, DONG WANG, Rice University, JEONG-MAN PARK, Rice University and The Catholic University of Korea, MAN CHEN, MICHAEL DEEM, Rice University — Biological systems are modular, and this modularity affects the evolution of biological systems over time and in different environments. We here develop a theory for the dynamics of evolution in a rugged, modular fitness landscape. We show analytically how horizontal gene transfer couples to the modularity in the system and leads to more rapid rates of evolution at short times. The model, in general, analytically demonstrates a selective pressure for the prevalence of modularity in biology. We use this model to show how the evolution of the influenza virus is affected by the modularity of the proteins that are recognized by the human immune system. A modular model of the fitness landscape of the virus better fits the observed virus evolution data.

### **9:00AM K39.00004 In-silico studies of neutral drift for functional protein interaction networks**

, MD ZULFIKAR ALI, Clark University, NED S WINGREEN, Princeton University, RANJAN MUKHOPADHYAY, Clark University — We have developed a minimal physically-motivated model of protein-protein interaction networks. Our system consists of two classes of enzymes, activators (e.g. kinases) and deactivators (e.g. phosphatases), and the enzyme-mediated activation/deactivation rates are determined by sequence-dependent binding strengths between enzymes and their targets. The network is evolved by introducing random point mutations in the binding sequences where we assume that each new mutation is either fixed or entirely lost. We apply this model to studies of neutral drift in networks that yield oscillatory dynamics, where we start, for example, with a relatively simple network and allow it to evolve by adding nodes and connections while requiring that dynamics be conserved. Our studies demonstrate both the importance of employing a sequence-based evolutionary scheme and the relative rapidity (in evolutionary time) for the redistribution of function over new nodes via neutral drift. Surprisingly, in addition to this redistribution time we discovered another much slower timescale for network evolution, reflecting hidden order in sequence space that we interpret in terms of sparsely connected domains.

### **9:12AM K39.00005 Phase transitions in the evolution of gene regulatory networks**, ANTUN SKANATA,

EDO KUSSELL, New York Univ NYU — The role of gene regulatory networks is to respond to environmental conditions and optimize growth of the cell. A typical example is found in bacteria, where metabolic genes are activated in response to nutrient availability, and are subsequently turned off to conserve energy when their specific substrates are depleted. However, in fluctuating environmental conditions, regulatory networks could experience strong evolutionary pressures not only to turn the right genes on and off, but also to respond optimally under a wide spectrum of fluctuation timescales. The outcome of evolution is predicted by the long-term growth rate, which differentiates between optimal strategies. Here we present an analytic computation of the long-term growth rate in randomly fluctuating environments, by using mean-field and higher order expansion in the environmental history. We find that optimal strategies correspond to distinct regions in the phase space of fluctuations, separated by first and second order phase transitions. The statistics of environmental randomness are shown to dictate the possible evolutionary modes, which either change the structure of the regulatory network abruptly, or gradually modify and tune the interactions between its components.

### **9:24AM K39.00006 ABSTRACT MOVED TO C39.004 —**

### **9:36AM K39.00007 Shannon Entropy of the Canonical Genetic Code<sup>1</sup>**, LOUIS NEMZER, Nova Southeastern

University — The probability that a non-synonymous point mutation in DNA will adversely affect the functionality of the resultant protein is greatly reduced if the substitution is conservative. In that case, the amino acid coded by the mutated codon has similar physico-chemical properties to the original. Many simplified alphabets, which group the 20 common amino acids into families, have been proposed. To evaluate these schema objectively, we introduce a novel, quantitative method based on the inherent redundancy in the canonical genetic code. By calculating the Shannon information entropy carried by 1- or 2-bit messages, groupings that best leverage the robustness of the code are identified. The relative importance of properties related to protein folding - like hydrophathy and size - and function, including side-chain acidity, can also be estimated. In addition, this approach allows us to quantify the average information value of nucleotide codon positions, and explore the physiological basis for distinguishing between transition and transversion mutations.

### **9:48AM K39.00008 Genome-scale modeling of the evolutionary path to C4 photosynthesis**, CHRISTOPHER R. MYERS, Cornell University, ELI BOGART, Cornell University & Brigham and Women's Hospital — In C4 photosynthesis, plants maintain a high carbon dioxide level in specialized bundle sheath cells surrounding leaf veins and restrict CO<sub>2</sub> assimilation to those cells, favoring CO<sub>2</sub> over O<sub>2</sub> in competition for Rubisco active sites. In C3 plants, which do not possess such a carbon concentrating mechanism, CO<sub>2</sub> fixation is reduced due to this competition. Despite the complexity of the C4 system, it has evolved convergently from more than 60 independent origins in diverse families of plants around the world over the last 30 million years. We study the evolution of the C4 system in a genome-scale model of plant metabolism that describes interacting mesophyll and bundle sheath cells and enforces key nonlinear kinetic relationships. Adapting the zero-temperature string method for simulating transition paths in physics and chemistry, we find the highest-fitness paths connecting C3 and C4 positions in the model's high-dimensional parameter space, and show that they reproduce known aspects of the C3-C4 transition while making additional predictions about metabolic changes along the path. We explore the relationship between evolutionary history and C4 biochemical subtype, and the effects of atmospheric carbon dioxide levels.

**10:00AM K39.00009 Precision matters for position decoding in the early fly embryo** , MARIELA D PETKOVA, Harvard University, GASPER TKACIK, IST Austria, ERIC F WIESCHAUS, WILLIAM BIALEK, THOMAS GREGOR, Princeton University — Genetic networks can determine cell fates in multicellular organisms with precision that often reaches the physical limits of the system. However, it is unclear how the organism uses this precision and whether it has biological content. Here we address this question in the developing fly embryo, in which a genetic network of patterning genes reaches 1% precision in positioning cells along the embryo axis. The network consists of three interconnected layers: an input layer of maternal gradients, a processing layer of gap genes, and an output layer of pair-rule genes with seven-striped patterns. From measurements of gap gene protein expression in hundreds of wild-type embryos we construct a “decoder”, which is a look-up table that determines cellular positions from the concentration means, variances and co-variances. When we apply the decoder to measurements in mutant embryos lacking various combinations of the maternal inputs, we predict quantitative changes in the output layer such as missing, altered or displaced stripes. We confirm these predictions by measuring pair-rule expression in the mutant embryos. Our results thereby show that the precision of the patterning network is biologically meaningful and a necessary feature for decoding cell positions in the early fly embryo.

**10:12AM K39.00010 Enhancing Functional Robustness of Gene Regulatory Networks Based on Fitness Landscape Design<sup>1</sup>** , KYUNG KIM, University of Washington — We aim to develop design principles for enhancing functional robustness of engineered cells using gene-network topology. We observed the effect of genetic regulation types (inhibition and activation) on robustness. Inhibition was much more stable than activation in *E. coli*. In the case of activation, if the upstream activator expression is shutdown by mutation, then its downstream expression is shut down as well. Without activation, the activator shutdown due to mutation will make its downstream expression remains “turned off”. Thus, the change in the metabolic load is higher in the activation case. Therefore, the stronger activation, the less robust the circuits are. In the inhibition case, we found that the story becomes opposite. When an inhibitor expression is shut down by mutation, the downstream expression turns on because the inhibitor is not expressed. This compensates changes in the metabolic load that might have been decreased without the inhibition. This result presents potential significant roles of network topology on the robustness of engineered cellular networks. This also emphasizes that the concept of fitness landscape, where the local slope corresponds to the fitness difference between different genotypes, can be useful to design robust gene circuits.

**10:24AM K39.00011 The ecology and evolution of microbial behavior in complex communities** , ALVARO SANCHEZ, Harvard Univ — Microbes form complex ecological communities with multiple species coexisting and interacting with each other. Often, the ecological interactions among these species are mediated by molecules that the microbes actively secrete to the outside world. A large number of microbes are decomposers, and thus particularly relevant examples of these secreted molecules are the enzymes that microbes use to break down complex organic matter (e.g. dead tissue) and extract nutrients from it. In this talk, I will present an overview of the work that we have done to understand the ecology and evolution of the genes responsible for the expression of these enzymes. In particular, I will discuss how by regulating the amount of investment in the production of extracellular enzymes, microbes may modulate ecological interactions and change the number and stability of equilibria in ecosystems.

**Wednesday, March 16, 2016 8:00AM - 11:00AM —**  
**Session K40 GSNP GSOF: Mechanical Metamaterials and Origami II** 343 - Katia Bertoldi, Harvard University

**8:00AM K40.00001 Combinatorial Mechanical Metamaterials** , MARTIN VAN HECKE, Amolf Amsterdam & Leiden University — The structure of most mechanical metamaterials is periodic so that their design space is that of the unit cell. Here we introduce a combinatorial strategy to create a vast number of distinct mechanical metamaterials, each with a unique spatial texture and response. These are aperiodic stackings of anisotropic building blocks, and their functionality rests on both the block design and their stacking configuration which is governed by a tiling problem. We realize such metamaterials by 3D printing, and show that they act as soft machines, capable of pattern recognition and pattern analysis.

**8:12AM K40.00002 Geometry Driven Pathways in Hierarchical Mechanical Metamaterials** , CORENTIN COULAIS, Leiden University / AMOLF, ALBERICO SABBADINI, Leiden University, MARTIN VAN HECKE, Leiden University / AMOLF — Using exactly positioned vacancies in flexible tessellations of squares, we create novel hierarchical mechanical metamaterials that can exhibit multiple shape changes under mechanical actuation. By designing bending, buckling and self-contact interactions, we unravel the link between geometry and dynamical pathways and engineer 2D transformers, which explore complex sequences of symmetrical shapes.

**8:24AM K40.00003 Rigidity loss in disordered network materials** , WOUTER G. ELLENBROEK, Eindhoven University of Technology, VARDA F. HAGH, AVISHEK KUMAR, Arizona State University, M.F. THORPE, Arizona State University and University of Oxford, MARTIN VAN HECKE, Leiden University and AMOLF — Weakly jammed sphere packings show a very peculiar elasticity, with a ratio of compression modulus to shear modulus that diverges as the number of contacts approaches the minimum required for rigidity. Creating artificial isotropic network materials with this property is a challenge: so far, the least elaborate way to generate them is to actually simulate weakly compressed repulsive spheres. The next steps in designing such networks hinge upon a solid understanding of what properties of the sphere-packing derived network are essential for its elasticity. We elucidate the topological aspects of this question by comparing the rigidity transition in these networks to that in other random spring network models, including the common bond-diluted triangular net and a self-stress-free variant of that. We use the pebble game algorithm for identifying rigid clusters in mechanical networks to demonstrate that the marginally rigid state in sphere packings is perfectly isostatic everywhere, and the addition or removal of a single bond creates a globally stressed or globally floppy network, respectively. By contrast, the other classes of random network random networks show a more localized response to addition and removal of bonds, and, correspondingly, a more gradual rigidity transition.

**8:36AM K40.00004 Foam-like compression behavior of fibrin networks** , XIAOJUN LIANG, University of Pennsylvania, OLEG KIM, University of Notre Dame, RUSTEM LITVINOV, JOHN WEISEL, University of Pennsylvania, MARK ALBER, University of Notre Dame, PRASHANT PUROHIT, University of Pennsylvania — The rheological properties of fibrin networks have been of long-standing interest, especially shear and tensile responses. Their compressive behavior, however, remains unexplored. We show that the compressive behavior of fibrin networks consists of three regimes: 1) an initial linear regime, in which most fibers are straight, 2) a plateau regime, in which more and more fibers buckle and collapse, and 3) a markedly non-linear regime, in which network densification occurs by bending of buckled fibers and inter-fiber contacts. Importantly, the spatially non-uniform network deformation included formation of a moving phase boundary along the axis of strain, which segregated the fibrin network into two phases with different fiber densities and structure. The Young's modulus of the linear phase depends quadratically on the fibrin volume fraction while that in the densified phase depends cubically on it. The viscoelastic plateau regime corresponds to a change of volume fraction in mixture of these two phases. We model this regime using a continuum theory of phase transitions and analytically predict the storage and loss moduli. We show they are in good agreement with the experimental data. Our work shows that fibrin networks are a member of a broad class of natural cellular materials.

**8:48AM K40.00005 Topological boundary modes in jammed matter** , DANIEL SUSSMAN, OLAF STENULL, TOM LUBENSKY, University of Pennsylvania — Granular matter at the jamming transition is poised on the brink of mechanical stability, and hence it is possible that these random systems have topologically protected surface phonons. Studying two model systems for jammed matter, we find states that exhibit distinct mechanical topological classes, protected surface modes, and ubiquitous Weyl points. The detailed statistics of the boundary modes enable tests of a standard understanding of the detailed features of the jamming transition, and show that parts of this argument are invalid.

**9:00AM K40.00006 Rigidity Percolation in Mechanical Metamaterials** , LUUK LUBBERS, MARTIN VAN HECKE, Leiden University / AMOLF — We explore rigidity percolation of non-generic diluted tilings of rigid squares coupled by hinges. These compose the backbone of a range of mechanical metamaterials, and allow for a single degree of freedom motion even for full filling. We numerically study the onset and nature of additional floppy modes which arises when sufficient square tiles are removed.

**9:12AM K40.00007 to be determined by you** , JULIA GREER, California Institute of Technology — No abstract available.

**9:48AM K40.00008 Multistable Compliant Auxetic Metamaterials Inspired by Geometric Patterns in Islamic Arts** , AHMAD RAFSANJANI, DAMIANO PASINI, Mechanical Engineering Department, McGill University, PASINILAB TEAM — Beyond their aesthetic significance, geometric patterns in Islamic arts can offer a rich source of inspiration that can be used to create new mechanical metamaterials. In this work, we follow this route and present a new class of compliant mechanical metamaterials which simultaneously exhibit negative Poisson's ratio and structural bistability. Designed by finite element simulations, this multifunctional metamaterial is fabricated by perforating a symmetric cut pattern into a sheet of natural rubber. Its building blocks are rotating units with square or triangular shapes connected together with compliant flexure hinges. Under the action of uniaxial extension, the relative rotation between the adjacent members triggers snap-through instability and brings together auxeticity and structural bistability. As a result, this metamaterial can accomplish reversible reconfiguration between two stable arrangements.

**10:00AM K40.00009 The topology of gyroscopic metamaterials** , LISA M. NASH, University of Chicago, DUSTIN KLECKNER, University of California, Merced, ALISMARI READ, University of Chicago, VINCENZO VITELLI, Instituut-Lorentz, Leiden University, ARI M. TURNER, Johns Hopkins University, WILLIAM T.M. IRVINE, University of Chicago — Mechanical metamaterials can have topologically protected states, much like their electronic and optical counterparts. We recently demonstrated this in experiment by building a meta-material composed of coupled gyroscopes on a honeycomb lattice. This system breaks time-reversal symmetry and exhibits topologically protected one-way edge modes. In this talk we will explore the relationship between the topology of the band structure and the geometry of the lattice.

**10:12AM K40.00010 Modeling the Mechanical Metamaterials with Confinement Controlled Response.** , NITIN SINGH, CORENTIN COULAIS, BASTIAAN FLORIJN, MARTIN VAN HECKE, Univ of Leiden / AMOLF — Much of the physics of two dimensional mechanical metamaterials can be understood from tiling of rigid-polygons connected by hinges. Here we map recently introduced programmable mechanical metamaterials which are elastic slabs patterned with circular holes of two different sizes to a tiling of hinged rectangles. Torsional springs in the hinges and linear springs at the outside of this mechanism allow us to capture the experimentally observed mechanical response, and we connect the physical design parameters to the shape of the rectangles, and the strength of the torsional springs. We finally show that this soft mechanism provides us with an inverse design tool for metamaterials.

**10:24AM K40.00011 Taming the Exceptional Points of Parity-Time Symmetric Acoustics** , MARC DUBOIS, CHENGZHI SHI, Univ of California - Berkeley, YUN CHEN, LEI CHENG, Fudan University, HAMIDREZA RAMEZANI, YUAN WANG, XIANG ZHANG, Univ of California - Berkeley — Parity-time (PT) symmetric concept and development lead to a wide range of applications including coherent perfect absorbers, single mode lasers, unidirectional cloaking and sensing, and optical isolators. These new applications and devices emerge from the existence of a phase transition in PT symmetric complex-valued potential obtained by balancing gain and loss materials. However, the systematic extension of such devices is adjourned by the key challenge in the management of the complex scattering process within the structure in order to engineer PT phase and exceptional points. Here, based on active acoustic elements, we experimentally demonstrate the simultaneous control of complex-valued potentials and multiple interference inside the structure at any given frequency. This method broadens the scope of applications for PT symmetric devices in many fields including optics, microwaves, electronics, which are crucial for sensing, imaging, cloaking, lasing, absorbing, etc.

**10:36AM K40.00012 Overcoming dissipation with structure: Stable propagation of mechanical signals in soft mechanical metamaterials** , KATIA BERTOLDI, JORDAN RANEY, Harvard University, NEEL NADKARNI, California Institute of Technology, CHIARA DARAIO, ETH, DENNIS KOCHMANN, California Institute of Technology, JENNIFER LEWIS, Harvard University — Soft structures with rationally designed architectures capable of large, nonlinear deformation present opportunities for the design of unprecedented, highly-tunable devices and machines. However, the highly-dissipative nature of soft materials has inherently limited the way in which such systems can be used. Here we present an architected soft system comprised of elastomeric, bistable beam elements connected by elastomeric linear springs. The dissipative nature of the polymer readily damps linear waves, preventing propagation of any mechanical signal beyond a short distance, as expected. However, the unique architecture of the system enables propagation of stable, nonlinear solitary transition waves with constant velocity and pulse geometry over arbitrary distances. Since the high damping of the material removes all other linear, small amplitude excitations, the desired pulse propagates with high fidelity and controllability. This phenomenon can be used for control signals as we demonstrate through the design of soft diodes and soft mechanical logic gates.

**10:48AM K40.00013 Combinatorial Origami** , PETER DIELEMAN, SCOTT WAITUKAITIS, MARTIN VAN HECKE, Leiden University, FOM Institute AMOLF — To design rigidly foldable quadrilateral meshes one generally needs to solve a complicated set of constraints. Here we present a systematic, combinatorial approach to create rigidly foldable quadrilateral meshes with a limited number of different vertices. The number of discrete, 1 degree-of-freedom folding branches for some of these meshes scales exponentially with the number of vertices on the edge, whilst other meshes generated this way only have two discrete folding branches, regardless of mesh size. We show how these two different behaviours both emerge from the two folding branches present in a single generic 4-vertex. Furthermore, we model generic 4-vertices as a spherical linkage and exploit a previously overlooked symmetry to create non-developable origami patterns using the same combinatorial framework.

**Wednesday, March 16, 2016 8:00AM - 11:00AM —**

Session K41 DBIO DPOLY DCOMP: Physics of Proteins: Protein-Protein Interactions 344 - Wei Wang, Nanjing University

**8:00AM K41.00001 Random close packing in protein cores<sup>1</sup>**, COREY OHERN, Yale University — Shortly after the determination of the first protein x-ray crystal structures, researchers analyzed their cores and reported packing fractions  $\phi \approx 0.75$ , a value that is similar to close packing equal-sized spheres. A limitation of these analyses was the use of 'extended atom' models, rather than the more physically accurate 'explicit hydrogen' model. The validity of using the explicit hydrogen model is proved by its ability to predict the side chain dihedral angle distributions observed in proteins. We employ the explicit hydrogen model to calculate the packing fraction of the cores of over 200 high resolution protein structures. We find that these protein cores have  $\phi \approx 0.55$ , which is comparable to random close-packing of non-spherical particles. This result provides a deeper understanding of the physical basis of protein structure that will enable predictions of the effects of amino acid mutations and design of new functional proteins.

<sup>1</sup>We gratefully acknowledge the support of the Raymond and Beverly Sackler Institute for Biological, Physical, and Engineering Sciences, National Library of Medicine training grant T15LM00705628 (J.C.G.), and National Science Foundation DMR-1307712 (L.R.).

**8:36AM K41.00002 Predicting protein-peptide interactions from scratch<sup>1</sup>**, CHENGFEI YAN, XIANJIN XU, XIAOQIN ZOU, University of Missouri, ZOU LAB TEAM — Protein-peptide interactions play an important role in many cellular processes. The ability to predict protein-peptide complex structures is valuable for mechanistic investigation and therapeutic development. Due to the high flexibility of peptides and lack of templates for homologous modeling, predicting protein-peptide complex structures is extremely challenging. Recently, we have developed a novel docking framework for protein-peptide structure prediction. Specifically, given the sequence of a peptide and a 3D structure of the protein, initial conformations of the peptide are built through protein threading. Then, the peptide is globally and flexibly docked onto the protein using a novel iterative approach. Finally, the sampled modes are scored and ranked by a statistical potential-based energy scoring function that was derived for protein-peptide interactions from statistical mechanics principles. Our docking methodology has been tested on the Peptidb database and compared with other protein-peptide docking methods. Systematic analysis shows significantly improved results compared to the performances of the existing methods. Our method is computationally efficient and suitable for large-scale applications.

**8:48AM K41.00003 Computational Studies of Protein-Protein Interface Designs**, JENNIFER GAINES, COREY O'HERN, LYNNE REGAN, Yale University — We implement a hard-sphere model for amino acid structure to study natural and designed protein-protein interfaces. Current computational methods have found limited success in designing novel interfaces and resorted to implementing several rounds of experimental mutation and selection to achieve successful designs. Here, we show that the hard-sphere model can recapitulate the side chain dihedral angle distributions for amino acids at natural protein-protein interfaces. In addition, we calculate the packing fraction in naturally occurring interfaces and find that it is comparable to dense random packing in protein cores. We then evaluate a number of successful and unsuccessful prior computational designs in terms of the number of allowed side chain dihedral angle conformations and the packing fraction of residues at the interface.

**9:00AM K41.00004 Characterizing the statistical properties of protein surfaces<sup>1</sup>**, JI HYUN BAK, ANNE-FLORENCE BITBOL, WILLIAM BIALEK, Princeton University — Proteins and their interactions form the body of the signaling transduction pathway in many living systems. In order to ensure the accuracy as well as the specificity of signaling, it is crucial that proteins recognize their correct interaction partners. How difficult, then, is it for a protein to discriminate its correct interaction partner(s) from the possibly large set of other proteins it may encounter in the cell? An important ingredient of recognition is shape complementarity. The ensemble of protein shapes should be constrained by the need for maintaining functional interactions while avoiding spurious ones. To address this aspect of protein recognition, we consider the ensemble of proteins in terms of the shapes of their surfaces. We take into account the high-resolution structures of E.coli non-DNA-binding cytoplasmic proteins, retrieved from the Protein Data Bank. We aim to characterize the statistical properties of the protein surfaces at two levels: First, we study the intrinsic dimensionality at the level of the ensemble of the surface objects. Second, at the level of the individual surfaces, we determine the scale of shape variation. We further discuss how the dimensionality of the shape space is linked to the statistical properties of individual protein surfaces.

**9:12AM K41.00005 Difference in aggregation between functional and toxic amyloids studied by atomistic simulations**, MARTIN CARBALLO PACHECO, Research Center Juelich and RWTH Aachen University, AHMED E. ISMAIL, RWTH Aachen University, BIRGIT STRODEL, Research Center Juelich and Heinrich Heine University Duesseldorf — Amyloids are highly structured protein aggregates, normally associated with neurodegenerative diseases such as Alzheimer's disease. In recent years, a number of nontoxic amyloids with physiologically normal functions, called functional amyloids, have been found. It is known that soluble small oligomers are more toxic than large fibrils. Thus, we study with atomistic explicit-solvent molecular dynamics simulations the oligomer formation of the amyloid- $\beta$  peptide A $\beta_{25-35}$ , associated with Alzheimer's disease, and two functional amyloid-forming tachykinin peptides: kassinin and neuromedin K. Our simulations show that monomeric peptides in extended conformations aggregate faster than those in collapsed hairpin-like conformations. In addition, we observe faster aggregation by functional amyloids than toxic amyloids, which could explain their lack of toxicity.

**9:24AM K41.00006 Oligomer stability of Amyloid- $\beta$  (A $\beta$ ) 25-35 : A Dissipative Particle Dynamics study**, IGOR PIVKIN, EMANUEL PETER, University of Lugano — Alzheimer's disease is strongly associated with an accumulation of Amyloid- $\beta$  (A $\beta$ ) peptide plaques in the human brain. A $\beta$  is a 43 residues long intrinsically disordered peptide and has a strong tendency to form aggregates. Evidence accumulates that A $\beta$  acts toxic to the neurons in the brain through the formation of small soluble oligomers. A $\beta$  25-35 is the smallest fragment of A $\beta$  which still retains its toxicity and its ability to form extended fibrils. In this talk we will present the results from simulations of aggregation of up to 100 A $\beta$  25-35 peptides using a novel polarizable coarse-grained protein model in combination with Dissipative Particle Dynamics.

**9:36AM K41.00007 A thermodynamic study of Abeta(16-21) dissociation from a fibril using computer simulations.**, CRISTIANO DIAS, FARBOD MAHMOUDINOBAR, ZHAOQIAN SU, New Jersey Institute of Technology — Here, I will discuss recent all-atom molecular dynamics simulations with explicit water in which we studied the thermodynamic properties of Abeta(16-21) dissociation from an amyloid fibril. Changes in thermodynamics quantities, e.g., entropy, enthalpy, and volume, are computed from the temperature dependence of the free-energy computed using the umbrella sampling method. We find similarities and differences between the thermodynamics of peptide dissociation and protein unfolding. Similarly to protein unfolding, Abeta(16-21) dissociation is characterized by an unfavorable change in enthalpy, a favorable change in the entropic energy, and an increase in the heat capacity. A main difference is that peptide dissociation is characterized by a weak enthalpy-entropy compensation. We characterize dock and lock states of the peptide based on the solvent accessible surface area. The Lennard-Jones energy of the system is observed to increase continuously in lock and dock states as the peptide dissociates. The electrostatic energy increases in the lock state and it decreases in the dock state as the peptide dissociates. These results will be discussed as well as their implication for fibril growth.

## 9:48AM K41.00008 Role of mutation on fibril formation in small peptides by REMD , FARBOD

MAHMOUDINOBAR<sup>1</sup>, CRISTIANO DIAS<sup>2</sup>, New Jersey Inst of Tech — Amyloid fibrils are now recognized as a common form of protein structure. They have wide implications for neurological diseases and entities involved in the survival of living organisms, e.g., silkworm eggshells. Biological functions of these entities are often related to the superior mechanical strength of fibrils that persists over a broad range of chemical and thermal conditions desirable for various biotechnological applications, e.g., to encapsulate drugs. Mechanical properties of fibrils was shown to depend strongly on the amino acid sequence of its constituent peptides whereby bending rigidities can vary by two orders of magnitude. Therefore, the rational design of new fibril-prone peptides with tailored properties depends on our understanding of the relation between amino acid sequence and its propensity to fibrillize. In this presentation I will show results from extensive Replica Exchange Molecular Dynamics (REMD) simulations of a 12-residue peptide containing the fibril-prone motif KFFE and its mutants. Simulations are performed on monomers, dimers, and tetramers. I will discuss effects of side chain packing, hydrophobicity, charges and beta-sheet propensity on fibril formation.

## 10:00AM K41.00009 Oligomerization of the protein tau in the Alzheimer's disease , LUCA LARINI,

Rutgers University - Camden — The Alzheimer's disease is characterized by the formation of protein aggregates both within and outside of the brain's cells, the neurons. Within the neurons, the aggregation of the microtubule associated protein tau leads to the destruction of the microtubules in the axon of the neuron. Tau is extremely flexible and is classified as an intrinsically disordered protein due to its low propensity to form secondary structure. Tau promotes tubulin assembly into microtubules, which are an essential component of the cytoskeleton of the axon. The microtubule binding region of tau consists of 4 pseudo-repeats that are critical for aggregation as well. In this study, we focus on the aggregation propensity of different segments of the microtubule binding region as well as post-translational modifications that can alter tau dynamics and structure. We have performed replica exchange molecular dynamics simulations to characterize the ensemble of conformations of the monomer and small oligomers as well as how these structures are stabilized or destabilized by mutations and post-translational modifications.

## 10:12AM K41.00010 Stability of ALS-related Superoxide Dismutase Protein variants , DANIEL

LUSEBRINK, STEVEN PLOTKIN, Department of Physics and Astronomy, University of British Columbia — Superoxide dismutase (SOD1) is a metal binding, homodimeric protein, whose misfolding is implicated in the neurodegenerative disease amyotrophic lateral sclerosis (ALS). Monomerization is believed to be a key step in the propagation of the disease. The dimer stability is often difficult to measure experimentally however, because it is entangled with protein unfolding and metal loss. We thus computationally investigate the dimer stability of mutants of SOD1 known to be associated with ALS. We report on systematic trends in dimer stability, as well as intriguing allosteric communication between mutations and the dimer interface. We study the dimer stabilities in molecular dynamics simulations and obtain the binding free energies of the dimers from pulling essays. Mutations are applied *in silico* and we compare the differences of binding free energies compared to the wild type.

## 10:24AM K41.00011 Nuclear magnetic resonance studies of bovine $\gamma$ B-crystallin<sup>1</sup> , GEORGE

THURSTON, JEFFREY MILLS, LEA MICHEL, KAYLEE MATHEWS, JOHN ZANET, ANGEL PAYAN, KEITH VAN NOSTRAND, MICHAEL KOTLARCHYK, DAVID ROSS, Rochester Institute of Technology, CHRISTOPHER WAHLE, University of Findlay, JOHN HAMILTON, Rochester Institute of Technology — Anisotropy of shape and/or interactions play an important role in determining the properties of concentrated solutions of the eye lens protein,  $\gamma$ B-crystallin, including its liquid-liquid phase transition. We are studying  $\gamma$ B anisotropic interactions with use of nuclear magnetic resonance (NMR) concentration- and temperature-dependent chemical shift perturbations (CSPs). We analyze two-dimensional heteronuclear spin quantum coherence (HSQC) spectra on backbone nitrogen and attached hydrogen nuclei for CSPs, up to 3 percent volume fraction. Cumulative distribution functions of the CSPs show a concentration and temperature-dependent spread. Many peaks that are highly shifted with either concentration or temperature are close (i) crystal intermolecular contacts (ii) locations of cataractogenic point mutations of a homologous human protein, human  $\gamma$ D-crystallin, and (iii) charged amino-acid residues. We also discuss the concentration- and temperature-dependence of NMR and quasielastic light scattering measurements of rotational and translational diffusion of  $\gamma$ B crystallin in solution, affected by interprotein attractions.

## 10:36AM K41.00012 Membrane Pore Formation by Amyloid beta (25-35) Peptide , NABIN KANDEL,

SUREN TATULIAN, University of Central Florida — Amyloid (A $\beta$ ) peptide contributes to Alzheimer's disease by a yet unidentified mechanism. One of the possible mechanisms of A $\beta$  toxicity is formation of pores in cellular membranes. We have characterized the formation of pores in phospholipid membranes by the A $\beta$ <sub>25–35</sub> peptide (GSNKGAIIGLM) using fluorescence, Fourier transform infrared spectroscopy (FTIR) and circular dichroism (CD) techniques. CD and FTIR identified formation of  $\beta$ -sheet structure upon incubation of the peptide in aqueous buffer for 2 hours. Unilamellar vesicles composed of a zwitterionic lipid, 1-palmitoyl-2-oleoyl-phosphatidylcholine (POPC), and 70% POPC plus 30% of an acidic lipid, 1-palmitoyl-2-oleoyl-phosphatidylglycerol (POPG), are made in 30 mM CaCl<sub>2</sub>. Quin-2, a fluorophore that displays increased fluorescence upon Ca<sup>2+</sup> binding, is added to the vesicles externally. Peptide addition results in increased Quin-2 fluorescence, which is interpreted by binding of the peptide to the vesicles, pore formation, and Ca<sup>2+</sup> leakage. The positive and negative control measurements involve addition of a detergent, Triton X-100, which causes vesicle rupture and release of total calcium, and blank buffer, respectively.

## 10:48AM K41.00013 Holographic characterization of protein aggregates<sup>1</sup> , CHEN WANG, XIAO ZHONG,

New York University, DAVID RUFFNER, Spheryx, Inc., ALEXANDRA STUTT, Packer Collegiate Institute, LAURA PHILIPS, Spheryx, Inc., MICHAEL WARD, DAVID GRIER, New York University — Holographic characterization directly measures the size distribution of subvisible protein aggregates in suspension and offers insights into their morphology. Based on holographic video microscopy, this analytical technique records and interprets holograms of individual aggregates in protein solutions as they flow down a microfluidic channel, without requiring labeling or other exceptional sample preparation. The hologram of an individual protein aggregate is analyzed in real time with the Lorenz-Mie theory of light scattering to measure that aggregates size and optical properties. Detecting, counting and characterizing subvisible aggregates proceeds fast enough for time-resolved studies, and lends itself to tracking trends in protein aggregation arising from changing environmental factors. No other analytical technique provides such a wealth of particle-resolved characterization data in situ. Holographic characterization promises accelerated development of therapeutic protein formulations, improved process control during manufacturing, and streamlined quality assurance during storage and at the point of use.

## Session K42 DPOLY: Polymer Dynamics - Insight from In-Situ Scattering 345 - Lilin He, Oak Ridge

National Laboratory

**8:00AM K42.00001 Local Dynamics of Acid- and Ion-containing Copolymer Melts.** , KAREN WINEY, ROBERT MIDDLETON, University of Pennsylvania, JACOB TARVER, MADHUSUDAN TYAGI, CHRISTOPHER SOLES, NIST, AMALIE FRISCHKNECHT, Sandia National Laboratory — Interest in acid- and ion-containing polymers arises in part from applications as single-ion conductors for selectively transporting a counter ion for battery applications. Structurally, the low dielectric constant of organic polymers and strong ionic interactions leads to ionic aggregation. Here the polymer backbone motion was investigated through quasi-elastic neutron scattering measurements (QENS) and compared with fully atomistic molecular dynamic simulations of precise poly(ethylene-acrylic acid) copolymers and their ionomers (pAA-y%Li). The effect of carbon spacer length ( $x=9, 15, 21$ ) between the acid groups and the degree of neutralization ( $y$ ) with Li on PE backbone dynamics were considered. Systematic slowing in chain dynamics were observed with increasing neutralization where polymer dynamics appear constrained due to anchoring effects. Simulations provide complementary viewpoints indicating a gradient in chain dynamics as a distance away from acid groups. These results indicate that the addition of pendant acid groups inhibit typical PE backbone motion and the neutralized forms strongly suppress the fraction of mobile PE chain.

**8:12AM K42.00002 Effect of Increasing Molecular Weight on the A and B blocks of a Single-ion-conducting Block Copolymer Electrolyte for Lithium Batteries** , ADRIANA ROJAS, University of California, Berkeley, SEBNEM INCEOGLU, Lawrence Berkeley National Laboratory, KANAV THAKKER, NIKOLAUS MACKAY, NITASH BALSARA, University of California, Berkeley — Single-ion-conducting block copolymer electrolytes are desirable for lithium metal batteries due to their ability to eliminate salt concentration gradients across the electrolyte; i.e., the lithium ion transference number is approximately unity. A series of poly(ethylene oxide)-*b*-poly(styrenesulfonyllithium(trifluoromethylsulfonyl)imide) (PEO-*b*-PSLiTFSI) copolymers was studied wherein the molecular weights of both blocks were varied. Small angle x-ray scattering and ac impedance spectroscopy were used to probe the dependence of ionic conductivity on morphology. Preliminary work suggests that increasing the molecular weights of the blocks results in increased disorder and lower conductivity.

**8:24AM K42.00003 SUPERCOOLED WATER IN SUPRAMOLECULAR HYDROGELS** , CLINTON WIENER, BRYAN VOGT, R.A. WEISS, University of Akron — The suppression of water crystallization with appreciable water supercooling is challenging due to its large enthalpy of fusion. A common theme to supercool water is to confine the water in the pores of microporous/mesoporous solids where mechanical confinement prevents water crystallization. Nature takes a different approach with crystallization suppression through a combination of preferential adsorption on ice nuclei and confinement between hydrophobic residues using organic components only. Here, we demonstrate that mechanically robust confinement within a hard material is not necessary to significantly supercool water. In this case, a supramolecular hydrogel, based on a random amphiphilic copolymer, is used to provide soft confinement of water between the hydrophobic aggregates with an interdomain spacing  $<8$  nm. Small angle neutron scattering (SANS) provides insight into the structural evolution of the supramolecular structure of the hydrogel on supercooling. The structural changes are sensitive to the composition of the copolymer as determined by contrast variation SANS. Similarly, the dynamics of both the copolymer and water are probed using quasielastic neutron scattering (QENS). Using QENS, a highly mobile water phase ( $\tau \approx 23$  ps) is identified to be present even when slowly cooling to as low as 220K.

**8:36AM K42.00004 Segmental chain dynamics of ABA triblock copolymer micelles in aqueous solution**<sup>1</sup> , VIVEK PRABHU, GUANGMIN WEI, NIST Material Measurement Laboratory, MICHIOHITO NAGAO, NIST Center for Neutron Research, SHRINIVAS VENKATARAMAN, YI YAN YANG, AStar-Singapore, Institute of Bioengineering and Nanotechnology, JAMES HEDRICK, IBM Almaden Research Center — The polymer physics of hierarchical, aqueous self-assembled ABA block copolymers is an active area of research for both advanced materials and biomaterial applications [1]. Scattering-based techniques provide a direct measure of the correlations and structure across multiple length and time scales. Hierarchical clusters of micelles are formed by well-defined poly(ethylene glycol) triblock copolymers with oligo-fluorene hydrophobic end-groups in aqueous solutions. The structure and dynamics of this system was studied by small-angle neutron scattering (SANS), and static and dynamic light scattering [2]. We will present new neutron spin-echo spectroscopy (NSE) results that provides direct insight into the segmental chain dynamics constrained by the  $\pi$ - $\pi$  stacking of the oligo-fluorene end groups. The dilute cluster regime within the temperature-composition phase diagram is of current interest. [1] S. Venkataraman, A.L. Lee, H.T. Maune, J.L. Hedrick, V.M. Prabhu, and Y.Y. Yang, *Macromolecules* 46, 4839 (2013). [2] V.M. Prabhu et al. "Equilibrium self-assembly, structure and dynamics of clusters of star-like micelles," *ACS Macro Letters*, 4, 1128 (2015).

<sup>1</sup>NIST Materials Genome Program

**8:48AM K42.00005 Viscoelastic hydrodynamic interactions and anomalous CM diffusion in polymer melts**<sup>1</sup> , HENDRIK MEYER, Institut Charles Sadron, CNRS Strasbourg, France — We have recently discovered that anomalous center-of-mass (CM) diffusion occurring on intermediate time scales in polymer melts can be explained by the interplay of viscoelastic and hydrodynamic interactions (VHI). The theory has been solved for unentangled melts in 3D [1] and 2D [2] and excellent agreement between theory and simulation is found, also for alkanes with a force field optimized from neutron scattering [3]. The physical mechanism considers that hydrodynamic interactions are not screened: they are time dependent because of increasing viscosity before the terminal relaxation time. The VHI are generally active in melts of any topology. They are most important at early times well before the terminal relaxation time and thus affect the nanosecond time range typically observable in dynamic neutron scattering experiments [1,3]. We illustrate the effects with recent molecular dynamics simulations of linear, ring and star polymers. [1] PRL 107, 178301 (2011); PRE 85, 051807 (2012). [2] PRL 109, 248304 (2012); Soft Matter 9, 4249 (2013). [3] PRL 111, 173003 (2013).

<sup>1</sup>Work performed with A.N. Semenov and J. Farago

**9:00AM K42.00006 Nanostructures and dynamics of macromolecules bound to attractive filler surfaces**<sup>1</sup> , TAD KOGA, DEBORAH BARKLEY, NAISHENG JIANG, MAYA ENDOH, Stony Brook University, TOMOMI MASUI, HIROYUKI KISHIMOTO, Sumitomo Rubber Industries Ltd., MICHIOHITO NAGAO, SUSHIL SATIJA, NIST Center for Neutron Research, TAKASHI TANIGUCHI, Kyoto University — We report in-situ nanostructures and dynamics of polybutadiene (PB) chains bound to carbon black (CB) fillers (the so-called "bound polymer layer (BPL)") in a good solvent. The BPL on the CB fillers were extracted by solvent leaching of a CB-filled PB compound and subsequently dispersed in deuterated toluene to label the BPL for small-angle neutron scattering and neutron spin echo techniques. Intriguingly, the results demonstrate that the BPL is composed of two regions regardless of molecular weights of PB: the inner unswollen region of  $\approx 0.5$  nm thick and outer swollen region where the polymer chains display a parabolic profile with a diffuse tail. This two-layer formation on the filler surface is similar to that reported for polymer chains adsorbed on planar substrates from melts [1]. In addition, the results show that the dynamics of the swollen bound chains can be explained by the so-called "breathing mode" and is generalized with the thickness of the swollen BPL. Furthermore, we will discuss how the breathing collective dynamics is affected by the presence of polymer chains in a matrix solution. [1] Gin et al., *Phys. Rev. Lett.*, (2012), 109, 265501.

<sup>1</sup>We acknowledge the financial support from NSF Grant No. CMMI-1332499.

**9:12AM K42.00007 SAXS/WAXS studies of shear-induced crystallization of poly(1-butene)** , MU SUNG KWEON, BINBIN LUO, WESLEY BURGHARDT, Northwestern University — Flow-induced crystallization of poly(1-butene) was studied in shear flow. Flow was produced using a Linkam shear cell that has been modified to allow x-ray access for in situ studies of polymer structure using synchrotron x-ray scattering techniques. After loading in the shear cell, samples were first heated well into the melt, and then cooled to a crystallization temperature selected such that negligible quiescent crystallization would occur on reasonable time scales. A short burst of shear flow was then applied at various rates, after which simultaneous wide- and small-angle x-ray scattering (WAXS and SAXS, respectively) data were collected to study the impact of both deformation rate and total applied strain on accelerated crystallization kinetics as well as the morphology of the resulting crystallites (e.g. degree of crystallite orientation). SAXS and WAXS data generally showed qualitative agreement in measures of the extent of crystallization and the degree of crystallite orientation. Average crystallite orientation was found to decrease over the course of crystallization. The crystalline volume fraction in the sample was calculated from the (i) SAXS invariant and (ii) integrated WAXS intensity profile to quantify the extent to which the sample crystallized at various flow c

**9:24AM K42.00008 Leveraging intrinsic chain anisotropy to align coil-coil block copolymers with magnetic fields** , YEKATERINA ROKHLENKO, KAI ZHANG, MANESH GOPINADHAN, Yale University, STEVE LARSON, University of WisconsinMadison, PAWEL MAJEWSKI, KEVIN YAGER, Brookhaven National Lab, PADMA GOPALAN, University of WisconsinMadison, COREY O'HERN, CHINEDUM OSUJI, Yale University — Magnetic field alignment of block copolymers (BCPs) has typically relied on the presence of liquid crystalline or crystalline assemblies to provide sufficient magnetic anisotropy to drive alignment. Recent experiments however show that alignment is also possible in simple coil-coil BCPs. In particular, alignment of lamellae was observed in poly(styrene-*b*-4-vinylpyridine) (PS-P4VP) on cooling across the order-disorder transition at field strengths as low as 1 T, with alignment improving markedly with increasing field strength and decreasing cooling rate. Here we discuss the intrinsic chain anisotropy which drives the observed alignment, and its display as a net microdomain anisotropy due to chain tethering at the block interface. We use in-situ X-ray scattering to study the phase behavior and temperature-, time-, and field- dependent dynamics of magnetic alignment in coil-coil BCPs, highlighting the important roles of chain anisotropy and grain size in alignment. For the right combination of field strength and grain size, we can leverage intrinsic chain anisotropy to magnetically direct self-assembly in other coil-coil systems, including cylinder-forming poly(styrene-*b*-dimethylsiloxane). Field alignment of PS-P4VP with PEO and other blends provides a route to form functional materials such as nanoporous films and ion conducting polymers.

**9:36AM K42.00009 Elucidating the Molecular Deformation Mechanism of Entangled Polymers in Fast Flow by Small Angle Neutron Scattering** , YANGYANG WANG, LUIS SANCHEZ-DIAZ, SHIWANG CHENG, KUNLUN HONG, WEI-REN CHEN, Oak Ridge National Laboratory, JIANNING LIU, PANPAN LIN, SHI-QING WANG, University of Akron — Understanding the viscoelastic properties of polymers is of fundamental and practical importance because of the vast and ever expanding demand of polymeric materials in daily life. Our current theoretical framework for describing the nonlinear flow behavior of entangled polymers is built upon the tube model pioneered by de Gennes, Doi, and Edwards. In this work, we critically examine the central hypothesis of the tube model for nonlinear rheology using small angle neutron scattering (SANS). While the tube model envisions a unique non-affine elastic deformation mechanism for entangled polymers, our SANS measurements show that the evolution of chain conformation of a well-entangled polystyrene melt closely follows the affine deformation mechanism in uniaxial extension, even when the Rouse Weissenberg number is much smaller than unity. This result provides a key clue for understanding the molecular deformation mechanism of entangled polymers in fast flow. Several implications from our analysis will be discussed in this talk.

**9:48AM K42.00010 Insights into the Dynamics of Polymers and Nanocomposites via Quasi-elastic Neutron Scattering** , MADHU SUDAN TYAGI, NIST Center for Neutron Research — Neutron scattering is a powerful technique to study polymer dynamics. In particular, its angular momentum (*Q*) dependence provide a unique opportunity to study polymer motions at different length scales of interest. This is particularly important when examining some of the crucial aspects related with glass transitions and in particular chain behavior under confinement. Of particular interests are the examples of nanocomposites and ionomers. The interactions between polymer chain and nanoparticle in nanocomposites can cause significant heterogeneities in the polymer dynamics and strongly affect its properties. Dynamical perturbations are generally expected to be limited to interfacial polymer segments. However, composites with highly anisotropic nanoparticles usually exhibit very low percolation threshold and in such systems a complex polymer relaxation behavior can be observed that is not anticipated from dilute nanoparticle dispersions in polymer matrix. A lot of progress has been made over the last decade, however, the effect of chemical binding, physical adsorption and inclusion of nanoparticles in polymer matrix on the local and global dynamics of chain molecules still remains controversial subject. In this talk I will present some examples of our recent work where neutron scattering has been able to make some important breakthroughs in these topics.

**10:24AM K42.00011 SAXS studies of the structure of a BCC-ordered block copolymer melt subjected to uniaxial extensional flow** , WESLEY BURGHARDT, ERICA MCCREADY, Northwestern University — We report in situ small-angle x-ray scattering (SAXS) investigations of a spherically-ordered block copolymer melt with a low styrene content (13%) resulting in spherical polystyrene microdomains ordered in BCC lattice. Melt annealing after clearing above the ODT produces ordered samples that have a macroscopically random orientation distribution of BCC 'grains'. Melt samples are subjected to uniaxial extensional flow in a counter-rotating drum extensional flow fixture housed in an oven with synchrotron x-ray access. During flow, initially isotropic diffraction rings in SAXS patterns become deformed, reflecting distortion of the BCC lattice. Diffracted intensity also concentrates azimuthally, indicating macroscopic alignment of the BCC lattice. There is evidence that extensional flow leads to progressive disordering of the BCC structure, with loss of higher order peaks and the emergence of a diffuse 'halo' of scattering. While the primary diffraction peak is visible in directions parallel and perpendicular to the stretching direction, the deformation of the lattice d-spacing follows affine deformation. Indications of ordering persist to higher strains in samples stretched at higher extension rates, and evidence of affine lattice deformation persists to very high strains (Hencky

**10:36AM K42.00012 Neutron Reflectivity Measurement for Polymer Dynamics near Graphene Oxide Monolayers.** , JASEUNG KOO, Korea Atomic Energy Research Institute — We investigated the diffusion dynamics of polymer chains confined between graphene oxide layers using neutron reflectivity (NR). The bilayers of polymethylmethacrylate (PMMA)/ deuterated PMMA (d-PMMA) films and polystyrene (PS)/d-PS films with various film thickness sandwiched between Langmuir-Blodgett (LB) monolayers of graphene oxide (GO) were prepared. From the NR results, we found that PMMA diffusion dynamics was reduced near the GO surface while the PS diffusion was not significantly changed. This is due to the different strength of GO-polymer interaction. In this talk, these diffusion results will be compared with dewetting dynamics of polymer thin films on the GO monolayers. This has given us the basis for development of graphene-based nanoelectronics with high efficiency, such as heterojunction devices for polymer photovoltaic (OPV) applications.

**Wednesday, March 16, 2016 8:00AM - 10:36AM –**  
**Session K43 GSNP: Complex Networks and their Applications I** 346 - Flaviano Morone, City College of New York

### 8:00AM K43.00001 Influence maximization in complex networks through optimal percolation

, FLAVIANO MORONE, HERNAN MAKSE, City College of New York, CUNY COLLABORATION, CUNY COLLABORATION — The whole frame of interconnections in complex networks hinges on a specific set of structural nodes, much smaller than the total size, which, if activated, would cause the spread of information to the whole network, or, if immunized, would prevent the diffusion of a large scale epidemic. Localizing this optimal, that is, minimal, set of structural nodes, called influencers, is one of the most important problems in network science. Here we map the problem onto optimal percolation in random networks to identify the minimal set of influencers, which arises by minimizing the energy of a many-body system, where the form of the interactions is fixed by the non-backtracking matrix of the network. Big data analyses reveal that the set of optimal influencers is much smaller than the one predicted by previous heuristic centralities. Remarkably, a large number of previously neglected weakly connected nodes emerges among the optimal influencers. Reference: F. Morone, H. A. Makse, Nature 524,65-68 (2015)

### 8:12AM K43.00002 Collective opinion formation on fluctuating networks

, VUDTIWAT NGAM-PRUETIKORN, Okinawa Institute of Science and Technology, GREG STEPHENS, Vrije Universiteit Amsterdam & Okinawa Institute of Science and Technology — Thanks to the advent of online social networks, not only are we more connected than ever but we are also able to design and maintain our own social networks. An insight into this phenomenon will be key to understanding modern societies. To this end, we argue that active network maintenance exposes individuals to selective exposure (preference for agreeing information sources) and we explore how this could affect the structure of social networks and collective opinion formation. More technically, we investigate opinion dynamics on a complex network with fast stochastic rewiring. We show that selective exposure while inducing segregation of agents with different opinions, stabilises consensus state regardless of opinion update rules. We argue further that selective exposure can lead to a shorter time to consensus. The time to consensus has non-trivial dependence on the magnitude of selective exposure. Moreover, we find for some opinion updating rules, selective exposure can increase the lifetime of opinion segregation (polarisation of opinions).

### 8:24AM K43.00003 Choice Shift in Opinion Network Dynamics<sup>1</sup>

, MICHAEL GABBAY, University of Washington — Choice shift is a phenomenon associated with small group dynamics whereby group discussion causes group members to shift their opinions in a more extreme direction so that the mean post-discussion opinion exceeds the mean pre-discussion opinion. Also known as group polarization, choice shift is a robust experimental phenomenon and has been well-studied within social psychology. In opinion network models, shifts toward extremism are typically produced by the presence of stubborn agents at the extremes of the opinion axis, whose opinions are much more resistant to change than moderate agents. However, we present a model in which choice shift can arise without the assumption of stubborn agents; the model evolves member opinions and uncertainties using coupled nonlinear differential equations. In addition, we briefly describe the results of a recent experiment conducted involving online group discussion concerning the outcome of National Football League games are described. The model predictions concerning the effects of network structure, disagreement level, and team choice (favorite or underdog) are in accord with the experimental results.

<sup>1</sup>This research was funded by the Office of Naval Research and the Defense Threat Reduction Agency.

### 8:36AM K43.00004 Social Network Influence and Personal Financial Status

, SHAOJUN LUO, FLAVIANO MORONE, City College of CUNY, CARLOS SARRAUTE, Grandata, Buenos Aires, Argentina, HERNAN MAKSE, City College of CUNY — Networks of social ties emerging from individual economic needs display a highly structured architecture. In response to socio-economic demands, people reshape their circle of contacts for maximizing their social status, and ipso facto, the pattern of their interconnections is strongly correlates with their personal financial situation. In this work we transform this qualitative and verbal statement into an operative definition, which allows us to quantify the economic wellness of individuals through a measure of their collective influence. We consider the network of mobile phone calls made by the Mexican population during three months, in order to study the correlation of person's economic situation with her network location. Notably, we find that rich people tend to be also the most influential nodes, i.e., they self-organize to optimally position themselves in the network. This finding may be also raised at the level of a principle, a fact that would explain the emergence of the phenomenon of collective influence itself as the result of the local optimization of socio-economic interactions. Our method represents a powerful and efficient indicator of socio-economic robustness, which may be applied to maximize the effect of large scale economic intervention and stimulus policies

### 8:48AM K43.00005 More Opportunities than Wealth: Inequality and Emergent Social Classes in a Network of Power and Frustration

, CRISTIANO NISOLI, Los Alamos National Laboratory, BENOIT MAHAULT, Service de Physique de l'Etat Condense, CNRS UMR 3680, CEA-Saclay, 91191 Gif-sur-Yvette, France, AVADH SAXENA, Los Alamos National Laboratory — We introduce a minimal agent-based model to qualitatively conceptualize the allocation of limited wealth among more abundant opportunities. There the interplay of power, satisfaction and frustration determines the distribution, concentration, and inequality of wealth. Our framework allows us to compare subjective measures of frustration and satisfaction to collective measures of fairness in wealth distribution, such as the Lorenz curve and the Gini index. We find that a completely libertarian, law-of-the-jungle setting, where every agent can acquire wealth from, or lose wealth to, anybody else invariably leads to large inequality. The picture is however dramatically modified when hard constraints are imposed over agents, and they are limited to share wealth with neighbors on a network. We address dynamical societies via an out of equilibrium coevolution of the network, driven by a competition between power and frustration. The ratio between power and frustration controls different dynamical regimes separated by kinetic transitions and characterized by drastically different values of the indices of equality. In particular, it leads to the emergence of three self-organized social classes, lower, middle, and upper class, whose interactions drive a cyclical regime.

### 9:00AM K43.00006 Dynamic networks community detection via low rank component recovery of adjacency matrices

, WEI BAO, GEORGE MICHAILIDIS, University of Michigan, Ann Arbor — Dynamic community detection in networks has been of high interest due to its various applications. In this work, we apply low rank extraction technique on adjacency matrices to approximate the community structures. Not only can we accurately identify the phase transition time points where significant changes in the community structures occur, but also we can increase the accuracy of the core community structures recovered in the peace time ranges by averaging the low rank components. A systematic methodology has been proposed as how to accomplish the target. Factor model, and stochastic block model (including weighted scenario) have been tested for the robustness of our model. Besides, applications on both Kuramoto model and US Senate Roll Call data are also carried out and interesting results are obtained.

### 9:12AM K43.00007 Multiway spectral community detection in networks

, XIAO ZHANG, MARK NEWMAN, Univ of Michigan - Ann Arbor — Spectral methods are widely used for community detection in networks because of their high efficiency and amenability to formal analysis. However, spectral algorithms have been limited to the division of networks into only two or three communities. Here we present a spectral algorithm that can directly divide a network into any number of communities. The algorithm makes use of a mapping from modularity maximization to a vector partitioning problem, combined with a fast heuristic for vector partitioning. We compare the performance of this spectral algorithm with previous approaches and find it to give superior results. We also give demonstrative applications of the algorithm to real-world networks and find that it produces results in good agreement with expectations for the networks studied.

**9:24AM K43.00008 Utilizing Maximal Independent Sets as Dominating Sets in Scale-Free Networks<sup>1</sup>** , N. DERZSY, Rensselaer Polytechnic Institute, F. MOLNAR JR., Northwestern University, B. K. SZYMANSKI, G. KORNISS, Rensselaer Polytechnic Institute — Dominating sets provide key solution to various critical problems in networked systems, such as detecting, monitoring, or controlling the behavior of nodes. Motivated by graph theory literature [Erdos, *Israel J. Math.* **4**, 233 (1966)], we studied *maximal independent sets* (MIS) as dominating sets in scale-free networks. We investigated the scaling behavior of the size of MIS in artificial scale-free networks with respect to multiple topological properties (size, average degree, power-law exponent, assortativity), evaluated its resilience to network damage resulting from random failure or targeted attack [Molnar et al., *Sci. Rep.* **5**, 8321 (2015)], and compared its efficiency to previously proposed dominating set selection strategies. We showed that, despite its small set size, MIS provides very high resilience against network damage. Using extensive numerical analysis on both synthetic and real-world (social, biological, technological) network samples, we demonstrate that our method effectively satisfies four essential requirements of dominating sets for their practical applicability on large-scale real-world systems: 1.) small set size, 2.) minimal network information required for their construction scheme, 3.) fast and easy computational implementation, and 4.) resiliency to network damage.

<sup>1</sup>Supported by DARPA, DTRA, and NSF.

**9:36AM K43.00009 Growing Networks with Positive and Negative Links** , CORYNNE DECH, SHADRACK ANTWI, LEAH SHAW, College of William and Mary — Scale-free networks grown via preferential attachment have been used to model real-world networks such as the Internet, citation networks, and social networks. Here we investigate signed scale-free networks where an edge represents a positive or negative connection. We present analytic results and simulation for a growing signed network model. We compare the signed network to an unsigned scale-free network. We discuss several options for preferential attachment in a signed network that could be further adapted to model the accumulation of links over time in real-world signed networks.

**9:48AM K43.00010 Robustness of networks of networks with degree-degree correlation** , BYUNGJOON MIN, City College of New York, SANTIAGO CANALS, Instituto de Neurociencias, HERNAN MAKSE, City College of New York — Many real-world complex systems ranging from critical infrastructure and transportation networks to living systems including brain and cellular networks are not formed by an isolated network but by a network of networks. Randomly coupled networks with interdependency between different networks may easily result in abrupt collapse. Here, we seek a possible explanation of stable functioning in natural networks of networks including functional brain networks. Specifically, we analyze the robustness of networks of networks focused on one-to-many interconnections between different networks and degree-degree correlation. Implication of the network robustness on functional brain networks of rats is also discussed.

