of Physics, Chinese Academy of Science, CHANDRA M. VARMA, University of California, Riverside — While phonon mediated conventional superconductors are revealed by comparing tunneling and neutron scattering experiment, high T<sub>c</sub> cuprate which has d-wave symmetry is still in debate. Laser-based AREPS can provide both momentum and energy dependence of spectral function that enables self-energy extraction using one particle Greens function. It is well known that anisotropy of electronic structure and d-wave superconducting gap on ARPES experiments. We analyzed high resolution APRES data of under and overdoped Bi2212 and extracted both normal and pairing self-energy. Here we report the extracted normal and pairing self-energy in superconducting state. Also we obtained bosonic spectrum from both self-energies by performing maximum entropy method. Implications of these results for understanding the superconductivity mechanism will be discussed.

**12:51PM F31.00009 Photoinduced Chemical Potential Shifts in Bi2212**, TRISTAN MILLER, CHRISTOPHER SMALLWOOD, WENTAO ZHANG, Lawrence Berkeley National Laboratory and UC Berkeley, HIROSHI EISAKI, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology, JOSEPH ORENSTEIN, ALESSANDRA LANZARA, Lawrence Berkeley National Laboratory and UC Berkeley — In superconducting materials, the chemical potential is particularly important because it is the energy of the superconducting condensate. The chemical potential may be perturbed by laser pulses, giving us new insight into the equilibrium properties of cuprate superconductors. Here, we report on studies of the photoinduced change of chemical potential in Bi2212 using time- and angle-resolved photoemission spectroscopy. We make an important distinction between the chemical potential relative to the vacuum energy, and relative to the valence band energy. The observations can be explained with considerations of the density of states. Measurements on different dopings of Bi2212 also provide new clues to the pseudogap phase.

**1:03PM F31.00010 Quasi-particles ultrafastly releasing kink bosons to form Fermi arcs in a cuprate superconductor**, Y. ISHIDA, T. SAITOH, ISSP, U. Tokyo, Japan, T. MOCHIKU, T. NAKANE, K. HIRATA, NIMS, Japan, S. SHIN, ISSP, U. Tokyo, Japan — In a conventional framework, superconductivity is lost at a critical temperature ( $T_c$ ) because, at higher temperatures, gluing bosons can no longer bind two electrons into a Cooper pair. In high  $T_c$  cuprates, it is still unknown how superconductivity vanishes at  $T_c$ . Recent angle-resolved photoemission (ARPES) studies revealed a remnant feature of the  $d$ -wave superconducting gap in the so-called Fermi arc occurring at  $T > T_c$ . The loss of superconductivity is thereby attributed to the filling of the near-nodal gap due to spectral broadenings as opposed to the closure of the gap at  $T_c$  [Reber *et al.*, PRB2013; Kondo *et al.*, Nature Phys. 2015]. The next step would be to elucidate the underlying mechanism of the spectral broadenings that cause the unconventional loss of superconductivity. We provide evidence that the so-called  $\sim 70$ -meV kink bosons that dress the quasi-particle excitations are playing the key role. We performed time-resolved ARPES on Bi2212 and monitored the responses of the superconducting gap and dressed quasi-particles to a light pulse. We observe an ultrafast loss of superconducting gap near the  $d$ -wave node, or light-induced Fermi arcs, which is accompanied by spectral broadenings and weight redistributions occurring within the kink binding energy. We discuss that the spectral broadening that induce the Fermi arc is due to the undressing of quasi-particles from the kink bosons. The loss mechanism is beyond the conventional framework, and can accept the unconventional phenomena such as the signatures of Cooper pairs remaining at  $T > T_c$ .

**1:15PM F31.00011 Superconducting Gap and Pseudogap in Heavily Underdoped Bi2212**, CHENG HU, LIN ZHAO, SHAOLONG HE, GUODONG LIU, LI YU, CHUANGTIAN CHEN, ZUYAN XU, GENDA GU, XINGJIANG ZHOU, Chinese Academy of Sci (CAS) — The relationship between the pseudogap and superconducting gap in high temperature cuprate superconductors remains an outstanding issue. In this talk, we will present laser-based angle-resolved photoemission spectroscopy results on underdoped Bi2Sr2(Ca,Dy)Cu2O8 high temperature superconductor. The latest generation of ARPES system equipped with the narrow-bandwidth VUV laser and the time-of-flight (TOF) electron energy analyzer is utilized here, which enables us to have super-high energy resolution, high momentum resolution, and simultaneous coverage of two-dimensional momentum space. From detailed temperature dependence near the nodal and antinodal regions, we will discuss the relationship between the pseudogap and superconducting gap in the underdoped cuprate superconductors.

**1:27PM F31.00012 Interplay of low-energy bosonic collective modes with incipient charge order in Bi-2212 characterized by momentum-resolved electron energy loss spectroscopy<sup>1</sup>**, SEAN VIG, ANSHUL KOGAR, Univ of Illinois - Urbana, VIVEK MISHRA, Argonne National Laboratory, MELINDA RAK, ALI HUSAIN, Univ of Illinois - Urbana, GENDA GU, Brookhaven National Laboratory, MIKE NORMAN, Argonne National Laboratory, PETER ABBAMONTE, Univ of Illinois - Urbana — Classifying the collective electronic dynamics of materials is critical to addressing the high temperature superconductivity problem and understanding related collective phenomena. Most current probes are unable to measure the full energy and momentum dependence of the dynamic charge susceptibility in these strongly correlated materials at the meV energy scale relevant to superconductivity. We use our momentum-resolved electron energy loss spectroscopy (M-EELS) technique to perform this measurement, characterizing both the static charge density and the bosonic electronic excitations in the cuprate superconductor Bi2Sr2CaCu2O8+ $\delta$  (Bi-2212). I present our measurement of a low temperature diffuse charge ordered state at optimal doping which modulates the observed dispersionless low energy collective excitations. Performing a one-loop correction to the bare electron dispersion, we show these modes reproduce the self-energy anomaly, or “kink”, as measured by ARPES. I discuss the nature of the charge dynamics that we measured with our technique and its relation to the superconducting state.

**1:39PM F31.00013 Resonant inelastic x-ray scattering as a band structure probe of high-temperature superconductors<sup>1</sup>**, MARTON KANASZ-NAGY, Harvard University, YIFEI SHI, ISRAEL KLICH, University of Virginia, EUGENE DEMLER, Harvard University — I will analyze recent resonant inelastic x-ray scattering (RIXS) experimental data on YBa2Cu3O6+x [Minola *et al.*, Phys. Rev. Lett. 114, 217003 (2015)] within quasi-particle theory. This measurement has been performed with the incoming photon energy detuned at several values from the resonance maximum, and, surprisingly, the data shows much weaker dependence on detuning than expected from recent measurements on a different cuprate superconductor, Bi2Sr2CuO6+x [Guarise *et al.*, Nat. Commun. 5, 5760 (2014)]. I will demonstrate, that this discrepancy, originally attributed to collective magnetic excitations, can be understood in terms of the differences between the band structures of these materials. We found good agreement between theory and experiment over a large range of dopings [M. Kanasz-Nagy *et al.*, arXiv:1508.06639]. Moreover, I will demonstrate that the RIXS signal depends sensitively on excitations at energies well above the Fermi surface, that are inaccessible to traditionally used band structure probes, such as angle-resolved photoemission spectroscopy. This makes RIXS a powerful probe of band structure, not suffering from surface preparation problems and small sample sizes, making it potentially applicable to a wide range of materials.

**1:51PM F31.00014 Doping dependent charge correlation in electron-doped cuprates.**, EDUARDO DA SILVA NETO, F. BOSCHINI, M. ZONNO, G. A. SAWATZKY, A. DAMASCELLI, Univ of British Columbia, M. MINOLA, M. BLUSCHKE, M. LE TACON, B. KEIMER, Max Planck Institute for Solid State Research, B. WU, Y. LI, G. YU, M. GREVEN, University of Minnesota, J. HIGGINS, Y. JIANG, R. L. GREENE, University of Maryland, R. SUTARTO, F. HE, Canadian Light Source, E. SCHIERLE, E. WESCHKE, Helmholtz-Zentrum Berlin — We use resonant x-ray scattering to measure the charge order in electron-doped high- $T_c$  superconductors and its relationship to antiferromagnetism and superconductivity. First, we establish the presence of charge order in a second family of electron-doped cuprates, LCCO thin films, with similar characteristics to previous observations in NCCO [1]. Second, doping and temperature dependent measurements of NCCO single crystals show that charge order is present in the  $x = 0.059$  to  $0.166$  doping range, and its doping-dependent wavevector is consistent with the separation between the hot spots on the Fermi surface. For NCCO samples near optimal doping ( $x = 0.14$ ) the charge order remains constant through the superconducting transition temperature and we find that magnetic fields up to  $6$  T have a negligible effect on its intensity. The implications of our data to the connections of charge order to antiferromagnetism and superconductivity will be discussed. [1] E. H. da Silva Neto, *et al.* Science 347, 282 (2015).

**2:03PM F31.00015 Resonant Soft X-ray Scattering studies of charge orders in high-temperature cuprates with Transition Edge Sensors<sup>1</sup>**, YIZHI FANG, Univ of Illinois - Urbana; Argonne National Laboratory, PETER ABBAMONTE, Univ of Illinois - Urbana, FANNY RODOLAKIS, JESSICA MCCHESENEY, Argonne National Laboratory, HIDEYUKI TATSUNO, National Institute of Standards and Technology; Lund University, YOUNG IL JOE, JOE FOWLER, KELSEY MORGAN, WILLIAM DORIESE, DANIEL SWETZ, JOEL ULLOM, National Institute of Standards and Technology — Resonant Soft X-ray studies of high  $T_c$  cuprates have implied a complex yet unresolved relationship between charge orders, antiferromagnetism and superconductivity. Unfortunately, at resonance the inelastic fluorescence background makes it hard to distinguish weak charge orders. To eliminate this issue, we have developed an energy-resolving detector comprised of 240-pixels superconducting Transition-Edge Sensor microcalorimeters. These superconducting sensors obtain exquisite resolution by exploiting the superconducting-to-normal transition to transduce photon energy to temperature and by operating at cryogenic temperatures ( $\sim 100$  mK) where thermal noise is minimal. Initial commissioning was accomplished at Advanced Photon Source Sector 29 in August 2015 and have demonstrated 1.0 eV resolution below 1 keV with efficiency (solid angle  $\times$  quantum efficiency)  $\sim 50$  times than that of grating spectrometers. An experiment to study charge orders in LBCO, LESCO and YBCO as a function of doping will take place in November 2015.

**11:15AM F33.00001 Coherent X-ray Scattering from Liquid-Air Interfaces<sup>1</sup>**, OLEG SHPYRKO, University of California, San Diego — Advances in synchrotron x-ray scattering techniques allow studies of structure and dynamics of liquid surfaces with unprecedented resolution. I will review x-ray scattering measurements of thermally excited capillary fluctuations in liquids, thin polymer liquid films and polymer surfaces in confined geometry. X-ray Diffuse scattering profile due to Debye-Waller like roughening of the surface allows to probe the distribution of capillary fluctuations over a wide range of length scales, while using X-ray Photon Correlation Spectroscopy (XPCS) one is able to directly couple to nanoscale dynamics of these surface fluctuations, over a wide range of temporal and spacial scales. I will also discuss recent XPCS measurements of lateral diffusion dynamics in Langmuir monolayers assembled at the liquid-air interface.

<sup>1</sup>This research was supported by NSF CAREER grant 0956131

**11:51AM F33.00002 A particle-in-mesh method for Brownian Dynamics simulation of many-particle systems with hydrodynamics interactions in a confined geometry**, XUJUN ZHAO, Argonne National Laboratory, JUAN HERNANDEZ-ORTIZ, Univ. Nacional de Colombia, DMITRY KARPEYEV, Argonne National Laboratory, JUAN DE PABLO, University of Chicago, BARRY SMITH, Argonne National Laboratory — In this work, we present an efficient parallel particle-in-mesh method for Brownian Dynamics simulations of many-particle systems confined in micro- and nano-fluidic devices. A general geometry Ewald-like method (GGEM) combined with finite element method is used to account for the hydrodynamic interaction. A fast parallel Krylov-type iterative solver with hybrid preconditioning techniques is developed for solving the large sparse systems of equations arising from finite element discretization of the Stokes equations. In addition, the current computer code is developed based on PETSc, a scalable library of numerical algorithms developed at Argonne, SLEPc - Scalable Library for Eigenvalue Problem Computations, and libMesh, a finite element library for numerical solution of PDEs built on top of PETSc, which allows for direct simulation of large scale systems with arbitrary confined geometries. This scheme is applied to Brownian dynamics simulations of flowing confined polymer solutions and colloidal dispersions in micro-fluid channels. The effects of hydrodynamics interactions and geometric confinement on the migration phenomena are illustrated.

**12:03PM F33.00003 Structural and dynamical properties of water on chemically modified surfaces: The role of the instantaneous surface<sup>1</sup>**, SELEMON BEKELE, MESFIN TSIGE, The University of Akron, Department of Polymer Science, Akron, Ohio — Surfaces of polymers such as atactic polystyrene (aPS) represent very good model systems for amorphous material surfaces. Such polymer surfaces are usually modified either chemically or physically for a wide range of applications that include friction, lubrication and adhesion. It is thus quite important to understand the structural and dynamical properties of liquids that come in contact with them to achieve the desired functional properties. Using molecular dynamics (MD) simulations, we investigate the structural and dynamical properties of water molecules in a slab of water in contact with atactic polystyrene surfaces of varying polarity. We find that the density of water molecules and the number distribution of hydrogen bonds as a function of distance relative to an instantaneous surface exhibit a structure indicative of a layering of water molecules near the water/PS interface. For the dynamics, we use time correlation functions of hydrogen bonds and the incoherent structure function for the water molecules. Our results indicate that the polarity of the surface dramatically affects the dynamics of the interfacial water molecules with the dynamics slowing down with increasing polarity.

**12:15PM F33.00004 Ion transport and dehydration in sub-nanoscale pores<sup>1</sup>**, SUBIN SAHU, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899, MASSIMILIANO DI VENTRA, Department of Physics, University of California, San Diego, CA 9500, MICHAEL ZWOLAK, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD — Ions in solution develop tightly bound layers of water – hydration layers – which stabilize disassociation and enable ionic currents to flow. Sub-nanometer pores in a membrane enable ions to pass provided that they shed their hydration shell. This process has an associated large energy penalty that is predicted to give rise to "quantized" steps in the ionic conductance.<sup>2,3</sup> Using all-atom molecular dynamics simulation, we demonstrate that the ionic current begins to show nonlinear behavior as the radius of the pore is reduced to the sub-nanometer scale. This nonlinear behavior is seen as a sharp rise in the pore resistance and excess noise in the current. Our work sheds light on basic mechanism of ion transport through sub-nanoscale pores.

**12:27PM F33.00005 Coordinated Water Under Confinement Eases Sliding Friction**, ADRIAN DE-FANTE, NISHAD DHOPOTKAR, ALI DHINOJWALA, Univ of Akron — Water is essential to a number of interfacial phenomena such as the lubrication of knee joints, protein folding, mass transport, and adsorption processes. We have used a biaxial friction cell to quantify underwater friction between a hydrophobic elastomeric lens and a hydrophobic self-assembled monolayer in the presence of surfactant solutions. To gain an understanding of the role of water in these processes we have coupled this measurement with surface sensitive sum frequency generation to directly probe the molecular constitution of the confined contact interface. We observe that role of confined coordinated water between two hydrophobic substrates covered with surfactants is the key to obtaining a low coefficient of friction.

**12:39PM F33.00006 Understanding dynamic changes in live cell adhesion with neutron reflectometry**, ANN JUNGHANS, Los Alamos National Laboratory — Understanding the structure and functionality of biological systems on a nanometer-resolution and short temporal scales is important for solving complex biological problems, developing innovative treatment, and advancing the design of highly functionalized biomimetic materials. For example, adhesion of cells to an underlying substrate plays a crucial role in physiology and disease development, and has been investigated with great interest for several decades. In the talk, we would like to highlight recent advances in utilizing neutron scattering to study bio-related structures in dynamic conditions (*e.g.* under the shear flow) including *in-situ* investigations of the interfacial properties of living cells. The strength of neutron reflectometry is its non-perturbative nature, the ability to probe buried interfaces with nanometer resolution and its sensitivity to light elements like hydrogen and carbon. That allows us to study details of cell - substrate interfaces that are not accessible with any other standard techniques. We studied the adhesion of human brain tumor cells (U251) to quartz substrates and their responses to the external mechanical forces. Such cells are isolated within the central nervous system which makes them difficult to reach with conventional therapies and therefore making them highly invasive. Our results reveal changes in the thickness and composition of the adhesion layer (a layer between the cell lipid membrane and the quartz substrate), largely composed of hyaluronic acid and associated proteoglycans, when the cells were subjected to shear stress. Further studies will allow us to determine more conditions triggering changes in the composition of the bio-material in the adhesion layer. This, in turn, can help to identify changes that correlate with tumor invasiveness, which can have significant medical impact for the development of targeted anti-invasive therapies.

**1:15PM F33.00007 Adsorption of CO<sub>2</sub> in hydrated MCM-41 Studied by SANS**, BO WANG, GARFIELD T. WARREN, MATTHEW BRYAN, PAUL E. SOKOL, Indiana University, INDIANA UNIVERSITY TEAM — Adsorption of CO<sub>2</sub> in hydrated MCM-41 was studied as a function of CO<sub>2</sub> pressure by Small-Angle Neutron Scattering (SANS). Measurements were carried out on hydrophobic Si-MCM-41 and hydrophilic Al-MCM-41 with pore sizes of 4nm with no aqueous layer as well as monolayers and bilayers of water pre-adsorbed on the surface. SANS was measured as CO<sub>2</sub> was introduced into the pores, which has the ability to probe the microscopic arrangement of water and CO<sub>2</sub> confined within the pores. We will present the results of analysis indicating whether water or CO<sub>2</sub> is more strongly attracted to the surface in these different samples. This study was prepared by Indiana University under award 70NANB10H255 from the National Institute of Standards and Technology, U.S. Department of Commerce.

**1:27PM F33.00008 Probing the Hydrodynamic Boundary Condition from Surface Perturbations in Thin Liquid Films**, OLIVER BAEUMCHEN, Max Planck Institute for Dynamics and Self-Organization (MPIDS), Goettingen, Germany, PAUL FOWLER, Department of Physics and Astronomy, McMaster University, Hamilton, Canada, THOMAS SALEZ, MICHAEL BENZAQUEN, ESPCI Paris-Tech, PSL Research University, Paris, France, MARK ILTON, Department of Physics and Astronomy, McMaster University, Hamilton, Canada, JOSHUA MCGRAW, Departement de Physique, Ecole Normale Supérieure, PSL Research University, Paris, France, ELIE RAPHAEL, ESPCI ParisTech, PSL Research University, Paris, France, KARI DALNOKI-VERESS, Department of Physics and Astronomy, McMaster University, Hamilton, Canada — For flows on the micro- and nanoscale, the hydrodynamic boundary condition of a liquid at a solid surface plays an enormous role. In recent years much has been learned about this slip boundary condition from flows that are driven by capillary forces, *e.g.* dewetting thin liquid films featuring a three-phase contact line [1]. Recently, we have shown that the amplification of surface perturbations in thin liquid films allows for a quantification of slippage in the absence of a contact line [2]. We also show that the opposite approach, *i.e.* the capillary levelling of initially perturbed free surfaces [3], is sensitive to the slip boundary condition at the solid/liquid interface. Thin film models comprising slip enable a quantification of the slip length of viscous liquids of various molecular properties. [1] O. Bäümchen et al., Phys. Rev. Lett. 113, 014501 (2014). [2] S. Haefner et al., Nature Comm. 6, 7409 (2015). [3] J.D. McGraw et al., Phys. Rev. Lett. 109, 128303 (2012).

**1:39PM F33.00009 Dynamic arrest of colloids in quenched-disordered nanofiber networks**, ANH PHAN, Department of Physics, University of Illinois at Urbana-Champaign, KENNETH SCHWEIZER, Department of Materials Science and Engineering, University of Illinois — The effect of quenched-disordered high aspect ratio nanorod networks on the kinetic arrest of relatively dilute colloid or nanoparticle suspensions is theoretically studied using equilibrium replica integral equation and dynamical activated hopping theories. The adsorbing templates act as an external field which can destroy macrophase separation and induce variable colloidal microstructures. When the colloid-template attraction is weak, a large-mesh network only weakly perturbs dynamical arrest in pores driven by colloid aggregation. Reducing the mesh size increases constraints and enhances colloid localization. For strong interfacial attraction templates, colloids can be kinetically arrested in large-mesh networks even when they are purely repulsive hard spheres due to dynamic blocking effects. However, the localization length is significantly larger, more akin to a glass-like, not gel-like, form of arrest. Decreasing the template mesh results in colloid localization at smaller interfacial attraction strengths. An overall kinetic arrest map is constructed based on the interplay of inter-colloid attraction, colloid-template attraction, and template mesh size. The effect of colloid localization on the composite dynamic elastic shear modulus can be estimated.

**1:51PM F33.00010 Effect of confinement on ionic liquid molecules in porous polymeric network**, PRASAD RAUT, Department of Polymer Engineering, The University of Akron, SHICHEN YUAN, DR. TOSHIKAZU MIYOSHI, Department of Polymer Science, The University of Akron, DR. SADHAN JANA, Department of Polymer Engineering, The University of Akron — Ionic liquids (ILs) have attractive physicochemical properties but their room temperature liquid state necessitates pairing of IL with other solid, porous materials for fabrication of devices. Such materials are called ionogels. Loading of bulky IL molecules in the pores can dramatically affect the physical properties as function of the pore surface chemistry, pore size, and IL polarity. In this study porous syndiotactic polystyrene (sPS) network was made via thermos-reversible gelation. 1-Butyl-1-methylpyrrolidinium bis(trifluoromethanesulfonyl)imide (PYR14TFSI) is incorporated into the pores of sPS. DSC study and the temperature dependence of <sup>13</sup>C-CPMAS NMR show that on confinement; the melting point of PYR14TFSI contained in the ionogel increased in comparison to the bulk PYR14TFSI. At room temperature, WAXD study of the ionogels showed diffraction pattern for PYR14TFSI in nanopores, correspondingly <sup>1</sup>H NOESY experiments show strong non-bonded cation-cation correlation in ionogels. The results for the bulk IL does not show non-bonded correlation at room temperature, this increment of local order in ionogel might be the results of crystallization of IL molecules in confined geometry.

**2:03PM F33.00011 Spacetime of Fluid and Gas**, DAYONG CAO, AEEA — The spacetime coordinates do not measure the spacetime. It measures a structure of the object. The structure is massenergy center and spacetime around. It is build up by massenergy and spacetime together. The density of massenergy of solid is bigger than the one of the fluid or gas; contrariwise, the density of spacetime of the fluid or gas is bigger than the one of the solid. Because the density of spacetime is inversely proportional to the density of massenergy. The Einstein's equation has the other formula for the structure of the center of spacetime. The spacetime is wave, and the spacetime effect of the fluid and gas are about buoyancy, pressure, resistance, and temperature will be taken into Einstein's equation. It should explain of the low density asteroid-1950 DA and a rock hull of 67P/Churyumov-Gerasimenko. <http://meetings.aps.org/link/BAPS.2015.APR.T1.24> <http://meetings.aps.org/link/BAPS.2015.APR.H14.8>

Session F34 GSOFD DBIO GSNP/DFD: Active Matter IV 337 - Cristina Marchetti, Syracuse University

**11:15AM F34.00001 Self-Pumping Active Gel.** , KUN-TA WU, JEAN BERNARD HISHAMUNDA, SETH FRADEN, ZVONIMIR DOGIC, Department of Physics, Brandeis University — Isotropic active gels are the network which is consist of cross-linked building blocks and the structure of which changes randomly and isotropically with time. Dogic et. al. show that pairs of anti-parallel microtubules form extensile bundles, which merge, extend, and buckle. In an unconfined system, the dynamics of these bundles causes spontaneous turbulent-like flow driven by motion of microscopic molecular motors. We found that confining these active gels in a millimeter sized toroids causes a transition into a new dynamical state characterized by circulation currents persisting for hours until ATP is depleted. We show how toroid dimensions impact the properties of self-organized circular currents, how directions of circulation can be designed by engineering ratchet-shaped boundaries, and how circulations of connected toroids can be either synchronized or antisynchronized. Furthermore, we demonstrate that the flow rate in the circulation is independent of curvature and length of flow path. The flow rate persists for centimeters without decay, disregarding conventional pipe flow resistance. Such findings pave the path to self-pumping pipe transport and performing physical work with biological system.

**11:27AM F34.00002 Synchronization of oscillations in hybrid gel-piezoelectric active materials.** , VICTOR V. YASHIN, Department of Chemical Engineering, University of Pittsburgh, STEVEN P. LEVITAN, Department of Electrical and Computer Engineering, University of Pittsburgh, ANNA C. BALAZS, Department of Chemical Engineering, University of Pittsburgh — We model the hybrid gel-piezoelectric active material that could perform oscillator based unconventional computing tasks (materials that compute). The material is assumed to have a cellular structure, where each cell contains a polymer gel, which undergoes cyclic swelling and deswelling due to the oscillatory Belousov-Zhabotinsky (BZ) reaction, and is coupled to a piezoelectric (PZ) film. Upon electrical connection, oscillations in the BZ-PZ units get synchronized, and the mode of synchronization is shown to depend on the number of units in the system, type of circuit connection, etc. Introduction of capacitors into the circuits allows us to further manipulate the synchronization modes, i.e., the distinctive patterns in phase of oscillations. The results indicate the BZ-PZ systems could be used for spatio-temporal pattern recognition.

**11:39AM F34.00003 Photo-programming Semicrystalline Shape Actuators<sup>1</sup>** , YUAN MENG, JASON YANG, MITCHELL ANTHAMATTEN, Univ of Rochester, ANTHAMATTEN LAB TEAM — A semi-crystalline double network is formed that contains two types of molecular junctions: covalent junctions and reversible molecular linkages. The reversible junctions have the ability to rearrange/reshuffle upon irradiation, and, therefore give rise to a competitive double network architecture that actuates upon crystallization without an applied external load. Poly(caprolactone) networks containing reconfigurable allyl-sulfide linkages are melted, strained to various elongations (hundreds of percent), and irradiated. The network connectivity is reconfigured through a series of light-induced AFCT events, causing a unique built-in stress to be introduced. After irradiation and unloading, the resulting double networks assume a mechanical state-of-ease, and polymer strands adopt biased configurations; when cooled, they crystallize along a preferred direction leading to fully reversible shape actuation. Sample networks can be programmed in multi-steps under constant strain or constant stress, leading to different dynamics and equilibrium states-of-ease. Stress free actuation of 18 percent was achieved.

<sup>1</sup>Pump Primer Award from Univ. of Rochester

**11:51AM F34.00004 Designing Self-powered Nanomotors and Pumps** , AYUSMAN SEN, Pennsylvania State University — Self-powered nano and microscale moving systems are currently the subject of intense interest due in part to their potential applications in nanomachinery, nanoscale assembly, robotics, fluidics, and chemical/biochemical sensing. We will demonstrate that one can build autonomous nanomotors over a wide range of length-scales “from scratch” that mimic biological motors by using catalytic reactions to create forces based on chemical gradients. These motors are autonomous in that they do not require external electric, magnetic, or optical fields as energy sources. Instead, the input energy is supplied locally and chemically. These “bots” can be directed by information in the form of chemical and light gradients. Furthermore, we have developed systems in which chemical secretions from the translating nano/micromotors initiate long-range, collective interactions among themselves. This behavior is reminiscent of quorum sensing organisms that swarm in response to a minimum threshold concentration of a signaling chemical. In addition, an object that moves by generating a continuous surface force in a fluid can, in principle, be used to pump the fluid by the same catalytic mechanism. Thus, by immobilizing the nano/micromotors, we have developed nano/microfluidic pumps that transduce energy catalytically. These non-mechanical pumps provide precise control over flow rate without the aid of an external power source and are capable of turning on in response to specific analytes in solution.

**12:27PM F34.00005 Emergent Ultra-Long-Range Interactions Between Active Particles in Hybrid Active-Inactive Systems** , JOSHUA STEIMEL, JUAN ARAGONES, HELEN HU, MIT, NASER QURESHI, UNAM, ALFREDO ALEXANDER-KATZ, MIT — Particle-particle interactions determine the state of a system. Control over the range and magnitude of such interactions has been an active area of research for decades due to the fundamental challenges it poses in science and technology. Effective interactions between active particles have gathered much attention as they can lead to out-of-equilibrium cooperative states such as flocking. Inspired by nature, where active living cells coexist with lifeless, immobile objects and structures, here we study the effective interactions that appear in systems composed of active and passive mixtures of colloids. Our system is a two dimensional colloidal monolayer composed primarily of passive (inactive) colloids and a very small fraction of active (sinning) ferromagnetic colloids. We find an emergent ultra-long-range attractive interaction between active particles induced by the activity of the spinning particles and mediated by the elasticity of the passive medium. Interestingly, the appearance of such interaction depends on the spinning protocol and has a minimum actuation time scale below which no attraction is observed. Overall, these results clearly show that in the presence of elastic components, active particles can interact across very long distances without any chemical modification of the environment. Such a mechanism might potentially be important for some biological systems and can be harnessed for newer developments in synthetic active soft materials.