**10:00AM K43.00011 Degree distributions of bipartite networks and their projections** , DEMIVAL VASQUES FILHO, DION O'NEALE, University of Auckland — Bipartite networks play an important role in the analysis of social and economic systems as they explicitly show the conceptual links between different types of entities. As an example, it is possible to build networks to investigate interactions regarding scientific and technological innovation that are well represented by a natural bipartite structure. Since we are often most interested in only one of the node types (e.g. the authors in an author-publication network), it is common to end up working with a projected version of the underlying bipartite network. The topology of projections and the dynamics that take place on it are highly dependent on the probability distribution of nodes degrees. We use the formalism of generating functions to infer how the degree distributions of the original bipartite network affect the distribution in the projected version. Moreover, we create artificial bipartite graphs by arbitrarily choosing degree distributions for the sets of nodes and construct the projection to analyze the resulting probability distribution. Our findings show that when projecting onto a particular set of nodes, the resulting degree distribution follows the behavior of the probability distribution of such nodes, subject, however, to the tail of the opposite distribution.

**10:12AM K43.00012 Spectra of Adjacency Matrices in Networks with Extreme Introverts and Extroverts<sup>1</sup>** , KEVIN E. BASSLER, Department of Physics, University of Houston, ROYCE K.P. ZIA, Department of Physics and Astronomy, Iowa State University, and Department of Physics, Virginia Tech — In recent studies of networks with preferred degrees (suitable for describing social networks in which individuals tend to prefer a certain number of contacts), the XIE model of extreme introverts and extroverts was found to display remarkable collective behavior and to raise interesting theoretical issues. Though this system is defined through its dynamics, i.e., introverts/extroverts always cut/add links, the steady state turns out to be a Boltzmann-like distribution. While the intra-group links are static, the cross-links are dynamic and lead to an ensemble of bipartite graphs, with extraordinary long-ranged correlations between elements of the incidence matrix (details in JSTAT P07013, 2015). Here, we report simulation studies of a different perspective of networks, namely, the spectra associated with this ensemble of adjacency matrices. As a baseline, we first consider the spectra associated with (the adjacency matrices of) a simple random (Erdős-Rényi) ensemble of bipartite graphs, where simulation results can be understood analytically.

<sup>1</sup>Work supported by the NSF through grants DMR-1206839 and DMR-1507371.

**10:24AM K43.00013 Complex root networks of Chinese characters** , PO-HAN LEE, Affiliated Senior High School of National Taiwan Normal University, Taipei, Taiwan, JIA-LING CHEN, Chinese Department, National Taiwan Normal University, Taipei, Taiwan, PO-CHENG WANG, Institute of Physics, Academia Sinica, Nankang, Taipei, Taiwan, TING-TING CHI, Chinese Department, National Taiwan Normal University, Taipei, Taiwan, ZHI-REN XIAO, ZIH-JIAN JHANG, Physics Department, National Taiwan University, Taipei, Taiwan, YEONG-NAN YEH, Institute of Mathematics, Academia Sinica, Nankang, Taipei, Taiwan, YIH-YUH CHEN, Physics Department, National Taiwan University, Taipei, Taiwan, CHIN-KUN HU, Institute of Physics, Academia Sinica, Taipei, Taiwan — There are several sets of Chinese characters still available today, including Oracle Bone Inscriptions (OBI) in Shang Dynasty, Chu characters (CC) used in Chu of Warring State Period, Small Seal Script in dictionary Shuowen Jiezi (SJ) in Eastern Han Dynasty, and Kangxi Dictionary (KD) in Qing Dynasty. Such as Chinese characters were all constructed via combinations of meaningful patterns, called roots. Our studies for the complex networks of all roots indicate that the roots of the characters in OBI, CC, SJ and KD have characteristics of small world networks and scale-free networks.

**Wednesday, March 16, 2016 8:00AM - 11:00AM —**  
**Session K44 GQI: Quantum Error Correction, Control & Simulation** 347 - Todd Brun, University of Southern California

**8:00AM K44.00001 Hamiltonian Engineering for High Fidelity Quantum Operations**, HUGO RIBEIRO, ALEXANDRE BAKSIC, AASHISH CLERK, McGill University — High-fidelity gates and operations are crucial to almost every aspect of quantum information processing. In recent experiments [1], fidelity is mostly limited by unwanted couplings with states living out of the logical subspace. This results in both leakage and phase errors. Here, we present a general method to deal simultaneously with both these issues and improve the fidelity of quantum gates and operations. Our method is applicable to a wide variety of systems. As an example, we can correct gates for superconducting qubits [1], improve coherent state transfer between a single NV centre electronic spin and a single nitrogen nuclear spin [2], improve control over a nuclear spin ensemble [3], etc. Our method is intimately linked to the Magnus expansion. By modifying the Magnus expansion of an initially given Hamiltonian  $H_i$ , we find analytically additional control Hamiltonians  $H_{\text{ctrl}}$  such that  $H_i + H_{\text{ctrl}}$  leads to the desired gate while minimizing both leakage and phase errors. [1] Zijun Chen, *et al.*, arXiv:1509.05470. [2] G. D. Fuchs, *et al.*, Nat. Phys. 7, 789793 (2011). [3] Mathieu Munsch, *et al.*, Nat. Nano. 9, 671675 (2014).

**8:12AM K44.00002 Method for generating all uniform  $\pi$ -pulse sequences used in deterministic dynamical decoupling<sup>1</sup>**, HAOYU QI<sup>2</sup>, JONATHAN DOWLING<sup>3</sup>, Department of Physics & Astronomy, Louisiana State University — Dynamical decoupling has been actively investigated since Viola first suggested using a pulse sequence to protect a qubit from decoherence. Since then, many schemes of dynamical decoupling have been proposed to achieve high-order suppression, both analytically and numerically. However, hitherto, there has not been a systematic framework to understand all existing uniform  $\pi$ -pulse dynamical decoupling schemes. In this report, we use the projection pulse sequences as basic building blocks and concatenation as a way to combine them. We derived a concatenated-projection dynamical decoupling, a framework in which we can systematically construct pulse sequences to achieve arbitrary high suppression order. All previously known uniform dynamical decoupling sequences using  $\pi$  pulse can be fit into this framework. Understanding uniform dynamical decoupling as successive projections on the Hamiltonian will also give insights on how to invent new ways to construct better pulse sequences.

**8:24AM K44.00003 Quantum gates with optimal bandwidth in noisy environments**, GUANG HAO LOW, YODER THEODORE, ISAAC CHUANG, Massachusetts Inst of Tech-MIT — The traditional approach of open-loop quantum error correction suppresses certain systematic imperfections  $\epsilon$  in quantum control to higher orders  $\epsilon^{\mathcal{O}(L)}$  by a well-designed sequence of  $L$  imperfect quantum gates. However, this philosophy of maximal flatness leads to an  $\epsilon$ -bandwidth that scales poorly with length and a residual that is easily overwhelmed by unaccounted sources of noise. We advance the paradigm of eiripple compensated gates that directly optimize for bandwidth given the limitations imposed by noise of magnitude  $\delta$ , leading to dramatically improved performance. Where  $\epsilon$  represent amplitude errors, we provide a formalism that generalizes both approaches and is effective at finding such gates. With it, we provide in closed-form the phase angles for an optimal family of population inversion gates with an  $\bar{\epsilon}$ -bandwidth of  $\mathcal{O}(\frac{\log \delta^{-1}}{L})$  — a quadratic improvement over optimal maximally flat variants. We also construct optimal NOT gates and discuss extensions to other gates and error models.

**8:36AM K44.00004 Engineering autonomous error correction in stabilizer codes at finite temperature**, C. DANIEL FREEMAN, University of California - Berkeley, CHRIS HERDMAN, University of Waterloo, BIRGITTA WHALEY, University of California - Berkeley — We present an error correcting protocol that enhances the lifetime of stabilizer code based qubits which are susceptible to string-like error modes at finite temperature, such as the toric code. The primary tool employed is dynamic application of the CSWAP operator, a local, unitary operator which exchanges defects and thereby translates quasiparticles. Crucially, the protocol does not require any information about the locations of quasiparticles, and can be used to enhance the lifetime of an encoded qubit in the absence of stabilizer measurement. This work was supported by the NSF grant DGE-1106400.

**8:48AM K44.00005 New class of photonic quantum error correction codes**, MATTI SILVERI, MARIOS MICHAEL, R. T. BRIERLEY, JUHA SALMILEHTO, VICTOR V. ALBERT, LIANG JIANG, S. M. GIRVIN, Departments of Physics and Applied Physics, Yale University — We present a new class of quantum error correction codes for applications in quantum memories, communication and scalable computation. These codes are constructed from a finite superposition of Fock states and can exactly correct errors that are polynomial up to a specified degree in creation and destruction operators. Equivalently, they can perform approximate quantum error correction to any given order in time step for the continuous-time dissipative evolution under these errors. The codes are related to two-mode photonic codes[1] but offer the advantage of requiring only a single photon mode to correct loss (amplitude damping), as well as the ability to correct other errors, e.g. dephasing. Our codes are also similar in spirit to photonic "cat codes" but have several advantages including smaller mean occupation number and exact rather than approximate orthogonality of the code words. We analyze how the rate of uncorrectable errors scales with the code complexity and discuss the unitary control for the recovery process. These codes are realizable with current superconducting qubit technology[2] and can increase the fidelity of photonic quantum communication and memories. [1] I.Chuang et al., Phys. Rev. A 56, 1114 (1997).[2] R.Heeres et al., Phys. Rev. Lett. 115, 137002 (2015).

**9:00AM K44.00006 Non-commuting two-local Hamiltonians for quantum error suppression**, ELEANOR RIEFFEL, NASA Ames Research Center, ZHANG JIANG, Stinger Ghaffarian Technologies Inc., NASA Ames Research Center, QUAIL TEAM — Physical constraints make it challenging to implement and control multi-body interactions. Designing quantum information processes with Hamiltonians consisting of only one- and two-local terms is a worthwhile challenge. A common approach to robust storage of quantum information is to encode in the ground subspace of a Hamiltonian. Even allowing particles with high Hilbert-space dimension, it is not possible to protect quantum information from single-site errors by encoding in the ground subspace of any Hamiltonian containing only commuting two-local terms [1]. We demonstrate how to get around this no-go result by encoding in the ground subspace of a Hamiltonian consisting of non-commuting two-local terms arising from the gauge operators of a subsystem code. Specifically, we show how to protect stored quantum information against single-qubit errors using a Hamiltonian consisting of sums of the gauge generators from Bacon-Shor codes [2] and generalized-Bacon-Shor code [3]. Thus, non-commuting two-local Hamiltonians have more error-suppressing power than commuting two-local Hamiltonians. Finally, we comment briefly on the robustness of the whole scheme. [1] I. Marvian and D. A. Lidar, PRL 113, 260504 (2014) [2] D. Bacon, PRA 73, 012340 (2006) [3] S. Bravyi, PRA 83, 012320 (2011)

**9:12AM K44.00007 Error threshold for the surface code in a superohmic environment<sup>1</sup>**, DANIEL A. LOPEZ-DELGADO, Universidade Estadual de Campinas - Brazil, E. NOVAIS, Universidade Federal do ABC - Brazil, EDUARDO R. MUCCILO, University of Central Florida, AMIR O. CALDEIRA, Universidade Estadual de Campinas - Brazil — Using the Keldysh formalism, we study the fidelity of a quantum memory over multiple quantum error correction cycles when the physical qubits interact with a bosonic bath at zero temperature. For encoding, we employ the surface code, which has one of the highest error thresholds in the case of stochastic and uncorrelated errors. The time evolution of the fidelity of the resulting two-dimensional system is cast into a statistical mechanics phase transition problem on a three-dimensional spin lattice, and the error threshold is determined by the critical temperature of the spin model. For superohmic baths, we find that time does not affect the error threshold: its value is the same for one or an arbitrary number of quantum error correction cycles.

**9:24AM K44.00008 Fidelity of a quantum state protected by the surface code in the presence of a finite-temperature bosonic bath<sup>1</sup>**, E. NOVAIS, Federal University of ABC (SP-BRAZIL), A. J. STANFORTH, EDUARDO R. MUCCIOLO, University of Central Florida — We evaluate the fidelity of a multi-qubit quantum state protected by the surface code during a single quantum error correction cycle when qubits couple to a gapless bosonic environment. We discuss the protection of the state for different spectral functions and bath temperatures. Analytical results are supported by finite-size scaling analyses based on Monte Carlo and exact numerical calculations. Our results demonstrate a finite threshold that explicitly depends on the bath-mediated qubit-qubit interaction range and bath spectral function and temperature.

**9:36AM K44.00009 Repeated quantum error correction by real-time feedback on continuously encoded qubits**, JULIA CRAMER, NORBERT KALB, M. ADRIAAN ROL, BAS HENSEN, MACHIEL S. BLOK, QuTech and Kavli Institute of Nanoscience Delft, MATTHEW MARKHAM, DANIEL J. TWITCHEN, Element Six Innovation, RONALD HANSON, TIM H. TAMINIAU, QuTech and Kavli Institute of Nanoscience Delft — Because quantum information is extremely fragile, large-scale quantum information processing requires constant error correction. To be compatible with universal fault-tolerant computations, it is essential that quantum states remain encoded at all times and that errors are actively corrected. I will present such active quantum error correction in a hybrid quantum system based on the nitrogen vacancy (NV) center in diamond [1]. We encode a logical qubit in three long-lived nuclear spins, detect errors by multiple non-destructive measurements using the optically active NV electron spin and correct them by real-time feedback. By combining these new capabilities with recent advances in spin control, multiple cycles of error correction can be performed within the dephasing time. We investigate both coherent and incoherent errors and show that the error-corrected logical qubit can indeed store quantum states longer than the best spin used in the encoding [1]. Furthermore, I will present our latest results on increasing the number of qubits in the encoding, required for quantum error correction for both phase- and bit-flip. [1] J. Cramer et al. 2015; arXiv:1508.01388v1

**9:48AM K44.00010 Serialized Quantum Error Correction Protocol for High-Bandwidth Quantum Repeaters**, ANDREW GLAUDELL, Univ. of Maryland, National Institute of Standards and Technology, EDO WAKS, Univ. of Maryland and the National Institute of Standards and Technology, JACOB TAYLOR, Univ. of Maryland, National Institute of Standards and Technology — Advances in single-photon creation, transmission, and detection suggest that sending quantum information over optical fibers may have low enough losses to be overcome using quantum error correction. Such error-corrected communication is equivalent to a novel quantum repeater scheme, but crucial questions regarding implementation and system requirements remain open. In this talk, I will show that long-range entangled bit generation with rates approaching  $10^8$  entangled bits per second may be possible using a completely serialized protocol, in which photons are generated, entangled, and error corrected via sequential, one-way interactions with as few matter qubits as possible. Provided loss and error rates of the required elements are below the threshold for quantum error correction, this scheme demonstrates improved performance over transmission of single photons. We find improvement in entangled bit rates at large distances using this serial protocol and various quantum error correcting codes.

**10:00AM K44.00011 Spectroscopy of cross-correlations of environmental noises with two qubits<sup>1</sup>**, LUKASZ CYWINSKI, Institute of Physics, Polish Academy of Sciences, PIOTR SZANKOWSKI, MAREK TRIPPENBACH, Faculty of Physics, University of Warsaw, — A single qubit driven by an appropriate sequence of control pulses can serve as a spectrometer of local noise affecting its energy splitting. We show that by driving and observing two spatially separated qubits, it is possible to reconstruct the spectrum of cross-correlations of noises acting at various locations. When the qubits are driven by the same sequence of pulses, real part of cross-correlation spectrum can be reconstructed, while applying two distinct sequence to the two qubits allows for reconstruction of imaginary part of this spectrum [1]. The latter quantity contains information on either causal correlations between environmental dynamics at distinct locations, or on the occurrence of propagation of noisy signals through the environment. While entanglement between the qubits is not necessary, its presence enhances the signal from which the spectroscopic information is reconstructed. [1] P. Szankowski, M. Trippenbach, and L. Cywinski, arXiv:1507.03897.

**10:12AM K44.00012 1D quantum simulation using a solid state platform<sup>1</sup>**, MEGAN KIRKENDALL, PATRICK IRVIN, MENGCHEN HUANG, JEREMY LEVY, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin - Madison — Understanding the properties of large quantum systems can be challenging both theoretically and numerically. One experimental approach—quantum simulation—involves mapping a quantum system of interest onto a physical system that is programmable and experimentally accessible. A tremendous amount of work has been performed with quantum simulators formed from optical lattices; by contrast, solid-state platforms have had only limited success. Our experimental approach to quantum simulation takes advantage of nanoscale control of a metal-insulator transition at the interface between two insulating complex oxide materials<sup>2</sup>. This system naturally exhibits a wide variety of ground states (e.g., ferromagnetic, superconducting) and can be configured into a variety of complex geometries. We will describe initial experiments that explore the magnetotransport properties of one-dimensional superlattices with spatial periods as small as 4 nm, comparable to the Fermi wavelength. The results demonstrate the potential of this solid-state quantum simulation approach, and also provide empirical constraints for physical models that describe the underlying oxide material properties.

**10:24AM K44.00013 Classical Emulation of a Two-Qubit Quantum Computer with Analog Electronics<sup>1</sup>**, BRIAN LA COUR, COREY OSTROVE, GRANVILLE OTT, MICHAEL STARKEY, GARY WILSON, Applied Research Laboratories, The University of Texas at Austin — Abstract: The Hilbert space mathematical structure of a gate-based quantum computer may be reproduced by mapping the computational basis states to corresponding functions in the space of complex exponentials and identifying an inner product between any two such functions. The span of these complex basis exponentials may then identified with the finite-dimensional Hilbert space of a gate-based quantum computer. By using classical analog electronic components, such as four-quadrant multipliers and operational amplifiers, voltage signals representing arbitrary four-dimensional quantum states, along with the equivalent gate and measurement operations of a quantum computer have been physically realized through the corresponding circuitry. The fidelity of the emulation is measured using both a direct evaluation of the signal as well as through an emulation of quantum state tomography to infer the quantum state. We demonstrate that for both state synthesis and gate operations, our quantum emulation device is capable of achieving over 99% fidelity.

**10:36AM K44.00014 Fourth-order master equation for a charged harmonic oscillator coupled to an electromagnetic field**, ARZU KURT<sup>1</sup>, RESUL ERYIGIT<sup>2</sup>, Abant İzzet Baysal University — Using Krylov averaging method, we have derived a fourth-order master equation for a charged harmonic oscillator weakly coupled to an electromagnetic field. Interaction is assumed to be of velocity coupling type which also takes into account the diamagnetic term. Exact analytical expressions have been obtained for the second, the third and the fourth-order corrections to the diffusion and the drift terms of the master equation. We examined the validity range of the second order master equation in terms of the coupling constant and the bath cutoff frequency and found that for the most values of those parameters, the contribution from the third and the fourth order terms have opposite signs and cancel each other. Inclusion of the third and the fourth-order terms is found to not change the structure of the master equation.

**10:48AM K44.00015 A Numerical Study of Entanglement Entropy of the Heisenberg Model on a Bethe Cluster**, BARRY FRIEDMAN, Physics, Sam Houston State University, GREG LEVINE, Physics and Astronomy, Hofstra University — Numerical evidence is presented for a nearest neighbor Heisenberg spin model on a Bethe cluster, that by bisecting the cluster, the generalized Renyi entropy scales as the number of sites in the cluster. This disagrees with spin wave calculations and a naive application of the area law but agrees with previous results for non interacting fermions on the Bethe cluster. It seems this scaling is not an artifact of non interacting particles. As a consequence, the area law in greater than one dimension is more subtle than generally thought and applications of the density matrix renormalization group to Bethe clusters face difficulties at least as a matter of principle.

**8:00AM K45.00001 Hamiltonian simulation for improved state transfer and readout in cavity QED**, FÉLIX BEAUDOIN, McGill University, ALEXANDRE BLAIS, Université de Sherbrooke, WILLIAM A. COISH, McGill University — Quantum state transfer into a memory, state shuttling over long distances via a quantum bus, and high-fidelity readout are important tasks for quantum technology. Generating the Hamiltonians that realize these tasks is challenging in the presence of realistic couplings to an environment. Here, we use average Hamiltonian theory to design the desired Hamiltonians in cavity QED. In particular, we present a protocol for state transfer between a qubit and a cavity. This approach makes use of a controllable qubit-cavity coupling strength to achieve a high fidelity even in the presence of inhomogeneous broadening that is stronger than the qubit-cavity coupling strength. In addition, we design a time-averaged interaction that allows for an improved quantum nondemolition readout. These ideas can be applied directly to propel novel systems coupling single spins to a microwave cavity into the strong coupling regime [Viennot et al, Science 349, 408 (2015)]. The approach can also be employed to improve quantum operations with spin ensembles.

**8:12AM K45.00002 Quantum efficiency of a double quantum dot microwave photon detector<sup>1</sup>**, CLEMENT WONG, MAXIM VAVILOV, Univ of Wisconsin-Madison — Motivated by recent interest in implementing circuit quantum electrodynamics with semiconducting quantum dots, we study charge transfer through a double quantum dot (DQD) capacitively coupled to a superconducting cavity subject to a microwave field. We analyze the DQD current response using input-output theory and determine the optimal parameter regime for complete absorption of radiation and efficient conversion of microwave photons to electric current. For experimentally available DQD systems, we show that the cavity-coupled DQD operates as a photon-to-charge converter with quantum efficiencies up to 80%

**8:24AM K45.00003 Optical-Fiber-Illuminated Response of a Superconducting Microwave Resonator Below 1 K**, KRISTEN VOIGT, J. B. HERTZBERG, S. K. DUTTA, J. E. HOFFMAN, J. A. GROVER, J. LEE, P. SOLANO, R. P. BUDYO, C. BALLARD, J. R. ANDERSON, C. J. LOBB, S. L. ROLSTON, F. C. WELLSTOOD, JQI and CNAM, Dept. of Physics, University of Maryland — As a step towards building a hybrid quantum system that couples superconducting elements to neutral atoms trapped on a tapered optical nanofiber, we have studied how the presence of the fiber dielectric and light scattered from a fiber affect the response of a translatable thin-film lumped-element superconducting Al microwave resonator that is cooled to 15 mK. The resonator has a resonance frequency of about 6 GHz, a quality factor  $Q \approx 2 \times 10^5$ , and is mounted inside a 3D Al superconducting cavity. An optical fiber is tapered to a 60  $\mu\text{m}$  diameter and passes through two small holes in the 3D cavity such that it sits near the resonator. The 3D cavity is mounted on an x-z piezo-translation stage that allows us to change the relative position of the thin-film resonator and fiber. When the resonator is brought closer to the fiber, the resonance frequency decreases slightly due to the presence of the fiber dielectric. When 200  $\mu\text{W}$  of 780 nm light is sent through the fiber, about 100 pW/mm is Rayleigh-scattered from the fiber. This causes a position-dependent illumination of the resonator, affecting its resonance frequency and Q. We compare our results to a model of the resonator response that includes the generation, diffusion, and recombination of quasiparticles in the resonator and find that the frequency response allows us to track the position of the fiber to within 10  $\mu\text{m}$ .

**8:36AM K45.00004 Connecting trapped ions and quantum dots with photons**, MICHAEL KOEHL, University of Bonn — Coupling individual quantum systems lies at the heart of building scalable quantum networks. Here, we report the first direct photonic coupling between a semiconductor quantum dot and a trapped ion and we demonstrate that single photons generated by a quantum dot controllably change the internal state of an  $\text{Yb}^+$  ion. We ameliorate the effect of the sixty-fold mismatch of the radiative linewidths with coherent photon generation and a high-finesse fiber-based optical cavity enhancing the coupling between the single photon and the ion. The transfer of information presented here via the classical correlations between the  $\sigma_z$  projection of the quantum-dot spin and the internal state of the ion provides a promising step towards quantum state-transfer in a hybrid photonic network.

**9:12AM K45.00005 Encoding a Qubit into a Cavity Mode in Circuit-QED using Phase Estimation**, BARBARA TERHAL, DANIEL WEIGAND, RWTH - Aachen — Gottesman, Kitaev and Preskill have formulated a way of encoding a qubit into an oscillator such that the qubit is protected against small shifts (translations) in phase space. The idea underlying this encoding is that error processes of low rate can be expanded into small shift errors. The qubit space is defined as an eigenspace of two mutually commuting displacement operators which act as large shifts/translations in phase space. We propose and analyze the approximate creation of these qubit states by coupling the oscillator to a sequence of ancilla qubits realizing the protocol of approximate phase estimation for a displacement operator. We analyze the performance of repeated and adaptive phase estimation as the experimentally most viable schemes given a realistic upper limit on the number of photons in the oscillator. We propose a physical implementation of the protocol using the dispersive coupling between an ancilla transmon qubit and a cavity mode in circuit-QED. We estimate that in a current experimental set-up one can prepare a good code state from a squeezed vacuum state using 8 rounds of adaptive phase estimation lasting in total about 4  $\mu\text{sec}$ , with at least 80

### 9:24AM K45.00006 Long-distance entanglement of spin qubits via quantum Hall edge states

, GUANG YANG, CHEN-HSUAN HSU, PETER STANO, RIKEN Center for Emergent Matter Science, Wako, Japan, JELENA KLINOVAJA, DANIEL LOSS, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland — The implementation of a functional quantum computer involves entangling and coherent manipulation of a large number of qubits. For qubits based on electron spins confined in quantum dots, which are among the most investigated solid-state qubits at present, architectural challenges are often encountered in the design of quantum circuits attempting to assemble the qubits within the very limited space available. Here, we provide a solution to such challenges based on an approach to realizing entanglement of spin qubits over long distances. We show that long-range Ruderman-Kittel-Kasuya-Yosida interaction of confined electron spins can be established by quantum Hall edge states, leading to an exchange coupling of spin qubits. The coupling is anisotropic and can be either Ising-type or XY-type, depending on the spin polarization of the edge state. Such a property, combined with the dependence of the electron-spin susceptibility on the chirality of the edge state, can be utilized to gain valuable insights into the topological nature of various quantum Hall states.

### 9:36AM K45.00007 Entangling distant resonant exchange qubits via circuit quantum electrodynamics

, VANITA SRINIVASA, Laboratory for Physical Sciences/University of Maryland, College Park, MD, JACOB M. TAYLOR, Joint Center for Quantum Information and Computer Science/Joint Quantum Institute/National Institute of Standards and Technology, Gaithersburg, MD, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD — Enabling modularity within a quantum information processing device relies on robust entanglement of coherent qubits at macroscopic distances. To address this challenge, we investigate theoretically a hybrid quantum system consisting of spatially separated resonant exchange qubits, defined in three-electron semiconductor triple quantum dots, that are coupled via a superconducting transmission line resonator. By analyzing three specific approaches drawn from circuit quantum electrodynamics and Hartmann-Hahn double resonance techniques for implementing resonator-mediated two-qubit entangling gates in both dispersive and resonant regimes, we show that methods for entangling superconducting qubits map directly to resonant exchange qubits. We also calculate the rate of relaxation via phonons for resonant exchange qubits in silicon triple dots and show that such an implementation is particularly well-suited to achieving the strong coupling regime. Our approach combines the robustness of encoded spin qubits in silicon with the rapid and robust long-range entanglement provided by circuit QED systems.

### 9:48AM K45.00008 Long distance coupling of resonant exchange qubits

, MAXIMILIAN RUSS, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — We investigate the effectiveness of a microwave cavity as a mediator of interactions between two resonant exchange (RX) qubits<sup>1,2</sup> in semiconductor quantum dots (QDs) over long distances<sup>3</sup>, limited only by the extension of the cavity. Our interaction model includes the orthonormalized Wannier orbitals constructed from Fock-Darwin states under the assumption of a harmonic QD confinement potential. We calculate the qubit-cavity coupling strength  $g_r$  in a Jaynes-Cummings Hamiltonian, and find that dipole transitions between two states with an asymmetric charge configuration constitute the relevant RX qubit-cavity coupling mechanism. The effective coupling between two RX qubits in a shared cavity yields a universal two-qubit iSWAP-gate with gate times on the order of nanoseconds over distances on the order of up to a millimeter. Funded by ARO through grant No. W911NF-15-1-0149.

### 10:00AM K45.00009 Injection locking of a semiconductor double-quantum-dot micromaser<sup>1</sup>

, Y.-Y. LIU, J. STEHLIK, Department of Physics, Princeton University, M. J. GULLANS, J. M. TAYLOR, Joint Quantum Institute/NIST, J. R. PETTA, Department of Physics, Princeton University — Narrow linewidth lasers and masers are desirable for applications such as frequency standards and low-noise amplifiers. Recently we have demonstrated a double-quantum-dot (DQD) micromaser, which generates photons through single electron tunneling events.<sup>2</sup> Charge noise couples to the DQD energy levels and results in a maser linewidth that is 100 times larger than the Schawlow-Townes prediction. We demonstrate linewidth narrowing by more than a factor of 10 using injection locking. The injection locking range is measured as a function of input power and shown to be in excellent agreement with the Adler equation. The position and amplitude of distortion sidebands that appear outside of the injection locking range are quantitatively examined. Our results show that this unconventional maser, which is impacted by strong charge noise and electron-phonon coupling, is well described by standard laser models.<sup>3</sup>

### 10:12AM K45.00010 Real-time tuning of a double quantum dot using a Josephson parametric amplifier<sup>1</sup>

, J. STEHLIK, Y.-Y. LIU, Department of Physics, Princeton University, C. M. QUINTANA, Department of Physics, UC Santa Barbara, C. EICHLER, T. R. HARTKE, J. R. PETTA, Department of Physics, Princeton University — Josephson parametric amplifiers (JPAs)<sup>2</sup> have enabled advances in readout of quantum systems. Here we demonstrate JPA-assisted readout of a cavity-coupled double quantum dot (DQD).<sup>3</sup> Utilizing a JPA we improve the signal-to-noise ratio (SNR) by a factor of 2000 compared to the situation with the parametric amplifier turned off. At an interdot charge transition we achieve a SNR of 76 (19 dB) with an integration time  $\tau = 400$  ns, which is limited by the linewidth of our cavity. By measuring the SNR as a function of  $\tau$  we extract an equivalent charge sensitivity of  $8 \times 10^{-5} e/\sqrt{\text{Hz}}$ . We develop a dual-gate-voltage rastering scheme that allows us to acquire a DQD charge stability diagram in just 20 ms. Such rapid data acquisition rates enable device tuning in live "video-mode," where the results of parameter changes are immediately displayed. Live tuning allows the DQD confinement potential to be rapidly tuned, a capability that will become increasingly important as semiconductor spin qubits are scaled to a larger number of dots.

**10:24AM K45.00011 Investigating the level broadening of a semiconductor charge qubit in microwave emission measurements**, A. STOCKKLAUSER, N. HEDRICH, V. F. MAISI, J. BASSET, K. CUJIA, C. REICHL, W. WEGSCHEIDER, T. IHN, K. ENSSLIN, A. WALLRAFF, ETH Zurich — We investigate a hybrid circuit quantum electrodynamics architecture in which a double quantum dot charge qubit is coupled to a nearby microwave cavity. The discussed experiments explore the emission of microwave radiation from a voltage-biased GaAs double dot similar to Ref. [1]. A superconducting coplanar waveguide resonator serves as a tool to study aspects of the quantum dot level structure that are difficult to access in transport measurements. We explore resonances in microwave emission that arise from inelastic interdot transitions resonant with the cavity [2]. In particular, the line width of the emission resonances is investigated and linked to the level broadening of the double dot charge qubit. We study the dependence of the emission line width on the tunnel rates to the leads and identify this as the dominant contribution to the broadening of the qubit levels. For the explored bias conditions qubit decoherence is low in comparison. We extract the tunnel rates to the leads from the linewidth of the emission signal and compare it with the tunnel rates extracted from current measurements.

**10:36AM K45.00012 Observation of magnon number states in a superconducting qubit spectrum**, DANY LACHANCE-QUIRION, Université de Sherbrooke, YUTAKA TABUCHI, SEIICHIRO ISHINO, ATSUSHI NOGUCHI, TOYOFUMI ISHIKAWA, REKISHU YAMAZAKI, KOJI USAMI, RCAST, The University of Tokyo, YASUNOBU NAKAMURA, RCAST, The University of Tokyo, CEMS, RIKEN — A quantum transducer interfacing qubits in the microwave domain to optical light requires a quantum system interacting with photons of both frequency domains. Coherent interaction between collective excitations (magnons) in the ferrimagnetic insulator yttrium iron garnet (YIG) and a superconducting qubit through virtual microwave photons has recently been demonstrated [1]. In this talk, we present results on the observation of magnon number states in a superconducting qubit spectrum when creating a coherent state in a magnetostatic mode of a YIG sphere interacting dispersively with the qubit. The dispersive interaction strength of 1.2 MHz measured in the straddling regime is in good agreement with numerical simulations. Furthermore the probability distribution of magnon number states, recovered from the qubit spectrum, is compared with the Poisson distribution expected for a coherent state. Resolving magnon number states constitutes a first step toward encoding quantum information into a quantum state of a magnetostatic mode [2].

**10:48AM K45.00013 Emergent Curved space induced by adiabatic approximation<sup>1</sup>**, RAN CHENG, XIAOCHUAN WU, DI XIAO, Carnegie Mellon University — Berry curvature, serving as the imaginary part of quantum geometric tensor (QGT), gives rise to an effective Lorentz force to the dynamics of the adiabatic parameter. However, it is not clear whether the real part of QGT, the quantum metric, has any dynamical consequence as the Berry gauge force. We show in a general way that during an adiabatic process, the particle in a hybrid quantum system governed by an equation of motion second order in time is subject to an induced gravitational force. The adiabatic dynamics can be described by a geodesic equation as if the spacetime is curved by the quantum metric. As an example, we demonstrate the above result in a simple toy model.

**8:00AM K46.00001 The influence of deformation rate on polymer nanomechanical properties as measured by Atomic Force Microscopy.**, BEDE PITTENGER, THOMAS MUELLER, Bruker Nano, AFM UNIT TEAM — Polymeric composites often have heterogeneities at the nanometer length scale. AFM based mechanical property measurements have the sensitivity and resolution necessary to visualize these features and better understand their influence on bulk properties. In the past few years, AFM mechanical property mapping has evolved from slow force volume to faster, but conceptually very similar, PeakForce Tapping. Currently, the time scale of tip-sample interaction spans from microseconds to seconds, tip sample forces can be controlled from piconewtons to micronewtons, and spatial resolution can reach sub-nanometer. AFM has become a unique mechanical measurement tool having large dynamic range (1kPa to >100GPa in modulus) with the flexibility to integrate with other physical property characterization techniques in versatile environments. In particular, researchers have begun to take advantage of the wide range of deformation rates accessible to AFM in order to study time dependent properties of materials such as viscoelasticity. This presentation will review this recent progress, providing examples that demonstrate the dynamic range of the measurements and the resolution with which they were obtained. Additionally, the effect of time dependent material properties on the types of measurements will be explored.

**8:12AM K46.00002 Atomic Force Tomography of a Nonplanar Molecule: Role of Lateral and Chemical Sample-Tip Interactions<sup>1</sup>**, XIANGHUA KONG, Ph. D candidate, WEI JI, Professor, PHYSICS DEPARTMENT, MCGILL TEAM, PHYSICS DEPARTMENT, RENMIN UNIVERSITY OF CHINA TEAM — Atomically identification of the molecular geometric structures is an important prerequisite to understand their chemical and electrical properties. TiOPc, a steric structure, gives rise to two adsorption configurations of TiOPc on Cu(111), namely O-dn and O-up. The roles of chemical specific interactions of different intramolecular atoms with the AFM tips were discussed at the submolecular level. For O-up, the molecular backbone of TiOPc is only visible out of a certain range from the center of the molecule, accompanied with significant dissipation signal. Theoretical calculation identifies such dissipation signal as the chemical attraction between the out-of-plane O in TiOPc and the Cu atoms behind the CO of a tip at a certain range of lateral distance between them. When they approach closer, the sample O repulses another O in the CO tip making it tilting strongly, which softens the tip and thus leads to even stronger O (sample) – Cu (tip) attraction. A direct demonstration of sample-tip electronic hybridization was manifested in the simpler O-dn case where an explicit wavefunction overlap between the tip O atom and the sample Ti atom. Given these results presented here, we anticipate that this method might be developed further generally useful in single-molecule chemistry and physics.

**8:24AM K46.00003 Scanning Ion Conductance Microscopy for living cell membrane potential measurement**, NAMUNA PANDAY, Florida Intl Univ — Recently, the existence of multiple micro-domains of extracellular potential around individual cells have been revealed by voltage reporter dye using fluorescence microscopy. One hypothesis is that these long lasting potential patterns play a vital role in regulating important cell activities such as embryonic patterning, regenerative repair and reduction of cancerous disorganization. We used multifunctional Scanning Ion Conductance Microscopy (SICM) to study these extracellular potential patterns of single cell with higher spatial resolution. To validate this novel technique, we compared the extracellular potential distribution on the fixed HeLa cell surface and Polydimethylsiloxane (PDMS) surface and found significant difference. We then measured the extracellular potential distributions of living melanocytes and melanoma cells and found both the mean magnitude and spatial variation of extracellular potential of the melanoma cells are bigger than those of melanocytes. As compared to the voltage reporter dye based fluorescence microscope method, SICM can achieve quantitative potential measurements of non-labeled living cell membranes with higher spatial resolution.

**8:36AM K46.00004 Local Imaging of Conductance Evolution in Ion-Gel-Gated Transitional Metal Dichalcogenide Transistors**, XIAOYU WU, DI WU, Univ of Texas, Austin, HONGTAO YUAN, HAROLD HWANG, YI CUI, Stanford University, KEJI LAI, Univ of Texas, Austin — Electrolyte-gated electric double layer transistors (EDLTs) have demonstrated carrier density modulation in a remarkably wide range in systems ranging from complex oxides to layered metal chalcogenides. Cryogenic microwave impedance microscopy (MIM) has been used to perform real-space mapping of nanoscale conductance evolution in oxide EDLT gated with an ultrathin ionic gel layer. However, such microwave imaging was previously only possible at temperatures lower than the glass transition temperature (frozen temperature) of the gel because of the contact-mode scanning. Here, we report in-situ imaging of conductance evolution in  $\text{WSe}_2$  transistors using a MIM based on the frequency-modulated atomic force microscopy (FM-AFM) mode. With a typical tip-sample distance of 30nm, the  $\text{WSe}_2$  EDLT can be simultaneously gate-modulated and imaged at 220K, which is above the frozen temperature of the gel. The microwave images vividly show the spatial evolution of channel conductance in  $\text{WSe}_2$  during the metal-insulator transition and mesoscopic electronic inhomogeneity with different configurations of source/drain/gate voltages. Such in-situ microwave imaging provides new opportunities to correlate the macroscopic transport results and microscopic conductivity distribution in both equilibrium and non-equilibrium states of the EDLTs.

**8:48AM K46.00005 Resolving local voltage variations in opto-electronic devices with Kelvin probe force microscopy**, ELIZABETH TENNYSON, University of Maryland College Park - Department of Materials Science and Engineering, JOSEPH GARRETT, University of Maryland College Park - Department of Physics, JEREMY MUNDAY, University of Maryland College Park - Department of Electrical and Computer, MARINA LEITE, University of Maryland College Park - Department of Materials Science and Engineering — We employ illuminated Kelvin probe force microscopy (KPFM) to spatially resolve the open-circuit voltage ( $V_{oc}$ ) of optoelectronic devices with nanoscale spatial resolution, >5 orders of magnitude better than previous methods. In illuminated-KPFM, we measure the difference in work function between the sample surface and the probe, termed the contact potential difference (CPD). By grounding the bottom contact of the solar cell to the AFM probe, the difference between the illuminated and the dark signals is proportional to quasi-Fermi level splitting and, therefore, the  $V_{oc}$ . We apply our scanning probe technique to a variety of solar cell materials, including polycrystalline CIGS, where we resolve local variations in  $V_{oc} > 150$  mV [1]. We use heterodyne-KPFM (where we map  $1 \mu\text{m}^2$  in 16 seconds) to probe hybrid perovskites solar cells, and quantify in real-time the voltage changes upon material relaxation after illumination. This metrology yields new insights into the local electrical properties of solar cells, and can be expanded to any optoelectronic device. [1] E.M. Tennyson et al., Adv. Energy Mat., **5** (2015) in press, front cover.

**9:00AM K46.00006 Multi-step atomic interchange mechanism for atom manipulation on semiconductor surfaces.**, BATNYAM ENKHTAIVAN, ATSUSHI OSHIYAMA, Department of Applied Physics, The University of Tokyo — We report on our total-energy electronic-structure calculations based on the density-functional theory that clarify atom-scale mechanisms of atom-manipulation recently realized on semiconductor surfaces [1]. We focus on Ge(111) and Si(111) surfaces and identify reaction pathways and corresponding reaction energy barriers. Considering the atom manipulation of Pb and Sn atoms on Ge(111) surfaces, we find that the substitutional Sn (Pb) diffuses to neighboring Ge adatom, and forms a dimer with Ge spontaneously. Then the Sn (Pb) and the Ge adatom exchange their position concertedly with the dimer structure kept. These diffusion and exchange processes are multi-step atomic processes consisting of multiple metastable states. For the case of Sb manipulation on the Si(111) surface, the dimer structure does not form spontaneously when the AFM tip is absent. We find that the roles of the AFM tip during the atom manipulation are the lowering of the diffusion energy barrier and stabilization of the dimer structure. [1] Y. Sugimoto et al., e-J. Surf. Sci. Nanotech. **4**, 376-383 (2006).

**9:12AM K46.00007 Measuring electron-phonon coupling with Scanning Tunneling Microscopy**, VIDYA MADHAVAN, University of Illinois, Urbana-Champaign — Electron-boson interactions are ubiquitous in systems ranging from simple metals to novel materials such as graphene, high-temperature superconductors and topological insulators. Of particular interest is the coupling between electrons and phonons. In general, electron-phonon coupling gives rise to quasiparticles of decreased mobility and increased effective mass. Nearly all information about electron-phonon coupling is contained in the Eliashberg function ( $\alpha^2 F(\omega; k, E)$ ) of the material. In this talk I discuss the various methods by which the effects of electron-phonon coupling can be measured by scanning tunneling microscopy. I will present STM data on a variety of systems ranging from metals to topological insulators and discuss the signatures of electron-phonon interactions in different types of STM data. In particular I discuss how high resolution measurements allow us to measure the dispersion and obtain the real part of the self-energy, which can in principle be inverted to obtain the Eliashberg function.

**9:48AM K46.00008 Lateral manipulation and interplay of local Kondo resonances in a two-impurity Kondo system.**, HAIMING GUO, Institute of Physics, Chinese Academy of Sciences — The control of a single spin of an atom is of great interest in Kondo physics and a potential application in spin based electronics. Low-temperature scanning tunneling microscopy and spectroscopy (LT-STM/STS) is a powerful tool to probe the single spin and its Kondo effect at the atomic scale on surfaces. I am going to present the modulation of magnetic properties and Kondo effect of Co adatoms on graphene layer. This is also the first discovery of a Kondo effect caused from a magnetic impurities doped in graphene layer in experiment. The tiny diverse interaction between magnetic impurity and graphene host further modulates the Kondo effect. Next, the atomic-scale spatial relationship of a two-impurity Kondo system at varying lateral distance will be reported. A notable interplay is determined between two individual Kondo singlet states, which are formed by the localized spins of two cobalt magnetic adatoms that are placed on different electrodes of an STM. The  $dI/dV$  spectra show the continuous changes of the resonance peak feature when approaching the Kondo tip laterally to the local sample-Kondo impurity on the surface.

**10:00AM K46.00009 Local Force Interactions and Image Contrast Reversal on Graphite Observed with Noncontact Atomic Force Microscopy**, OMUR DAGDEVIREN, JAN GOETZEN, ERIC ALTMAN, UDO SCHWARZ, Yale University — Surface interactions of graphene-based nanostructures remain a topic of considerable interest in nanotechnology. Similarly, tip-dependent imaging contrasts have attracted attention as they allow conclusions to be made about the surface's chemical structure and local reactivity. In this talk, we present noncontact atomic force microscopy data recorded in the attractive regime on highly oriented pyrolytic graphite that reveals image contrast reversal for the first time. While larger tip-sample separations feature bright spots on atomic sites, the maximum of the tip-sample interaction flips to the hollow site positions upon further approach, which represents the contrast predominantly observed in previous studies during attractive-mode imaging. This cross over of the local chemical interaction is confirmed in force spectroscopy experiments. The results will be discussed in light of recent theoretical simulations that have predicted the occurrence of such contrast reversal for specific tip terminations.

**10:12AM K46.00010 Theoretical model of the tunneling current between a metallic tip and a ferroelectric material.**<sup>1</sup>, RAVI NEUPANE, ANDREW YOST, TEYU CHIEN, Univ of Wyoming — We present a model to calculate the tunneling current for a ferroelectric (FE) material in a metal/vacuum/Ferroelectric tunneling junction. Using this model, we try to explore the effect of the FE dipole orientation's direction on  $I - V$  spectrum using scanning tunneling spectroscopy (STS). The STM tunneling current for non-FE materials depends upon various factors such as tip-sample distance (vacuum gap), temperature, density of states (DOS) of tip and of sample, and tip-sample bias. FE materials have internal electric dipoles giving rise to internal and external electric fields. The electric field induced by these dipoles will distort the Fermi level as a function of depth in the material. In our model, the Fermi level is assumed to be inclined with a slope as a function of the depth. The slope depends upon the orientation and the strength of the electric dipole moment. In this model we use the WKB method accounting for the slope of the Fermi level to calculate the tunneling probability from tip to different depths then summing all contributions to obtain the total current as a function of tip-sample bias, i.e.  $I - V$  curves.

**10:24AM K46.00011 The power laws of nanoscale forces in ambient conditions**, MATTEO CHIESA, SERGIO SANTOS, CHIA-YUN LAI, Laboratory for Energy and NanoScience, Masdar Institute — Power laws are ubiquitous in the physical sciences and indispensable to qualitatively and quantitatively describe physical phenomena. A nanoscale force law that accurately describes the phenomena observed in ambient conditions at several nm or fractions of a nm above a surface however is still lacking. Here we report a power law derived from experimental data and describing the interaction between an atomic force microscope AFM tip modelled as a sphere and a surface in ambient conditions. By employing a graphite surface as a model system the resulting effective power is found to be a function of the tip radius and the distance. The data suggest a nano to mesoscale transition in the power law that results in relative agreement with the distance-dependencies predicted by the Hamaker and Lifshitz theories for van der Waals forces for the larger tip radii only

**10:36AM K46.00012 Development of tip Scanning High Speed AFM operating at 1,000 Lines/s & 15m**, UMIT CELIK, Material Science and Engineering, Istanbul Technical University, Turkey, IHSAN KEHRIBAR, NanoMagnetics Instruments, Turkey, KUBRA CELIK, Material Science and Engineering, Istanbul Technical University, Turkey, H. ZGR ZER, Physics Department, Istanbul Technical University, Turkey, AHMET ORAL, Physics Department, Middle East Technical University, Turkey — High speed atomic force microscope allows imaging dynamic processes on the surfaces. We have developed a very high speed tip scanning atomic force microscope (HS-AFM). We designed the tip scanning system to overcome the sample size limits, with a beam tracking capability to follow the cantilever motion. A high resonance frequency flexure scanner developed which has 15m scan range in XY and 3m in Z axis. A novel FPGA based high speed scanning and data acquisition system was developed. The scanner is driven by sine wave in X-axis to avoid resonances and data were captured at equal sample intervals. 1 KHz line scan rate is achieved at 15m scan range with the HS-AFM.

**8:00AM K47.00001 Accurate path integral molecular dynamics simulation of ab-initio water at near-zero added cost<sup>1</sup>**, DANIEL ELTON, Stony Brook University, MICHELLE FRITZ, JOS SOLER, Universidad Autonoma de Madrid, MARIVI FERNANDEZ-SERRA, Stony Brook University — It is now established that nuclear quantum motion plays an important role in determining waters structure and dynamics. These effects are important to consider when evaluating DFT functionals and attempting to develop better ones for water. The standard way of treating nuclear quantum effects, path integral molecular dynamics (PIMD), multiplies the number of energy/force calculations by the number of beads, which is typically 32. Here we introduce a method whereby PIMD can be incorporated into a DFT molecular dynamics simulation at virtually zero cost. The method is based on the cluster (many body) expansion of the energy. We first subtract the DFT monomer energies, using a custom DFT-based monomer potential energy surface. The evolution of the PIMD beads is then performed using only the more-accurate Partridge-Schwenke monomer energy surface. The DFT calculations are done using the centroid positions. Various bead thermostats can be employed to speed up the sampling of the quantum ensemble. The method bears some resemblance to multiple timestep algorithms and other schemes used to speed up PIMD with classical force fields. We show that our method correctly captures some of key effects of nuclear quantum motion on both the structure and dynamics of water.

**8:12AM K47.00002 ABSTRACT WITHDRAWN –**

**8:24AM K47.00003 X-ray absorption of liquid water studied by advanced *ab initio* methods<sup>1</sup>**, ZHAORU SUN, JIANPING WANG, Temple University, WEI KANG, Peking University, ROBERTO CAR, Princeton University, XIFAN WU, Temple University — Oxygen K-edge X-ray absorption spectra (XAS) provide a sensitive local probe of the H-bond structure of liquid water. Based on the static COHSEX approach, we computed the XAS spectra of liquid water from molecular structures generated by *ab initio* molecular dynamics (AIMD) simulations using a van der Waals (vdW) inclusive hybrid functional (PBE0) that gives ambient water structure in quantitative agreement with experiment [JCP 141, 084502 (2014)]. We find that good agreement between experimental and theoretical XAS requires both improved molecular modeling and excitation treatment. In our simulation the over-structured H-bond network resulting from GGA-AIMD is systematically reduced as the directional H-bond strength is lowered by the mitigated self-interaction error in PBE0 and the increased population of interstitial water molecules promoted by vdW interactions. The better H-bond structure in turn gives improved XAS spectra. Moreover, we find that the orbitals obtained from the self-consistent diagonalization of the self-energy are crucial in obtaining spectra that compare well with experiment.

<sup>1</sup>DOE SciDAC: DE-SC0008626 and DE-SC0008726

**8:36AM K47.00004 Why does hydronium diffuse faster than hydroxide in liquid water?<sup>1</sup>**, LIXIN ZHENG, Temple University, BISWAJIT SANTRA, Princeton University, ROBERT DISTASIO, Cornell University, MICHAEL KLEIN, Temple University, ROBERTO CAR, Princeton University, XIFAN WU, Temple University — Experiments show that the hydronium ion ( $\text{H}_3\text{O}^+$ ) diffuses much faster than the hydroxide ion ( $\text{OH}^-$ ) in liquid water. *ab initio* molecular dynamics (AIMD) simulations correctly associated the diffusion mechanism to proton transfer (PT) but have been unable so far to clearly identify the reason for the faster diffusion of hydronium compared to hydroxide, as the diffusion rate was found to depend sensitively on the adopted functional approximation. We carried out AIMD simulations of the solvated water ions using a van der Waals (vdW) inclusive PBE0 hybrid density functional. It is found that not only hydronium diffuses faster than hydroxide but also the absolute rates agree with experiment. The fast diffusion of  $\text{H}_3\text{O}^+$  occurs via concerted PT that enables the ion to jump across several H-bonded molecules in successful transfer events; in contrast, such concerted motion is significantly hindered in  $\text{OH}^-$  where the ion is easily trapped in a hyper-coordination configuration (a local solvation structure that forbids PT). As a result multiple PT events are rare and the diffusion of  $\text{OH}^-$  is significantly slowed down. Such a clear difference between the two ions results from the combined effect of vdW interactions and self-interaction correction.

**8:48AM K47.00005 Electrical Mobility of Protons and Proton-Holes in Pure Water Characterized by Physics-Based Water Model.**, BINBIN JIE, CHIHTANG SAH, Department of Physics, Xiamen University, China — Pure water has been characterized empirically for nearly a century, as dissociation into hydronium ( $\text{H}_3\text{O}^+$ )<sup>1+</sup> and hydroxide ( $\text{OH}^-$ )<sup>1-</sup> ions. Last March, we reported that the ~40 year experimental industrial standard of chemical equilibrium reaction constant, the ion product, can be accounted for by a statistical-physics-based concentration product of two electrical charge carriers, the positively charged protons,  $\text{p}^+$ , and the negatively charged proton holes or proholes,  $\text{p}^-$ , with a thermal activation energy or proton trapping well depth of  $E_{\text{p}^+/\text{p}^-} = 576$  meV, in the 0-100°C pure liquid water. We now report that the empirically fitted industrial standard experimental data (1985, 1987, 2005) of the two dc ion mobilities in liquid water, can also be accounted for by trapping-limited drift of protons and proholes through proton channels of lower proton electrical potential valleys,  $E_{\text{p}^+/\text{p}^-} \leq E_{\text{p}^+/\text{p}^-} < (E_{\text{p}^+/\text{p}^-}/3)$ , in the tetrahedrally-directed electron-pair-bonded oxygen ions,  $\text{O}^{2-}$ , in hexagonal lattice based on the 1935 Pauling statistical model using the 1933 Bernal-Fowler water rule.

**9:00AM K47.00006 Nuclear Quantum Effects in Different Ice Phases<sup>1</sup>** , MARIVI FERNANDEZ-SERRA, Stony Brook University, BETUL PAMUK, CNRS and Université Pierre et Marie Curie, PHILIP B. ALLEN, Stony Brook University — We have previously explained that the anomalous isotope effect in hexagonal ices is linked to the anticorrelation between the covalent OH bond and the hydrogen bond by using the quasiharmonic approximation combined with *ab initio* density functional theory. [1] In this study, we show that similar physics plays a role in the isotope effect on temperature of the proton-order/disorder phase transition between ice XI and ice<sub>lh</sub>. By using a van der Waals density functional, we calculate a temperature difference between heavy and light ices of 6 K as compared to the experimental value of 4 K. [2] Furthermore, we extend our study to analyze the zero-point effects in different ice phases and ice-like structures with different densities and crystal structures to understand how this can be linked to the anomalous isotope effect in liquid water. **9:12AM K47.00007 Electron Traps at the Ice Surface** , MICHEL BOCKSTEDTE, PHILIPP AUBURGER, ANJA MICHL, Theor. Festkörperphysik, FAU Erlangen-Nuernberg, Erlangen, Germany — Water, water clusters and ice possess the fascinating ability to solvate electrons. On the surface of water cluster<sup>1</sup> and thin crystalline ice structures on a metal substrate<sup>2</sup> long-living solvated electron states were observed that evolve from pre-existing surface traps. The identification of such traps provides important insight into the electronic structure of the water or ice surface, and the dissociative interaction of electrons with adsorbates. Models<sup>2,3</sup> based on the bilayer terminated Ih-(0001) surface related such traps to orientational defects or vacancies. So far, the understanding of the electronic structure of the ice surface with the electron traps is incomplete. Here we address this issue including also water ad-structures<sup>4</sup> within hybrid density functional theory and many-body perturbation theory ( $G_0W_0$ ). We identify a hierarchy of traps with increasing vertical electron affinity, ranging from hexagonal adrows to clusters of orientational defects and vacancies with dangling OH-groups. Siefermann and Abel, Angew. Chem. Int. Ed. **50**, 5264 (2011). Bovensiepen *et al.*, J. Chem. Phys. C **113**, 979 (2013). Hermann *et al.*, J. Phys.: cond. matter **20**, 225003 (2008). **9:24AM K47.00008 Quantum Water Ice** , NIC SHANNON, OWEN BENTON, Okinawa Institute of Science and Technology Graduate University, OLGA SIKORA, Jagiellonian University, Krakow — There is now a growing body of evidence, from both simulation [1] and experiment [2], that the protons in common, hexagonal water ice are not merely disordered, but mobile, collectively tunnelling from one configuration to another. In this talk we revisit the theory of proton correlations in hexagonal water ice, showing how the disordered state selected by the ice rules changes, once collective quantum tunnelling is taken into account [3]. We find that correlations are governed by a lattice-gauge theory with exactly the same structure as electromagnetism, in which the low-energy excitations of protons have the character of “photons”. The predictions of the quantum theory are shown to be in quantitative agreement with the results of quantum Monte Carlo simulations of hexagonal water ice, and to reproduce the “wings” of incoherent inelastic neutron scattering observed by Bove *et al.* [2]. These results raise the intriguing possibility that the protons in hexagonal water ice could form a quantum liquid with many of the same properties as the quantum spin liquids sought in frustrated magnets. [1] C. Drechsel-Grau and D. Marx, Phys. Rev. Lett. **112**, 148302 (2014). [2] L. Bove *et al.*, Phys. Rev. Lett. **103**, 165901 (2009). [3] O. Benton, O. Sikora and N. Shannon, arXiv:1504.04158.

**9:36AM K47.00009 Role of Inter-molecular Charge Transfer in Simulating Concentration Dependent Water Diffusivity of Aqueous Salt Solutions** , YI YAO, MAX BERKOWITZ, YOSUKE KANAI, Univ of NC - Chapel Hill — The translational diffusivity of water in solutions of alkali halide salts depends on the identity of ions, exhibiting dramatically different behavior even in solutions of similar salts of NaCl and KCl. The water diffusion coefficient decreases as the salt concentration increases in NaCl. Yet, in KCl solution it slightly increases and remains above bulk value as salt concentration increases. Previous classical molecular dynamics simulations have failed to describe this important behavior even with polarizable models. Here we show that the missing physical effect in previous simulations was charge transfer; its inclusion produces results in a quantitative agreement with experiments. We found that the concentration-dependent diffusivity reflects the importance of many-body effects among the water molecules when the ions are present. Explicit inclusion of charge transfer allows us to model accurately the difference in the concentration-dependent water diffusivity between Na<sup>+</sup> and K<sup>+</sup> ions in simulations, and it is likely to impact modeling of a wide range of systems.

**9:48AM K47.00010 Ab initio Determination of Formation Energies and Charge Transfer Levels of Charged Ions in Water.** , ANOOP KISHORE VATTI, MIRA TODOROVA, JOERG NEUGEBAUER, Department for Computational Materials Design, Max-Planck-Institut fuer Eisenforschung GmbH, Duesseldorf, Germany — The ability to describe the complex atomic and electronic structure of liquid water and hydrated ions on a microscopic level is a key requirement to understand and simulate electro-chemical and biological processes. Identifying theoretical concepts which enable us to achieve an accurate description in a computationally efficient way is thereby of central importance. Aiming to unravel the importance and influence of different contributions on the hydration energy of ions we perform extensive ab-initio molecular dynamics simulations for charged and neutral cations (Zn, Mg) and anions (Cl, Br, I) in water. The structural correlations and electronic properties of the studied ions are analysed and compared to experimental observations. Following an approach inspired by the defect chemistry in semiconductors [1] and aligning the water band edges on an absolute scale allows us to benchmark the calculated formation energies, identify transition states and compare the results to experiment. Based on these results we discuss the performance of various DFT xc-functionals to predict charge transfer levels and photo-emission experiments [2]. [1] M. Todorova and J. Neugebauer, Phys. Rev. Applied **1**, 014001 (2014). [2] B. Winter *et al.*, JACS **127**, 7203 (2005).

**10:00AM K47.00011 Orientational relaxation of OH-bond in water over short to intermediate timescales** , PING-HAN TANG, SUAN-JEN LIN, TEN-MING WU, Natl Chiao Tung Univ — By simulating the rigid simple point charge extended model at 300K, the orientational relaxation of the OH-bond in water was investigated over short to intermediate timescales, within which molecules undergo inertial rotation and libration and then enter the rotational diffusion regime. Simulated molecules were classified into subensembles according to their H-bond connections. For global molecules and classified subensembles of molecules, the simulation results of the orientational time correlation functions (TCFs) were compared with the second-cumulant predictions obtained using the rotational stable instantaneous-normal-mode (INM) spectra and the power spectra of angular velocity autocorrelation functions (AVAFs). On short timescales, the OH-bond in water behaves similar to an inertial rotor and its anisotropy is lower than that of a water molecule. For molecules connected with three or more H-bonds, the OH-bond orientational TCFs are characterized by a recurrence, which is an indication for OH-bond libration. By contrast, the OH-bond orientational TCFs of molecules initially connected with one or two H-bonds decay monotonically or exhibit a weak recurrence, indicating rapid relaxation into the rotational diffusion regime after the initial Gaussian decay.

**10:12AM K47.00012 What is the effective molecular polarizability of water in condensed phases?**<sup>1</sup> , XIAOCHUAN GE, DEYU LU, Brookhaven National Laboratory — Electronic polarization plays a crucial role in determining the structural and dynamical properties of water with different boundary conditions. Although it is well known that the molecular polarization in condensed phases behaves substantially differently from that in the vacuum due to the intermolecular interaction, these environmental effects have not been fully understood from first principles methods. As a result, how to rigorously define and calculate the effective molecular polarizability of a water molecule in different chemical environments remains an open question. The answer to this question not only improves our fundamental understanding of water, but also has immediate practical impact on computational modeling of water, e.g. through an accurate polarizable force field model. A main challenge to this puzzle arises from the intrinsic non-local nature of the electronic susceptibility. Recently we developed an ab initio local dielectric response theory [arxiv 1508.03563] that partitions dielectric response in real space based on a Wannier representation. In this work we apply this method to compute the effective molecular polarizability of water in the condensed phase, and discuss how the effective molecular polarizability evolves from gas phase to the condensed phase.

**10:24AM K47.00013 Metastable liquid-liquid phase separation and criticality in water-like models** , RAKESH SINGH, Princeton University, JOHN BIDDLE, University of Maryland, PABLO DEBENEDETTI, Princeton University, MIKHAIL ANISIMOV, University of Maryland — Water shows intriguing thermodynamic and dynamic anomalies in the supercooled liquid state. A possible explanation of the origin of these anomalies lies in the existence of a metastable first order liquid-liquid phase transition (LLPT) between two (high and low density) forms of liquid water. Unambiguous experimental proof of existence of LLPT in bulk supercooled water is so far hampered by ultra-fast ice crystallization. Computer simulations of water models are therefore crucial for exploring the possibility of LLPT in deeply supercooled water. We present computer simulation results that elucidate the possibility of a metastable LLPT in one of the most accurate atomistic models of water, TIP4P/2005. To describe the computed properties, we have applied two-state thermodynamics, viewing water as a non-ideal mixture of two inter-convertible states. The thermodynamic behavior of the model in the one-phase region suggests the existence of energy-driven LLPT. We compare the behavior of TIP4P/2005 with other popular water models, and with real water, all of which are well-described by two-state thermodynamics. Additionally, we also elucidate the relation between the phenomenological order parameter of the two-state thermodynamics and the microscopic nature of the low-density structure.

**10:36AM K47.00014 Structure Evolution of Metal Nanoparticles in Water Environment.** , YI GAO, BEIEN ZHU, Shanghai Institute of Applied Physics, Chinese Academy of Sciences — Metal nanoparticles have drawn extensive attentions in materials science due to their widespread applications in electronics, engineering and catalysis. A very fundamental question is their structure evolution and surface segregation. Many recent observations have shown that reactive gases or supports may have strong effects on the morphology change and surface segregation. However, the effect of water—the most common solvent and environment—has not received enough attention. Here, we will give two examples to show water adsorption could induce the morphology change and strong surface segregation tendencies for the metal nanoparticles. This finding not only prompts us to re-examine the potential effects of water on metal nanoparticles, but would be also very helpful as a guide for the further theoretical and experimental studies in this field.

**10:48AM K47.00015 Ionic structure in electrolyte confined by dielectric interfaces** , YUFEI JING, Northwestern University, VIKRAM JADHAO, Johns Hopkins University, JOS W. ZWANIKKEN, University of Massachusetts, Lowell, MONICA OLVERA DE LA CRUZ, Northwestern University — The behavior of ions in liquids confined between macromolecules determines the outcome of many nanoscale assembly processes in synthetic and biological materials. To model these systems, both the macromolecules and the surrounding solvent are treated as continuous media characterized with different dielectric permittivities. As the macromolecule-liquid boundary is modeled as a dielectric interface, an important quantity of interest is the ionic structure in a liquid confined between two such interfaces. We compute the ionic structure in a model system of electrolyte confined by two planar dielectric interfaces using molecular dynamics simulations and liquid state theory. We give a comprehensive description of the effects of high electrolyte concentrations, multivalent ions, dielectric contrasts, and external electric field on the ionic distributions. We observe novel features in ionic structure near polarizable/unpolarizable macromolecules which is attributed to the competition between electrostatic and steric (entropic) interactions. We argue that the combined effect of ionic correlations and inhomogeneous dielectric permittivity significantly changes the character of the effective interaction between the two macromolecules.

Session K48 GQI: Novel Superconducting Qubits & Architectures 349 - John Martinis, Google, Inc.

**8:00AM K48.00001 The gatemon: a transmon with a voltage-variable superconductor-semiconductor junction**<sup>1</sup> , KARL PETERSSON, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, Denmark — We have developed a superconducting transmon qubit with a semiconductor-based Josephson junction element.<sup>2,3</sup> The junction is made from an InAs nanowire with *in situ* molecular beam epitaxy-grown superconducting Al contacts. This gate-controlled transmon, or gatemon, allows simple tuning of the qubit transition frequency using a gate voltage to vary the density of carriers in the semiconductor region. In the first generations of devices we have measured coherence times up to  $\sim 10 \mu\text{s}$ . These coherence times, combined with stable qubit operation, permit single qubit rotations with fidelities of  $\sim 99.5\%$  for all gates including voltage-controlled  $Z$  rotations. Towards multi-qubit operation we have also implemented a two qubit voltage-controlled cPhase gate. In contrast to flux-tuned transmons, voltage-tunable gatemons may simplify the task of scaling to multi-qubit circuits and enable new means of control for many qubit architectures.

**8:36AM K48.00002 Progress toward coupled flux qubits with high connectivity and long coherence times** , STEVEN WEBER, DAVID HOVER, DANNA ROSENBERG, GABRIEL SAMACH, JONILYN YODER, ANDREW KERMAN, WILLIAM OLIVER, MIT Lincoln Laboratory — The ability to engineer interactions between qubits is essential to all areas of quantum information science. The capability to tune qubit-qubit couplings *in situ* is desirable for gate-based quantum computing and analog quantum simulation and necessary for quantum annealing. Consequently, tunable coupling has been the subject of several experimental efforts using both transmon qubits and flux qubits. Recently, our group has demonstrated robust and long-lived capacitively shunted (C-shunt) flux qubits. Here, we discuss our efforts to develop architectures for tunably coupling these qubits. In particular, we focus on optimizing the RF SQUID coupler to achieve high connectivity. This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

**8:48AM K48.00003 Three coupled qubits in a single superconducting quantum circuit<sup>1</sup>**, MADHAVI CHAND, SUMAN KUNDU, N. NEHRA, COSMIC RAJ, TANAY ROY, A. RANADIVE, MEGHAN P. PATANKAR, R. VIJAY, Tata Institute of Fundamental Research, Mumbai 400005 — We propose a new design for a 3-qubit system in the 3D circuit QED architecture. Our design exploits the geometrical symmetry of a single superconducting circuit with three degrees of freedom to generate three coupled qubits. However, only one of these is strongly coupled to the environment while the other two are protected from the Purcell effect. Nevertheless, all three qubits can be measured using the standard dispersive technique. We will present preliminary data on this circuit showing evidence of three distinct qubits that retain the essential properties of a 3D transmon, namely insensitivity to charge noise, sufficient anharmonicity and good coherence times. We will also characterize the coupling of the three qubits to each other, to the environment and to a neighboring transmon qubit. Finally, we will compare our design to previous multi-qubit circuits and discuss possible applications in quantum computing and quantum simulations.

**9:00AM K48.00004 Analog approaches to quantum computation using highly-controllable superconducting qubits**, C. NEILL, UCSB, P. ROUSHAN, R. BARENDSE, Google Inc., B. CAMPBELL, UCSB, Y. CHEN, Google Inc., Z. CHEN, B. CHIARO, A. DUNSWORTH, UCSB, A. FOWLER, E. JEFFREY, J. KELLY, E. LUCERO, A. MEGRANT, J. MUTUS, M. NEELEY, Google Inc., P. O'MALLEY, C. QUINTANA, UCSB, D. SANK, Google Inc., J. WENNER, UCSB, T. WHITE, J. MARTINIS, Google Inc. — The first generation of quantum hardware that outperforms classical computers will likely be analog in nature. In an effort to realize such a platform, we have built a one-dimensional chain of 9 superconducting qubits. This device provides individual time-dependent control over all nearest-neighbor couplings and local fields (X, Y, Z) in the multi-qubit Hamiltonian. In this talk, I will focus on open problems in non-equilibrium statistical mechanics where dynamical properties become impossible to compute for only a few 10s of qubits. In particular, I will review device performance and the scaling of analog errors with system size. By studying how errors scale during practical applications, we aim to predict if otherwise-intractable computations could be carried out with 30 to 40 qubits.

**9:12AM K48.00005 Concentric transmon qubit featuring fast tunability and site-selective Z coupling**, MARTIN WEIDES, JOCHEN BRAUMUELLER, Karlsruhe Institute of Technology, MARTIN SANDBERG, MICHAEL VISSERS, National Institute of Standards and Technology, ANDRE SCHNEIDER, STEFFEN SCHLOER, LUKAS GRUENHAUPT, HANNES ROTZINGER, MICHAEL MARTHALER, ALEXANDER LUKASHENKO, AMADEUS DIETER, ALEXEY USTINOV, Karlsruhe Institute of Technology, DAVID PAPPAS, National Institute of Standards and Technology — We present a planar qubit design based on a superconducting circuit that we call concentric transmon. While employing a simple fabrication process using Al evaporation and lift-off lithography, we observe qubit lifetimes and coherence times in the order of 10  $\mu$ s. We systematically characterize loss channels such as incoherent dielectric loss, Purcell decay and radiative losses. The implementation of a gradiometric SQUID loop allows for a fast tuning of the qubit transition frequency and therefore for full tomographic control of the quantum circuit. The presented qubit design features a passive direct Z coupling between neighboring qubits, being a pending quest in the field of quantum simulation.

**9:24AM K48.00006 Blackbox quantization and numerical simulation of a concentric transmon superconducting qubit**, ALIREZA NAJAFI-YAZDI, KEVIN LALUMIERE, Anyon Systems Inc., J. BRAUMÜLLER, MARTIN WEIDES, KIT — We present a blackbox quantization [1] and numerical study of a planar concentric transmon superconducting qubit. This architecture has been recently proposed and experimentally investigated by Braumüller et al [2]. The device involves a gradiometric SQUID loop for a fast tuning of the qubit transition frequency. This allows for full tomographic control of the quantum circuit. A fully automatized numerical package for quantization of superconducting qubits is developed and used for the study of the concentric transmon. A systematic characterization of loss channels such as Purcell decay and radiative losses are also studied. Numerical results are in close agreement with experimental data and suggest the platform to be a useful tool in the design of superconducting circuits. References: [1] Firat, S., DiVincenzo, D. W., David, P., Physical Review B, Vol. 90, No. 13, pp. 134-504, 2014. [2] J. Braumüller et al., arXiv:1509.08014

**9:36AM K48.00007 Weakly-tunable transmon qubits in a multi-qubit architecture**, JARED HERTZBERG, NICHOLAS BRONN, ANTONIO CORCOLES, MARKUS BRINK, GEORGE KEEFE, MAIKA TAKITA, IBM T J Watson Res Ctr, M. HUTCHINGS, B. L. T. PLOURDE, Syracuse University, JAY GAMBETTA, JERRY CHOW, IBM T J Watson Res Ctr — Quantum error-correction employing a 2D lattice of qubits requires a strong coupling between adjacent qubits and consistently high gate fidelity among them. In such a system, all-microwave cross-resonance gates offer simplicity of setup and operation. [1] However, the relative frequencies of adjacent qubits must be carefully arranged in order to optimize gate rates and eliminate unwanted couplings. [2] We discuss the incorporation of weakly-flux-tunable transmon qubits into such an architecture. Using DC tuning through filtered flux-bias lines, we adjust qubit frequencies while minimizing the effects of flux noise on decoherence. [1] J.M. Chow et al, Nat Comm 5, 4015 (2014). [2] A.D. Corcoles et al, Nat Comm 6, 6979 (2015).

**9:48AM K48.00008 Semiconductor-inspired superconducting quantum computing**, YUN-PIL SHIM, Laboratory for Physical Sciences — Superconducting circuits offer tremendous design flexibility in the quantum regime culminating most recently in the demonstration of few qubit systems supposedly approaching the threshold for fault-tolerant quantum information processing. Competition in the solid-state comes from semiconductor qubits, where nature has bestowed some very useful properties which can be utilized for spin qubit based quantum computing. Here we present an architecture for superconducting quantum computing based on selective design principles deduced from spin-based systems [1]. We propose an encoded qubit approach realizable with state-of-the-art tunable Josephson junction qubits. Our results show that this design philosophy holds promise, enables microwave-free control, and offers a pathway to future qubit designs with new capabilities such as with higher fidelity or, perhaps, operation at higher temperature. The approach is especially suited to qubits based on variable super-semi junctions. [1] Yun-Pil Shim and Charles Tahan, arXiv:1507.07923

**10:24AM K48.00009 Coupling a Transmon Qubit to a Superconducting Metamaterial Resonator**, HAOZHI WANG, M. HUTCHINGS, SAGER INDRAJEET, FRANCISCO ROUXINOL, MATTHEW LAHAYE, B.L.T. PLOURDE, Syracuse Univ, BRUNO G. TAKETANI, FRANK K. WILHELM, Saarland University — Arrays of lumped circuit elements can be used to form metamaterial resonant structures that exhibit significantly different mode structures compared to resonators made from conventional distributed transmission lines. In particular, it is possible to produce a high density of modes in the microwave regime where a superconducting qubit can be operated and coupled to the various modes. We will present our low-temperature measurements of such a superconducting metamaterial resonator coupled to a tunable transmon qubit. By tuning the magnetic flux biasing the qubit, we observe vacuum Rabi splittings in the modes that the qubit transition passes through. We will also discuss our measurements of an interaction between neighboring modes of the metamaterial system that is mediated by the qubit. Because of the dispersive coupling of the qubit to the various modes of the system, driving a microwave tone near one mode of the system can have a significant influence on the transmission through another mode, with a strong dependence on the bias point of the qubit. We will compare these measurements with a theoretical model of the system.

**10:36AM K48.00010 Coplanar waveguide flux qubit suitable for quantum annealing<sup>1</sup>**, CHRIS QUINTANA, UC Santa Barbara, YU CHEN, D. SANK, D. KAFRI, A. MEGRANT, T. C. WHITE, A. SHABANI, R. BARENDTS, Google, Santa Barbara, B. CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, UC Santa Barbara, A. FOWLER, E. JEFFREY, J. KELLY, E. LUCERO, J. Y. MUTUS, M. NEELEY, Google, Santa Barbara, C. NEILL, P. J. J. O'MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, A. VAINSENER, J. WENNER, UC Santa Barbara, J. M. MARTINIS, University of California and Google, Santa Barbara — We introduce the "fluxmon" flux qubit, designed with the goal of practical quantum annealing. The qubit's capacitance and linear inductance are provided by a coplanar waveguide on a low loss substrate, minimizing dielectric dissipation and in principle allowing for GHz-scale inter-qubit coupling in a highly connected tunable architecture. Utilizing a dispersive microwave readout scheme, we characterize single-qubit noise and dissipation, and present a simple tunable inter-qubit coupler. We discuss tradeoffs between coherence and coupling in a quantum annealing architecture.

**10:48AM K48.00011 Proposal for a cavity based superconducting qubit**, ANDREI VRAJITOAREA, Princeton University, JENS KOCH, Northwestern University, ANDREW HOUCK, Princeton University — Various technological challenges need to be resolved in order to demonstrate a working cQED network of superconducting qubits. For single Josephson junction devices important factors include improving coherence times and reducing fluctuations in junction critical current that ultimately lead to dephasing and unwanted frequency collisions. Superconducting microwave resonators show great potential for storing and manipulating quantum states and are known for their accurate reproducibility. We propose the direct addressability of a two level cavity state by dispersively coupling a fluxonium qubit to a coplanar lumped element resonator. We report preliminary experimental results that point towards an induced cavity anharmonicity due to the large dispersive shifts of the fluxonium system.

**8:00AM K50.00001 Magnetic phases of spin-1 spin-orbit coupled Bose gases<sup>1</sup>**, DANIEL CAMPBELL, RYAN PRICE, ANDIKA PUTRA, ANA VALDÉS-CURIEL, DIMITRIOS TRYPOGEORGOS, IAN SPIELMAN, Joint Quantum Institute, University of Maryland, College Park, Maryland, 20742, USA, SPIELMAN TEAM — We experimentally explore the magnetic phases present in a near-zero temperature spin-1 spin-orbit coupled atomic Bose gas. We observe ferromagnetic and unpolarized phases which are stabilized by the spin-orbit couplings explicit locking between spin and motion. In the limit of weak spin-orbit coupling, these phases are separated by a critical curve of 1st order quantum phase transitions, with an observed width as small as  $\hbar \times 4Hz$ . These phase transitions give rise to long-lived metastable states.

**8:12AM K50.00002 Quantum double-exchange physics with ultracold atoms and synthetic gauge potentials<sup>1</sup>**, JOHANNES SCHACHENMAYER, LEONID ISAEV, ANA MARIA REY, JILA, NIST and Dept. of Physics, University of Colorado Boulder — We study an interplay between local spin exchange and Néel antiferromagnetism in a two-band optical lattice. The lowest narrow band is half-filled and implements the magnetic background, while a higher band contains mobile atoms. When the local spins are locked in a Néel state, the motion of itinerant atoms is hindered by exchange energy barriers and the system is a flat-band insulator. As we show, this picture breaks down when exchange interaction between local and mobile spins is comparable to an energy scale of the Néel state. In this regime, formation of singlets between local and itinerant spins gives rise to a metallic phase of mobile atoms dressed by the spin fluctuations. This state is characterized by coupled spin-charge excitations whose spin is transverse to the Néel vector. Our predictions can be realized with ultracold alkaline-earth fermionic atoms coupled to a laser-induced staggered magnetic field, which stabilizes the Néel order and controls the amount of quantum fluctuations of local spins. By tuning the strength of this laser coupling relative to the exchange interaction, one can either adiabatically drive the crossover between the flat-band insulator and correlated metal phases, or explore non-equilibrium spin-charge dynamics in quench experiments.

**8:24AM K50.00003 Interaction effects in cold gases in synthetic gauge fields<sup>1</sup>**, THOMAS BILITEWSKI, NIGEL COOPER, T.C.M. Group, Cavendish Laboratory, J.J. Thomson Avenue, Cambridge CB3 0HE, United Kingdom — There has been a long-standing goal to find ways to cause neutral atoms to experience synthetic gauge fields, extending the capabilities of ultracold gases as simulators of quantum many-body systems. Such gauge fields can mimic the effect of magnetic fields and generate topological energy bands. Recent proposals to generate synthetic gauge fields rely on time-dependent periodic forcing of the quantum system.

Interactions are of particular interest in these systems, as the interplay of time dependence and interactions can lead to inelastic scattering and the combined effect of synthetic gauge fields and strong correlations could lead to a variety of novel many body phases of degenerate fermionic or bosonic atoms.

In the framework of Floquet Theory we study the effects of inelastic scattering induced by the intrinsic time dependence of the eigenstates and the elastic two-body interactions [1]. Specifically, we discuss this mechanism as a potential explanation of heating and band population dynamics in current experimental setups.

**8:36AM K50.00004 Spin-Orbit Coupled Fermions in Harmonic Trap**, DOGA MURAT KURKCUOGLU, Georgia Southern University, Georgia Inst of Tech — After the realization of artificial spin-orbit coupling in ultracold atoms experimentally, there is an interest in spin-orbit coupled systems in ultracold atoms. In this abstract, I will discuss the emergence of two-body bound states between two Fermi atoms in the presence of spin-orbit coupling and Zeeman fields. The fermions are assumed to have only two internal states and to have attractive contact (zero-ranged) interactions. We also add an isotropic three-dimensional harmonic trap to the system, since it is the experimentally relevant case. For such a system, I will describe the few-body solutions and the effective masses of the bound-states as a function of spin-orbit and Zeeman fields.

**8:48AM K50.00005 Thermodynamics of interacting cold atomic Fermi gases with spin-orbit coupling<sup>1</sup>**, SCOTT JENSEN, YORAM ALHASSID, CHRISTOPHER GILBRETH, Center for Theoretical Physics, Yale University — New physics is suggested with the prediction of novel phases in cold atom systems when a synthetic spin-orbit coupling is introduced. In particular, recent studies show that a new type of Bose-Einstein condensate, termed Rashbon-BEC, is formed when a generalized Rashba spin-orbit term is present [1]. The Rashbon-BEC phase can be obtained by tuning the spin-orbit coupling strength even in the case of finite negative scattering length. This stands in contrast to the BCS-BEC crossover in the absence of spin-orbit coupling where a negative scattering length is associated with BCS physics, and its divergence signals the crossover. In our work we apply finite-temperature quantum Monte Carlo methods to a spherical Rashba spin-orbit coupled two-species Fermi gas with contact s-wave interaction in three dimensions. We will discuss the phase diagram for this system, and its crossover behavior from BCS to Rashbon-BEC.

**9:00AM K50.00006 Spin-orbit coupling in the strongly interacting Fermi gas: an exact quantum Monte Carlo study<sup>1</sup>**, PETER ROSENBERG, HAO SHI, SIMONE CHIESA, SHIWEI ZHANG, College of William and Mary — Spin-orbit coupling (SOC) plays an essential role in a variety of intriguing condensed matter phenomena, including the quantum Hall effect, and topological insulators and superconductors. The recent experimental realization of spin-orbit coupled Fermi gases provides a unique opportunity to study the effects of SOC in a tunable, disorder-free system. Motivated by this experimental progress, we present here the first exact numerical results on the two-dimensional, unpolarized, uniform Fermi gas with attractive interactions and Rashba SOC. Using auxiliary-field quantum Monte Carlo and incorporating recent algorithmic advances, we carry out exact calculations on sufficiently large system sizes to provide accurate results systematically as a function of experimental parameters. We obtain the equation of state, study the spin behavior and momentum distribution, and examine the interplay of SOC and pairing in real and momentum space. Our results help illuminate the rich pairing structure induced by SOC, and provide important guidance to future experimental efforts.

**9:12AM K50.00007 Melting of phase-strips in Bose-Einstein condensates with synthetic spin-orbit coupling<sup>1</sup>**, ASLE SUDBO, PEDER GALTELAND, Norwegian Univ Tech (NTNU), EGOR BABAEV, Royal Institute of Technology, Stockholm, Sweden — We study a two-component, density imbalanced Bose-Einstein condensate with density-density interactions and synthetic spin-orbit coupling, focusing on the impact of thermal fluctuations and density-density interactions on spin-orbit induced effects. We find that for intermediate density imbalance and small intercomponent density-density interactions, the ground state is non-uniform, represented by a striped state of modulated phases of the individual complex order parameter components. By using mean-field stability arguments, we calculate a critical value for the intercomponent density-density interaction, above which the non-uniform ground state collapses into a uniform single-component state. This is reproduced in Monte-Carlo simulations for intermediate values of the spin-orbit coupling. We also find that the non-uniform ground state is disordered by thermal fluctuations when heated, through a Berizinskii-Kosterlitz-Thouless unbinding of dislocation pairs. We argue that, to lowest order, the spin-orbit coupling can be seen as an effective Josephson-type locking of the phase difference  $\theta_1 - \theta_2$  while simultaneously allowing the system to gain energy by modulating the phase sum  $\theta_1 + \theta_2$ .

**9:24AM K50.00008 Pairing of fermions with unequal charges in an artificial magnetic field**, NUR UNAL, Cornell Univ, M. O. OKTEL, Bilkent Univ — Artificial magnetic fields (AMFs) created for ultra cold systems depend sensitively on the internal structure of the atoms. In a mixture, each component couples to the AMF with a different charge. This enables the study of Bardeen-Cooper-Schrieffer pairing of fermions with unequal charges. We investigate the superconducting (SC) transition of a system formed by such pairs as a function of the field strength. We consider a homogeneous two-component Fermi gas of unequal charges but equal densities with attractive interactions. We find that the phase diagram is altered drastically compared to the usual equal charge case. First, for some AMFs there is no SC transition and isolated SC phases are formed, reflecting the discrete Landau level (LL) structure. SC phases become reentrant both in AMF and temperature. For extremely high fields where both components are confined to their lowest LLs, the effect of the charge imbalance is suppressed. Charge asymmetry reduces the critical temperature even in the low-field semiclassical regime. We discuss a pair breaking mechanism due to the unequal Lorentz forces acting on the components of the Cooper pairs to identify the underlying physics.

**9:36AM K50.00009 SPECTRUM OF THE RASHBA SPIN-ORBIT COUPLED HAMILTONIAN WITH SPIN-DEPENDENT CONTACT INTERACTION IN DIMENSION THREE**, RYTIS JURSENAS, Vilnius University, Institute of Theoretical Physics and Astronomy — The presentation provides functional analytic interpretation for the spectrum of the Rashba spin-orbit coupled Hamiltonian considered in the presence of the out-of-plane magnetic field. The impurity scattering is treated by means of a spin-dependent contact interaction. The research was inspired by a recently proposed technique [1, 2, 3] for producing the Rashba-type spin-orbit coupling for a three-dimensional ultracold atom. The analysis of the resolvent formula shows that, for nonzero spin-orbit coupling, the eigenvalues solve the transcendental equation. For small spin-orbit-coupling strength  $\alpha$ , the eigenvalues are derived analytically with the accuracy up to  $O(\alpha^4)$ . It is shown that there are no eigenvalues above the threshold no matter the form of a nonzero coupling parameter of contact interaction. When the lower branch of dispersion relation attains two minima, the eigenvalues are situated only below the threshold or above the minimum of the upper branch of dispersion relation; the upper bound of discrete states is also obtained. [1] B. M. Anderson et al, Phys. Rev. Lett. 111 (2013), 125301. [2] D. L. Campbell et al, Phys. Rev. A 84 (2011), 025602. [3] F. Jendrzejewski et al, Nature Physics 8 (2012), 398.

**9:48AM K50.00010 Vortex line of spin-orbit coupled Fermi superfluid through BCS to BEC Crossover<sup>1</sup>**, JUAN YAO, SHIZHONG ZHANG, The Univ of Hong Kong — Superfluid Fermi gases with spin-orbit interaction provides a unique opportunity to investigate possible effects of strong interaction in a topological superfluid. It has been suggested that with addition of Rashba-type spin-orbit coupling, a two-component Fermi gas with strong s-wave interaction can become a topological superfluid with zero-energy bound state at the core of the vortex. In this talk, I discuss the evolution of vortex structure in a spin-orbit coupled Fermi gas through the BCS-BEC crossover within Bogoliubov-de Gennes formalism. We find that the largest critical current occurs in the BEC side of the resonance, in contradiction to the usual crossover without spin-orbit coupling where it occurs at unitarity. Furthermore, we discuss the core structure of the vortex by calculating the spin and density distribution around the vortex.

**10:00AM K50.00011 Stripe phase and double-roton excitations in interacting spin-orbit-coupled spin-1 Bose-Einstein condensates**, KUEI SUN, The University of Texas at Dallas, Richardson, Texas, USA, CHUNLEI QU, The University of Texas at Dallas, Richardson, Texas, USA and Università di Trento, Povo, Italy, YONG XU, The University of Texas at Dallas, Richardson, Texas, USA, YONGPING ZHANG, OIST Graduate University, Onna, Okinawa, Japan, CHUANWEI ZHANG, The University of Texas at Dallas, Richardson, Texas, USA — Spin-orbit (SO) coupling plays a major role in many important phenomena in condensed matter physics. However, the SO coupling physics in high-spin systems, especially with superfluids, has not been well explored because of the spin half of electrons in solids. In this context, the recent experimental realization of spin-orbit coupling in spin-1 Bose-Einstein condensates (BECs) has opened a completely new avenue for exploring SO-coupled high-spin superfluids. Nevertheless, the experiment has only revealed the single-particle physics of the system. Here, we study the effects of interactions between atoms on the ground states and collective excitations of SO-coupled spin-1 BECs in the presence of a spin-tensor potential. We find that ferromagnetic interaction between atoms can induce a stripe phase exhibiting two modulating patterns. We characterize the phase transitions between different phases using the spin-tensor density as well as the collective dipole motion of the BEC. We show that there exists a new type of double maxon-roton structure in the Bogoliubov-excitation spectrum, attributing to the three band minima of the SO-coupled spin-1 BEC. Our work could motivate further theoretical and experimental study along this direction.

**10:12AM K50.00012 Finite temperature theory of spin-orbit coupled fermions in three dimensions in the presence of external Zeeman fields and tunable s-wave interactions**, PHILIP POWELL, Lawrence Livermore National Laboratory, GORDON BAYM, University of Illinois at Urbana-Champaign, CARLOS SA DE MELO, Georgia Institute of Technology, Joint Quantum Institute — We develop a finite temperature theory of ultracold three-dimensional Fermi gases in the presence of artificial spin-orbit coupling, Zeeman fields, and tunable s-wave interactions. With the inclusion of quadratic fluctuations, we compute both the critical temperature for superfluidity and the population of bound and unbound fermions throughout the evolution from the Bardeen-Cooper-Schrieffer (BCS) to Bose-Einstein condensate (BEC) regimes. In particular, we show that in the BEC regime, spin-orbit coupling is capable of increasing the critical temperature relative to the no-field case, by inducing a triplet component to the superfluid order parameter, while decreasing the many-body effective mass. We also derive the time-dependent Ginzburg-Landau equation to sixth-order in the superfluid order parameter, and obtain explicit expressions for the coefficients of the effective theory valid across the entire evolution from BCS to BEC superfluidity.

**10:24AM K50.00013 Entanglement of Vortex Lattices for Ultracold Bose Gases in a Non-Abelian Gauge Potential**, SZU-CHENG CHENG, Department of Optoelectric Physics, Chinese Culture University, Taiwan, ROC, T. F. JIANG, SHIH-DA JHENG, Institute of Physics, National Chiao Tung University, Taiwan, ROC, ATOMIC AND MOLECULAR PHYSICS TEAM, ATOMIC AND MOLECULAR PHYSICS TEAM — We develop a theory, referred to as the von Neumann lattice in a higher Landau level, for vortex lattices labelled by an integral number of flux quanta per unit cell in a higher Landau level. Using this lattice theory, we study the vortex lattice states of a pseudospin-1/2 ultracold Bose gas with contact interactions in a non-Abelian gauge potential. In addition to a uniform magnetic field, the Bose gas is also subjected to a non-Abelian gauge field, which creates an effect of the spin-orbit coupling to lift the spin degeneracy of the Landau levels. Because of interactions from the spin-orbit coupling, there are new degenerate points of the single particle spectrum due to the crossings of two Landau levels at certain coupling strengths. We show that interactions from the spin-orbit coupling force the nature and structure of the vortex lattice changing dramatically if the strength of the non-Abelian gauge field is increasing. We also find that the ground state of the vortex lattice at a degenerate point exhibits strong correlation and entanglement involving vortex lattices from different Landau levels. This entangled state builds the connection between two phases of vortex lattices during the first order phase transition of the adiabatic evolution.

**10:36AM K50.00014 Baryon squishing in synthetic dimensions by effective  $SU(M)$  gauge fields<sup>1</sup>**, SUDEEP KUMAR GHOSH, UMESH K. YADAV, VIJAY B. SHENOY, Indian Institute of Science Bangalore — We investigate the physics of  $SU(M)$  symmetric interactions in the “synthetic dimensions” (Celi et al., PRL 112, 043001 (2014)) that provides a cold atom realization of the Hofstadter model. We show that this system is equivalent to particles (with  $SU(M)$  symmetric interactions) experiencing an  $SU(M)$  Zeeman field at each lattice site *and* a non-Abelian  $SU(M)$  gauge potential that affects their hopping. This equivalence brings out the possibility of generating *non-local* interactions between particles at different sites of the optical lattice. In addition, the gauge field induces a *flavor-orbital coupling*, which mitigates the “baryon breaking” effect of the Zeeman field. For  $M$  particles, concomitantly, the  $SU(M)$  singlet baryon which is site localized in the usual 1d optical lattice, is deformed to a non-local object (“squished baryon”). We conclusively demonstrate this effect by analytical arguments and exact (numerical) diagonalization studies. Our study promises a rich many-body phase diagram for this system. It also uncovers the possibility of using the synthetic dimension system to laboratory realize condensed matter models such as the  $SU(M)$  random flux model, inconceivable in conventional experimental systems. Reference: arXiv:1503.02301

**10:48AM K50.00015 Cavity-Assisted Spin Orbit Coupling**, CHUANZHOU ZHU, LIN DONG, HAN PU, Rice University — We consider a single ultracold atom trapped inside a single-mode optical cavity, where a two-photon Raman process induces an effective coupling between atom's pseudo-spin and external center-of-mass (COM) motion. Without the COM motion, this system is described by the Jaynes-Cummings (JC) model. We show how the atomic COM motion dramatically modifies the predictions based on the JC model. We also investigated the situation when cavity pumping and decay are taken into account. We take a quantum Master equation approach to study this open system and again show how the cavity-induced spin-orbit coupling affects the properties of the system.

**Session K51 FIAP: Fractional QHE: Topological, Non-Abelian, and 5/2 States** Hilton Baltimore Holiday Ballroom 2 - John Cumings, University of Maryland

**8:00AM K51.00001 Possibility of topological order in partially flat band systems**, ABOLHASSAN VAEZI, Stanford University — In this talk, we discuss the possibility of topological order in two-dimensional partially flat bands. We first consider a tight-binding model whose valence band is (nearly) flat only in some regions of the Brillouin zone, where the Berry curvature is mostly concentrated, and dispersive otherwise. We then investigate the ground-states of these systems when the flat regions are fractionally filled. We argue that under certain conditions spontaneous symmetry breaking orders such as charge density wave (CDW) can emerge. The resulting CDW enlarges the unit cell and separates the flat regions from the rest of the valence band by a finite energy gap. Interestingly, the broken symmetry state can exhibit fractional Chern insulator phase with quantized Hall conductivity. Finally, we present our numerical results for the phase diagram of such systems.

**8:12AM K51.00002 Measurement of 2D topological invariants from anomalous edge spectral flow**, SRIRAM GANESHAN, Simons center of geometry and physics, Stony Brook University, SUNIL MITTAL, JINGYUN FAN, Joint Quantum Institute, NIST/University of Maryland, College Park, ABOLHASSAN VAEZI, Stanford University, MOHAMMAD HAFEZI, Joint Quantum Institute, NIST/University of Maryland, College Park MD — A hallmark example of a TQFT is the 2+1 D Chern-Simons (CS) theory, which describes topological properties of both integer and fractional quantum Hall effects. The gauge invariant form of the CS theory with boundaries, encompassing both edge and bulk terms, provides an unambiguous way to relate bulk topological invariants to the edge dynamics. This bulk-edge correspondence is manifested as a gauge anomaly in the bulk and chiral anomaly at the edge, and provides a direct insight into the bulk topological order. In this work, we experimentally implement the integer quantum Hall model in a photonic system where the edge modes are described by the anomalous chiral conformal field theory. By selectively manipulating and probing the edge, we exploit the chiral anomaly of the edge theory, for the first time. The associated spectral edge flow associated to the chiral anomaly allows us to unambiguously measure topological invariants, i.e., the winding number of the edge states. This experiment provides a new approach for direct measurement of topological invariants, independent of the microscopic details, and thus could be extended to probe strongly-correlated topological orders.

**8:24AM K51.00003 Bose condensation in topologically ordered quantum liquids**, TITUS NEUPERT, HUAN HE, CURT VON KEYSERLINGK, Princeton University, GERMAN SIERRA, UAM-CSIC Madrid, ANDREI BERNEVIG, Princeton University — The condensation of bosons can induce transitions between topological quantum field theories (TQFTs). This has been previously investigated through the formalism of Frobenius algebras and with the use of Vertex lifting coefficients. We discuss an alternative, algebraic approach to boson condensation in TQFTs that is physically motivated and computationally efficient. With a minimal set of assumptions, such as commutativity of the condensation with the fusion of anyons, we can prove a number of theorems linking boson condensation in TQFTs with algebra extensions in conformal field theories and with the problem of factorization of completely positive matrices over the positive integers. We propose an algorithm for obtaining a condensed theory fusion algebra and its modular matrices. For example, this formalism can be used to build multi-layer TQFTs which could be a starting point to build three-dimensional topologically ordered phases. Using this formalism, we also give examples of bosons that cannot undergo a condensation transition due to topological obstructions.

**8:36AM K51.00004 Fermion Parity Flips and Majorana Defects in Superconducting Fractional Topological Phases**, MAYUKH KHAN, University of Illinois at Urbana-Champaign, JEFFREY TEO, University of Virginia, TAYLOR HUGHES, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We consider layered heterojunctions of s-wave superconductors and Abelian topologically ordered (TO) phases. We derive the emergent theories for a wide variety of fractional quantum Hall states promoted by a  $Z_2$  gauge theory. The theory always carries an anyonic symmetry (AS) which effects a fermion parity flip. The associated twist defects, which flip the parities of some types of orbiting quasiparticles, trap ordinary zero energy Majorana bound states (MBS), and can bind fractional charge. For example, an  $h/2e$  flux vortex of the superconductor that circulates around the MBS undergoes a fermion parity flip and is accompanied by a level crossing in the vortex energy spectrum. We show numerical evidence of the level crossing in the simplest examples: a Chern insulator and a normal insulator/topological insulator/superconductor junction. Finally, we briefly describe the resulting twist liquid theory after gauging the AS where the twist defects become deconfined anyonic excitations.

**8:48AM K51.00005 A New Kind of Topological Quantum Order: A Dimensional Hierarchy of Quasiparticles Built from Stationary Excitations**, S. VIJAY, JEONGWAN HAAH, LIANG FU, Massachusetts Inst of Tech-MIT — We introduce exactly solvable models of interacting (Majorana) fermions in  $d \geq 3$  spatial dimensions that realize a new kind of topological quantum order, building on a model presented in ref. [1]. These models have extensive topological ground-state degeneracy and a hierarchy of point-like, topological excitations that are only free to move within sub-manifolds of the lattice. In particular, one of our models has fundamental excitations that are completely stationary. To demonstrate these results, we introduce a powerful polynomial representation of commuting Majorana Hamiltonians. Remarkably, the physical properties of the topologically-ordered state are encoded in an algebraic variety, defined by the common zeros of a set of polynomials over a finite field. This provides a “geometric” framework for the emergence of topological order. [1] S. Vijay, T. H. Hsieh and L. Fu, arXiv:1504.01724 (2015).

**9:00AM K51.00006 Particle-vortex duality of 2d Dirac fermion from electric-magnetic duality of 3d topological insulators**, MAX METLITSKI, Perimeter Institute for Theoretical Physics, ASHVIN VISHWANATH, University of California, Berkeley — Particle-vortex duality is a powerful theoretical tool that has been used to study systems of bosons. In arXiv:1505.05142, we propose an analogous duality for Dirac fermions in 2+1 dimensions. The physics of a single Dirac cone is proposed to be described by a dual theory, QED3 with a dual Dirac fermion coupled to a  $u(1)$  gauge field. This duality is established by considering two alternate descriptions of the 3d topological insulator (TI) surface. The first description is the usual Dirac cone surface state. The second description is accessed via an electric-magnetic duality of the bulk TI coupled to a gauge field, which maps it to a gauged topological superconductor. This alternate description ultimately leads to a new surface theory - dual QED3. The dual theory provides an explicit derivation of the T-Pfaffian state, a proposed surface topological order of the TI, which is simply the paired superfluid state of the dual fermions. The roles of time reversal and particle-hole symmetry are exchanged by the duality, which connects some of our results to a recent conjecture by Son on particle-hole symmetric quantum Hall states at  $\nu = 1/2$ .

**9:12AM K51.00007 Half-filled topological flat bands, dualities and SPT surface states**, ANDREW POTTER, Univ of California - Berkeley, MAX METLITSKI, Perimeter Institute, ASHVIN VISHWANATH, Univ of California - Berkeley — The surface states of 3D symmetry protected topological phases are impossible to realize in pure 2D systems with a local implementation of symmetry. However, systems with non-local symmetries, e.g. associated with filling or emptying a topological flat band, can circumvent this limitation. A well studied recent example is that of the  $1/2$ -filled Landau level, which effectively realizes the physics of a particular type of time-reversal invariant topological superconductor. In this talk, I will generalize these concepts to other classes of 2D topological flat bands with non-local symmetries, that are related to 3D SPT surface states with local implementations of the same symmetry. This generalization reveals new dualities between strongly interacting gapless phases. In addition, physical implications for new gapless and topologically ordered states in multicomponent quantum Hall systems will be mentioned.

**9:24AM K51.00008 Non-Abelian states in Fractional Quantum Hall effect in charge carrier hole systems<sup>1</sup>**, GEORGE SIMION, YULI LYANDA-GELLER, Department of Physics and Astronomy, Purdue University — Quasiparticle excitations obeying non-Abelian statistics represent the key element of topological quantum computing. Crossing of levels and strong coupling between angular momentum and orbital motion, described by Luttinger Hamiltonian, make properties of charge carrier holes different from those of electrons. Peculiarities of hole spectrum in magnetic field provide an opportunity for controlling Landau level mixing in charge carrier hole systems. In order to describe Fractional Quantum Hall effect for holes, we propose a method to map hole spectrum and wavefunctions using a spherical shell. We investigate the experimentally observed  $\nu = 1/2$  state in spherical geometry. Haldane pseudopotentials are computed and the effect of Landau level mixing is evaluated. Exact diagonalization of Coulomb interaction in systems with eight to fourteen holes is performed. We determine that the ground state superposition with Abelian 331 state is very small and the overlap with Moore-Read state is significant. The quasihole and quasielectron excitations are discussed.

**9:36AM K51.00009 The Fractional Quantum Hall States at  $\nu = 13/5$  and  $12/5$  and their Non-Abelian Nature<sup>1</sup>**, W. ZHU, Cal State Univ - Northridge, S. S. GONG, National High Magnetic Field Lab, D. N. SHENG, Cal State Univ - Northridge — Topological quantum states with non-Abelian Fibonacci anyonic excitations are widely sought after for their exotic fundamental physics and potential applications in universal quantum computing. The fractional quantum Hall (FQH) state at filling factor  $\nu = 12/5$  is such a promising candidate, however, its precise nature is still under debate and no consensus has been achieved so far. Here, we investigate the nature of the FQH  $\nu = 13/5$  state and its particle-hole conjugate state at  $12/5$  with the Coulomb interaction, and address the issue of possible competing states. Based on a large-scale density-matrix renormalization group (DMRG) calculation in spherical geometry, we present evidence that the essential physics of the Coulomb ground state (GS) at  $\nu = 13/5$  and  $12/5$  is captured by the  $k = 3$  parafermion Read-Rezayi state ( $RR_3$ ), including a robust excitation gap and the topological fingerprint from entanglement spectrum and topological entanglement entropy. Furthermore, by considering the infinite-cylinder geometry (topologically equivalent to torus geometry), we expose the non-Abelian GS sector corresponding to a Fibonacci anyonic quasiparticle, which serves as a signature of the  $RR_3$  state at  $13/5$  and  $12/5$  filling numbers.

**9:48AM K51.00010 Interferometric measurements to test non-Abelian properties of  $e/4$  charges in the fractional quantum Hall state at  $5/2$** , ROBERT WILLETT, Alcatel-Lucent/Bell Labs, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, Princeton University, KIRILL SHTENGEL, University of California, Riverside, CHETAN NAYAK, University of California, Santa Barbara, and Microsoft Q — The excitations of charge  $e/4$  at  $5/2$  filling factor are proposed to obey non-Abelian statistics. To test this, interferometry at fractional quantum Hall states can be performed that controllably braids edge currents around localized charges. We have conducted these measurements in a large number of interferometers of different sizes, also using multiple designs of high quality 2D electron heterostructures. We observe properties of the interference measurements at  $5/2$  that are specifically consistent with non-Abelian  $e/4$ . In particular, magnetic field sweeps around  $5/2$  show interference oscillations with frequency spectra that are consistent in detail with non-Abelian  $e/4$  properties. Four frequency spectra peaks are observed corresponding to both  $e/4$  and  $e/2$  charges; importantly a rapid non-Abelian  $e/4$  component is seen that is split due to beating between the two  $e/4$  braiding processes. We review these results and their observation in a range of interferometer dimensions and in different heterostructure designs.

**10:00AM K51.00011 Abelian and non-Abelian states in  $\nu = 2/3$  bilayer fractional quantum Hall systems<sup>1</sup>**, MICHAEL PETERSON, Cal State Univ- Long Beach, YANG-LE WU, Joint Quantum Institute, University of Maryland, MENG CHENG, MAISSAM BARKESHLI, Microsoft, ZHENGHAN WANG, Microsoft, University of California Santa Barbara — There are several possible theoretically allowed non-Abelian fractional quantum Hall (FQH) states that could potentially be realized in one- and two-component FQH systems at total filling fraction  $\nu = n + 2/3$ , for integer  $n$ . Some of these states even possess quasiparticles with non-Abelian statistics that are powerful enough for universal topological quantum computation, and are thus of particular interest. Here we initiate a systematic numerical study, using both exact diagonalization and variational Monte Carlo, to investigate the phase diagram of FQH systems at total filling fraction  $\nu = n + 2/3$ , including in particular the possibility of the non-Abelian  $Z_4$  parafermion state. In  $\nu = 2/3$  bilayers we determine the phase diagram as a function of interlayer tunneling and repulsion, finding only three competing Abelian states, without the  $Z_4$  state. On the other hand, in single-component systems at  $\nu = 8/3$ , we find that the  $Z_4$  parafermion state has significantly higher overlap with the exact ground state than the Laughlin state, together with a larger gap, suggesting that the experimentally observed  $\nu = 8/3$  state may be non-Abelian. Our results from the two complementary numerical techniques agree well with each other qualitatively.

<sup>1</sup>We acknowledge the Office of Research and Sponsored Programs at California State University Long Beach and Microsoft Station Q.

**10:12AM K51.00012 Particle-hole symmetry without particle-hole symmetry in the quantum Hall effect at  $\nu = 5/2$ .<sup>1</sup>**, DMITRI FELDMAN, PHILIP ZUCKER, Brown Univ — Numerical results suggest that the quantum Hall effect at  $\nu = 5/2$  is described by the Pfaffian or anti-Pfaffian state in the absence of disorder and Landau level mixing. In realistic samples both disorder and Landau level mixing are strong on the  $5/2$  plateau. The experimental observation of the upstream neutral mode on the sample edge is incompatible with the Pfaffian state. Tunneling experiments give an upper bound on the universal exponent  $g$  in the zero bias conductance  $G \sim T^{2g-2}$ . That bound is inconsistent with the anti-Pfaffian state. We show that a recent proposal of the PH-Pfaffian topological order by Son is compatible with the tunneling experiments and the observation of the upstream mode. The quasiparticle statistics of the PH-Pfaffian state is similar to the statistics in the Pfaffian and anti-Pfaffian states and its interferometric signatures are also similar to those of the Pfaffian and anti-Pfaffian topological orders. The absence of the particle-hole symmetry at  $\nu = 5/2$  is not an obstacle to the existence of the PH-Pfaffian order since the order is robust to symmetry breaking.

**10:24AM K51.00013 Electric Fields in the  $5/2$  fractional quantum Hall effect<sup>1</sup>**, ANTHONY TYLANTYLER, Univ of Pittsburgh, YULI LYANDA-GELLER, Purdue University — The potential for non-Abelian quasiholes in the  $5/2$  fractional quantum Hall effect makes the state of interest theoretically and experimentally. The presence of such features in the ground state of the system would allow for the implementation of a topological quantum computation scheme. In order to probe the system for these features, a small measuring voltage, i.e. an electric field, is applied. In Corbino geometries, these electric fields are applied radially. This breaks the Galilean invariance, which in an infinite planar geometry allows us to transform to a moving frame of reference, eliminating the electric field. To study the effects of these fields, we carry out exact diagonalization calculations in a disk geometry. We find that application of small fields can lead to an improvement in the overlap with the Moore-Read Pfaffian long before the state is destroyed by the field. Additionally, we find that the coherence length of quasiholes travelling along the edge of the sample increases significantly when compared to the case with no applied field.

**10:36AM K51.00014 Probing bulk physics in the 5/2 fractional quantum Hall effect using the Corbino geometry**, BENJAMIN SCHMIDT, McGill University, KEYAN BENNACEUR, Sherbrooke University, SIMON BILODEAU, SAMUEL GAUCHER, McGill University, MICHAEL LILLY, JOHN RENO, Sandia National Laboratories, LOREN PFEIFFER, KEN WEST, Princeton University, BERTRAND REULET, Sherbrooke University, GUILLAUME GERVAIS, McGill University — We present two- and four-point Corbino geometry transport measurements in the second Landau level in GaAs/AlGaAs heterostructures. By avoiding edge transport, we are able to directly probe the physics of the bulk quasiparticles in fractional quantum Hall (FQH) states including 5/2. Our highest-quality sample shows stripe and bubble phases in high Landau levels, and most importantly well-resolved FQH minima in the second Landau level. We report Arrhenius-type fits to the activated conductance, and find that  $\sigma_0$  agrees well with theory and existing Hall geometry data in the first Landau level, but not in the second Landau level. We will discuss the advantages the Corbino geometry could bring to various experiments designed to detect the non-Abelian entropy at 5/2, and our progress towards realizing those schemes. The results of these experiments could complement interferometry and other edge-based measurements by providing direct evidence for non-Abelian behaviour of the bulk quasiparticles. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL8500.

**10:48AM K51.00015 Discovery of competing 5/2 fractional quantum Hall states<sup>1</sup>**, XI LIN, HAILONG FU, PENGJIE WANG, PUJIA SHAN, LIN XIONG, Peking University, LOREN PFEIFFER, KEN WEST, Princeton University, MARC KASTNER, MIT & Science Philanthropy Alliance — With an even denominator,  $\nu = 5/2$  fractional quantum Hall state (FQH) is different from most of the other FQH states. Some of its proposed wave functions may exhibit novel non-Abelian statistics, which is related to topological quantum computation. We carried out tunneling measurements within a quantum point contact (QPC) at the 5/2 state and we were able to match the QPC's density to the two-dimensional electron gas bulk density. Such a density match guarantees the uniform filling factor inside and outside the QPC. The interaction parameter  $g$  and the effective charge  $e^*$  can be extracted through the weak tunneling theory [1]. We found  $g$  and  $e^*$  similar to what people believed to be the Abelian 331 state [2, 3]. By tuning the confinement, we observed another region where the experimental data agree well with the weak tunneling theory, which leads to  $e^*=0.25$  and  $g=0.52$ , implying non-Abelian wavefunctions such as anti-Pfaffian or  $U(1)SU(2)$ . Our discovery suggests that there are competing 5/2 fractional quantum Hall ground states depending on the confinement. [1] Science 320, 899 (2008). [2] Phys. Rev. B 85, 165321 (2012). [3] Phys. Rev. B 90, 075403 (2014).

**8:00AM K52.00001 Ligand engineering of lead chalcogenide nanoparticle solar cells<sup>1</sup>**, MARTON VOROS, Materials Science Division, Argonne National Laboratory, NICHOLAS BRAWAND, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Semiconductor nanoparticles (NP) are promising materials to build cheap and efficient solar cells. One of the key challenges in their utilization for solar energy conversion is the control of ligand-NP interfaces. Recent experiments have shown that by carefully choosing the ligands terminating the NPs, one can tailor electronic and optical absorption properties of NP assemblies, along with their transport properties.[1] By using density functional theory based methods, we investigated how the opto-electronic properties of lead chalcogenide NPs may be tuned by using diverse organic and inorganic ligands. We interpreted experiments, and we showed that an essential prerequisite to avoid detrimental trap states is to ensure charge balance at the ligand-NP interface, possibly with the help of hydrogen treatment. **8:12AM K52.00002 Verifying field-effect passivation of a SiN<sub>x</sub> layer on a silicon nanopillar array using surface photovoltage characterization**, EUNAH KIM, YUNAE CHO, AHRUM SOHN, DONG-WOOK KIM, Ewha Womans University, HYEONG-HO PARK, Korea Advanced Nanofab Center, JOONDONG KIM, Incheon National University — In silicon (Si) wafer based photovoltaic (PV) devices, light-trapping strategies to improve optical absorption are very important due to the indirect bandgap of Si. Surface nano-patterned Si enable omnidirectional broadband antireflection (AR) effects with the help of graded refractive index, multiple scattering, diffraction, and Mie resonance. In this work, the surface photovoltage (SPV) of periodic nanopillar (NP) arrays were investigated using Kelvin probe force microscopy (KPFM). The SPV characteristics clearly revealed that positive fixed charges in SiN<sub>x</sub> layers induced downward band bending at the Si surface and increased SPV at the NP top surface. The similar SPV value of NPs and planar counterpart suggests that field effect passivation by the dielectric layer coating could help improve PV performance of nanostructure-based Si solar cells and that KPFM measurements are useful tool for quantitative investigation of surface electrical properties of Si nanostructures.

**8:24AM K52.00003 Ultra-dense silicon nanowire array solar cells by nanoimprint lithography<sup>1</sup>**, PENG ZHANG, PEI LIU, STYLIANOS SIONTAS, ALEXANDER ZASLAVSKY, DOMENICO PACIFICI, Brown Univ, JONG-YOON HA, SERGIY KRYLYUK, Univ of Maryland & National Institute of Standards and Technology, ALBERT DAVYDOV, National Institute of Standards and Technology — Nanowire (NW) solar cells have been attracting increasing interest due to their potentially superior light absorption compared to thin bulk films. In order to improve light trapping, we have used nanoimprint lithography (NIL) to fabricate high-density NW arrays with deep sub-micron pitch (P) and diameter (D). We have grown dense vertical arrays of Si axial  $p-i-n$  junction NWs of  $D = 170$  nm and  $P = 500$  nm by vapor-liquid-solid epitaxy on seed arrays produced by NIL. The NWs were 9  $\mu$ m length long with a 5  $\mu$ m intrinsic section. The NW arrays were planarized using SU-8 photoresist, followed by reactive ion etching to expose the NW tips. Top  $n$ -contact was realized by sputter deposition of a transparent 200 nm IZO layer. The nanoimprinted NW array samples measured under AM 1.5 G illumination showed a peak external quantum efficiency of  $\sim 8\%$  and internal quantum efficiency of  $\sim 90\%$  in the visible spectral range. Three-dimensional finite-difference time-domain simulations of Si NW periodic arrays with varying P confirm the importance of high NW density. Specifically, due to diffractive scattering and light trapping, absorption efficiency close to 100% in the 400–650 nm spectral range is predicted for a Si NW array with an even smaller  $P = 250$  nm, significantly outperforming a blanket Si film of the same thickness. Such pitch values are accessible to NIL and work on such arrays is in progress.

**8:36AM K52.00004 High Efficiency InP Solar Cells Through Nanostructuring**, DANIEL GOLDMAN, JOSEPH MURRAY, JEREMY MUNDAY, University of Maryland, College Park — We describe high efficiency InP solar cells which utilize a periodic array of optically designed TiO<sub>2</sub> nanocylinders. Optical and electronic simulations were performed to determine the spectrally resolved reflectivity and I-V characteristics of potential devices under AM1.5G illumination. The reflectivity of InP solar cells with these nanocylinders is found to have an average value of 2% over the visible and near-IR spectral range, which outperforms traditional antireflection coatings. Coupling between Mie scattering resonances and thin film interference effects is found to accurately describe the optical enhancement provided by the nanocylinders. These nanostructured solar cells have power conversion efficiencies greater than 23%, which is comparable to the highest quoted efficiencies for InP solar cells.

**8:48AM K52.00005 Roles of SiN<sub>x</sub> layers in light trapping and carrier collection of nanostructured crystalline Si solar cells**, YUNAE CHO, EUNAH KIM, MINJI GWON, DONG-WOOK KIM, Ewha Womans University, HYEONG-HO PARK, Korea Advanced Nanofab Center, JOONDONG KIM, Incheon National University — We investigated optical properties and photovoltaic (PV) performance of nanostructured Si solar cells with and without SiN<sub>x</sub> dielectric layers. The SiN<sub>x</sub> layer contributed to the enhancement of internal quantum efficiency of the nanostructured cells at both short and long wavelengths. In contrast, the surface passivation of SiN<sub>x</sub> layers on flat cells helped the carrier collection mainly at short wavelength. The surface nanopatterned array enhanced the optical absorption and also concentrated incoming light near the surface in broad wavelength range, revealed by experimental data and optical simulation results. As a result, the nanostructured cells had high density of photo-generated carriers near the surface. This could lead to significant recombination loss of the cells without SiN<sub>x</sub> layers. Our work suggested that the SiN<sub>x</sub> layer played a crucial role in the improved carrier collection of the nanostructured Si PV devices.