**12:39PM F34.00006 Noise and diffusion in vibrated self-propelled particles** , LEE WALSH, University of Massachusetts Amherst, SARAH SCHLOSSBERG, University of California San Diego, APARNA BASKARAN, Brandeis University, NARAYANAN MENON, University of Massachusetts Amherst — Active-matter systems are often modeled in the lab by studying the two-dimensional dynamics of granular particles driven by vibration in the third dimension. If the vibrational noise is rectified by the shape of the particle, the resulting motion of the particle shows directed motion superimposed on diffusion. We use particles designed for polar motion along a body axis as well as others that break isotropy in various ways. The long-term motion is typically theoretically modeled by a Langevin equation that encodes a self-propulsion velocity along the body axis as well as uncorrelated rotational and translational noise, all of which are treated as independent parameters. For a dilute system of granular tiles confined to a horizontal plane and vertically vibrated, we measure the long-time single-particle dynamics as well as the short-time distributions of translational and rotational motion. From these we characterize the different correlation functions that determine the noise and test the assumptions of the conventional Langevin dynamics used for self-propelled particles.

**12:51PM F34.00007 Glassy dynamics of self-propelled particles** , ELIJAH FLENNER, Colorado State University, LUDOVIC BERTHIER, CNRS and Universite Montpellier, GRZEGORZ SZAMEL, Colorado State University — We examine the glassy dynamics of a system of self-propelled, interacting particles. The self-propulsion is described as an internal driving force that evolves according to the Ornstein-Uhlenbeck process. It can be characterized by an effective temperature and a persistence time for the self-propelled motion. For a fixed effective temperature, as the persistence time approaches zero the particles dynamics becomes equivalent to overdamped Brownian (thermal) dynamics. Our goal is to investigate how the average structure and dynamics evolves with increasing persistence time, which corresponds to increasing departure from the Brownian limit. To this end we simulate a system whose glassy dynamics has been extensively studied in Brownian dynamics simulations, the Kob-Andersen binary mixture. We examine how the effective mode-coupling transition, the fragility and heterogeneous dynamics change with increasing persistence time.

**1:03PM F34.00008 Emergent motion patterns of delay-coupled swarms<sup>1</sup>**, KLEMENTYNA SZWAYKOWSKA, U.S. Naval Research Laboratory, Code 6792, Plasma Physics Division, LUIS MIER-Y-TERAN-ROMERO, Department of Epidemiology, Johns Hopkins University Bloomberg School of Public Health, IRA SCHWARTZ, U.S. Naval Research Laboratory, Code 6792, Plasma Physics Division — Emergent pattern-forming behaviours of aggregates of interacting autonomous agents are a topic of great interest in complex systems research, with applications including biology, environmental monitoring, and defence. We model, and experimentally verify, pattern formation in a swarm of delay-coupled agents, using a simple but general model of agent interactions. Using mean-field dynamics, we perform a thorough analytical study of the bifurcation structure as a function of network connectivity and delay to describe the emergence of pattern formation. We show that swarm motion patterns observed for a homogeneous swarm with all-to-all communication are robust to decreasing network connectivity and to heterogeneity in the parameters governing individual agent behaviours. We perform systematic numerical studies to show where the mean-field theory deviates from simulation and experiment.

**1:15PM F34.00009 Trapping and sorting active granular rods**, SRIRAM RAMASWAMY<sup>1</sup>, TIFR Centre for Interdisciplinary Sciences, 21 Brundavan Colony, Narsingi, Hyderabad 500 075, NITIN KUMAR, James Franck Institute, University of Chicago, Chicago IL 60637, HARSH SONI, School of Engineering, Brown University, Providence RI 02912, RAHUL GUPTA, TIFR Centre for Interdisciplinary Sciences, 21 Brundavan Colony, Narsingi, Hyderabad 500 075, AJAY SOOD, Department of Physics, Indian Institute of Science, Bangalore 560 012 — We report experiments and simulations on collective trapping in a horizontal monolayer of tapered granular rods rendered motile by mechanical vibration. A macroscopic fraction of the particles are trapped by a V-shaped obstacle if its opening angle is less than a threshold value of about 120 degrees, consistent with active Brownian simulations [PRL 108, 268307 (2012)]. the transition between trapped and untrapped states becomes sharper with increasing system size in our numerical studies. We offer a theoretical understanding of this nonequilibrium phase transition based on collective noise suppression and an analysis of fluxes. We show also that the trap can serve to separate particles based on their motility and rotational diffusivity.

<sup>1</sup>on leave from Dept of Physics, Indian Institute of Science

**1:27PM F34.00010 Pattern Formation in Driven Systems<sup>1</sup>**, KATHERINE KLYMKO, Univ of California - Berkeley — Model colloidal particles of two types, driven in opposite directions, will in two dimensions segregate into lanes, a phenomenon studied extensively by Lowen and co-workers [Dzubiella et al. Phys. Rev. E 65, 021402 (2002)]. We have simulated mixtures of oppositely-driven particles using three numerical protocols. We find that laning results from enhanced diffusion, in the direction perpendicular to the drive, of particles surrounded by particles of the opposite type, consistent with the observation of Vissers et al. [Soft Matter 7, 6, 2352 (2011)]. By comparing protocols we find that enhanced diffusion follows from a simple geometrical constraint: oppositely-driven particles must, in the time taken to encounter each other in the direction of the drive, diffuse in the perpendicular direction by about one particle diameter. This constraint implies that the effective lateral diffusion constant grows linearly with drive speed and as the square root of the packing fraction, a prediction supported by our numerics. By invoking an analogy between hard particles with environment-dependent mobilities and mutually attractive particles we argue that there exists an equilibrium system whose pattern-forming properties are similar to those of the driven system.

<sup>1</sup>Katherine Klymko acknowledges support from the NSF Graduate Research Fellowship.

**1:39PM F34.00011 How many dissenters does it take to disorder a flock?<sup>1</sup>**, DAVID YLLANES, M. CRISTINA MARCHETTI, Syracuse University — Minimal models of active particles have had much success in the study of flocking behavior. Typically one considers a system of self-propelled particles with noisy aligning interactions. By varying the density of the system or the intensity of the noise one can switch between a disordered phase where the particles move randomly and independently and a flocking state where the velocities of the particles are aligned. In this work we consider what happens if a fraction  $p$  of the particles does not experience the aligning interaction. This is an interesting problem from a statistical mechanics point of view, with applications to collective behavior of living systems, where not all the members of a community (a flock of birds, a herd of sheep, etc.) behave in the same way. By carrying out extensive molecular dynamics simulations we show that even a very small fraction of such "individualistic" particles can have a dramatic effect on the whole system and, indeed, that the flocking can be destroyed for a very low value of  $p$ .

**11:15AM F35.00001 The effect of extrinsic noise on the dynamics of simple gene network motifs**, MICHAEL ASSAF, Hebrew University of Jerusalem — Cellular processes do not follow deterministic rules; even in identical environments genetically identical cells can make random choices leading to different phenotypes. This randomness originates from fluctuations present in the biomolecular interaction networks. Most previous work has been focused on the intrinsic noise of these networks. Yet, especially for high-copy-number biomolecules, extrinsic or environmental noise has been experimentally shown to dominate the variation. Here we develop an analytical formalism that allows for calculation of the combined effect of intrinsic and extrinsic noise on gene expression motifs. We introduce a new and generic method for modeling bounded extrinsic noise as an auxiliary species in the master equation. We focus our study on motifs that can be viewed as the building blocks of genetic switches: a non-regulated gene, a self-inhibiting gene, and a self-promoting gene. The role of the extrinsic noise properties (magnitude, correlation time, and distribution) on the statistics of interest are systematically investigated, and the effect of fluctuations in different reaction rates is compared. Due to its analytical nature, our formalism can be used to quantify the effect of extrinsic noise on the dynamics of biochemical networks and can also be used to improve the interpretation of data from single-cell gene expression experiments.

**11:51AM F35.00002 Backward evolution from gene network dynamics**, MERZU BELETE, University of Houston and Laufer Center for Physical and Quantitative Biology, Stony Brook University, Stony Brook, New York, United States of America, DANIEL CHARLEBOIS, GÁBOR BALÁZSI, Laufer Center for Physical and Quantitative Biology, Stony Brook University, Stony Brook, New York, United States of America — Gene expression is often controlled by regulator genes that form gene regulatory network cascades. How mutation in the genes comprising regulatory cascades influences cell populations dynamics has not been adequately investigated. In this study, we developed a model to study how a mutation in a regulator gene that reaches the effector gene with a time delay affects short-term and long-term population growth. We find a paradoxical outcome of evolution, where a mutation in a regulator gene leads to an interaction between gene regulatory network dynamics and population dynamics, causing in certain cases a permanent decrease in population fitness.

**12:03PM F35.00003 Collective evolution of cyanobacteria and cyanophages mediated by horizontal gene transfer**, HONG-YAN SHIH, Department of Physics and Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, TIM ROGERS, Department of Mathematical Sciences, University of Bath, NIGEL GOLDENFELD, Department of Physics and Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign — We describe a model for how antagonistic predator-prey coevolution can lead to mutualistic adaptation to an environment, as a result of horizontal gene transfer. Our model is a simple description of ecosystems such as marine cyanobacteria and their predator cyanophages, which carry photosynthesis genes. These genes evolve more rapidly in the virosphere than the bacterial pan-genome, and thus the bacterial population could potentially benefit from phage predation. By modeling both the barrier to predation and horizontal gene transfer, we study this balance between individual sacrifice and collective benefits. The outcome is an emergent mutualistic coevolution of improved photosynthesis capability, benefiting both bacteria and phage. This form of multi-level selection can contribute to niche stratification in the cyanobacteria-phage ecosystem. This work is supported in part by a cooperative agreement with NASA, grant NNA13AA91A/A0018.

**12:15PM F35.00004 Environmental quality modulates the cooperative and competitive nature of a microbial cross-feeding mutualism**, TIM HOEK, CSnD Master Program, University Utrecht, Utrecht, The Netherlands, KEVIN AXELROD, Biophysics PhD Program, Harvard University, Cambridge, MA, EUGENE YURTSEV, JEFF GORE, Physics of Living Systems, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA — Mutualisms are essential for ecosystem function and stability. However, in some environments the competitive aspects of an interaction may dominate the mutualistic aspects. Although these transitions could have far-reaching implications, it has been difficult to study the causes and consequences of this mutualistic-competitive transition in experimentally tractable systems. Here we experimentally study a microbial cross-feeding mutualism in which each yeast strain supplies an essential amino acid for its partner strain. We find that, depending upon the amino acid concentration, this pair of strains can exhibit any of: obligatory mutualism, facultative mutualism, competition, parasitism, competitive exclusion, or failed mutualism leading to extinction of the population. A simple model capturing the essential features of this interaction predicts that environmental quality specifies the outcome and provides a “phase diagram” of net interactions in this mutualism. In addition, the model accurately predicts that changes in the dynamics of the mutualism in deteriorating environments can predict that population collapse is imminent. Our results provide a general framework for how mutualisms may transition between qualitatively different regimes of interaction.

**12:27PM F35.00005 Predicting evolutionary dynamics**, GABOR BALAZSI, Laufer Center for Physical and Quantitative Biology, Stony Brook University — We developed an ordinary differential equation-based model to predict the evolutionary dynamics of yeast cells carrying a synthetic gene circuit. The predicted aspects included the speed at which the ancestral genotype disappears from the population; as well as the types of mutant alleles that establish in each environmental condition. We validated these predictions by experimental evolution. The agreement between our predictions and experimental findings suggests that cellular and population fitness landscapes can be useful to predict short-term evolution.

**12:39PM F35.00006 Complex dynamics of selection and cellular memory in adaptation to a changing environment<sup>1</sup>**, EDO KUSSELL, WEI-HSIANG LIN, New York University — We study a synthetic evolutionary system in bacteria in which an antibiotic resistance gene is controlled by a stochastic on/off switching promoter. At the population level, this system displays all the basic ingredients for evolutionary selection, including diversity, fitness differences, and heritability. At the single cell level, physiological processes can modulate the ability of selection to act. We expose the stochastic switching strains to pulses of antibiotics of different durations in periodically changing environments using microfluidics. Small populations are tracked over a large number of periods at single cell resolution, allowing the visualization and quantification of selective sweeps and counter-sweeps at the population level, as well as detailed single cell analysis. A simple model is introduced to predict long-term population growth rates from single cell measurements, and reveals unexpected aspects of population dynamics, including cellular memory that acts on a fast timescale to modulate growth rates.

<sup>1</sup>This work is supported by NIH grant no. R01-GM097356.

**12:51PM F35.00007 Exploiting temporal gradients of antibiotic concentration against the emergence of resistance**, MARIANNE BAUER, Ludwig-Maximilians-Universitt Munich, VUDTIWAT NGAMPRUETIKORN<sup>1</sup>, Okinawa Institute of Science and Technology, ERWIN FREY, Ludwig-Maximilians-Universitt Munich, GREG STEPHENS, Vrije Universiteit Amsterdam and Okinawa Institute of Science and Technology — A very simple model for antibiotic resistance - involving one normal and one more resistant species interacting indirectly through a carrying capacity - shows that the temporal variation of the antibiotic can affect the effect of the antibiotic. For a single antibiotic pulse, we find that for different minimal inhibitory concentrations of the two species an optimal pulse shape may exist, which increases the likelihood of bacterial extinction. For a long series of pulses, efficiency does not vary monotonically with the length of the gap between two individual pulses, but instead, the gap length can be optimised by exploiting the competition between the two species. Finally, a series of pulses is not always more efficient than a single pulse. Shorter pulses may be more efficient in an initial time window without risking population level resistance. We elucidate this behaviour with a phase diagram, and discuss the meaning of this work for current experiments.

<sup>1</sup>(equally contributing author)

**1:03PM F35.00008 Emergence of elevated levels of multiple infections in spatial host-virus dynamics**, BRADFORD TAYLOR, Georgia Inst of Tech, CATHERINE PENINGTON, Queensland Univ of Tech, JOSHUA WEITZ, Georgia Inst of Tech — Bacteria are subject to infection and potentially to multiple simultaneous infections by viruses. Multiply infected hosts have altered life-history traits (e.g., viral burst size) and evolutionary rates (e.g., viral recombination). Yet our understanding of multiple infections of microbes is limited to lab settings where the ratio of inoculant viruses to hosts is controlled. In contrast, rates of multiple infection in natural environments are unknown. Here, we develop an individual based model to quantify rates of multiple infections by a single viral type. We explore different dispersal regimes by varying the viral adsorption rate. High dispersal regimes lead to spatial dynamics and rates of multiple infection equivalent to predictions from mean field models. Local clustering of bacterial hosts occurs for low dispersal. Comparing to mean field, the clustering leads to increased rates of multiple infection and fatter tails in the distribution of the number of internal viruses. The emergence of increased colocalization of viruses with infected hosts leads to these deviations. We show these deviations result from the wave-like spread of viruses when invading clusters of bacteria. Our work represents a key step in understanding the population-level effects of multiple infections.

### 1:15PM F35.00009 Focusing antibody responses against distraction and loss in diversity<sup>1</sup>

SHENSHEN WANG<sup>2</sup>, MEHRAN KARDAR, ARUP CHAKRABORTY, Massachusetts Institute of Technology — Pathogens are complex and evolving fast. They have developed full ranges of disguises to divert immune responses and often manage to escape recognition and thereby outpace natural immunity. A prominent example is the scarce and staggered development of broadly neutralizing antibodies against highly mutable viruses. It remains unclear under what evolutionary conditions these exceptional antibodies could emerge and dominate the response. To address this challenge, we construct an individual-based stochastic model of the Darwinian evolution of antibody-producing immune cells. We consider complexity of viral epitopes, vary seeding diversity of the immune cell population, and allow a time varying population size and extinction – new aspects essential for designing a realistic vaccine. We show that various temporal statistics of antigenic environments would select distinct evolutionary paths that lead to predominantly non-neutralizing, strain-specific or broadly neutralizing antibody responses. We suggest strategies to focus antibody responses on the targeted vulnerability of the virus and confer selective advantage to cross-reactive lineages. This implies a new step toward an effective vaccine against rapidly mutating complex pathogens.

### 1:27PM F35.00010 Modeling the interactions between pathogenic bacteria, bacteriophage and immune response

, CHUNG YIN (JOEY) LEUNG, JOSHUA S. WEITZ, School of Biology and School of Physics, Georgia Institute of Technology — The prevalence of antibiotic-resistant strains of pathogenic bacteria has led to renewed interest in the use of bacteriophage (phage), or virus that infects bacteria, as a therapeutic agent against bacterial infections [1]. However, little is known about the theoretical mechanism by which phage therapy may work. In particular, interactions between the bacteria, the phage and the host immune response crucially influences the outcome of the therapy. Few models of phage therapy have incorporated all these three components, and existing models [2] suffer from unrealistic assumptions such as unbounded growth of the immune response. We propose a model of phage therapy with an emphasis on nonlinear feedback arising from interactions with bacteria and the immune response. Our model shows a synergistic effect between the phage and the immune response which underlies a possible mechanism for phage to catalyze the elimination of bacteria even when neither the immune response nor phage could do so alone. We study the significance of this effect for different parameters of infection and immune response, and discuss its implications for phage therapy. References: [1] C. Potera, Environ. Health Perspect. 121, A48 (2013). [2] B. R. Levin and J. J. Bull, Nature Rev. Microbiol. 2, 166 (2004).

### 1:39PM F35.00011 Modeling HIV Cure<sup>1</sup>

, ALAN PERELSON, Los Alamos National Laboratory, JESSICA CONWAY, Pennsylvania State University, YOUFANG CAO, Los Alamos National Laboratory — A large effort is being made to find a means to cure HIV infection. I will present a dynamical model of post-treatment control (PTC) or functional cure of HIV-infection. Some patients treated with suppressive antiviral therapy have been taken off of therapy and then spontaneously control HIV infection such that the amount of virus in the circulation is maintained undetectable by clinical assays for years. The model explains PTC occurring in some patients by having a parameter regime in which the model exhibits bistability, with both a low and high steady state viral load being stable. The model makes a number of predictions about how to attain the low PTC steady state. Bistability in this model depends upon the immune response becoming exhausted when over stimulated. I will also present a generalization of the model in which immunotherapy can be used to reverse immune exhaustion and compare model predictions with experiments in SIV infected macaques given immunotherapy and then taken off of antiretroviral therapy. Lastly, if time permits, I will discuss one of the hurdles to true HIV eradication, latently infected cells, and present clinical trial data and a new model addressing pharmacological means of flushing out the latent reservoir.

### 1:51PM F35.00012 The kinetics and location of intra-host HIV evolution to evade cellular immunity are predictable

, JOHN BARTON, Massachusetts Inst of Tech-MIT, NILU GOONETILLEKE, University of North Carolina, THOMAS BUTLER, Massachusetts Inst of Tech-MIT, BRUCE WALKER, Ragon Institute of MGH, MIT & Harvard, ANDREW MCMICHAEL, University of Oxford, ARUP CHAKRABORTY, Massachusetts Inst of Tech-MIT — Human immunodeficiency virus (HIV) evolves within infected persons to escape targeting and clearance by the host immune system, thereby preventing effective immune control of infection. Knowledge of the timing and pathways of escape that result in loss of control of the virus could aid in the design of effective strategies to overcome the challenge of viral diversification and immune escape. We combined methods from statistical physics and evolutionary dynamics to predict the course of *in vivo* viral sequence evolution in response to T cell-mediated immune pressure in a cohort of 17 persons with acute HIV infection. Our predictions agree well with both the location of documented escape mutations and the clinically observed time to escape. We also find that that the mutational pathways to escape depend on the viral sequence background due to epistatic interactions. The ability to predict escape pathways, and the duration over which control is maintained by specific immune responses prior to escape, could be exploited for the rational design of immunotherapeutic strategies that may enable long-term control of HIV infection.

### 2:03PM F35.00013 Outbreak and Extinction Dynamics in a Stochastic Ebola Model

, GARRETT NIEDDU, Montclair State University, SIMONE BIANCO, IBM Almaden Research Center, LORA BILLINGS, Montclair State University and National Science Foundation, ERIC FORGOSTON, Montclair State University, JAMES KAUFMAN, IBM Almaden Research Center — A zoonotic disease is a disease that can be passed between animals and humans. In many cases zoonotic diseases can persist in the animal population even if there are no infections in the human population. In this case we call the infected animal population the reservoir for the disease. Ebola virus disease (EVD) and SARS are both notable examples of such diseases. There is little work devoted to understanding stochastic disease extinction and reintroduction in the presence of a reservoir. Here we build a stochastic model for EVD and explicitly consider the presence of an animal reservoir. Using a master equation approach and a WKB ansatz, we determine the associated Hamiltonian of the system. Hamilton's equations are then used to numerically compute the 12-dimensional optimal path to extinction, which is then used to estimate mean extinction times. We also numerically investigate the behavior of the model for dynamic population size. Our results provide an improved understanding of outbreak and extinction dynamics in diseases like EVD.

**11:15AM F36.00001 The Effect of Water Molecules on Mechanical Properties of Bamboo Microfibrils<sup>1</sup>** , NIMA RAHBAR, Worcester Polytechnic Institute — Bamboo fibers have higher strength-to-weight ratios than steel and concrete. The unique properties of bamboo fibers come from their natural composite structures that comprise mainly cellulose nanofibrils in a matrix of intertwined hemicellulose and lignin called lignin-carbohydrate complex (LCC). Here, we have utilized atomistic simulations to investigate the mechanical properties and mechanisms of interactions between these materials, in the presence of water molecules. Our results suggest that hemicellulose exhibits better mechanical properties and lignin shows greater tendency to adhere to cellulose nanofibrils. Consequently, the role of hemicellulose found to be enhancing the mechanical properties and lignin found to be providing the strength of bamboo fibers. The abundance of Hbonds in hemicellulose chains is responsible for improving the mechanical behavior of LCC. The strong van der Waals forces between lignin molecules and cellulose nanofibrils is responsible for higher adhesion energy between LCC/cellulose nanofibrils. We also found out that the amorphous regions of cellulose nanofibrils is the weakest interface in bamboo Microfibrils. In presence of water, the elastic modulus of lignin increases at low water content (less than 10

<sup>1</sup>NSF CAREER grant no. 1261284

**11:27AM F36.00002 Water-Floating Giant Nanosheets from Helical Peptide Pentamers.<sup>1</sup>** , JAE-HUN LEE, KI TAE NAM, Seoul Natl Univ — One of the important challenges in the development of protein-mimetic materials is to understand the sequence specific assembly behavior and the dynamic folding change. Conventional strategies to construct two dimensional nanostructures from the peptides have been limited to beta-sheet forming sequences in use of basic building blocks because of their natural tendency to form sheet like aggregations. Here we identified a new peptide sequence, YFCFY that can form dimers by the disulfide bridge, fold into helix and assemble into macroscopic flat sheet at the air/water interface. Because of large driving force for two dimensional assembly and high elastic modulus of the resulting sheet, the peptide assembly induces the flattening of initially round water droplet. Additionally, we found that stabilization of helix by the dimerization is a key determinant for maintaining macroscopic flatness over a few tens centimeter even with a uniform thickness below 10 nm. Furthermore, the capability to transfer 2D film from water droplet to other substrates allows for the multiple stacking of 2D peptide nanostructure, suggesting possible applications in the biomimetic catalysts, biosensor and 2D related electronic devices.

**11:39AM F36.00003 DNA-linked NanoParticle Lattices with Diamond Symmetry: Stability and Shape** , HAMED EMAMY, Wesleyan University, Physics Department, ALEXEI TKACHENKO, OLEG GANG, Brookhaven National Laboratory, Center for Functional Nanomaterials, FRANCIS STARR, Wesleyan University, Physics Department — The linking of nanoparticles (NP) by DNA has been proven to be an effective means to create NP lattices with specific order. Lattices with diamond symmetry are predicted to offer novel photonic properties, but self-assembly of such lattices has proven to be challenging due to the low packing fraction, sensitivity to bond orientation, and local heterogeneity. Recently, we reported an approach to create diamond NP lattices based on the association between anisotropic particles with well-defined tetravalent DNA binding topology and isotropically functionalized NP. Here, we use molecular dynamics simulations to evaluate the Gibbs free energy of these lattices, and thereby determine the stability of these lattices as a function of NP size. The lattice free energy has a minimum for NP size near 50 nm, and rapid increases for larger NP, destabilizing the lattice. We also predict the equilibrium shape for the cubic diamond crystallite using the Wulff construction method. Specifically, we predict the equilibrium shape using the surface energy for different crystallographic planes. We evaluate surface energy directly from molecular dynamics simulation, which we correlate with theoretical estimates from the expected number of broken DNA bonds along a facet.

**11:51AM F36.00004 Multifunctional Memprocessor Device with DNA-Guided Nickel Ions Chain<sup>1</sup>** , CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, WEN-BIN JIAN, YU-CHANG CHEN, Department of Electrophysics, National Chiao Tung University, YUN-LIANG SOO, Department of Physics, National Tsing Hua University, CHIUN-JYE YUAN, Department of Biological Science and Technology, National Chiao Tung University, MASSIMILIANO DI VENTRA, Department of Physics, University of California, San Diego — Molecular metal ion wires are highly desirable for their potential applications in the field of molecular electronics. However, synthesis of a scaffold-free and long metal chain is exceptional challenging. DNA is a self-assembly wire that chelates metal ions with its base-pairs. By using DNA as template, an 830-nm equivalent conducting nickel ion chain was fabricated. This nickel ion chain device demonstrates the functionality of memristor (memory resistor), memcapacitor (memory capacitor), and redox-induced hysteresis effects. The memory state operation is attributed to the dynamic response of nickel-ion states caused by redox reaction. The redox state of Ni ions is controllable by external bias, making it a multi-state memory component for a possible memcomputer, namely a computer that uses memory to store and process information simultaneously [1]. Ref: [1] M. Di Ventra and Y.V. Pershin, Nature Physics, 9, 200 (2013).

**12:03PM F36.00005 Elastic Properties of Lysozyme Confined in Nanoporous Polymer Films** , HAOYU WANG, PINAR AKCORA, Stevens Inst of Tech — Retaining the conformational structure and bioactivity of immobilized proteins is important for biosensor designs and drug delivery systems. It is known that confined media provide a protective environment to the encapsulated proteins and prevent diffusion of the denaturant. In this study, different types of proteins (streptavidin, lysozyme and fibrinogen) were chemically attached into the nanopores of poly(methyl methacrylate) thin films. Heterogeneous flat surfaces with varying cylinder pore sizes (10-50 nm) were used to confine proteins of different sizes and shapes. Stiffness of protein functionalized nanopores was measured in nanoindentation experiments. Our results showed that streptavidin behaved more stiffly when pore dimension changed from micron to nanosize. Further, it was found that lysozyme confined within nanopores showed higher specific bioactivity than proteins on flat surfaces. These results on surface elasticity and protein activity may help in understanding protein interactions with surfaces of different topologies and chemistry.

**12:15PM F36.00006 Bioinspired Non-iridescent Structural Color from Polymer Blend Thin Films** , ASRITHA NALLAPANENI, MATTHEW SHAWKEY, ALAMGIR KARIM, Univ of Akron — Colors exhibited in biological species are either due to natural pigments, sub-micron structural variation or both. Structural colors thus exhibited can be iridescent (ID) or non-iridescent (NID) in nature. NID colors originate due to interference and coherent scattering of light with quasi-ordered micro- and nano- structures. Specifically, in Eastern Bluebird (*Sialia sialis*) these nanostructures develop as a result of phase separation of  $\beta$ -keratin from cytoplasm present in cells. We replicate these structures *via* spinodal blend phase separation of PS-PMMA thin films. Colors of films vary from ultraviolet to blue. Scattering of UV-visible light from selectively leached phase separated blends are studied in terms of varying domain spacing (200nm to 2 $\mu$ m) of film. We control these parameters by tuning annealing time and temperature. Angle-resolved spectroscopy studies suggest that the films are weakly iridescent and scattering from phase-separated films is more diffused when compared to well-mixed films. This study offers solutions to several color-based application in paints and coatings industry.

**12:27PM F36.00007 Colloidal-based additive manufacturing of bio-inspired composites**, ANDRE R STUDART, ETH Zurich — Composite materials in nature exhibit heterogeneous architectures that are tuned to fulfill the functional demands of the surrounding environment. Examples range from the cellulose-based organic structure of plants to highly mineralized collagen-based skeletal parts like bone and teeth. Because they are often utilized to combine opposing properties such as strength and low-density or stiffness and wear resistance, the heterogeneous architecture of natural materials can potentially address several of the technical limitations of artificial homogeneous composites. However, current man-made manufacturing technologies do not allow for the level of composition and fiber orientation control found in natural heterogeneous systems. In this talk, I will present two additive manufacturing technologies recently developed in our group to build composites with exquisite architectures only rivaled by structures made by living organisms in nature. Since the proposed techniques utilize colloidal suspensions as feedstock, understanding the physics underlying the stability, assembly and rheology of the printing inks is key to predict and control the architecture of manufactured parts. Our results will show that additive manufacturing routes offer a new exciting pathway for the fabrication of biologically-inspired composite materials with unprecedented architectures and functionalities.

**1:03PM F36.00008 Mesh Size Control of Friction**, ANGELA PITENIS, JUAN MANUEL URUENA, KYLE D. SCHULZE, ANDREW C. COOPER, THOMAS E. ANGELINI, W. GREGORY SAWYER, Univ of Florida - Gainesville — Soft, permeable sliding interfaces in aqueous environments are ubiquitous in nature but their ability to maintain high lubricity in a poor lubricant (water) has not been well understood. Hydrogels are excellent materials for fundamental soft matter and biotribology studies due to their high water content. While mesh size controls the material and transport properties of a hydrogel, its effects on friction were only recently explored. Polyacrylamide hydrogels slid in a Gemini (self-mated) interface produced low friction under low speeds, low pressures, macroscopic contact areas, and room temperature aqueous environments. The friction coefficients at these interfaces are lowest at low speeds and are speed-independent. This behavior is due to thermal fluctuations at the interface separating the surfaces, with water shearing in this region being the main source of dissipation. We found that mesh size had an inverse correlation with friction. We further investigated a transition from this behavior at higher speeds, and found that the transition speed correlated with the mesh size and relaxation time of the polymer network. Very soft and correspondingly large mesh size Gemini hydrogels show superlubricity under specific conditions with friction being less than 0.005.

**Session F37 GSOF: Clustering and Gelation with Competing Interactions I** 340 - Emanuela Del Gado, Georgetown University

**11:15AM F37.00001 Inverse design of voids: clusters of nothing**, BETH LINDQUIST, RYAN JADRIC, THOMAS TRUSKETT, University of Texas at Austin — Much work has been done to find and characterize potentials (both pair and many-body) that result in interesting fluid architectures, particularly with respect to clustered fluids. In this work, we inverse design a pair potential possessing competitive attractions and repulsions that forms voids/clusters of empty space. We show that these voids are relatively spherical and reasonably monodisperse in size. We study the behavior of this potential with respect to modulating system density and temperature and we find that, like clusters of particles, these voids are capable of self-assembling into columns, lamellar sheets, as well as a bicontinuous structure. Moreover, we find that this potential can form both clusters and voids, depending on the state point, demonstrating a correspondence between the competitive interactions that are suitable to form these two structural motifs.

**11:27AM F37.00002 Inverse Design of Equilibrium Cluster Fluids**, RYAN JADRIC, JONATHAN BOLLINGER, BETH LINDQUIST, THOMAS TRUSKETT, University of Texas at Austin — Equilibrium cluster fluids have garnered much recent attention, but the types of interparticle forces that can lead to self-assembly of such entities have not been systematically explored. As a step towards addressing this, we leverage powerful inverse design tools to fabricate a fluid of monodisperse, spherical, liquid-droplet-like clusters of a desired size and good center of mass mobility. The inverse designed pair potential possesses a broad attractive well and narrow repulsive barrier at larger separations a qualitatively different form as compared to the so-called SALR potential [short-range attractive (SA) and long-range repulsive (LR)] often associated with equilibrium cluster formation in colloids. Such differences suggest alternative mechanisms for cluster formation leading to structured fluids with qualitatively different static and dynamic properties. Lastly, we explore the representability of our inverse designed potentials through simple parametrized forms.

**11:39AM F37.00003 Decoding the pair correlations and properties of equilibrium microscopic cluster phases**, JONATHAN BOLLINGER, RYAN JADRIC, THOMAS TRUSKETT, University of Texas at Austin — Due to competing interactions acting between particles, dispersed colloidal suspensions can reversibly transition to phases comprising aggregate clusters. Cluster phases have been reported for both model colloidal particles and complex monomers (e.g., proteins); however, many questions remain regarding how to detect and characterize cluster phases given only pair structural correlations (the information most accessible across diverse systems) and how to relate clustering susceptibility and behavior to underlying monomer-monomer interactions. Using molecular simulations and liquid-state theory across a wide survey of conditions, we decode the widely-observed intermediate range order pre-peak in the structure factor by: (1) validating a physically-intuitive rule for detecting clustering based on the pre-peak thermal correlation length; and (2) relating pre-peak position to cluster size and bulk monomer density. We further demonstrate how clustering transitions and resultant properties relate to monomer interactions along coordinates tunable in experiments. These trends are suitable for comparing against clustering systems that can be directly visualized (via, e.g., confocal microscopy), which should aid in assessing the realism of commonly-adopted monomer interaction potentials.

**11:51AM F37.00004 Multiscale modeling of the thixotropic behavior of aggregating soft colloidal particle suspensions<sup>1</sup>**, PAUL MWASAME, NORMAN WAGNER, ANTONY BERIS, University of Delaware — A multiscale model is presented that incorporates microscopic information at the soft, aggregating, colloidal particle level to a macroscopic description of a thixotropic suspension with a yield stress. This is accomplished by incorporating the relevant physics describing aggregation and breakage at the particle level into a population balance microscopic framework. A moment approach is followed to allow for model coarsening and its incorporation into a macroscopic description. Furthermore, to describe the aggregate dynamics under flow, it is necessary to include an additional description of the aggregate deformation. The yielding behavior of gel networks observed in thixotropic suspensions is modeled by adapting micromechanical models of emulsions and pastes to describe aggregate deformation under flow. A key outcome of this work is the recognition of the important role of competition between orthokinetic and perikinetic aggregation on polydispersity and dynamical behavior. Comparison to rheological experiments on a model thixotropic suspension will also be presented to validate the model developed.

**12:03PM F37.00005 Elasto-hydrodynamic network analysis of colloidal gels**, JAMES SWAN, ZSIGMOND VARGA, Massachusetts Inst of Tech-MIT — Colloidal gels formed at low particle volume fractions result from a competition between two rate processes: aggregation of colloids and compaction of pre-gel aggregates. Recent work has shown that the former process is highly sensitive to the nature of the hydrodynamic interactions between suspended colloids. This same sensitivity to hydrodynamic flows within the gel leads to pronounced differences in the spectrum of relaxation times and response to deformation of the gel. This talk explores those differences and their consequences through computational simulations and the framework of elasto-hydrodynamic network analysis. We demonstrate a significant impact of hydrodynamic interactions between gelled colloids on macroscopic gel dynamics and rheology as well as the effect of hydrodynamic screening in gelled materials.

**12:15PM F37.00006 Shape mismatch in self assembly leads to fiber-like aggregates<sup>1</sup>**, MARTIN LENZ, CNRS - Orsay, EFRIM EFRATI, Weizmann Institute of Science, THOMAS A. WITTEN, University of Chicago — Aggregating proteins tend to form fibers, often for the worse - think of Alzheimer's disease. Could this propensity to form fibers be a generic physical property of irregular aggregating objects, rather than something specific to protein chemistry? We investigate the aggregation of simple ill-fitting, deformable objects and find that geometrical frustration can lead to self-assembly into slender aggregates.

**12:27PM F37.00007 Gelation And Mechanical Response of Patchy Rods.<sup>1</sup>**, NAVID KAZEM, Carnegie Mellon Univ, CARMEL MAJIDI, Carnegie Mellon University, CRAIG MALONEY, Northeastern University — We perform Brownian Dynamics simulations to study the gelation of suspensions of attractive, rod-like particles. We show that details of the particle-particle interactions can dramatically affect the dynamics of gelation and the structure and mechanics of the networks that form. If the attraction between the rods is perfectly smooth along their length, they will collapse into compact bundles. If the attraction is sufficiently corrugated or patchy, over time, a rigid space spanning network forms. We study the structure and mechanical properties of the networks that form as a function of the fraction of the surface that is allowed to bind. Surprisingly, the structural and mechanical properties are non-monotonic in the surface coverage. At low coverage, there are not a sufficient number of cross-linking sites to form networks. At high coverage, rods bundle and form disconnected clusters. At intermediate coverage, robust networks form. The elastic modulus and yield stress are both non-monotonic in the surface coverage. The stiffest and strongest networks show an essentially homogeneous deformation under strain with rods re-orienting along the extensional axis. Weaker, clumpy networks at high surface coverage exhibit relatively little re-orienting with strong non-affine deformation. These results suggest design strategies for tailoring surface interactions between rods to yield rigid networks with optimal properties.

**12:39PM F37.00008 Protein gelation kinetics near the overlap concentration**, PASHA TABATABAI, Georgetown University, BENJAMIN PARTLOW, DAVID KAPLAN, Tufts University, DANIEL BLAIR, Georgetown University — Proteins can be crosslinked to form gel networks either as a tool to study biological problems or as a method for creating novel materials. The bulk mechanical properties of protein gels in steady state are a manifestation of the gel structure, but the polymerization kinetics are often disregarded. Using the gelation of an aqueous denatured silk protein solution as a model polymer system, we probe the gelation kinetics (modulus vs. time) and find two regimes that depend on whether the initial protein concentration ( $c$ ) is near or below the overlap concentration ( $c^*$ ). We find that systems with  $c/c^* \sim 1$  exhibit immediate and single-mode modulus growth until the completion of polymerization that can be scaled onto a characteristic polymerization curve. However, systems with  $c/c^* < 1$  display delayed modulus development followed by two-stage modulus growth that can be normalized onto a separate distinctive polymerization curve. These two regimes are probed by changing both the initial concentration and the overlap concentration separately, emphasizing the importance of the overlap concentration on the assembly of polymeric/complex fluids.

**12:51PM F37.00009 Coupled diffusion processes and 2D affinities of adhesion molecules at synthetic membrane junctions**, CHRISTOPHER PEEL, University of Oxford, KAUSHIK CHOUDHURI, University of Michigan Medical School, EVA M. SCHMID, MATTHEW H. BAKALAR, HYOUNG SOOK ANN, DANIEL A. FLETCHER, University of California, Berkeley, CELINE JOURNOT, ANDREW TURBERFIELD, MARK WALLACE, MICHAEL DUSTIN, University of Oxford — A more complete understanding of the physically intrinsic mechanisms underlying protein mobility at cellular interfaces will provide additional insights into processes driving adhesion and organization in signalling junctions such as the immunological synapse. We observed diffusional slowing of structurally diverse binding proteins at synthetic interfaces formed by giant unilamellar vesicles (GUVs) on supported lipid bilayers (SLBs) that shows size dependence not accounted for by existing models. To model the effects of size and intermembrane spacing on interfacial reaction-diffusion processes, we describe a multistate diffusion model incorporating entropic effects of constrained binding. This can be merged with hydrodynamic theories of receptor-ligand diffusion and coupling to thermal membrane roughness. A novel synthetic membrane adhesion assay based on reversible and irreversible DNA-mediated interactions between GUVs and SLBs is used to precisely vary length, affinity, and flexibility, and also provides a platform to examine these effects on the dynamics of processes such as size-based segregation of binding and non-binding species.

**1:03PM F37.00010 Enhanced gel formation in binary mixtures of nanocolloids with tunable short-range attraction**, R. LEHENY, Johns Hopkins University, H. GUO, NIST, M. BERTRAND, University of Ottawa, T. SHENDRUK, University of Oxford, S. RAMAKRISHNAN, Florida State University, J. HARDEN, University of Ottawa — We report a combined experimental, theoretical, and simulation study of the phase behavior and microstructural dynamics of concentrated binary mixtures of spherical nanocolloids with a size ratio near two and with a tunable, intrinsic short-range attraction. In the absence of the attraction, the suspensions behave as well mixed, hard-sphere liquids. For sufficiently strong attraction, the suspensions undergo a gel transition. Rheometry measurements show that the fluid-gel boundary of the mixtures does not follow an ideal mixing law, but rather the gel state is stable at weaker interparticle attraction in the mixtures than in the corresponding monodisperse suspensions. X-ray photon correlation spectroscopy measurements reveal that, in contrast with depletion-driven gelation at larger size ratio, gel formation in the mixtures coincides with dynamic arrest of the smaller colloids while the larger colloids remain mobile. Molecular dynamics simulations indicate the arrest results from microphase separation that is caused by a subtle interplay of entropic and enthalpic effects and that drives the smaller particles to form dense regions.

**1:15PM F37.00011 Gelation of calcium-silicate-hydrate in cement**, KATERINA IOANNIDOU, MSE2, joint MIT-CNRS lab, MIT, Cambridge, MA 02139, US, MATEJ KANDUC, Department of Physics, Free University Berlin, D-14195 Berlin, Germany, LUNNA LI, DAAN FRENKEL, Department of Chemistry, University of Cambridge, Cambridge, UK, JURE DOBNIKAR, IRCSM, Beijing University of Chemical Technology, Beijing, P. R. China, ROLAND PELLENG, MSE2, joint MIT-CNRS lab, MIT, Cambridge, MA 02139, US, EMANUELA DEL GADO, Department of Physics and Institute for Soft Matter Synthesis and Metrology, Georgetown University, Washington, DC 20057, US — The calcium-silicate-hydrate (C-S-H) gel forms and densifies via precipitation and aggregation of nano-scale hydrates within a couple of hours during cement hydration and it is the main responsible for cement strength. We have investigated equilibrium and arrested states representative of the effective interactions between the nano-scale C-S-H at different stages of the hydration. The inter-hydrate interactions are due to ion correlation forces arising from strong surface charge heterogeneities and change from repulsive to strongly attractive during the early stages of cement hydration, according to the ionic concentration. We analyze the cluster size distributions, the morphology, the local packing and the free energy of aggregates and crystalline phases, using molecular dynamics and Monte Carlo simulations. We compare the results of equilibrium calculations with non-equilibrium simulations that capture the main features of the hydration kinetics. The emerging picture is that the evolving effective interactions provide a thermodynamic driving for the growth of the gel and for its continuous densification that is crucial to cement strength.

**1:27PM F37.00012 Effects on gelation transition by tuning the interaction of solvent-solute molecules in a bridging system<sup>1</sup>**, GUANGCUI YUAN, NIST - Natl Inst of Stds & Tech, JUNHUA LUO, CHARLES C. HAN, Institute of Chemistry CAS, YUN LIU, University of Delaware — A mixed suspension of large hard spheres and small soft microgels with well-defined bridging interaction is used to construct a new short-range attractive system. Soft poly (N-isopropylacrylamide) microgels ( $R = 80$  nm) are absorbable to the surface of hard polystyrene spheres ( $R = 960$  nm) in aqueous solution. For a constant volume fraction of hard spheres ( $\Phi_{MS}$ ), gradually increasing amount of microgels ( $\Phi_{MG}$ ) leads to a liquid-gel-liquid transitions through bridging and steric stabilized mechanisms. Rheological measurements were performed on suspensions with  $\Phi_{MS}$  ranging up to 0.35 to carefully identify the transition boundaries between liquid-like and solid-like behaviors triggered by  $\Phi_{MG}$ . Meanwhile, neutron scattering technique with Baxter's sticky hard-sphere potential fit was used to investigate the effective interparticle potential at and around the gelation boundaries. By exhibiting a set of experimental results from this explicit model system and comparing with the theoretical data, we try to clarify a debate issue about the relative position of the gel line and the liquid-gas coexistence line in the potential  $U - \Phi$  plane.

**1:39PM F37.00013 Gelation of anisotropic silica colloids with thermoreversible short-range interactions**, RYAN MURPHY, NORMAN WAGNER, University of Delaware — Colloidal suspensions containing anisotropic particles are widely used in particle-based technologies including pharmaceuticals, consumer products, and coatings. The rheological properties of colloidal suspensions are known to be affected by particle shape; however, the combined influence of particle shape and attraction strength is not quantitatively understood for dynamic arrest transitions such as gelation. A model system of anisotropic silica colloids with thermoreversible, short-range attractions was developed to quantify the effect of particle shape and attractions on the gelation behavior. This tunable model system aims to map a fundamental state diagram for anisotropic particle suspensions as a function of particle shape, volume fraction, and interaction strength. Macroscopic rheological properties of thermoreversible gels were explored to determine the influence of particle shape on the gel transition. Neutron and x-ray scattering methods further probed the underlying fluid and gel microstructure at various temperatures, volume fractions, and aspect ratios. Linking these fundamental macroscopic and microscopic measurements will provide practical insight into particle technologies and manufacturing processes containing anisotropic colloidal suspensions.

**1:51PM F37.00014 Colloidal interactions: bridging the gap from atomistic-scale descriptions to the mesoscale Primitive Model and introducing the Explicit Solvent Primitive Model approach**, ROLAND PELLENQ, CNRS/MIT, jMSE<sub>2</sub>, MIT, 77 Massachusetts Avenue, Cambridge, US, BENOIT CARRIER, MATTHIEU VANDAMME, Laboratoire Navier (ENPC/IFSTTAR/CNRS), Marne-la-Vallée, France, HENRI VAN DAMME, CNRS/MIT, jMSE<sub>2</sub>, MIT, 77 Massachusetts Avenue, Cambridge, US, CNRS/MIT, jMSE<sub>2</sub> TEAM, LABORATOIRE NAVIER TEAM — We investigated the interactions responsible for the cohesion of colloidal materials such as clays, cement... The swelling/cohesive properties of these (lamellar) materials depend both on the nature of the (interlayer) cations and on the surface charge of the layers. The overall goal of this work is determining the right level of modelling complexity required to capture the cohesive behaviour of charged materials immersed in an electrolyte. In addition to the analytical mean-field DLVO theory, we used various numerical modelling approaches of increasing complexity from the so-called Primitive Model to full-atomistic description. In particular, we introduced the Explicit Solvent Primitive Model (ESPM), in which ions are modelled as charged hard spheres and solvent molecules as soft spheres with embedded point dipoles. We showed that taking explicitly into account the solvent in such a Primitive Model description, significantly impacts the cohesion. Ionic correlation interactions are always present between charged objects immersed in an electrolyte and always play an important role, even in the case of system carrying a low surface charge balanced by monovalent counter-ions.

**2:03PM F37.00015 Coupling of gelation and glass transition in a biphasic colloidal mixture—from gel-to-defective gel-to-glass<sup>1</sup>**, HE CHENG, DI JIA, CHARLES HAN, Chinese Academy of Sci (CAS) — The state transition from gel to glass is studied in a biphasic mixture of polystyrene core/poly (N-isopropylacrylamide) shell (CS) microgels and sulfonated polystyrene (PSS) particles. At 35 °C, the interaction between CS is due to short-range Van der Waals attraction while that between PSS is from long-range electrostatic repulsion. During variation of the relative ratio of the two species at a fixed apparent total volume fraction, the mixture exhibits a gel-to-defective gel-to-glass transition. When small amounts of PSS are introduced into the CS gel network, some of them are kinetically trapped, causing a change in its fractal structure, and act as defects to weaken the macroscopic gel strength. An increase of PSS content in the mixture promotes the switch from gel to defective gel, *e.g.*, the typical two-step yielding gel merges into one-step yielding. This phenomenon is an indication that inter-cluster bond breakage coincides with intra-cluster bond fracture. As the relative volume fraction of PSS exceeds a critical threshold, the gel network can no longer be formed; hence, the mixture exhibits characteristics of glass. A state diagram of the biphasic mixture is constructed, and the landscape of the different transitions will be described in future studies

**Tuesday, March 15, 2016 11:15AM - 1:15PM —**

**Session F38 DPOLY: Padden Award Symposium 341 - Wesley Burghardt, Northwestern University**

**11:15AM F38.00001 Dispersion-Aggregation and Wetting-Dewetting Phase Transitions in Mixtures of Polymer Grafted Nanoparticles and a Chemically Dissimilar Polymer Matrix**, TYLER MARTIN, U Colorado, KATRINA MONGCOPA, U Houston, RANA ASHKAR, PAUL BUTLER, NIST, RAMANAN KRISHNAMOORTI, U Houston, ARTHI JAYARAMAN, U Delaware — Significant efforts have been focused towards controlling morphology of the nanoscale fillers and matrix polymer in polymer nanocomposites as the composite morphology is directly related to the macroscopic properties of that material. For nanocomposites with chemically identical graft and matrix polymers, it is well understood that the polymer grafted particle dispersion to aggregation transition is directly linked to and synonymous with wetting/dewetting of the graft and matrix polymer. Our recent work has focused on exploring composites with chemically different graft and matrix polymers, specifically those with attractive graft-matrix interactions that lead to a dispersed filler state at low temperature and aggregated filler state at high temperatures. We show, using coarse-grained molecular simulations, that the sharp phase transition from dispersed to aggregated states is distinct from the continuous wetting-dewetting transition. The onset of wetting to dewetting occurs at temperatures lower than the dispersion to aggregation transition, and dewetting continues at temperatures above the transition temperature in the aggregated state. Furthermore, the graft and matrix chain composition can be varied to tune the dispersion-aggregation transition temperature and the degree of wetting of the grafted layer. Experiments using SANS and SAXS of deuterated poly(styrene) grafted silica particles in a poly(vinyl methyl ether) matrix show remarkable agreement with our simulations.

**11:27AM F38.00002 Dynamics of associating networks**, SHENGCHANG TANG, Massachusetts Institute of Technology, AXEL HABICHT, Freie Universitt Berlin, MUZHOU WANG, SHUAILI LI, Massachusetts Institute of Technology, SEBASTIAN SEIFFERT, Freie Universitt Berlin, BRADLEY OLSEN, Massachusetts Institute of Technology — Associating polymers offer important technological solutions to renewable and self-healing materials, conducting electrolytes for energy storage and transport, and vehicles for cell and protein deliveries. The interplay between polymer topologies and association chemistries warrants new interesting physics from associating networks, yet poses significant challenges to study these systems over a wide range of time and length scales. In a series of studies, we explored self-diffusion mechanisms of associating polymers above the percolation threshold, by combining experimental measurements using forced Rayleigh scattering and analytical insights from a two-state model. Despite the differences in molecular structures, a universal super-diffusion phenomenon is observed when diffusion of molecular species is hindered by dissociation kinetics. The molecular dissociation rate can be used to renormalize shear rheology data, which yields an unprecedented time-temperature-concentration superposition. The obtained shear rheology master curves provide experimental evidence of the relaxation hierarchy in associating networks.

**11:39AM F38.00003 Tuning the Assembly of Spherical Nanoparticles in Semicrystalline Polymers**, DAN ZHAO, Columbia Univ, JACQUES JESTIN, Laboratoire Lon Brillouin, CEA Saclay, LONGXI ZHAO, SANAT K. KUMAR, Columbia Univ, MOHAMMAD MOHAMMADKHANI, BRIAN C. BENICEWICZ, University of South Carolina — We propose a simple, novel strategy to controlling nanoparticle (NPs) dispersion states in a semi-crystalline polymer matrix exploiting the kinetics of polymer crystallization. The system consists of poly(methyl methacrylate) grafted spherical silica NPs and poly(ethylene oxide) matrices, which are thermodynamically miscible in the melt. We first show that no remarkable change was observed in the spatial dispersion of NPs upon fast crystallization. However, for slow crystallization, both TEM and X-ray/neutron scattering reveal that the system starts to be organized in a “layer-by-layer” architecture, where the NPs are aligned in the amorphous phases intercalated by the crystalline lamellar phases. More importantly, we have found that the resulting “sheet-like” NP morphology gives rise to a 2-fold increase in the storage modulus but without compromising the fracture toughness of the neat polymer. These results open pathways for creating in-situ biomimetic hierarchical structures with improved mechanical properties through a simple, single-step crystallization processing, which could lead to new applications for this largest class of commercially relevant polymeric materials.

**11:51AM F38.00004 Direct measurement of the critical pore size in a polymer membrane**, MARK ILTON, CHRISTIAN DIMARIA, KARI DALNOKI-VERESS, Department of Physics & Astronomy, McMaster University, Hamilton, Ontario, Canada, L8S 4M1 — The formation of pores is an important process in cellular membranes. Here we use freestanding polymer films as model membranes to study the stability of nucleated pores. Polymer membranes with pores of varying size are patterned using a lithographic technique. The membranes are heated above their glass transition temperature to allow viscous flow to occur. Pores with a radius larger than a critical value grow, while pores smaller than the critical radius are observed to shrink and eventually close. Remarkably, holes that are close enough to the critical radius neither grow nor shrink, even though the film is in the melt state. A simple model which takes into account the energy cost of having additional surface area at the edge of a pore describes the experiments with no free parameters. Biological membranes have an additional energetic cost of forming a pore, which we mimic using a lamellar-forming diblock copolymer. Indeed, we find that the critical pore radius is increased when pore formation is frustrated by molecular architecture.

**12:03PM F38.00005 Pinpointing the onset of mechanical rejuvenation in a polymer glass by monitoring segmental dynamics before and after a constant strain rate pulse<sup>1</sup>**, KELLY HEBERT, JOSH RICCI, KELLY SURALIK, M.D. EDIGER, Univ of Wisconsin, Madison — Over time, dynamics in polymer glasses become slower through physical aging; it is thought that post-yield mechanical deformation may reverse the effects of physical aging in what has been termed “rejuvenation”. We have monitored segmental dynamics in a poly(methyl methacrylate) glass before and after reversing constant strain rate pulses of varying magnitude to explore the onset of mechanical rejuvenation. We find that the segmental dynamics in the glass is unperturbed after pulses to  $\varepsilon/\varepsilon_{\text{yield}} = 0.6$  or less. For pre-yield pulses of higher magnitude, we find evidence of rejuvenation, which is indicated by faster dynamics after the pulse. We find that full rejuvenation only occurs at a strain of  $\varepsilon/\varepsilon_{\text{yield}} = 3$  or higher. This work is qualitatively consistent with recent simulations of Smessaert and Rottler and additionally shows quantitative agreement with predictions from the theory of Chen and Schweizer. However, in spite of observed enhanced dynamics on a molecular level, we find that large pre-yield pulses do not alter the mechanical response of the polymer during subsequent deformation. We explore the apparent contradiction between the macroscopic mechanical and molecular-level dynamical response of the glass to deformation.

<sup>1</sup>We are thankful for funding from NSF-DMR (1404614)

**12:15PM F38.00006 High resolution imaging of the dynamics of nanoparticles in/on liquids**, PAUL KIM, ALEXANDER RIBBE, THOMAS RUSSELL, DAVID HOAGLAND, Univ of Mass - Amherst — Electron microscopy for the study of nanoscale structure and dynamics in solvated soft materials has only recently been proposed, and since this technique requires high vacuum, significant challenges must be confronted. Specimens can be encapsulated in vacuum-sealed devices for TEM but this approach is not without difficulties, including beam damage, cumbersome specimen handling, and propensity for wall artifacts. Here, we report an alternative SEM approach, obviating need for a liquid cell by exploiting the nonvolatility of ionic liquids, which is illustrated by visualizations of nanoscale dynamics for two solvated systems, dispersed nanospheres and nanorods in/on thin, free-standing IL films. The translational and rotational Brownian of these nanoparticles were quantitatively tracked. In ultra-thin films, a striking and unanticipated dynamical pairing of the nanospheres was observed, manifesting a balance of capillary and hydrodynamic interactions. Concentrated nanorods were seen to assemble into finite stacks that could be tracked over their entire lifetimes. Broadly applicable to solvated soft nanoscopic materials, the new imaging protocol offers a breakthrough in the study of their structure and dynamics.

**12:27PM F38.00007 Predicting Thermomechanical Responses of Polymer Thin Films and Nanocomposites via an Innovative Coarse-grained Approach**, WENJIE XIA, DAVID HSU, SINAN KETEN, Northwestern University — Understanding and predicting the thermomechanical responses of nanoscale polymer systems are very challenging as their responses are greatly influenced by many factors, such as interfacial energy, filler volume fraction and molecule weight, giving rise to the presence of nanoscale interface and free surface. To overcome these issues, here we employ a novel atomistically informed coarse-grained computational technique, called thermomechanically consistent coarse graining (TCCG), to investigate how the nanoscale interface and free surface influence the elastic modulus (E) and glass transition temperature (T<sub>g</sub>) of polymer films and nanocomposites. By performing tensile tests and nanoindentation simulations, we are able to predict the size dependent elastic properties of polymer films and quantify the length scale of the local mechanical interphase. Finally, taking cellulose nanocrystal (CNC) and poly(methyl-methacrylate) (PMMA) nanocomposites as a relevant model system, we present a multi-scale framework built upon our CG approach to allow the prediction of T<sub>g</sub> of nanocomposite as a function of interfacial energy and filler volume fractions by drawing the analogy between thin film and nanocomposites. Our established multi-scale framework is validated by recent experiments and breaks new ground in predicting, without any empirical parameters, key structure-property relationships for polymer nanomaterials.