**9:00AM K52.00006 Gold Nanoparticles Assisted Photocurrent Enhancement in Hybrid Nanostructures Based Heterojunction Solar Cell Device<sup>1</sup>**, GEN LONG, MICHAEL BEATTIE, HUIZHONG XU, MOSTAFA SADOQI, Department of Physics, St John's University — In this presentation, we report a first hand study of plasmon enhanced photocurrent observed in hybrid nanostructures based heterojunction solar cell. The heterojunction solar cell was fabricated, using chemically synthesized narrow gap, IV-VI group semiconductor nanoparticles (PbS and PbSe), wide gap semiconductor ZnO nanowires, and gold nanoparticles, by spin-coating onto FTO glasses, in ambient conditions (25C, 1atm). The synthesized nanostructures were characterized by XRD, UV-VIS absorption, SEM, AFM, TEM, solar simulator, etc. Nanostructures of variant sizes were integrated in to the heterojunction devices to study the effects on photocurrent and solar cell performance. The architecture of film stack, i.e., the positions of Au nanoparticles and PbS, PbSe nanoparticles were also studied. We believe that introducing Au nanoparticles with proper size will lead to increase of photocurrent as well as solar cell devices.

**9:12AM K52.00007 Dielectric micro-resonator arrays for optical coupling to solar cells**, DONGHEON HA, CHEN GONG, MARINA S. LEITE, JEREMY N. MUNDAY, Univ of Maryland-College Park, MUNDAY LAB TEAM, LEITE LAB COLLABORATION — Reflection occurs at the interface of a semiconductor and air as a result of the index of refraction contrast between the two media. In order to increase the coupling efficiency of free-space light to the modes of a solar cell, single- or double-layer dielectric thin-film anti-reflection coatings (ARC) are typically used. As an alternative approach, we introduce a new anti-reflection coating based on silicon dioxide (SiO<sub>2</sub>) nanospheres that enable high absorption and low-cost photovoltaic devices through a combination of effects including scattering, thin-film interference, and sphere-sphere coupling. From experiments and Finite Difference Time Domain (FDTD) simulations, we show that there is ~15-20% enhancement in light absorption within the substrate (Si), which ultimately leads to increased spectral current density. We also show the enhancement of the optoelectronic properties via photo-response measurement on multi-crystalline Si solar cells with SiO<sub>2</sub> nanosphere arrays on top. Because the layer can be made with an easy, inexpensive, and scalable process, this proposed ARC is an excellent candidate for substituting conventional ARC technologies relying on complicated, high temperature and expensive processes.

**9:24AM K52.00008 Importance of Depletion Width on Charge Transport and Interfacial Recombination in Extremely Thin Absorber Solar Cells**, MICHAEL EDLEY, TREAVOR JONES, JASON BAXTER, Drexel University — The dynamics of charge carrier transport and recombination and their dependence on physical and electrochemical length scales in extremely thin absorber (ETA) solar cells is vital to cell design. We used J-V characterization, transient photocurrent / photovoltage, and electrochemical impedance spectroscopy to study electron transport and interfacial recombination in ETA cell. ETA cells were composed of ZnO nanowires coated with an ultrathin (5 nm) CdS buffer layer and CdSe absorbers with thicknesses of 10 – 40 nm, with polysulfide electrolyte. In thinner absorbers near short circuit, the depletion region can extend radially into the nanowire, inhibiting interfacial recombination rate. However, depleting the periphery of the nanowire reduces the cross sectional area for charge transport, resulting in longer characteristic collection times. Thicker absorbers suffered more significant bias-dependent collection, and we conclude that slight radial penetration of the depletion region into the nanowires enhances charge collection. This work highlights the importance of considering the impact of depletion width on charge transport and interfacial recombination in the design of liquid junction, semiconductor-sensitized solar cells.

**9:36AM K52.00009 MOVED ABSTRACT TO R26.011 —**

**9:48AM K52.00010 Exciton Transfer in Carbon Nanotube Aggregates for Energy Harvesting Applications<sup>1</sup>**, AMIRHOSSEIN DAVOODY, FARHAD KARIMI, IRENA KNEZEVIC, Univ of Wisconsin, Madison — Carbon nanotubes (CNTs) are promising building blocks for organic photovoltaic devices, owing to their tunable band gap, mechanical and chemical stability. We study intertube excitonic energy transfer between pairs of CNTs with different orientations and band gaps. The optically bright and dark excitonic states in CNTs are calculated by solving the Bethe-Salpeter equation. We calculate the exciton transfer rates due to the direct and exchange Coulomb interactions, as well as the second-order phonon-assisted processes. We show the importance of phonons in calculating the transfer rates that match the measurements. In addition, we discuss the contribution of optically inactive excited states in the exciton transfer process, which is difficult to determine experimentally. Furthermore, we study the effects of sample inhomogeneity, impurities, and temperature on the exciton transfer rate. The inhomogeneity in the CNT sample dielectric function can increase the transfer rate by about a factor of two. We show that the exciton confinement by impurities has a detrimental effect on the transfer rate between pairs of similar CNTs. The exciton transfer rate increases monotonically with increasing temperature.

**10:00AM K52.00011 Ultrafast Spectroscopy Reveals Frenkel-CT Mixed Excitonic States in Copper Phthalocyanine**, ROBERT YOUNTS, TERRY MCAFEE, BHOJ GAUTAM, DANIEL DOUGHERTY, HARALD ADE, KENAN GUNDOGU, North Carolina State University — In organic semiconducting systems, intermolecular charge transport and energy diffusion take place along the  $\pi$ - $\pi$  stacking direction, which is beneficial for opto-electronic devices. Therefore it is essential to study electronic state structure in the  $\pi$ - $\pi$  stacking direction in organic solids. We studied a model quasi-one-dimensional molecular crystal copper phthalocyanine, which has strong intermolecular coupling along the  $\pi$ - $\pi$  stack. In this work, we used polarization resolved transient absorption spectroscopy and identified the coupling of low-lying singlet Frenkel (intramolecular) excitons with CT (intermolecular) excitons. Our study shows an evolution between localized and delocalized excitations which can be utilized to tune charge transport properties in molecular crystals. These studies provide fundamental understanding of electronic state structures, which will be essential for tailoring electronic properties of desired applications.

**10:12AM K52.00012 Investigation of transport properties of ZnO/PbS heterojunction solar cells<sup>1</sup>**, YANG CHENG, MICHAEL D. C. WHITAKER, VINCENT R. WHITESIDE, LLOYD A. BUMM, IAN R. SELLERS, Department of Physics & Astronomy, University of Oklahoma, Norman OK 73019 — Lead sulfide (PbS) and lead selenide (PbSe) colloidal quantum dots (CQDs) are considered as a potential candidate material for solar cell applications due to their large band gap tunability range (0.5 to 1.7 eV) and cost-effective solution based processing. A series of Glass/ITO/ZnO/PbS/MoO<sub>3</sub>/Au heterojunction solar cells were processed and analyzed. A stable (reproducible) 2% conversion efficiency under 1-sun is achieved based on the result of  $J - V$  measurements. Absorbance and external quantum efficiency (EQE) measurements clearly show photo-generated carrier extraction from PbS active layers in the solar cell. However, a non-ideal  $J - V$  behavior is observed in current-voltage measurements. This behavior may be attributed to a high density of trap states at the QD surface or defect states at the PbS/ZnO or ITO/ZnO interfaces. C-V and Impedance spectroscopy measurements are used to study this unusual behavior. These techniques could also help probe the transport properties and limitation of these heterojunction solar cells.

**10:24AM K52.00013 Limits of Plasmonic Nanoparticle Enhancement in Solution-Processed Solar Cells**, EBUKA ARINZE, BOTONG QIU, GABRIELLE NYIRJESY, SUSANNA THON, Johns Hopkins Univ — Solution-processed solar cells are particularly suited to benefit from plasmonic absorption enhancement due to their transport-limited film thicknesses, and the favorable compatibility of material integration. To date, experimental demonstrations of device enhancements via plasmonic nanoparticle-based strategies have achieved photocurrents that still fall below the theoretical predicted limits. We critically evaluate the prospects for plasmonic enhancements in solution-processed thin-film solar cells. We develop an effective medium model for embedded plasmonic nanostructures in photovoltaic thin films, evaluate the model in the context of previous results achieved in the field, and use the model as a framework for identifying the most promising avenues to realizing plasmonic performance enhancements in practical photovoltaic devices. Our model results indicate that further plasmonic enhancement gains may be possible in organic photovoltaic cells. For achieving maximum photocurrent potential, we identify fine-tuning of the concentration of embedded plasmonic enhancers within the absorbing medium as the crucial factor in achieving a balance between useful scattering and detrimental parasitic absorption losses.

**8:00AM K53.00001 Ferrofluid-based Diamagnetic Particle Separation in U-shaped Microchannels.<sup>1</sup>**, YILONG ZHOU, XIANGCHUN XUAN, Clemson University — We demonstrate in this talk a continuous-flow sheath-free separation method of diamagnetic particles in ferrofluids through U-shaped microchannels. Due to the action of a size-dependent magnetic force, diamagnetic particles are focused into a single stream in the inlet branch of the U-turn and then continuously separated into two streams in its outlet branch. We also develop a 3D numerical model to predict and understand the diamagnetic particle transport during the separation process. The numerical predictions are found to agree well with the experimental observations in a systematic study of multiple parameter effects including ferrofluid flow rate, concentration and magnet-channel distance.

**8:12AM K53.00002 Smart microgels for controlling two-phase fluid structure in porous media<sup>1</sup>**, JING FAN, DAVID WEITZ, Harvard University — Understanding the transport of microgels in porous media directly benefits the conformance improvement technique using preformed gels in the oil industry. We develop a new type of microgels that can swell in response to specific stimuli in an aqueous environment. From a practical point of view, this enables us to deliver the microgels to the deep reservoir formation and control the permeability profile more effectively. With confocal microscopy imaging, we show that we can deliver such smart microgels to the high-permeability region in a stratified porous medium, which subsequently changes the two-phase fluid structure in the medium. From a scientific point of view, this allows for characterizing the permeability change due to homogeneous pore-clogging by soft particles instead of surface clogging; using the typical microgels this can hardly be done because we cannot place gel particles with comparable size to the pore uniformly into a porous medium. This study may shed light on understanding many other processes involving the transport of soft particles in porous structures.

**8:24AM K53.00003 Effect of Microstructural Geometry for Computing Closure Models in Multiscale Modeling of Shocked Particle Laden Flow**, OISHIK SEN, H.S. UDAYKUMAR, Univ of Iowa, GUSTAAF JACOBS, San Diego State University — Interaction of a shock wave with dust particles is a complex physical phenomenon. A computational model for studying this two-phase system is the Particle-Source in Cell (PSIC) approach. In this method, the dust particles are tracked as point particles in a Lagrangian frame of reference immersed in a compressible fluid. Two-way interaction between the carrier and the dispersed phases is ensured by coupling the momentum and energy transfer between the two phases as source terms in the respective governing equations. These source terms (e.g. drag force on particles) may be computed from resolved numerical simulations by treating each macroscopic point particle as an ensemble of cylinders immersed in a compressed fluid. However the drag so computed must be independent of the geometry of the mesoscale. In this work, the effect of the stochasticity of the microstructural geometry in construction of drag laws from resolved mesoscale computations is studied. Several different arrangement of cylinders are considered and the mean drag law as a function of Mach Number and Volume Fraction for each arrangement is computed using the Dynamic Kriging Method. The uncertainty in the drag forces arising because of the arrangement of the cylinders for a given volume fraction is quantified as 90% credible sets and the effect of the uncertainty on PSIC computations is studied.

**8:36AM K53.00004 Time dependent behavior of impact angle in turbulent pipe flows experience erosion.**<sup>1</sup>, AMADOR GUZMAN, Pontificia Universidad Catolica de Chile, DIEGO OYARZUN<sup>2</sup>, Universidad de Santiago de Chile, MAGDALENA WALCZAK<sup>3</sup>, JAVIERA AGUIRRE<sup>4</sup>, Pontificia Universidad Catolica de Chile — Erosion-corrosion in pipe systems transporting slurry turbulent flows is of a great importance in industrial and mining applications, where large volumes of suspended solids are sent up to hundreds of kilometers, to be further processed. The slurry is typically sent over large diameter steel pipes, which not always have an anti-abrasion coating. During the transport, the thickness of the pipe diminishes and eventually leaks and breaks, due to the combined effects of wear and corrosion. The processes of pipe degradation are further enhanced by the content of the slurry electrolytes that might switch from neutral to aggressive. The understanding of these processes in terms of operational parameters is critical for anticipating and mitigating a catastrophic outcome. This paper describes turbulent flow numerical simulations in a slurry transporting steel pipe with an emphasis on the correlation between the time dependent impact angle in the vicinity of the steel pipe and the rate of material loss. Full numerical simulations in a 3D long domain by using an Eulerian –Eulerian two phase flow approach coupled to a  $\kappa$ -epsilon turbulent model are performed for different solid particle concentration and flow velocity and compared to existing experimental and numerical results for validation with and without gravity. Time-dependent axisymmetric turbulent flow simulations are performed for determining both the time dependent behavior of the axial and radial velocities near the pipe wall and the impact angle.

**8:48AM K53.00005 Caustics and the growth of droplets**<sup>1</sup>, RAMA GOVINDARAJAN, S RAVICHANDRAN, TIFR Centre for Interdisciplinary Sciences, Hyderabad, India, SAMRIDDHI RAY, International Centre for Theoretical Sciences, TIFR, Bangalore, P DEEPU, TIFR Centre for Interdisciplinary Sciences, Hyderabad, India — Caustics are formed when inertial particles of very different velocities collide in a flow, and are a consequence of the dissipative nature of particle motion in a suspension. Using a model vortex-dominated flow with heavy droplets in a saturated environment, we suggest that sling caustics form only within a neighbourhood around a vortex, the square of whose radius is proportional to the product of circulation and particle inertia. Droplets starting close to this critical radius congregate very close together, resulting in large spikes in (Lagrangian) number density. Allowing for merger when droplets collide, we show that droplets starting out close to the critical radius display a much more rapid growth in size than those starting elsewhere, and a large fraction of the large droplets are those that originate within the caustics-forming region. We test these predictions in a two-dimensional simulation of turbulent flow. We hope that our study will be of interest in long-standing problems of physical interest such as the mechanism of broadening of droplet spectra in a turbulent flow.

**9:00AM K53.00006 Soft Sphere Suspensions: Flow and Relaxation**, MARCEL WORKAMP, JOSHUA A. DIJKSMAN, Physical Chemistry and Soft Matter, Wageningen University — We experimentally study the role of particle elasticity on the rheology of soft sphere suspensions. Experiments consist of custom designed particles with tuneable stiffness. These particles allow us to probe the role of elastic timescales, relaxation and anisotropy in a custom 3D printed shear cell. We find robust rheological features, such as a flow instability, that are not well captured by existing models for suspension flows. In addition, we find relaxation effects after shear even in the absence of shear or thermal fluctuations. We aim to integrate these findings in the emerging unified framework for structured fluids.

**9:12AM K53.00007 Impact cratering on granular beds: From the impact of raindrops to the strike of hailstones**<sup>1</sup>, LEONARDO GORDILLO, JUNPING WANG, FRED JAPARDI, WARREN TEDDY, MING GAO, XIANG CHENG, CEMS - University of Minnesota — Impact craters generated by the impact of a spherical object onto a granular bed strongly depend on the material properties of impactors. As an example, impact cratering by liquid drops and by solid spheres exhibits qualitatively different power-law scalings for the size of resulting impact craters. While the basic energy conservation and dimensional analysis provide simple guiding rules, the detailed dynamics governing the relation between these power-law scalings is still far from clear. To analyze the transition between liquid-drop and solid-sphere impact cratering, we investigate impact cratering by liquid drops for a wide range of viscosities over 7 decades. Using high-speed photography and laser profilometry, we delineate the liquid-to-solid transition and show the emergence of the two asymptotic behaviors and their respective power laws. We find that granular avalanches triggered by impacts are crucial in understanding the energy partition between impacted surfaces and impactors, which directly determines the observed scaling relations. A simple model is constructed for the initial stage of the impact that explains the energy partition during crater formation.

**9:24AM K53.00008 Scaling of liquid-drop impact craters in granular media**<sup>1</sup>, RUNCHEN ZHAO, QIANYUN ZHANG, HENDRO TJUGITO, MING GAO, XIANG CHENG, University of Minnesota — Granular impact cratering by liquid drops is a ubiquitous phenomenon, directly relevant to many important natural and industrial processes such as soil erosion, drip irrigation, and dispersion of micro-organisms in soil. Here, by combining the high-speed photography with high precision laser profilometry, we investigate the liquid-drop impact dynamics on granular surfaces and monitor the morphology of resulting craters. Our experiments reveal novel scaling relations between the size of granular impact craters and important control parameters including the impact energy, the size of impinging drops and the degree of liquid saturation in a granular bed. Interestingly, we find that the scaling for liquid-drop impact cratering in dry granular media can be quantitatively described by the Schmidt-Holsapple scaling originally proposed for asteroid impact cratering. On the other hand, the scaling for impact craters in wet granular media can be understood by balancing the inertia of impinging drops and the strength of impacted surface. Our study sheds light on the mechanism governing liquid-drop impacts on dry/wet granular surfaces and reveals a remarkable analogy between familiar phenomena of raining and catastrophic asteroid strikes.

<sup>1</sup>Scaling of liquid-drop impact craters in granular media

**9:36AM K53.00009 Scaling of granular convective velocity and timescale of asteroidal resurfacing**, TOMOYA YAMADA, KOUSUKE ANDO, TOMOKATSU MOROTA, HIROAKI KATSURAGI, Department of Earth and Environmental Sciences, Nagoya University — Granular convection is one of the well-known phenomena observed in a vertically vibrated granular bed. Recently, the possible relation between granular convection and asteroidal surface processes has been discussed. The granular convection on the surface of small asteroids might be induced by seismic vibration resulting from meteorite impacts. To quantitatively evaluate the timescale of asteroidal resurfacing by granular convection, the granular convective velocity under various conditions must be revealed. As a first step to approach this problem, we experimentally study the velocity scaling of granular convection using a vertically vibrated glass-beads layer. By systematic experiments, a scaling form of granular convective velocity has been obtained. The obtained scaling form implies that the granular convective velocity can be written by a power-law product of two characteristic velocity components: vibrational and gravitational velocities. In addition, the system size dependence is also scaled. According to the scaling form, the granular convective velocity is almost proportional to gravitational acceleration. Using this scaling form, we have estimated the resurfacing timescale on small asteroid surface.

**9:48AM K53.00010 The Larger the Viscosity, the Higher the Bounce**, MENACHEM STERN, MARTIN KLEIN SCHAARSBERG, IVO PETERS, KEVIN DODGE, WENDY ZHANG, HEINRICH JAEGER, The Physics Department and the James Franck Institute, The University of Chicago — A low-viscosity liquid drop can bounce upon impact onto a solid. A high-viscosity drop typically just flattens, i.e., it splats. Surprisingly, our experiments with a droplet made of densely packed glass beads in silicone oil display the opposite behavior: the low-viscosity oil suspension drop splats. The high-viscosity oil suspension bounces. Increasing solvent viscosity *increases* the rebound energy. To gain insight into the underlying mechanism, we model the suspension as densely packed elastic spheres experiencing viscous lubrication drag between neighbors. The model reproduces the observed trends. Plots of elastic compression and drag experienced by the particles show that rebounds are made possible by (1) a fraction of the impact energy being stored during initial contact via elastic compression, (2) a rapid broadening of local lubrication drag interactions at the initial impact site into a spatially uniform upward force throughout the drop. Including finite wall drag due to the presence of ambient air into the numerical model diminishes and eventually cuts off the rebound.

**10:00AM K53.00011 Percolation velocity dependence on local concentration in bidisperse granular flows<sup>1</sup>**, RYAN P. JONES, HONGYI XIAO, ZHEKAI DENG, PAUL B. UMBANHOWAR, RICHARD M. LUEPTOW, Northwestern University — The percolation velocity,  $u_p$ , of granular material in size or density bidisperse mixtures depends on the local concentration, particle size ratio, particle density ratio, and shear rate,  $\dot{\gamma}$ . Discrete element method computational results were obtained for bounded heap flows with size ratios between 1 and 3 and for density ratios between 1 and 4. The results indicate that small particles percolate downward faster when surrounded by large particles than large particles percolate upward when surrounded by small particles, as was recently observed in shear-box experiments. Likewise, heavy particles percolate downward faster when surrounded by light particles than light particles percolate upward when surrounded by heavy particles. The dependence of  $u_p/\dot{\gamma}$  on local concentration results in larger percolation flux magnitudes at high concentrations of large (or light) particles compared to high concentrations of small (or heavy) particles, while local volumetric flux is conserved. The dependence of  $u_p/\dot{\gamma}$  on local concentration can be incorporated into a continuum model, but the impact on global segregation patterns is usually minimal.

**10:12AM K53.00012 Impact of Overburden on Segregation in Sheared Granular Flow**, ALEXANDER M. FRY, PAUL B. UMBANHOWAR, RICHARD M. LUEPTOW, Northwestern University — Dense granular materials tend to segregate into size or density graded regions when subjected to shear. Previous experiments demonstrated that overburden – normal confining pressure on a granular system – can slow the rate of size segregation in an annular shear cell. Here, we explore the effects of overburden on sheared granular material through Discrete Element Method (DEM) simulations in a planar shear cell geometry in which shear is applied by a moving bottom wall, while a massive upper wall provides the overburden. Segregation decreases with increasing overburden, but the picture is complicated by concurrent changes in the streamwise velocity profile. To decouple these effects, we also test an idealized system in which a desired streamwise velocity profile – and therefore shear rate – is imposed by applying additional horizontal forces to each particle. Based on this approach, we link the effect of overburden on segregation to the grain-scale behavior of the system. Partially funded by Procter & Gamble.

**10:24AM K53.00013 Impact of a hydrophobic granular stream in water<sup>1</sup>**, BRIAN UTTER, Bucknell University, HARRY MANDELES, JACOB PARKHOUSE, James Madison University — We experimentally investigate the flow of a stream of hydrophobic granular particles impacting a water surface from above. The granular sample is composed of a mixture of hydrophobic and hydrophilic grains and the concentration, stream diameter, and drop height are independently controlled. While granular flows are common in nature and industry, effects of surface chemistry on flow behavior have received relatively little attention. The present experiment complements rheological measurements performed in parallel and aims to elucidate prior experiments on hydrophobic samples in a rotating drum. The present experimental geometry allows us to compare the behavior of granular streams to prior work on impacts of solids and fluid streams. Sequential images of the granular stream in water are taken and analyzed. We present data on the size, length, and shape of the aggregate streams with variations in concentration, entering stream diameter, and drop height. We find that increased hydrophobic grain concentration leads to increased aggregation due to an effectively cohesive interaction mediated by entrained air. At lower concentrations, the stream exhibits a lateral instability. Finally, we will make connections to rheology and rotating drum results.

**10:36AM K53.00014 Numerical Simulation and Performance Optimization of a Magnetophoretic Bio-separation chip.**, MATIN GOLOZAR, JEFF DARABI, MAJID MOLKI, Southern Illinois University Edwardsville — Separation of micro/nanoparticles is important in biomedicine and biotechnology. This research presents the modeling and optimization of a magnetophoretic bio-separation chip for the isolation of biomaterials, such as circulating tumor cells (CTCs) from the peripheral blood. The chip consists of a continuous flow through microfluidic channels that contains locally engineered magnetic field gradients. The high gradient magnetic field produced by the magnets is spatially non-uniform and gives rise to an attractive force on magnetic particles that move through the flow channel. The computational model takes into account the magnetic and fluidic forces as well as the effect of the volume fraction of particles on the continuous phase. The model is used to investigate the effect of two-way particle-fluid coupling on both the capture efficiency and the flow pattern in the separation chip. The results show that the microfluidic device has the capability of separating CTCs from their native environment. Additionally, a parametric study is performed to investigate the effects of the channel height, substrate thickness, magnetic bead size, bioparticle size, and the number of beads per cell on the cell separation performance.

**10:48AM K53.00015 A Statistical investigation of sloshing parameters in offshore separators**, MD MAHMUD, Lamar University, RAFIQUK KHAN, Cameron Corporation, QIANG XU, Lamar University — Offshore separators have been the subject of intense investigations for last several decades both by experiments and numerical simulations. However, some others have developed new methods to describe sloshing phenomenon. Mathematical models are developed to characterize sloshing phenomenon. However, a comprehensive statistical analysis is not yet been studied. In this study, statistical approach will be considered to determine the significant parameters for liquid sloshing. Principal component analysis techniques are considered to identify the significant parameters for liquid sloshing. Computation Fluid Dynamics (CFD) technique using ANSYS Fluent software. The input parameters considered are wave acceleration, wave frequencies, amplitudes in various sea state conditions. The measured variables include hydrodynamic pressure, kinetic energy, height of the free surface, vorticity. Mathematical correlations may be developed from the data.

## Wednesday, March 16, 2016 8:00AM - 9:30AM –

Session K54 APS: Tutorial for Authors and Referees Hilton Baltimore Holiday Ballroom 5 -

### 8:00AM K54.00001 TUTORIAL FOR AUTHORS AND REFEREES

— Editors from Physical Review Letters and Physical Review will provide information and tips for our less experienced referees and authors. This session is aimed at anyone looking to submit to or review for any of the APS journals, as well as anyone who would like to learn more about the authoring and refereeing processes. Topics for discussion will include advice on how to write good manuscripts, similarities and differences in writing referee reports for PRL and PR, and other ways in which authors, referees, and editors can work together productively. Following a short presentation from the editors, there will be a moderated discussion.

## Wednesday, March 16, 2016 8:00AM - 11:00AM –

Session K55 DBIO GSOF: Physics of Cancer Metastasis Hilton Baltimore Holiday Ballroom 6 - Michael Espey, National Institute of Health

8:00AM K55.00001 Why do tumor cells spread? , KENNETH PIENTA, Johns Hopkins Univ — No abstract available.

### 8:36AM K55.00002 Mechanical induction of transitions into mesenchymal and amoeboid states

, JAN LIPHARDT, Stanford University — One of the fundamental mysteries of biology lies in the ability of cells to convert from one phenotype to another in response to external control inputs. We have been studying the Epithelial-to-Mesenchymal Transition (EMT), which allows organized assemblies of epithelial cells to scatter into lone mesenchymal cells. EMT is critical for normal development and wound healing, and may be important for cancer metastasis. I'll present recent data on disorganizing mammary epithelial structures. We have used CRISPR to insert fluorescent tags directly into eight EMT-related genes (such as E-cadherin and Vimentin), which allows us to monitor the dynamics of the transition in real time, subject only to delays imposed by fluorophore folding/maturation times. With this information, we can begin to order events in time (temporal resolution ~30 minutes), starting with external signal inputs and proceeding through a secession of intracellular changes of gene expression on the path to the mesenchymal state.

### 9:12AM K55.00003 The Genetics and Biophysics of the Epithelial-Mesenchymal Transition (EMT): Can Theoretical Physics Help Cancer Biology

, HERBERT LEVINE, Rice University — In order to spread from the primary tumor to distant sites, cancer cells must undergo a coordinated change in their phenotypic properties referred to as the "epithelial-to-mesenchymal" transition. We have studied the nonlinear genetic circuits that are responsible for this cellular decision-making process and propose that the transition actually goes through a series of intermediate states. At the same time, we have formulated motility models which allow for the correlation of the state of this network and the cell's biophysical capabilities. Hopefully, these thereby efforts will help us better understand the transition to metastatic disease and possible treatments thereof.

### 9:48AM K55.00004 Critical high-dimensional state transitions in cell populations or why cancers follow the principle "What does not kill me makes me stronger"<sup>1</sup>

, SUI HUANG, Institute for Systems Biology — Transitions between high-dimensional attractor states in the quasi-potential landscape of the gene regulatory network, induced by environmental perturbations and/or facilitated by mutational rewiring of the network, underlie cell phenotype switching in development as well as in cancer progression, including acquisition of drug-resistant phenotypes. Considering heterogeneous cell populations as statistical ensembles of cells, and single-cell resolution gene expression profiling of cell populations undergoing a cell phenotype shift allow us now to map the topography of the landscape and its distortion. From snapshots of single-cell expression patterns of a cell population measured during major transitions we compute a quantity that identifies symmetry-breaking destabilization of attractors (bifurcation) and concomitant dimension-reduction of the state space manifold (landscape distortion) which precede critical transitions to new attractor states. The model predicts, and we show experimentally, the almost inevitable generation of aberrant cells associated with such critical transitions in multi-attractor landscapes: therapeutic perturbations which seek to push cancer cells to the apoptotic state, almost always produce "rebellious" cells which move in the "opposite direction": instead of dying they become more stem-cell-like and malignant. We show experimentally that the inadvertent generation of more malignant cancer cells by therapy indeed results from transition of surviving (but stressed) cells into unforeseen attractor states and not simply from selection of inherently more resistant cells. Thus, cancer cells follow not so much Darwin, as generally thought (survival of the fittest), but rather Nietzsche (What does not kill me makes me stronger).

### 10:24AM K55.00005 Cell-ECM Interactions During Cancer Invasion<sup>1</sup>

, YI JIANG, Georgia State University — The extracellular matrix (ECM), a fibrous material that forms a network in a tissue, significantly affects many aspects of cellular behavior, including cell movement and proliferation. Transgenic mouse tumor studies indicate that excess collagen, a major component of ECM, enhances tumor formation and invasiveness. Clinically, tumor associated collagen signatures are strong markers for breast cancer survival. However, the underlying mechanisms are unclear since the properties of ECM are complex, with diverse structural and mechanical properties depending on various biophysical parameters. We have developed a three-dimensional elastic fiber network model, and parameterized it with in vitro collagen mechanics. Using this model, we study ECM remodeling as a result of local deformation and cell migration through the ECM as a network percolation problem. We have also developed a three-dimensional, multiscale model of cell migration and interaction with ECM. Our model reproduces quantitative single cell migration experiments. This model is a first step toward a fully biomechanical cell-matrix interaction model and may shed light on tumor associated collagen signatures in breast cancer.

Session L1 DCMP: Design and Control of the Superconducting Order Parameter in Low Dimensions Ballroom I - Trivedi Nandini, Ohio State University

**11:15AM L1.00001 Gate tunability and collapse of superconductivity in hybrid tin-graphene Josephson junction arrays**, VINCENT BOUCHIAT, NEEL Institute, CNRS-Grenoble — The accessible and surface-exposed 2D electron gas offered by graphene provides indeed an ideal platform on which to tune, via application of an electrostatic gate, the coupling between adsorbates deposited on its surface. We have experimentally studied the case of graphene transistors which channel is decorated with an array of superconducting tin nanoparticles. They induce via percolation of proximity effect a global 2D superconducting state which critical temperature  $T_c$  can be tuned by gate voltage. When the Graphene show strong disorder, it is possible to tune via the applied gate voltage the system towards an insulating state, demonstrating the possibility to trigger a superconducting to insulator transition [1], which features resembles those found in granular superconductors. In this work, graphene monolayers are surface-conjugated to regular arrays of superconducting disk-shaped metal islands, whose inter-island distances were patterned to be in the quasi-ballistic limit of the underlying 2D electron gas. Arrays can be made on a large range of geometry and density, up to the highly diluted limit with less than 5% surface coverage and few micrometers in between islands. In the lower temperature limit ( $<100$  mK), despite of the long distance (2 microns) in between islands, a supercurrent was observed among the whole graphene sheet. Interestingly, the superconducting state vanishes exponentially in gate voltage and rests in a metallic state [2], caused by quantum fluctuations of phase is found for diluted and regular arrays. This peculiar behaviour provides evidence for recently developed theory, and may provide a hint to the understanding of long-standing issue of "zero-temperature" bosonic metallic state. [1] A. Allain, et al. Nat. Mat., **11**, 590, (2012). [2] Z. Han et al., Nat. Phys. **10**, 380 (2014).

**11:51AM L1.00002 The Emergence of Superconductivity in Inhomogeneous, Mesoscopic Systems<sup>1</sup>**, NADYA MASON, Univ of Illinois - Urbana — Although low-dimensional, inhomogeneous superconductors have been intensely studied, the nature of the onset of superconductivity in these systems is still largely unknown. In this talk we present transport measurements on mesoscopic disks of granular, inhomogeneous Nb, where we determine the superconducting transition temperature as a function of disk diameter. We observe an unexpected suppression of superconductivity at micron diameters, length scales that are considerably longer than the coherence length of Nb. This suppression does not appear in large-scale films, and cannot be explained by single-grain small-size effects. By considering the diameter-dependence of the transition, as well as observations of strong fluctuations in the transition temperature as disk diameters decrease, we are able to explain this long length scale dependence by an extremal-grain model, where superconducting order first appears in unusually large grains and, due to proximity coupling, spreads to other grains. The extremal-grain onset of superconductivity has not previously been observed experimentally, and explains how superconductivity can emerge in granular or inhomogeneous superconductors.

**12:27PM L1.00003 Cooper Pair Insulators<sup>1</sup>**, JAMES VALLES, Brown University — One of the recent advances in the field of the Superconductor to Insulator Transition (SIT) has been the discovery and characterization of the Cooper Pair Insulator phase. This bosonic insulator, which consists of localized Cooper pairs, exhibits activated transport and a giant magneto-resistance peak. These features differ markedly from the weakly localized transport that emerges as pairs break at a "fermionic" SIT. I will describe how our experiments on films nano-patterned with a nearly triangular array of holes have enabled us to 1) distinguish bosonic insulators from fermionic insulators, 2) show that Cooper pairs, rather than quasi-particles dominate the transport in the Cooper Pair insulator phase, 3) demonstrate that very weak, sub nano-meter thickness inhomogeneities control whether a bosonic or fermionic insulator forms at an SIT and 4) reveal that Cooper pairs disintegrate rather than becoming more tightly bound deep in the localized phase. We have also developed a method, using a magnetic field, to tune flux disorder reversibly in these films. I will present our latest results on the influence of magnetic flux disorder and random gauge fields on phenomena near bosonic SITs.

**1:03PM L1.00004 Designing Quantum Matter with Superconducting Nanowires<sup>1</sup>**, NINA MARKOVIC, Goucher College — Superconducting nanowires are an experimental realization of a model quantum system that features collective degrees of freedom and exhibits a host of non-equilibrium and non-local phenomena. The nature of the quantum states in nanowires is particularly sensitive to size and shape quantization, coupling with the environment and proximity effects. I will demonstrate how we can utilize these features to tailor the quantum states in nanowires in desirable ways. Specifically for this purpose, we have developed a unique nanoprinting method for fabrication of ultranarrow nanowires with unprecedented control over their physical texture and their transport properties. I will show how short nanowires exhibit a tunable vortex-in-a-box blockade phenomenon, and how tunable interfaces with graphene and topological insulators lead to unusual properties. Finally, I will discuss the bigger picture for how the texture of the superconducting wavefunction can be precisely controlled by the size, shape, magnetic field and tunable interfaces with materials that exhibit unconventional order, spin texture or topological properties.

**1:39PM L1.00005 Proximity and Anti-proximity effects in nanowires<sup>1</sup>**, MOSES CHAN, Penn State University — Near a superconductor/normal-metal interface, the leakage of Cooper pairs extends superconducting behavior into the metal. The spatial range of this proximity effect in a normal metal can be as long as 1  $\mu$ m. However, when a ferromagnet is placed in contact with a superconductor, the Cooper pairs from the superconductor are not expected to survive beyond at most a few nanometers into the ferromagnet. Surprisingly we find when a cobalt nanowire as long as 600 nm is sandwiched between superconducting electrodes, it attains zero resistance at low temperature. For even longer wires, the transition to incomplete superconductivity via this (long range) proximity effect is foreshadowed by a large resistance peak (1). On the other hand when Zn nanowires of 40 nm diameter are contacted by superconducting electrodes, their superconductivity is unexpectedly suppressed (2). 1. **Session L2 DCMP: Physics of Interacting Particles in Two Dimensional Electron Systems at Half-Filling** Ballroom II - Mansour Shayegan, Princeton University

**11:15AM L2.00001 Do composite fermions satisfy Luttinger's area rule?**<sup>1</sup>, JAINENDRA JAIN, Pennsylvania State Univ — While an ordinary Fermi sea is perturbatively robust to interactions, the paradigmatic composite-fermion Fermi sea [1] arises as a non-perturbative consequence of emergent gauge fields in a system where there was no Fermi sea to begin with. A mean-field picture suggests two Fermi seas, of composite fermions made from electrons or holes in the lowest Landau level, which occupy different areas away from half filling and thus appear to represent distinct states. We show [2] that in the microscopic theory of composite fermions, which satisfies particle-hole symmetry in the lowest Landau level to an excellent degree, the Fermi wave vectors at filling factors  $\nu$  and  $1 - \nu$  are the same, and are generally consistent with the experimental findings of Kamburov *et al.* [3]. Our calculations [2] suggest that the area of the CF Fermi sea may slightly violate the Luttinger area rule. We further determine the area of the spin unpolarized composite-fermion Fermi sea, for which the Fermi seas at  $\nu$  and  $1 - \nu$  are not related by particle hole symmetry. [1] B.I. Halperin, P.A. Lee, N. Read, PRB 47, 7312 (1993). [2] A. C. Balram, C. Töke, J. K. Jain, Phys. Rev. Lett. 115, 186805 (2015). [3] D. Kamburov *et al.* Phys. Rev. Lett. 113, 196801 (2014).

**11:51AM L2.00002 Spontaneous time reversal symmetry breaking in atomically confined two-dimensional impurity bands in silicon and germanium**<sup>1</sup>, ARINDAM GHOSH, Indian Inst of Science — Three-dimensional bulk-doped semiconductors, in particular phosphorus (P)-doped silicon (Si) and germanium (Ge), are among the best studied systems for many fundamental concepts in solid state physics, ranging from the Anderson metal-insulator transition to the many-body Coulomb interaction effects on quantum transport. Recent advances in material engineering have led to vertically confined doping of phosphorus (P) atoms inside bulk crystalline silicon and germanium, where the electron transport occurs through one or very few atomic layers, constituting a new and unique platform to investigate many of these phenomena at reduced dimensions. In this talk I shall present results of extensive quantum transport experiments in delta-doped silicon and germanium epilayers, over a wide range of doping density that allow independent tuning of the on-site Coulomb interaction and hopping energy scales. We find that low-frequency flicker noise, or the  $1/f$  noise, in the electrical conductance of these systems is exceptionally low, and in fact among the lowest when compared with other low-dimensional materials. This is attributed to the physical separation of the conduction electrons, embedded inside the crystalline semiconductor matrix, from the charged fluctuators at the surface. Most importantly, we find a remarkable suppression of weak localization effects, including the quantum correction to conductivity and universal conductance fluctuations, with decreasing doping density or, equivalently, increasing effective on-site Coulomb interaction. In-plane magneto-transport measurements indicate the presence of intrinsic local spin fluctuations at low doping although no signatures of long range magnetic order could be identified. We argue that these results indicate a spontaneous breakdown of time reversal symmetry, which is one of the most fundamental and robust symmetries of nonmagnetic quantum systems. While the microscopic origin of this spontaneous time reversal symmetry breaking remains unknown, we believe this indicates a new many-body electronic phase in two-dimensionally doped silicon and germanium with a half-filled impurity band.

**12:27PM L2.00003 The half-filled Landau level and topological insulator surfaces**, T SENTHIL, Massachusetts Institute of Technology — The metallic state of the half-filled Landau level - described originally in pioneering work by Halperin, Lee, and Read as a liquid of composite fermions - was proposed recently by Son to be described by a particle-hole symmetric effective field theory distinct from that in the prior literature. This talk will develop a simple picture of the particle-hole symmetric composite fermion through a modification of older pictures as electrically neutral "dipolar" particles. This picture, and the proposed particle-hole symmetric theory, will be further substantiated through a recently developed deep connection between the half-filled Landau level and correlated surface states of certain three dimensional topological insulators. The phenomenology of composite fermi liquids (with or without particle-hole symmetry) will be revisited. It will be shown that their heat/electrical transport dramatically violates the conventional Wiedemann-Franz law but satisfies a modified one. References: 1. Chong Wang and T. Senthil, Half-filled Landau Level, Topological Insulator Surfaces, and Three Dimensional Quantum Spin Liquids, cond-mat arXiv:1507.08290 (2015).

**1:03PM L2.00004 Experimental Observations of Particle-hole Asymmetry for Composite Fermions**<sup>1</sup>, YANG LIU, Electrical engineering, Princeton University — In this talk, I will present our experimental study of the breaking of particle-hole symmetry for composite fermions (CFs), quasi-particles formed by attaching two flux quanta to each electron at large perpendicular magnetic fields. We measure the Fermi contour of the spin-polarized CFs near  $\nu = 1/2$  via commensurability oscillations, and find an asymmetry of the Fermi wave vector for  $\nu < 1/2$  and  $> 1/2$ . In particular, we find that the deduced wave vector is smaller for  $\nu > 1/2$  compared to  $\nu < 1/2$ , and on both sides consistent with the density of minority carriers in the lowest Landau level. We also study the spin-polarization transitions of fractional quantum Hall states near  $\nu = 3/2$  and  $1/2$ ; these states are particle-hole conjugates of each other and are expected to have the same polarization energies. Our systematic results clearly show the transition energies are about three times larger for states near  $\nu = 3/2$  compared to those near  $\nu = 1/2$ . Work done in collaboration with D. Kamburov, M. A. Mueed, S. Hasdemir, A. Wojs, J.K. Jain, L.N. Pfeiffer, K.W. West, K.W. Baldwin, and M. Shayegan.

<sup>1</sup>We acknowledge support from the DOE, NSF, the Gordon and Betty Moore Foundation and the Keck Foundation. The experiments were partly performed at the National High Magnetic Field Laboratory.

**1:39PM L2.00005 A model wavefunction for the composite Fermi liquid: its geometry and entanglement.**<sup>1</sup>, F. D. M. HALDANE, Princeton University — I will describe a model wavefunction for the composite Fermi liquid in a partially-filled Landau level, recently formulated in a torus geometry (Shao *et al.*, Phys. Rev. Lett. 114, 206402 (2015)), that allows a manifold of gapless composite Fermi-liquid states to be characterized, parametrized by an analog of the "occupation number" that defines the Fermi surface in a free-electron gas. Unlike incompressible FQHE states, which only occur in an inversion-symmetric momentum sector, these CFL states occur in each distinct momentum sector allowed by the periodic boundary condition. The fundamental wavefunction of this type describes a system with  $\nu = 1/2$ , but multiplication by (or division by) a Vandermonde factor describes states at  $\nu = 1/m$ . The CFL states are characterized by an "intrinsic metric" which determines the shape of the Fermi surface, and corresponds to the shape of the "flux-attachment" that forms the composite fermion. The wavefunction is well-suited for Monte-Carlo calculations, as it is analogous to a determinant form used by Jain in spherical geometry. The violation of "area-law" (perimeter-law) entanglement found in Monte-Carlo calculations will be described.

**Session L3 DCMP GSNP GSOF: Buckley, Lilienfeld and Onsager Prize Session** Ballroom III - Sharon Glotzer, University of Michigan

**11:15AM L3.00001 Photonic Crystals-Inhibited Spontaneous Emission: Optical Antennas-Enhanced Spontaneous Emission** , ELI YABLONOVITCH, UC Berkeley Electrical Engineering and Computer Sciences Dept. — Photonic crystals are also part of everyday technological life in opto-electronic telecommunication devices that provide us with internet, cloud storage, and email. But photonic crystals have also been identified in nature, in the coloration of peacocks, parrots, chameleons, butterflies and many other species.

In spite of its broad applicability, the original motivation of photonic crystals was to create a “bandgap” in which the spontaneous emission of light would be inhibited. Conversely, the opposite is now possible. The “optical antenna” can accelerate spontaneous emission. Over 100 years after the radio antenna, we finally have tiny “optical antennas” which can act on molecules and quantum dots. Employing optical antennas, spontaneous light emission can become faster than stimulated emission.

**11:51AM L3.00002 Julius Edgar Lilienfeld Prize: Lilienfeld Prize Lecture: Emergent Behavior in Quantum Matter** , DAVID PINES, Physics Dept., U C Davis and UIUC, Santa Fe Institute — We live in an **emergent universe** in which interactions between the basic building blocks of matter and their environment give rise to unpredicted and unexpected **emergent** behavior at every scale. As physicists we seek to identify the organizing principles responsible for that behavior, construct soluble models that incorporate these, and explain experiment. In this lecture, I illustrate this approach to understanding emergent behavior in quantum matter through three examples: collective modes in electron, helium, and nuclear liquids; the emergence of superconductivity in conventional and unconventional superconductors, nuclei, and neutron stars; and the emergence of heavy electrons in Kondo lattice materials.

**12:27PM L3.00003 Lars Onsager Prize: Phase transitions in massive data acquisition** , MARC MEZARD, Ecole normale supérieure - PSL Research University — The rapid increase in the amount of data that is presently being generated, acquired and processed opens new perspectives in many branches of science. In order to take full advantage of this data revolution, and to turn it into a major tool for scientific discoveries, new concepts and methods need to be developed, thus allowing us to focus on the extraction of significant information. Referring to the case of compressed sensing, the talk will show how ideas and methods in statistical physics -from spin glass theory to crystal nucleation - can help design faster, less destructive, and more efficient signal acquisition protocols, with possible applications in numerous fields -from magnetic resonance imaging to astronomy, tomography, or gene interaction network reconstruction.

**1:03PM L3.00004 Lars Onsager Prize: The mean field solution for Hard Sphere Jamming and a new scenario for the low temperature landscape of glasses.** , GIORGIO PARISI, University of Rome, “La Sapienza”, Italy — In a hard spheres system particles cannot overlap. Increasing the density we reach a point where most of the particles are blocked and the density cannot be increased any more: this is the jamming point. The jamming point separates the phase, where all the constraints can be satisfied, from an unsatisfiable phase, where spheres do have to overlap. A scaling theory of the behavior around the jamming critical point has been formulated and a few critical exponents have been introduced. The exponents are apparently super-universal, as far as they do seem to be independent from the space dimensions. The mean field version of the model (i.e. the infinite dimensions limit) has been solved analytically using broken replica symmetry techniques and the computed critical exponents have been found in a remarkable agreement with three-dimensional and two-dimensional numerical results and experiments. The theory predicts in hard spheres (in glasses) a new transition (the Gardner transition) from the replica symmetric phase to the replica broken phase at high density (at low temperature), in agreement with simulations on hard sphere systems. I will briefly discuss the possible consequences of this new picture on the very low temperature behavior of glasses in the quantum regime.

**1:39PM L3.00005 Lars Onsager Prize: Optimization and learning algorithms from the theory of disordered systems** , RICCARDO ZECCHINA, Politecnico di Torino — The extraction of information from large amounts of data is one of the prominent cross disciplinary challenges in contemporary science. Solving inverse and learning problems over large scale data sets requires the design of efficient optimization algorithms over very large scale networks of constraints. In such a setting, critical phenomena of the type studied in statistical physics of disordered systems often play a crucial role. This observation has led in the last decade to a cross fertilization between statistical physics, information theory and computer science, with applications in a variety of fields. In particular a deeper geometrical understanding of the ground state structure of random computational problems and novel classes of probabilistic algorithms have emerged. In this talk I will give a brief overview of these conceptual advances and I will discuss the role that subdominant states play in the design of algorithms for large scale optimization problems. I will conclude by showing how these ideas can lead to novel applications in computational neuroscience.

**Wednesday, March 16, 2016 11:15AM - 2:15PM –**

**Session L4 DMP: Physics for Everyone** Ballroom IV - Daniel Dessau, University of Colorado, Boulder

**11:15AM L4.00001 Nanoscience and Reminiscences of a Woman in Physics** , MILDRED DRESSELHAUS, Massachusetts Inst of Tech-MIT — My entry into carbon science and nanoscience at an early stage in my career occurred in part because I was a woman in physics. In these reminiscences I will relate why working on carbon science started because I was a woman interested in working on a topic that interested me greatly, but was unpopular at the time; carbon science and thermoelectricity are two examples. I will elaborate on how our research system allows safe study of unpopular topics so that both the researcher and research sponsor are satisfied with outcomes. I also learned a lot from my family and acknowledge their contributions as well as those of sponsors who supported high-risk projects.

**11:51AM L4.00002 Physics Behind Optical Fiber Communications: Technologies that Drive the Internet Capacity Growth** , ALAN WILLNER, Univ. of Southern California — Optical fiber communications forms the backbone for global communications, especially as it relates to the Internet. Indeed, the Internet as we know it today would not exist without optical communications. The data transmission capacity through an optical fiber has undergone an exponential growth increase for decades, progressing from Megabits/sec to now Petabits/sec in just the past 40 years. This growth came about due to many physics advances in the field of optical fiber communications, dating back to 1966 when Sir Charles Kao proposed the idea of a communication system based on low-loss optical glass fiber. This presentation will explore the past and present physics-based crucial innovations needed for this continuing story. Specific topics to be highlighted include: (a) ultra-pure fiber that decreased the attenuation losses through glass by many orders of magnitude, (b) single-frequency lasers that defined a specific data channel that could propagate with low signal distortion, (c) Erbium-doped fiber amplifiers that had high gain and low additive noise allowing for amplifier cascades and conquering enormous distances, (d) the simultaneous transmission of multiple wavelength-division-multiplexing data channels down the optical fiber, and (e) the tackling of various dispersive and nonlinear effects that are introduced by the optical fiber itself, cause the data to degrade, and necessitate some form of compensation or management.

**12:27PM L4.00003 Computational Social Science: Exciting Progress and Future Challenges**, DUNCAN WATTS, Microsoft Research, NYC — The past 15 years have witnessed a remarkable increase in both the scale and scope of social and behavioral data available to researchers, leading some to herald the emergence of a new field: computational social science. Against these exciting developments stands a stubborn fact: that in spite of many thousands of published papers, there has been surprisingly little progress on the big questions that motivated the field in the first place: questions concerning systemic risk in financial systems, problem solving in complex organizations, and the dynamics of epidemics or social movements, among others. In this talk I highlight some examples of research that would not have been possible just a handful of years ago and that illustrate the promise of CSS. At the same time, they illustrate its limitations. I then conclude with some thoughts on how CSS can bridge the gap between its current state and its potential.

**1:03PM L4.00004 Are There Two Forms of Liquid Water?**, H. E. STANLEY, Departments of Physics, Chemistry, Physiology, & Biomedical Engineering: Boston University — We will introduce some of the 73 documented anomalies of the most complex of liquids, water, focusing on recent progress in understanding these anomalies by combining information provided by recent experiments and simulations on water in bulk, nanoconfined and biological environments designed to test the hypothesis that liquid water has behavior consistent with the novel phenomenon of liquid polymorphism in that water can exist in two distinct phases [1]. We will also discuss very recent work on nanoconfined water anomalies as well as the apparently related, and highly unusual, behavior of water in biological environments. Finally, we will discuss how the general concept of liquid polymorphism is proving useful in understanding anomalies in other liquids, such as silicon, silica, and carbon, as well as metallic glasses, which have in common that they are characterized by two characteristic length scales in their interactions.

This work has been supported by the NSF Chemistry Division grant CHE-1213217 and was performed in collaboration with, among others, C. A. Angell, S. V. Buldyrev, S.-H. Chen, D. Corradini, P. G. Debenedetti, G. Franzese, P. Kumar, E. Lascaris, F. Mallamace, O. Mishima, P. H. Poole, S. Sastry, F. Sciortino, and L. Xu.

**1:39PM L4.00005 Is the Choice Bad Science or No Science?**, RUSH HOLT, American Association for the Advancement of Science — In our efforts to teach good scientists we leave everyone else with the impression that they cannot do science or appreciate it and should not even try. Should we be surprised when many in the public adopt unscientific beliefs?

## Wednesday, March 16, 2016 11:15AM - 2:15PM —

**Session L5 GMAG DMP: Frustrated Magnetism: Artificial Spin Ice** 301 - Jayasimha Atulasimha, Virginia Commonwealth University

**11:15AM L5.00001 Nearest neighbor correlations in perpendicular artificial spin ice arrays in the presence of an applied field**, SUSAN KEMPINGER, ROBERT FRALEIGH, PAUL LAMMERT, VINCENT CRESPI, NITIN SAMARTH, Pennsylvania State University, PETER SCHIFFER, University of Illinois — By studying the field dependent magnetization switching process in perpendicular artificial spin ice arrays, we hope to gain insight into the dynamical properties of interacting spin systems. To this end, we have used diffraction-limited Kerr imaging to study lithographically patterned arrays of single domain, nanoscale islands of Co/Pt multilayers. We can tune the interaction strength and introduce geometric frustration in to the patterned systems by changing the lattice spacing and geometry of the arrays. Using MOKE microscopy we are able to optically resolve, spatially isolate, and extract the switching field of each island in an array in the presence of an external field. These switching fields allow us to calculate the magnetization and nearest neighbor spin-spin correlation throughout a hysteresis loop. These quantities help us determine the effect of increased interactions and geometric frustration on the switching process of dipole coupled arrays. Funded by DOE.

**11:27AM L5.00002 Dimensionality Reduction in Artificial Spin Ice<sup>1</sup>**, IAN GILBERT<sup>2</sup>, YUYANG LAO, ISAAC CARRASQUILLO, University of Illinois at Urbana-Champaign, LIAM O'BRIEN<sup>3</sup>, JUSTIN WATTS, MICHAEL MANNO, CHRIS LEIGHTON, University of Minnesota, ANDREAS SCHOLL, Lawrence Berkeley National Laboratory, CRISTIANO NISOLI, Los Alamos National Laboratory, PETER SCHIFFER, University of Illinois at Urbana-Champaign — Over the past ten years, square and hexagonal arrays of single-domain nanomagnets, known as artificial spin ice, have been used to study the microscopic properties of geometrical frustration. Here we describe the fabrication of a new type of artificial spin ice, the tetris lattice. The ground state configuration of the nanomagnets' moments was determined with photoemission electron microscopy. This lattice is designed such that its vertices (small clusters of nanomagnets) cannot all simultaneously achieve their ground state. As a consequence, the lattice decomposes into alternating ordered and disordered one-dimensional bands of moments. The disordered bands can be described by a thermal one-dimensional Ising model, underscoring the emergent dimensionality reduction found in this lattice.

**11:39AM L5.00003 DC Magnetization and FMR results of Fibonacci Distortions on the Honeycomb Artificial Spin Ice**, JUSTIN WOODS, BARRY FARMER, TODD HASTINGS, JUSTIN VISAK, LANCE DE LONG, Univ of Kentucky — Nanofabrication techniques allow magnetic thin films to be lithographically-patterned into arrays of interacting macro-spins that can be designed to study emergent physical properties. Here we discuss the effects of continuous symmetry breaking on the equilibrium and dynamic magnetic properties of frustrated magnetic metamaterials. We have patterned five Permalloy ( $\text{Ni}_{0.80}\text{Fe}_{0.20}$ ) samples of distorted Kagome ASI arrays that are generated by repeated application of a substitution algorithm. This algorithm employs an aperiodic Fibonacci sequence of binary digits that can be mapped into short ( $d_1$ ) and long ( $d_2$ ) distances. This distorts film segment lengths while the width (nominally 70 nm) and thickness (25 nm) remain constant. Additionally, the coordination of each three-fold Kagome vertex is continuously modified via these distortions. Micromagnetic simulations predict the Fibonacci distortions causes jamming of Dirac String propagation. We report DC magnetization and FMR dispersion for different magnitudes of distortion, and compare these results to simulation. Research at University of Kentucky supported by U.S. National Science Foundation grant no. DMR-1506979.

**11:51AM L5.00004 Beller Lecture: Artificial Ferroic Systems**, LAURA HEYDERMAN, ETH Zurich - Paul Scherrer Institute — In artificial ferroic systems [1], novel functionality is engineered through the combination of structured ferroic materials and the control of the interactions between the different components. I will present two classes of these systems, beginning with hybrid mesoscopic structures incorporating two different ferromagnetic layers whose static and dynamic behaviour result from the mutual imprint of the magnetic domain configurations [2]. Here we have demonstrated a new vortex core reversal mechanism [3], which occurs when it is displaced across domain boundaries with a magnetic field. I will then describe our progress on artificial spin ice, consisting of arrays of dipolar-coupled nanomagnets arranged in frustrated geometries. We have employed photoemission electron microscopy to observe the behaviour of emergent magnetic monopoles in an array of nanomagnets placed on the kagome lattice [4]. We have also created artificial spin ice with fluctuating magnetic moments and observed the evolution of magnetic configurations with time. This has provided a means to study relaxation processes with a controlled route to the lowest-energy state [5]. Recently, we have demonstrated with muon spin relaxation that these magnetic metamaterials can support thermodynamic phase transitions [6], and future directions include the incorporation of novel magnetic materials such as ultrathin magnetic films [7], the investigation of 3D structures [8], as well as the implementation of x-ray resonant magnetic scattering to study magnetic correlations in smaller nanomagnets and at faster timescales [9]. Farhan et al., Nature Phys. and PRL (2013); [6] L. Anghinolfi et al., Nature Comms (2015); [7] V. Kapaklis et al., Nature Nanotech. (2014); [8] C. Donnelly et al., PRL (2015); [9] J. Perron et al., PRB (2013)

**12:27PM L5.00005 Doped Artificial Spin Ice**, CYNTHIA OLSON REICHHARDT, Theoretical Division, Los Alamos National Laboratory, ANDRAS LIBAL, Faculty of Mathematics and Computer Science, Babes-Bolyai University, CHARLES REICHHARDT, Theoretical Division, Los Alamos National Laboratory — We examine square and kagome artificial spin ice for colloids confined in arrays of double-well traps. Unlike magnetic artificial spin ices, colloidal and vortex artificial spin ice realizations allow creation of doping sites through double occupation of individual traps. We find that doping square and kagome ice geometries produces opposite effects. For square ice, doping creates local excitations in the ground state configuration that produce a local melting effect as the temperature is raised. In contrast, the kagome ice ground state can absorb the doping charge without generating non-ground-state excitations, while at elevated temperatures the hopping of individual colloids is suppressed near the doping sites. These results indicate that in the square ice, doping adds degeneracy to the ordered ground state and creates local weak spots, while in the kagome ice, which has a highly degenerate ground state, doping locally decreases the degeneracy and creates local hard regions.