**12:39PM F38.00008 Nanoparticle Order through Entropic Confinement**, REN ZHANG, Univ of Akron, BONGJOON LEE, Carnegie Mellon University, CHRISTOPHER STAFFORD, JACK DOUGLAS, NIST, MICHAEL BOCKSTALLER, Carnegie Mellon University, ALAMGIR KARIM, Univ of Akron — As has been addressed in colloidal science, visual order transitions can be achieved with entropy contributions alone. Herein, entropy-driven ordering of nanoparticle (NP) structures is generated where entropy increase and visual order are achieved simultaneously. We study an "athermal" NP-polymer blends where NPs are densely grafted with polymer brush of the same chemical composition as the polymer matrix. Visual order of the NPs is induced by geometrically confining the thin film blends with meso-scale topographic patterns. When the residual layer thickness of the patterned blend films approaches the nanoparticle dimension, exclusive segregation of NPs to less confining imprinted mesa region occurs. This preferential segregation of NPs, defined by partition coefficient  $K = 0$ , is attributed to purely entropic penalty, where  $K$  denotes the particle density ratio at highly confined residual layer to that at mesa region. We further demonstrate  $K$  is fully tunable and even invertible with increasing matrix chain dimension. The associated entropic free energy change ( $\Delta F = -\ln K$ ) is calculated to explain NP segregation preference. Accordingly, variation of residual layer thickness and polymer matrix molecule size can both affect NP distribution among patterned thick and thin regions.

**12:51PM F38.00009 Design of Bicontinuous Donor/Acceptor Morphologies for Use as Organic Solar Cell Active Layers**, DYLAN KIPP, Univ of Texas, Austin, JORGE MOK, RAFAEL VERDUZCO, Rice Univ, VENKAT GANESAN, Univ of Texas, Austin — Two of the primary challenges limiting the marketability of organic solar cells are i) the smaller device efficiency of the organic solar cell relative to the conventional silicon-based solar cell and ii) the long term thermal instability of the device active layer. The achievement of *equilibrium* donor/acceptor morphologies with the characteristics believed to yield high device performance characteristics could address each of these two challenges. In this work, we present the results of a combined simulations and experiments-based approach to investigate if a conjugated BCP additive can be used to control the self-assembled morphologies taken on by conjugated polymer/PCBM mixtures. First, we use single chain in mean field Monte Carlo simulations to identify regions within the conjugated polymer/PCBM composition space in which addition of copolymers can lead to bicontinuous equilibrium morphologies with high interfacial areas and nanoscale dimensions. Second, we conduct experiments as directed by the simulations to achieve such morphologies in the PTB7 + PTB7-*b*-PNDI + PCBM model blend. We characterize the results of our experiments via a combination of transmission electron microscopy and X-ray scattering techniques and demonstrate that the morphologies from experiments agree with those predicted in simulations. Accordingly, these results indicate that the approach utilized represents a promising approach to intelligently design the morphologies taken on by organic solar cell active layers.

**1:03PM F38.00010 Predicting the Phase Behavior of Polymer Nanocomposites using Field-Based Simulations<sup>1</sup>**, JASON KOSKI, ROBERT RIGGLEMAN, University of Pennsylvania — Polymer nanocomposites (PNCs) have been shown to improve mechanical, electric, and optical properties, which are not achievable with polymers or nanoparticles alone. The parameter space associated with PNCs is vast and having efficient tools to study and characterize PNCs is critical to understand parameter-structure-property relationships. In recent years, we have extended the powerful polymer field theory framework to capture particle correlations and allow for efficient characterization of PNCs. We have made numerous strides in extending the class of PNC systems that are able to be studied with polymer field theory; namely, nanospheres, nanorods, complex grafted particles, and liquid crystals. In this talk, I provide details in developing this framework and illustrate its potential by demonstrating its applicability to bulk polymer nanocomposite systems where we can relax the mean-field approximation, study systems with several nanoparticles, and systems that can macro- or microphase separate (e.g. polymer blends or block copolymers). I will also discuss recent advances we have made in incorporating dynamics into our framework which has exciting implications in understanding the phase behavior of PNCs.

**Session F39 DBIO GSOFT: Cell Motility: From Single Cell to Collective Dynamics II** 342 - Jay Tang, Brown University

**11:15AM F39.00001 Effects of physical factors on the swarming motility of text itPseudomonas aeruginosa**, TIEYAN SI, Harbin Institute of Technology, ZIDONG MA, Brown University, WAI SHING TANG, Chinese University of Hong Kong, ALEXANDER YANG, JAY TANG, Brown University — Many species of bacteria can spread over a semi-solid surface via a particular form of collective motion known as surface swarming. Using *Pseudomonas aeruginosa* as a model organism, we investigate physical factors that either facilitate or restrict the swarming motility. The semi-solid surface is typically formed by 0.5-1% agar containing essential nutrients for the bacterial growth and proliferation. Most bacterial species, including *P. aeruginosa*, synthesize bio-surfactants to aid in swarming. We found addition of exogenous surfactants such as triton into the agar matrix enhances the swarming. In contrast, increasing agar percentage, infusing osmolytes, and adding viscous agents all decrease swarming. We propose that the swarming speed is restricted by the rate of water supply from within the agar gel and by the line tension at the swarm front involving three materials in contact: the air, the bacteria propelled liquid film, and the agar substrate.

**11:27AM F39.00002 Quantifying Spatiotemporal Patterns in the Advancing Front of Twitching Bacterial Colonies**, ERIN SHELTON, MAX GIULIANI, University of Guelph, LORI BURROWS, McMaster University, JOHN DUTCHER, University of Guelph — Type IV pili (T4P) are very thin (5-8 nm in diameter) protein filaments that can be extended and retracted by certain classes of Gram-negative bacteria including *P. aeruginosa* [1]. These bacteria use T4P to move across viscous interfaces, referred to twitching motility. Twitching can occur for isolated cells or in a collective manner [2]. Using a custom-built, temperature and humidity controlled environmental chamber, together with particle image velocimetry and Fourier analysis techniques, we characterized the evolution of the advancing front of expanding colonies. We find that the advancing front consists of finger-like protrusions consisting of many bacteria, with the cells within the expanding colony arranged in a lattice-like pattern. We have characterized the average speed, width and bacterial orientation within the fingers as a function of agar concentration/stiffness. In addition, we have analyzed the motion of individual cells within the fingers at high spatial and temporal resolution. [1] Burrows, L.L. (2012) Annu. Rev. Microbiol. 66: 493520. [2] Semmler, A.B., Whitchurch, C.B., Mattick, J.S. (1999) Microbiology 145: 2863-2873.

**11:39AM F39.00003 Pattern formation in Dictyostelium discoideum aggregates in confined microenvironments<sup>1</sup>**, ADRIEN HALLOU, Department of Engineering, Bioengineering Group, University of Cambridge, Cambridge, UK, PASCAL HERSEN, JEAN-MARC DI MEGLIO, Laboratoire Matière et Systèmes Complexes, UMR CNRS 7057 & Université Paris Diderot, Paris, France, ALEXANDRE KABLA, Department of Engineering, Bioengineering Group, University of Cambridge, Cambridge, UK — Dictyostelium Discoideum (Dd) is often viewed as a model system to study the complex collective cell behaviours which shape an embryo. Under starvation, Dd cells form multicellular aggregates which soon elongate, starting to display an anterior-posterior axis by differentiating into two distinct cell populations; prestalk (front) and prespore (rear) cells zones. Different models, either based on positional information or on differentiation followed up by cell sorting, have been proposed to explain the origin and the regulation of this spatial pattern.

To decipher between the proposed hypotheses, we have developed an experimental platform where aggregates, made of genetically engineered Dd cells to express fluorescent reporters of cell differentiation in either prestalk or prespore cells, are allowed to develop in 20 to 400  $\mu\text{m}$  wide hydrogel channels. Such a setup allows us to both mimic Dd confined natural soil environment and to follow the patterning dynamics using time-lapse microscopy. Tracking cell lineage commitments and positions in space and time, we demonstrate that Dd cells differentiate first into prestalk and prespore cells prior to sorting into an organized spatial pattern on the basis of collective motions based on differential motility and adhesion mechanisms.

<sup>1</sup>A. Hallou would like to thank the University of Cambridge for the award of an "Oliver Gatty Studentship in Biophysical and Colloid Science".

**11:51AM F39.00004 Evolutionary aspects of collective motility in pathogenic bacteria.**, MAXIME DEFORET, JOAO XAVIER, Memorial Sloan-Kettering Cancer Center — Pseudomonas aeruginosa is a pathogenic bacteria that can use its single polar flagellum to swim through liquids. It can move collectively over semisolid surfaces, a behavior called swarming. It can also settle and form surface-attached communities called biofilms that protect them from antibiotics. The transition from single motility (swimming) to collective motility (swarming) is biologically relevant as it enables exploring environments that a single bacterium cannot explore on its own. It is also clinically relevant since swarming and biofilm formation are thought to be antagonistic. We investigate the mechanisms of bacterial collective motility using a multidisciplinary approach that combines mathematical modeling, quantitative experiments, and microbial genetics. We aim to identify how these mechanisms may evolve under the selective pressure of population expansion, and consequently reinforce or hinder collective motility. In particular, we clarify the role of growth rate and motility in invasive populations.

**12:27PM F39.00005 Self-organized, near-critical behavior during aggregation in Dictyostelium discoideum**, GIOVANNA DE PALO, Imperial College London, DARVIN YI, THOMAS GREGOR, Princeton University, ROBERT ENDRES, Imperial College London — During starvation, the social amoeba Dictyostelium discoideum aggregates artfully via pattern formation into a multicellular slug and finally spores. The aggregation process is mediated by the secretion and sensing of cyclic adenosine monophosphate, leading to the synchronized movement of cells. The whole process is a remarkable example of collective behavior, spontaneously emerging from single-cell chemotaxis. Despite this phenomenon being broadly studied, a precise characterization of the transition from single cells to multicellularity has been elusive. Here, using fluorescence imaging data of thousands of cells, we investigate the role of cell shape in aggregation, demonstrating remarkable transitions in cell behavior. To better understand their functional role, we analyze cell-cell correlations and provide evidence for self-organization at the onset of aggregation (as opposed to leader cells), with features of criticality in this finite system. To capture the mechanism of self-organization, we extend a detailed single-cell model of D. discoideum chemotaxis by adding cell-cell communication. We then use these results to extract a minimal set of rules leading to aggregation in the population model. If universal, similar rules may explain other types of collective cell behavior.

**12:39PM F39.00006 ABSTRACT WITHDRAWN —**

**12:51PM F39.00007 Asymmetric Nano/Microtopography Biases Cytoskeletal Dynamics and Promotes Unidirectional Cell Guidance**, XIAOYU SUN, MEGHAN DRISCOLL, CAN GUVEN, SATARUPA DAS, Univ of Maryland-College Park, CAROLE PARENT, National Institute of Health, JOHN FOURKAS, WOLFGANG LOSERT, Univ of Maryland-College Park — Many biological and physiological processes depend upon directed migration of cells, which is typically mediated by chemical or physical gradients or by signal relay. Here we show that cells can be guided in a single preferred direction based solely on local asymmetries in nano/microtopography on subcellular scales. These asymmetries can be repeated, and thereby provide directional guidance, over arbitrarily large areas. The direction and strength of the guidance is sensitive to the details of the nano/microtopography, suggesting that this phenomenon plays a context-dependent role in vivo. We demonstrate that asymmetric nano/microtopography guides the direction of internal actin polymerization waves (esotaxis), and that cells move in the same direction as these waves (microthigmotaxis). This phenomenon is observed both for the pseudopod-dominated migration of the amoeboid Dictyostelium discoideum and for the lamellipod-driven migration of human neutrophils. The conservation of this mechanism across cell types and the asymmetric shape of many natural scaffolds suggests that actin-wave-based guidance is important in biology and physiology.

**1:03PM F39.00008 Limits to Chemically Guided Multicellular Migration**, JULIEN VARENNES, BUMSOO HAN, ANDREW MUGLER, Purdue Univ — Collective cell migration in response to a chemical cue requires both multicellular sensing of chemical gradients and coordinated mechanical action. Examples from morphogenesis and cancer metastasis demonstrate that clusters of migratory cells are extremely sensitive, responding to gradients of less than 1% difference in chemical concentration across a cell body. While the limits to multicellular sensing are becoming known, the ensuing consequences for coherent migration remain poorly understood. We develop a model of multicellular sensing and migration based on the cellular Potts model. Multicellular sensing of noisy chemical gradients is modeled as a process of local excitation and global inhibition (LEGI) among communicating cells. The output of the sensing process is coupled to individual cells polarization to model migratory behavior. We find that larger clusters of cells detect the gradient direction with higher precision and thus achieve stronger polarization bias. At the same time, larger clusters are also accompanied by less coherent collective motion. The trade-off between these two effects leads to an optimally efficient cluster size. We discuss how our results relate to cancer metastasis.

**1:15PM F39.00009 Chemotaxis and Actin Oscillations<sup>1</sup>**, EBERHARD BODENSCHATZ, HSIN-FANG HSU, MPI Dynamics and Self-Organization, JOSE NEGRETE, MPI Physics of Complex Systems, CARSTEN BETA, MPI Dynamics and Self-Organization, ALAIN PUMIR, ENS Lyon, AZAM GHOLAMI, MARCO TARANTOLA, CHRISTIAN WESTENDORF, VLADIMIR ZYKOV, MPI Dynamics and Self-Organization — Recently, self-oscillations of the cytoskeletal actin have been observed in Dictyostelium, a model system for studying chemotaxis. Here we report experimental results on the self-oscillation mechanism and the role of regulatory proteins and myosin II. We stimulate cells rapidly and periodically by using photo un-caging of the chemoattractant in a micro-fluidic device and measured the cellular responses. We found that the response amplitude grows with stimulation strength only in a very narrow region of stimulation, after which the response amplitude reaches a plateau. Moreover, the frequency-response is not constant but rather varies with the strength of external stimuli. To understand the underlying mechanism, we analyzed the polymerization and de-polymerization time in the single cell level. Despite of the large cell-to-cell variability, we found that the polymerization time is independent of external stimuli and the de-polymerization time is prolonged as the stimulation strength increases. Our conclusions will be summarized and the role of noise in the signaling network will be discussed.

**1:27PM F39.00010 Nanotopography guides and directs cell migration in amoeboid and epithelial cells**, RACHEL LEE, Department of Physics, University of Maryland, College Park, SATARUPA DAS, Institute for Physical Science and Technology, University of Maryland, College Park, MATTHEW HOURWITZ, XIAOYU SUN, Department of Chemistry and Biochemistry, University of Maryland, College Park, Maryland, CAROLE PARENT, Laboratory of Cellular and Molecular Biology, Center for Cancer Research, National Cancer Institute, JOHN FOURKAS, Department of Chemistry and Biochemistry, University of Maryland, College Park, Maryland, WOLFGANG LOSERT, Department of Physics, University of Maryland, College Park — Cell migration plays a critical role in development, angiogenesis, immune response, wound healing, and cancer metastasis. In many cases, cells also move in the context of a matrix of collagen fibers, and the alignment of these fibers can both affect the migration phenotype and guide cells. Here we show that both fast and slow migrating cells – amoeboid HL-60 and epithelial MCF10A – are affected in similar ways by micro/nanostructures with dimensions similar to those of collagen fibers. Cell alignment enhances the efficiency of migration by increasing directional persistence.

**1:39PM F39.00011 Flow-driven waves and sink-driven oscillations during aggregation of Dictyostelium discoideum**<sup>1</sup>, AZAM GHOLAMI, VLADIMIR ZYKOV, Max-Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, OLIVER STEINBOCK, Department of Chemistry and Biochemistry, Florida State University, Tallahassee, FL, EBERHARD BODENSCHATZ, Max-Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — The slime mold Dictyostelium discoideum (D.d.) is a well-known model system for the study of biological pattern formation. Under starvation, D.d. cells aggregate chemotactically towards cAMP signals emitted periodically from an aggregation center. In the natural environment, D.d. cells may experience fluid flows that can profoundly change the underlying wave generation process. We investigate spatial-temporal dynamics of a uniformly distributed population of D.d. cells in a flow-through narrow microfluidic channel with a cell-free inlet area. We show that flow can significantly influence the dynamics of the system and lead to a flow-driven instability that initiates downstream traveling cAMP waves. We also show that cell-free boundary regions have a significant effect on the observed patterns and can lead to a new kind of instability. Since there are no cells in the inlet to produce cAMP, the points in the vicinity of the inlet lose cAMP due to advection or diffusion and gain only a little from the upstream of the channel (inlet). In other words, there is a large negative flux of cAMP in the neighborhood close to the inlet, which can be considered as a sink. This negative flux close to the inlet drives a new kind of instability called sink-driven oscillations.

**1:51PM F39.00012 Texture sensing of cytoskeletal dynamics in cell migration**, SATARUPA DAS, Institute for Physical Science and Technology, University of Maryland, College Park, RACHEL LEE, Department of Physics, University of Maryland, College Park, MATTHEW J. HOURWITZ, XIAOYU SUN, Department of Chemistry and Biochemistry, University of Maryland, College Park, CAROLE PARENT, Center for Cancer Research, NCI, NIH, 37 Convent Drive, Bethesda, JOHN T. FOURKAS, Department of Chemistry and Biochemistry, University of Maryland, College Park, WOLFGANG LOSERT, Department of Physics, University of Maryland, College Park — Migrating cells can be directed towards a target by gradients in properties such as chemical concentration or mechanical properties of the surrounding microenvironment. In previous studies we have shown that micro/nanotopographical features on scales comparable to those of natural collagen fibers can guide fast migrating amoeboid cells by aligning actin polymerization waves to such nanostructures. We find that actin microfilaments and microtubules are aligned along the nanoridge topographies, modulating overall cell polarity and directional migration in epithelial cells. This work shows that topographic features on a biologically relevant length scale can modulate migration outcomes by affecting the texture sensing property of the cytoskeleton.

**2:03PM F39.00013 Influence of electric field on cellular migration**<sup>1</sup>, ISABELLA GUIDO, EBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — Cells have the ability to detect continuous current electric fields (EFs) and respond to them with a directed migratory movement. Dictyostelium discoideum (D.d.) cells, a key model organism for the study of eukaryotic chemotaxis, orient and migrate toward the cathode under the influence of an EF. The underlying sensing mechanism and whether it is shared by the chemotactic response pathway remains unknown. Whereas genes and proteins that mediate the electric sensing as well as that define the migration direction have been previously investigated in D.d. cells, a deeper knowledge about the cellular kinematic effects caused by the EF is still lacking. Here we show that besides triggering a directional bias the electric field influences the cellular kinematics by accelerating the movement of cells along their path. We found that the migratory velocity of the cells in an EF increases linearly with the exposure time. Through the analysis of the PI3K and Phg2 distribution in the cytosol and of the cellular adherence to the substrate we aim at elucidating whereas this speed up effect in the electric field is due to either a molecular signalling or the interaction with the substrate.

**11:15AM F40.00001 Fractions, trees and unfinished business.**, BORIS SHRAIMAN, KITP, UC Santa Barbara — In this talk, mourning the loss of a teacher and a dear friend, I would like to share some unfinished thoughts loosely connecting - via Farey fraction trees - Kadanoff's study of universality of quasi-periodic route to chaos with the effort to understand universal features of genealogical trees.

**11:27AM F40.00002 A potential mechanism for a singular solution of the Euler Equations**, MICHAEL BRENNER, Harvard University, SAHAND HORMOZ, California Institute of Technology, ALAIN PUMIR, ENS Lyon — We describe a potential mechanism for a singular solution of the Euler equation. The mechanism involves the interaction of vortex filaments, but occurs sufficiently quickly and at small enough scales that it could have plausibly evaded experimental and computational detection. Scaling estimates for the characteristics of this solution will be presented, as well as numerical simulations of the initial stages.

**11:39AM F40.00003 Nonlinear dynamics of a strongly driven single spin solid state qubit**<sup>1</sup>, S. N. COPPERSMITH, University of Wisconsin-Madison, Madison, WI 53706, USA, THIBAUT JULLIEN, P. SCARLINO, E. KAWAKAMI, QuTech and Kavli Institute of Nanoscience, TU Delft, Lorentzweg 1, 2628 CJ Delft, The Netherlands, D. R. WARD, D. E. SAVAGE, M. G. LAGALLY, MARK FRIESEN, M. A. ERIKSSON, University of Wisconsin-Madison, Madison, WI 53706, USA, L. M. K. VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, TU Delft, Lorentzweg 1, 2628 CJ Delft, The Netherlands — This talk will discuss how dynamical systems theory can yield new insight into some exotic behavior found in experiments on strongly driven quantum spins in silicon/silicon-germanium heterostructures. Spin resonance experiments were performed by using ac voltages to drive an electron wavefunction in a strong magnetic field gradient. Nontrivial dependence of the resonance frequency on applied power, including the observation of multiple resonant frequencies at one power, are shown to be consistent with frequency-dependent attenuation in the high-frequency lines. The method of analysis is very similar to that presented in the course on nonlinear dynamics that Leo Kadanoff developed at the University of Chicago in the early 1990's.

**11:51AM F40.00004 Learning in a noisy environment: a Lyapunov equation approach**, SARA A SOLLA, Northwestern University, YARDEN COHEN, Weizmann Institute of Science, PREDRAG CVITANOVIC, Georgia Institute of Technology — Consider a behavioral task described as a finite time trajectory through a  $d$ -dimensional space, segmented in  $K$  time steps, and thus fully specified by a vector  $X$  in the  $n = dK$  dimensional state space of possible trajectories. Consider the dynamics of learning a desired target trajectory  $X^*$ . In the vicinity of  $X^*$ , the learning dynamics at the  $t$ -th discrete learning time step can be linearized to  $Y_{t+1} = MY_t + \xi_t$ , where,  $Y_t = X_t - X^*$  and  $\xi$  is independent Gaussian noise of zero mean and covariance  $\Delta$ . The balance between contracting dynamics and noise leads to an asymptotic covariance  $Q$  that obeys the Lyapunov equation  $Q = MQM^T + \Delta$ . Given  $Q$ , how can the unknown deterministic component  $M$  be estimated the presence of noise? We propose the use of systematic target perturbations  $X^* \rightarrow X^* + \epsilon V_j$ , with unit vectors  $V_j$ ,  $1 \leq j \leq n$  that span the space  $X$ . We argue, convincingly if not rigorously, that the linear response to these perturbations fully characterizes the asymptotic dynamics of the learning process. We illustrate the method by analyzing networks of neurons with either intrinsic or extrinsic noise, at time resolutions that span from spike timing to spiking rates.

**12:03PM F40.00005 ABSTRACT WITHDRAWN** —

**12:15PM F40.00006 Nonlinear dynamics, Waddington landscape and stem cells**, CHAO TANG, Peking University — There are hundreds of different cell types (skin, neuron, muscle, etc.) in human body, all derived from the stem cell and all have the same genetic information. About 60 years ago, Waddington speculated that the different cell types correspond to different minima in a landscape emerged from genetic interactions. Recently, biologists succeeded in transforming one cell type to another by perturbing the genetic interactions in a cell. I will discuss the experiments and a mathematical model of a set of such cell type transformations in mice, in which we can see an actual example of the Waddington landscape and ways to alter it to facilitate cell type transformation – in particular, to reprogram a differentiated cell back into a stem cell.

**12:27PM F40.00007 From Glaciers to Icebergs**, WENDY ZHANG<sup>1</sup>, University of Chicago — I will describe works from a collaboration between physics and glaciology that grew out of interactions at the *Computations in Science* seminar Leo Kadanoff organized at the University of Chicago. The first project considers the interaction between ocean waves and Antarctic ice shelves, large floating portions of ice formed by glacial outflows. Back-of-envelope calculation and seismic sensor data suggest that crevasses may be distributed within an ice shelf to shield it from wave energy. We also examine numerical scenarios in which changes in environmental forcing causes the ice shelf to fail catastrophically. The second project investigates the aftermath of iceberg calving off glacier terminus in Greenland using data recorded via time-lapse camera and terrestrial radar. Our observations indicate that the mangle of icebergs within the fjord experiences widespread jamming during a calving event and therefore is always close to being in a jammed state during periods of terminus quiescence. Joint work with Jason Amundson, Ivo R. Peters, Julian Freed Brown, Nicholas Guttenberg, Justin C Burton, L. Mac Cathles, Ryan Cassotto, Mark Fahnestock, Kristopher Darnell, Martin Truffer, Dorian S. Abbot and Douglas MacAyeal.

<sup>1</sup>Kadanoff Session DCMF

**12:39PM F40.00008 Multifractals, random walks and Arctic sea ice**<sup>1</sup>, SAHIL AGARWAL, Yale University, JOHN WETTLAUER, Yale University and Nordic Institute of Theoretical Physics (NORDITA) — We examine the long-term correlations and multifractal properties of daily satellite retrievals of Arctic sea ice albedo, extent, and ice velocity for decadal periods. The approach harnesses a recent development called Multifractal Temporally Weighted Detrended Fluctuation Analysis (MF-TW DFA), which exploits the intuition that points closer in time are more likely to be related than distant points. In both data sets we extract multiple crossover times, as characterized by generalized Hurst exponents, ranging from synoptic to decadal. The method goes beyond treatments that assume a single decay scale process, such as a first-order autoregression, which cannot be justifiably fit to these observations. The ice extent data exhibits white noise behavior from seasonal to bi-seasonal time scales, whereas the clear fingerprints of the short (weather) and long ( $\sim 7$  and 9 year) time scales remain, the latter associated with the recent decay in the ice cover. Thus, long term persistence is reentrant beyond the seasonal scale and it is not possible to distinguish whether a given ice extent minimum/maximum will be followed by a minimum/maximum that is larger or smaller in magnitude. The ice velocity data show long term persistence in auto covariance.

**12:51PM F40.00009 Phase transition to turbulence in a pipe**<sup>1</sup>, NIGEL GOLDENFELD<sup>2</sup>, University of Illinois at Urbana-Champaign — Leo Kadanoff taught us much about phase transitions, turbulence and collective behavior. Here I explore the transition to turbulence in a pipe, showing how a collective mode determines the universality class. Near the transition, turbulent puffs decay either directly or through splitting, with characteristic time-scales that exhibit a super-exponential dependence on Reynolds number. Direct numerical simulations reveal that a collective mode, a so-called zonal flow emerges at large scales, activated by anisotropic turbulent fluctuations, as represented by Reynolds stress. This zonal flow imposes a shear on the turbulent fluctuations that tends to suppress their anisotropy, leading to a Landau theory of predator-prey type, in the directed percolation universality class. Stochastic simulations of this model reproduce the functional form and phenomenology of pipe flow experiments. Talk based on work performed with Hong-Yan Shih and Tsung-Lin Hsieh.

**11:15AM F41.00001 Learning probabilities from random observables in high dimensions: the maximum entropy distribution and others** , TOMOYUKI OBUCHI<sup>1</sup>, Tokyo Institute of Technology, SIMONA COCCO, Laboratoire de Physique Statistique de l'Ecole Normale Supérieure, REMI MONASSON, Laboratoire de Physique Théorique de l'Ecole Normale Supérieure — We consider the problem of learning a target probability distribution over a set of  $N$  binary variables from the knowledge of the expectation values (with this target distribution) of  $M$  observables, drawn uniformly at random. The space of all probability distributions compatible with these  $M$  expectation values within some fixed accuracy, called version space, is studied. We introduce a biased measure over the version space, which gives a boost with the entropy of the distributions and with an arbitrary 'temperature'. The choice of the temperature allows us to interpolate between the flat measure over all the distributions and the pointwise measure concentrated at the maximum entropy distribution. Using the replica method we compute the volume of the version space and other quantities of interest, such as the distance  $R$  between the target distribution and the center-of-mass distribution over the version space. Some phase transitions are found, corresponding to qualitative improvements in the learning of the target distribution and to the decrease of the distance  $R$ . However, the distance  $R$  does not vary with the temperature, meaning that the maximum entropy distribution is not closer to the target distribution than any others.

**11:27AM F41.00002 Semiparametric energy-based models of systems exhibiting criticality** , JAN HUMPLIK, GASPER TKACIK, Institute of Science and Technology Austria — Over the last decade, several empirical studies have found evidence that many biological and natural systems exhibit critical fluctuations analogous to those observed during second-order phase transitions in equilibrium systems. In many cases, these fluctuations were shown to be equivalent to a thermodynamic version of Zipf's law—if the system is sufficiently large, then a log-log plot of the probability of a state vs. its rank yields a straight line with slope  $-1$ . Because the origin of critical fluctuations cannot be traced to a unique mechanism, it is important that data-driven phenomenological models of natural systems are flexible enough so as to easily capture any kind of criticality. Here we study a class of models with exactly this property. This class consists of energy-based models in which the exponential Boltzmann factor is replaced by an arbitrary nonlinear function. We demonstrate the usefulness of our method by modeling the spiking activity of a population of retinal neurons, and the distribution of light intensities in small patches of natural images. In light of recent work on models with hidden variables, the proposed method can separate interactions induced by an unknown fluctuating environment from interactions intrinsic to the system.