**12:39PM L5.00006 Systematic Angular Study of Magnetoresistance in Permalloy Connected Kagome Artificial Spin Ice**, JUNGSIK PARK, BRIAN LE, Univ of Illinois - Urbana, JUSTIN WATTS, CHRIS LEIGHTON, University of Minnesota, NITIN SAMARTH, Pennsylvania State University, PETER SCHIFFER, Univ of Illinois - Urbana — Artificial spin ices are nanostructured two-dimensional arrays of ferromagnetic elements, where frustrated interactions lead to unusual collective magnetic behavior. Here we report a room-temperature magnetoresistance study of connected permalloy ( $\text{Ni}_{81}\text{Fe}_{19}$ ) kagome artificial spin ice networks, wherein the direction of the applied in-plane magnetic field is systematically varied. We measure both the longitudinal and transverse magnetoresistance in these structures, and we find certain transport geometries of the network show strong angular sensitivity – even small variations in the applied field angle lead to dramatic changes of the magnetoresistance response. We also investigate the magnetization reversal of the networks using magnetic force microscopy (MFM), demonstrating avalanche behavior in the magnetization reversal. The magnetoresistance features are analyzed using an anisotropic magnetoresistance (AMR) model. Supported by the US Department of Energy. Work at the University of Minnesota was supported by Seagate Technology, NSF MRSEC, and a Marie Curie International Outgoing Fellowship within the 7th European Community Framework Programme.

**12:51PM L5.00007 Spin wave band structure of artificial square ices<sup>1</sup>**, EZIO IACocca, University of Colorado - Boulder, Co, USA; Chalmers University of Technology, Sweden, SEBASTIAN GLIGA, ETZ, Switzerland; PSI, Switzerland, ROBERT STAMPS, University of Glasgow, UK, OLLE HEINONEN, Argonne National Laboratory, IL, USA — Artificial square spin ices are structures composed of magnetic elements located on the sites of a geometrically frustrated, two-dimensional square lattice. Using a semi-analytical approach, we show that square spin ices exhibit a rich spin wave band structure that is tunable both by external magnetic fields and the magnetic state of individual elements. Internal degrees of freedom can give rise to equilibrium states with bent magnetization at the edges of each element, leading to characteristic excitations; in the presence of magnetostatic interactions these form separate bands analogous to impurity bands in semiconductors. Full-scale micromagnetic simulations corroborate our semi-analytical approach. This study shows that the magnon spectra, and therefore group and phase velocities and band gap, can be manipulated by external fields, temperature, or more sophisticated techniques such as using spin torque on individual elements, and suggesting that artificial square spin ices can be used as metamaterials for spin waves. Our results close the gap between the research fields of artificial spin ices and magnonics.

**1:03PM L5.00008 Lithography patterns and data analysis for topologically frustrated artificial spin ice**, THOMAS MARSH, JASPER DRISKO, JOHN CUMINGS, University of Maryland, College Park — Artificial spin ices (ASIs), lattices composed of nanoscale single-domain magnetic islands, have been studied extensively for their insights on frustrated systems. Recently, the square and kagome geometries have received the most attention. We study a variation of the square lattice, where we include one or more edge dislocations in an otherwise perfect arrangement, resulting in topological frustration of the system. We create lithography patterns using a MATLAB script that models the system as a lattice of connected nodes and starts by removing partial rows or columns of elements. We then allow the system to relax, reshaping these patterns with an algorithm that attempts to equalize the angles of the elements at each node and also maintain identical island lengths throughout the lattice. We then analyze experimental Lorentz Transmission Electron Microscopy (TEM) images of these lattices using another program, which manipulates the images in order to find and index all of the individual magnetic islands, and then uses the Lorentz contrast of the element to determine the direction of each island's magnetic moment. These moment directions are then combined to determine the type of each lattice vertex, using the traditional type I-IV notation for square lattices. The script then marks the TEM images to reflect the vertex classification, which allows us to clearly identify chains of type II & III vertices in the Lorentz images. The chains carry net magnetic moment, in a direction defined by the type II vertices, which may then reverse at the type III vertices.

**1:15PM L5.00009 Topological frustration of artificial spin ice**, JASPER DRISKO, THOMAS MARSH, JOHN CUMINGS, University of Maryland, College Park — Dislocations are topological defects ubiquitous in crystalline materials, although they are often neglected in experimental and theoretical studies due to their complexity. Artificial spin ices (ASIs), lithographically patterned arrays of ferromagnetic nanostructures, are highly tunable systems that allow for detailed investigations of frustration by providing exquisite control and insight at the single-spin level. Here, we introduce controlled topological defects into thermally active square ASI lattices and directly observe the resulting spin configurations upon annealing. Whereas a canonical square ASI lattice can support perfect ground state ordering, we find the presence of a dislocation results in extended frustration within the system. Locally, the magnets are unfrustrated, but frustration of the lattice persists due to its topology. A chain of higher energy vertices always originates from each dislocation point and either extends to an edge of our finite crystal, or rarely, to a second dislocation point if it is present in the same crystal. We also simulate our work using a kinetic Monte Carlo technique and find remarkably similar behavior between the simulations and our experiments, with the same types of domain walls and domain patterns as in our experimental samples. Our results indicate that topological defects have non-trivial consequences and should receive more attention in investigations of three dimensional crystals with  $\mathbf{q} \neq \mathbf{0}$  order parameters.

**1:27PM L5.00010 Nanomagnetic field-driven thermal mobility of emergent monopoles in artificial spin ice.** , SOPHIE MORLEY, MARK C. ROSAMOND, University of Leeds, DIEGO ALBA VENERO, ISIS, ALES HRABEC, Université Paris Sud, JOSE MARIA PORRO, ISIS, MI-YOUNG IM, CXRO, LBNL and DGIST, PETER FISCHER, UC Santa Cruz, SEAN LANGRIDGE, ISIS, CHRISTOPHER H. MARROWS, University of Leeds — Artificial spin ices are nanomagnetic islands confined in 2D and their size means they can be considered as single domain and Ising-like. In the square geometry, each vertex has four nanomagnets which can point either in or out. The lowest energy arrangement consists of two-in and two-out and obeys the so-called 'ice-rule'. It is possible to construct an ordered state by tiling such vertices, above which it is possible to have ice-rule-violating excitations known as emergent magnetic monopoles. It is their propagation which has been imaged with a transmission X-ray microscope and, due to a novel on-membrane heater, elevated temperatures applied up to 700 K. Square ice arrays were fabricated on a SiN membrane, the CoFeB islands were 80x250 nm, 10nm thick and had lattice spacings in the 350-500nm. Increased avalanche length and faster string velocities were observed for both stronger interaction and increased temperature. We have also been able to define a magnetic mobility in our systems and observed increased mobility in more interacting systems or elevated temperature. The largest change in the magnetic mobility was found for the most strongly interacting array, increasing by  $1.7 \pm 0.7 \text{ mm}^2 \text{ A}^{-1} \text{ s}^{-1}$  for  $\Delta T \approx 30 \text{ K}$ .

**1:39PM L5.00011 Macroscopic Artificial Magnetic Honeycomb Lattice of Thermally Controlled Ultra-Small Bonds** , BROCK SUMMERS, ASHUTOSH DAHAL, Univ of Missouri - Columbia, LISA DEBEER-SCHITT, Oak Ridge National Lab , JAGATH GUNASEKERA, DEEPAK SINGH , Univ of Missouri - Columbia — The two-dimensional artificial magnetic honeycomb lattice system is evolving into a new research arena to explore a plethora of novel magnetism that are predicted to occur as functions of temperature and magnetic field: a long-range spin ice, spin liquid, an entropy-driven magnetic charge-ordered state involving topological vortex pairs and a spin-order due to the spin chirality. We have created macroscopic samples of artificial magnetic honeycomb lattices of Cobalt and Permalloy having connected ultra-small elements (bonds), with length scales of sub-10 nm to 30 nm, which have never before been possible. The equivalent energy of the resulting systems is 10-100 K and is thus amenable to both temperature- and field-dependent exploration of novel magnetic phenomena. We have performed detailed magnetic and small angle neutron scattering measurements (SANS) on the newly fabricated honeycomb lattice of Permalloy that show the thermal character of the system. Furthermore, the experimental data reveals the onset of magnetic ordered regimes in temperature that are consistent with the predicted novel phase diagram in artificial honeycomb lattice. Research is supported by U.S. Department of Energy, Office of Basic Energy Sciences under Grant No. DE-SC0014461.

**1:51PM L5.00012 Real time dynamic behavior of vertex frustrated artificial spin ice.** , YUYANG LAO, JOSEPH SKLENAR, University of Illinois at Urbana-Champaign, IAN GILBERT, National Institute of Standards and Technology, ISAAC CARRASQUILLO, University of Illinois at Urbana-Champaign, ANDREAS SCHOLL, ANTHONY YOUNG, Lawrence Berkeley National Laboratory, CRISTIANO NISOLI, Los Alamos National Laboratory, PETER SCHIFFER, University of Illinois at Urbana-Champaign — Artificial spin ice systems comprise two dimensional arrays of nanoscale single domain ferromagnets designed to have frustrated interactions among the moments. By decimating islands from the common square artificial spin ice, one can design lattices with so called 'vertex frustration'. In such lattices, the geometry prevents all vertices from occupying local ground states simultaneously. Using Photoemission Electron Microscopy (PEEM), we access the real time thermally induced dynamics of the moment behavior in those lattices. Operating at a proper temperature, the moment direction of each island fluctuates with a sufficiently slow frequency that it can be resolvable by acquiring successive PEEM images. We can extract information regarding the collective excitations of the moments and understand how they reflect the frustration of lattice. **2:03PM L5.00013 Monte Carlo simulations of kagome lattices with magnetic dipolar interactions** , MARTIN PLUMER, Memorial University Newfoundland, MARK HOLDEN, University of Waterloo, ANDREW WAY, Memorial University of Newfoundland, IVAN SAIKA-VOIVOD, Memorial University Newfoundland, BYRON SOUTHERN, University of Manitoba — Monte Carlo simulations of classical spins on the two-dimensional kagome lattice with only dipolar interactions are presented [1]. In addition to revealing the sixfold-degenerate ground state, the nature of the finite-temperature phase transition to long-range magnetic order is discussed. Low-temperature states consisting of mixtures of degenerate ground-state configurations separated by domain walls can be explained as a result of competing exchange-like and shape-anisotropy-like terms in the dipolar coupling. Fluctuations between pairs of degenerate spin configurations are found to persist well into the ordered state as the temperature is lowered until locking in to a low-energy state. Results suggest that the system undergoes a continuous phase transition at  $T \approx 0.43$  in agreement with previous MC simulations [2] but the nature of the ordering process differs [3]. Preliminary results which extend this analysis to the 3D fcc ABC-stacked kagome systems will be presented [4].

**11:15AM L6.00001 Mutual synchronization of two spin transfer oscillators coupled through their self-emitted microwave currents** , V. CROS, R. LEBRUN, Unit Mixte CNRS/Thales, Univ. Paris-Sud, Univ. Paris-Saclay, Palaiseau, France, S. TSUNEGI, Spintronic Research Center, AIST, Tsukuba, Japan, P. BORTOLOTTI, Unit Mixte CNRS/Thales, Univ. Paris-Sud, Univ. Paris-Saclay, Palaiseau, France, H. KUBOTA, Spintronic Research Center, AIST, Tsukuba, Japan, M. ROMERA, Unit Mixte CNRS/Thales, Univ. Paris-Sud, Univ. Paris-Saclay, Palaiseau, France, K. YAKUSHIJI, A. FUKUSHIMA, Spintronic Research Center, AIST, Tsukuba, Japan, J. GROLLIER, Unit Mixte CNRS/Thales, Univ. Paris-Sud, Univ. Paris-Saclay, Palaiseau, France, S. YUASA, Spintronic Research Center, AIST, Tsukuba, Japan, UNIT MIXTE DE PHYSIQUE CNRS/THALES COLLABORATION, SPINTRONICS RESEARCH CENTER, AIST COLLABORATION — Here, we demonstrate the mutual synchronization of two vortex STOs through electrical coupling. We describe how in using a delay line, we can optimize the locking range of the synchronization. We also evidence that the coupling efficiency is tuned by the nonlinear parameters of STOs but also more originally through the ratio between the two components of spin transfer torques. This represents a definite advantage of our vortex-STNOs for their future implementation in large arrays of synchronized STOs. We find that the linewidth of the two synchronized STOs decreases by a factor 2 and the output power increases by factor 4 ( $\sim 1.6 \text{ W}$ ) compared to non-interacting STOs. These results provide a solid basis towards the efficient synchronization of multiple STOs. EU FP7 grant (MOSAIC No. ICT-FP7-317950 is acknowledged).

**11:27AM L6.00002 Toggling synchronization of nano-contact spin torque oscillators with spin wave beams<sup>1</sup>**, RANDY DUMAS, AFSHIN HOUSHANG, PHILIPP DURRENFELD, JOHAN AKERMAN, University of Gothenburg-Physics — The synchronization of multiple nano-contact spin torque oscillators (NC-STOs) [1-3] is mediated by propagating spin waves (SWs) [4]. Furthermore, it has been shown that the Oersted field in the vicinity of the NC can induce highly directional SW beams [5, 6]. Not only have we recently demonstrated the robust synchronization between two oscillators separated by over 1 micron, but also the driven synchronization of up to five oscillators by purposefully taking advantage of such SW beams [7]. Here, we demonstrate that when the NC diameters differ by a significant amount, the Oersted field scale in such a way as to promote or block synchronization depending on the SW propagation direction, allowing one to easily toggle between synchronized and un-synchronized states by simply altering the applied field direction. **11:39AM L6.00003 Theory of mode coupling in spin torque oscillators coupled to a thermal bath of magnons**, YAN ZHOU<sup>1</sup>, University of Hong Kong, SHULEI ZHANG<sup>2</sup>, University of Missouri, DONG LI, Hong Kong Baptist University, OLLE HEINONEN<sup>3</sup>, Argonne National Lab and Northwestern University — Recently, numerous experimental investigations have shown that the dynamics of a single spin torque oscillator (STO) exhibits complex behavior stemming from interactions between two or more modes of the oscillator. Examples are the observed mode-hopping and mode coexistence. There has been some initial work indicating how the theory for a single-mode (macro-spin) spin torque oscillator should be generalized to include several modes and the interactions between them. In this work, we rigorously derive such a theory starting with the generalized Landau-Lifshitz-Gilbert equation in the presence of the current-driven spin transfer torques. We will first show, in general, that how a linear mode coupling would arise through the coupling of the system to a thermal bath of magnons, which implies that the manifold of orbits and fixed points may shift with temperature. We then apply our theory to two experimentally interesting systems: 1) a STO patterned into nano-pillar with circular or elliptical cross-sections and 2) a nano-contact STO. For both cases, we found that in order to get mode coupling, it would be necessary to have either a finite in-plane component of the external field or an Oersted field. We will also discuss the temperature dependence of the linear mode coupling.

**11:51AM L6.00004 Nonlocal spin-transfer with low-resistance  $\text{AlO}_x$  spin injection interface and ohmic spin absorption interface**, YUNJIAO CAI, CHUAN QIN, SHUHAN CHEN, YI JI, Univ of Delaware — Mesoscopic nonlocal spin valves are fabricated for the purpose of spin-transfer with pure spin current. The device consists of a 300 nm wide Py (NiFe alloy) spin injector (F1), an 80 nm wide Py spin detector (F2) and an 80 nm wide Cu channel. The thickness of F1, F2, and Cu is 15 nm, 3 nm, and 110 nm, respectively. A 3 nm layer of low-resistance  $\text{AlO}_x$  is placed at the F1/Cu interface to mitigate the spin resistance mismatch between Py and Cu and to provide substantial injection spin polarization. The F1 injector and the F1/ $\text{AlO}_x$ /Cu interface are robust enough to sustain a d.c. injection current up to 6 mA. The F2/Cu interface remains ohmic to facilitate an efficient absorption of the pure spin current from the Cu channel into the F2. A nanoscale magnetic domain in F2 underneath the F2/Cu interface can be reversibly switched between 5 K and 150 K via spin-transfer by the pure spin current. The critical injection current for the reversal at 100 K is ~1.5 mA, which is significantly lower than those in previous studies for nonlocal spin-transfer.

**12:03PM L6.00005 Spin current valve effect in normal metal/magnetic insulator/normal metal sandwiches<sup>1</sup>**, JUNXUE LI, YADONG XU<sup>2</sup>, MOHAMMED ALDOSARY, CHI TANG, ZHISHENG LIN, UC Riverside, SHUFENG ZHANG, University of Arizona, ROGER LAKE, JING SHI, UC Riverside, SHINES COLLABORATION — Pure spin current is generated in two common ways. One makes use of the spin Hall effect in normal metals (NM), the other utilizes spin waves with the quasi-particle excitations called magnons. A popular material for the latter is yttrium iron garnet (YIG), a magnetic insulator (MI). Here we demonstrate in NM/MI/NM sandwiches that these two types of spin current are interconvertible, which allows transmitting an electrical signal across the MI, predicted as the magnon-mediated current drag phenomenon. We show experimentally that the spin current can be switched on or off by controlling the magnetization orientation of MI, analogous to conventional spin valves for spin-polarized charge current. The transmitted current drag signal scales linearly with the driving current without any threshold and follows the power-law  $T^n$  with  $n$  ranging from 1.5 to 2.5. Our results indicate that the NM/MI/NM sandwich structure can serve as a scalable pure spin current valve device which is an essential ingredient in spintronics.

**12:15PM L6.00006 Comparison of spin transfer mechanisms in three terminal spin-torque-oscillators**, EMILIE JUE, WILLIAM RIPPARD, MATTHEW PUFALL, ERIC R. EVARTS, NIST - Boulder, QUANTUM ELECTROMAGNETICS DIVISION TEAM — The manipulation of magnetization by electric current is one of the most active field of spintronics due to its interests for memory and logic applications. This control can be achieved through the transfer of angular momentum via a spin polarized current (the mechanism of spin-transfer torque - STT) or through a direct transfer of angular momentum from the crystal lattice through the spin-orbit interaction (the mechanism of spin-orbit torque - SOT). Over the five past years, SOT gained a lot of attention especially for the new possibilities that it offers for data storage application. However, the quantification and the comparison of both mechanisms' efficiencies remains uncertain. In this work, we compare for the first time the STT and SOT efficiencies in individual devices. For this, we created 3-terminal spin-torque oscillators (STO) composed of spin-valves (SV) on top of a Pt wires. The devices can be excited either by STT or by SOT depending on whether the current is applied through the SV or through the Pt wire. By varying the Pt width and the dimensions of the SV, we tune the SOT and STT and compare their efficiencies. We will discuss the complexity of such a structure and the differences in the magnetization dynamics induced by the different excitation mechanisms.

**12:27PM L6.00007 Characterization of perpendicular STT-MRAM by spin torque ferromagnetic resonance<sup>1</sup>**, CHENG CEN SHA, LIU YANG, HAN KYU LEE, IGOR BARSUKOV, JIEYI ZHANG, ILYA KRIVOROTOV, University of California, Irvine — We describe a method for simple quantitative measurement of magnetic anisotropy and Gilbert damping of the MTJ free layer in individual perpendicular STT-MRAM devices by spin torque ferromagnetic resonance (ST-FMR) with magnetic field modulation. We first show the dependence of ST-FMR spectra of an STT-MRAM element on out-of-plane magnetic field. In these spectra, resonances arising from excitation of the quasi-uniform and higher order spin wave eigenmodes of the free layer as well as acoustic mode of the synthetic antiferromagnet (SAF) are clearly seen. The quasi-uniform mode frequency at zero field gives magnetic anisotropy field of the free layer. Then we show dependence of the quasi-uniform mode linewidth on frequency is linear over a range of frequencies but deviates from linearity in the low and high frequency regimes. Comparison to ST-FMR spectra reveals that the high frequency line broadening is linked to the SAF mode softening near the SAF spin flop transition at 5 kG. In the low field regime, the SAF mode frequency approaches that of the quasi-uniform mode, and resonant coupling of the modes leads to the line broadening. A linear fit to the linewidth data outside of the high and low field regimes gives the Gilbert damping parameter of the free layer.

**12:39PM L6.00008 Spin-torque ferromagnetic resonance (ST-FMR) spectroscopy of localized spin wave modes engineered by applied dipole-field localization**, CHI ZHANG, YONG PU, SERGEI A. MANUILOV, DENIS V. PELEKHOV, P. CHRIS HAMMEL, The Ohio State University — Maintaining efficient spin-Hall anti-damping torque in micron-scale devices is challenging near the critical current for auto-oscillation, likely due to spin wave mode degeneracies and nonlinear magnon scattering between them [1]. Localized spin wave modes confined by the strongly inhomogeneous dipole magnetic field of a nearby micro-spherical magnet [2] provides a potentially powerful tool to study these multi-mode interactions by allowing systematic tunability while avoiding potential spurious effects arising from imperfections in fabricating microscopic structures. We demonstrate electrical ST-FMR detection of well-resolved localized modes in a Py/Pt stripe. We find that magnon spectral engineering by means of a micromagnetic particle enables clear observation of damping control and significant reduction of linewidth by means of the anti-damping torque arising from an imposed DC current. The observed linewidth variation suggests that localized modes can be controlled as effectively as the uniform mode. References: [1] V. E. Demidov et al, Phys. Rev. Lett. 107, 107204 (2011) Z. **12:51PM L6.00009 First-principles theory of current-induced spin torques in noncollinear antiferromagnets**, ALLAN MACDONALD, HUA CHEN, The University of Texas at Austin, YIMING WU, Peking University, YASUFUMI ARAKI, Tohoku University — We propose a new theoretical approach for calculating current induced torques in hybrid systems containing magnetic and heavy metal thin films. The theory is based on ab-initio density functional theory (DFT) and appeals explicitly to the local-spin-density approximation for exchange and correlation. Because the effective magnetic field from exchange and correlation is everywhere parallel to the spin-density in the ferromagnet, it does not contribute to the current-induced torque, which is due entirely to spin-orbit coupling near heterojunctions involving heavy metals. The theoretical picture can be combined with any theory of the electronic steady state produced by electrochemical potential gradients, and involves response of the single-particle density matrix that is partially diagonal and partially off-diagonal in an unperturbed eigenstate representation. The theory is formulated using the basis of Wannier functions and can be readily interfacing with existing DFT codes. This approach predicts strong current-induced torques due to either antiferromagnetic or non-magnetic heavy metal layers. As an illustration, we use it to calculate specifically the spin torque in a ferromagnet induced by an adjacent noncollinear antiferromagnet (Mn3Ir).

**1:03PM L6.00010 Spin Torque Generated by the Spin Hall Effect in Ferromagnets**, JONATHAN GIBBONS, Department of Physics, Cornell University, ROBERT BUHRMAN, School of Applied and Engineering Physics, Cornell University, DANIEL RALPH, Department of Physics, Cornell University — Ferromagnetic materials exhibit the anomalous Hall effect, the generation of a transverse charge current due to spin-orbit coupling. The anomalous Hall effect is closely related to the spin Hall effect, and hence this transverse charge current is expected to be accompanied by a strong transverse spin current, whose direction can be manipulated by rotating the magnetic moment. We measure the torque from this spin current generated by Gd-doped Fe and acting on an in-plane magnetized free layer. We use the harmonic measurement technique, applying a current to an in-plane pinned ferromagnet/spacer/in-plane free ferromagnet stack and measuring the second harmonic Hall voltage. We report the angular dependence of the spin torque for a variety of initial exchange bias directions, and as the spin torque changes with an external magnetic field.

**1:15PM L6.00011 Enhanced spin orbit torques by oxygen incorporation in tungsten films**, TIMOTHY PHUNG, KAI-UWE DEMASIU, WEIFENG ZHANG, BRIAN P. HUGHES, SEE-HUN YANG, ANDREW KELLOCK, WEI HAN, AAKASH PUSH, STUART S. P. PARKIN, IBM Almaden Res Ctr — Spin orbit torques are generated by the conversion of charge to spin currents in non-magnetic materials. The origin of these torques is of considerable debate. One of the most interesting materials is metallic tungsten for which large spin orbit torques have been found in thin films that are stabilized in the A15 ( $\beta$ -phase) structure. Here we report, using spin transfer torque ferromagnetic resonance, large spin Hall angles of up to  $\sim 0.5$  by incorporating oxygen into tungsten films. Whilst the incorporation of oxygen into the tungsten leads to significant changes in its microstructure and electrical resistivity, the large spin Hall angles measured are found to be remarkably insensitive to the oxygen doping level (12-44%). This invariance of the spin Hall angle with the bulk W(O) properties for higher oxygen concentrations suggests that the spin orbit torques in this system may actually be partly interfacial in origin, and induced by scattering of the electrons at the W(O) | CoFeB interface rather than from the interior of the W(O) film. Our results show an intriguing novel path towards enhanced spin orbit torques.

**1:27PM L6.00012 Optically Detected Ferromagnetic Resonance in Metallic Ferromagnets Via Off-Resonant Detection of Nitrogen Vacancy Centers in Diamond**, MICHAEL R. PAGE, VIDYA P. BHALLAMUDI, JOE SCHULZE, CAROLA M. PURSER, SERGEI MANUILOV, CHRISTOPHER WOLFE, JACK T. BRANGHAM, FENGYUAN YANG, P. CHRIS HAMMEL, The Ohio State University Department of Physics — We report optical detection of ferromagnetic resonance in thin film metallic ferromagnets using a recently discovered approach employing nitrogen vacancy centers in nanodiamonds. While conventional optically detected magnetic resonance measures magnetic fields through their impact on the magnetic resonance frequency of the nitrogen vacancy center, we measure a change in the nitrogen vacancy center photoluminescence at the ferromagnets resonance condition without need to work at the NV resonance frequency. This measurement technique allows sensitive, local detection of ferromagnetic resonance and can enable the study of magnetic dynamics at the nanoscale in a wide range of materials. While this measurement protocol was first reported in the study of ferromagnetic resonance in YIG, here we demonstrate the measurement in commonly used metallic ferromagnets to establish the generality of the technique and open the possibility of measuring nanoscale patterned devices and magnetic textures based on metallic ferromagnets of both commercial and scientific interest.

**1:39PM L6.00013 Phase-resolved ferromagnetic resonance detection using heterodyning**, SEUNGHA YOON, ROBERT D. MCMICHAEL, National Institute of Standards and Technology — We have developed a new phase-resolved ferromagnetic (FMR) detection method using a heterodyne method. Phase resolution is important to determine the characteristics of spin transfer torques in magnetization dynamics under microwave excitation [1]. Specifically, field-like torques and damping-like torques result in magnetization precession with different phases. In this method, we drive spin precession in a Permalloy thin film using microwaves. The resulting precession is detected using 1550 nm laser light, that is modulated at a frequency slightly shifted with respect to the driving frequency. In the reflected light, beating of the spin precession and the light modulation produces an oscillating Kerr rotation signal with a phase equal to the precession phase plus a phase due to the path length difference between the excitation microwave and the optical signal. This detection method eliminates the need for field modulation and allows detection at higher frequencies where the  $1/f$  noise floor is reduced. [1] M. Weiler, J. M. Shaw, H. T. Nembach, and T. J. Silva, *Phys. Rev. Lett.* 113, 157204 (2014).

**1:51PM L6.00014 Anomalous Hall Effect in a Kagome Ferromagnet**<sup>1</sup>, LINDA YE, CHRISTINA WICKER, TAKEHITO SUZUKI, JOSEPH CHECKELSKY, Massachusetts Inst of Tech-MIT, JOSEPH CHECKELSKY TEAM — The ferromagnetic kagome lattice is theoretically known to possess topological band structures [1,2]. We have synthesized large single crystals of a kagome ferromagnet  $\text{Fe}_3\text{Sn}_2$  which orders ferromagnetically well above room temperature [3]. We have studied the electrical and magnetic properties of these crystals over a broad temperature and magnetic field range. Both the scaling relation of anomalous Hall effect and anisotropic magnetic susceptibility show that the ferromagnetism of  $\text{Fe}_3\text{Sn}_2$  is unconventional. We discuss these results in the context of magnetism in kagome systems and relevance to the predicted topological properties in this class of compounds. [1] *Phys. Rev. B* 87 144101 (2013) [2] *Phys. Rev. Lett.* 106 236802 (2011) [3] *J. Phys. Cond. Mat.* 21 452202 (2009)

**2:03PM L6.00015 Interaction and multiband effects in the intrinsic spin-Hall effect of an interacting multi-orbital metal**, NAOYA ARAKAWA, RIKEN CEMS — The spin-Hall effect is a spin-current version of the usual-Hall effect, and its potential for application may be great. For the efficient application utilizing the spin-Hall effect, an understanding of interaction effects may be helpful because the interaction effects sometimes become remarkable in transport phenomena (e.g., fractional-quantum-Hall effect). However, a lot of theoretical studies neglected the interaction effects, and the interaction effects in the spin-Hall effect had been little understood. To improve this situation, I developed a general formalism for the intrinsic spin-Hall effect including the interaction effects and multiband effects by using the linear-response theory with approximations appropriate for an interacting multi-orbital metal (see arXiv:1510.03988). In this talk, I explain how the electron-electron interaction modifies the spin-Hall conductivity and show several new and remarkable interaction effects, new mechanisms of the damping dependence and a crossover of the damping dependence in a clean system and a temperature-dependent correction due to the spin-Coulomb drag. I also show guidelines useful for general formulations of other transport phenomena including the interaction effects and multiband effects.

## Wednesday, March 16, 2016 11:15AM - 2:15PM –

### Session L7 DMP FIAP: Dopants and Defects in Semiconductors: Novel experimental techniques

303 - James Speck, University of California, Santa Barbara

**11:15AM L7.00001 Tailoring of materials properties under extreme conditions**<sup>1</sup>, THOMAS SCHENKEL, Lawrence Berkeley Natl Lab — Materials can be driven far from equilibrium e. g. with intense pulses of lasers and ions, in mostly destructive processes. When combined with micro- and nano-structuring, the ability to rapidly excite and then quench local excitations opens up. Now opportunities emerge to form and stabilize novel materials phases and to tailor materials properties for applications. Examples are color centers in diamond and silicon carbide for sensing and qubit applications and proposed ordered dopant structures in cuprate superconductors. Results from studies of materials processing under transient extreme conditions, far from equilibrium will be presented.

**11:51AM L7.00002 Polarization spectroscopy of defect-based single photon sources in ZnO**<sup>1</sup>, NICHOLAS JUNGWIRTH, HUNG-SHEN CHANG, MINGDE JIANG, GREGORY FUCHS, Cornell University — Isolated point-defects in wide bandgap semiconductors are promising candidates for future applications requiring quantum light sources. Recently, defect-based single photon sources have been observed in ZnO that are very bright ( $>100$  kCounts/s) and remain photoactive from 4.5 K to room temperature. Despite several investigations, the structure and electronic states of these emitters remain unknown. In this work, we establish a procedure to distinguish a Z dipole from an XY dipole when studying quantum emitters that are randomly oriented. Our cryogenic and room temperature polarization measurements collectively establish that these unidentified ZnO quantum emitters have a Z dipole. We show that the associated absorption and emission dipoles are parallel within experimental uncertainty for all 32 individuals studied. Additionally, we apply group theory and find that, assuming the defect symmetry belongs to a point-group relevant to the ZnO wurtzite lattice, the ground and excited states are orbital singlets. These results are a significant step in identifying the structure and electronic states of defect-based single photon sources in ZnO.

<sup>1</sup>We acknowledge support from the National Science Foundation.

**12:03PM L7.00003 A first principle approach using Maximally Localized Wannier Functions for computing and understanding elasto-optic response**<sup>1</sup>, XIN LIANG, SOHRAB ISMAIL-BEIGI, Yale University — Strain-induced changes of optical properties are of use in the design and functioning of devices that couple photons and phonons. The elasto-optic (or photo-elastic) effect describes a general materials property where strain induces a change in the dielectric tensor. Despite a number of experimental and computational works, it is fair to say that a basic physical understanding of the effect and its materials dependence is lacking: e.g., we know of no materials design rule for enhancing or suppressing elasto-optic response. Based on our previous work, we find that a real space representation, as opposed to a k-space description, is a promising way to understand this effect. We have finished the development of a method of computing the dielectric and elasto-optic tensors using Maximally Localized Wannier Functions (MLWFs). By analyzing responses to uniaxial strain, we find that both tensors respond in a localized manner to the perturbation: the dominant optical transitions are between local electronic states on nearby bonds. We describe the method, the resulting physical picture and computed results for semiconductors.

**12:15PM L7.00004 Modification of a scanning electron microscope (SEM) for insitu, nanometer size contact, electrical measurements of III-nitride transistors**, CAMELIA SELCU, Department of Physics, The Ohio State University, ZHICHAO YANG, SRIRAM KRISHNAMOORTHY, SIDDHARTH RAJAN, Department of Electrical and Computer Engineering, The Ohio State University — As the transistors become smaller and smaller, proximity effects become important, therefore there is a need for characterization instruments. We modified a scanning electron microscope (SEM) by adding the capability to make mechanical contacts to devices for electrical measurements with nanometer precision. We will discuss ongoing work involving III-nitride transistors and nanowires.

**12:27PM L7.00005 Second-Harmonic Generation scanning microscopy of strain fields around Through-Silicon-Vias**, YUJIN CHO, FARBOD SHAFIEI, Univ of Texas, Austin, BERNARDO MENDOZA, Centro de Investigaciones en Optica, Leon, Mexico, TENGFEI JIANG, PAUL HO, MICHAEL DOWNER, Univ of Texas, Austin — Through-Silicon-Vias (TSVs) improve electrical performance of integrated circuits and reduce power consumption by interconnecting vertically stacked silicon layers. Cu has been commonly used for TSVs because of its good electrical and mechanical properties. However, mismatch in thermal expansion coefficient of Si and Cu induces strain fields on the surfaces, which can degrade the performance of nearby devices and crack the surfaces. In this work, using non-invasive Second Harmonic Generation (SHG) microscopy, we successfully characterized inhomogeneous distribution of the thermally induced strain fields. High strain gradients strengthen SHG intensity, since it breaks centrosymmetry in Si. In p-polarized incoming beam and s-polarized SHG configuration, we were able to see the strain effect directly, while in p-in/ p-out polarization, strain-induced SHG was coupled with background SHG from Si [1]. We will present SHG micrographs compared with Raman measurement and the theory of strain-induced SHG, as well as wavelength and power dependence of SHG. [1] Mendoza et al. 'Surface second harmonic generation induced by 3D strain fields', Phys. Status Solidi B. 1-8 (2015)

**12:39PM L7.00006 Probing the effect of dopants (donors) within InAs/InGaAs/InAlAs Asymmetric Heterostructure wafer by magneto-THz spectroscopy**, MEHDI PAKMEHR, University at Buffalo (SUNY), Shiraz University, CHRISTIAN HEYN, WOLFGANG HANSEN, University of Hamburg — Probing the effect of impurities within semiconductor structures have been the topic of interest both from applied and scientific point of views. We studied the effect of dopants (donors) within InAs/InGaAs/InAlAs asymmetric heterostructure wafer by means of THz magneto-transmission (TR) spectroscopy, in conjunction with THz magneto-photoresponse (PR) spectroscopy. The sample wafer has been immersed in pumped liquid Helium at 1.6 K, while being exposed to sweeping magnetic field up to 10 Tesla, with THz laser beam (1.4 THz) being focused on sample by off-axis parabolic mirror. The transmitted beam was detected by silicon composite bolometer. Two broad absorption features other than sharp Cyclotron resonance (CR) absorption dip within magneto-TR signal attributed to  $1s \rightarrow 2P$  transition within donors of doped layer (InAlAs) in heterostructure. We plan to discuss the analysis of magneto-TR signal, in conjunction with Magneto-PR signals from Hall bar samples made from same type of wafer at same frequency to clarify how dopants could possibly alter these signals.

**12:51PM L7.00007 Sub-surface single ion detection in diamond: A path for deterministic color center creation**, JOHN ABRAHAM, BRANDON AGUIRRE, JOSE PACHECO, RYAN CAMACHO, EDWARD BIELEJEC, Sandia National Laboratories, SANDIA NATIONAL LABORATORIES TEAM — Deterministic single color center creation remains a critical milestone for the integrated use of diamond color centers. It depends on three components: focused ion beam implantation to control the location, yield improvement to control the activation, and single ion implantation to control the number of implanted ions. A surface electrode detector has been fabricated on diamond where the electron hole pairs generated during ion implantation are used as the detection signal. Results will be presented demonstrating single ion detection. The detection efficiency of the device will be described as a function of implant energy and device geometry. It is anticipated that the controlled introduction of single dopant atoms in diamond will provide a basis for deterministic single localized color centers. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**1:03PM L7.00008 ABSTRACT WITHDRAWN —**

**1:15PM L7.00009 Uniaxial stress studies of H centers in  $\text{In}_2\text{O}_3$** <sup>1</sup>, PHILIP WEISER, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh University, LYNN A. BOATNER, Oak Ridge National Laboratory —  $\text{In}_2\text{O}_3$  single crystals have been grown for our experiments that are sufficiently large to make possible IR absorption measurements in conjunction with uniaxial stress. The introduction of H produces an IR line at  $3306\text{ cm}^{-1}$  that has been assigned to the OH stretching mode of an interstitial H shallow donor in  $\text{In}_2\text{O}_3$  [1]. We have performed IR absorption experiments in which the splitting of the  $3306\text{ cm}^{-1}$  line under stresses applied at low temperatures provides information about the symmetry of the OH center. Stress measurements made at elevated temperatures reveal a stress-induced dichroism that provides information about the motion of hydrogen associated with the  $3306\text{ cm}^{-1}$  center. [1] W. Yin et al., Phys. Rev. B **91**, 075208 (2015).

<sup>1</sup>NSF Grant DMR 1160756

**1:27PM L7.00010 Diffusion of H in  $\text{In}_2\text{O}_3$  single crystals**<sup>1</sup>, YING QIN, WEIKAI YIN, MIKE STAVOLA, BEALL FOWLER, Lehigh University, LYNN BOATNER, Oak Ridge National Laboratory — An IR absorption line observed at  $3306\text{ cm}^{-1}$  for  $\text{In}_2\text{O}_3$  single crystals annealed in an  $\text{H}_2$  ambient has been assigned to an interstitial hydrogen center that acts as a shallow donor [1]. Experiments have been performed to determine the indiffusion depth of interstitial H into  $\text{In}_2\text{O}_3$  at temperatures near 400 C. We have also performed annealing experiments in which the outdiffusion of interstitial H is monitored by IR spectroscopy. The goal of these studies is to determine the diffusion constant of interstitial H in  $\text{In}_2\text{O}_3$  over a range of temperatures so that the activation energy for diffusion can be determined. [1] W. Yin et al., Phys. Rev. B **91**, 075208 (2015).

<sup>1</sup>Supported by NSF grant DMR 1160756

**1:39PM L7.00011 Profiling the local carrier concentration and dopant distribution across a semiconductor quantum dot**, J.C. WALRATH, A.S. CHANG, Y.H. LIN, S. HUANG, R.S. GOLDMAN, Univ of Michigan - Ann Arbor — We profile the local carrier concentration,  $n$ , across epitaxial InAs/GaAs quantum dots (QDs) consisting of 3D islands on top of a 2D alloy layer. We use scanning thermoelectric microscopy to profile the temperature gradient-induced voltage, which is converted to a profile of the local Seebeck coefficient,  $S$ . The  $S$  profile is then converted to a conduction band-edge profile and compared with Poisson-Schrodinger band-edge simulations. Our combined computational-experimental approach suggests a reduced carrier concentration in the QD center in comparison to that of the 2D alloy layer. We further use 3D atom probe tomography, which enables 3D imaging with a few Angstrom resolution, to profile the distribution of Si dopants. We discuss the correlation between the Si dopant distribution and the observed carrier concentration profile.

**1:51PM L7.00012 Characterisation of potential barriers in a donor quantum dot defined by hydrogen resist lithography.**<sup>1</sup>, ANDREAS FUHRER, NIKOLA PASCHER, IBM Research - Zurich — We use a four terminal donor quantum dot (QD) to characterize potential barriers between degenerately doped nanoscale contacts. The QD is fabricated by hydrogen resist lithography on Si(001) in combination with n-type doping from the gas-phase. The four contacts have different separations ( $d = 9, 12, 16$  and  $29$  nm) to a central  $6 \text{ nm} \times 6 \text{ nm}$  island, leading to different tunnel- and capacitive coupling. We use cryogenic transport measurements in the Coulomb blockade regime to simultaneously probe current flow in the four terminals for various voltage configurations. The magnitude of the measured tunnelling currents as a function of applied bias and contact separation sets a limit of about  $15 \text{ nm}$  for tunnelling contacts and shows a strong increase of the barrier transmission with applied bias. Using a constant interaction picture we extract the mutual capacitances between the QD and the four contacts which are found to be in excellent agreement with numerically calculated values. Our results contribute to a better understanding of tunnelling barriers and gate electrodes in planar dopant devices and pave the way towards reliable quantum device fabrication at the atomic scale.

<sup>1</sup>Support from EU grants PAMS, SiSpin, SiAM and from Swiss NCCR QSIT is gratefully acknowledged

**2:03PM L7.00013 Nanoscale Imaging of Band Gap and Defects in Polycrystalline CdTe Photovoltaic Devices**, NIKOLAI ZHITENEV, CNST, NIST, YOHAN YOON, JUNGSEOK CHAE, AARON KATZENMEYER, HEAYOUNG YOON, SANGMIN AN, U. Maryland / CNST, JOSHUA SHUMACHER, ANDREA CENTRONE, CNST, NIST — To further increase the power efficiency of polycrystalline thin film photovoltaic (PV) technology, a detailed understanding of microstructural properties of the devices is required. In this work, we investigate the microstructure of CdTe PV devices using two optical spectroscopies. Sub-micron thickness lamella samples were cut out from a PV device, either in cross-section or in-plane, by focused ion beam. The first technique is the photothermal induced resonance (PTIR) used to obtain absorption spectra over a broad range of wavelengths. In PTIR, a wavelength tunable pulsed laser is combined with an atomic force microscope to detect the local thermal expansion of lamella CdTe sample induced by light absorption. The second technique based on a near-field scanning optical microscope maps the local absorption at fixed near-IR wavelengths with energies at or below CdTe band-gap energy. The variation of the band gap throughout the CdTe absorber determined from PTIR spectra is  $\approx 20 \text{ meV}$ . Both techniques detect strong spatial variation of shallow defects over different grains. The spatial distribution of mid-gap defects appears to be more uniform. The resolution, the sensitivity and the applicability of these two approaches are compared.

## Wednesday, March 16, 2016 11:15AM - 2:15PM – Session L8 DMP: Electron Transport in Nanowires 304 - Jonathan Baugh, University of Waterloo

**11:15AM L8.00001 1D Coulomb drag between coupled nanowires formed at oxide interfaces**<sup>1</sup>, YUHE TANG, MICHELLE TOMCZYK, MENGCHEN HUANG, Univ of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, Univ of Wisconsin at Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — “Coulomb drag” is a transport phenomenon where Coulomb interaction between two close but electrically isolated conductors induces voltage in one conductor when an electric current is injected in the other conductor. It is a powerful approach to probe electronic correlations. Here we examine 1D electronic correlations in a proximally coupled nanowire system where two parallel nanowires are created with conductive atomic force microscopy at the  $\text{LaAlO}_3/\text{SrTiO}_3$  interface. Coulomb drag measurements are made by injecting current into one wire (drive wire) and measuring the induced voltage in the other wire (drag wire). This geometry offers experimental insights into the interplay of electron pairing and superconductivity in reduced dimensions.

<sup>1</sup>We gratefully acknowledge financial support from DOE DE-SC0014417 (JL).

**11:27AM L8.00002 1D-1D Coulomb drag in a 6 Million Mobility Bi-layer Heterostructure**, SIMON BILODEAU, McGill University, DOMINIQUE LAROCHE, Sandia National Laboratories, JIAN-SHENG XIA, University of Florida, MIKE LILLY, JOHN RENO, Sandia National Laboratories, LOREN PFEIFFER, KEN WEST, Princeton University, GUILLAUME GERVAIS, McGill University — We report Coulomb drag measurements in vertically-coupled quantum wires. The wires are fabricated in  $\text{GaAs}/\text{AlGaAs}$  bilayer heterostructures grown from two different MBE chambers: one at Sandia National Laboratories ( $1.2\text{M}$  mobility), and the other at Princeton University ( $6\text{M}$  mobility). The previously observed positive and negative drag signals are seen in both types of devices, demonstrating the robustness of the result. However, attempts to determine the temperature dependence of the drag signal in the 1D regime proved challenging in the higher mobility heterostructure (Princeton), in part because of difficulties in aligning the wires within the same transverse subband configuration. Nevertheless, this work, performed at the Microkelvin laboratory of the University of Florida, is an important proof-of-concept for future investigations of the temperature dependence of the 1D-1D drag signal down to a few mK. Such an experiment could confirm the Luttinger charge density wave interlocking predicted to occur in the wires. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL8500.

**11:39AM L8.00003 Electronic structure and transport properties of III-V core/shell nanowires**, FLORINDA VIÑAS, MARTIN LEIJNSE, Solid State Physics, Lund University, Sweden — We have modeled electron structure and low-temperature transport in III-V core/shell nanowires to establish a relationship between electron-hole hybridization and signatures in thermoelectrical measurements. Nanowires with a  $\text{GaSb}$  core and an  $\text{InAs}$  shell (and inverted) are interesting for studies of hybridization effects due to the bulk broken band gap alignment at the material interface. By varying the core radius and shell thickness of such wires we can modify the size of the band gap and create wires with band structures that exhibit hole-electron hybridization states. The band structures are obtained using 8-band  $k \cdot p$  theory together with the envelope function approximation. The calculated energy dispersions are used as input to the Boltzmann equation to study thermoelectric transport quantities such as the Seebeck coefficient, in the diffusive limit.

**11:51AM L8.00004 Visualizing One-Dimensional Electronic States and their Scattering in Semi-conducting Nanowires**<sup>1</sup>, HAIM BEIDENKOPF, JONATHAN REINER, ANDREW NORRIS, ABHAY KUMAR NAYAK, NURIT AVRAHAM, HADAS SHTRIKMAN, Department of Condensed Matter Physics, Weizmann Institute of Science — One-dimensional electronic systems constitute a fascinating playground for the emergence of exotic electronic effects and phases, within and beyond the Tomonaga-Luttinger liquid paradigm. More recently topological superconductivity and Majorana modes were added to that long list of phenomena. We report scanning tunneling microscopy and spectroscopy measurements conducted on pristine, epitaxially grown  $\text{InAs}$  nanowires. We resolve the 1D electronic band structure manifested both via Van-Hove singularities in the local density-of-states, as well as by the quasi-particle interference patterns, induced by scattering from surface impurities. By studying the scattering of the one-dimensional electronic states off various scatterers, including crystallographic defects and the nanowire end, we identify new one-dimensional relaxation regimes and yet unexplored effects of interactions. Some of these may bear implications on the topological superconducting state and Majorana modes therein.

<sup>1</sup>The authors acknowledge support from the Israeli Science Foundation (ISF)

**12:03PM L8.00005 Electrical characterization of surface passivation in III-V nanowires**, GREGORY HOLLOWAY, University of Waterloo, RAY LAPIERRE, McMaster University, JONATHAN BAUGH, University of Waterloo — III-V nanowires are promising for implementing many useful technologies including optical sensing and quantum information processing. However, most native nanowires have a significant density of surface states, which cause electron accumulation at the surface and make the optoelectronic characteristics very sensitive to surface conditions and variable from device to device. To achieve optimum device performance it is imperative to decrease the density of these defects, since they are responsible for charge noise (e.g. random telegraph noise) and decreased carrier mobility. Here we report on experimental results from low temperature transport studies of a series of InAs nanowire field effect transistors, each fabricated with a different surface passivation technique. The different surface treatments include combinations of chemical passivation, growth of a thermal oxide, and deposition of a high- $k$  dielectric to determine the optimum process for passivating the surface states. To better quantify the density of surface states, we also study the axial field magnetoconductance of short-channel nanowire transistors, and show how the results can be used to estimate the degree of surface band-bending.

**12:15PM L8.00006 Electron transport in doped GaAs nanowires contacted by evaporated metal films<sup>1</sup>**, ZHUTING SUN, ANDREI KOGAN, Univ of Cincinnati, TIMOTHY BURGESS, CHENNUPATI JAGADISH, Australian National University — We present electron transport measurements in doped GaAs nanowire samples contacted by metal interfaces as function of temperature. We show that the contact resistance is strongly dependent on  $T$  ( $5K < T < 300K$ ), even though the resistance of the moderately doped nanowires ( $N_D \approx 10^{18} \text{ cm}^{-3}$ ), as expected, display little or no variation with  $T$ . We further show that the classical treatment of the Schottky barriers by Padovani and Stratton [1] fails to adequately describe the temperature dependence of the metal-nanowire interface, and present a corrected model that takes into account charge distribution in the contact region and the effect of the surface states on the nanowire. The nanowires, 100 nm in diameter, were grown by MOCVD growth method. The metal contacts, a 20nm Ti/ 300nm Al films were deposited via e-beam and thermal evaporation. We perform a detailed comparison between data on 9 nominally identical samples to the modified theory and find a good agreement. We also show how the measurement can be used to obtain an estimate of the effective doping density and the mobility of the nanowire. [1]: F.A. Padovani, R. Stratton, Field and thermionic-field emission in Schottky barriers, Solid-State Electronics, Volume 9, Issue 7, 1966

<sup>1</sup>The work is supported by NSF grant DMR-1206784 and University of Cincinnati

**12:27PM L8.00007 Electrostatically-tuned dimensional crossover in nanowires<sup>1</sup>**, MICHELLE TOMCZYK, GUANGLEI CHENG, MENGCHEN HUANG, Univ of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, Univ of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — The electron system at the interface of two complex oxides,  $\text{LaAlO}_3$  and  $\text{SrTiO}_3$ , exhibits a number of interesting strongly-correlated electronic properties, such as superconductivity and spin-orbit coupling. Reduced dimensionality is made accessible through nanowire devices created with conducting AFM lithography. Here, we describe an electrostatically-controlled dimensionality crossover in weak antilocalization behavior of  $\text{LaAlO}_3/\text{SrTiO}_3$  nanowires at low temperature. These measurements give insight to the interplay of spin-orbit coupling and dimensionality. Characterizing the behavior of the strongly-correlated electronic properties in these reduced dimensions is necessary in order to develop this system as a multifunctional nanoelectronics platform.

<sup>1</sup>We gratefully acknowledge financial support from the following agencies and grants: ARO (W911NF-08-1-0317), AFOSR FA9550-10-1-0524 (JL) and FA9550-12-1-0342 (CBE), and NSF (DMR-1104191, DMR-1124131 (JL), ONR N00014-15-1-2847 (JL) and DMR-1234096 (CBE).

**12:39PM L8.00008 Transport studies of quantum dots sensitized single Mn-ZnO nanowire field effect transistors<sup>1</sup>**, KESHAB R SAPKOTA, FRANCIS SCOTT MALONEY, GAURAB RIMAL, UMA POUDYAL, JINKE TANG, WENYONG WANG, Univ of Wyoming — We present opto-electrical transport properties of Mn-CdSe quantum dots (QDs) sensitized single Mn-ZnO nanowire (NW) field effect transistors (FET). The ZnO NWs with 2 atomic % of Mn doping are grown by chemical vapor deposition. The NWs are ferromagnetic at low temperature. The as grown nanowires are transferred to clean  $\text{SiO}_2/\text{Si}$  substrate and single nanowire field effect transistors (FET) are fabricated by standard e-beam lithography. Mobility and carrier concentration of Mn-ZnO NWs are estimated from FET device measurement which shows NWs are n-type semiconductors. Pulse laser deposition of Mn-CdSe QDs on the single NW FET significantly increases carrier concentration of the QD-NW system in dark where the QD monolayer conduction is negligibly small. The photoconductivity study of QD sensitized NW FET enlightens the conduction spectrum of QD-NW system and QD to NW carrier transfer mechanism.

<sup>1</sup>This work has been supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02- 10ER46728.

**12:51PM L8.00009 Thermally Active Screw Dislocations in Si, SiC, PbSe, and SiGe Nanowires.**, JIHONG AL-GHALITH, YUXIANG NI, University of Minnesota, Twin Cities, SHIYUN XIONG, Max Planck Institute for Polymer Research, SEBASTIAN VOLZ, Ecole Centrale Paris, TRAIAN DUMITRICA, University of Minnesota, Twin Cities — We elucidate thermal conductivity along the screw dislocation line, which represents a transport direction inaccessible to classical theories. By using equilibrium and non-equilibrium molecular dynamics simulations, and the atomistic Green function method, we uncover a Burgers vector dependent thermal conductivity reduction in Si, SiC, PbSe, and SiGe nanowires. The effect is uncorrelated with the classical theory of Klemens. The influence of dislocations on thermal transport originates in the highly deformed core region, which represents a significant source of anharmonic phonon-phonon scattering. High strain reduces the phonon relaxation time, especially in the longitudinal acoustic branches, and creates an effective internal thermal resistance around the dislocation axis. The effect can be distinguished from the thermal transport reduction caused by the nanowire surface imperfections and vacancies. Our results have implications for designing materials useful for high-temperature electronics and thermoelectric applications.

**1:03PM L8.00010 A New One-dimensional Quantum Material -  $\text{Ta}_2\text{Pd}_3\text{Se}_8$  Atomic Chain**, XUE LIU, JINYU LIU, JIN HU, CHUNLEI YUE, ZHIQIANG MAO, JIANG WEI, Tulane University, LIUBOV ANTIPINA, PAVEL SOROKIN, Technological Institute for Superhard and Novel Carbon Materials, ANA SANCHEZ, University of Warwick — Since the discovery of carbon nanotube, there has been a persistent effort to search for other one dimensional (1D) quantum systems. However, only a few examples have been found. We report a new 1D example - semiconducting  $\text{Ta}_2\text{Pd}_3\text{Se}_8$ . We demonstrate that the  $\text{Ta}_2\text{Pd}_3\text{Se}_8$  nanowire as thin as 1.3nm can be easily obtained by applying simple mechanical exfoliation from its bulk counterpart. High resolution TEM shows an intrinsic 1D chain-like crystalline morphology on these nano wires, indicating weak bonding between these atomic chains. Theoretical calculation shows a direct bandgap structure, which evolves from 0.53eV in the bulk to 1.04eV in single atomic chain. The field effect transistor based on  $\text{Ta}_2\text{Pd}_3\text{Se}_8$  nanowire achieved a promising performance with  $10^4$  On/Off ratio and  $80 \text{ cm}^2\text{V}^{-1}\text{s}^{-1}$  mobility. Low temperature transport study reflects two different mechanisms, variable range hopping and thermal activation, which dominate the transport properties at different temperature regimes.  $\text{Ta}_2\text{Pd}_3\text{Se}_8$  nanowire provides an intrinsic 1D material system for the study low dimensional condensed matter physics.

**1:15PM L8.00011 Gate field induced switching of electronic current in Si-Ge Core-Shell nanowire quantum dots: A first principles study**, KAMAL B DHUNGANA, University of Iowa, MEGHNATH JAISHI, RANJIT PATI, Michigan Technological University — Core-shell nanowires are formed by varying the radial composition of the nanowires. One of the most widely studied core-shell nanowire groups in recent years is the Si-Ge and Ge-Si core-shell nanowires. Compared to their pristine counterparts, they are reported to have superior electronic properties. For example, the scaled ON state current value in a Ge-Si core-shell nanowire field effect transistor (FET) is reported to be three to four times higher than that observed in state-of-the-art-metal oxide semiconductor FET (MOSFET) (*Nature*, 441, 489 (2006)). Here, we study the transport properties of the pristine Si and Si-Ge core-shell nanowire quantum dots of similar dimension to understand the superior performance of Si-Ge core-shell nanowire field effect transistor. Our calculations yield excellent gate field induced switching behavior in current for both pristine Si and Si-Ge core-shell hetero-structure nanowire quantum dots. The threshold gate bias for ON/OFF switching in the Si-Ge core-shell nanowire is found to be much smaller than that found in the pristine Si nanowire. A single particle many-body Green's function approach in conjunction with density functional theory is employed to calculate the electronic current.

**1:27PM L8.00012 Exploring Dynamics and Band Structure in Mid Infrared GaAsSb and GaAsSb/InP Nanowire Heterostructures<sup>1</sup>**, LEIGH SMITH, YUDA WANG, NADEEKA WICKRAMASURIYA, SAMUEL LINSE, HOWARD JACKSON, Department of Physics, University of Cincinnati, XIAOMING YUAN, PHILIPPE CAROFF, HOE TAN, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Australian National University — We study the carrier recombination dynamics and band structure of GaAs<sub>1-x</sub>Sb<sub>x</sub> and GaAs<sub>1-x</sub>Sb<sub>x</sub>/InP core/shell nanowires (NWs) grown by MOCVD. Using Transient Rayleigh Scattering (TRS) measurements and Raman scattering measurements in single unstrained bare core and strained core-shell NWs, we measure the strain distributions in the core and shell and its effect on band structures. At 10 K, the band gap of the GaAs<sub>0.7</sub>Sb<sub>0.3</sub> core is seen using TRS to move to lower energy because of the tensile strain from the InP shell. This tensile strain is confirmed by micro-Raman which show the InP phonons shift to higher frequencies while the GaAs<sub>0.7</sub>Sb<sub>0.3</sub> phonons move to lower frequencies. The recombination lifetimes in bare GaAs<sub>0.7</sub>Sb<sub>0.3</sub> NWs are found to be less than the 50 ps at all temperatures, which is limited by our system response. In contrast, the lifetimes measured in the GaAs<sub>0.7</sub>Sb<sub>0.3</sub>/InP core/shell NWs are 820ps at 10K and 130ps at 300K. This significant lifetime enhancement reflects the effectiveness of the InP shell surface passivation. We infer that the surface recombination velocity reduces from ~100,000 cm/s to ~3,000 cm/s in the core-shell NW.

**1:39PM L8.00013 ABSTRACT WITHDRAWN —**

**1:51PM L8.00014 WHY A MAGNETIZED QUANTUM WIRE CAN ACT AS AN OPTICAL AMPLIFIER**, MANVIR KUSHWAHA, Rice University — We discuss the fundamental issues associated with the magnetoplasmon excitations in a semiconducting quantum wire characterized by a harmonic confining potential and subjected to an applied (perpendicular) magnetic field. The problem involves two length scales:  $l_0 = \sqrt{\hbar/m^*\omega_0}$  and  $l_c = \sqrt{\hbar/m^*\omega_c}$ , which characterize the strengths of the confinement and the magnetic field ( $B$ ). Essentially, we focus on the device aspects of the intersubband collective (magnetoroton) excitation, which observes a negative group velocity between maxon and roton. Existence of the negative group velocity is a clear manifestation of a medium with population inversion brought about due to a metastable state caused by the magnetic field that satisfies the condition  $B > B_{th}$ ;  $B_{th}$  being the threshold value below which the magnetoroton does not exist. A medium with an inverted population has the remarkable ability of amplifying a small optical signal of definite wavelength. An extensive scrutiny of the gain coefficient suggests an interesting and important application: the electronic device designed on the basis of such magnetoroton modes can act as an optical amplifier<sup>1</sup>. 1. M.S. Kushwaha, J. Appl. Phys. 109, 106102 (2011).

**2:03PM L8.00015 Focused Gold Ion Implantation for Conducting Wires**, TODD BRINTLINGER, Naval Research Lab — With the advent of non-Ga ion sources in commercial focused-ion-beam (FIB) systems, new possibilities have arisen for lithographic devices. We demonstrate that focused gold ions can be directly implanted into silicon nitride to form conducting wires. The focused gold ion beam is formed from a binary alloy AuSi source with a deep eutectic temperature, where the gold ions are sorted from the silicon ions with in an ExB filter. Using a 15 pA beam, single-pass lines (dose 1.0-1.5 nC/cm) are written to create several wires in the gap between existing gold electrodes on a silicon nitride membrane. To allow for overlap between the deposited gold wires and the electrodes, the lines are written on top of the existing gold electrodes, as well as in the gap, giving rise to rapid gold-on-gold sputtering in the electrodes, but leaving behind the aforementioned gold wire in the silicon nitride. Full-width, half-max linewidth of wires is 110-140 nm. Atomic force microscopy reveals significant ion sputtering in existing gold electrodes, as already seen in scanning electron microscope, but shows that implanted gold ion wires exist in subsurface with minimal topographic distortion to silicon nitride membrane. Voltage sweeps reveal linear, length-dependent, currents passing through the gold wires.

**Session L11 DMP: Novel Physics of Fe-Pnictide Superconductors** 307 - Ming Yi, UC Berkeley

**11:15AM L11.00001 Origin of superconductivity in KFe<sub>2</sub>As<sub>2</sub> under positive and negative pressures and relation to other Fe-based families<sup>1</sup>**, ROSER VALENTI, Institute of Theoretical Physics, University of Frankfurt — KFe<sub>2</sub>As<sub>2</sub> shows an intricate behavior as a function of pressure. At ambient pressure the system is superconductor with a low critical temperature  $T_c=3.4$  K and follows a V-shaped pressure dependence of  $T_c$  for moderate pressures with a local minimum at a pressure of 1.5 GPa. Under high pressures  $P_c=15$  GPa, KFe<sub>2</sub>As<sub>2</sub> exhibits a structural phase transition from a tetragonal to a collapsed tetragonal phase accompanied by a boost of the superconducting critical temperature up to 12 K. On the other hand, *negative* pressures realized through substitution of K by Cs or Rb decrease  $T_c$  down to 2.25K. In this talk we will discuss recent progress on the understanding of the microscopic origin of this pressure-dependent behavior by considering a combination of ab initio density functional theory with dynamical mean field theory and spin fluctuation theory calculations [1-3]. We will argue that a Lifshitz transition associated with the structural collapse changes the pairing symmetry from *d*-wave (tetragonal) to  $s_{\pm}$  (collapsed tetragonal) at high pressures while at ambient and negative pressures correlation effects appear to be detrimental for superconductivity. Further, we shall establish cross-links to the chalcogenide family, in particular FeSe under pressure [4]. [1] S. Backes, D. Guterding, H. O. Jeschke, R. Valenti, New J. Phys. 16, 083025 (2014). **11:51AM L11.00002 ARPES investigation of Fe-based superconductor  $\text{KFe}_2\text{As}_2$  and related compounds**, PIERRE RICHARD, X. SHI, B.-Q. LV, P. ZHANG, T. QIAN, H. DING, Institute of Physics, Chinese Academy of Sciences (CAS), T. K. KIM, M. HOESCH, Diamond Light Source, D.-L. FANG, H.-H. WEN, Nanjing University, X.-H. CHEN, University of Science and Technology of China, A. VAN ROEKEGHEM, P. SETH, S. BIERMANN, Ecole Polytechnique (France) —  $\text{KFe}_2\text{As}_2$  is the end-member of the  $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$  family of Fe-based superconductors. Despite a small  $T_c$  of 3 K, this compound is of particular interest because unlike the other members of this family of superconductors, the Fermi surface of  $\text{KFe}_2\text{As}_2$  is free of electron pocket. Interest for this material was intensified following various reports on possible nodal superconducting order parameters in this system. Due to its momentum-resolved capabilities, angle-resolved photoemission spectroscopy (ARPES) is particularly suitable for investigating the key aspects of the electronic structure of materials. In this work we present recent ARPES data of  $\text{KFe}_2\text{As}_2$  and related materials.

**12:03PM L11.00003 Pauli Limiting and Multi-Band Superconductivity in  $\text{KFe}_2\text{As}_2$  Studied by Small-Angle Neutron Scattering**<sup>1</sup>, M.R. ESKILDSEN, S.J. KUHN, University of Notre Dame, H. KAWANO-FURUKAWA, M. ONO, Ochanomizu University, Japan, E.M. FORGAN, E. JELLYMAN, R. RIYAT, University of Birmingham, United Kingdom, C.H. LEE, K. KIHOU, AIST, Japan, F. HARDY, TH. WOLF, C. MEINGAST, Karlsruhe Institute of Technology, Germany, J.L. GAVILANO, Paul Scherrer Institute, Switzerland — We have studied the intrinsic anisotropy of the superconducting state in  $\text{KFe}_2\text{As}_2$ , using used small-angle neutron scattering to image the vortex lattice (VL) as the applied magnetic field is rotated towards the FeAs planes. The anisotropy is found to be strongly field dependent, indicating multi-band superconductivity. Furthermore, the high field anisotropy significantly exceeds that of the upper critical field, providing further support for Pauli limiting in  $\text{KFe}_2\text{As}_2$  for field applied along the basal plane. Finally, we are able determine the contribution to the field modulation in the mixed state due to Pauli Paramagnetic Effects by measuring both the non-spin flip and spin flip VL scattered intensity. This represents the first instance where all the effects listed above have been obtained simultaneously and in a comprehensive manner by a single experimental technique.

**12:15PM L11.00004 Correlation-enhanced odd-parity inter-orbital singlet pairing in the iron-pnictide superconductor  $\text{LiFeAs}$** <sup>1</sup>, REZA NOURAFKAN, Université de Sherbrooke, GABRIEL KOTLIAR, Rutgers University, A.-M. S. TREMBLAY, Université de Sherbrooke — The rich variety of iron-based superconductors and their complex electronic structure lead to a wide range of possibilities for gap symmetry and pairing components. Here we solve in the 2-Fe Brillouin zone the full frequency-dependent linearized Eliashberg equations for  $\text{LiFeAs}$  with spin-fluctuation mediated pairing interactions. The magnetic excitations are calculated with the random phase approximation on a correlated electronic structure obtained with density functional theory and dynamical mean field theory. Correlations induce long-lived local moments with orbital-dependent dynamics. The interaction between electrons through Hund's coupling promotes both the intra-orbital  $d_{xz}(yz)$  and the inter-orbital magnetic susceptibility. As a consequence, the leading pairing channel acquires sizeable inter-orbital  $d_{xy}-d_{xz}(yz)$  singlet pairing with odd parity under glide-plane symmetry. These components reduce the superconducting gap magnitude induced by the intra-orbital components of the gap function at the electron pockets intersection where the Fe-d  $t_{2g}$  orbitals strongly mix. The combination of intra- and inter-orbital components makes the results consistent with available experiments on the angular dependence of the gaps observed on the different Fermi surfaces.

March 14 (Monday) to March 16 (Wednesday) in the program, since I have to depart Baltimore on March 17 (Thursday).

**12:27PM L11.00005 Superconducting mechanism in Fe-based superconductors**, HIROSHI KONTANI, YOUNG KIM, University of Tokyo — The rich variety of the phase diagrams in Fe-based superconductors, such as the coexistence of superconductivity and magnetic order, has been explained by the mean-field level approximations. Recently, we explained the phase diagrams including the Aslamazov-Larkin vertex correction (AL-VC). The nematoclastic study, we analyze the superconducting states in FeSe and  $\text{LaFeAsO}$ , by a study of the structures are induced by the strong orbital and spin fluctuations driven by orbital fluctuations is strongly enlarged by the AL-VC for the anomalous superconducting mechanism. [1] Y. Yamakawa, S. Onari and H. Kontani, arXiv:1509.01163.

I would appreciate your consideration of my request.

**12:39PM L11.00006 ABSTRACT WITHDRAWN —**

**12:51PM L11.00007 The Magnetic Excitations in Optimal Doped  $\text{BaFe}_2(\text{As}_{0.7}\text{P}_{0.3})_2$** <sup>1</sup>, DING HU, SHILIANG LI, Chinese Academy of Sci (CAS), PENGCHENG DAI, Rice University — High temperature superconductivity in iron based superconductors emerges near the boundary of static antiferromagnetic order which is suppressed by doping or pressure. Although spin fluctuations may be responsible for superconductivity, there is still no consensus on the mechanism. As a unique system in 122-type iron pnictides, the phosphorus doping in the arsenic position in  $\text{BaFe}_2\text{As}_2$  does not induce external carrier and impurity scattering, but the maximum  $T_c = 30\text{K}$ . We have carried out inelastic neutron scattering experiment on Time of Flight Spectrometers, and mapped out the whole spin fluctuation up to 300meV. Our results are consistent with the combined DFT and DMFT calculation results, which confirm that pnictogen height is correlated with the electron-electron correlation strength and consequently the effective bandwidth of magnetic excitations in iron pnictides.

**1:03PM L11.00008 Doping evolution of magnetization hysteresis in (Ba<sub>1-x</sub>K<sub>x</sub>)Fe<sub>2</sub>As<sub>2</sub> single crystals: Crossover from the second magnetization peak to peak effect<sup>1</sup>**, YONG LIU<sup>2</sup>, THOMAS LOGRASSO, Ames Lab — Magnetic hysteresis loops (MHLs) have been systematically measured in a series of (Ba<sub>1-x</sub>K<sub>x</sub>)Fe<sub>2</sub>As<sub>2</sub> single crystals from underdoped  $x=0.177$  to end member  $x=1$  with applied magnetic fields parallel to  $c$  axis ( $H//c$ ). The second magnetization peak (SMP) or fishtail effect was observed within the doping range  $0.177 \leq x \leq 0.650$ . Remarkably, with further increasing doping the SMP becomes narrow and emerges very close to the irreversible field ( $H_{irr}$ ) for the samples  $0.692 \leq x \leq 0.910$ . The similar peak effect (PE) had been widely observed in various conventional or low  $T_c$  superconductors. Meanwhile, the magnetization curves change from symmetrical to asymmetric hysteresis loops, which suggests a dominant surface pinning instead of bulk pinning in the samples. Our findings demonstrate that (Ba<sub>1-x</sub>K<sub>x</sub>)Fe<sub>2</sub>As<sub>2</sub> system is a very unique system that links the SMP and PE by its doping dependence. Our results will lead to a better understanding of the underlying mechanisms for the origin of the SMP and PE.

<sup>2</sup>crystal growth, superconductivity, magnetism

**1:15PM L11.00009 Orbital and Pauli limiting effects in heavily doped Ba<sub>0.05</sub>K<sub>0.95</sub>Fe<sub>2</sub>As<sub>2</sub>.<sup>1</sup>**, S. ZHANG, Y. P. SINGH, X. Y. HUANG, Kent State University, X. J. CHEN, Shanghai Laboratory of High Pressure Science & Technology Advanced Research, M. DZERO, C. C. ALMASAN, Kent State University — We investigated the thermodynamic properties of the Fe-based lightly-disordered superconductor Ba<sub>0.05</sub>K<sub>0.95</sub>Fe<sub>2</sub>As<sub>2</sub> in external magnetic field  $H$  applied along the FeAs layers ( $H||ab$  planes). The superconducting (SC) transition temperature for this doping level is  $T_c = 6.6$  K. Our analysis of the specific heat  $C(T,H)$  measured for  $T < T_c$  implies a sign change of the superconducting order parameter across different Fermi pockets. We provide experimental evidence for the three components superconducting order parameter. We find that all three components have values which are comparable with the previously reported ones for the stoichiometric compound KFe<sub>2</sub>As<sub>2</sub>. Our data for  $C(T,H)$  and resistivity  $\rho(T, H)$  can be interpreted in favor of the dominant orbital contribution to the pair-breaking mechanism at low fields, while Pauli limiting effect dominates at high fields, giving rise to a gapless superconducting state with only the leading non-zero gap.

<sup>1</sup>This work has been supported by the US NSF (Grant Nos. DMR-1506547 and DMR-1505826) at KSU. M.D. also acknowledges financial support from KSU and MPI-PKS.

**1:27PM L11.00010 Can oxygen deficient SmFeAsO<sub>1-x</sub> be synthesized?: Unintentional incorporation of hydride ion at oxygen vacancy site**, YOSHINORI MURABA, Materials Research Center for Element Strategy, SUSHI IIMURA, Materials and Structures Laboratory, Tokyo Institute of Technology, SATORU MATSUSHI, HIDEO HOSONO, Materials Research Center for Element Strategy, Tokyo Institute of Technology — Hydrogen substitution and introduction of oxygen vacancy are effective electron doping methods for the  $LnFeAsO$ . However, their  $T_c$  vs  $e^-/Fe$  diagrams do not entirely overlap each other, while  $T_c$  vs lattice dimension relationships are very similar. These contradictions can be understood by assuming that unintentional hydrogen is incorporated into the oxygen vacancy. To examine the preferred electron-dopant species in  $LnFeAsO$  and the influence of the atmosphere during synthesis on the formation of  $LnFeAsO_{1-x}$ , we try to synthesize the SmFeAsO<sub>1-x</sub> under three well-controlled atmosphere ( $H_2O$ ,  $H_2$  and  $H_2O$ - and  $H_2$ -free). Under  $H_2O$  and  $H_2$  atmosphere, hydrogen were incorporated at oxygen sites as the hydride ion and SmFeAsO<sub>1-x</sub>H<sub>x</sub> was formed. On the other hand, when  $H_2O$  and  $H_2$  were removed from synthetic process, nearly stoichiometric SmFeAsO was formed. Furthermore, DFT calculations showed that H-substituted samples are more stable than oxygen deficient samples. These results strongly imply that the reported  $LnFeAsO_{1-x}$  was contaminated with unintentional hydrogen and  $LnFeAsO_{1-x}H_x$  was misidentified as  $LnFeAsO_{1-x}$ .

**1:39PM L11.00011 Neutron diffraction study of 154SmFeAsO<sub>1-x</sub>D<sub>x</sub>**, SUSHI IIMURA, HIROSHI OKANISHI, Materials and Structures Laboratory, Tokyo Tech., SATORU MATSUSHI, Materials Research Center for Element Strategy, Tokyo Tech., HARUHIRO HIRAKA, KAZUTAKA IKEDA, Institute of Materials Structure Science, KEK, THOMAS HANSEN, Institut Laue-Langevin, TOSHIYA OTOMO, Institute of Materials Structure Science, KEK, HIDEO HOSONO, Materials and Structures Laboratory, Tokyo Tech. — Hot issue in unconventional superconductors (SC) is why the 2nd highest- $T_c$  of 56 K after cuprates is accomplished in the 1111-type iron-oxyarsenides  $LnFeAsO_{1-x}Fx$  ( $Ln =$  lanthanide). Recently, utilizing a hydride-substitution-method ( $O^{2-} = H^- + e^-$ ) in the  $LnFeAsO_{1-x}H_x$  [1], we found a second SC phase in  $0.18 \leq x \leq 0.45$  at  $Ln = La$  in addition to the first one adjacent to the antiferromagnetic (AFM) order [2], and another AFM order accompanying a unique structural transition in over-doped region  $x > 0.4$  [3]. However, since the  $T_c$  of La-system is lower than the other systems, i.e.,  $Ln = Ce, Sm$  and so on, it is still unclear whether the second AFM phase is essential for their high- $T_c$  or not. Thus, we synthesized the isotope-substituted 154SmFeAsO<sub>1-x</sub>D<sub>x</sub> and performed neutron powder diffraction (NPD) to examine the structural and magnetic properties of the high- $T_c$  1111 system. In this talk, we show the results of NPD data and discuss the relation between the superconducting, magnetic, and structural properties of the 154SmFeAsO<sub>1-x</sub>D<sub>x</sub> and electron-doping-effect on it. [1] T. Hanna, et al. PRB 85, 024521 (2011). [2] S. Iimura, et al. Nat. Commun. 3, 943 (2012). [3] M. Hiraishi et al. Nat. Phys. 10, 300 (2014).

**1:51PM L11.00012 Role of Hydrogen in the Electronic Properties of H-rich Pnictide Superconductors**, YINA HUANG, University of California Davis, XIANGLONG YU, DAYONG LIU, Institute of Solid State Physics, Chinese Academy of Sciences, LIANGJIAN ZOU, University of Science and Technology of China — The electronic and magnetic properties of the parent material CaFeAsH and its La/Co-doped compounds are investigated using first-principles calculations based on the generalized gradient approximation (GGA). We predict that the ground state of CaFeAsH is a spin-density-wave (SDW)-type striped antiferromagnet driven by Fermi surface nesting. We find a sandglass-type hole pocket near the  $\Gamma$  point in CaFeAsH that is not present in CaFeAsF. In comparison with CaFeAsF, the sandglass-shaped pocket, mainly contributed from Fe  $d_{xz} + d_{yz}$  orbitals, arises from the weak oxidation of CaH layers and the hybridization enhancement between FeAs layers. In contrast, the electronic properties of electron doped Ca<sub>0.75</sub>La<sub>0.25</sub>FeAsH and CaFe<sub>0.75</sub>Co<sub>0.25</sub>AsH indicate that La or Co doping almost does not affect the sandglass-type Fermi surface, while the suppression of Fermi surface nesting in Ca<sub>0.75</sub>La<sub>0.25</sub>FeAsH is weaker than that in CaFe<sub>0.75</sub>Co<sub>0.25</sub>AsH. This features may contribute to the higher  $T_c$  in La-substituted CaFeAsH.

**2:03PM L11.00013 Nanofabrication of Point Contact Junctions for Spectroscopic Studies of High-Temperature Superconductors<sup>1</sup>** , HAN ZHAO, OMAR MEHIO, WAN KYU PARK, JAMES ECKSTEIN, University of Illinois Urbana-Champaign, LAURA GREENE, National High Magnetic Field Laboratory, Florida State University — Point contact spectroscopy (PCS) probes the superconducting order parameter from Andreev reflection conductance spectrum. A new method to achieve robust junctions with a precise control of the geometry of the point contact by focused ion beam (FIB) nanofabrication techniques is currently under development. Preliminary application on niobium thin films shows consistent data that is insensitive to thermal cycling. This opens the possibility to perform PCS on a series of materials as a function of external variables, including temperature, magnetic field as a function of angle, and stress. Our preliminary data as a function of junction size show the expected resistance dependence, which will help us to determine more precisely when junctions are in the ballistic, or spectroscopic regime. Our plan is to apply this newly-developed method to probe the electronic nematic state in iron-based superconductors under applied magnetic field and uniaxial stress, to further understand the origin of the nematicity.

<sup>1</sup>This work is carried out in part in the Materials Research Lab, University of Illinois and is supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the US DOE, Office of Science, Award No. DE-AC0298CH1088.

**Wednesday, March 16, 2016 11:15AM - 2:15PM –**  
**Session L12 DPOLY FIAP: From Nano to Meso: Assembly Structure and Dynamics of Polymers and Polymer Nanocomposite Thin Films II - Industry Day** 308 - Neal Brant, Miliken, Inc.

**11:15AM L12.00001 Nanoparticles in Polymers: Assembly, Rheology and Properties** , YUANQIAO RAO<sup>1</sup>, The Dow Chemical Company — Inorganic nanoparticles have the potential of providing functionalities that are difficult to realize using organic materials; and nanocomposites is an effective mean to impart processibility and construct bulk materials with breakthrough properties. The dispersion and assembly of nanoparticles are critical to both processibility and properties of the resulting product. In this talk, we will discuss several methods to control the hierarchical structure of nanoparticles in polymers and resulting rheological, mechanical and optical properties. In one example, polymer-particle interaction and secondary microstructure were designed to provide a low viscosity composition comprising exfoliated high aspect ratio clay nanoparticles; in another example, the microstructure control through templates was shown to enable unique thermal mechanical and optical properties.

<sup>1</sup>Jeff Munro, Stephanie Potisek, Phillip Hustad; all of the Dow Chemical Company are co-authors

**11:51AM L12.00002 Pressure-Directed Assembly: Nanostructures Made Easy** , HONGYOU FAN, Sandia National Laboratories — Precise control of structural parameters through nanoscale engineering to improve optical and electronic properties of functional nanomaterials continuously remains an outstanding challenge. Previous work has been conducted largely at ambient pressure and relies on specific chemical or physical interactions such as van der Waals interactions, dipole-dipole interactions, chemical reactions, ligand-receptor interactions, etc. In this presentation, I will introduce a new pressure-directed assembly method that uses mechanical compressive force applied to nanoparticle arrays to induce structural phase transition and to consolidate new nanomaterials with precisely controlled structures and tunable properties. By manipulating nanoparticle coupling through external pressure, instead of through chemistry, a reversible change in their assemblies and properties can be achieved and demonstrated. In addition, over a certain threshold, the external pressure will force these nanoparticles into contact, thereby allowing the formation and consolidation of one- to three-dimensional nanostructures. Through pressure induced nanoparticle assembly, materials engineering and synthesis become remarkably flexible without relying on traditional crystallization process where atoms/ions are locked in a specific crystal structure. Therefore, morphology or architecture can be readily tuned to produce desirable properties for practical applications. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**12:27PM L12.00003 X-ray Studies of Nano Composites<sup>1</sup>** , ALEXANDER HEXEMER, LBNL — Nano composite materials are an exciting and fast expanding field. X-ray scattering has been used in order to study the structure properties relation. During the last few years the field has expanded more towards the field of thin films where there's been a dramatic increase in the use of grazing incidence small angle X-ray scattering (GISAXS). The main issue of GISAXS has been the complex analysis framework necessary for simulating and fitting. In addition, existing software has restricted the scientist in systems that can be simulated and the speed to analyze large amounts of data. Over the last few years we have worked closely with our computational research and supercomputer division to enable the use of supercomputers to simulate at scattering data. We have developed a comprehensive analysis framework to simulate and fit a wide variety of materials and morphologies. The framework is designed to supply scientists with close to real-time feedback during beam times. Therefore, HipGISAXS (High Performance GISAXS) has been developed to run simulations on massively parallel platforms such as the Oak Ridge Supercomputer Titan (OLCF). Further, with inverse modeling algorithms for fitting available in HipGISAXS, such as particle swarm optimization, it can handle a large number of parameters during the structure fitting process. In September of 2014, HipGISAXS was used in a real time demonstration that married the SAXS/WAXS beamline at the ALS with the data handling and processing capabilities at NERSC, and simulation capabilities of running at-scale simulations on Titan at OLCF.

<sup>1</sup>DOE Early Career Award, SPOT and CAMERA

**1:03PM L12.00004 Swelling and viscoelasticity in photoresist thin films** , PRAVEEN AGARWAL, The Dow Chemical Company — For a wide range of electronic applications, polymers are processed in the thin film state with the film thickness lower than 100 nm. Understanding the polymer structure property relationship at those characteristic length scales is important to enable the material design for various applications. Extreme ultraviolet lithography (EUVL) is the next generation lithographic technique using low wavelength (13.5 nm) ultraviolet radiation. Quality of the final pattern in the lithographic process depends on the performance of the photoresist polymer during multiple processing steps. Photoresist material development for the EUV lithography presents several challenges for controlling the thin film swelling, density and outgassing. In particular, it has been proposed in the literature that pattern collapse, a lithographic defect where the desired features become deformed, can be caused by the swelling of the photoresist material. In this presentation, the effect of photoresist formulation and architecture on the thin film swelling and viscoelasticity will be discussed. We find that the quencher base could have a significant effect on the swelling characteristics of the photoresist. Additionally, swelling characteristics of the photoresists with covalently bound vs. blended photoacid generator (PAG) were found to be significantly different.

**1:39PM L12.00005 Patterning Multicomponent Polymer Thin Films via Dynamic Thermal Processing** , GURPREET SINGH, Intel Corporation — Bottom-up patterning is gaining increased importance owing to the physical limitations and rising costs of top-down patterning. One example of bottom-up patterning is self-assembling polymer thin films. Although there are several pathways to facilitate polymer thin film self-assembly, this presentation will focus on dynamic thermal field based processes for patterning multicomponent polymer thin films. Dynamic thermal field processing is an attractive rolltoroll (R2R) amenable directed selfassembly (DSA) method for molecular level organization of multicomponent polymer systems such as block copolymer thin films over large areas without requiring guiding templates. The talk will first outline how parameters such as magnitude of the temperature gradient, velocity of annealing, thermal expansion, and molecular weight of the polymer can be optimized to finely tune the morphology of the block copolymer thin films and also elucidate their associated physical mechanisms. The second part of the talk will outline application of dynamic thermal field processes for fabricating functional nanomaterials and discuss the recent advancements achieved using these processes.

Session L13 DAMOP: New Phenomena in 2D Fermi Gases 309 - Cheng Chin, University of Chicago

### 11:15AM L13.00001 A strongly interacting two-dimensional Fermi gas , SELIM JOCHIM, Heidelberg University

— We will present our progress realizing two-dimensional superfluids with ultracold fermionic lithium atoms confined in a quasi two-dimensional potential. In this setting, a generic two-dimensional Fermi gas is realized with interactions tunable to any value within the short-range limit. We measured the phase diagram for this system and found the coherence properties to be decaying algebraically, a signature of the Beresinskii-Kosterlitz-Thouless phase which is expected for a homogeneous two-dimensional superfluid. We furthermore extracted from our data the equation of state, which will be an important benchmark for many body theories. We are currently working to transfer our fermionic atoms into an optical lattice potential. Our vision to realize exotic superfluidity in this system will be discussed.

### 11:51AM L13.00002 Experimental studies of spin-imbalanced Fermi gases in 2D geometries<sup>1</sup> , JOHN THOMAS, North Carolina State University

— We study the thermodynamics of a quasi-two-dimensional Fermi gas, which is not quite two-dimensional (2D), but far from three dimensional (3D). This system offers opportunities to test predictions that cross interdisciplinary boundaries, such as enhanced superfluid transition temperatures in spin-imbalanced quasi-2D superconductors, and provides important benchmarks for calculations of the phase diagrams. In the experiments, an ultra-cold Fermi gas is confined in an infrared CO<sub>2</sub> laser standing-wave, which produces periodic pancake-shaped potential wells, separated by 5.3  $\mu\text{m}$ . To study the thermodynamics, we load an ultra-cold mixture of  $N_1 = 800$  spin-up and  $N_2 < N_1$  spin-down <sup>6</sup>Li atoms into each well and image the individual cloud profiles as a function of interaction strength and spin imbalance  $N_2/N_1$ . The measured properties are in disagreement with 2D-BCS theory, but can be fit by a 2D-polaron gas model, where each atom is surrounded by a cloud of particle-hole pairs of the opposite spin. However, this model fails to predict a transition to a spin-balanced central region as  $N_2/N_1$  is increased.

### 12:27PM L13.00003 Fermi-to-Bose crossover in a trapped quasi-2D gas of fermionic atoms , ANDREY TURLAPOV, Institute of Applied Physics, Russian Academy of Sciences

— Neither long-range order nor Bose condensation may appear in uniform 2D systems at finite temperature. Despite that, 2D superconductors, such as cuprates, are among the systems with highest critical temperatures. 2D quantum systems remain intriguing, and their understanding is incomplete despite huge progress seen in the recent decades. Ultracold atoms are a platform for studying 2D physics. Using tunability of atomic gases, we have realized a crossover between a 2D gas of Fermi atoms and a 2D gas of weakly-bound diatomic Bose molecules by varying s-wave interactions in the gas. Between these two asymptotic states, there is a regime of strong interactions, whose quantitative description is challenging, e. g., a mean field of Cooper pairs fails to describe the crossover even qualitatively, unlike in 3D gases. At the lowest achievable temperatures,  $\sim 10\%$  of the Fermi energy, the pressure is measured in the whole Fermi-to-Bose crossover and compared with the available theoretical models, including those which appeared over the last year. In the Fermi regime of weak interactions, the pressure is systematically above a Fermi-liquid-theory prediction, which maybe due to mesoscopic effects. Alternatively, this upshift is partially reproduced within a recent mean-field theory supplemented with fluctuations. On the Bose side of the crossover, the molecules easily condense, which is found in interferometric measurements. On one hand, such condensation is expected because the gas is held in a nearly harmonic trap, which favors condensation unlike the uniform space. On the other hand, each molecule is locally in a flat potential, which is the sum of the trap and the strong repulsive mean field, and this should inhibit the condensation.

### 1:03PM L13.00004 Quasi-condensation in trapped two-dimensional Fermi gases<sup>1</sup> , BRANDON ANDERSON, James Franck Institute

— It is well known that the Mermin-Wagner theorem prohibits true long range order 2D systems. Nevertheless, recent experiments [1,2] provide strong evidence that 2D Fermi gases undergo a form of pair condensation, along with aspects of BKT physics. In this talk we apply a BCS-BEC theory (which is compatible with the Mermin-Wagner theorem) to characterize the nature of pair (quasi-) condensation in 2D Fermi gases. Here we follow the same analysis and protocols of these recent experiments. We find a strong zero momentum peak in the pair momentum distribution which importantly occurs at a reasonably well defined onset temperature. We demonstrate that the resulting phase diagram, pair momentum distribution, and algebraic power law decay are compatible with these experiments throughout the continuum from BEC to BCS. Finally, we present sharp qualitative experimental signatures to test this physical picture. [1] Phys. Rev. Lett. 114, 230401 (2015) [2] Phys. Rev. Lett. 115, 010401 (2015) [3] Phys. Rev. Lett. (To be published.)

### 1:39PM L13.00005 BKT physics in trapped 2D Bose and Fermi gases , MARKUS HOLZMANN, LPMCM, CNRS and UJF, Grenoble

— I will discuss superfluid and spatial coherence properties of two-dimensional trapped Fermi gases in the BEC-BCS crossover regime [1]. On the bosonic side, experimental data are in quantitative agreement with path-integral quantum Monte Carlo calculations of point like molecules up to large values of the interaction. Algebraic correlations in the first-order correlation function characterize the phase below the Kosterlitz-Thouless transition temperature. Whereas the inhomogeneous trapping potential introduces important quantitative modifications, the effective exponent of the power-law decay at the superfluid transition remains approximately constant for all interaction strengths in the BEC-BCS crossover regime.

Session L14 FEd: Impacts and Experiences with Hybrid and Online Courses 310 - Michael Schatz,

Georgia Institute of Technology

### 11:15AM L14.00001 Fully On-line Introductory Physics with a Lab , MICHAEL SCHATZ, School of Physics, Georgia Institute of Technology, Atlanta, GA, USA

— We describe the development and implementation of a college-level introductory physics (mechanics) course and laboratory that is suited for both on-campus and on-line environments. The course emphasizes a Your World is Your Lab approach whereby students first examine and capture on video (using cellphones) motion in their immediate surroundings, and then use free, open-source software both to extract data from the video and to apply physics principles to build models that describe, predict, and visualize the observations. Each student reports findings by creating a video lab report and posting it online; these video lab reports are then distributed to the rest of the class for peer review. In this talk, we will discuss the student and instructor experiences in courses offered to three distinct audiences in different venues: (1) a Massively Open On-line Course (MOOC) for off-campus participants, (2) a flipped/blended course for on-campus students, and, most recently, (3) a fully-online course for off-campus students.

**11:51AM L14.00002 A Flipped Pedagogy for Expert Problem Solving**, DAVID PRITCHARD, MIT — The internet provides free learning opportunities for declarative (Wikipedia, YouTube) and procedural (Kahn Academy, MOOCs) knowledge, challenging colleges to provide learning at a higher cognitive level. Our “Modeling Applied to Problem Solving”<sup>1 2</sup> pedagogy for Newtonian Mechanics imparts *strategic knowledge* - how to systematically determine which concepts to apply and why. Declarative and procedural knowledge is learned online before class via an e-text, checkpoint questions, and homework on edX.org (see <http://relate.mit.edu/physicscourse>); it is organized into five Core Models. Instructors then coach students on simple “touchstone problems”, novel exercises, and multi-concept problems - meanwhile exercising three of the four C's: communication, collaboration, critical thinking and problem solving. Students showed 1.2 standard deviations improvement on the MIT final exam after three weeks instruction, a significant positive shift in 7 of the 9 categories in the CLASS, and their grades improved by 0.5 standard deviation in their following physics course (Electricity and Magnetism).

<sup>2</sup>Improved Student Performance In Electricity And Magnetism Following Prior MAPS Instruction In Mechanics, Rayyan, S et. al. Physics Education Research Conference 2010 AIP Conf. Proc. 1289, 273(2010).

**12:27PM L14.00003 Online activities to optimize in person learning.**, TIM STELZER, Univ of Illinois - Urbana — Students' unprecedented access to content on the web is providing a unique opportunity to transform the role lectures in education, moving the focus from content delivery to helping students synthesize the content into knowledge. We have introduced a variety of activities to facilitate this transformation at the University of Illinois, including web-based preflight assessments of student understanding before lecture, peer instruction (clickers) to assess and facilitate student understanding during lecture, and web-based multimedia pre-lectures designed to provide students with content before lecture. In this talk I will discuss the pedagogical motivation for introducing these activities, and the impact they have had at the University of Illinois.

**1:03PM L14.00004 Lessons from two decades of hybrid and online physics courses at Michigan State University**, GERD KORTEMEYER, Michigan State University — In Fall 1992, at Michigan State University we first offered online homework to one section of an introductory physics course; students received randomized assignments as printouts and entered answers through Telnet sessions, frequently using text terminals. Now, over two decades later, all of our introductory physics courses have significant online components, and students can choose between different formats, including hybrid courses with free online textbook materials, as well as courses that are completely online. What have we learned over the years about which formats are most effective for which students? What are the respective learning outcomes? Which logistical models work best for homework, exams, videos, and textbook materials? What about academic integrity? In our talk we will reflect on how our courses have been developing over the years, report educational research results, relate anecdotes and experiences, and point out pitfalls that we have encountered.

**1:39PM L14.00005 Apples vs. Oranges: Comparison of Student Performance in a MOOC vs. a Brick-and-Mortar Class**, MICHAEL DUBSON, University of Colorado at Boulder — In the fall of 2013, my colleagues and I taught the calculus-based introductory physics course to 800 tuition-paying students at the University of Colorado at Boulder. At the same time we taught a free massive open online version of the same course (MOOC), through Coursera.com. The initial enrollment in the MOOC was 10,000 students, of whom 255 completed the course. Students in both courses received identical lectures with identical embedded clicker questions, identical homework assignments, and identical timed exams. We present data on participation rates and exam performance for the two groups. We find that the MOOC is like a drug targeted at a very specific population. When it works, it works well, but it works for very few students. This MOOC worked well for older, well-educated students, who already had a good understanding of Newtonian mechanics.

## Wednesday, March 16, 2016 11:03AM - 2:27PM –

Session L15 DCMP DMP: Phenomena in Dirac Systems 314 - Adam Friedman, Naval Research Laboratory

**11:03AM L15.00001 Dirac Materials**, ALEXANDER BALATSKY, Los Alamos Natl Lab — Discoveries of superfluid phases in <sup>3</sup>He, high T<sub>c</sub> superconductors, graphene and topological insulators have brought into focus materials where quasiparticles are described by same Dirac and Weyl equation that governs behavior of relativistic particles. This class of materials, called Dirac materials [1], exhibits unusual universal features: Klein tunneling, chirality and impurity resonances. I will explore these similarities and discuss the unique role of symmetries that protect the Dirac spectrum. As an example of universal behavior of Dirac-Weyl materials I will consider impurity resonances, filling of the gap and gapless spectra in the magnetically doped topological insulators [2]. I will also discuss Dirac materials quantum imaging and how the ripples in the Dirac sea produced by defects can induce fascinating features in local magnetism and Kondo effect. At the end I will outline future opportunities to design Dirac materials that host bosonic Dirac excitations, something that would not be possible in particle physics [3]. Work supported by US DOE E304. [1] T.O. Wehling, A.M. Black-Schaffer, A.V. Balatsky (2014) Dirac materials, *Advances in Physics*, 63:1, 1-76. [2] A. M. Black-Schaffer, A. V. Balatsky, and J. Fransson, *Phys. Rev. B* 91, 201411(R) (2015). [3] S. Banerjee, A. M. Black-Schaffer, J. Fransson, H. Agren, A.V. Balatsky, Bosonic Dirac Materials in 2 Dimensions, preprint [2015], J. Fransson et.al, Dirac Magnons, preprint [2015].

**11:39AM L15.00002 Artificial Graphene in Nano-patterned GaAs Quantum Wells**<sup>1</sup>, SHENG WANG, DIEGO SCARABELLI, Department of Applied Physics, Columbia University, YULIYA Y. KUZNETSOVA, Department of Physics, Columbia University, LOREN N. PFEIFFER, KEN WEST, Department of Electrical Engineering, Princeton University, GEOFF C. GARDNER, MICHAEL J. MANFRA, Department of Physics and Astronomy, and School of Materials Engineering, and School of Electrical and Computer Engineering, Purdue University, VITTORIO PELLEGRINI, Istituto Italiano di Tecnologia, Graphene Labs, Genova, Italy and NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Pisa, Italy, SHALOM J. WIND, Department of Applied Physics, Columbia University, ARON PINCZUK, Department of Physics and Department of Applied Physics, Columbia University — We report the realization of artificial graphene (AG) in a 2D electron gas in a highly tunable semiconductor quantum well system. Very short period (as small as 40 nm) honeycomb lattices were formed in a GaAs heterostructure by electron beam lithography followed by dry etching. Characterization of the AG samples by photoluminescence at low temperature (about 4K) indicates modulation of 2D electron states. Low-lying electron excitations observed by resonant inelastic light scattering and interpreted with a calculated AG band structure confirm the formation of AG bands with a well-defined Dirac cone, evidence for the presence of massless Dirac fermions. These results suggest that engineered semiconductor nano-scale structures can serve as advanced quantum simulators for probing novel electron behavior in low dimensional systems.

<sup>1</sup>Supported by DOE-BES Award DE-SC0010695

**11:51AM L15.00003 Fabrication of artificial graphene in a GaAs heterostructure<sup>1</sup>**, DIEGO SCARBELLI, SHENG WANG, YULIYA KUZNETSOVA, Columbia University, LOREN PFEIFFER, KEN WEST, Princeton University, GEOFF GARDNER, MICHAEL MANFRA, Purdue University, VITTORIO PELLEGRINI, Italian Institute of Technology, ARON PINCZUK, SHALOM WIND, Columbia University — Engineered honeycomb lattices, known as artificial graphene, constitute a platform for the exploration of graphene-like phenomena in a highly controllable and tunable manner, offering insight into a broader parameter range inaccessible to natural graphene. The electronic states of a 2D electron gas whose density is modulated by a potential with honeycomb topology have been predicted to generate massless Dirac fermions (MDFs) with tunable Fermi velocity. In this work we present the fabrication of artificial graphene in an ultrahigh quality GaAs/AlGaAs quantum well, with lattice period as small as 40nm, the smallest reported so far for this type of system. The combination of high precision electron-beam lithography, used to define an etch mask with honeycomb geometry on the surface of the sample, and precise anisotropic reactive ion etching allows to create artificial graphene with excellent uniformity and long range order. Different methodologies for preparation of the mask are compared and their limits are discussed. Thanks to the achievement of such high-resolution artificial graphene we expected to be able to observe, for the first time, MDFs in an engineered semiconductor and the possibility of access to novel topological phases.

**12:03PM L15.00004 Berry's Phase and Giant Non-Reciprocity in Dirac Quantum Dots**, JOAQUIN RODRIGUEZ-NIEVA, MILDRED DRESSSELHAUS, LEONID LEVITOV, MIT — Recently, nanoscale pn-junction rings have been introduced as a vehicle for coherent control of electronic states in Dirac materials [1]. Confined states in such ring-shaped electron resonators arise due to constructive interference of electronic waves incident at the pn junction at oblique angles and inward-reflected from the ring. Contrary to confined electronic states in conventional quantum dots, Dirac electrons are characterized by a non-trivial Berry's phase. Here we show [2] that the Dirac quantum dot energy levels are sensitive to the Berry's phase. In particular, we predict that the Berry's phase can induce a giant spectral non-reciprocity arising in weak magnetic fields. The effect is maximal for massless Dirac electrons, e.g. graphene, and is manifested in anomalously large splittings of the resonances which are degenerate at B=0 due to time reversal symmetry. This non-reciprocity effect overwhelms the conventional orbital and spin-induced non-reciprocity. The predicted giant non-reciprocity is readily accessible by Faraday and Kerr optical rotation measurements as well as by scanning tunneling spectroscopy. [1] Zhao, et al., Science 348, 672 (2015). [2] JRN, et al., arXiv:1508.06609.

**12:15PM L15.00005 a universal regulation for the angle resolved transport properties of Dirac cones and beyond**, ZHENZHU LI, ZHIRONG LIU, Peking Univ — A universal regulation for the angle resolved transport properties of two-dimensional (2D) Dirac cones, such as graphene, graphynes or even beyond, was established for the first time. The anisotropy and isotropy properties of 2D Dirac cones were investigated theoretically combining with first-principles calculation. It was found the moving direction of Dirac cones ( $\theta_{\text{move}}$ ) varies with the strain orientation ( $\theta_q$ ) can be approximately described by a linear law. Moreover,  $\theta_{\text{move}}$  is related the hopping ( $S_{12}$ ) between two bases with respect to the strain. The coefficients,  $a_x$ ,  $a_y$ ,  $a_z$ , in the Taylor expansion formula of  $S_{12}$  and strain were determined with DFT calculations. Graphene and graphynes were calculated to check the universality of the theory, which turns out to be working well. This new regulation could also be recommended into semiconductive systems to predict their transport behaviors, such as phosphorene or MoS<sub>2</sub>, whose angle resolved transport properties have been widely investigated experimentally for comparison.

**12:27PM L15.00006 Graphene quantum dots for high-performance THz hot electron bolometers<sup>1</sup>**, A EL FATIMY, P HAN, Department of Physics, Georgetown University, Washington DC, 20057, R.L MYERS-WARD, A.K BOYD, K.M DANIELS, U.S. Naval Research Laboratory, Washington, DC 20375, A.B SUSHKOV, D DREW, Department of Physics, University of Maryland, Maryland, 20742, USA, D.K GASKILL, U.S. Naval Research Laboratory, Washington, DC 20375, P BARBARA, Department of Physics, Georgetown University, Washington DC, 20057 — We study graphene quantum dots patterned from epitaxial graphene on SiC with a resistance strongly dependent on temperature. The combination of weak electron-phonon coupling and small electronic heat capacity in graphene makes these quantum dots ideal hot-electron bolometers. We characterize their response to THz radiation as a function of dot size, with sizes ranging from 30 to 700 nm and temperature, from 2.4K to 80K. We show that quantum dots exhibit a variation of resistance with temperature higher than 430 M $\Omega$ /K below 6K, leading to electrical responsivities for an absorbed THz power above 110<sup>10</sup> V/W. The high responsivity, the potential for operation above 80 K and the process scalability show great promise towards practical applications of graphene quantum dot THz detectors. <sup>1</sup>A. El Fatimy, R.L.Myers-Ward, A.K. Boyd, K.M. Daniels, D. K. Gaskill, and P. Barbara, Nature Nanotechnology, Accepted (2015).

<sup>1</sup>This work was sponsored by the U.S. Office of Naval Research (award number N000141310865)

**12:39PM L15.00007 Ballistic Transport in Graphene Antidot Lattices**, RYUTA YAGI, RYOJI SAKAKIBARA, RYOYA EBISUOKA, JUMPEI ONISHI, Hiroshima University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Sciences (NIMS), YASUHIRO IYE, Institute for Solid State Physics, the University of Tokyo — We observed commensurability magnetoresistance arising from ballistic electron transport in the triangular antidot lattice of high-mobility graphene. For both the monolayer and bilayer, magnetoresistance peaks were observed at the commensurability magnetic elds of the cyclotron orbit with antidot lattice. This condition was approximately unchanged for massless and massive Dirac fermions. The peaks appeared when the carrier mean free path was roughly larger than the lattice constant of the antidot, which indicates that the effect stems from the short-range characteristics of the carrier's scattering with antidots. We also found that the magnitude of commensurability peak diminished with changing the gate voltages to the charge neutrality point. This arose from the screening of charged impurity in graphene, which is dependent on carrier density.

**12:51PM L15.00008 Magneto Transport of Graphene Monolayer with Antidot Arrays**, LEI WANG, University of South Carolina, MING YIN, Benedict College, TIMIR DATTA, University of South Carolina, GODWIN MBAMALU, Benedict College, DHEYAA ALAMERI, University of South Carolina — Graphene has a significant potential for electronics application as well as in high precision resistive metrological standard. Here we report magneto transport studies of monolayer graphene with antidot in hexagonal arrays on SiO<sub>2</sub>/Si substrate. The choice of antidot array was motivated by the potential to enhance quantum interference effect amongst charge carriers. The graphene-antidot arrays were fabricated by electron beam lithography followed by reactive ion etching. In our samples the dc magnetic field (B) was applied continuously up to 18 Tesla while the measurement temperature (T) was held steady at desired set points, ranging from 200 mK to 20 K. The effect of nanoarrays on the temperature and field dependence of the electrical properties (MR) and quantum hall effect with particular attention to Aharonov-Bohm oscillations will be reported.

**1:03PM L15.00009 An Einzel lens apparatus for deposition of levitated graphene on a substrate in UHV**, JOYCE COPPOCK, PAVEL NAGORNYKH, IAN MCADAMS, University of Maryland, College Park, BRUCE KANE, Laboratory for Physical Sciences, College Park, MD and Joint Quantum Institute, University of Maryland, College Park — The goal of our research is to levitate a charged micron-scale graphene flake in an electrical AC quadrupole trap in ultra-high vacuum (UHV) in order to study its properties and dynamics while decoupled from any substrate [1,2]. As a complement to the optical measurements that can be performed on the levitated flake, we are developing a method of depositing the same flake on a substrate, which can be removed from the system for further study using such probes as atomic force microscopy (AFM) and scanning tunneling microscopy (STM). As the flake is released from the trap and propelled toward the substrate, its trajectory will be controlled by an Einzel (electrostatic) lens to achieve accurate positioning on the substrate. This talk will discuss the design of the lens as well as particle tracing simulations to determine the proper lens voltage to focus the particle's trajectory. In the future, deposited graphene may be used to passivate H-terminated silicon. The method is expected to be generalizable to achieve deposition of 2D materials on surfaces in a clean UHV environment. [1] Kane, B.E. *Phys. Rev. B.*, **82**, 115441 (2010). [2] Nagornyykh, P., et. al. *Appl. Phys. Lett.* **106**, 244102 (2015).

**1:15PM L15.00010 Rotational dynamics of levitated graphite flakes**, PAVEL NAGORNYKH, JOYCE COPPOCK, BRUCE KANE, University of Maryland, College Park — Trapping of charged graphene multilayer flakes in a quadrupole ion trap provides a unique method of characterization of 2D materials via complete separation of the flake and the environment. As the ability to cool the center-of-mass temperature of the flakes levitated in high vacuum was shown in the previous work [1], in this talk we concentrate on probing the internal dynamics of the spinning flake. A 671 nm circularly polarized laser was used to provide a spinning torque to the levitated micron-sized flakes, while a linear 532 nm laser, oriented orthogonal to the first one, acted as a light source. We have studied the effects of 671 nm laser power on measured frequency spectra at pressures of  $10^{-7} - 10^{-9}$  Torr, where spinning frequencies of greater than 6 MHz have been achieved. Frequency decay data was collected by turning the laser on and off, which allowed us to estimate damping ratios from the flake deceleration. The spectra measured during the spinning acceleration showed multiple harmonics and other non-commensurate frequencies. We compare the observed frequencies to the behavior expected from a rigid body and from a membrane under the centrifugal tension. [1] P. Nagornyykh, J. E. Coppock, B. E. Kane, *Appl. Phys. Lett.* **106**, 244102 (2015)

**1:27PM L15.00011 Bosonic Dirac Materials in 2 dimensions<sup>1</sup>**, SAIKAT BANERJEE, Los Alamos Natl Lab, Nordita, A.M. BLACK-SCHAEFFER, J. FRANSSON, Uppsala University, H. AGREN, KTH, Royal Institute of Technology, A.V. BALATSKY, Los Alamos Natl Lab — We examine the low energy effective theory of phase oscillations in a two dimensional granular superconducting sheet where the grains are arranged in honeycomb lattice structure. Two different types of collective phase oscillations are obtained, which are analogous to the massive Leggett and massless Bogoliubov-Anderson-Gorkov modes for two-band superconductor. It is explicitly shown that the spectra of these collective Bosonic modes cross each other at  $\$K\$$  and  $\$K'\$$  points in the Brillouin zone and form a Dirac node. This Dirac node behavior in Bosonic excitations represent the case of Bosonic Dirac Materials (BDM). Dirac node is preserved in presence of an inter-grain interaction despite induced changes of the qualitative features of the two collective modes. Finally, breaking the sub lattice symmetry by choosing different on-site potentials for the two sub lattices leads to a gap opening near the Dirac node, in analogy with Fermionic Dirac material.

<sup>1</sup>Supported by US DOE E304, ERC DM 321031, KAW, VR2012-3447

**1:39PM L15.00012 Double Dirac cones in two-dimensional phononic crystals.<sup>1</sup>**, JUN MEI, South China University of Technology — By utilizing the accidental degeneracy of two double-degenerate Bloch eigenstates, a double Dirac cone is realized at the center of the Brillouin zone of a two-dimensional phononic crystal. Using a perturbation method, we demonstrate that the double Dirac cone is composed of two identical and overlapping Dirac cones whose linear slopes can be accurately predicted by the method from first-principles. A slab of the PC can be mapped onto a slab of zero refractive index material by using a standard retrieval method. Total transmission without phase change and energy tunneling at the double Dirac point frequency are unambiguously demonstrated.

<sup>1</sup>Supported by NSFC (Grant No. 11274120)

**1:51PM L15.00013 Mechanical Flip-Chip for Ultra-High Electron Mobility Devices**, KEYAN BENNACEUR, SIMON BILODEAU, BENJAMIN SCHMIDT, SAMUEL GAUCHER, McGill University, DOMINIQUE LAROCHE, MIKE LILLY, JOHN RENO, Sandia National Laboratories, KEN WEST, LOREN PFEIFFER, Princeton University, GUILLAUME GERVAIS, McGill University — We present a novel “flip-chip” microfabrication method that was used to make a quantum point contact (QPC) on a two-dimensional electron gas (2DEG) without any fabrication process on the 2DEG. Electrostatic gates are of paramount importance for the physics of devices based on 2DEG since they allow depletion of electrons in selected areas. This field-effect gating enables the fabrication of a wide range of devices such as, electron interferometers and quantum dots. To fabricate these gates, processing is usually performed on the 2DEG, which is in many cases detrimental to its electron mobility. Our approach does not require any processing of the 2DEG material leaving it pristine and reusable. It relies on processing a separate wafer that is then mechanically mounted on the 2DEG material in a flip-chip fashion. This technique proved successful to fabricate QPC on GaAs/AlGaAs materials with high electron mobility ranging from  $1e6$  to  $1e7$   $cm^2V/s$ . (Bennaceur, K. et al. Scientific Reports 5, 13494 (2015)). Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**2:03PM L15.00014 Topological States in Multi-Orbital Honeycomb Lattices of HgTe Quantum Dots**, CHRISTOPHE DELERUE, IEMN, Lille, France, WOUTER BEUGELING, TU Dortmund, Germany, EFTERPI KALES AKI, University of Luxembourg, YANN-MICHEL NIQUET, Grenoble Alpes University and CEA, Grenoble, France, DANIEL VANMAEKELBERGH, CRISTIANE MORAIS SMITH, University of Utrecht, The Netherlands — Recent works demonstrate that 2D single-crystalline sheets of semiconductors forming a honeycomb lattice can be synthesized by oriented attachment of semiconductor nanocrystals. Inspired by these results, we have performed atomistic tight-binding calculations of the band structure of CdSe [1] and HgTe [2] sheets with honeycomb nano-geometry. In the case of CdSe [1], we predict that their conduction band exhibits Dirac cones at two distinct energies. The lowest one has s-orbital character. The bands higher in energy present a Dirac cone and nontrivial flat bands because of their p-orbital character. We show that lattices of HgTe [2] combine the effects of the honeycomb geometry and strong spin-orbit coupling. The conduction bands can be described by a tight-binding lattice model as in graphene, but including multi-orbital degrees of freedom and spin-orbit coupling. This results in very large topological gaps and a flattened band detached from the others. Honeycomb structures of HgTe constitute a promising platform for the observation of a fractional Chern insulator or a fractional quantum spin Hall phase. [1] E. Kalesaki et al., *Phys. Rev. X* **4**, 011010 (2014). [2] W. Beugeling et al., *Nat. Commun.* doi: 10.1038/ncomms7316 (2015).

## 2:15PM L15.00015 Interaction of water molecules with hexagonal 2D systems. A DFT study<sup>1</sup>

, NGELA ROJAS, RAFAEL REY, Universidad Nacional de Colombia — Over the years water sources have been contaminated with many chemical agents, becoming issues that affect health of the world population. The advances of the nanoscience and nanotechnology in the development new materials constitute an alternative for design molecular filters with great efficiencies and low cost for water treatment and purification. In the nanoscale, the process of filtration or separation of inorganic and organic pollutants from water requires to study interactions of these atoms or molecules with different nano-materials. Specifically, it is necessary to understand the role of these interactions in physical and chemical properties of the nano-materials. In this work, the main interest is to do a theoretical study of interaction between water molecules and 2D graphene-like systems, such as silicene (h-Si) or germanene (h-Ge). Using Density Functional Theory we calculate total energy curves as function of separation between of water molecules and 2D systems. Different spatial configurations of water molecules relative to 2D systems are considered. Structural relaxation effects and changes of electronic charge density also are reported.

## Wednesday, March 16, 2016 11:15AM - 2:15PM –

Session L16 DMP: Black Phosphorus Device Physics 315 - Yuanbo Zhang, Fudan University, China

## 11:15AM L16.00001 Black Phosphorus Optoelectronics and Electronics<sup>1</sup>, FENGNIAN XIA, Yale University

— Black phosphorus recently emerged as a promising new 2D material due to its widely tunable and direct bandgap, high carrier mobility and remarkable in-plane anisotropic electrical, optical and phonon properties. It serendipitously bridges the zero-gap graphene and the relatively large-bandgap transition metal dichalcogenides such as molybdenum disulfide (MoS<sub>2</sub>). In this talk, I will first cover the basic properties of few-layer and thin-film black phosphorus, followed by a discussion of recent observation of highly anisotropic robust excitons in monolayer black phosphorus. Finally I will present a few potential applications of black phosphorus such as radio-frequency transistors and wideband photodetectors.

## 11:51AM L16.00002 Anisotropic Raman Spectroscopy of Few-Layer Phosphorene<sup>1</sup>, YUCHEN DU, WANGRAN WU, JESSE MAASSEN, ZHE LUO, MARK LUNDSTROM, XIANFAN XU, PEIDE YE, Purdue Univ

— Much recent research of black phosphorus (BP) and phosphorene has been focused on their unique anisotropy of this novel 2D material in terms of electrical, optical and thermal properties. Here we report the emerging Raman spectroscopy measurements of BP with respect to its isolation from bulk BP down to single layer phosphorene. The found frequency shift of BP in Raman spectra is to be correlated with atomic motion of modes, which can be explained by applying classical model of coupled harmonic oscillators. Raman intensity of different modes has also been included in our studies, which is confirmed as a solid strategy to quickly determine BP layer thickness. In addition, more information of their mechanical properties can also be obtained from Raman spectroscopy.

<sup>1</sup>The work was supported in part by NSF ECCS-1449270, NSF/AFOSR EFRI 2DARE Program, and ARO W911NF-15-1-0574.