**11:39AM F41.00003 From Maximum Entropy Models to Non-Stationarity and Irreversibility<sup>1</sup>** , RODRIGO COFRE, Department of Theoretical Physics, University of Geneva, Switzerland, BRUNO CESSAC, Inria, Neuromathcomp team, CESAR MALDONADO, Centro de Modelamiento Matemático, Universidad de Chile —

The maximum entropy distribution can be obtained from a variational principle. This is important as a matter of principle and for the purpose of finding approximate solutions. One can exploit this fact to obtain relevant information about the underlying stochastic process. We report here in recent progress in three aspects to this approach.

1- Biological systems are expected to show some degree of irreversibility in time. Based on the transfer matrix technique to find the spatio-temporal maximum entropy distribution, we build a framework to quantify the degree of irreversibility of any maximum entropy distribution.

2- The maximum entropy solution is characterized by a functional called Gibbs free energy (solution of the variational principle). The Legendre transformation of this functional is the rate function, which controls the speed of convergence of empirical averages to their ergodic mean. We show how the correct description of this functional is determinant for a more rigorous characterization of first and higher order phase transitions.

3- We assess the impact of a weak time-dependent external stimulus on the collective statistics of spiking neuronal networks. We show how to evaluate this impact on any higher order spatio-temporal correlation.

**11:51AM F41.00004 Learning Maximal Entropy Models from finite size datasets: a fast Data-Driven algorithm allows to sample from the posterior distribution.<sup>1</sup>** , ULISSE FERRARI, Institut de la Vision, Sorbonne Universités, UPMC, INSERM U968, CNRS, UMR 7210, Paris, F-75012, France. — A maximal entropy model provides the least constrained probability distribution that reproduces experimental averages of an observables set. In this work we characterize the learning dynamics that maximizes the log-likelihood in the case of large but finite datasets. We first show how the steepest descent dynamics is not optimal as it is slowed down by the inhomogeneous curvature of the model parameters space. We then provide a way for rectifying this space which relies only on dataset properties and does not require large computational efforts. We conclude by solving the long-time limit of the parameters dynamics including the randomness generated by the systematic use of Gibbs sampling. In this stochastic framework, rather than converging to a fixed point, the dynamics reaches a stationary distribution, which for the rectified dynamics reproduces the posterior distribution of the parameters. We sum up all these insights in a "rectified" Data-Driven algorithm that is fast and by sampling from the parameters posterior avoids both under- and over-fitting along all the directions of the parameters space. Through the learning of pairwise Ising models from the recording of a large population of retina neurons, we show how our algorithm outperforms the steepest descent method.

**12:03PM F41.00005 UniEnt: uniform entropy model for the dynamics of a neuronal population**<sup>1</sup>, DAMIAN HERNANDEZ LAHME, Department of Physics, Emory University, ILYA NEMENMAN, Department of Physics and Department of Biology, Emory University — Sensory information and motor responses are encoded in the brain in a collective spiking activity of a large number of neurons. Understanding the neural code requires inferring statistical properties of such collective dynamics from multicellular neurophysiological recordings. Questions of whether synchronous activity or silence of multiple neurons carries information about the stimuli or the motor responses are especially interesting. Unfortunately, detection of such high order statistical interactions from data is especially challenging due to the exponentially large dimensionality of the state space of neural collectives. Here we present UniEnt, a method for the inference of strengths of multivariate neural interaction patterns. The method is based on the Bayesian prior that makes no assumptions (uniform a priori expectations) about the value of the entropy of the observed multivariate neural activity, in contrast to popular approaches that maximize this entropy. We then study previously published multi-electrode recordings data from salamander retina, exposing the relevance of higher order neural interaction patterns for information encoding in this system.

**12:15PM F41.00006 Modeling the Mass Action Dynamics of Metabolism with Fluctuation Theorems and Maximum Entropy.**, WILLIAM CANNON, DENNIS THOMAS, DOUGLAS BAXTER, JEREMY ZUCKER, GARRETT GOH, Pacific Northwest National Laboratory — The laws of thermodynamics dictate the behavior of biotic and abiotic systems. Simulation methods based on statistical thermodynamics can provide a fundamental understanding of how biological systems function and are coupled to their environment. While mass action kinetic simulations are based on solving ordinary differential equations using rate parameters, analogous thermodynamic simulations of mass action dynamics are based on modeling states using chemical potentials. The latter have the advantage that standard free energies of formation/reaction and metabolite levels are much easier to determine than rate parameters, allowing one to model across a large range of scales. Bridging theory and experiment, statistical thermodynamics simulations allow us to both predict activities of metabolites and enzymes and use experimental measurements of metabolites and proteins as input data. Even if metabolite levels are not available experimentally, it is shown that a maximum entropy assumption is quite reasonable and in many cases results in both the most energetically efficient process and the highest material flux.

**12:27PM F41.00007 On the sufficiency of pairwise interactions in maximum entropy models of networks**<sup>1</sup>, ILYA NEMENMAN, Emory University, LINA MERCHAN, Savannah State University — Biological information processing networks consist of many components, which are coupled by an even larger number of complex multivariate interactions. However, analyses of data sets from fields as diverse as neuroscience, molecular biology, and behavior have reported that observed statistics of states of some biological networks can be approximated well by maximum entropy models with only pairwise interactions among the components. Based on simulations of random Ising spin networks with p-spin ( $p \geq 2$ ) interactions, here we argue that this reduction in complexity can be thought of as a natural property of some densely interacting networks in certain regimes, and not necessarily as a special property of living systems.

**12:39PM F41.00008 Insights in connecting phenotypes in bacteria to coevolutionary information.**<sup>1</sup>, RYAN CHENG, Rice University, FARUCK MORCOS, University of Texas at Dallas, RYAN HAYES, University of Michigan, RODNEY HELM, University of Houston, HERBERT LEVINE, JOSE ONUCHIC, Rice University — It has long been known that protein sequences are far from random. These sequences have been evolutionarily selected to maintain their ability to fold into stable, three-dimensional folded structures as well as their ability to form macromolecular assemblies, perform catalytic functions, etc. For these reasons, there exist quantifiable mutational patterns in the collection of sequence data for a protein family arising from the need to maintain favorable residue-residue interactions to facilitate folding as well as cellular function. Here, we focus on studying the correlated mutational patterns that give rise to interaction specificity in bacterial two-component signaling (TCS) systems. TCS proteins have evolved to be able to preferentially bind and transfer a phosphate group to their signaling partner while avoiding phosphotransfer with non-partners. We infer a Potts model Hamiltonian governing the correlated mutational patterns that are observed in the sequence data of TCS partners and apply this model to recently published in vivo mutational data. Our findings further support the notion that statistical models built from sequence data can be used to predict bacterial phenotypes as well as engineer interaction specificity between non-partner TCS proteins.

**12:51PM F41.00009 Computational Amide I Spectroscopy for Refinement of Disordered Peptide Ensembles: Maximum Entropy and Related Approaches**, MICHAEL REPERT, Massachusetts Inst of Tech-MIT, ANDREI TOKMAKOFF, University of Chicago — The structural characterization of intrinsically disordered peptides (IDPs) presents a challenging biophysical problem. Extreme heterogeneity and rapid conformational interconversion make traditional methods difficult to interpret. Due to its ultrafast (ps) shutter speed, Amide I vibrational spectroscopy has received considerable interest as a novel technique to probe IDP structure and dynamics. Historically, Amide I spectroscopy has been limited to delivering global secondary structural information. More recently, however, the method has been adapted to study structure at the local level through incorporation of isotope labels into the protein backbone at specific amide bonds. Thanks to the acute sensitivity of Amide I frequencies to local electrostatic interactions—particularly hydrogen bonds—spectroscopic data on isotope labeled residues directly reports on local peptide conformation. Quantitative information can be extracted using electrostatic frequency maps which translate molecular dynamics trajectories into Amide I spectra for comparison with experiment. Here we present our recent efforts in the development of a rigorous approach to incorporating Amide I spectroscopic restraints into refined molecular dynamics structural ensembles using maximum entropy and related approaches. By combining force field predictions with experimental spectroscopic data, we construct refined structural ensembles for a family of short, strongly disordered, elastin-like peptides in aqueous solution.

**1:03PM F41.00010 Coevolutionary modeling of protein sequences: Predicting structure, function, and mutational landscapes**, MARTIN WEIGT, Université Pierre et Marie Curie, Paris — Over the last years, biological research has been revolutionized by experimental high-throughput techniques, in particular by next-generation sequencing technology. Unprecedented amounts of data are accumulating, and there is a growing request for computational methods unveiling the information hidden in raw data, thereby increasing our understanding of complex biological systems. Statistical-physics models based on the maximum-entropy principle have, in the last few years, played an important role in this context. To give a specific example, proteins and many non-coding RNA show a remarkable degree of structural and functional conservation in the course of evolution, despite a large variability in amino acid sequences. We have developed a statistical-mechanics inspired inference approach - called Direct-Coupling Analysis - to link this sequence variability (easy to observe in sequence alignments, which are available in public sequence databases) to bio-molecular structure and function. In my presentation I will show, how this methodology can be used (i) to infer contacts between residues and thus to guide tertiary and quaternary protein structure prediction and RNA structure prediction, (ii) to discriminate interacting from non-interacting protein families, and thus to infer conserved protein-protein interaction networks, and (iii) to reconstruct mutational landscapes and thus to predict the phenotypic effect of mutations. **1:39PM F41.00011 Phase transitions in Hidden Markov Models<sup>1</sup>**, JOHN BECHHOEFER, EMMA LATHOUWERS, Simon Fraser Univ — In *Hidden Markov Models* (HMMs), a Markov process is not directly accessible. In the simplest case, a two-state Markov model emits one of two symbols at each time step. We can think of these symbols as noisy measurements of the underlying state. With some probability, the symbol implies that the system is in one state when it is actually in the other. The ability to judge which state the system is in sets the efficiency of a Maxwell demon that observes state fluctuations in order to extract heat from a coupled reservoir. The *state-inference problem* is to infer the underlying state from such noisy measurements at each time step. We show that there can be a phase transition in such measurements:<sup>2</sup> for measurement error rates below a certain threshold, the inferred state always matches the observation. For higher error rates, there can be continuous or discontinuous transitions to situations where keeping a memory of past observations improves the state estimate. We can partly understand this behavior by mapping the HMM onto a 1d random-field Ising model at zero temperature. We also present more recent work that explores a larger parameter space and more states.

**1:51PM F41.00012 Distinguishing cell type using epigenotype<sup>1</sup>**, THOMAS WYTOCK, ADILSON E MOTTER, Dept. Physics and Astronomy, Northwestern University — Recently, researchers have proposed that unique cell types are attractors of their epigenetic dynamics including gene expression and chromatin conformation patterns. Traditionally, cell types have been classified by their function, morphology, cytochemistry, and other macroscopically observable properties. Because these properties are the result of many proteins working together, it should be possible to predict cell types from gene expression or chromatin conformation profiles. In this talk, I present a maximum entropy approach to identify and distinguish cell type attractors on the basis of correlations within these profiles. I will demonstrate the flexibility of this method through its separate application to gene expression and chromatin conformation datasets. I show that our method out-performs other machine-learning techniques and uncorrelated benchmarks. We adapt our method to predict growth rate from gene expression in *E. coli* and *S. cerevisiae* and compare our predictions with those from metabolic models. In addition, our method identifies a nearly convex region of state-space associated with each cell type attractor basin. Estimates of the growth rate and attractor basin make it possible to rationally control gene regulatory networks independent of a model.

**2:03PM F41.00013 Can simple interactions capture complex features of neural activity underlying behavior in a virtual reality environment?**, LEENOY MESHULAM, JEFFREY GAUTHIER, CARLOS BRODY, DAVID TANK, WILLIAM BIALEK, Princeton University — The complex neural interactions which are abundant in most recordings of neural activity are relatively poorly understood. A prime example of such interactions can be found in the *in vivo* neural activity which underlies complex behaviors of mice, imaged in brain regions such as hippocampus and parietal cortex. Experimental techniques now allow us to accurately follow these neural interactions in the simultaneous activity of large neuronal populations of awake behaving animals. Here, we demonstrate that pairwise maximum entropy models can predict a surprising number of properties of the neural activity. The models, that are constrained with activity rates and interactions between pairs of neurons, are well fit to the activity 'states' in the hippocampus and cortex of mice performing cognitive tasks while navigating in a virtual reality environment.

**11:15AM F42.00001 Chain exchange kinetics of block copolymer micelles in ionic liquids**, YUANCHI MA, TIMOTHY LODGE, University of Minnesota — The chain exchange kinetics of block copolymer micelles has been studied using time-resolved small-angle neutron scattering (TR-SANS), a key tool in determining the average micelle composition in contrast-matched solvents. In this work, PMMA-*block*-PnBMA was selected as the model block copolymer, which has a LCST behavior in the common ionic liquids, [EMIM][TFSI] and [BMIM][TFSI]. We examined the chain exchange kinetics of three PMMA-*block*-PnBMA copolymers, with identical PMMA block length ( $M_{\text{PMMA}} = 25000$ ) and different PnBMA block lengths ( $M_{\text{PnBMA}} = 24000, 35000$  and  $53000$ ); the Flory-Huggins interaction parameter ( $\chi$ ) between the core (PnBMA) and the solvent were varied by mixing [EMIM][TFSI] and [BMIM][TFSI] in different ratios. We found that the relaxation of the initial segregation of h- and d- micelles followed the same form with the time as previously developed by our group. Assuming that single chain expulsion is the rate limiting step, the thermal barrier was found to depend linearly on the core block length ( $N_{\text{core}}$ ). Furthermore, the effect of  $\chi$  on the chain exchange kinetics will also be discussed.

**11:27AM F42.00002 Self-assembly of Coordination Macroions — the Effect of Small Polymer Chains<sup>1</sup>**, HUI LI, TIANBO LIU, University of Akron, ALEX ZHUKHOVITSKIY, JEREMIAH JOHNSON, Massachusetts Institute of Technology — In the presence of small simple counterions, macroions with modest charge density could self-assemble into one-layer hollow spherical structures. The driving force to form this vesicle-like structure is considered as counter-ion mediated attractions. On the other hand, overall hydrophilic transition metal-organic macrocations, consisting of hydrophobic ligands (pyridine-based) and hydrophilic palladium (Pd) metal ions, can be used as nanosized macrocations. One of the positively charged coordination macroions, Pd<sub>12</sub>L<sub>24</sub> (Pd = Pd (II), L = (1,3-di(pyridin-4-yl)benzene), is famous for its controllable and precise assembly structure and possible functional sites. By functionalizing the organic ligand with polymer ethylene glycol (PEG), the macroions could possess larger size thus lower charge density. Detecting their self-assembled structures will tell the difference of their solution behavior as well as the discrepancy of macroion clusters. In summary, the small non-charged PEG chains have been observed to reduce the surface charge density, and furthermore, significantly change the solution behavior.

<sup>1</sup>National Science Foundation (CHE1305756)

**11:39AM F42.00003 Simulation and Numerical Modeling of the Self-assembly of an Optoelectronic Peptide**, RACHAEL MANSBACH, ANDREW FERGUSON, Univ of Illinois - Urbana — We report molecular dynamics simulations of the self-assembly of synthetic  $\pi$ -conjugated oligopeptides into optoelectronic nanostructures. The electronic properties provide the basis for an array of organic electronic devices, such as light-emitting diodes, field-effect transistors, and solar cells. Control of the structure, stability, and kinetics of self-assembled organic electronics by tuning monomer chemistry and environmental conditions presents a powerful route to the fabrication of biocompatible designer materials. We have performed coarse-grained simulations of the self-assembly of several hundred peptides over microsecond time scales to probe the morphology and kinetics of aggregation with molecular-level detail. We have subsequently used this simulation data to parameterize a kinetic aggregation model based on Smoluchowski coagulation theory to enable prediction of aggregation dynamics on millisecond time scales. These numerical models are now being integrated into a multi-physics model of peptide aggregation in a microfluidic flow cell developed by our experimental collaborators to model the self-assembly of diverse peptide architectures under tailored flow-fields for the fabrication of biocompatible assemblies with defined morphology and optoelectronic function.

## 11:51AM F42.00004 Complexation Between Cationic Diblock Copolymers and Plasmid DNA

, SEYOUNG JUNG, THERESA REINEKE, TIMOTHY LODGE, Univ of Minnesota - Twin Cities — Deoxyribonucleic acids (DNA), as polyanions, can spontaneously bind with polycations to form polyelectrolyte complexes. When the polycation is a diblock copolymer with one cationic block and one uncharged hydrophilic block, the polyelectrolyte complexes formed with plasmid DNA (pDNA) are often colloiddally stable, and show great promise in the field of polymeric gene therapy. While the resulting properties (size, stability, and toxicity to biological systems) of the complexes have been studied for numerous cationic diblocks, the fundamentals of the pDNA-diblock binding process have not been extensively investigated. Herein, we report how the cationic block content of a diblock influences the pDNA-diblock interactions. pDNA with 7164 base pairs and poly(2-deoxy-2-methacrylamido glucopyranose)-block-poly(N-(2-aminoethyl) methacrylamide) (PMAG-b-PAEMA) are used as the model pDNA and cationic diblock, respectively. To vary the cationic block content, two PMAG-b-PAEMA copolymers with similar PMAG block lengths but distinct PAEMA block lengths and a PAEMA homopolymer are utilized. We show that the enthalpy change from pDNA-diblock interactions is dependent on the cationic diblock composition, and is closely associated with both the binding strength and the pDNA tertiary structure.

## 12:03PM F42.00005 Complexation of $AB^+$ , $AB^+C$ , $ACB^+$ , and $A(B^+-stat-C)$ block copolymer micelles with poly(styrene sulfonate) as models for tunable gene delivery vectors

, JENNIFER LAASER, YAMING JIANG, ELISE LOHMANN, THERESA REINEKE, TIMOTHY LODGE, University of Minnesota — We investigate the complexation of poly(styrene sulfonate) with micelles with mixed cationic/hydrophilic coronas as models for tunable gene delivery vectors. The micelles are self-assembled from  $AB^+$ ,  $AB^+C$ ,  $ACB^+$ , and  $A(B^+-stat-C)$  block polymer architectures, where the hydrophobic A blocks (poly(styrene)) form the micelle cores, and the cationic B blocks (poly(dimethylamino ethyl methacrylate)) and hydrophilic, nonionic C blocks (poly(poly(ethylene glycol) methyl ether methacrylate)) form the coronas. We find that hydrophilic units do not change the colloidal stability of the complexes, and complexes based on all four micelle architectures form broad, multimodal size distributions. While complexes based on the  $AB^+$ ,  $AB^+C$ , and  $ACB^+$  polymer architectures are kinetically trapped at low ionic strength, however, those based on the  $A(B^+-stat-C)$  architecture rapidly rearrange into single-micelle complexes when the linear polyanion is in excess. This suggests that the randomly-placed hydrophilic units break up the ion pairing between the cationic and anionic chains and promote formation of over-charged complexes. Design of the micelle architecture may thus provide a powerful way control the structure and stability of micelle-polyelectrolyte complexes for gene delivery applications.

## 12:15PM F42.00006 Computational Insight into Solvent Effects on Conformation and Assembly of Structured Ionic Polymer<sup>1</sup>

, MANJULA SENANAYAKE, DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY GREEST, Sandia National Laboratories — Structured ionomers are in the core of numerous current and potential new applications including clean energy, water purification membranes and sensors. The ability to facilitate ions and solvents transport is a key to their function and is controlled by their structure. One effective path for structural control is tuning their conformation by solvent interactions. Here, the conformation and association of an ABCBA co-polymer where C is a randomly sulfonated polystyrene with sulfonation fractions  $f = 0$  to 0.55, B is poly (ethylene-r-propylene), and A is poly (t-butyl styrene), in n-propanol are studied by molecular dynamic simulation. In contrast to the collapsed conformation of the ionizable block in hydrophobic solvents, we find that it remains swollen. Similar to hydrophobic solutions the co-polymers aggregate to form an ionizable core surrounded by extended hydrophobic chains. In contrast to the “locked-in” ionizable segments observed in cyclohexane/heptane, here the ionic clusters remain dynamic.

<sup>1</sup>Supported in part by DOE Grant No. DE-SC007908

## 12:27PM F42.00007 Continuous monitoring of structural dynamics in polymer assemblies.

, JOSE RAFAEL GUZMAN SEPULVEDA<sup>1</sup>, JINAN DENG<sup>2</sup>, JIYU FANG<sup>3</sup>, ARISTIDE DOGARIU<sup>4</sup>, Univ of Central Florida — Due to their flexibility, optical methods are preferred approaches for monitoring the dynamics and mechanical properties of scattering systems such as polymer solutions, colloidal suspensions, and complex media in general. In particular, their potential noninvasiveness is critical for the passive assessment of dynamic processes. Practical implementations however suffer sometimes from limitations due to effects such as multiple scattering or strong attenuation. Here we introduce an optical technique that overcomes some of these limitations and permits accessing the dynamics of complex colloidal systems under realistic conditions and inherent external influences. This interferometric technique operates based on the coherence-gated isolation of single scattering and allows for the spatially-resolved evaluation of the system's dynamics in optically isolated picoliter-sized volumes. This effective isolation permits a fully passive characterization of nonstationary dynamic processes in complex systems including aggregation and self-assembling, sedimentation, structural evolution and phase transitions, interface dynamics, and dynamics in inhomogeneous or stratified solvents.

## 12:39PM F42.00008 Inclusion Kinetics of Polyrotaxanes

, HIDEAKI YOKOYAMA, SHOKO TAKAHASHI, KOHZO ITO, The University of Tokyo, NORIFUMI YAMADA, High Energy Accelerator Research Organization, KEK — Inclusion complex (IC) formation of  $\alpha$ -cyclodextrin ( $\alpha$ -CD) and poly(ethylene glycol) (PEG) brush in water was investigated by Surface Plasmon Resonance Spectroscopy (SPR), neutron reflectometry (NR) and grazing incident wide angle X-ray scattering (GISANS). Spontaneous IC formation of  $\alpha$ -CD with PEG (polyrotaxanes) is believed to be due to hydrophobic interaction between the hydrophobic interior of  $\alpha$ -CD and PEG; however, the detail of the IC formation kinetics has not been observed because IC formation results in aggregation and precipitation of the complex. SPR revealed that IC formation occurs after induction period, which often appears in crystallization. When concentration of  $\alpha$ -CD solution is 10%, IC consisting randomly oriented  $\alpha$ -CD polycrystal appeared. In contrast, when the concentration of  $\alpha$ -CD solution is 5%, a uniform 10-nm-thick IC layer with  $\alpha$ -CD stacked perpendicular to the substrate appeared. 10-nm-thick IC was also found in the diluted PEG brush in contact with a 10%  $\alpha$ -CD solution. The characteristic 10-nm-thick layer is related to the folded crystalline structure of  $\alpha$ -CD on PEG brush. Such crystallization was proved to be the main driving force for IC formation.

## 12:51PM F42.00009 Crystallization in Micellar Cores: confinement effects and dynamics

, REIDAR LUND, THOMAS ZINN, Department of Chemistry, University of Oslo, LUTZ WILLNER, Forschungszentrum Jlich, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF OSLO TEAM, FORSCHUNGSZENTRUM JILICH COLLABORATION — It is well known that liquids confined to small nanoscopic pores and droplets exhibit thermal behavior very different from bulk samples. Here we demonstrate that n-alkanes forming 2-3 nm small micellar cores are considerably affected by confinement in analogue with hard confined systems. We study micelles form by self-assembly of a series of well-defined n-Alkyl-PEO polymers in aqueous solutions [1]. By using small-angle X-ray scattering (SAXS), densimetry and differential scanning calorimetry (DSC), we show that n-alkane exhibit a first-order phase transition i.e. melting. Correlating the structural and thermodynamic data, we find that a melting depression can be accurately described by the Gibbs-Thomson equation [2]. The effect of core crystallinity on the molecular exchange kinetics is investigated using time-resolved small-angle neutron scattering (TR-SANS) [3-6]. We show that there are considerable entropic and enthalpic contributions from the chain packing that affect the kinetic stability of micelles. [7] T. Zinn *et al.*, *Soft Matter*, 2014, **10**, 5212. **1:03PM F42.00010 Assembly, Conformation, and Thermodynamics of Star-Branched Poly(N-isopropylacrylamide) (PNIPAM) in Solution**, MICHAEL J. A. HORE, XIAOLONG LANG, WILLIAM R. LENART, Case Western Reserve University — The synthetic route and molecular architecture of poly(N-isopropylacrylamide) (PNIPAM) affects its assembly and thermoresponsive behavior. Here, the structure and assembly of star-branched PNIPAM is studied in water using a new model based on the random phase approximation (RPA), and small-angle neutron scattering (SANS) for  $f = 3, 4$ , and 6 arm star polymers, synthesized using either click chemistry, RAFT, or ATRP. Unlike linear PNIPAM, we find that for star-branched polymers, the radius of gyration scales with the degree of polymerization  $N$  as  $R_g \sim N^{0.65}$  indicating physical excluded volume effects in the polymer chain conformation.  $R_g$  decreases monotonically as the system temperature approaches the lower critical solution temperature (LCST). Interestingly, PNIPAM chains begin to associate well below the LCST, depending on whether the polymers were synthesized via ATRP or RAFT, and a strong structure factor peak can be observed as  $T$  increases. Finally, the Flory-Huggins interaction parameters between PNIPAM and water are extracted from the scattering data, and indicate that molecular architecture does not substantially influence the interaction between water and PNIPAM. These observations are compared to recent studies in the literature.

**1:15PM F42.00011 Monodisperse Block Copolymer Particles with Controllable Size, Shape, and Nanostructure.**, JAE MAN SHIN, Department of Chemical and Biomolecular Engineering, KAIST, YONGJOO KIM, Department of Material Science and Engineering, KAIST, BUMJOON KIM, Department of Chemical and Biomolecular Engineering, KAIST, PNEL TEAM — Shape-anisotropic particles are important class of novel colloidal building block for their functionality is more strongly governed by their shape, size and nanostructure compared to conventional spherical particles. Recently, facile strategy for producing non-spherical polymeric particles by interfacial engineering received significant attention. However, achieving uniform size distribution of particles together with controlled shape and nanostructure has not been achieved. Here, we introduce versatile system for producing monodisperse BCP particles with controlled size, shape and morphology. Polystyrene-*b*-polybutadiene (PS-*b*-PB) self-assembled to either onion-like or striped ellipsoid particle, where final structure is governed by amount of adsorbed sodium dodecyl sulfate (SDS) surfactant at the particle/surrounding interface. Further control of molecular weight and particle size enabled fine-tuning of aspect ratio of ellipsoid particle. Underlying physics of free energy for morphology formation and entropic penalty associated with bending BCP chains strongly affects particle structure and specification.

**1:27PM F42.00012 Shape-designed single-polymer micelles: a proof-of-concept simulation<sup>1</sup>**, BRIAN MOTHS, THOMAS A. WITTEN, University of Chicago — Much effort has been directed towards self-assembling nanostructures. Strong, local interactions between specific building blocks often determine these structures (e.g., globular proteins). We seek to produce designed structures that are instead determined by collective effects of weak interactions (e.g., surfactant self-assembly). Such structures may reversibly change conformation or disassemble in response to changing solvent conditions, and, being soft, have potential to adapt to fluctuating or unknown application-imposed shape requirements. Concretely, we aim to realize such a structure in the form of a single polymer micelle—an amphiphilic polymer exhibiting a condensed, phase-segregated conformation when immersed in solvent. Connecting all amphiphiles into a single chain provides geometric constraints controlling the surface curvature profile, thus dictating a non-trivial shape. We present 2D Monte Carlo simulation results demonstrating the feasibility of such soft, shape-designed micelles. Preliminary results demonstrate a stable concave “dimple” in a micelle composed of a single A-B multiblock linear copolymer. We discuss both current limitations on shape robustness and effects of block asymmetry, block molecular weights and overall chain length on micelle shape.

**1:39PM F42.00013 Mechanism of polymer nanoparticle formation by nanoprecipitation**, CHEN ZHAO, TINGTING LI, EDWARD VAN KEUREN, Georgetown Univ — Nanoprecipitation method is a simple and convenient way to produce nanoparticles from polymers in solution. The control of nanoparticle size and size distribution plays a pivotal role in the use of nanoprecipitation for drug delivery. We investigated various factors and initial conditions that affect the particle size, such as the initial solute concentration, solvent/non-solvent ratio and the molecular weight of the polymer samples. The results shed light on the mechanisms of particle formation and phase separation which occurs in nanoprecipitation. Spinodal decomposition, which takes place as a result of a quench to a sufficiently high supersaturation, is believed to be the main mechanism that governs the phase separation. In addition, the glass transition of the polymers will also be a key factor that contributes to the thermodynamics and kinetics of the phase separation and the resulting particle size and morphology.