## 12:03PM L16.00003 Interlayer Interaction that is Decisive in the Energy Gap of a Few Layer Phosphorene, YUKI SUGIHARA, ATSUSHI OSHIYAMA, Dept. of App. Phys., Univ. of Tokyo

— We report on our first-principles calculations that clarify the microscopic origin of the band-gap variation in a few-layer phosphorene (i.e. layered phosphorous) and also rectify a prevailed picture of the electronic structure of this new layered material [1]. Calculations have been done either using GGA with inclusion of van der Waals correction in the density-functional theory or GW approximation in the self-energy. We unequivocally reveal that the interlayer interaction causes the bonding-antibonding splitting of the highest valence band state, thus reducing the fundamental energy gap. This is due to the highest state consists mainly of *p* orbitals along the direction perpendicular to the layers. It was predicted that phosphorene has four polytypes named  $\alpha$  (black),  $\beta$  (blue),  $\gamma$  and  $\delta$  and all these polytypes exhibit common feature of the band-gap variation [2]. Especially,  $\gamma$  phosphorene is proposed to show the metal-insulator transition from the semiconductor mono-layer to the metal bi-layer. We reveal that this transition takes place in thicker region. [1] L. Li, Y. Yu, G. J. Ye, Q. Ge, X. ou, H. Wu, D. Feng, X. H. Chen, and Y. Zhang, Nat. Nanotechnol. 9, 372 (2014), [2] J. Guan, Z. Zhu, and D. Tomanek, PRL, 113, 046804 (2014)

## 12:15PM L16.00004 Quantum Hall Effect in Black Phosphorus Two-dimensional Electron System, LIKAI LI, FANGYUAN YANG, Fudan University, GUO JUN YE, University of Science and Technology of China, ZUOCHENG ZHANG, Tsinghua University, ZENGWEI ZHU, Huazhong University of Science and Technology, WENKAI LOU, XIAOYING ZHOU, Chinese Academy of Sciences, LIANG LI, Huazhong University of Science and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, KAI CHANG, Chinese Academy of Sciences, YAYU WANG, Tsinghua University, XIAN HUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University

— The recent advent of black phosphorus has greatly enriched the material base of two-dimensional electron systems (2DES). In this work, we reached a milestone in black phosphorus research: the observation of integer quantum Hall (QH) effect in high quality black phosphorus 2DES. We achieved high carrier mobility by embedding the black phosphorus 2DES in a van der Waals heterostructure close to a graphite back gate; the graphite gate screens the impurity potential in the 2DES, and brings the Hall mobility up to 6000 cm<sup>2</sup>/V.s. The exceptional mobility enabled us, for the first time, to observe QH effect, and to gain important information on the energetics of the spin-split Landau levels in black phosphorus. Our results set the stage for further study on quantum transport and device application in the ultrahigh mobility regime.

## 12:27PM L16.00005 Nanoscopy Reveals Surface-Metallic Black Phosphorus. , YOHANNES ABATE, Georgia State University

— Nanolayer and two-dimensional (2D) materials.....<sup>1</sup> such as graphene...<sup>2,3</sup>, boron nitride...<sup>1,4</sup>, transition metal dichalcogenides...<sup>1,5-8</sup> (TMDCs), and black phosphorus (BP)...<sup>1,9-13</sup> have intriguing fundamental physical properties and bear promise of important applications in electronics and optics...<sup>9,14,15</sup>. Of them, BP...<sup>11,12,16</sup> is a novel layered material that has been theoretically predicted...<sup>10</sup> to acquire plasmonic behavior for frequencies below ~0.4 eV when highly doped. The electronic properties of BP are unique due to its anisotropic structure. Advantages of BP as a material for nanoelectronics and nanooptics are due to the fact that, in contrast to metals, the free carrier density in it can be dynamically controlled by chemical or electrostatic gating, which has been demonstrated by its use in field-effect transistors....<sup>9,14,15</sup> Despite all the interest that BP attracts, near-field and plasmonic properties of BP have not yet been investigated experimentally. Here we report the first observation of nanoscopic near-field properties of BP. We have discovered near-field patterns of outside bright fringes and high surface polarizability of nanofilm BP consistent with its surface-metallic, plasmonic behavior at mid-infrared (mid-IR) frequencies below critical frequency  $\omega_m \approx 1176 \text{ cm}^{-1}$ . This has allowed us to estimate plasma frequency  $\omega_p \approx 0.4 \text{ eV}$ , carrier density  $n \approx 1.1 \times 10^{11} \text{ cm}^{-2}$  and the thickness of the surface metallic layer of ~1nm. We have also observed similar behavior in other nanolayer semiconductors such as TMDC MoS<sub>2</sub> and topological insulator Bi<sub>2</sub>Te<sub>3</sub> but not in insulators such as boron nitride. This new phenomenon is attributed to surface band-bending and charging of the semiconductor nanofilms. The surface plasmonic behavior has been found for 10-40 nm BP thickness but absent for 4 nm BP thickness. This discovery opens up a new field of research and potential applications in nanoelectronics, plasmonics, and optoelectronics.

**12:39PM L16.00006 Near-field optical microscopy and spectroscopy of few-layer black phosphorus** , A. J. FRENZEL, Department of Physics, University of California, San Diego, S. TRAN, Department of Physics & Astronomy, University of California, Riverside, J. P. HINTON, A. J. STERNBACH, Department of Physics, University of California, San Diego, J. YANG, N. GILLGREN, C. N. LAU, Department of Physics & Astronomy, University of California, Riverside, D. N. BASOV, Department of Physics, University of California, San Diego — Few-layer black phosphorous is a recent addition to the family of two-dimensional (2D) materials which exhibits strongly anisotropic transport and optical properties due to its puckered honeycomb structure. It was recently predicted that this intrinsic anisotropy should manifest in the plasmon dispersion. Additionally, tuning layer number and carrier density can control the dispersion of these collective modes. Scanning near-field optical microscopy (SNOM) has been demonstrated as a powerful method to probe electronic properties, including propagating collective modes, in layered 2D materials. We used SNOM to investigate anisotropic carrier response in few-layer black phosphorous encapsulated by hexagonal boron nitride. In addition to exploring gate-voltage tunability of the electronic response, we demonstrate effective modulation of the near-field signal by ultrafast photoexcitation.

**12:51PM L16.00007 Resonant optical third-harmonic generation in few-layer black phosphorus**<sup>1</sup> , CHRISTIANO J. S. DE MATOS, MackGraphe, Mackenzie Presbyterian University, MANUEL J. L. F. RODRIGUES, Centre for Advanced 2D Materials and Graphene Research Centre, National University of Singapore, RAFAEL E. P. DE OLIVEIRA, MackGraphe, Mackenzie Presbyterian University, HÉLDER X. P. PEIXOTO, HSIN-YU WU, HO Y. WEI, ANTONIO H. CASTRO NETO, JOSÉ C. VIANA-GOMES, Centre for Advanced 2D Materials and Graphene Research Centre, National University of Singapore — Black phosphorus (BP), a layered monoatomic anisotropic crystal, has recently re-emerged due to demonstrations of its exfoliation down to few-layer thicknesses. It has been shown that BP remains a direct bandgap semiconductor from the bulk to the monolayer, which has triggered interest in its optoelectronic applications. However, optical characterization has been largely restricted to the linear regime, with nonlinear characterization limited to z-scan and saturable absorption measurements. In this work, we show optical third-harmonic generation measurements in bulk and few-layer BP. Results indicate a resonant increase in the generation efficiency of the latter, with signal intensities reaching values three orders of magnitude higher than those of graphene. The mechanisms leading to the resonant increase will be discussed.

**1:03PM L16.00008 Transmission pump-probe spectroscopy on multilayer black phosphorus**<sup>1</sup> , RYAN J. SUESS, MOHAMMAD M. JADIDI, THOMAS E. MURPHY, MARTIN MITTENDORFF, University of Maryland-College Park, Institute for Research in Electronics and Applied Physics — Black phosphorus is a two-dimensional material that has recently attracted interest due to its high mobility and direct bandgap. In this work we examine the pump-induced change in optical transmission of mechanically exfoliated black phosphorus flakes using a two-color optical pump-probe measurement. The time-resolved data reveal a fast pump-induced transparency accompanied by a slower absorption that we attribute to Pauli blocking and free-carrier absorption, respectively. Polarization studies show that these effects are also highly anisotropic - underscoring the importance of crystal orientation in the design of optical devices based on this material. Ongoing work suggests that exploring the carrier density dependence of the pump-probe signals, which can be accessed experimentally via electrostatic gating, may allow for improved understanding of the optical response and carrier dynamics in the material.

<sup>1</sup>Supported by NSF and ONR-MURI

**1:15PM L16.00009 Electronic Structure and Optical Properties of Twisted Bilayer Black Phosphorus**<sup>1</sup> , TING CAO, ZHENGLU LI, DIANA Y. QIU, STEVEN G. LOUIE, Physics Department, UC Berkeley and Lawrence Berkeley National Lab — Using first-principles calculations, we find that the electronic structure and optical properties of bilayer black phosphorus can be modified significantly through changing the interlayer twist angle. We demonstrate the origin of these twist angle dependent effects, and connect our predicted results to experimental measurements.

<sup>1</sup>This work was supported by NSF Grant No. DMR15-1508412, and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility.

**1:27PM L16.00010 Phosphorene Nanoribbons: Electronic Structure and Electric Field Modulation**<sup>1</sup> , SINA SOLEIMANIKAHNOJ, IRENA KNEZEVIC, University of Wisconsin Madison — Phosphorene, a newcomer among the 2D van der Waals materials, has attracted the attention of many scientists due to its promising electronic properties. Monolayer phosphorene has a direct band gap of 2 eV located at the Gamma point of the Brillouin zone. Increasing the number of layers reduces the bandgap due to the van der Waals interaction. The direct nature of the bandgap makes phosphorene particularly favorable for electronic transport and optoelectronic applications. While multilayer phosphorene sheets have been studied, the electronic properties of their 1D counterparts are still unexplored. An accurate tight-binding model was recently proposed for multilayer phosphorene nanoribbons. Employing this model along with the non-equilibrium Greens function method, we calculate the band structure and electronic properties of phosphorene nanoribbons. We show that, depending on the edge termination, phosphorene nanoribbons can be metallic or semiconducting. Our analysis also shows that the electronic properties of phosphorene nanoribbons are highly tunable by in-plane and out-of-plane electric fields. In metallic ribbons, the conductance can be switched off by a threshold electric field, similar to field effect devices.

**1:39PM L16.00011 Two dimensional disorder in black phosphorus and layered monochalcogenides** , SALVADOR BARRAZA-LOPEZ, MEHRSHAD MEHBOUDI, PRADEEP KUMAR, EDMUND O. HARRISS, HUGH O. H. CHURCHILL, ALEX M. DORIO, University of Arkansas, WENJUAN ZHU, AREND VAN DER ZANDE, University of Illinois, ALEJANDRO A. PACHECO SANJUAN, Universidad del Norte — The degeneracies of the structural ground state of materials with a layered orthorhombic structure such as black phosphorus and layered monochalcogenides GeS, GeSe, SnS, and SnSe, lead to an order/disorder transition in two dimensions at finite temperature. This transition has consequences on applications based on these materials requiring a crystalline two-dimensional structure. Details including a Potts model that explains the two-dimensional transition, among other results, will be given in this talk. References: M. Mehboudi, A.M. Dorio, W. Zhu, A. van der Zande, H.O.H. Churchill, A.A. Pacheco Sanjuan, E.O.H. Harris, P. Kumar, and S. Barraza-Lopez. arXiv:1510.09153.

**1:51PM L16.00012 Two-dimensional massless Dirac fermions, chiral pseudo-spins, and Berry's phase in few-layer black phosphorus<sup>1</sup>**, SEUNG SU BAIK, HYOUNG JOON CHOI, Dept. of Physics, IPAP, and CCSAEMP, Yonsei University, Korea — Black phosphorus (BP) and its two-dimensional (2D) derivative phosphorene are rapidly emerging nanoelectronic materials with potential applicability to field effect transistors and optoelectronic devices. Unlike the gapless semiconductor graphene, multilayer BP has a substantial band gap of 0.2 eV, and this band-gap size is predicted being sensitive to the external perturbations such as pressure, strain, and electric field. Very recently, a semiconductor-semimetal transition in BP was realized by the surface potassium (K) doping, producing a Dirac semimetal state with a linear dispersion in the armchair direction and a quadratic one in the zigzag direction [1,2]. Here, based on first-principles density functional calculations, we present that beyond the critical K density, 2D massless Dirac fermions emerge in K-doped few-layer BP, and the electronic states around Dirac points have chiral pseudo-spins and Berry's phase. These features are robust with respect to the spin-orbit interaction. The switchable massless Dirac fermions discussed here may open a new way for the development of high performance devices in 2D materials beyond graphene. [1] J. Kim, S. S. Baik, S. H. Ryu, Y. Sohn, S. Park, B. Park, J. Denlinger, Y. Yi, H. J. Choi, and K. S. Kim, *Science* **349**, 723-725, (2015). [2] S. S. Baik, K. S. Kim, Y. Yi and H. J. Choi, arXiv:1508.04932.

**2:03PM L16.00013 Two-dimensional exciton states in monolayer semiconducting phosphorus allotropes<sup>1</sup>**, ALEXANDRE R ROCHA, CESAR E P VILLEGAS, Instituto de Física Teórica - Unesp, São Paulo, Brazil — During the last decade, novel two-dimensional (2D) semiconducting materials have been synthesized and characterized. As a result, there have been several theoretical and experimental proposals to incorporate 2D materials for designing next generation electronic and optoelectronics devices. In particular, it has been demonstrated that light absorption in phosphorus-based monolayers can span the whole visible spectrum, suggesting they could be used for optoelectronic applications. A key ingredient for optoelectronic applications is the presence of excitons and their subsequent diffusion along a donor material. This is influenced by the character of the different excitations taking place, as well as, the exciton binding energy. Therefore, in this work we use accurate many-body corrected density functional theory by means of GW-BSE methodology to elucidate the most important optical transitions, exciton energy spectrum as well as exciton extension in different types of phosphorene materials. In addition, we solve the Schrödinger equation for different 2D screened potentials and estimate the 2D exciton energy levels and radius extension. Finally, in order to assess further studies based on these systems, we provide a simple analytic expression for estimating 2D exciton energy levels.

**11:15AM L17.00001 Properties of Edge States at the Graphene P-N Junction Interface**, SON LE, NIKOLAI KLIMOV, DAVID NEWELL, NIST - Natl Inst of Stds & Tech, JUN YAN, University of Massachusetts, Amherst, JI UNG LEE, SUNY PI, NY, CURT RICHTER, NIST - Natl Inst of Stds & Tech — The Landau level edge states from the p- and the n-section of a graphene P/N junction (*pnJ*) interact with each other differently across the junction depending upon the properties of the junction and the graphene. Full equilibration was reported for a two terminal graphene *pnJ* device in Williams et al. [1]. In our four-terminal device, however, only the lowest Landau level edge state is equilibrated across the *pnJ* [2]. When the two devices are compared, the LL energy spacings, the length of the edge states along the *pnJ* interface, and the carrier mobility are similar. Electrostatic simulations for our device geometry and that of [1] contrast the rate of change of the electrostatic potential across the *pnJs*. Edge states at an electrostatically smooth junction are spatially further apart than those at a relatively abrupt junction, which decreases the probability of edge states mixing. Thus, we attribute the difference in equilibration in our device and that of [1] to the dramatic difference in the shape of the electrostatic junction. [1] J. R. Williams, L. DiCarlo, and C. M. Marcus, *Science* **317**, 638 (2007) [2] Nikolai N. Klimov, Son T. Le, *et al.*, *Phys. Rev. B: Rapid Comm.* (2015)

**11:27AM L17.00002 Quantum oscillations as a probe of massive Dirac fermions**, SCOTT DIETRICH, CARLOS FORSYTHE, JESSE BALGLEY, CORY DEAN, Department of Physics, Columbia University — Significant band structure engineering has been recently accomplished by stacking monolayer and bilayer graphene onto hexagonal Boron Nitride (hBN). The slightly mismatched lattice constants and varying alignment angle of the two materials creates a tunable moiré superlattice potential and breaks the naturally occurring valley symmetry of graphene. These effects open a gap and distort the band dispersion near the charge neutrality point as well as at location of the moiré minibands. In this study, effective band mass as a function of density is extracted from Shubnikov-de Haas oscillations in devices with varying superlattice wavelengths. Our results demonstrate quantitative control of band mass in graphene devices, and could help clarify the possible role of the many-body physics in these systems.

**11:39AM L17.00003 Nanoscale Tunable Strong Carrier Density Modulation of 2D Materials for Metamaterials and Other Tunable Optoelectronics**, CHENG PENG, DMITRI EFETOV, REN-JYE SHIUE, Massachusetts Institute of Technology, SEBASTIEN NANOT, ICFO, the Institute of Photonic Sciences, MAREK HEMPEL, JING KONG, Massachusetts Institute of Technology, FRANK KOPPENS, ICFO, the Institute of Photonic Sciences, DIRK ENGLUND, Massachusetts Institute of Technology — Strong spatial tunability of the charge carrier density at nanoscale is essential to many 2D-material-based electronic and optoelectronic applications. As an example, plasmonic metamaterials with nanoscale dimensions would make graphene plasmonics at visible and near-infrared wavelengths possible. However, existing gating techniques based on conventional dielectric gating geometries limit the spatial resolution and achievable carrier concentration, strongly restricting the available wavelength, geometry, and quality of the devices. Here, we present a novel spatially selective electrolyte gating approach that allows for in-plane spatial Fermi energy modulation of 2D materials of more than 1 eV (carrier density of  $n = 10^{14} \text{ cm}^{-2}$ ) across a length of 2 nm. We present electrostatic simulations as well as electronic transport, photocurrent, cyclic voltammetry and optical spectroscopy measurements to characterize the performance of the gating technique applied to graphene devices. The high spatial resolution, high doping capacity, full tunability and self-aligned device geometry of the presented technique opens a new venue for nanoscale metamaterial engineering of 2D materials for complete optical absorption, nonlinear optics and sensing, among other applications.

**11:51AM L17.00004 Optical study of low-dimensional materials**, FENG WANG, Univ of California - Berkeley — Electrons in monolayer graphene are described by massless Dirac electrons, which exhibit unique quantum phenomena due to the pseudospin and Berry phase of the massless electrons. In this talk, I will discuss our effort in probing massive Dirac electrons in gapped bilayer graphene, which can be described by a quantum valley Hall insulator with non-trivial Chern number for individual valleys. A topologically protected 1D conducting channel was predicted to exist at the layer-stacking domain boundary of AB-BA bilayers. We show that near-field infrared imaging provides a versatile tool to visualize the layer stacking domain walls, and demonstrate conducting channels arising from the quantum valley Hall edge states through electrical transport in gapped bilayer graphene.

**12:27PM L17.00005 Pseudo Magnetic Faraday and Quantum Hall Effect In Oscillating Graphene<sup>1</sup>**, ANITA BHAGAT, KIERAN MULLEN, Homer L. Dodge Department of Physics and Astronomy, Univ. of Oklahoma — When a graphene layer is stressed, the strain changes the phase between sites in a tight binding model of the system. This phase can be viewed as a pseudo-magnetic vector potential. The corresponding pseudo-magnetic field has been experimentally verified in static cases.<sup>2</sup> We examine the case of oscillating graphene ribbons and explore two new effects. The first is to investigate an oscillating pseudo-magnetic field that produces a quantum Hall effect: we calculate the I-V characteristic of an oscillating graphene nanoribbon as a function of frequency, and amplitude in both the oscillations and the applied driving voltage. Second, the time dependent pseudo-magnetic field should produce a pseudo-Faraday effect driving electrons in different valleys in opposite directions. In both cases, we make explicit calculations for experiment.

**12:39PM L17.00006 Twisted bilayer graphene with interlayer potential asymmetry<sup>1</sup>**, PILKYUNG MOON, New York University Shanghai, YOUNG-WOO SON, Korea Institute for Advanced Study, MIKITO KOSHINO, Tohoku University — A twisted stack of two graphene layers (twisted bilayer graphene) exhibits an extremely long potential period arising from the moiré interference between the layers<sup>2-3,4</sup>. We investigate the band structure and optical absorption spectrum of twisted bilayer graphenes with changing interlayer bias and Fermi energy simultaneously<sup>5</sup>. We show that the interlayer bias lifts the degeneracy of the superlattice Dirac point, while the amount of the Dirac point shift is significantly suppressed in small rotation angles, and even becomes opposite to the applied bias, by the interlayer interaction. In addition, we show that the spectroscopic features are highly sensitive to the interlayer bias and the Fermi energy, and widely tunable by the external field effect.

**12:51PM L17.00007 Control of commensuration between graphene and boron nitride**, MATTHEW YANKOWITZ, University of Arizona, K. WATANABE, T. TANIGUCHI, National Institute for Materials Science, PABLO SAN-JOSE, Instituto de Ciencia de Materiales de Madrid, BRIAN J. LEROY, University of Arizona — The electronic properties of van der Waals (vdW) heterostructures can be controlled through the choice and ordering of materials, as well as through the relative rotation between the atomic layers. However, little has been done to directly control the interactions between these layers, which may act as another tunable degree of freedom in these systems. Here, we demonstrate the ability to control the interlayer interaction strength between graphene and boron nitride using pressure resulting from the vdW interaction of a nearby STM tip. In particular, controlling the relative layer separation dynamically modifies the adhesion-induced strains in the graphene as it forms a partially commensurate structure with the boron nitride.

**1:03PM L17.00008 Negative Electronic Compressibility and Tuneable Spin Splitting in WSe<sub>2</sub>**, J.M. RILEY, Univ of St Andrews and Diamond Light Source, W. MEEVASANA, Suranaree Univ of Tech, L. BAWDEN, Univ of St Andrews, M. ASAKAWA, Tokyo Inst of Tech, T. TAKAYAMA, Univ of Tokyo, T. EKNAPAKUL, Suranaree Univ of Tech, T.K. KIM, M. HOESCH, Diamond Light Source, S.-K. MO, Advanced Light Source, H. TAKAGI, Univ of Tokyo, T. SASAGAWA, Tokyo Inst of Tech, M.S. BAHARAMY, Univ of Tokyo and RIKEN, P.D.C. KING, Univ of St Andrews — Recently, semiconducting transition metal dichalcogenides have gained attention for their extraordinarily large exciton-binding energies [1,2] and locking of the spin with valley and layer pseudospins [3,4]. Through sub-monolayer deposition of alkali metals onto the surface of WSe<sub>2</sub>, analogous to the gating in a field-effect transistor, we create a 2DEG at the sample surface with tuneable carrier concentration [5]. Counter-intuitively, we find that the addition of carriers induces a reduction of the chemical potential in the near-surface. We attribute this to negative electronic compressibility [6] where strong Coulomb effects lead to the lowering of the chemical potential with band filling, which we find persists to remarkably high electron densities. Simultaneously, we show this is accompanied by a giant tuneable spin-splitting of the valence band states and a reduction of the quasiparticle band gap. [1] Ugeda, et al., *Nature Mat.* **13** (2014) 1091 [2] Ye et al., *Nature* **513** (2014) 214 [3] Xu et al., *Nature Phys.* **10** (2014) 343 [4] Riley et al., *Nature Phys.* **10** (2014) 835 [5] Riley et al. doi:10.1038/nnano.2015.217 [6] Eisenstein et al. *Phys. **1:15PM L17.00009 Floquet-Engineered Valleytronics in Dirac Systems<sup>1</sup>**, BABAK SERADJEH, ARIJIT KUNDU<sup>2</sup>, HERBERT FERTIG, Indiana University — Valley degrees of freedom offer a potential resource for quantum information processing if they can be effectively controlled. We discuss an optical approach to this problem in which intense light breaks electronic symmetries of a two-dimensional Dirac material. The resulting quasienergy structures may then differ for different valleys, so that the Floquet physics of the system can be exploited to produce highly polarized valley currents. This physics can be utilized to realize a valley valve whose behavior is determined optically. We propose a concrete way to achieve such valleytronics in graphene as well as in a simple model of an inversion-symmetry broken Dirac material, such as monolayer transition-metal dichalcogenides. Simulating the system numerically, we find that the effect is robustness against moderate disorder and small deviations in optical parameters. We also study designs for coherent manipulation of valley degrees of freedom suitable for quantum information processing.

<sup>2</sup>Present Address: Israel Institute of Technology

**1:27PM L17.00010 Transition-metal dichalcogenide-based dipolariton optoelectronic devices**, GERMAN KOLMAKOV, NYC College of Technology, CUNY, TIM BYRNES, New York University, ANDY HE, ROMAN YA. KEZERASHVILI, NYC College of Technology, CUNY — Using computational modeling, we simulate the dynamics of dipolaritons in an optical microcavity, which encompasses the transition-metal dichalcogenide double-layer structure. We demonstrate that dipolaritons, a three-way superposition of photons, direct excitons and indirect excitons, are guided by a pattern deposited on the microcavity and can be driven by an external electric field or voltage applied to the structure. Focusing on a normal dipolariton gas in Y- and Psi-shaped patterns, we isolate conditions when the dipolariton flow can be switched between the channel branches of the pattern by the electric field. We also studied the superfluid dynamics of dipolariton Bose-Einstein condensates in patterned substrates at low temperatures, showing that the condensate in the channels can be accelerated and then directed by the electric field. We compare the obtained results with those for GaAs-based microcavities and demonstrate that dipolaritons in transition-metal dichalcogenide-based microcavities can be utilized for the design of optical switches and transistors for optoelectronic integrated circuits.

**1:39PM L17.00011 Electrical and optical properties of SnS<sub>2</sub>/WSe<sub>2</sub> van der Waals Heterojunction FETs**, AHMAD ZUBAIR, AMIRHASAN NOURBAKSH, MILDRED DRESSSELHAUS, TOMAS PALACIOS, Massachusetts Institute of Technology — Two dimensional crystals based on atomically thin films of transition metal dichalcogenides offer an exciting platform for various optoelectronic applications. Their unique crystal properties make them particularly attractive for van der Waals heterostructures which open up an additional degree of freedom to tailor the material properties into new physics and device applications. In this work, we explore, for the first time, the optoelectronic properties of van der Waals SnS<sub>2</sub>/WSe<sub>2</sub> heterojunction. WSe<sub>2</sub> is an ambipolar semiconductor while SnS<sub>2</sub> is an *n*-type wide bandgap semiconductor. We use the pickup and dry transfer methods to fabricate SnS<sub>2</sub>/WSe<sub>2</sub> heterojunction transistors (hetero-FETs). We observe negative differential transconductance in the SnS<sub>2</sub>/WSe<sub>2</sub> hetero-FET. Also, the heterostructure couples strongly to incident light and shows high photovoltaic responsivity which can find applications in nano-devices such as photo-detectors and solar cells.

**1:51PM L17.00012 Mapping of the photo-induced metastable and hidden phases in 2D electronic materials**, FARAN ZHOU, TIANYIN SUN, TZONG-RU HAN, Michigan State University, CHRISTOS MALLIAKAS, Northwestern University, PHILLIP DUXBURY, SUBHENDRA MAHANTI, Michigan State University, MERCOURI KANATZIDIS, Northwestern University, CHONG-YU RUAN, Michigan State University, MSU TEAM, NU TEAM — Using the ultrafast electron imaging techniques, we studied the light-induced phase transitions in transition-metal dichalcogenide materials. A succession of different phases was introduced transiently using femtosecond mid-infrared pulses and the local atomic scale charge-density-wave dynamics and morphological evolution of the long-range textured domains were *in situ* characterized using the ultrashort coherent electron pulses. The various metastable and hidden states emerging under the controlled nonthermal, nonadiabatic driving highlight the interaction-driven nature of these transitions with limited involvement of lattice entropy. The methodology introduced here can be generally applied to survey the complex energy landscape in strongly correlated electron systems, avoiding the difficulty of electrostatic gating or confounding effects due to defects and/or disorder. In particular, the observation of robust non-thermal switching at meso-scales and at ultrafast timescales, provides a platform for designing high-speed low-energy consumption nano-photonics and electronics devices.

**2:03PM L17.00013 Transport properties of heterostructures composed of Mo(S,Se)<sub>2</sub> on *h*-BN**, QIONG ZHOU, NIHAR PRADHAN, SHAHRIAR MERAMAN, DANIEL RHODES, LUIS BALICAS, National High Magnetic Field Laboratory and Florida State University — The thickness-dependent tunable band gap of transition metal dichalcogenides in the visible region has generated a lot of interest on their optoelectronic properties. Our single crystals of molybdenum disulphide (MoS<sub>2</sub>) and molybdenum diselenide (MoSe<sub>2</sub>) were grown through a chemical vapor transport technique. Few-layered flakes of MoS<sub>2</sub> and MoSe<sub>2</sub> were mechanically exfoliated and transferred onto *h*-BN flakes, with this stack subsequently transferred onto pre-evaporated molybdenum bottom gate(s). Here, we report the fabrication and temperature-dependent electrical transport properties of few-layered MoS<sub>2</sub> and MoSe<sub>2</sub> field-effect transistors on *h*-BN.

Session L18 GMAG DMP FIAP: Ultrafast Magnetization Dynamics 317 - Emrah Turgut, Cornell University

**11:15AM L18.00001 Tabletop soft x-ray magnetic circular dichroism measurements using circularly polarized high harmonic sources**, T FAN, R KNUT, C HERNANDEZ GARCA, D HICKSTEIN, D ZUSIN, C GENTRY, F DOLLAR, C MANCUSO, C HOGLE, J ELLIS, K DORNEY, JILA - University of Colorado, D LEGUT, Charles University, K CARVA, P OPPENEER, Department of Physics - Uppsalla University, O SHPYRKO, E FULLERTON, University of California at San Diego, O KFIR, O COHEN, Physics Department - Technion, D MILOSEVIC, University of Sarajevo, A BECKER, A JARON BECKER, T POPMINTCHEV, M MURNANE, H KAPTEYN, P GRYCHTOL, JILA - University of Colorado — X-ray magnetic circular dichroism (XMCD) allows for the extraction of the orbital and spin contributions to the magnetization and its interaction with phononic and electronic degrees of freedom on fs time and nm length scales, with element-specificity. However, to date, circular soft x-ray beams were restricted to large-scale x-ray facilities. These facilities have great advantages of high peak and average powers, but have limited access and temporal resolution. In this work, we present the first direct tabletop approach for generating bright circularly polarized light exceeding 160 eV. This makes it possible to implement XMCD on the tabletop for the first time, allowing to probe not only the 3d ferromagnets, but also the 4f rare earth materials with element-specificity. We demonstrate the stability, circularity and brightness of our high harmonic source by extracting the magneto-optical coefficients near the *N* edge of Gd (145 eV), as well as at the *M* edges of Fe (52eV), for an out-of-plane magnetized Gd/Fe multilayer sample thus enabling ultrafast studies of magnetization dynamics.

**11:27AM L18.00002 Localization of Fe d-states in Ni-Fe-Cu alloys and implications for ultrafast demagnetization**, TOM SILVA, NIST, Boulder, CO, USA, RONNY KNUT, JILA, Boulder, CO, USA, ERNA DELCZEG-CZIRJAK, Uppsalla University, Uppsalla, Sweden, JUSTIN SHAW, HANS NEMBACH, NIST, Boulder, CO, USA, PATRIK GRYCHTOL, DMITRIY ZUSIN, CHRISTIAN GENTRY, EMRAH TURGUT, HENRY KAPTEYN, MARGARET MURNANE, JILA, Boulder, CO, USA, DARIO ARENA, University of South Florida, Tampa, FL, USA, OLLE ERIKSSON, OLOF KARIS, Uppsalla University, Uppsalla, Sweden — Ni<sub>0.8</sub>Fe<sub>0.2</sub> (Py) and Py-Cu exhibit intriguing ultrafast demagnetization behavior, where the Ni magnetic moment shows a delayed response relative to the Fe. To unravel the mechanism responsible for this behavior, we have studied Py-Cu alloys for a wide range of Cu concentrations using X-ray magnetic circular dichroism (XMCD). The magnetic moments of Fe and Ni are found to respond very differently to Cu alloying: Fe becomes a strong ferromagnet in Py, with the magnetic moment largely unaffected by Cu alloying. In contrast, the Ni magnetic moment decreases continuously with increasing Cu concentration. Ab-initio calculations corroborate these results and we discuss the electronic structure in the framework of virtual bound states (VBSs). Fe exhibits VBSs in the minority band that lie approximately 1 eV above the Fermi level in pure Py, and which move closer to the Fermi level upon Cu alloying. A strong interaction between the VBSs and electrons above the Fermi level enhances the formation of magnons at Fe sites. This mechanism is consistent with a demagnetization delay between Fe and Ni, as found experimentally.

**11:39AM L18.00003 Time Resolved X-ray Magnetic Circular Dichroism at the Linac Coherent Light Source**<sup>1</sup>, W. SCHLOTTER, D. HIGLEY, E. JAL, G. DAKOVSKI, E. YUAN, J. MACARTHUR, A. LUTMAN, K. HIRSCH, P. GRANITZKA, Z. CHEN, G. COSLOVICH, M. HOFFMAN, A. MITRA, A. REID, P. HART, H.-D. NUHN, H. DUERR, SLAC - Natl Accelerator Lab, E. ARENHOLZ, P. SHAFER, P. DENNES, J. JOSEPH, Lawrence Berkeley Natl Lab, L. GUYADER, Helmholtz-Zentrum Berlin, Germany, A. TSUKAMOTO, Nihon University, Chiba, Japan — We demonstrate ultrafast time resolved X-ray Magnetic Circular Dichroism on optically switchable GdFeCo thin film samples. This method extends the element specificity of time resolved x-ray absorption spectroscopy to characterize the evolution of electron spin and orbital angular momenta. These measurements were enabled by a recent upgrade at the Linac Coherent Light Source (LCLS) to generate circularly polarized x-rays. Additionally these measurements were enhanced by new detection systems that benefit all x-ray absorption spectroscopy experiments performed in transmission. Consequently static XMCD data are in excellent agreement with similar measurements at synchrotron light sources. The LCLS is an x-ray free electron laser user facility accessible via a peer-reviewed proposal process.

<sup>1</sup> Acknowledgement: The Linac Coherent Light Source (LCLS), SLAC National Accelerator Laboratory, is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-76SF00515.

### 11:51AM L18.00004 Spin pumping in electrodynamically coupled magnon-photon systems<sup>1</sup>

LIHUI BAI, Department of Physics and Astronomy, University of Manitoba, Winnipeg, Canada R3T 2N2 — The electronics industry is quickly approaching the limitation of Moore's Law due to Joule heating in high density-integrated devices. To achieve new higher-speed devices and reduce energy consumption, researchers are turning to spintronics where the intrinsic spin, rather than the charge of electrons, is used to carry information in devices. Advances in spintronics have led to the discovery of giant magnetoresistance (GMR), spin transfer torque etc. Another subject, cavity electrodynamics, promises a completely new quantum algorithm by studying the properties of a single electron interacting with photons inside of a cavity. By merging both spintronics and cavity electrodynamics, a new cutting edge field called Cavity Spintronics is forming, which draws on the advantages of both subjects to develop new spintronics devices utilizing light-matter interaction. In this work, we use electrical detection, in combination with microwave transmission, to investigate both resonant and nonresonant magnon-photon coupling in a microwave cavity at room temperature. Spin pumping in a dynamically coupled magnon-photon system is found to be distinctly different from previous experiments. Characteristic coupling features such as modes anticrossing, linewidth evolution, peculiar line shape, and resonance broadening are systematically measured and consistently analyzed by a theoretical model set on the foundation of classical electrodynamic coupling. Our experimental and theoretical approach paves the way for pursuing microwave coherent manipulation of pure spin current via the combination of spin pumping and magnon-photon coupling.

### 12:27PM L18.00005 Ultrafast magnetization dynamics in heterogeneous granular FePt media

PATRICK GRANITZKA, ALEXANDER REID, EMMANUELLE JAL, TIANMIN LIU, SLAC - National Accelerator Laboratory, WILLIAM SCHLOTTER, SLAC - Linac Coherent Light Source, PADRAIC SHAFER, LBNL, VIRAT METHA, OLAV HELLWIG, HGST, YUKIKO TAHAKASHI, National Institute for Materials Science, Japan, ERIC FULLERTON, UCSD, Center for Magnetic Recording Research, JOACHIM STOHR, HERMANN DURR, SLAC - National Accelerator Laboratory — Granular FePt in the L<sub>10</sub> phase is a key material for future magnetic data storage devices, supporting stable magnetic domains less than 10 nm in diameter. To switch the magnetization of magnetically hard materials like FePt, new writing techniques are needed such as Heat Assisted Magnetic Recording (HAMR). However, it is not known how HAMR works on the fundamental length and time scales of magnetization in FePt. Here we investigate the nanoscale aspects of magnetization dynamics in FePt HAMR with fs X-ray pulses from the Linac Coherent Light Source at Stanford using resonant X-ray diffraction. We show that while many spins display switching in a magnetic field following a fs duration optical excitation. The remaining spins do not switch. Surprisingly the ratio of spins that switch to spins that do not, stays constant over a large fluence range. Furthermore we observe that the spin reservoir which displays heat assisted magnetic recording is quenched homogeneously over the size distribution of grains, while the spins that do not follow the field display a length-scale dependent quenching.

### 12:39PM L18.00006 A simple and effective theory for all-optical helicity-dependent spin switching<sup>1</sup>

GUOPING ZHANG, Department of Physics, Indiana State University, Terre Haute, IN 47809, USA, YIHUA BAI, Office of Information Technology, Indiana State University, USA, THOMAS F GEORGE, University of Missouri-St. Louis — All-optical helicity-dependent spin switching (AOS) represents a new frontier in magnetic recording technology, where a single ultrafast laser pulse, without any assistance from an external magnetic field, can permanently switch spin within a few hundred femtoseconds. By contrast, the existing theory does rely on an artificial magnetic field to switch spins. Here we develop a microscopic spin switch theory, free of any artificial field, and demonstrate unambiguously that both circularly and linearly polarized lights can switch spins faithfully. Our theory is based on the Hookean theory, but includes two new elements: spin-orbit coupling and exchange interaction. We predict that left (right) circularly polarized light only flips (flops) spin, a symmetry constraint that strongly favors ferrimagnetic orderings over ferromagnetic ones, with the allowable exchange interaction within 10 meV, consistent with all prior theories. The effect of the laser amplitude is highly nonlinear: If it is too weak, AOS does not occur, but if too strong, the spin cants; a compromise between them produces a narrow spin reversal window as observed experimentally. We envision that our model can be easily extended to describe spin frustrated systems and multiferroics, where the light-spin interaction

### 12:51PM L18.00007 A fast time-dependent density functional theory method for the simulation of ultrafast demagnetization induced by laser

ZHANGHUI CHEN, LIN-WANG WANG, Lawrence Berkeley Natl Lab, MAGNETIC PROJECT TEAM — We present a fast real-time time-dependent density functional theory method to investigate the ultrafast spin dynamics induced by laser. The Hamiltonian considers non-collinear magnetic moment, spin-orbital coupling and electron-laser interaction. An accelerated method with leapfrog prediction of charge matrix is used to solve the time-evolving equation. The investigation of Ni bulk found that the spin demagnetization consists of one time-lag stage and one fast demagnetization stage followed by one slow demagnetization stage. The time-lag and fast stages are mainly affected by the spin-electron interaction and their interactions with photons while the slow stage is affected by phonon-related interaction. Demagnetization appears only when spin-orbital coupling effect is considered. We further demonstrated how to manipulate the spin dynamics by changing laser fluence, duration and wavelength.

### 1:03PM L18.00008 A comparative study of laser-induced demagnetization dynamics in Fe, Co, and Ni

MAITHREYI GOPALAKRISHNAN, CHRISTIAN GENTRY, DMITRIY ZUSIN, PATRIK GRYCHTOL, RONNY KNUT, JILA, University of Colorado Boulder, JUSTIN SHAW, HANS NEMBACH, Electromagnetics Division, NIST, Boulder, STEFAN MATHIAS, Department of Physics, Georg-August-Universität Göttingen, MARTIN AESCHLIMANN, Department of Physics, University of Kaiserslautern, PETER OPPENEER, Department of Physics and Astronomy, Uppsala University, CLAUDIUS SCHNEIDER, Peter Grünberg Institut, Forschungszentrum Jülich, HENRY KAPTEYN, MARGARET MURNANE, JILA, University of Colorado Boulder — Even twenty years after the discovery of ultrafast demagnetization of ferromagnetic materials induced by a femtosecond laser pulse there is still an ongoing debate about the mechanisms that drive the process. Surprisingly, a comprehensive study that compares demagnetization dynamics in different materials on equal footing is lacking. Yet, the scientific community would greatly benefit from such study. We fill this gap by performing a systematic comparison of ultrafast demagnetization behavior in Iron, Cobalt and Nickel, the simplest itinerant ferromagnets, under a wide range of pump fluences. In this experiment, we utilize a tabletop broadband extreme ultraviolet source to probe magnetization dynamics at the M<sub>2,3</sub> absorption edges of these three elements using the transverse magneto-optical Kerr effect. The obtained data can be used to inform theory and, thereby, assist in resolving the remaining questions about the micro- and macroscopic mechanisms behind ultrafast laser-induced magnetization dynamics in materials.

**1:15PM L18.00009 Ultrafast demagnetization, spin-dependent Seebeck effect, and thermal spin transfer torque in Pt/TbFe/Cu and Pt/TbFe/Cu/Fe thin films<sup>1</sup>**, JOHANNES KIMLING, University of Illinois, BIRGIT HEBLER, University of Augsburg, JUDITH KIMLING, University of Illinois, MANFRED ALBRECHT, University of Augsburg, DAVID G. CAHILL, University of Illinois — We investigate diffusive spin currents in Pt(20nm)/TbFe(10nm)/Cu(100nm) and Pt(20 nm)/TbFe(10nm)/Cu(100nm)/Fe(3nm) stacks using time-resolved magneto-optic Kerr effect (TRMOKE) and time-domain thermoreflectance measurements. Our experiments are based on two hypothesis: (1) fast changes of magnetization due to laser excitation are transferred into spin accumulation, e.g., via electron-magnon scattering; the generated spin accumulation drives a diffusive spin current into adjacent normal metal layers; (2) electronic thermal transport through the ferromagnetic layer injects a spin current into adjacent normal metal layers, based on the spin-dependent Seebeck effect. [1] We excite the Pt layer with ps-laser pulses. Resulting diffusive spin currents generate nonequilibrium magnetization in the Cu layer (sample I) and induce a precession of the magnetization of the Fe layer via spin transfer torque (sample II). Both responses are probed using TRMOKE. Prior experiments used [Co(0.2nm)/Pt(0.4nm)]<sub>x5</sub>/Co(0.2nm) instead of TbFe. [1] The ferrimagnetic TbFe layer with introduces two major modifications: (1) slow demagnetization behavior, and (2) large thermal resistance. Hence, thermal spin transfer torques can be observed on significantly longer time scales. [1] G.-M. Choi, C.-H. Moon, B.-C. Min, K.-J. Lee, and D. G. Cahill, Nature Physics 11, 576 (2015).

**1:27PM L18.00010 Electronic properties of solids excited with intermediate laser power densities.**, FAUSTO SIROTTI, None, TEMPO BEAMLINE TEAM — Intermediate laser power density up to about 100 GW/cm<sup>2</sup> is below the surface damage threshold is currently used to induce modification in the physical properties on short time scales. The absorption of a short laser pulse induces non-equilibrium electronic distributions followed by lattice-mediated equilibrium taking place only in the picosecond range. The role of the hot electrons is particularly important in several domains as for example fast magnetization and demagnetization processes [1], laser induced phase transitions, charge density waves. Angular resolved photoelectron spectroscopy measuring directly energy and momentum of electrons is the most adapted tool to study the electronic excitations at short time scales during and after fast laser excitations. The main technical problem is the space charge created by the pumping laser pulse. I will present angular resolved multiphoton photoemission results obtained with 800 nm laser pulses [2] showing how space charge electrons emitted during fast demagnetization processes can be measured.

**1:39PM L18.00011 Ultrafast Study of Dynamic interfacial Exchange Coupling in Ferromagnet/Oxide/Semiconductor Heterostructures<sup>1</sup>**, YU-SHENG OU, YI-HSIN CHIU, The Ohio State University, NICHOLAS HARMON, The University of Iowa, PATRICK ODENTHAL, University of California, Riverside, MATTHEW SHEFFIELD, MICHAEL CHILCOTE, ROLAND KAWAKAMI, The Ohio State University, MICHAEL FLATT, The University of Iowa, EZEKIEL JOHNSTON-HALPERIN, The Ohio State University — Time-resolved Kerr/Faraday rotation (TRKR/TRFR) is employed to study GaAs spin dynamics in the regime of strong and dynamic exchange coupling to an adjacent MgO/Fe layer. This study reveals a dramatic, resonant suppression in the inhomogeneous spin lifetime (T<sub>2</sub><sup>\*</sup>) in the GaAs layer. Further investigation of the magnetization dynamics of the neighboring Fe layer, also using TRKR/TRFR, reveals not only the expected Kittel-dispersion but also additional lower frequency modes with very short lifetime (65 ps) that are not easily observed with conventional ferromagnetic resonance (FMR) techniques. These results suggest the intriguing possibility of resonant dynamic spin transfer between the GaAs and Fe spin systems. We discuss the potential for this work to establish GaAs spin dynamics as an efficient detector of spin dissipation and transport in the regime of dynamically-driven spin injection in ferromagnet/semiconductor heterostructures.

**1:51PM L18.00012 Heisenberg vs. Stoner: Ultrafast magnon generation and exchange renormalization in the course of laser-induced demagnetization**, DMITRIY ZUSIN, EMRAH TURGUT, PATRIK GRZYCHOL, RONNY KNUT, JILA, University of Colorado - Boulder, DOMINIK LEGUT, Department of Condensed Matter Physics, Charles University, Prague, JUSTIN SHAW, HANS NEMBACH, THOMAS SILVA, Electromagnetics Division, NIST, Boulder, STEFAN MATHIAS, MARTIN AESCHLIMANN, Department of Physics, University of Kaiserslautern and Research Center OPTIMAS, CLAUS SCHNEIDER, Peter-Grunberg-Institut, Forschungszentrum Julich, KAREL CARVA, PETER OPPENEER, Department of Physics and Astronomy, Uppsala University, HENRY KAPTEYN, MARGARET MURNANE, JILA, University of Colorado - Boulder — In this work, we access the microscopic mechanisms responsible for the ultrafast magnetization dynamics of ferromagnets following a femtosecond laser excitation. Using a tabletop high-harmonic source of extreme ultraviolet light, we perform magneto-optical pump-probe spectroscopic studies across the M<sub>2,3</sub> absorption edge of Cobalt with time, energy and angle resolution. This novel approach allows us to extract the time-dependent resonant magneto-optical properties of the Cobalt sample. In combination with ab-initio calculations of the density of states and the magneto-optical response, this gives us indirect access to ultrafast dynamics of the band structure. A comparison of our theoretical simulations with the experimental measurements suggests a variety of demagnetization mechanisms, which include ultrafast magnon excitations, enhanced electron temperature and transient renormalization of exchange splitting.

**2:03PM L18.00013 Studies of Ultrafast Demagnetization in Ferromagnetic Metal Alloys using TDDFT**, PETER ELLIOTT, KEVIN KRIEGER, JOHN KAY DEWHURST, SANGEETA SHARMA, E.K.U. GROSS, Max Planck Institute of Microstructure Physics — Time dependent density functional theory (TDDFT) has recently [1,2] been applied to study magnetization dynamics in periodic systems. In particular it was found for short intense pulses, a significant source of demagnetization is spin-flips mediated by the spin-orbit interaction. In this work, we perform TDDFT simulations for the case of bulk Heusler compounds under the same conditions, and find a similar loss of the global magnetic moment can occur. Furthermore, we also see local loss of moment due to transfer of moment from one sublattice to another during the optical excitation process. This is then followed by the spin-orbit mediated demagnetization in certain cases. Additionally we will analyze the spin-current densities to better understand the various processes at work. **Session L19 GMAG DMP: Emergent Magnetic and Electronic States in Oxide Heterostructures**

318 - Gervasi Herranz, ICMAB-CSIC

**11:15AM L19.00001 Engineering a spin-orbital magnetic insulator by tailoring iridate-based superlattices**, JOBU MATSUNO, RIKEN Center for Emergent Matter Science — In 5d Ir oxides with an interplay of spin-orbit coupling and electron correlations, we have tailored a spin-orbital magnetic insulator out of a semimetal SrIrO<sub>3</sub> by tuning the structure through superlattices [(SrIrO<sub>3</sub>)<sub>m</sub>, SrTiO<sub>3</sub>] ( $m = 1, 2, 3, 4$ , and  $\infty$ ) grown on SrTiO<sub>3</sub>(001) substrates. We observed the systematic decrease of the magnetic ordering temperature and the resistivity as a function of  $m$ . The transition from the semimetal to the insulator is found to be closely linked to the appearance of magnetism at  $m \simeq 3$ . Long range magnetic ordering was realized even in the  $m = 1$  single layer superlattice, implying that the design and realization of novel electronic phases is feasible at the level of a single atomic layer in complex Ir oxides. We also report the fabrication of (111)-oriented superlattice structures with alternating  $2m$ -layers ( $m = 1, 2$ , and  $3$ ) of Ca<sub>0.5</sub>Sr<sub>0.5</sub>IrO<sub>3</sub> perovskite and two layers of SrTiO<sub>3</sub> perovskite on SrTiO<sub>3</sub>(111) substrates. In the case of  $m = 1$  bilayer films, the Ir sublattice is a buckled honeycomb, where a topological state may be anticipated. The ground states of the superlattice films were found to be magnetic insulators, which may suggest the importance of electron correlations in Ir perovskites in addition to the much discussed topological effects.

**11:51AM L19.00002 Novel magnetic and electronic states in manganite-iridate heterostructures**<sup>1</sup>, JOHN NICHOLS, SHINBUHM LEE, JON PETRIE, TRICIA MEYER, XIANG GAO, ERJIA GUO, Oak Ridge National Laboratory, JOHN FREELAND, Argonne National Laboratory, DI YI, JIAN LIU, University of Tennessee, DANIEL HASKEL, Argonne National Laboratory, THOMAS ZAC WARD, GYULA ERES, VALERIA LAUTER, MICHAEL R. FITZSIMMONS, HO NYUNG LEE, Oak Ridge National Laboratory — Strong correlation between spin, charge, lattice, and orbital order parameters has proven to give rise to exotic physical phenomena, while epitaxial design of materials with strong interfacial coupling is an efficient technique to tune such parameters. Although there have been numerous studies of interfaces between 3d-3d and 4d-3d compounds, only few studies reported work on 3d and 5d materials and there has been no report on strong interfacial coupling in such systems. We have synthesized high quality [(AMnO<sub>3</sub>)<sub>m</sub>/(SrIrO<sub>3</sub>)<sub>n</sub>]<sub>z</sub> ( $A = \text{Sr, La}$ ) heterostructures by pulsed laser epitaxy on SrTiO<sub>3</sub> (001) substrates and have observed interesting novel magnetic and electronic ground states, which are highly sensitive to the degree of dimensional confinement in the heterostructures. Based on studies with x-ray diffraction, SQUID,  $dc$ -transport, x-ray circular dichroism, and polarized neutron reflectometry measurements, we will report intriguing magnetic and transport properties that provide the first evidence of strong interfacial coupling between 5d and 3d materials.

**12:03PM L19.00003 Strain control of magnetic structure in Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub>**, CHOONG H. KIM, IBS-CCES & Seoul Nat'l Univ. — We have studied from first principles the structural, electronic, and magnetic properties of the layered-perovskite iridates Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub> as a function of epitaxial strain. In Sr<sub>3</sub>Ir<sub>2</sub>O<sub>7</sub>, bilayer iridates, an easy  $c$ -axis collinear antiferromagnetic structure have been reported, a significant contrast to single layer Sr<sub>2</sub>IrO<sub>4</sub> with in-plane canted moments. This behavior is understood by competition among intra- and interlayer bond-directional pseudodipolar interactions. From our first-principles calculations, we show that these two energy scales are controllable via strain to drive spin-flop transition.

**12:15PM L19.00004 Realization of a Ferroelectric-Domain-Wall Tunnel Junction**, JACOBO SANTA-MARIA, G. SANCHEZ-SANTOLINO, J. TORNOS, D. HERNANDEZ-MARTIN, J. I. BELTRAN, M. CABERO, A. PEREZ-MUOZ, Z. SEFRIQUI, C. LEON, M. VARELA, GFMC. Univ Complutense. 28040 Madrid, C. MUNUERA, F. MOMPEAN, M. GARCIA-HERNANDEZ, M. C. MUOZ, Instituto de Ciencia de Materiales de Madrid ICM-ICMM-CSIC 28049 Madrid, S. J. PENNYCOOK, Department of Materials Science & Engineering, National University of Singapore, Singapore 117575. — Incorporating ferroelectric domain walls as an active part of electronic devices holds the promise of interesting new functionalities. Here we form a ferroelectric BaTiO<sub>3</sub> tunnel barrier just 4.4-nanometer thick, with ferromagnetic La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> electrodes, containing a head-to-head domain wall within its thickness. A confined electron gas is formed at the domain wall, stabilized by oxygen vacancies, which controls the tunneling transport of the magnetic tunnel junction. Resonant tunneling assisted by the discrete levels of the ferroelectric quantum well gives rise to strong quantum oscillations of the tunneling conductance. Our engineered, highly constrained, domain wall provides a major step forward towards the new concept "The Wall is the Device", exploiting the electronic properties of domain walls for ferroelectric tunnel barriers with new functionalities. Work at UCM supported by MINECO MAT2014-52405-C02-01 and ERC Starting Investigator Grant #239739 STEMOX. MCM acknowledges financial support from MICINN through grant MAT2012-38045-C04-04.

**12:27PM L19.00005 Tailoring magneto-electro-resistance in La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub>/BaTiO<sub>3</sub>multiferroic tunnel junctions**, MARIONA CABERO, A.M. PEREZ-MUOZ, D. HERNANDEZ-MARTIN, Z. SEFRIQUI, M. VARELA, C. LEON, J. SANTA-MARIA, GFMC Univ Complutense. 28040 Madrid, S. VALENCIA, Helmholtz-Zentrum Berlin fr Materialien & Energie, Albert-Einstein-Strasse 15, 12489 Berlin, Germany, R. ABRUDAN<sup>1</sup>, Helmholtz-Zentrum Berlin fr Materialien & Energie, Albert-Einstein-Strasse 15, 12489 Berlin, S. J. PENNYCOOK, Department of Materials Science & Engineering, National University of Singapore, Singapore 117575. — Controlling and manipulating the electronic states of oxide interfaces using external stimuli has become a major direction towards oxide-based electronics. Here, we present a study of the transport properties of multiferroic La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub>/BaTiO<sub>3</sub> (LSMO/BTO) ferromagnetic/ferroelectric heterostructures. Multiferroic tunnel junctions (MTJ's) have been obtained introducing an ultrathin La/Sr cuprate (LSCO) layer between the ferroelectric barrier and the top ferromagnetic electrode. The LSCO introduces an asymmetry in the screening of polarization charges at both interfaces, which yields electroresistance values in excess of 105 % and triggers an inversion of the sign of the tunneling magnetoresistance controlled by ferroelectric switching. We will discuss these results in the light of the generation and transport of oxygen vacancies. Work at UCM supported by MINECO MAT2014-52405-C02-01 and ERC Starting Investigator Grant #239739 STEMOX.

<sup>1</sup>AND Institut fr Experimentalphysik/Festkperphysik, Ruhr-Universitt Bochum, 44780 Bochum, Germany.

**12:39PM L19.00006 DFT+ $U$  study of electronic structure and Curie temperature of  $A_2B\text{ReO}_6$  ( $A=\text{Sr, Ca}$  and  $B=\text{Cr, Fe}$ )**, ALEX LEE, CHRIS MARIANETTI, Applied Physics and Applied Math, Columbia University — Re-based double perovskites (DPs) have attracted much attention due to their high Curie temperature ( $T_C$ ) and colossal magneto resistance with large potential for spintronic applications. Here we investigate the electronic and magnetic properties of the Re-based DPs  $A_2B\text{ReO}_6$  ( $A=\text{Sr, Ca}$  and  $B=\text{Cr, Fe}$ ) using density functional theory +  $U$  (DFT+ $U$ ) calculations. While monoclinic Ca<sub>2</sub>CrReO<sub>6</sub> and Ca<sub>2</sub>FeReO<sub>6</sub> (monoclinic) are insulating within GGA+ $U$ , tetragonal Sr<sub>2</sub>CrReO<sub>6</sub> ( $a^0a^0c^0$ ) and Sr<sub>2</sub>FeReO<sub>6</sub> ( $a^0a^0c^-$ ) remain metallic. We show that both on-site interaction  $U$  and octahedral tilting are critical to obtain the insulating phases. The  $a^0a^0c^-$ -phase of Sr<sub>2</sub>CrReO<sub>6</sub> is most stable and insulating with nonzero  $U$ , suggesting that the high quality Sr<sub>2</sub>CrReO<sub>6</sub> film on STO substrate can be a semiconductor as reported in recent experiments. We explain that the insulator-to-metal transition (MIT) of Ca<sub>2</sub>FeReO<sub>6</sub> at 140K is predominantly due to a structural phase transition which drives the insulating state. Curie temperatures of Re-based DPs are calculated using the classical Monte Carlo simulations based on the Heisenberg model.

**12:51PM L19.00007 Magnetism and Nanoscale Structural and Compositional Irregularities in MBE-grown  $\text{La}_2\text{MnNiO}_6$  on  $\text{SrTiO}_3(001)$** , SCOTT CHAMBERS, YINGGE DU, TIMOTHY DROUBAY, PETER SUSHKO, STEVEN SPURGEON, ARUN DEVARAJ, MARK BOWDEN, V SHUTTHANANDAN, Pacific Northwest Natl Lab, TORGNY GUSTAFSSON, Rutgers University — Double perovskites ( $\text{A}_2\text{BB}'\text{O}_6$ ) are a fascinating class of oxides with considerable potential for applications requiring ferromagnetic and semiconducting properties. We have investigated MBE-grown  $\text{La}_2\text{MnNiO}_6$  and have found that despite the fact that Mn and Ni are present as  $4+$  ( $d^3 : t_{2g}^3 e_g^0$ ) and  $2+$  ( $d^8 : t_{2g}^6 e_g^2$ ) respectively, and exhibit suitable XMCD signatures, the volume-averaged moment per formula unit is considerably less than 5 Bohr magnetons. Our electron energy loss spectroscopy (STEM-EELS) and atom probe tomography (APT) results to date reveal that there is considerable disorder in the B-site sublattice for as-deposited films, despite excellent volume-averaged stoichiometry. While air annealing results in substantial ordering, the moment remains low due to the nucleation of NiO inclusions with needle-like shapes revealed only by APT. First principles modeling suggests that even though the double perovskite is quite stable if nucleated in excess O, the presence of O vacancies facilitates structural disorder. In this talk, we will present our latest results on this fascinating material.