**1:51PM F42.00014 Assembly and Structural Evolution of Micelleplexes**, YAMING JIANG, DUSTIN SPROUSE, JENNIFER LAASER, THERESA REINEKE, TIMOTHY LODGE, University of Minnesota-Twin Cities — Cationic micelles complex with DNA to form micelleplexes, which are attractive vehicles for gene delivery. We investigate the formation and structural evolution of micelleplexes in buffered solutions. The micelles are composed of poly((2-dimethylamino)ethyl methacrylate)-block-poly(*n*-butyl methacrylate). The formation of the micelleplexes is monitored via turbidimetric titration. With DNA oligomers, solutions of the complexes are homogeneous until near the charge neutral point, at which point the complexes precipitate. With plasmid DNA, more than a stoichiometric amount of DNA is needed to reach the inhomogeneous region, which suggests that binding is partially inhibited. This inhibition is not fully relieved when the plasmid DNA is linearized, suggesting that the stiffness of the DNA is the main source of the inhibition. With micelles in excess, the micelleplexes formed at low ionic strength exhibit bimodal size distributions and remain stable in solution. With DNA in excess, soluble micelleplexes aggregate over time and precipitate. We explain the structural evolution of the micelleplexes as an interplay between kinetic trapping and thermodynamic equilibrium, and compare the results for DNA with those for a flexible polyanion.

**2:03PM F42.00015 Soft Patchy Particles of Block Copolymers from Interface-Engineered Emulsions**, YONGJOO KM, KANG HEE KU, Korea Adv Inst of Sci & Tech, GI-RA YI, Sungkyunkwan University, YEON SIK JUNG, BUMJOON J. KIM, Korea Adv Inst of Sci & Tech — We report a simple and practical method for creating colloidal patchy particles with a variety of three-dimensional shapes via the evaporation-induced assembly of polystyrene-*b*-poly(4-vinylpyridine) (PS-*b*-P4VP) block copolymer (BCP) in an oil-in-water emulsion. Depending on the particle volume, a series of patchy particles in the shapes of snowmen, dumbbells, triangles, tetrahedra, and raspberry can be prepared, which are then precisely tuned by modulating the interfacial interaction at the particle/water interface using a mixture of two different surfactants. In this talk, theoretic calculations of free energy of the system based on the strong segregation theory (SST) will be mainly discussed to support the experimental observation of various soft patchy particles and identified the underlying principles of their formation with tunable 3D structures.

**11:15AM F43.00001 Jamming vs Caging in Three Dimensional Jamming Percolation** , YAIR SHOKEF, NIMROD SEGALL, EIAL TEOMY, Tel Aviv University — We study a three-dimensional kinetically-constrained lattice-gas model [1], in which the ability of a particle to move depends on the occupation of neighboring sites in an orientational manner. The kinetic rules are constructed such that chains of permanently-frozen particles reach an infinite length at the critical density of directed percolation. Thus at this critical density the system undergoes a jamming transition, above which there is a finite fraction of jammed particles. We demonstrate that the three-dimensional mesh-like structure of the one-dimensional jammed chains enables the free particles to propagate through the holes in this mesh. This diffusive motion is terminated at a second critical density above which all particles are caged. The largest and second largest clusters of dynamically-connected sites exhibit singularities at both densities. Thus our model assists in separating between the two distinct phenomena of jamming and caging. [1] A. Ghosh, E. Teomy and Y. Shokef, Europhys. Lett. 106, 16003 (2014).

**11:27AM F43.00002 Relation between structure of blocked clusters and relaxation dynamics in kinetically constrained models** , EIAL TEOMY, YAIR SHOKEF, Tel Aviv University — In a liquid all the particles are mobile, while in a glass only some of them are mobile at any given time. Although overall the structure is amorphous in both cases, the difference is that in glasses there are local structures that inhibit the movement of particles inside them. We investigate the size of these structures by considering the minimum number of particles that need to move before a specific particle can move. In kinetically-constrained models this structural property, the mean culling time, is easy to find by iteratively culling mobile particles from a snapshot of the system. We use the Kob-Andersen, Fredrickson-Andersen, and the spiral models, which are either lattice gases in which a particle may hop to a nearby site if its local environment satisfies some constraint, or Ising-like models in which a spin, representing regions of high and low mobility, can flip if its environment satisfies some constraint. We compare these structural properties to the dynamics in these models by measuring the persistence time, which is the average time it takes a particle to move for the first time. We find an algebraic relation between the mean culling time and the persistence time, with a model-dependent exponent.

**11:39AM F43.00003 Growing Hyperuniformity of Bidisperse Soft Discs on Approach to Jamming** , ANTHONY CHIECO, CARL GOODRICH, ANDREA LIU, DOUGLAS DURIAN, University of Pennsylvania — We study the development of hyperuniformity in simulated systems of bidisperse soft discs as the packing fraction  $\phi$  is increased from below to above jamming, using the real-space spectrum of hyperuniformity disorder lengths,  $h(L)$ . For a set of randomly placed  $L \times L$  measuring windows,  $h(L)$  specifies the distance from the window boundaries over which fluctuations are important; for liquid-like systems,  $h(L)$  scales like  $L$ ; but for strongly hyperuniform systems,  $h(L) = h_e$  is constant. We use two preparation protocols, one rapidly-quenches a system by immediately minimizing particle overlap and the other allows particles to move under low temperature thermal driving. Above jamming, both systems become strongly hyperuniform as signified by  $h(L) \rightarrow R_{small}/5$  at large  $L$ . Below jamming, but near the transition, the behavior of  $h(L)$  at small  $L$  is just like above jamming. But for larger  $L$ ,  $h(L)$  breaks away and grows in a protocol-dependent fashion. In general, thermal systems are more uniform than quenched systems, as signified by smaller hyperuniformity disorder lengths. And the development of hyperuniformity happens simultaneously with the onset of jamming.

**11:51AM F43.00004 Crossover from facilitation to hopping in a colloidal glass-former** , SHREYAS GOKHALE, Indian Inst of Science, RAJESH GANAPATHY, K HIMA NAGAMANASA<sup>1</sup>, Jawaharlal Nehru Centre for Advanced Scientific Research, A K SOOD, Indian Inst of Science — Despite extensive research, it remains to be established whether glass formation is a fundamentally thermodynamic or dynamic phenomenon. In particular, it is not yet clear whether structural relaxation is dominated by the correlated motion of localized excitations, as postulated by the dynamical facilitation (DF) theory, or by the collective hopping of groups of particles, as envisioned by various thermodynamic approaches. Here, by analyzing data from experiments on dense colloidal suspensions, we critically compare the role of facilitation and hopping in governing structural relaxation in glass-forming liquids. In particular, we investigate the spatial organization of localized excitations within clusters of most mobile particles as well as their partitioning into shell-like and core-like regions. Our study reveals the existence of a dynamical crossover from a facilitation dominated regime at low area fractions to one dominated by collective hopping close to the glass transition. Our findings strongly suggest that glass formation is thermodynamic in origin.

**12:03PM F43.00005 Measuring Temperaturelike State Variables in History-Dependent Jammed Granular Systems** , EPHRAIM BILILIGN, KAREN DANIELS, North Carolina State University — Granular systems are athermal, thus a complete statistical mechanics framework must be based on a set of macroscopic state variables which excludes temperature. One leading theory incorporates a stress-based ensemble, and predicts a Boltzmann-like distribution of the force-moment tensor with respect to the conjugate, temperature-like variable, angoricity. We experimentally test this theory on a static, bidisperse, two-dimensional packing of discs. Basal friction is eliminated by floating the discs on a sub-fluidizing upflow of air, and the packings are subjected to either uniaxial compression or simple shear. We simultaneously measure the contact forces acting on each disc using photoelasticity. These measurements are repeated over many configurations of discs by dilating and rearranging the system, and the angoricity is computed as a function of the confining pressure. In particular, we test the predicted linear relationship between angoricity and pressure. Comparison to prior results and numerical simulations also suggests a history-dependent angoricity, an undesirable feature in the proposed state variable.

**12:15PM F43.00006 Universal, non-Debye scaling in the density of states for jammed amorphous systems** , ERIC CORWIN, Univ of Oregon, ALEXIS PONCET, cole Normale Suprieure — The presence of anomalous modes in amorphous packings close to jamming is well known: the density of states of packings close to jamming goes to a constant at low frequency. But the scaling at higher densities is still unclear. Naively, one might expect to find simple Debye scaling. However, newly available theories for systems thought to belong to the same universality class as jamming predict anomalous, non-Debye scaling, but are only strictly applicable to the infinite dimensional case. Do these (mean-field) predictions bring some information about finite-dimensional systems? Here we study packings of soft spheres in dimensions 3 through 7 and show that indeed, far from jamming, we find a universal non-Debye scaling in the density of states, consistent with the mean-field predictions.

**12:27PM F43.00007 Nonconvex optimization and jamming**<sup>1</sup> , YOAV KALLUS, Santa Fe Institute — Recent work on the jamming transition of particles with short-range interactions has drawn connections with models based on minimization problems with linear inequality constraints and a concave objective. These properties reduce the continuous optimization problem to a discrete search among the corners of the feasible polytope. I will discuss results from simulations of models with and without quenched disorder, exhibiting critical power laws, scaling collapse, and protocol dependence. These models are also well-suited for study using tools of algebraic topology, which I will discuss briefly.

### 12:39PM F43.00008 Configurational entropy of glass-forming systems from graph isomorphism

, YUXING ZHOU, SCOTT MILNER, The Pennsylvania State University — The configurational entropy plays a central role in the thermodynamic scenarios of glass transition, such as Adam-Gibbs theory and random first-order transition theory. By definition, the configurational entropy  $S_c$  is the difference between the entropy of liquid and the vibrational entropy with structural rearrangement restricted, both of which can be obtained by means of thermodynamic integration. On the other hand,  $S_c$  is essentially a measure of the number of basins in the energy landscape, and therefore it can also be estimated by explicitly enumerating inherent structures. To this end, we first coarse-grain the vibrational motions by mapping configurations to Voronoi diagrams and then categorize them using canonical labelling. The Voronoi graph entropy is calculated as  $S_G/k_B = -\sum p_i \log(p_i)$ , where  $p_i$  is the probability of finding distinct graph  $i$ . We find for an  $n$ -particle subsystem of glass-forming hard-disk/sphere fluids,  $S_G(n)$  scales linearly with  $n$ , and  $S_c$  can be estimated from the slope.

### 12:51PM F43.00009 Suppression of the threshold of a granular solid by mechanical fluctuations

, AXELLE AMON, Université Rennes 1, ADELIN PONS, THIERRY DARNIGE, PMMH, ESPCI, Université Paris 6 & 7, JÉRÔME CRASSOUS, Université Rennes 1, ERIC CLÉMENT, PMMH, ESPCI, Université Paris 6 & 7 — For a granular material, when the ratio between the shear stress and the confining pressure is smaller than the Mohr-Coulomb threshold, the system can be considered as a solid. Nevertheless, a long-term creep is observed in this solid phase in stress imposed experiments. We present recent experimental and theoretical results demonstrating that the superposition of tiny modulations to the imposed stress are sufficient to change the response of the system from a logarithmic creep to a linear one even deep in the jammed phase. We give a theoretical interpretation of this fluidization without invoking an effective temperature due to a mechanical noise. We interpret our observations as a secular effect, i.e. a ratcheting process which is revealed only on very long times. We show that a local fluidity model is sufficient to interpret fully our experimental observations.

### 1:03PM F43.00010 Fast magnetic resonance imaging of the internal impact response of dense granular suspensions

, CHRISTOPH MLLER, Laboratory for Energy Science and Engineering, ETH Zurich, ALEXANDER PENN, Laboratory for Energy Science and Engineering, ETH Zurich and Institute for Biomedical Engineering, University and ETH Zurich, KLAAS P. PRUESSMANN, Institute for Biomedical Engineering, University and ETH Zurich — Dense granular suspensions exhibit a number of intriguing properties such as discontinuous shear-thickening and the formation of dynamic jamming fronts when impacted by a solid. Probing non-intrusively these phenomena experimentally in full three-dimensional systems is, however, highly challenging as suspensions are commonly opaque and thus, not accessible optically. Here we report the development and implementation of a fast magnetic resonance imaging (MRI) methodology allowing us to image the internal dynamics of dense granular suspensions at high temporal resolutions. An important facet of this work is the implementation of parallel MRI using tailored multi-channel receive hardware and the optimization of magnetic properties (susceptibility and NMR relaxivity) of the liquid phase. These two improvements enable us to utilize fast single-shot pulse sequences while yielding sufficient signal intensity at temporal resolutions of less than 50 ms. Furthermore, using motion-sensitive MR pulse sequences we are able to image bulk motion within the system and the response of dense granular suspensions to fast impacts.

### 1:15PM F43.00011 Local fluctuations in the relaxation rate in a glassy system

, RAJIB PANDIT, Ohio University, ELIJAH FLENNER, Colorado State University, HORACIO E. CASTILLO, Ohio University — We numerically study the equilibrium dynamics of a glass-forming binary hard-sphere mixture, for different packing fractions. We extract a correlator that probes the integrated fluctuations in the local relaxation rate in the system. We find that the strength of this correlator at  $t = \tau_\alpha$  (the  $\alpha$ -relaxation time) grows with packing fraction approximately as a power of  $\tau_\alpha$ . We also find that for a fixed packing fraction, the correlator grows as a power of time, for very long times, with an exponent that depends on the packing fraction. This exponent probes the time correlations of the relaxation rate fluctuations. We find that the exponent is around 3 for very low packing fractions, and gradually decreases to a value below 2 as the glass transition is approached. We conclude that a description of fluctuations in terms of local relaxation rates is only applicable at long times and for packing fractions close to the glass transition.

### 1:27PM F43.00012 Finite temperature mechanical instability in disordered lattices

, LEYOU ZHANG, XIAOMING MAO, Univ of Michigan - Ann Arbor — Mechanical instability takes different forms in various ordered and disordered systems, and little is known about how thermal fluctuations affect different classes of mechanical instabilities. We develop an analytic theory involving renormalization of rigidity and coherent potential approximation that can be used to understand finite-temperature mechanical stabilities in various disordered systems. We used this theory to study two disordered lattices: randomly diluted triangular lattice and randomly braced square lattice. These two lattices belong to two different universality classes as they approach mechanical instability at  $T = 0$ . We show that thermal fluctuations stabilize both lattices. In particular, the triangular lattice displays a critical regime in which the shear modulus scales as  $G \sim T^{1/2}$ , whereas the square lattice shows  $G \sim T^{2/3}$ . We discuss generic scaling laws for finite  $T$  mechanical instabilities and relate to experimental systems including jamming and glass transitions.

### 1:39PM F43.00013 Scaling theory for the jamming transition

, CARL GOODRICH, Harvard University, ANDREA LIU, University of Pennsylvania, JAMES SETHNA, Cornell University — We propose a scaling ansatz for the elastic energy of a system near the critical jamming transition in terms of three relevant fields: the compressive strain  $\Delta\phi$  relative to the critical jammed state, the shear strain  $\epsilon$ , and the inverse system size  $1/N$ . We also use  $\Delta Z$ , the number of contacts relative to the minimum required at jamming, as an underlying control parameter. Our scaling theory predicts new exponents, exponent equalities and scaling collapses for energy, pressure and shear stress that we verify with numerical simulations of jammed packings of soft spheres. It also yields new insight into why the shear and bulk moduli exhibit different scalings; the difference arises because the shear stress vanishes as  $1/\sqrt{N}$  while the pressure approaches a constant in the thermodynamic limit. The success of the scaling ansatz implies that the jamming transition exhibits an emergent scale invariance, and that it should be possible to develop a renormalization-group theory for jamming.

### 11:15AM F44.00001 Constraining Dark Energy in Table-Top Quantum Experiments

, HOLGER MUELLER, UC Berkeley — If dark energy is a light scalar field, it might interact with normal matter. The interactions, however, are suppressed in the leading models, which are thus compatible with current cosmological observations as well as solar-system and laboratory studies. Such suppression typically relies on the scalar's interaction with macroscopic amounts of ordinary matter but can be bypassed by studying the interaction with individual particles.<sup>1</sup> Using an atom interferometer, we have placed tight constraints on so-called chameleon models, ruling out interaction parameters smaller than  $2.3 \times 10^{-5}$ , while  $M \sim 1$  or larger would lead to conflict with macroscopic experiments.<sup>2</sup> In order to close this gap, we have already increased the sensitivity hundredfold and are expecting a new constraint soon. Purpose-built experiments in the lab or on the international space station will completely close the gap and rule out chameleons and other theories such as symmetrons or  $f(R)$  gravity.

**11:51AM F44.00002 Gravity and Quantum Mechanics<sup>1</sup>** , MILES BLENOWE, Dept. of Physics and Astronomy, Dartmouth College, Hanover NH 03755 — The emergence of the macroscopic classical world from the microscopic quantum world is commonly understood to be a consequence of the fact that any given quantum system is open, unavoidably interacting with unobserved environmental degrees of freedom that will cause initial quantum superposition states of the system to decohere, resulting in classical mixtures of either-or alternatives. A fundamental question concerns how large a macroscopic object can be placed in a manifest quantum state, such as a center of mass quantum superposition state, under conditions where the effects of the interacting environmental degrees of freedom are reduced (i.e. in ultrahigh vacuum and at ultralow temperatures). Recent experiments have in fact demonstrated manifest quantum behavior in nano-to-micron-scale mechanical systems. Gravity has been invoked in various ways as playing a possible fundamental role in enforcing classicality of matter systems beyond a certain scale. Adopting the viewpoint that the standard perturbative quantization of general relativity provides an effective description of quantum gravity that is valid at ordinary energies, we show that it is possible to describe quantitatively how gravity as an environment can induce the decoherence of matter superposition states. The justification for such an approach follows from the fact that we are considering laboratory scale systems, where the matter is localized to regions of small curvature. As with other low energy effects, such as the quantum gravity correction to the Newtonian potential between two ordinary masses, it should be possible to quantitatively evaluate gravitationally induced decoherence rates by employing standard perturbative quantum gravity as an effective field theory; whatever the final form the eventual correct quantum theory of gravity takes, it must converge in its predictions with the effective field theory description at low energies.

**12:27PM F44.00003 Bidirectional holographic codes and sub-AdS locality<sup>1</sup>** , ZHAO YANG, PATRICK HAYDEN, XIAOLIANG QI, Stanford Univ — Tensor networks implementing quantum error correcting codes have recently been used as toy models of the holographic duality which explicitly realize some of the more puzzling features of the AdS/CFT correspondence. These models reproduce the Ryu-Takayanagi entropy formula for boundary intervals, and allow bulk operators to be mapped to the boundary in a redundant fashion. These exactly solvable, explicit models have provided valuable insight but nonetheless suffer from many deficiencies, some of which we attempt to address in this talk. We propose a new class of tensor network models that subsume the earlier advances and, in addition, incorporate additional features of holographic duality, including: (1) a holographic interpretation of all boundary states, not just those in a "code" subspace, (2) a set of bulk states playing the role of "classical geometries" which reproduce the Ryu-Takayanagi formula for boundary intervals, (3) a bulk gauge symmetry analogous to diffeomorphism invariance in gravitational theories, (4) emergent bulk locality for sufficiently sparse excitations, and the ability to describe geometry at sub-AdS resolutions or even flat space.

**12:39PM F44.00004 An extension to Galilean relativity gives rise to quantum mechanics framework** , SIMON BERKOVICH<sup>1</sup>, The George Washington University — The presented scheme for quantum mechanics appeared from considering Cellular Automaton Universe in view of the hidden energy associated with the property of inertia [1]. Galilean relativity states that all inertial frames are equivalent. Our consideration reveals one seemingly small exception - the original frame of reference for the material formations of the Cellular Automaton infrastructure is not isotropic. This frame of reference has a distinctive direction as long as elementary particles of matter are generated by cellular automaton relocations. As a result, Cellular Automaton Universe basically complying with the laws of macrophysics for bulk bodies, could exhibit peculiar characteristics for microphysics. Why the states of microobjects are described by complex numbers is obscure. The observables are presented by real numbers through corresponding macro manipulations. In the inertial frame with unidirectional anisotropy isolated particles are characterized by two numbers; magnitude of their velocity and inclination angle to motion direction. So, these quantum states are mapped to a complex Hilbert space with zero vector representing bulk bodies. The effect of spin may be associated with the sign of the inclination angle trending separations for Stern-Gerlach output and Pauli Principle. [1]Simon Berkovich, Law of inertia and the primal energy in the cellular automaton universe , Journal of Energy Challenges and Mechanics, vol.2(2015), issue 2, pp. 62-67

**12:51PM F44.00005 Asymptotically Limitless Quantum Energy Teleportation via Qudit Probes<sup>1</sup>** , GUILLAUME VERDON-AKZAM, Institute for Quantum Computing - University of Waterloo, EDUARDO MARTIN-MARTINEZ, Institute for Quantum Computing - Perimeter Institute - University of Waterloo, ACHIM KEMPF, Perimeter Institute - Institute for Quantum Computing - University of Waterloo — We propose a modified Quantum Energy Teleportation (QET) scheme that uses arbitrary-dimensional qudit probes and polynomially localized Hamiltonians. We find that with an appropriate scaling of parameters, the teleported energy scales with the teleportation distance more favourably than the nonlocal tails of the Hamiltonians. We show that by allowing the exchange of arbitrary amounts of information between agents and in a suitable limit, an arbitrarily large amount of energy can be teleported through a massless quantum field.

<sup>1</sup>arXiv:1510.03751 - E.M-M and AK acknowledge funding from the NSERC Discovery program.

**1:03PM F44.00006 Relativistic Quantum Communication and the Structure of Spacetime** , EDUARDO MARTIN-MARTINEZ, University of Waterloo and Perimeter Institute — We study the transmission of information and correlations through quantum fields in cosmological backgrounds. With this aim, we make use of quantum information tools to quantify the classical and quantum correlations induced by a quantum massless scalar field in two particle detectors, one located in the early universe (Alice's) and the other located at a later time (Bob's). In particular, we focus on two phenomena: a) the consequences on the transmission of information of the violations of the strong Huygens principle for quantum fields, and b) the analysis of the field vacuum correlations via correlation harvesting from Alice to Bob. We will study a standard cosmological model first and then assess whether these results also hold if we use other than the general relativistic dynamics. As a particular example, we will study the transmission of information through the Big Bounce, that replaces the Big Bang, in the effective dynamics of Loop Quantum Cosmology. We show that much more information reaches us through timelike channels (not mediated by real photons) than it is carried by rays of light, which are usually regarded as the only carriers of information.

**1:15PM F44.00007 Einstein's Equivalence Principle and Universal Decoherence in Massive Composite Quantum Systems** , BELINDA PANG, YANBEI CHEN, Caltech — We demonstrate that in matter wave interferometry, the presence of a uniform gravitational field acting on massive particles with internal degrees of freedom will lead to dephasing and a loss of visibility in the interference pattern, as also shown by previous authors. However, unlike the previous authors, we argue that this is not a universal decoherence mechanism in the sense that any quantum information is lost, and furthermore, that the quantum interference is recoverable. This is a key distinction, because irreversible effects such as decoherence on a quantum system due to uniform gravity implies a violation of Einstein's Equivalence Principle (EEP) in the quantum regime. We show that the dephasing result can be recovered by considering an accelerating observer measuring a freely propagating system, and can be simply understood in terms of the difference in the internal state dependent time of arrival of particles to the screen. One can contrive detection schemes that adjust the path lengths of particles to compensate for this difference and recover the full visibility, while coupling to no additional degrees of freedom. Therefore, the dephasing is an observer dependent effect. EEP is not violated, and uniform gravity is not a mechanism for universal decoherence.

**1:27PM F44.00008 Complete Sets of Solutions in Quantum Mechanics and their Connection with Gravity**, RAFAEL SIERRA, Southern Methodist University — In typical non-relativistic quantum mechanical theory, solutions which are not normalizable are thrown away on the basis of being non-physical. The author does not contend that these solutions exist or are physically reasonable, but, these solutions do introduce interesting physics that can serve to connect the force of gravity with the laws of thermodynamics in a shockingly intimate way. The author will discuss the necessary extensions to the formalism of Schrodinger in order to better deal with and make sense of these solutions. In particular, some time will be devoted to the notion of entropy in systems involving these solutions. For particles sufficiently spaced-out, the second law of thermodynamics will yield dynamics that resemble classical expectations for gravity. Ultimately, gravity will be presented as a force necessary for the preservation of the second law of thermodynamics. Gravity and statistical mechanics will become connected at the quantum domain, provided the quantum domain is enlarged to include wave functions that are generally considered unreasonable.

**1:39PM F44.00009 Geodesics and Acceleration in Influence Theory**, JAMES WALSH, KEVIN KNUTH, University at Albany (SUNY) — Influence theory is concerned with a foundational approach where it is assumed that particles influence one another in a discrete one-to-one fashion. This results in a partially ordered set of influence events, called the influence network, where particles are represented by totally ordered chains of events. Information physics considers physical laws to result from consistent quantification of physical phenomena. Knuth and Bahreyni (2014) demonstrated that the mathematics of spacetime emerges from consistent quantification of influence events by embedded coordinated observers. Knuth (2014) showed that in 1+1 dimensions observer-based predictions about a free (uninfluenced) particle result in the Dirac equation. Here, we show that when a particle in 1+1 dimensions is influenced, it is uniquely and consistently described in terms of relativistic acceleration for constant rate of influence and in general obeys equations of the form of the geodesic equations of general relativity. This suggests that Influence Theory can also account for forces (like gravity), which give rise to well-known relativistic effects such as time dilation.

**1:51PM F44.00010 Gravity and Quantum Theory Unified**, GARY WARREN, None — Historic arguments against Aether theories disappear if the Aether is a 4D compressible hyperfluid in which each particle is our observation of a hypervortex, formed in and comprised of hyperfluid. Such Aether resolves “spooky action at a distance” which allows unification of gravity and quantum theory. Light is transverse waves in free space (away from hypervortices) in the hyperfluid. Their detailed behavior is why we observe a curved 3D Lorentz universe – a slice through the 4D hypervortex. Meanwhile, detailed hypervortex behavior, including faster-than-light longitudinal waves in and along hypervortices, explain quantum phenomena. A particular Lagrangian for such a hyperfluid regenerates Maxwell’s equations, plus an equation for gravity, and an equation for electric charge. Couplings among these equations generate a discrete spectrum of hypervortex solutions that we observe as a spectrum of particles. Gravity results from gradients in the fluid density near vortices. Observed clock rates depend on fluid density, and vortex motion thus intertwining gravity, clock rates and quantum phenomena. Implied experiments will be discussed.

**2:03PM F44.00011 Geometry and dynamics of emergent spacetime from entanglement spectrum**, HIROAKI MATSUEDA, Sendai National College of Technology — We examine geometry and dynamics of classical spacetime derived from entanglement spectrum for 1D lattice free fermions. The spacetime is a kind of canonical parameter space defined by the Fisher information metric. The spectrum has exponential family form like thermal probability. Then, the metric is given by the second derivative of the Hessian potential that can be identified with the entanglement entropy. We emphasize that the canonical parameters are nontrivial functions of partial system size by the truncation, filling fraction of fermions, and time. We find that the emergent geometry becomes anti-de Sitter spacetime with imaginary time, and a radial axis as well as spacetime coordinates appears spontaneously. We also find that the information of the UV limit of the original fermions lives in the boundary of the anti-de Sitter spacetime. These findings strongly suggest that the Hessian potential for free fermions has enough geometrical meaning associated with gauge-gravity correspondence.

**Session F45 GQI: Adiabatic Quantum Computation and Quantum Annealing: Energy Landscapes, Speedup and Embedding** 348 - Daniel Lidar, Univ. of Southern California

**11:15AM F45.00001 Quantum Annealing at Google: Recent Learnings and Next Steps**, HARTMUT NEVEN, Google — Recently we studied optimization problems with rugged energy landscapes that featured tall and narrow energy barriers separating energy minima. We found that for a crafted problem of this kind, called the weak-strong cluster glass, the D-Wave 2X processor achieves a significant advantage in runtime scaling relative to Simulated Annealing (SA). For instances with 945 variables this results in a time-to-99%-success-probability  $10^9$  times shorter than SA running on a single core. When comparing to the Quantum Monte Carlo (QMC) algorithm we only observe a pre-factor advantage but the pre-factor is large, about  $10^6$  for an implementation on a single core. We should note that we expect QMC to scale like physical quantum annealing only for problems for which the tunneling transitions can be described by a dominant purely imaginary instanton. We expect these findings to carry over to other problems with similar energy landscapes. A class of practical interest are k-th order binary optimization problems. We studied 4-spin problems using numerical methods and found again that simulated quantum annealing has better scaling than SA. This leaves us with a final step to achieve a wall clock speedup of practical relevance. We need to develop an annealing architecture that supports embedding of k-th order binary optimization in a manner that preserves the runtime advantage seen prior to embedding.

**11:51AM F45.00002 Ground States of Random Spanning Trees on a D-Wave 2X<sup>1</sup>**, J.S. HALL, Mississippi State University, L. HOBL, RWTH Aachen University, Julich Supercomputing Centre, M.A. NOVOTNY, Mississippi State University, KRISTEL MICHIELSEN, Julich Supercomputing Centre, RWTH Aachen University — The performances of two D-Wave 2 machines (476 and 496 qubits) and of a 1097-qubit D-Wave 2X were investigated. Each chip has a Chimera interaction graph  $\mathcal{G}$ . Problem input consists of values for the fields  $h_j$  and for the two-qubit interactions  $J_{i,j}$  of an Ising spin-glass problem formulated on  $\mathcal{G}$ . Output is returned in terms of a spin configuration  $\{s_j\}$ , with  $s_j = \pm 1$ . We generated random spanning trees (RSTs) uniformly distributed over all spanning trees of  $\mathcal{G}$ . On the 476-qubit D-Wave 2, RSTs were generated on the full chip with  $J_{i,j} = -1$  and  $h_j = 0$  and solved one thousand times. The distribution of solution energies and the average magnetization of each qubit were determined. On both the 476- and 1097-qubit machines, four identical spanning trees were generated on each quadrant of the chip. The statistical independence of these regions was investigated. In another study, on the D-Wave 2X, one hundred RSTs with random  $J_{i,j} \in \{-1, 1\}$  and  $h_j = 0$  were generated on the full chip. Each RST problem was solved one hundred times and the number of times the ground state energy was found was recorded. This procedure was repeated for square subgraphs, with dimensions ranging from  $7 \times 7$  to  $11 \times 11$ .

**12:03PM F45.00003 Instantons and scaling of the transitions rates in Quantum Monte Carlo simulations of thermally-assisted quantum tunneling in spin systems<sup>1</sup>**, VADIM SMELYANSKIY, Google, ZHANG JIANG, Stinger Ghaffarian Technologies, Inc., SERGIO BOIXO, SERGEI ISSAKOV, Google, GUGLIELMO MAZZOLA, MATTHIAS TROYER, Swiss Federal Institute of Technology in Zurich, HARTMUT NEVEN, Google — We study analytically and numerically the dynamics of the quantum Monte Carlo (QMC) algorithm to simulate thermally-assisted tunneling in mean-field spin models without conservation of total spin. We use Kramers escape rate theory to calculate the scaling of the QMC time with the problem size to simulate the tunneling transitions. We develop path-integral instanton approach in coherent state and Suzuki-Trotter representations to calculate the escape rate and most probable escape path in QMC dynamics. Analytical results are in a good agreement with numerical studies. We identify the class of models where the exponent in the scaling of the QMC time is the same as that in physical tunneling but the pre-factor depends very significantly on the QMC path representation. We propose the classes of problems where QMC can fail to simulate tunneling efficiently.

**12:15PM F45.00004 Validating the solutions of the D-Wave quantum annealers through graph mirroring<sup>1</sup>**, DILINA PERERA, J.S. HALL, M.A. NOVOTNY, Mississippi State University — D-Wave quantum annealers seek to find the ground states of Ising spin glasses. The problem Hamiltonian is formulated as an undirected graph that can be embedded into the devices native disordered Chimera graph structure. However, depending on the complexity of the problem and the specifications of the annealing schedule, the device may not necessarily find the global minimum during a given annealing process. We present a method, which we call answer checking, that enhances the expectation that the solution provided by the device is the true ground state of the problem. The underlying principle is to embed a mirrored graph  $G'$  of the original graph  $G$ , and connect the two graphs via ferromagnetic/antiferromagnetic couplers. This allows one to rule out solutions for the composite graph that do not comply with the underlying mirror symmetry inherent to the true ground state, which in turn, reduces the uncertainty associated with the solutions. Using the 1097 qubit D-Wave 2X, we test this approach by applying it to a range of problems, including random spanning trees and generally allowed graphs  $G$ .

**12:27PM F45.00005 Quantum Annealing for Constrained Optimization**, ITAY HEN, FEDERICO SPEDALIERI, Information Sciences institute, USC — Recent advances in quantum technology have led to the development and manufacturing of experimental programmable quantum annealers that could potentially solve certain quadratic unconstrained binary optimization problems faster than their classical analogues. The applicability of such devices for many theoretical and practical optimization problems, which are often constrained, is severely limited by the sparse, rigid layout of the devices' quantum bits. Traditionally, constraints are addressed by the addition of penalty terms to the Hamiltonian of the problem, which in turn requires prohibitively increasing physical resources while also restricting the dynamical range of the interactions. Here we propose a method for encoding constrained optimization problems on quantum annealers that eliminates the need for penalty terms and thereby removes many of the obstacles associated with the implementation of these. We argue the advantages of the proposed technique and illustrate its effectiveness. We then conclude by discussing the experimental feasibility of the suggested method as well as its potential to boost the encodability of other optimization problems.

**12:39PM F45.00006 Embedding parameters for Quantum Annealing**, DAVIDE VENTURELLI, NASA Ames Research Center — Many optimization problems are defined on highly connected graphs and many interesting physical spin-glass systems are featuring long-range interactions. One method to solve for the optimum/ground state is quantum annealing (QA). Most architectures for QA devices, manufactured or proposed, are based on optimizing Hamiltonians having spins connected in a non-complete graph, with nodes with a small maximum degree, compared to the requirements. To overcome this limitation 'embedding' is employed: the native graph is tiled with ferromagnetic chains of spins that now are meant to represent the logical binary variables. While it is known how the strength of the ferromagnetic bonds can ensure that the classical Ising ground state of the embedded system can be univocally mapped to the ground state of the original system, there is very little study on the impact of these parameters on QA. Programmers have taken conservative choices for the parameters and the common practices can be improved. Starting from the physics of connected ferromagnetic Ising chains, we will review several parameter choices and discuss previous and new results obtained on the D-Wave 2X machine, on carefully designed problems that allow to isolate and evaluate the role of connectivity in embedded systems.

**12:51PM F45.00007 Systematic and Deterministic Graph-Minor Embedding of Cartesian Products of Complete Graphs**, ARMAN ZARIBAFIYAN, DOMINIC J.J. MARCHAND, SEYED SAEED CHANGIZ REZAEI, 1QBit — The limited connectivity of current and next-generation quantum annealers motivates the need for efficient graph-minor embedding methods. The overhead of the widely used heuristic techniques is quickly proving to be a significant bottleneck for real-world applications. To alleviate this obstacle, we propose a systematic deterministic embedding method that exploits the structures of both the input graph of the specific combinatorial optimization problem and the quantum annealer. We focus on the specific case of the Cartesian product of two complete graphs, a regular structure that occurs in many problems. We first divide the problem by embedding one of the factors of the Cartesian product in a repeatable unit. The resulting simplified problem consists of placing copies of this unit and connecting them together appropriately. Aside from the obvious speed and efficiency advantages of a systematic deterministic approach, the embeddings produced can be easily scaled for larger processors and show desirable properties with respect to the number of qubits used and the chain length distribution.

**1:03PM F45.00008 Simulating highly nonlocal Hamiltonians with less nonlocal Hamiltonians<sup>1</sup>**, YIGIT SUBASI, CHRISTOPHER JARZYNSKI, University of Maryland at College Park — The need for Hamiltonians with many-body interactions arises in various applications of quantum computing. However, interactions beyond two-body are difficult to realize experimentally. Perturbative gadgets were introduced to obtain arbitrary many-body effective interactions using Hamiltonians with two-body interactions only. Although valid for arbitrary  $k$ -body interactions, their use is limited to small  $k$  because the strength of interaction is  $k$ 'th order in perturbation theory. Here we develop a nonperturbative technique for obtaining effective  $k$ -body interactions using Hamiltonians consisting of at most  $l$ -body interactions with  $l < k$ . This technique works best for Hamiltonians with a few interactions with very large  $k$  and can be used together with perturbative gadgets to embed Hamiltonians of considerable complexity in proper subspaces of two-local Hamiltonians. We describe how our technique can be implemented in a hybrid (gate-based and adiabatic) as well as solely adiabatic quantum computing scheme.

<sup>1</sup>We gratefully acknowledge financial support from the Lockheed Martin Corporation under contract U12001C.

**1:15PM F45.00009 Crushing runtimes in adiabatic quantum computation with Energy Landscape Manipulation (ELM): Application to Quantum Factoring** , NIKE DATTANI, Kyoto University, RICHARD TANBURN, OLIVER LUNT, Oxford University — We introduce two methods for speeding up adiabatic quantum computations by increasing the energy between the ground and first excited states. Our methods are even more general. They can be used to shift a Hamiltonian's density of states away from the ground state, so that fewer states occupy the low-lying energies near the minimum, hence allowing for faster adiabatic passages to find the ground state with less risk of getting caught in an undesired low-lying excited state during the passage. Even more generally, our methods can be used to transform a discrete optimization problem into a new one whose unique minimum still encodes the desired answer, but with the objective function's values forming a different landscape. Aspects of the landscape such as the objective function's range, or the values of certain coefficients, or how many different inputs lead to a given output value, can be decreased \*or\* increased. One of the many examples for which these methods are useful is in finding the ground state of a Hamiltonian using NMR. We apply our methods to an AQC algorithm for integer factorization, and the first method reduces the maximum runtime in our example by up to 754%, and the second method reduces the maximum runtime of another example by up to 250%.

**1:27PM F45.00010 On universal adiabatic quantum computation** , ARI MIZEL, Laboratory for Physical Sciences — We give a careful proof that ground state quantum computation can efficiently simulate universal gate model quantum computation. The proof allows for general gate model quantum computations; no restrictions are required on qubit geometry or on the locality of two-qubit gates. Our lower-bound technique may have more general application.

**1:39PM F45.00011 Quantum Annealing and Many-Body Localization<sup>1</sup>** , NOAH BRAY-ALI, Joint Quantum Institute, University of Maryland, College Park and National Institute of Standards and Technology, Gaithersburg, MD 20899 — The quantum phase transition separating the Ising spin glass from the quantum paramagnet phase in one-dimension is many-body localized. We study quantum annealing across this transition using the recently developed, dynamical strong-disorder renormalization group approach. The probability of successful adiabatic quantum computation of the spin glass ground-state obeys a universal scaling function of system size, anneal rate, and strength of disorder, which we obtain. Measurement of this universal scaling behavior in a quantum annealing device, for example, would be the first direct test of the activated dynamics of a many-body localized quantum phase transition.

<sup>1</sup>Support provided by National Research Council Post-Doctoral Research Associateship

**1:51PM F45.00012 Bifurcation-based adiabatic quantum computation with a nonlinear oscillator network** , HAYATO GOTO, Toshiba Corporation — The dynamics of nonlinear systems qualitatively change depending on their parameters, which is called bifurcation. A quantum-mechanical nonlinear oscillator can yield a quantum superposition of two oscillation states, known as a Schrödinger cat state, via its bifurcation with a slowly varying parameter. Here we propose a quantum computer comprising such quantum nonlinear oscillators, instead of quantum bits, to solve hard combinatorial optimization problems. The nonlinear oscillator network finds optimal solutions via quantum adiabatic evolution, where nonlinear terms are increased slowly, in contrast to conventional adiabatic quantum computation or quantum annealing. To distinguish them, we refer to the present approach as bifurcation-based adiabatic quantum computation. Our numerical simulation results suggest that quantum superposition and quantum fluctuation work effectively to find optimal solutions.

**Session F46 GIMS: Instrumentation III: Scattering, Diffraction, Imaging** 311 - Dennis Mills, Argonne National Laboratory

**11:15AM F46.00001 What is the diffraction limit? From Airy to Abbe using direct numerical integration.** , Y. M. CALM, J. M. MERLO, M. J. BURNS, K. KEMPA, M. J. NAUGHTON<sup>1</sup>, Boston College — The resolution of a conventional optical microscope is sometimes taken from Airy's point spread function (PSF),  $0.61\lambda/NA$ , and sometimes from Abbe,  $\lambda/2NA$ , where  $NA$  is the numerical aperture<sup>2</sup>, however modern fluorescence and near-field optical microscopies achieve spatial resolution far better than either of these limits<sup>3</sup>. There is a new category of 2D metamaterials called planar optical elements (POEs), which have a microscopic thickness ( $< \lambda$ ), macroscopic transverse dimensions ( $> 100\lambda$ ), and are composed of an array of nanostructured light scatterers. POEs are found in a range of micro- and nano-photonics technologies<sup>4</sup>, and will influence the future optical nanoscopy. With this pretext, we shed some light on the 'diffraction limit' by numerically evaluating Kirchhoff's scalar formulae (in their exact form) and identifying the features of highly non-paraxial, 3D PSFs. We show that the Airy and Abbe criteria are connected, and we comment on the design rules for a particular type of POE: the flat lens.

**11:27AM F46.00002 Imaging of Biological Tissues by Visible Light CDI** , DMITRY KARPOV, New Mexico State University, Los Alamos National Laboratory, TOMY DOS SANTOS ROLO, Karlsruhe Institute of Technology, HANNAH RICH, EDWIN FOHTUNG, New Mexico State University, Los Alamos National Laboratory — Recent advances in the use of synchrotron and X-ray free electron laser (XFEL) based coherent diffraction imaging (CDI) with application to material sciences and medicine proved the technique to be efficient in recovering information about the samples encoded in the phase domain. The current state-of-the-art algorithms of reconstruction are transferable to optical frequencies, which makes laser sources a reasonable milestone both in technique development and applications. Here we present first results from table-top laser CDI system for imaging of biological tissues and reconstruction algorithms development and discuss approaches that are complementing the data quality improvement that is applicable to visible light frequencies due to its properties. We demonstrate applicability of the developed methodology to a wide class of soft bio-matter and condensed matter systems. This project is funded by DOD-AFOSR under award No FA9550-14-1-0363 and the LANSCE Professorship at LANL.

**11:39AM F46.00003 A New Experimental Approach in Digital Holographic Microscopy to Insight into Submicron-sized Particle's Scattering Properties.** , NAVA SUBEDI, MATTHEW BERG, Mississippi State University — A novel application of digital holographic microscopy is presented. In this work, a submicron-sized particle is illuminated by two different wavelengths. Then, a special filtering technique is used so that the one wavelength only contributes to form the hologram of the particle in a flow-through, contact-free manner and other to produce the scattering pattern of the illuminating wave in the same plane. Later, an algorithm is applied to separate these two overlapping information. The separated holographic information is used to reconstruct the image of the particle and scattering pattern is used to analyze redistribution of energy on the medium caused by the particle. This information is unique to the particle's shape and size, thus provides the insight into a particle's scattering properties simultaneously with an image of the particle.

**11:51AM F46.00004 HOMER: the Holographic Optical Microscope for Education and Research**<sup>1</sup>, ANALI LUVIANO, Norwich University — Holography was invented in 1948 by Dennis Gabor and has undergone major advancements since the 2000s leading to the development of commercial digital holographic microscopes (DHM). This noninvasive form of microscopy produces a three-dimensional (3-D) digital model of a sample without altering or destroying the sample, thus allowing the same sample to be studied multiple times. HOMER-the Holographic Optical Microscope for Education and Research-produces a 3-D image from a two-dimensional (2-D) interference pattern captured by a camera that is then put through reconstruction software. This 2-D pattern is created when a reference wave interacts with the sample to produce a secondary wave that interferes with the unaltered part of the reference wave. I constructed HOMER to be an efficient, portable in-line DHM using inexpensive material and free reconstruction software. HOMER uses three different-colored LEDs as light sources. I am testing the performance of HOMER with the goal of producing tri-color images of samples. I'm using small basic biological samples to test the effectiveness of HOMER and plan to transition to complex cellular and biological specimens as I pursue my interest in biophysics.

**12:03PM F46.00005 Bayesian Library for the Analysis of Neutron Diffraction Data**<sup>1</sup>, WILLIAM RATCLIFF, NIST - National Institute of Standards & Technology, JOSEPH LESNIEWSKI, Georgetown University, DYLAN QUINTANA, Carnegie Mellon University — During this talk, I will introduce the Bayesian Library for the Analysis of Neutron Diffraction Data. In this library we use of the DREAM [1] algorithm to effectively sample parameter space. This offers several advantages over traditional least squares fitting approaches. It gives us more robust estimates of the fitting parameters, their errors, and their correlations. It also is more stable than least squares methods and provides more confidence in finding a global minimum. I will discuss the algorithm and its application to several materials. I will show applications to both structural and magnetic diffraction patterns. I will present examples of fitting both powder and single crystal data. [1] Jasper A. Vrugt, Cajo J. F. ter Braak, Martyn P. Clark, James M. Hyman, and Bruce A. Robinson, WATER RESOURCES RESEARCH, VOL. 44, W00B09 (2008)

**12:15PM F46.00006 On Polarized Neutron Scattering from a Prototypical NMR Spin-Modulated System**, MICHAEL KOTLARCHYK, GEORGE THURSTON, Rochester Institute of Technology — The potential for utilizing the scattering of polarized neutrons from nuclei whose spin has been modulated using nuclear magnetic resonance (NMR) has previously been considered by Buckingham (1). That work broadly considered the overall feasibility and utility of such experiments with a potential aim, for example, of studying slow structural changes such as those that occur in biological macromolecules. Here, from first principles, we present a more in-depth development of the differential scattering cross-sections that would arise in such measurements from a prototypical and simplified model target system containing non-interacting nuclei with non-zero spins. In particular, we investigate the modulation of the polarized scattering cross-sections following the application of RF pulses that impart initial transverse rotations to selected sets of spin-1/2 nuclei. The aim is to lay the foundation for enhancing scattering signals from chosen nuclei, so as to advance knowledge of macromolecular or liquid structure. (1) A.D. Buckingham, Chem. Phys. Letts. 2003(371):517-521

**12:27PM F46.00007 Phase sensitive small angle neutron scattering**, ERIK BROK, Univ. of Maryland, NIST, CHARLES F MAJKRZAK, KATHRYN KRYCKA, NIST — It is a well-known problem that information about the scattered wave is lost in scattering experiments because the measured quantity is the modulus squared of the complex wave function. This "phase problem" leads to ambiguity in determining the physical properties of the scattering sample. Small angle neutron scattering (SANS) is a useful technique for determining the structure of biomolecules, in particular proteins that cannot be crystallized and studied with x-ray crystallography. However, because the biomolecules are usually suspended in a liquid the observed scattering is an average of all possible orientations, making it difficult to obtain three dimensional structural information. In a proposed method polarized SANS and magnetic nanoparticle references attached to the sample molecules is used to obtain phase sensitive structural information and simultaneously circumvent the problem of orientational averaging (Majkrzak et al. J. Appl. Cryst. 47, 2014) If realized and perfected the technique is very promising for unambiguous determination of the three dimensional structure of biomolecules. We demonstrate the principles of our method and show the first experimental data obtained on a simple test system consisting of core shell magnetic nanoparticles.

**12:39PM F46.00008 Current and Future Scientific Investigations at GP-SANS**, LISA DEBEER-SCHMITT, KATHERINE BAILEY, YURI MELNICHENKO, LILIN HE, KEN LITRELL, Oak Ridge National Lab — The general-purpose small-angle neutron scattering beam line, GP-SANS, in operation since 2007, is optimized for investigation of structures with dimensions from 0.5 to 200 nm. Along with high neutron flux, sample environments can easily be integrated into the beam line providing the user a versatile temperature range from 30 mK to 1600 K. In addition, there are two cryomagnets (horizontal 4.5 T and vertical 8 T), pressure cells, stop flow cell, electrochemical cell, load frames and custom-build equipment available to users allowing for significant flexibility in experimental setup. GP-SANS has supported investigation of a diverse array of intriguing scientific topics, including polymer solutions, gel and blends, colloids, micelles, molecular self-assembly and interactions in complex fluids, microemulsions, spin textures and magnetic domains in novel materials, porosity in geological materials and phase separation, grain growth, and orientation in metallurgical alloys.

**12:51PM F46.00009 Ptychographic coherent x-ray surface scattering imaging**<sup>1</sup>, JONG WOO KIM, ZHANG JIANG, TAO SUN, JIN WANG, Argonne National Lab — Lensless x-ray coherent diffraction imaging enables the determination of nano-scaled structures in physical and biological sciences. Several coherent diffractive imaging (CDI) methods have been developed in both transmission and reflection modes such as Bragg CDI, plane-wave CDI, Fresnel CDI, coherent surface scattering imaging (CSSI) and so on. The grazing-incidence coherent surface scattering (CSSI) technique, which is recently developed by T. Sun et al., takes advantage of enhanced x-ray surface scattering and interference near total external reflection, and thereby overcomes some limitations that the transmission mode have. However, the sample size can be investigated is limited by x-ray beam size because the sample is supposed to be isolated. We incorporated ptychographic algorithm with coherent surface scattering imaging to overcome this limitation and make it more useful and applicable. The ptychographic coherent surface scattering imaging technique enables us to measure 2D roughness of the flat surface such as thin film and silicon wafer regardless of the surface area.

<sup>1</sup>LDRD

**1:03PM F46.00010 Design and Characterization of a Novel Near Field Detector for Three Dimensional X-ray Diffraction**, SCOTT ANNETT, LAWRENCE MARGULIES, Univ of Guelph, DARREN DALE, Cornell High Energy Synchrotron Source, Cornell University, STEFAN KYCIA, Univ of Guelph — Three dimensional x-ray diffraction microscopy (3DXRD) is a powerful technique that provides crystallographic and spatial information of a large number of grains in a sample simultaneously. A key component of a 3DXRD experiment is the near field detector which provides high resolution spatial information of the sample. A novel design for a near field detector was developed and characterized. This design, called the Quad Near Field Detector, utilizes four quadrants, each with a dedicated scintillating phosphor and optical microscope. A novel translation stage for focusing the microscopes was developed, tested, and implemented. The near field detector was calibrated and characterized at the Cornell High Energy Synchrotron Source. A flood field correction was developed for the detector to correct for variations in intensity response. Diffraction data of all four quadrants was able to reproduce the crystal orientation of the ruby calibrant. In conclusion, the design and implementation of the Quad Near Field Detector was a success and will be a useful tool for future 3DXRD experiments.

**1:15PM F46.00011 A novel design of coherent and efficient electron beam-splitter based on quantum interaction-free measurement<sup>1</sup>**, YUJIA YANG, CHUNG-SOO KIM, RICHARD HOBBS, AKSHAY AGARWAL, MIT, PIETER KRUIT, TU Delft, KARL K. BERGGREN, MIT — We propose the design and theoretical analysis of a novel coherent and efficient electron beam-splitter utilizing quantum interaction-free measurement. A coherent electron beam-splitter is a necessary component in electron interferometry, electron holography, and recently emerging quantum electron optics. For most of these applications, a coherent, highly efficient, lossless, and two-port beam-splitter is preferred, which currently available electron beam-splitters cannot readily provide. Our electron beam-splitter design combines a weak phase grating with a resonator. Beam-splitting is achieved by passing the electron beam through the weak phase grating multiple times in the resonator. The beam-splitting ratio is controlled by the number of passes through the grating. Higher-order diffractions can be suppressed by inserting an aperture in the diffraction plane. The loss introduced by the aperture can be arbitrarily low according to quantum interaction-free measurement, thus enabling a lossless, two-port electron beam-splitter. Moreover, this novel design is not limited to electron optics, and can be generalized to light, atom, and molecular optics.

<sup>1</sup>This work is funded by Gordon and Betty Moore Foundation.

**1:27PM F46.00012 High-brightness electron beams for ultrafast electron microdiffraction and imaging**, TIANYIN SUN, FARAN ZHOU, KISEOK CHANG, ZHENSHENG TAO, JOE WILLIAMS, CHONG-YU RUAN, Michigan State University, MSU UEM COLLABORATION — Currently the ultrafast electron diffraction has achieved sub-picosecond temporal resolution and atomic resolution. However, direct ultrafast imaging of a nanometer scale specimen through coherent single-particle diffraction has not been achieved largely due to insufficient intensity when tuned to a coherence length that matches the size of the specimen under the projected phase space density. Utilizing a recently implemented high-brightness electron source with flexible optical design, we test the performance of ultrafast electron microdiffraction and coherence imaging. We demonstrate the feasibilities of single-shot microdiffraction on a single micrometer-sized domain in Highly Ordered Pyrolytic Graphite (HOPG) and coherent diffractive imaging of 10 nm scale charge-ordered domain structures in single-crystal complex materials, as validated by the measured brightness at the sample plane. These initial results show that source-limited performance even from a sub-relativistic electron beamline can drastically improve the current performance of ultrafast electron imaging and diffraction.

**1:39PM F46.00013 Imaging Acoustic Phonon Dynamics on the Nanometer-Femtosecond Spatiotemporal Length-Scale with Ultrafast Electron Microscopy**, DAYNE PLEMMONS<sup>1</sup>, DAVID FLANNIGAN<sup>2</sup>, University of Minnesota — Coherent collective lattice oscillations known as phonons dictate a broad range of physical observables in condensed matter and act as primary energy carriers across a wide range of material systems. Despite this omnipresence, analysis of phonon dynamics on their ultrashort native spatiotemporal length scale — that is, the combined nanometer (nm), spatial and femtosecond (fs), temporal length-scales — has largely remained experimentally inaccessible. Here, we employ ultrafast electron microscopy (UEM) to directly image discrete acoustic phonons in real-space with combined nm-fs resolution. By directly probing electron scattering in the image plane (as opposed to the diffraction plane), we retain phase information critical for following the evolution, propagation, scattering, and decay of phonons in relation to morphological features of the specimen (i.e. interfaces, grain boundaries, voids, ripples, etc.). We extract a variety of morphologically-specific quantitative information from the UEM videos including phonon frequencies, phase velocities, and decays times. We expect these direct manifestations of local elastic properties in the vicinity of material defects and interfaces will aid in the understanding and application of phonon-mediated phenomena in nanostructures.

**1:51PM F46.00014 Dark-Field Scanning Transmission Ion Microscopy *via* Direct Detection of Transmitted Helium Ions with a Multichannel Plate**, TAYLOR WOEHL, RYAN WHITE, ROBERT KELLER, Material Measurement Laboratory, National Institute of Standards and Technology — A multichannel plate was used as an ion sensitive transmission detector in a commercial helium ion microscope for annular dark-field imaging of nanomaterials, i.e. scanning transmission ion microscopy. In contrast to previous transmission helium ion microscopy approaches that used secondary electron conversion holders, our new approach directly detects transmitted helium ions on an annular detector. Monte Carlo simulations are used to predict detector collection angles at which annular dark-field images with atomic number contrast are obtained. We demonstrate atomic number contrast imaging *via* scanning transmission ion imaging of silica-coated gold nanoparticles and magnetite nanoparticles. While the resolution of this transmission technique is limited by beam broadening in the substrate, we image magnetite nanoparticles with high contrast on a relatively thick silicon nitride substrate. We expect this new approach to annular dark-field scanning transmission ion microscopy will open avenues for more quantitative ion imaging techniques, such as direct mass-thickness determination, and advance fundamental understanding of underlying ion scattering mechanisms leading to image formation.

**2:03PM F46.00015 Structure of deuterated liquid n-butanol by neutron diffraction and molecular dynamics simulations**, VIVIANA CRISTIGLIO, Institut Laue Langevin, Grenoble, MIGUEL ANGEL GONZALEZ, GABRIEL JULIO CUELLO, Institut Laue Langevin, Grenoble, FRANCE, CARLOS CABRILLO, CSIS, Instituto de Estructura de la Materia, Madrid, SPAIN, LUIS CARLOS PARDO, ALVARO SILVA-SANTISTEBAN, ETSEIB, Universitat Politècnica de Catalunya, Barcelona, SPAIN — Aliphatic alcohols are the simpler molecular liquids possessing a polar hydroxylic group and a nonpolar alkyl tail. While the structure of the smallest alcohols has been relatively well studied, no much attention has been paid to the temperature dependence of the pre-peak observed before the main diffraction peak. The role of H-bonding in causing this feature and the direct relation between the number of C atoms and their distance were discovered very early, suggesting a liquid picture constituted of straight chains joined by H-bonds with the formation of mesoscopic size clusters. X-rays and neutron diffraction measurements showed that the height of the pre-peak associated with the formation of H-bonds increases with temperature. To explain this counterintuitive effect, a complete diffraction study using two neutron diffractometers D4 and D16 (ILL, Grenoble, France) allowing to cover the range 0.01-23 Å<sup>-1</sup> and exploring a temperature range from 100 K (glassy butanol) to 400 K (moderately supercritical conditions) has been conducted. Molecular Dynamics simulations using the OPLS-AA potential were also carried out as a function of temperature and compared to experiment. Experimental and numerical results of liquid n-butanol and its glassy transition will be presented.

**Session F47 APS: Sexual and Gender Diversity Issues in Physics C-LGBT Ad Hoc Committee**  
**Report 312 - Monica Plisch, APS**

**11:15AM F47.00001 Report of the APS Ad-Hoc Committee on LGBT Issues Presentation of Findings and Recommendations**, MICHAEL FALK, Johns Hopkins University — In 2014 the Executive Officer of the American Physical Society (APS), Kate Kirby, created an Ad-Hoc Committee on LGBT Issues (C-LGBT) charged with reporting on the obstacles to inclusion of LGBT physicists, a term which for the purpose of this report refers to persons who self-identify as lesbian, gay, bisexual, transgender, queer, questioning, intersex, or asexual, as well as other sexual and gender minorities. The full charge was as follows: “The committee will advise the APS on the current status of LGBT issues in physics, provide recommendations for greater inclusion, and engage physicists in laying the foundation for a more inclusive physics community. ?More specifically, the committee will investigate LGBT representation in physics, assess the educational and professional climate in physics, recommend changes in policies and practices that impact LGBT physicists, and address other issues that affect inclusion.” We will present the findings and recommendations of the C-LGBT final report, and a panel discussion will be held following the presentation to discuss the future of APS efforts toward LGBT inclusion in physics.

**11:51AM F47.00002 Panel Discussion : Report of the APS Ad-Hoc Committee on LGBT Issues**, TIM ATHERTON, Tufts University, RAMON BARTHELEMY, APS/AIP Science & Technology Fellow, American Association for the Advancement of Science, SAVANNAH GARMON, Osaka Prefecture University, KYLE REEVES, University of North Carolina, APS AD-HOC COMMITTEE ON LGBT ISSUES TEAM — Following the presentation of the findings and recommendations of the APS Ad-Hoc Committee on LGBT Issues (C-LGBT) by Committee Chair Michael Falk, a panel discussion will be held featuring several members of the committee. The discussion will focus on how APS can best ensure the recommendations of the committee are carried out in a timely fashion and other ideas on future APS efforts toward LGBT inclusion in physics. Discussion topics will also include the research and other input that shaped the committee's findings and recommendations.

**Tuesday, March 15, 2016 11:15AM - 2:15PM –**  
**Session F48 GQI: Quantum Gates in Superconducting Circuits** 349 - Jerry Chow, IBM T.J. Watson Research Center

**11:15AM F48.00001 High-fidelity resonator-induced phase gate with single-mode squeezing**, SHRUTI PURI, Dpartement de Physique, Universit de Sherbrooke, ALEXANDRE BLAIS, Dpartement de Physique, Universit de Sherbrooke and Canadian Institute for Advanced Research — Despite recent breakthroughs in the demonstration of small-scale quantum error correction, reaching the fidelity required for fault tolerance with entangling gates still remains a challenge. We propose a protocol to increase the fidelity of a two-qubit resonator induced phase gate by using a off-resonant narrowband squeezing drive. For this gate, two superconducting transmon qubits are dispersively coupled to a microwave resonator. By off-resonantly driving the resonator, a controlled-Z gate can be implemented between the qubits [1]. However, photons leaving the resonator reveal the qubit which-path information leading to decoherence. We show that driving the resonator with a field squeezed at an optimal angle and strength erases the qubit which-path information and consequently increases the gate fidelity. We find that, under realistic conditions and modest squeezing power, it is possible to implement a high-fidelity two-qubit controlled-Z gate with short gate times. [1] A. W. Cross and J. M. Gambetta Phys Rev A 91, 032325 (2015).

**11:27AM F48.00002 Characterization of the resonator induced phase gate<sup>1</sup>**, ANTONIO MEZZACAPO, H. PAIK, M. O. SANDBERG, D. T. MCCLURE, B. ABDO, O. E. DIAL, A. W. CROSS, A. D. CORCOLES, S. SHELDON, E. MAGESAN, S. J. SRINIVASAN, J. M. CHOW, J. M. GAMBETTA, IBM T.J. Watson Research Center, Yorktown Heights, NY 10598, USA, D. BOGORIN, B. L. T. PLOURDE, Department of Physics, Syracuse University, Syracuse, New York, 13244 - 1130, USA — The Resonator induced phase (RIP) gate is a versatile microwave gate that can perform collective qubit operations. We characterize the performance of the RIP gate using various drive powers and detunings in a 4-qubit superconducting system. We find a good agreement between the experimental results and the theoretical predictions in the gate rate and minimum gate time. The minimum gate time is limited by residual photons in the bus cavity caused by a non-adiabatic response to the drive. We measure the multi-qubit interactions and analyze how the rates depend on the cavity-qubit coupling and the detuning to the drive and how these interactions can be used for quantum information processing.

**11:39AM F48.00003 Demonstrating Multi-Qubit Operations in a Superconducting 3D circuit QED Architecture<sup>1</sup>**, HANHEE PAIK, M.O. SANDBERG, A. MEZZACAPO, D. T. MCCLURE, B. ABDO, O.E. DIAL, A.W. CROSS, A.D. CORCOLES, S. SHELDON, E. MAGESAN, S.J. SRINIVASAN, J.M. GAMBETTA, J.M. CHOW, IBM T. J. Watson Research Center, Yorktown Heights, NY 10598 USA, D. BOGORIN, B.L.T. PLOURDE, Department of Physics, Syracuse University, Syracuse, NY 13244, USA — We present our recent results on multi-qubit operations in a superconducting 3D circuit QED (cQED) system using a resonator-induced phase (RIP) gate. In our system, four qubits are coupled by a single bus resonator. The RIP gate is implemented by applying a microwave pulse to the bus that performs entangling operations. We demonstrate controlled-phase gates using RIP on 2-qubit subsystems with gate fidelities between 95%-97% evaluated by randomized benchmarking. Via a multi-qubit echo scheme, we perform isolated two-qubit interactions in the full 4-qubit system to generate a GHZ state.

<sup>1</sup>We acknowledge support from IARPA under contract W911NF-10-1-0324

**11:51AM F48.00004 Understanding and improving the cross resonance gate in superconducting qubits<sup>1</sup>**, SARAH SHELDON, EASWAR MAGESAN, JERRY M. CHOW, JAY M. GAMBETTA, IBM T.J. Watson Research Center — We present improvements in both theoretical understanding and experimental implementation of the cross resonance (CR) gate that have led to shorter two qubit gatetimes and interleaved randomized benchmarking fidelities exceeding 99%. The CR gate is an all-microwave two qubit gate offers that does not require tunability and is therefore well suited to quantum computing architectures based on 2D superconducting qubits. The performance of the gate has previously been hindered by long gatetimes and fidelities averaging 96-97%. We have developed a calibration procedure that accurately measures the full CR Hamiltonian. The resulting measurements agree with theoretical analysis of the gate and also elucidate the error terms that have previously limited the gate fidelity. The increase in fidelity that we have achieved was accomplished by introducing a second microwave drive tone on the target qubit to cancel unwanted components of the CR Hamiltonian.

**12:03PM F48.00005 High-fidelity single-shot three-qubit gates via machine learning<sup>1</sup>**, EHSAN ZAHEDINEJAD, JOYDIP GHOSH, BARRY C. SANDERS, University of Calgary — Three-qubit quantum gates play a crucial role in quantum error correction and quantum information processing. Here I discuss how to generate policies for quantum control to design three-qubit gates namely, Toffoli, Controlled-Not-Not and Fredkin gates for an architecture of nearest-neighbor-coupled superconducting artificial atoms. The resulted fidelity for each gate is above the 99.9% which is the threshold fidelity for fault-tolerant quantum computing. We test our policy in the presence of decoherence-induced noise as well as show its robustness under random external noise. The three-qubit gates are designed via our machine learning algorithm called Subspace-Selective Self-Adaptive Differential Evolution (SuSSADE).

**12:15PM F48.00006 All-microwave cavity-mediated three-qubit gate between superconducting qubits**, SOPHIA ECONOMOU, ED BARNES, Department of Physics, Virginia Tech — While single-qubit and entangling two-qubit operations are universal for quantum computing, in practice the availability of a single-shot multi-qubit entangling gate can be faster and of higher fidelity. For the case of three qubits coupled to a common cavity mode, we show that a high fidelity, fast CCZ gate can be implemented. Our proposal is based on partial spectrum engineering and pulse shaping. Because our approach does not rely on frequency selectivity, instead driving more than one transitions simultaneously, our three-qubit gate can be achieved on a timescale comparable to that of a two-qubit gate. Our protocol generalizes our recently introduced SWIPHT two-qubit gates.

**12:27PM F48.00007 Tunable coupling between fixed-frequency superconducting transmon qubits, Part I: Concept, design, and prospects<sup>1</sup>**, STEFAN FILIPP, IBM Research - Zurich, 8803 Rueschlikon, Switzerland, DAVID C. MCKAY, EASWAR MAGESAN, ANTONIO MEZZACAPPO, JERRY M. CHOW, JAY M. GAMBETTA, IBM TJ Watson Research Center, Yorktown Heights, NY, USA — The controlled realization of qubit-qubit interactions is essential for both the physical implementation of quantum error-correction codes and for reliable quantum simulations. Ideally, the fidelity and speed of corresponding two-qubit gate operations is comparable to those of single qubit operations. In particular, in a scalable superconducting qubit architecture coherence must not be compromised by the presence of additional coupling elements mediating the interaction between qubits. Here we present a coupling method between fixed-frequency transmon qubits based on the frequency modulation of an auxiliary circuit coupling to the individual transmons. Since the coupler remains in its ground state at all times, its coherence does not significantly influence the fidelity of consequent entangling operations. Moreover, with the possibility to create interactions along different directions, our method is suited to engineer Hamiltonians with adjustable coupling terms. This property can be utilized for quantum simulations of spins or fermions in transmon arrays, in which pairwise couplings between adjacent qubits can be activated on demand.

<sup>1</sup>We acknowledge support from ARO under contract W911NF-14-1-0124.

**12:39PM F48.00008 Tunable coupling between fixed-frequency superconducting transmon qubits, Part II: Implementing a two-qubit XX-90 gate**, DAVID C. MCKAY, IBM T.J. Watson Research Center, Yorktown Heights NY, USA, STEFAN FILIPP, IBM Research Zurich, 8803 Rueschlikon, Switzerland, ANTONIO MEZZACAPPO, EASWAR MAGESAN, JERRY M. CHOW, JAY M. GAMBETTA, IBM T.J. Watson Research Center, Yorktown Heights NY, USA — In this talk we will present a two-qubit gate implemented in a tunable coupling architecture which consists of a flux-tunable qubit ("coupler") coupling two fixed-frequency transmons ("qubits"). In this architecture, a resonant SWAP (XX+YY) interaction is generated between the qubits when the coupler is modulated at the qubit frequency difference, typically a few hundred MHz. This interaction has a number of advantages, in particular, it only requires AC flux control and can resonantly address individual qubit pairs. Here we present a protocol which realizes the XX-90 gate based on this interaction. This gate has the specific characteristic that it takes any of the four basis states ( $|00\rangle, |10\rangle, |01\rangle, |11\rangle$ ) to Bell states. We demonstrate gate fidelities greater than 96% characterized by state tomography and randomized benchmarking. Looking forward, this gate is a prime candidate for implementing the surface code because it can couple highly coherent qubits which are spaced far apart in frequency thereby minimizing crosstalk and collisions. This work is supported by ARO under contract W911NF-14-1-0124.

**12:51PM F48.00009 Gatemon Benchmarking and Two-Qubit Operation<sup>1</sup>**, LUCAS CASPARIS, THORVALD LARSEN, MICHAEL OLSEN, KARL PETERSSON, FERDINAND KUEMMETH, PETER KROGSTROP, JESPER NYGARD, CHARLES MARCUS, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark — Recent experiments have demonstrated superconducting transmon qubits with semiconductor nanowire Josephson junctions<sup>2,3</sup>. These hybrid gatemon qubits utilize field effect tunability singular to semiconductors to allow complete qubit control using gate voltages, potentially a technological advantage over conventional flux-controlled transmons. Here, we present experiments with a two-qubit gatemon circuit. We characterize qubit coherence and stability and use randomized benchmarking to demonstrate single-qubit gate errors of  $\sim 0.5\%$  for all gates, including voltage-controlled  $Z$  rotations. We show coherent capacitive coupling between two gatemons and coherent SWAP operations. Finally, we perform a two-qubit controlled-phase gate with an estimated fidelity of  $\sim 91\%$ , demonstrating the potential of gatemon qubits for building scalable quantum processors.

**1:03PM F48.00010 Dephasing-induced Leakage in Superconducting Qubits**, FREDERICK STRAUCH, Williams College — Superconducting quantum devices such as the transmon or xmon are described as weakly anharmonic oscillators with multiple energy levels, the lowest two of which constitute a qubit. Quantum logic operations using these devices typically involve states outside of the qubit subspace; residual population in such states is known as leakage. While control methods are known to eliminate leakage from ideal devices, I will show that dephasing limits the effectiveness of these methods and discuss the implications of this dephasing-induced leakage for quantum information processing.

**1:15PM F48.00011 Suppressing Leakage in High Fidelity Single Qubit Gates for Superconducting Qubits<sup>1</sup>**, Z. CHEN, J. KELLY, C. QUINTANA, UC Santa Barbara, R. BARENDTS, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, B. CHIARO, A. DUNSWORTH, UC Santa Barbara, A.G. FOWLER, E. LUCERO, E. JEFFREY, A. MEGGRANT, J. MUTUS, M. NEELEY, Google, Santa Barbara, C. NEILL, P.J.J. O'MALLEY, UC Santa Barbara, P. ROUSHAN, D. SANK, Google, Santa Barbara, A. VAINSENER, J. WENNER, T. WHITE, UC Santa Barbara, A.N. KOROTKOV, UC Riverside, J.M. MARTINIS, UC Santa Barbara and Google, Santa Barbara — Recent results show that superconducting qubits are approaching the threshold for fault tolerant quantum error correction. However, leakage into non-qubit states remains a significant hurdle because leakage errors are highly detrimental for error correction schemes such as the surface code. I will demonstrate that with a simple addition to DRAG pulse shaping, leakage can be suppressed to the  $10^{-5}$  level while simultaneously maintaining  $10^{-3}$  gate fidelity. I will also show that the remaining leakage errors are due to heating of the qubit, suggesting further avenues for improvement.

**1:27PM F48.00012 Circuit design implementing longitudinal coupling: a scalable scheme for superconducting qubits**, SUSANNE RICHER, DAVID DIVINCENZO, JARA Institute for Quantum Information, RWTH Aachen University, D-52056 Aachen, Germany — We present a circuit construction for a new fixed-frequency superconducting qubit and show how it can be scaled up to a grid with strictly local interactions. The circuit QED realization we propose implements  $\sigma_z$ -type coupling between a superconducting qubit and any number of  $LC$  resonators. The resulting *longitudinal coupling* is inherently different from the usual  $\sigma_x$ -type *transverse coupling*, which is the one that has been most commonly used for superconducting qubits. In a grid of fixed-frequency qubits and resonators with a particular pattern of always-on interactions, coupling is strictly confined to nearest and next-nearest neighbor resonators<sup>1</sup>; we note that just four distinct resonator frequencies, and only a single unique qubit frequency, suffice for the scalability of this scheme. There is never any direct coupling between the qubits. A controlled phase gate between two neighboring qubits can be realized with microwave drives on the qubits, without affecting the other qubits. This fact is a supreme advantage for the scalability of this scheme.

**1:51PM F48.00014 Design and Measurement of a Tunable Thin-Film LC Resonator for Coupling to Superconducting Circuits**, C. J. BALLARD, R. P. BUDOYO, K. D. VOIGT, S. K. DUTTA, C. J. LOBB, F. C. WELLSTOOD, University of Maryland-College Park — We have designed and measured a tunable lumped element LC resonator for coupling to transmon qubits. We use an rf SQUID loop as a variable inductive element that shunts the inductor of the resonator and produces a shift in the resonator frequency that depends on the flux applied to the loop. In order to achieve a balanced response, we shunt the inductor with two single junction SQUID loops. Each junction has a critical current of approximately 300pA, which is small enough to prevent multiple trapped flux states. We tune the effective inductance of the loops by using a split, gradiometric modulation coil that is well isolated from the cavity at the resonance frequency. Our resonator is made of thermally evaporated aluminum on a sapphire substrate and has a resonance frequency of 5.3 GHz. It is mounted inside a 3D microwave cavity that has a TE101 frequency of 6.3 GHz.

**2:03PM F48.00015 Quantization of lumped elements electrical circuits revisited**, KEVIN LALUMIERE, ALIREZA NAJAFI-YAZDI, Anyon Systems Inc. — In 1995, the Les Houches seminar of Michel Devoret introduced a method to quantize lumped elements electrical circuits [1]. This method has since been formalized using the matricial formalism, in particular by G. Burkard [2,3]. Starting from these seminal contributions, we present a new algorithm to quantify electrical circuits. This algorithm unites the features of Devoret's and Burkard's approaches. We minimize the set of assumptions made so that the method can treat directly most electrical circuits. This includes circuits with resistances, mutual inductances, voltage and current sources. We conclude with a discussion about the choice of the basis in which the Hamiltonian operator should be written, an issue which is often overlooked. [1] M. H. Devoret, Les Houches, Session LXIII, 1995 [2] G. Burkard et al., *Phys. Rev. B*, 69, 064503, 2004 [3] F. Solgun, Ph.D. Dissertation, RWTH Aachen, 2015

**11:15AM F50.00001 The Way to Phase Space Crystals**<sup>1</sup>, LINGZHEN GUO, MARTHALER MICHAEL, GERD SCHÖN, Karlsruhe Institute of Technology (KIT) — A novel way to create a band structure of the quasienergy spectrum for driven systems is proposed based on the discrete symmetry in phase space. The system, e.g., an ion or ultracold atom trapped in a potential, shows no spatial periodicity, but it is driven by a time-dependent field. Under rotating wave approximation, the system can produce a periodic lattice structure in phase space. The band structure in quasienergy arises as a consequence of the  $n$ -fold discrete periodicity in phase space induced by this driving field. We propose explicit models to realize such a phase space crystal and analyze its band structure in the frame of a tightbinding approximation. The phase space lattice differs fundamentally from a lattice in real space, because its coordinate system, i.e., phase space, has a noncommutative geometry. The phase space crystal opens new ways to engineer energy band structures, with the added advantage that its properties can be changed in situ by tuning the driving fields parameters.

**11:27AM F50.00002 Floquet topological systems in the vicinity of level crossings: Reservoir induced coherence of the Floquet density matrix and steady-state entropy production**<sup>1</sup>, HOSSEIN DEGHANI, ADITI MITRA, New York University — Results are presented for a Floquet topological system for the case where the separation between quasi-energy levels becomes small, and in particular, comparable to the coupling strength to an external reservoir. For this case, even at steady-state, the reduced density matrix in the Floquet basis has non-zero off-diagonal elements, with the strength of the off-diagonal elements increasing as one approaches the level crossings. The steady-state reduced density matrix has oscillations at integer multiples of the periodic drive, and a Fourier decomposition allows the extraction of the occupation of the Floquet quasi-energy levels, which also depends on the coupling to the reservoir. The lack of detailed balance is quantified in terms of an entropy production rate.

### 11:39AM F50.00003 A quantum resonance catastrophe for a periodically driven impurity

, SEBASTIAN EGGERT, Univ Kaiserslautern, DANIEL THUBERG, SEBASTIÁN REYES, Pontificia Universidad Católica de Chile — There has been much interest in creating novel quantum states through active dynamic manipulations (quenches and driving) in a variety of state-of-the-art systems, such as molecular electronics, ultra-cold quantum gases, nanodot arrays, and photonic crystals. We now consider the transport in an extended one-dimensional array of coupled quantum sites which is periodically driven at one impurity location by using an exact solution with help of the Floquet theory. While a static potential barrier is known to always allow transport via tunneling, a corresponding time-periodic impurity shows resonances at special driving frequencies where the transmission is completely blocked. We find that even for an infinitesimally small periodic perturbation there is a breakdown of conductance. Such a quantum resonance catastrophe occurs when the frequency is tuned to couple to bound states just outside the band. Our results show an abundance of tuning possibilities for the transmission and the width of the resonance with frequency, potential barrier and particle energy, leading to versatile opportunities in the design of switches.

### 11:51AM F50.00004 Stroboscopic Symmetry-Protected Topological Phases

, LUIZ SANTOS, UIUC, THOMAS IADECOLA, CLAUDIO CHAMON, Boston University — Symmetry-protected topological (SPT) phases of matter have been the focus of many recent theoretical investigations, but controlled mechanisms for engineering them have so far been elusive. In this talk, I demonstrate that by driving interacting spin systems periodically in time and tuning the available parameters, one can realize lattice models for bosonic SPT phases in the limit where the driving frequency is large. We provide concrete examples of this construction in one and two dimensions, and discuss signatures of these phases in stroboscopic measurements of local observables. Phys. Rev. B 92, 125107 (2015); arXiv:1503.07871

### 12:03PM F50.00005 Statistical Transmutation in Periodically Driven Optical Lattices<sup>1</sup>

, TIGRAN SEDRAKYAN, W. I. Fine Theoretical Physics Institute, University of Minnesota, Joint Quantum Institute, University of Maryland - College Park, VICTOR GALITSKI, Joint Quantum Institute, University of Maryland - College Park, ALEX KAMENEV, W. I. Fine Theoretical Physics Institute, University of Minnesota — We show that interacting bosons in a periodically driven two dimensional (2D) optical lattice may effectively exhibit fermionic statistics. The phenomenon is similar to the celebrated Tonks-Girardeau regime in 1D. The Floquet band of a driven lattice develops the moat shape, i.e., a minimum along a closed contour in the Brillouin zone. Such degeneracy of the kinetic energy favors fermionic quasiparticles. The statistical transmutation is achieved by the Chern-Simons flux attachment similar to the fractional quantum Hall case. We show that the velocity distribution of the released bosons is a sensitive probe of the fermionic nature of their stationary Floquet state.

### 12:15PM F50.00006 Driven impurity in an ultracold 1D Bose gas with intermediate interaction strength

, JEAN-SEBASTIEN CAUX, University of Amsterdam, STEVE SIMON, University of Oxford, CLAUDIO CASTELNOVO, University of Cambridge — We study a single impurity driven by a constant force through a 1D Bose gas using a Lieb-Liniger based approach. Our calculation is exact in the interaction amongst the particles in the Bose gas, and is perturbative in the interaction between the gas and the impurity. In contrast to previous studies of this problem, we are able to handle arbitrary interaction strength for the Bose gas. We find very good agreement with recent experiments [Phys. Rev. Lett. 103, 150601 (2009)].

### 12:27PM F50.00007 The anomalous Floquet-Anderson insulator as a non-adiabatic quantized charge pump.

, PARAJ TITUM, Institute for Quantum Information and Matter, Caltech, Pasadena, California 91125, USA, EREZ BERG, The Weizmann Institute of Science, Rehovot, 76100, Israel, MARK S. RUDNER, Niels Bohr International Academy and Center for Quantum Devices, University of Copenhagen, 2100 Copenhagen, Denmark, GIL REFAEL, Institute for Quantum Information and Matter, Caltech, Pasadena, California 91125, USA, NETANEL H. LINDNER, Physics Department, Technion, 320003 Haifa, Israel — Periodically driven quantum systems provide a novel and versatile platform for realizing topological phenomena. Among these are analogs of topological insulators and superconductors, attainable in static systems; however, some of these phenomena are unique to the periodically driven case. Here, we show that disordered, periodically driven systems admit an anomalous two dimensional phase, whose quasi-energy spectrum consists of chiral edge modes that coexist with a fully localized bulk - an impossibility for static Hamiltonians. This unique situation serves as the basis for a new topologically-protected non-equilibrium transport phenomenon: quantized non-adiabatic charge pumping. We identify the bulk topological invariant that characterizes the new phase (which we call the anomalous Floquet Anderson Insulator, or AFAI). We provide explicit models which constitute a proof of principle for the existence of the new phase. Finally, we present evidence that the disorder-driven transition from the AFAI to a trivial, fully localized phase is in the same universality class as the quantum Hall plateau transition.

### 12:39PM F50.00008 Exact nonadiabatic steering of quantum particles between arbitrary instantaneous eigenstates of time-dependent Hamiltonians

, RAFAEL HIPOLITO, PAUL GOLDBART, Georgia Institute of Technology — We consider a system governed by a Hamiltonian  $H[R_n]$  that depends on a set of parameters  $R_n(t)$  that can be varied with time. We address the task of steering this system between a pair of eigenstates, one corresponding to  $H[R_n(t_i)]$ , the other to  $H[R_n(t_f)]$ . For any parameter history connecting  $R_n(t_i)$  and  $R_n(t_f)$ , we formulate a measure of success with this task, based on a path-integral expression for the overlap between the time-evolved initial state (as driven by  $H[R_n(t)]$ ) and the final state, which is obtained by integrating out the system degrees of freedom but which retains a dependence on the parameter history  $R_n(t)$ . We discuss various settings in which this program may be carried out with perfect accuracy, by optimizing the measure of success with respect to the parameter history. The task may be accomplished over timescales that are much shorter than simple adiabaticity would require and are on the order of the intrinsic timescale of the system dynamics. For illustration, we consider the example of a particle (possibly with internal freedoms) that is confined by a harmonic potential having time-varying center, curvature and squeezing parameters, for which we determine the parameter history required to steer the particle with perfect accuracy.

### 12:51PM F50.00009 Geodesic paths for quantum many-body systems<sup>1</sup>

, MICHAEL TOMKA, TIAGO SOUZA, STEVE ROSENBERG, MICHAEL KOLODRUBETZ, ANATOLI POLKOVNIKOV, Boston University — The quantum length is a distance between parameter-dependent eigenstates of an adiabatically driven quantum system. Its associated metric has many intriguing properties, for example it is related to the fidelity susceptibility, an important quantity in the study of quantum phase transitions. The metric also appears as the leading adiabatic correction of the energy fluctuations of a quantum system and gives rise to a time-energy uncertainty principle and a geometric interpretation of time. The adiabatic response of an open quantum system can as well be expressed through this metric. Further, the quantum length introduces the notion of Riemannian geometry to the manifold of eigenstates and hence allows one to define geodesics in parameter space. We study the geodesics in parameter space of certain quantum many-body systems, emerging from this quantum distance. These geodesic paths provide a well-defined optimal control protocol on how to drive the systems parameters in time, to get from one eigenstate to another. Generating optimal evolution plays a central role in quantum information technology, adiabatic quantum computing and quantum metrology.

**1:03PM F50.00010 Hysteresis of Current in Noninteracting Atomic Fermi Gases in Optical Ring Potentials**, MEKENA METCALF, CHIH-CHUN CHIEN, CHEN-YEN LAI, Univ of California - Merced — Hysteresis is a ubiquitous phenomenon, which can be found in magnets, superfluids, and other many-body systems. Although interactions are present in most systems exhibiting hysteresis, here we show the current of a non-interacting Fermi gas in an optical ring potential produces hysteresis behavior when driven by a time-dependent artificial gauge field and subject to dissipation. Fermions in a ring potential threaded with flux can exhibit a persistent current when the system is in thermal equilibrium, but cold-atoms are clean and dissipation for reaching thermal equilibrium may be introduced by an external, thermal bath. We use the standard relaxation approximation to model the dynamics of cold-atoms driven periodically by an artificial gauge field. A competition of the driven time and the relaxation time leads to hysteresis of the mass current, and work done on the system, as a function of the relaxation time, exhibits similar behavior as Kramers transition rate in chemical reaction and one-dimensional thermal transport.

**1:15PM F50.00011 On Exact Solutions of Novel Multistate Landau-Zener Problems.**<sup>1</sup>, ANIKET PATRA, EMIL YUZBASHYAN, Rutgers University — A multistate Landau-Zener (MLZ) Hamiltonian is used to model numerous non-equilibrium experiments involving cold atoms, quantum dots and quantum dot molecules. We recently showed that all the known MLZ problems either reduce to the  $2 \times 2$  Landau Zener problem or belong to a family of mutually commuting Hamiltonians (that are polynomial in time).<sup>2</sup> Based on this classification we identify previously unknown MLZ problems, explicitly obtain their solutions and discuss relevant experimental scenarios.

**1:27PM F50.00012 Adiabaticity in a dimerised optical lattice site with increasing laser intensity**, SCOTT TAYLOR, CHRIS HOOLEY, University of St Andrews, UK — Recent experiments attempting to simulate magnetic phenomena with cold atoms in optical lattices rely on systems of a few atoms in dimerised lattice sites. These atoms may be manipulated by deformations of the lattice potential, which often need to be adiabatic, but must also happen quickly. We consider such a system of two fermions in a time-dependent double well potential, described by a two-site Hubbard model with time-dependent hopping and interaction energies. The adiabaticity of the following process is analysed: the system is prepared in the ground state of a shallow potential, which is smoothly transformed to a deep potential over some period of time. Experimentally, this corresponds to ramping up the intensity of the lasers generating the lattice. We present numerical and analytical results, demonstrating principles to design fast, adiabatic ramp profiles.

**1:39PM F50.00013 Non-equilibrium dynamics of a quantum gas in a box**, ZORAN HADZIBABIC, University of Cambridge — For the past two decades harmonically trapped ultracold atomic gases have been used with great success to study both equilibrium and non-equilibrium many-body physics in a flexible experimental setting. Recently, we achieved the first atomic Bose-Einstein condensate in an essentially uniform potential of an optical-box trap<sup>1</sup>, which has opened new possibilities for closer connections with other many-body systems and the theories that rely on the translational symmetry of the system. I will present our recent experiments on non-equilibrium phenomena in this system, including the study of the Kibble-Zurek dynamics of spontaneous symmetry breaking in a quenched homogeneous gas<sup>2</sup>.