**1:03PM L19.00008 Magnetism, Chemical Ordering, and Defects in Epitaxial Double Perovskite  $\text{La}_2\text{MnNiO}_6$  Thin Films.**, TIM DROUBAY, STEVEN SPURGEON, YINGGE DU, ARUN DEVARAJ, Pacific Northwest National Laboratory, STEVE HEALD, Advanced Photon Source, Argonne National Laboratory, PETER SUSHKO, Pacific Northwest National Laboratory, TORGNY GUSTAFSSON, Rutgers University, DAVID KEAVNEY, Advanced Photon Source, Argonne National Laboratory, SCOTT CHAMBERS, Pacific Northwest National Laboratory — Oxide double perovskites ( $\text{A}_2\text{BB}'\text{O}_6$ ) exhibit an interesting variety of electronic and magnetic properties such as half-metallicity and high temperature ferromagnetism holding promise for potential technological applications. We have investigated  $\text{La}_2\text{MnNiO}_6/\text{SrTiO}_3$  grown using molecular beam epitaxy and have found different proportions of two ferromagnetic phase transitions ( $\sim 130\text{K}$  and  $\sim 290\text{K}$ ) and various saturation magnetization values ( $< 4.6 \mu_B/\text{f.u.}$ ) dependent upon post-growth annealing. Contrary to previous reports, neither the increase in the saturation magnetization nor the Curie temperature(s) after annealing can be attributed to changing Mn and Ni valence. Instead, using aberration-corrected transmission electron microscopy and atom probe tomography, we observe large-scale chemical ordering as a result of annealing. We also find the coexistence of NiO-derived extended defects that appear to prevent the magnetic moment from reaching the maximum possible value ( $5 \mu_B/\text{f.u.}$ ). We will describe these results in light of first principles calculations which suggest that local deviations from the ideal stoichiometry facilitate the formation of the NiO phase and structural disorder in the double perovskite phase.

**1:15PM L19.00009 Half-metallic ferromagnetism on surfaces of insulating and antiferromagnetic  $\text{LaFeO}_3$  thin films**, ROHAN MISHRA, Washington University in St. Louis, YOUNG-MIN KIM, Korea Basic Science Institute, QIAN HE, Oak Ridge National Laboratory, SEONG-KEUN KIM, Korea Institute of Science & Technology, SEOHYOUNG CHANG, ANAND BHATTACHARYA, Argonne National Laboratory, SOKRATES T. PANTELIDES, Vanderbilt University, Oak Ridge National Laboratory, ALBINA BORISEVICH, Oak Ridge National Laboratory — The surfaces of perovskite transition metal oxides having correlated electrons show novel electronic and magnetic phenomena. In this work, we combine scanning transmission electron microscopy imaging and electron energy loss spectroscopy (EELS) with density functional theory (DFT) calculations to study the surface of  $(\text{LaFeO}_3)_m/(\text{SrFeO}_3)_n$  heterostructure thin films. Using EELS, we observe a reduction in the oxidation state of Fe on moving from the bulk to the surface over a length of  $\sim 5$  unit cells. Simultaneously acquired STEM images allow us to map the associated changes in their structure, such as cation displacements and changes in oxygen polyhedral tilts. DFT calculations coupled with the STEM results show that by reducing the surface layer of a  $\text{LaFeO}_3$  film such that the surface is terminated with  $\text{FeO}_4$  tetrahedra instead of the  $\text{FeO}_6$  octahedra as present in the bulk, it is possible to stabilize an exotic phase where the surface layer displays a half-metallic ferromagnetic behavior, while the bulk remains antiferromagnetic and insulating, similar to the class of topological insulators. The calculations also predict that the magnetism and conductivity at the surface can be controlled by the partial pressure of oxygen.

**1:27PM L19.00010 X-ray Magnetic circular dichroism study of hexagonal  $\text{YbFeO}_3$  thin films**, XIAO WANG, Bryn Mawr College, KISHAN SINHA, XIAOSHAN XU, University of NebraskaLincoln, YAOHUA LIU, Oak Ridge National Laboratory, DAVID KEAVNEY, Argonne National Laboratory, X.M. CHENG, Bryn Mawr College — Multiferroic materials exhibit multiple ferroic orders simultaneously and thus have potential applications in information technology, sensing, and actuation. Hexagonal  $\text{YbFeO}_3$  is a promising candidate for a multiferroic material with room temperature ferromagnetism because of the expected enhanced Fe moment and higher transition temperature due to the exchange interaction between magnetic Yb and Fe ions. Here we report an x-ray magnetic circular dichroism (XMCD) study of (0001) Hexagonal  $\text{YbFeO}_3$  thin films deposited on (111) yttria-stabilized zirconia substrates via pulsed laser deposition. XMCD spectra for the Fe  $L_{2,3}$  edges and Yb  $M_5$  edge were measured with the magnetic field applied parallel to the x-ray propagation direction and 20 degree away from the film normal at beamline 4ID-C of the APS at ANL. Field dependence of the XMCD spectra show that Fe and Yb each has a ferromagnetic ordering at around 6.7 K but with opposite orientations in between. The saturation magnetic moment for Fe is determined by the sum rules to be  $0.07 \mu_B / \text{Fe cation}$  at around 6.7 K, about 4 times larger than that in Hexagonal  $\text{LuFeO}_3$ .

**1:39PM L19.00011 MAGNETO-OPTIC ENHANCEMENT IN NANO-SCALE IRON GARNET FILMS**, ASHIM CHAKRAVARTY, MIGUEL LEVY, Physics Department, Michigan Technological University, 49931, USA — This work addresses dimensionality-induced magneto-optic effects in liquid-phase-epitaxy magnetic garnet thin films. It is found that the Faraday rotation (FR) per unit length evinces a marked and steady enhancement as the film thickness is reduced approximately below 100 nm in  $\text{Bi}_{0.8}\text{Gd}_{0.2}\text{Lu}_2\text{Fe}_5\text{O}_{12}$ , although it remains constant in the micron- and most of the sub-micron-regime. The reported specific FR change in such reduced dimensions is due to size-dependent modifications in diamagnetic transition processes in the garnet film. These processes correspond to the electronic transitions from the singlet  $^6\text{S}$  ground state to spin-orbit split excited states of the  $\text{Fe}^{3+}$  ions in the garnet. A measurable reduction in the corresponding ferrimagnetic resonance linewidths is found, thus pointing to an increase in electronic relaxation times and longer lived excitations at reduced thicknesses than in the bulk. These changes together with a shift in vibrational frequency of the Bi-O bonds in the garnet at reduced thicknesses result in magneto-optical enhancement in ultra-thin garnet films.

**1:51PM L19.00012 Enhancement of Magnetization in  $\text{Y}_3\text{Fe}_5\text{O}_{12}$  Epitaxial Thin Films.**, JACK T. BRANGHAM, JAMES C. GALLAGHER, ANGELA S. YANG, SHANE P. WHITE, ROHAN ADUR, WILLAM T. RUANE, BRYAN D. ESSER, MICHAEL R. PAGE, P. CHRIS HAMMEL, Ohio State Univ - Columbus, DAVID W. MCCOMB, Center for Electron Microscopy and Analysis, Dept of Materials Science and Engineering, The Ohio State University, Columbus, OH 43212, FENGYUAN YANG, Ohio State Univ - Columbus — The ability to generate pure spin currents has applications in telecommunications, radar, and spin-based logic.  $\text{Y}_3\text{Fe}_5\text{O}_{12}$  (YIG) is one of the best materials for dynamic generation of spin currents due to its low damping, narrow ferromagnetic resonance (FMR) linewidth, and insulating behavior. We grow stoichiometric, high quality, epitaxial YIG thin films with thicknesses ranging from 4 to 250 nm on  $\text{Gd}_3\text{Ga}_5\text{O}_{12}$  by off-axis magnetron sputtering and characterize the YIG films by various techniques. The temperature dependence of the saturation magnetization was independently measured by in-plane vibrating sample magnetometry, out-of-plane magnetic shape anisotropy, and angular-dependent FMR absorption from 10 K to the Curie temperature of 530 K. The room temperature saturation magnetization was also measured with frequency dependent FMR. All measurements show a magnetization enhancement of 15% or greater when compared to reported magnetization values of bulk YIG crystals. We speculate this is due to suppression of the long wavelength magnons due to the finite size of the films.

**2:03PM L19.00013 Strain induced structural, electronic, and magnetic properties of SrFeO<sub>2</sub> and BaFeO<sub>2</sub>**, WEIDONG LUO, XIAOLE ZHANG, Shanghai Jiao Tong University, China — The structural, electronic and magnetic properties of SrFeO<sub>2</sub> and BaFeO<sub>2</sub> under tensile strains are studied using first-principles density-functional theory calculations. Strain-induced Jahn-Teller-like behaviors involving the cooperative displacements of oxygen atoms are predicted in both compounds. Lattice dynamical properties are also investigated and the strain-induced imaginary phonon modes are consistent with the Jahn-Teller-like distortion. The usual Jahn-Teller instability of degenerate energy levels does not contribute to the interesting phenomena. Besides the structural and electronic properties, a transition of magnetic orderings from G-type anti-ferromagnetic phase to C-type anti-ferromagnetic phase is predicted in both compounds, which originates from the combined effects of the lattice-orbital coupling and the spin-orbital coupling due to exchange interaction between orthogonal Fe 3d orbitals.  
We acknowledge funding support from the National Natural Science Foundation of China.

**Wednesday, March 16, 2016 11:15AM - 2:15PM –**  
**Session L20 DCOMP: Quantum Many-Body Systems and Methods II** 319 - Eric Andrade, TU Dresden, Germany

**11:15AM L20.00001 Scaling and Locality properties of the Entanglement Hamiltonian in Critical Fermionic systems**, NICOLA LANATA, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, USA, YONG-XIN YAO, Ames Laboratory-U.S. DOE and Department of Physics and Astronomy, Iowa State University, Ames, Iowa, XIAOYU DENG, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08856-8019, USA, MOHAMMAD POURANVARI, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, USA — We study the entanglement Hamiltonian of several gapless Fermionic systems. In particular, we consider an infinite metallic one dimensional chain of free Fermions, and show that the corresponding entanglement Hamiltonian  $F(L)$  for a subsystem of length  $L$  is local. Furthermore, we show that  $F(L)$  displays a well defined continuum limit, which is related with the so called logarithmically enhanced area law of the entanglement entropy,  $S(L) \sim \log(L)$ . Finally, using the “Gutzwiller renormalization group” [arXiv:1509.05441], we discuss these concepts in relation with the physics of the Anderson impurity model.

**11:27AM L20.00002 Entanglement dynamics in quantum many-body systems<sup>1</sup>**, WEN WEI HO, DMITRY ABANIN, Department of Theoretical Physics, University of Geneva — The dynamics of quantum entanglement  $S(t)$  has proven useful to distinguishing different quantum many-body phases. In particular, the growth of entanglement following a quantum quench can be used to distinguish between many-body localized ( $S(t) \sim \log t$ ) and ergodic ( $S(t) \sim t$ ) phases. Here, we provide a theoretical description of the growth of entanglement in a quantum many-body system, and propose a method to experimentally measure it. We show that entanglement growth is related to the spreading of local operators. In ergodic systems, the linear spreading of operators results in a universal, linear in time growth of entanglement. Furthermore, we show that entanglement growth is directly related to the decay of the Loschmidt echo in a composite system comprised of many copies of the original system, subject to a perturbation that reconnects different parts of the system. Using this picture, we propose an experimental set-up to measure entanglement growth by using a quantum switch (two-level system) which controls connections in the composite system. Our work provides a way to directly probe dynamical properties of many-body systems, in particular, allowing for a direct observation of many-body localization.

**11:39AM L20.00003 Measuring Entanglement Spectrum via Density Matrix Exponentiation**, GUANYU ZHU, ALIREZA SEIF, Joint Quantum Institute, University of Maryland, College Park, Maryland, USA, HANNES PICHLER, PETER ZOLLER, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, Innsbruck, Austria, MOHAMMAD HAFEZI, Joint Quantum Institute, University of Maryland, College Park, Maryland, USA — Entanglement spectrum (ES), the eigenvalues of the reduced density matrix of a subsystem, serves as a powerful theoretical tool to study many-body systems. For example, the gap and degeneracies of the entanglement spectrum have been used to identify various topological phases. However, the usefulness of such a concept in real experiments has been debated, since it is believed that obtaining the ES requires full state tomography, at a cost which exponentially grows with the systems size. Inspired by a recent density matrix exponentiation technique, we propose a scheme to measure ES by evolving the system with a Hamiltonian that is the subsystem's own reduced density matrix. Such a time evolution can be induced by an ancilla photon that is coupled to multiple qubits at the same time. The phase associated with the time evolution can be detected and converted into ES through either a digital or an analogue scheme. The digital scheme involves a modified quantum phase estimation algorithm based on random time evolution, while the analogue scheme is in the spirit of Ramsey interferometry. Both schemes are not limited by the size of the system, and are especially sensitive to the gap and degeneracies. We also discuss the implementation in cavity/circuit-QED and ion trap systems.

**11:51AM L20.00004 Flow equation holography**, STEFAN KEHREIN<sup>1</sup>, University Goettingen — The Ryu-Takayanagi conjecture [1] about the holographic derivation of the entanglement entropy provides a remarkable geometric picture by relating minimal surfaces to the entanglement entropy. Underlying this conjecture is the AdS/CFT correspondence, which limits the applicability of this geometric picture in its original formulation to a very specific set of theories. In this talk I will show how the flow equation method [2,3] can be used to construct an emergent geometric picture for generic quantum many-body systems. Results for the emergent Riemannian geometry of certain low-dimensional quantum systems are presented based on analytical and numerical solution of the flow equations. Minimal surfaces on these Riemannian manifolds show behavior in agreement with the entanglement entropy of the corresponding quantum theory, both for gapped and critical systems.

**12:03PM L20.00005 Irreversibility in Quantum Many-Body Systems**, MARKUS SCHMITT, STEFAN KEHREIN, Univ Goettingen — The question of thermalization in closed quantum many-body systems has received a lot of attention in the past few years. An intimately related question is whether a closed quantum system shows irreversible dynamics. However, irreversibility and what we actually mean by this in a quantum many-body system with unitary dynamics has been explored very little. In our work we investigate the irreversibility of dynamics in quantum many-body systems by studying echo dynamics. In order to quantify the (ir)reversibility we study the time evolution involving an imperfect effective time reversal. Our measure for the recovery of the initial state are the echo peaks occurring in the time evolution of observables. Specifically, we investigate non-interacting and interacting one-dimensional spin chains. We study the characteristics of the echo peak decay and especially focus on whether this depends on the (non-)integrability of the model.

**12:15PM L20.00006 Quantum Quench Dynamics in the Transverse Field Ising Model at Non-zero Temperatures<sup>1</sup>** , NILS ABELING, STEFAN KEHREIN, Univ Goettingen — The recently discovered *Dynamical Phase Transition* denotes non-analytic behavior in the real time evolution of quantum systems in the thermodynamic limit and has been shown to occur in different systems at zero temperature [Heyl *et al.*, Phys. Rev. Lett. **110**, 135704 (2013)]. In this talk we present the extension of the analysis to non-zero temperature by studying a generalized form of the Loschmidt echo, the work distribution function, of a quantum quench in the transverse field Ising model. Although the quantitative behavior at non-zero temperatures still displays features derived from the zero temperature non-analyticities, it is shown that in this model dynamical phase transitions do not exist if  $T > 0$ . This is a consequence of the system being initialized in a thermal state. Moreover, we elucidate how the Tasaki-Crooks-Jarzynski relation can be exploited as a symmetry relation for a global quench or to obtain the change of the equilibrium free energy density.

**12:27PM L20.00007 Nonequilibrium electron dynamics: Formation of the quasiparticle peak** , SHARAREH SAYYAD, MARTIN ECKSTEIN, Max Planck Inst Structure and Dynamics of Matter — We characterize how the narrow quasiparticle band of the one-band Hubbard model forms out of a bad metallic state in a time-dependent metal-insulator transition, using nonequilibrium slave-rotor dynamical mean field theory. Our results exhibit a nontrivial electronic timescale which is much longer than the width of the quasiparticle peak itself. To study this timescale, we perform a fast ramp from the insulating phase into the metallic region of the phase diagram, resulting in a highly excited state, and study the equilibration of the system with a weakly coupled phononic bath. The slow relaxation behavior is explained by surveilling the interplay between spinon and rotor degrees of freedom. Since the system is initially prepared in an insulating phase, the quasi-particle peak emerges when spinons catch up the metal-insulator crossover region, which is reached earlier by the rotor. At this point, spinon and rotor become weakly coupled, and the resulting very slow equilibration of the spinon is a bottleneck for the dynamics. After the birth of the quasiparticle peak, its height enhances by the construction of the low-energy spectrum of the rotor, which then lags behind the relaxation of the spinon.

**12:39PM L20.00008 Nonequilibrium Kondo physics in the Anderson impurity model: Auxiliary master equation approach<sup>1</sup>** , ANTONIUS DORDA, Graz University of Technology, MARTIN GANAHL, Perimeter Institute for Theoretical Physics, HANS GERD EVERTZ, WOLFGANG VON DER LINDEN, ENRICO ARRIGONI, Graz University of Technology — An accurate investigation of the evolution of the Kondo peak as a function of bias voltage is presented for the single impurity Anderson model (SIAM). We greatly enhance the capability of the recently introduced auxiliary master equation approach (AMEA) [1,2] by making use of matrix product states [3]. This allows us to obtain highly accurate spectral functions and observables for the SIAM at large values of the interaction and low temperatures  $T$ , well below the Kondo scale  $T_K$ . For  $T \approx T_K/4$  and  $T \approx T_K/10$  we find a clear splitting of the Kondo resonance into a two-peak structure at bias voltages just above  $T_K$ . A benchmark in the equilibrium case for  $T \approx T_K/4$  reveals a remarkably close agreement to the numerical renormalization group. This, together with the high flexibility and the applicability to various problems such as dynamical mean field theory [1,4,5], demonstrates the great potential of AMEA for correlated systems, both in nonequilibrium as well as in equilibrium situations.

**12:51PM L20.00009 Fixed Order Real-Time Simulation of Nonequilibrium Transport** , JONG HAN, University at Buffalo, SUNY — Finding a reliable formalism for an impurity model out of equilibrium, despite intense effort in recent years, is still one of the major obstacles in nonequilibrium quantum many-body theory. We note that the Keldysh formalism with the close-time contour has the statistical weight given by the non-interacting limit, which enables direct evaluation of perturbation series at a fixed order. The Green function expansions are carried out up to the sixth order of the Coulomb parameter in the Anderson impurity model out of equilibrium, and demonstrate how the self-energy evolves as the voltage bias increases. We discuss the remarkable cancellation between self-energy diagrams in equilibrium which justifies the low-order approximations, and further investigate the deviation of this behavior in nonequilibrium.

**1:03PM L20.00010 State of the Polaron: Criticality in the Spin Boson Model** , ZACH BLUNDEN-CODD, Imperial College London, AHSAN NAZIR, University of Manchester, ALEX CHIN, University of Cambridge — In strongly coupled open quantum systems it can become necessary to take into account the behaviour of environmental degrees of freedom more rigorously than is usual with standard weak coupling techniques. We investigate the use of a variational ansatz, making use of a multitude of coherent states, to obtain more precise information about the interaction between an open system and its environment. We provide a thorough study of the ground state of the ubiquitous spin boson model; presenting analytic and numerical results concerning the nature of its much debated quantum phase transition.

**1:15PM L20.00011 Quantum Phase Transitions detected by a local probe using Time Correlations and Violations of Leggett-Garg Inequalities** , FERNANDO GOMEZ, Universidad de los Andes, JUAN MENDOZA, University of Oxford, FERNEY RODRIGUEZ, Universidad de los Andes, CARLOS TEJEDOR, Universidad Autónoma de Madrid, LUIS QUIROGA, Universidad de los Andes — We introduce a new way of identifying quantum phase transitions of many-body systems by means of local time correlations and Leggett-Garg inequalities. This procedure allows to experimentally determine the quantum critical points not only of finite-order transitions but also those of infinite-size as the Kosterlitz-Thouless transition that is not always easy to detect with current methods. By means of an analytical calculation on a general spin-1/2 Hamiltonian, and matrix product simulations of one-dimensional  $XXZ$  and anisotropic  $XY$  models, we argue that finite-order quantum phase transitions can be determined by singularities of the time correlations or their derivatives at criticality. The same features are exhibited by corresponding Leggett-Garg functions, which remarkably indicate violation of the Leggett-Garg inequalities for early times and all the Hamiltonian parameters considered. In addition, we find that the infinite-order transition of the  $XXZ$  model at the isotropic point can be revealed by the maximal violation of the Leggett-Garg inequalities.

**1:27PM L20.00012 Scaling behaviors at discontinuous quantum transitions** , JACOPO NESPOLO, MASSIMO CAMPOSTRINI, Dipartimento di Fisica dell'Università di Pisa and INFN, Sez. di Pisa, ANDREA PELISSETTO, Dipartimento di Fisica di 'Sapienza' Università di Roma and INFN, Sez. di Roma I, ETTORE VICARI, Dipartimento di Fisica dell'Università di Pisa and INFN, Sez. di Pisa — First-order (or discontinuous) quantum phase transitions (FOQTs) are characterized by a vanishing energy gap and jumps in the values of some observables across the critical point in the thermodynamic limit. Unlike what happens at continuous transitions, the correlation lengths remain finite at FOQTs. Nevertheless, finite systems at FOQTs exhibit finite-size effects, in the form of a rounding and smoothing of the discontinuities. We show that a scaling theory, similar to the usual finite-size scaling, can be formulated at FOQTs, and that the relevant scaling variable is extremely sensitive to the choice of boundary conditions. We further consider the scaling effects due to the presence of spatial inhomogeneities, in analogy with trap-size scaling at continuous transitions. Our results are supported by numerical simulations on the ferromagnetic quantum Ising chain and on the  $q$ -state quantum Potts chain with  $q > 4$ . We provide FSS predictions for the energy gap and the magnetization of finite quantum chains, which can be relevant for quantum computation applications.

**1:39PM L20.00013 Order  $O(1)$  algorithm for first-principles transient current through open quantum systems**, KING TAI CHEUNG, ZHIZHOU YU, BIN FU, JIAN WANG, The University of Hong Kong — First principles transient current through molecular devices is known to be extremely time consuming with typical computational complexity  $T^3N^3$  where  $N$  and  $T$  are the dimension of the scattering system and the number of time steps respectively. Various algorithms have been developed which eventually brings the complexity down to  $cTN^3$ , a linear scaling in  $T$ , where  $c$  is a large coefficient comparable to  $N$ . Here we provide an order  $O(1)$  algorithm that reduces it further to  $c_1N^3 + c_2TN^2$  where  $c_1$  and  $c_2$  are  $\sim 50$  and  $0.1$  respectively. Hence for  $T < N$ , the transient calculation is independent of  $T$ , thus order  $O(1)$  is achieved. To make this happening four important ingredients are essential: (1). availability of exact solution based on non-equilibrium Green's function (NEGF) that goes beyond wideband limit; (2). the use of complex absorbing potential (CAP) so that all the pole of Green's function can be found; (3). the exact solution is separable between real space and time domain; (4). the exploit of Vandermonde matrix further reduces the scaling of  $TN^2$  to  $T\ln TN$  for  $T > N$ . Benchmark calculation has been done on graphene nanoribbons using Tight-binding (TB) Hamiltonian with a huge speed up factor of  $100T$ , confirmed the  $O(1)$  scaling.

**1:51PM L20.00014 Generalized non-equilibrium vertex correction method in coherent medium theory for quantum transport simulation of disordered nanoelectronics<sup>1</sup>**, JIAWEI YAN, YOUQI KE, School of Physical Science and Technology, ShanghaiTech University — In realistic nanoelectronics, disordered impurities/defects are inevitable and play important roles in electron transport. However, due to the lack of effective quantum transport method, the important effects of disorders remain poorly understood. Here, we report a generalized non-equilibrium vertex correction (NVC) method with coherent potential approximation to treat the disorder effects in quantum transport simulation. With this generalized NVC method, any averaged product of two single-particle Greens functions can be obtained by solving a set of simple linear equations. As a result, the averaged non-equilibrium density matrix and various important transport properties, including averaged current, disordered induced current fluctuation and the averaged shot noise, can all be efficiently computed in a unified scheme. Moreover, a generalized form of conditionally averaged non-equilibrium Green's function is derived to incorporate with density functional theory to enable first-principles simulation. We prove the non-equilibrium coherent potential equals the non-equilibrium vertex correction. Our approach provides a unified, efficient and self-consistent method for simulating non-equilibrium quantum transport through disorder nanoelectronics.

**2:03PM L20.00015 Efficient heat-bath sampling in Fock space<sup>1</sup>**, ADAM HOLMES, Laboratory of Atomic and Solid State Physics, Cornell University, HITESH CHANGLANI, University of Illinois at Urbana-Champaign, CYRUS UMRIGAR, Laboratory of Atomic and Solid State Physics, Cornell University — We introduce an algorithm for sampling many-body quantum states in Fock space. The algorithm efficiently samples states with probability approximately proportional to an arbitrary function of the second-quantized Hamiltonian matrix elements connected to the current state. We apply the new sampling algorithm to the recently-developed Semistochastic Full Configuration Interaction Quantum Monte Carlo method (S-FCIQMC), a semistochastic implementation of the power method for projecting out the ground state energy in a basis of Slater determinants. The heat-bath sampling requires modest additional computational time and memory compared to uniform sampling but results in newly-spawned weights that are approximately of the same magnitude, thereby greatly improving the efficiency of projection. A comparison in efficiency between uniform and approximate heat-bath sampling is performed on the all-electron nitrogen dimer at equilibrium in Dunning's cc-pVXZ basis sets with  $X \in \{D, T, Q, 5\}$ , demonstrating a large gain in efficiency that increases with basis set size.

**Session L21 GSCCM DCOMP DMP: Materials in Extremes: Energetic Materials** 320 - Tariq Aslam, Los Alamos National Laboratory

**11:15AM L21.00001 Modeling the anisotropic shock response of single-crystal RDX**, DARBY LUSCHER, Los Alamos National Laboratory — Explosives initiate under impacts whose energy, if distributed homogeneously throughout the material, translates to temperature increases that are insufficient to drive the rapid chemistry observed. Heterogeneous thermomechanical interactions at the meso-scale (i.e. between single-crystal and macroscale) leads to the formation of localized hot spots. Direct numerical simulations of mesoscale response can contribute to our understanding of hot spots if they include the relevant deformation mechanisms that are essential to the nonlinear thermomechanical response of explosive molecular crystals. We have developed a single-crystal model for the finite deformation thermomechanical response of cyclotrimethylene trinitramine (RDX). Because of the low symmetry of RDX, a complete description of nonlinear thermoelasticity requires a careful decomposition of free energy into components that represent the pressure-volume-temperature (PVT) response and the coupling between isochoric deformation and both deviatoric and hydrostatic stresses. An equation-of-state (EOS) based on Debye theory that defines the PVT response was constructed using experimental data and density functional theory calculations. This EOS replicates the equilibrium states of phase transformation from alpha to gamma polymorphs observed in static high-pressure experiments. Lattice thermoelastic parameters defining the coupled isochoric free energy were obtained from molecular dynamics calculations and previous experimental data. Anisotropic crystal plasticity is modeled using Rowan's expression relating slip rate to dislocation density and velocity. Details of the theory will be presented followed by discussion of simulations of flyer plate impact experiments, including recent experiments diagnosed with in situ X-ray diffraction at the Advanced Photon Source. Impact conditions explored within the experimental effort have spanned shock pressures ranging from 1-10 GPa for several crystallographic orientations. Simulation results will be used to motivate conclusions about the nature of dislocation-mediated plasticity in RDX, as well as, future directions to improve these models and quantitatively compare them to the average lattice response recorded with in situ X-ray diffraction.

**11:51AM L21.00002 Role of microstructure and thermal transport in determining the rate of hot spot growth in aluminized PBX**, KAUSHIK JOSHI, SANTANU CHAUDHURI, Univ of Illinois - Urbana — The mechanisms of initiation and propagation of a hot spot in non-ideal explosives with aluminum additives are poorly understood due to greater complexity introduced by the different thermal and mechanical behavior of the components. In aluminized composites such as PBXN-109, the binder, RDX and Aluminum phases have been studied separately. However, not much is known about deflection of hot spots in the microstructured composite. Especially, the role of adhesion, debonding and thermal conductivity of binder phase is critical in moderating the sensitivity of such interfaces. Using reactive molecular dynamics simulations, the primary binder interfaces in PBXN-109 was investigated. Depending on the temperature of the growing hot spot reaching an RDX or Al/Al<sub>2</sub>O<sub>3</sub> grain, the thermal conductivity and viscoplastic behavior of the binder interface determine the attenuation of reaction front and thermal shock leading the hot spot. Different mechanisms like melt-dispersion and failure of oxide layer for the release of Al in the hot spot regions remain underexplored to connect the chemistry to the microstructure. Although Al/Al<sub>2</sub>O<sub>3</sub>/RDX and Al/Al<sub>2</sub>O<sub>3</sub>/HTPB interfaces are chemically stable, the hot spot melts the Al<sub>x</sub>O<sub>y</sub> layers and create shear bands in aluminum domain due to thermomechanical strain created due to different thermal environment. In a shock-compressed microstructure without voids, the cohesive interaction and chemical composition of such interfaces for different phases of RDX will be presented.

**12:03PM L21.00003 An extreme pressure attenuation in metals from a miniaturized pyrotechnic train configuration<sup>1</sup>**, JACK YOH, BOHOON KIM, HYEONJU YU, Seoul National University, SEOUL NATIONAL UNIVERSITY TEAM — A pyrotechnic device that consists of donor/acceptor pair separated by a bulkhead relies on shock attenuation in metal and shock sensitivity of the energetic materials. Despite of its common use, full-scale numerical simulation of such explosive train configuration is seldom reported because the proper modeling of the entire process requires precise capturing of extreme pressure waves from the donor charge during its attenuation in the metal before triggering of an acceptor charge and the accurate material modeling of high strain rate dynamics of both reactive and inert solids. The considered train consists of HMX as donor, STS 304 as the bulkhead, and RDX as acceptor. The simulation of such multi-material configuration reveals the critical bulkhead thickness for successful initiation of a pyrotechnic device. Furthermore, the miniaturization of such system is considered by obtaining the distance to shock front sharpening for building an analytical theory of pressure attenuation in STS sample of microscale thickness, and a new shock Hugoniot data is provided from the laser-based shock experiment using such samples.

**12:15PM L21.00004 Mechanisms of laser-induced photocatalytic decomposition of high explosives**, ANATOLY MITROFANOV, ANTON ZVEREV, Kemerovo State University, Russia, SERGEY RASHKEEV, ROMAN TSYSHEVSKY, University of Maryland, MAIJA KUKLJA, National Science Foundation — Using laser irradiation for triggering explosive decomposition of high density energy materials opens up new opportunities in design of safe optical detonators by removing primary explosive from the devices. Precise tuning of sensitivity to initiation of detonation via photo-excitation appears challenging because all secondary explosives are insulators with the band gap of 4-8 eV. We will discuss our combined experimental and theoretical studies that suggest feasible mechanisms of photocatalytic decomposition of explosives triggered by the laser excitation with the energy of 1.17 - 2.3 eV and the wavelength of 1064-532 nm. The first approach considers tuning the optical absorption via the controlled modification of the electronic structure of the explosive-metal oxide interfaces. The second approach involves incorporating photoactive organic molecules in the crystalline matrix of the explosive material.

**12:27PM L21.00005 Emergent molecular theory of initiation of detonation: the effect of molecular and crystal structure on thermal stability of high density energy materials**, MAIJA KUKLA, National Science Foundation, ROMAN TSYSHEVSKY, ONISE SHARIA, University of Maryland — The sensitivity to detonation initiation of high density energy materials along with their performance are two most important criteria for choosing the best material for explosive formulations, booster engines, detonators, etc. After numerous experimental and theoretical attempts to develop a single parameter describing sensitivity of different classes of energetic materials, one concludes that the complexity of physical and chemical explosive properties cannot be trivialized. We report here the results of our theoretical and computational studies of thermal decomposition mechanisms and kinetics of five classes of EM: pentaerythritol tetranitrate (PETN), nitramine cyclotetramethylene-tetranitramine (HMX), diamino-dinitroethene (DADNE), bis-(nitrofurazano)-furoxane (BNFF) and benchmark triamino-trinitrobenzene (TATB). Our modeling reveals how the thermal stability depends on the molecular structure of the material and how the crystal structure may additionally hinder or catalyze decomposition reactions. We will also discuss an effect of crystalline defects on sensitivity and performance of materials.

**12:39PM L21.00006 Ignition Prediction of Pressed HMX based on Hotspot Analysis Under Shock Pulse Loading**, SEOKPUM KIM, CHRISTOPHER MILLER, Georgia Institute of Technology, YASUYUKI HORIE, (ret.) Air Force Research Lab, CHRISTOPHER MOLEK, ERIC WELLE, Air Force Research Lab, MIN ZHOU, Georgia Institute of Technology — The ignition behavior of pressed HMX under shock pulse loading with a flyer is analyzed using a cohesive finite element method (CFEM) which accounts for large deformation, microcracking, frictional heating, and thermal conduction. The simulations account for the controlled loading of thin-flyer shock experiments with flyer velocities between 1.7 and 4.0 km/s. The study focuses on the computational prediction of ignition threshold using James criterion which involves loading intensity and energy imparted to the material. The predicted thresholds are in good agreement with measurements from shock experiments. In particular, it is found that grain size significantly affects the ignition sensitivity of the materials, with smaller sizes leading to lower energy thresholds required for ignition. In addition, significant stress attenuation is observed in high intensity pulse loading as compared to low intensity pulse loading, which affects density of hotspot distribution. The microstructure-performance relations obtained can be used to design explosives with tailored attributes and safety envelopes.

**12:51PM L21.00007 The Dynamic Behaviors of Single Crystal RDX Under Ramp Wave Loading to 15GPa**, GUIJI WANG, JINTAO CAI, JIANHENG ZHAO, FENG ZHAO, GANG WU, FULI TAN, CHENGWEI SUN, institute of fluid physics — Based on high pulsed power generator CQ-4, the single crystal RDX explosive was researched along different crystal orientations under ramp wave loadings up to 15 GPa. The typical three-wave structures were obtained by means of laser interferometry PDV, which show the elastic-plastic transition and  $\alpha$  to  $\gamma$  phase transition. The ramp elastic limit (REL) and yield strength of RDX along 210 and 100 crystal orientations were respectively calculated and the results show obvious effects of crystal orientations for RDX. The ramp elastic limit  $\sigma_{IEL}$  of RDX along 210 orientation is 0.688-0.758GPa, and the  $\sigma_{IEL}$  of RDX along 100 is 1.039 -1.110 GPa. The  $\alpha$  to  $\gamma$  phase transformation characteristics were also analyzed based on the experimental data. The initial phase transition pressure for the two crystal orientation of RDX are about 3.5 to 4 GPa, which agree well with the data of about 4-5GPa given by MD simulation. The data directly validate the results given by Raman Spectrum under shock compression and static high pressure, which couldn't be observed by wave profiles. The experimental data can be used to verify and validate the new models of RDX under dynamic loading. Supported by NSFC of China under contract No.11327803 and 11176002

**1:03PM L21.00008 Experimental and numerical study of deformation modes of a pressed HMX-based explosive composition**, DIDIER PICART, JEROME VIAL, CEA DAM Le Ripault, PATRICE BAILLY, INSA Centre Val de Loire — Safety of industrial or military explosives is still studied to prevent inadvertent ignition of pressed HMX-based explosive compositions submitted to a low-velocity impact. Our aim is to determine the dissipative mechanisms leading to the local heating of the material. To observe the dissipative mechanisms, a reversed edge-on impact test has been developed. This test enables real-time observations of the microstructural scale. No friction is observed between the biggest HMX grains and the matrix (the smallest grains, the binder and the porosity). Plasticity of HMX grains is obtained as well as damage by micro-cracking. Meanwhile, a biphasic numerical representation (HMX grains and matrix) is used to mimic our material. A comparison between experimental observations and simulations is used to determine the yield stress of HMX. The behavior of the matrix has been determined to account for the effect of strain rate and damage. Lastly, a comparison between tests and simulations has highlighted (1) that heating should rather be located in the matrix than in the biggest HMX grains and (2) that the most likely heating mechanism is the friction of micro(or meso)-cracks lips.

**1:15PM L21.00009 Decomposition products of TATB under high static pressure.**, JONATHAN CROWHURST, ELISSAIOS STAVROU, JOSEPH ZAUG, Lawrence Livermore Natl Lab — We have investigated the decomposition products of 2,4,6-triamino-1,3,5-trinitrobenzene (TATB) at static pressures up to 50 GPa using Raman and IR absorption spectroscopy. Decomposition was driven by various continuous wave and pulsed laser drives. We compare decomposition behavior and products obtained at the different pressures. Preliminary results at lower pressures indicate the formation of carbon dioxide, nitrogen, amorphous carbon and possibly hydrogen. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344

**1:27PM L21.00010 Modified Gap Experiment and Simulation** , GERRIT SUTHERLAND, RICHARD BENJAMIN, U.S. Army Research Laboratory — Modified Gap Experiment hydrocode simulations and data are presented. The modified gap experiment is a variation of the large scale gap test (LSGT) experiment. A 50.8-mm diameter  $\times$  12.7-mm long disk of sample explosive replaces the confined sample and witness plate in the LSGT. Either a framing camera or a photonic Doppler velocimeter measures the free surface velocity. The free surface velocity is measured for varying levels of input pressure. The Plexiglas gap thickness controls the input pressure. Features of the free surface velocity versus input pressure curve show the pressure at which detonation and ignition thresholds occur. The amount of reaction in various regions of the sample is predicted by the simulations and compared to experiment. Additionally, the simulations will predict how the release waves traveling backward into the sample affect the amount of reaction in the sample. Further, simulations of a non-ideal explosive will predict the response of an explosive whose reaction zone length is on the order of the 12.7-mm sample length.

**1:39PM L21.00011 ABSTRACT WITHDRAWN —**

**1:51PM L21.00012 Secondary decomposition reactions in nitramines<sup>1</sup>** , IGOR SCHWEIGERT, U.S. Naval Research Laboratory — Thermal decomposition of nitramines is known to proceed via multiple, competing reaction branches [1], some of which are triggered by secondary reactions between initial decomposition products and unreacted nitramine molecules. Better mechanistic understanding of these secondary reactions is needed to enable extrapolations of measured rates to higher temperatures and pressures relevant to shock ignition. I will present density functional theory (DFT) based simulations of nitramines that aim to re-evaluate known elementary mechanisms [2,3] and seek alternative pathways in the gas and condensed phases. [1] S. Maharrey and R. Behrens, J. Phys. Chem. A, 109, 11236 (2005) [2] C. F. Melius and M. C. Piqueras, P. Combust. Inst., 29, 2863 (2002) [3] K. Irikura, J. Phys. Chem. A, 117, 2233 (2013)

**2:03PM L21.00013 Shock-induced decomposition of high energy materials: A ReaxFF molecular dynamics study<sup>1</sup>** , SUBODH TIWARI, ANKIT MISHRA, KEN-ICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Atomistic simulations of shock-induced detonation provide critical information about high-energy (HE) materials such as sensitivity, crystallographic anisotropy, detonation velocity, and reaction pathways. However, first principles methods are unable to handle systems large enough to describe shock appropriately. We report reactive-force-field ReaxFF simulations of shock-induced decomposition of 1, 3, 5-triamino-2, 3, 6-trinitrobenzene (TATB) and 1,1-diamino 2-2-dinitroethane (FOX-7) crystal. A flyer acts as mechanical stimuli to introduce a shock, which in turn initiated chemical reactions. Our simulation showed a shock speed of 9.8 km/s and 8.23 km/s for TATB and FOX-7, respectively. Reactivity analysis proves that FOX-7 is more reactive than TATB. Chemical reaction pathways analysis revealed similar pathways for the formation of N<sub>2</sub> and H<sub>2</sub>O in both TATB and FOX-7. However, abundance of NH<sub>3</sub> formation is specific to FOX-7. Large clusters formed during the reactions also shows different compositions between TATB and FOX-7. Carbon soot formation is much more pronounced in TATB. Overall, this study provides a detailed comparison between shock induced reaction pathway between FOX-7 and TATB.

**Session L22 DCOMP: Theory and Simulations of Strongly Correlated Systems with Disorder**

321 - Richard Scalettar, University of California, Davis

**11:15AM L22.00001 Magnetic moments and non-Fermi-liquid behavior in quasicrystals<sup>1</sup>** , ERIC ANDRADE, Instituto de Física Terica/UNESP — Motivated by the intrinsic non-Fermi-liquid behavior observed in the heavy-fermion quasicrystal Au<sub>51</sub>Al<sub>34</sub>Yb<sub>15</sub>, we study the low-temperature behavior of dilute magnetic impurities placed in metallic quasicrystals. We find that a large fraction of the magnetic moments are not quenched down to very low temperatures, leading to a power-law distribution of Kondo temperatures, accompanied by a non-Fermi-liquid behavior, in a remarkable similarity to the Kondo-disorder scenario found in disordered heavy-fermion metals.

**11:51AM L22.00002 The Knight shift anomaly in the disordered periodic Anderson model** , RAIMUNDO DOS SANTOS, NATANAEL COSTA, THEREZA PAIVA, Universidade Federal do Rio de Janeiro, NICHOLAS CURRO, RICHARD SCALETTAR, UC Davis — In some materials, the coherence temperature  $T^*$  signals the regime in which one has a heavy-electron fluid and 'dissolved' local moments. An experimental signature of  $T^*$  is provided by the Knight shift anomaly in NMR measurements. Further, the contribution of the heavy-electron fluid to the Knight shift,  $K_{\text{HF}}$ , displays universal character over a wide range of temperatures. An important probe of the physical mechanisms at play is the random substitution of say, La for Ce in CeRhIn<sub>5</sub>: this amounts to removing local moments at random sites, and one may wonder whether these universal features are sensitive to the presence of disorder. The Periodic Anderson Model (PAM) captures many aspects of heavy-fermion materials, so here we consider the two-dimensional PAM with a fraction  $x$  of the  $f$ -sites removed at random. Through Determinant Quantum Monte Carlo simulations we find that universality of  $K_{\text{HF}}$  persists even in the presence of disorder, which, in turn, allows us to establish that  $T^*$  decreases monotonically with  $x$ , in agreement with available experimental data. Our simulations also shed light into the low temperature behavior of the disordered PAM at low temperatures: the spin liquid phase of the local moments is suppressed upon dilution.

**12:03PM L22.00003 Strong correlations generically protect d-wave superconductivity against disorder** , SHAO TANG, V. DOBROSAVLJEVIĆ, Department of Physics and National High Magnetic Field Laboratory, Florida State University, E. MIRANDA, Campinas State University, Brazil — We address the question of why strongly correlated d-wave superconductors, such as the cuprates, prove to be surprisingly robust against the introduction of non-magnetic impurities. We show that, very generally, both the pair-breaking and the normal state transport scattering rates are significantly suppressed by strong correlations effects arising in the proximity to a Mott insulating state. We also show that the correlation-renormalized scattering amplitude is generically enhanced in the forward direction, an effect which was previously often ascribed to the specific scattering by charged impurities outside the copper-oxide planes.

**12:15PM L22.00004 Study of the Anderson localization in real materials using typical medium dynamical cluster approximation**, YI ZHANG, RYKY NELSON, Louisiana State Univ - Baton Rouge, HANNA TERLETSKA, University of Michigan, CONRAD MOORE, Louisiana State Univ - Baton Rouge, CHINEDU EKUMA, United States Naval Research Laboratory, KA-MING TAM, Louisiana State Univ - Baton Rouge, TOM BERLIJN, Oak Ridge National Laboratory, WEI KU, Brookhaven National Laboratory, JUANA MORENO, MARK JARRELL, Louisiana State Univ - Baton Rouge — We generalize the typical medium dynamical cluster approximation to multi-orbital disordered systems. Combining it with the first principals downfolding and unfolding methods to derive an effective low energy model, we apply our extended formalism to real materials where strong disorder exists. These include, e.g., the iron selenide superconductors  $K_xFe_{2-y}Se_2$  with Fe vacancies,  $Ga_{1-x}Mn_xN$  and S doped Si. By looking at the typical density of states, we study the mobility edge and the localization effects in these materials, which is useful to understand the mechanism of their insulating behavior. We find for example, that even the disorder associated with 12% vacancies in  $K_xFe_{2-y}Se_2$  together with the anisotropy is not sufficient to cause localization.

**12:27PM L22.00005 Rounding of the first-order phase transition in the four-color Ashkin-Teller model**, AHMED IBRAHIM, THOMAS VOJTA, Missouri Univ of Sci & Tech — The two-dimensional four-color Ashkin-Teller model is investigated by Monte Carlo simulations to analyze the effects of quenched disorder on the first-order phase transition. We show that the quenched disorder destroys the first-order phase transition and turns into a continuous one. We study the emerging critical behavior of the disordered Ashkin-Teller model by using a finite-size-scaling analysis and confirm it to be in the clean two-dimensional Ising universality class with universal logarithmic corrections. This concurs with perturbative renormalization-group predictions by Cardy. We discuss the universality of the arising critical behavior and we compare with earlier results in the literature.

**12:39PM L22.00006 Charge density waves in disordered media circumventing the Imry-Ma argument**, NORM TUBMAN, University of California, Berkeley, HITESH CHANGLANI, TAYLOR HUGHES, University of Illinois — Two powerful theoretical predictions, Anderson localization and the Imry-Ma argument, impose significant restrictions on which phases of matter can exist in the presence of even the smallest amount of disorder in one-dimensional systems. These predictions forbid conducting states and ordered states respectively. It was thus of great interest to find out that Anderson localization can indeed be circumvented in one dimensional systems in the presence of correlated disorder. In a similar manner, but for a different physical phenomenon, we show that the Imry-Ma argument can be circumvented resulting in the formation of stable ordered states in disordered one dimensional systems. We explicitly simulate a family of Hamiltonians of spinless fermions with correlated disorder, where we find that a charge density wave is stable up to a finite critical disorder strength. Having circumvented the Imry-Ma mechanism, we then investigate other mechanisms in which disordered systems can destroy an ordered state.

**12:51PM L22.00007 Entanglement Holographic Mapping of Many-Body Localized System by Spectrum Bifurcation Renormalization Group**, YI-ZHUANG YOU, University of Californian, Santa Barbara, XIAO-LIANG QI, Stanford University, CENKE XU, University of Californian, Santa Barbara — We introduce the spectrum bifurcation renormalization group (SBRG) as a generalization of the real-space renormalization group for the many-body localized (MBL) system without truncating the Hilbert space. Starting from a disordered many-body Hamiltonian in the full MBL phase, the SBRG flows to the MBL fixed-point Hamiltonian, and generates the local conserved quantities and the matrix product state representations for all eigenstates. The method is applicable to both spin and fermion models with arbitrary interaction strength on any lattice in all dimensions, as long as the models are in the MBL phase. In particular, we focus on the  $1d$  interacting Majorana chain with strong disorder, and map out its phase diagram using the entanglement entropy. The SBRG flow also generates an entanglement holographic mapping, which duals the MBL state to a fragmented holographic space decorated with small blackholes.

**1:03PM L22.00008 Disordered XYZ Spin Chain Simulations using the Spectrum Bifurcation Renormalization Group**, KEVIN SLAGLE, YI-ZHUANG YOU, CENKE XU, Univ of California - Santa Barbara — We study the disordered XYZ spin chain using the recently developed Spectrum Bifurcation Renormalization Group (SBRG) numerical method. With large disorder, the phase diagram of the eigenstates consists of three many body localized (MBL) spin glass phases separated by marginal MBL critical phases. We examine the critical phases of this model by probing the entanglement entropy and Edwards-Anderson spin glass order parameter. We also show how long-range mutual information can be used to distinguish these phases (Jian, Kim, Qi 2015).

**1:15PM L22.00009 Many-body Localization Transition in Rokhsar-Kivelson-type wave functions<sup>1</sup>**, XIAO CHEN, XIONGJIE YU, University of Illinois at Urbana-Champaign, GIL YOUNG CHO, Korea Advanced Institute of Science and Technology, BRYAN CLARK, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We construct a family of many-body wave functions to study the many-body localization phase transition. The wave functions have a Rokhsar-Kivelson form, in which the weight for the configurations are chosen from the Gibbs weights of a classical spin glass model, known as the Random Energy Model, multiplied by a random sign structure to represent a highly excited state. These wave functions show a phase transition into an MBL phase. In addition, we see three regimes of entanglement scaling with subsystem size: scaling with entanglement corresponding to an infinite temperature thermal phase, constant scaling, and a sub-extensive scaling between these limits. Near the phase transition point, the fluctuations of the Renyi entropies are non-Gaussian. We find that Renyi entropies with different Renyi index transition into the MBL phase at different points and have different scaling behavior, suggesting a multifractal behavior.

**1:27PM L22.00010 Computational Analysis of many-body localized phases beyond 1D**, BENJAMIN VILLALONGA CORREA, Department of Physics, University of Illinois at Urbana-Champaign, DAVID PEKKER, Department of Physics and Astronomy, University of Pittsburgh, BRYAN CLARK, Department of Physics, University of Illinois at Urbana-Champaign — Anderson localization can persist in the presence of finite interactions, giving rise to what is known as a many-body localized (MBL) phase. The need to access interior eigenstates makes their computational analysis hard for large system sizes. Recently, an MPS ansatz has been successfully applied to the study of long 1D chains in the MBL phase; however, higher dimensional systems remain largely inaccessible to computational methods. We explore a variational approach to overcome this limitation and report on two-dimensional MBL phases.

**1:39PM L22.00011 A tensor network approach to many-body localization<sup>1</sup>**, XIONGJIE YU, University of Illinois at Urbana-Champaign, DAVID PEKKER, University of Pittsburgh, BRYAN CLARK, University of Illinois at Urbana-Champaign — Understanding the many-body localized phase requires access to eigenstates in the middle of the many-body spectrum. While exact-diagonalization is able to access these eigenstates, it is restricted to systems sizes of about 22 spins. To overcome this limitation, we develop tensor network algorithms which increase the accessible system size by an order of magnitude. We describe both our new algorithms as well as the additional physics about MBL we can extract from them. For example, we demonstrate the power of these methods by verifying the breakdown of the Eigenstate Thermalization Hypothesis (ETH) in the many-body localized phase of the random field Heisenberg model, and show the saturation of entanglement in the MBL phase and generate eigenstates that differ by local excitations.

<sup>1</sup>Work was supported by AFOSR FA9550-10-1-0524 and FA9550-12-1-0057, the Kaufmann foundation, and SciDAC FG02-12ER46875.

**1:51PM L22.00012 Absence of diffusion in disordered spin-chains**, SNIR GAZIT, Physics Department, University of California at Berkeley, ILIA KHAIT, Physics Department, Technion, NORMAN YAO, Physics Department, University of California at Berkeley, ASSA AUERBACH, Physics Department, Technion — We study the dynamical properties of the one dimensional XXZ model at infinite temperature in the presence of quench disorder. This model is expected to exhibit a many body localization (MBL) transition at finite disorder. We compute the local dynamical spin correlation function using a non-perturbative continued fraction expansion. The expansion up to 15th order is sufficient to achieve convergence of our extrapolation scheme. We compare the continued fraction result to the exact diagonalization (ED) on 22 sites. The phase diagram is determined in the disorder-anisotropy plane. Our main finding is the emergence of sub-diffusive transport and absence of a diffusive behavior ( $\omega^{-1/2}$  at low frequencies) in the weak disorder regime. The lack of a true diffusive phase contrasts with previous results and expectations obtained from smaller system sizes. In addition, the MBL transition is determined to occur at lower values than those deduced by ED on finite systems. Lastly, the finite frequency-momentum dynamical structure factor is computed and we explore its space-time scaling behavior.

**2:03PM L22.00013 Pseudospin representation of the two-site Anderson-Hubbard model<sup>1</sup>**, RACHEL WORTIS, Trent University, MALCOLM KENNETT, Simon Fraser University — The state of an Anderson localized system can be described in terms of the occupation of a set of single-particle wave functions which are localized in space. When interactions are added, single-particle wave functions are no longer well defined, so what is a useful description of the state of a many-body localized system and what about it is localized? Given that any system with Hilbert-space dimension  $2^N$  may be described by an Ising-type Hamiltonian, it has been proposed that in a fully many-body localized system the Ising pseudospins in this representation may be chosen to be local. Actually constructing these spins is non-trivial. While a number of approaches have been proposed, few explicit examples exist and almost all work has been on spin systems. Here we present the Hamiltonian of a two-site Hubbard model with disorder and nearest-neighbor interactions written in terms of pseudospins, and we explore the form of these pseudospins and their evolution as a function of hopping amplitude.

**Wednesday, March 16, 2016 11:15AM - 2:15PM –**  
**Session L23 DMP DCOMP: Computational Materials Discovery and Design - Graphene and 2D Materials** 322 - Mahesh Neupane, Army Research Lab

**11:15AM L23.00001 Computational design and optimization of energy materials**, MARIA CHAN, Argonne National Laboratory — The use of density functional theory (DFT) to understand and improve energy materials for diverse applications – including energy storage, thermal management, catalysis, and photovoltaics – is widespread. The further step of using high throughput DFT calculations to design materials and has led to an acceleration in materials discovery and development. Due to various limitations in DFT, including accuracy and computational cost, however, it is important to leverage effective models and, in some cases, experimental information to aid the design process. In this talk, I will discuss efforts in design and optimization of energy materials using a combination of effective models, DFT, machine learning, and experimental information.

**11:51AM L23.00002 High-throughput prediction of novel two-dimensional materials**, NICOLAS MOUNET, PHILIPPE SCHWALLER, ANDREA CEPPELLOTTI, Ecole Polytechnique Federale de Lausanne, Switzerland, ANDRIUS MERKYS, Vilnius University, Lithuania, IVANO ELIGIO CASTELLI, MARCO GIBERTINI, GIOVANNI PIZZI, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne, Switzerland — As a crucial step towards the identification of novel and promising 2D materials, we provide here a large scale first-principles exploration and characterization of such compounds. More than 300,000 three-dimensional structures from several crystallographic databases are screened systematically by checking the absence of chemical bonds between adjacent layers, identifying close to 5,000 layered systems. Then DFT calculations of the van der Waals interlayer bonding are performed with automatic workflows, while systematically assessing the metallic, insulating or magnetic character of the materials obtained. Following full atomic and cell relaxations, phonon dispersions are computed as a first step towards the assessment of thermodynamic properties. Thanks to the AiiDA materials' informatics platform [1], and in particular its automatic workflow engine, database structure, sharing capabilities, and pipelines to/from crystallographic repositories, the systematic and reproducible calculation of these properties becomes straightforward, together with seamless accessibility and sharing. [1] G. Pizzi, A. Cepellotti, R. Sabatini, N. Marzari and B. Kozinsky, Comp. Mat. Sci. 111, 218 (2016).

**12:03PM L23.00003 New Monolayered Materials Exhibiting Unusual Electronic Properties<sup>1</sup>**, ALEJANDRO LOPEZ-BEZANILLA, IVAR MARTIN, Argonne Natl Lab, PETER B. LITTLEWOOD, Argonne Natl Lab & James Franck Institute, University of Chicago — Computationally based approaches are allowing to progress in the discovery and design of nano-scaled materials. Here we propose a series of new mono-layered compounds with exotic properties. By means of density functional theory calculations we demonstrate that the pentagonal arrangement of SiC<sub>2</sub> yields an inverted distribution of the p-bands which leads to an unusual electronic behaviour of the material under strain [J. Phys. Chem. C, 2015, 119 (33), pp 19469]. A different pentagonal arrangement of C atoms enables the formation of Dirac cones which, unlike graphene, exhibit a strain-mediated tunable band gap.

**12:15PM L23.00004 First-principles Study of Size and Edge Dependent Properties of MXene Nanoribbons<sup>1</sup>**, LIANG HONG, ROBERT KLIE, SERDAR OGUT, Univ of Illinois - Chicago — One-dimensional nanoribbons can be created with considerably different physical properties from their two-dimensional (2D) counterparts due to quantum confinement and surface effects. MXenes are a new class of 2D materials with many potential applications and have drawn significant attention. We perform first-principles calculations to explore the size and edge dependent properties of a wide range of MXene nanoribbons cut from 2D semiconducting MXenes. Our results suggest that semiconducting versus metallic nature as well as the size of the band gap for semiconducting MXene nanoribbons can be tuned as a function of size, chemical composition, and functional groups, which can be useful for future designs of MXene nanostructures with interesting electronic and optical properties.

**12:27PM L23.00005 First-principles study of 2D electride : Gadolinium carbide**, CHANDANI NADADASA, SEONG-GON KIM, SUNGHO KIM, Mississippi State University, Starkville, MS39762, SUNG WNG KIM, sungkyunkwan university, Suwon, Korea — Electrides are an exclusive class of ionic compounds in which some electrons are occupying crystal voids instead of attaching to specific atoms or bonds. Using first-principles density functional theory calculations, we study structural, electronic and magnetic properties of Gd<sub>2</sub>C. The theoretically predicted structure of Gd<sub>2</sub>C is in good agreement with the available experimental data. Energy band diagram of Gd<sub>2</sub>C shows that they are crossing the Fermi level. Projected electronic density of states plots indicate that the interstitial sites are the main contributor to the density of states at the Fermi level. Charge of individual atoms including interstitial site are obtained using Bader analysis. Magnetic properties of Gd<sub>2</sub>C is determined from magnetization density plots. Work functions of Gd<sub>2</sub>C are determined for (001) and (100) surfaces with the technique of macroscopic average of electrostatic potential with the Fermi energy of bulk.

**12:39PM L23.00006 Phase Transition between Black and Blue Phosphorenes: A Quantum Monte Carlo Study**, LESHENG LI, YI YAO, KYLE REEVES, YOSUKE KANAI, Univ of NC - Chapel Hill — Phase transition of the more common black phosphorene to blue phosphorene is of great interest because they are predicted to exhibit unique electronic and optical properties[1]. However, these two phases are predicted to be separated by a rather large energy barrier. In this work, we study the transition pathway between black and blue phosphorenes by using the variable cell nudge elastic band method combined with density functional theory calculation. We show how diffusion quantum Monte Carlo method can be used for determining the energetics of the phase transition and demonstrate the use of two approaches for removing finite-size errors. Finally, we predict how applied stress can be used to control the energetic balance between these two different phases of phosphorene. [1] Zhu, Zhen, and David Tománek. "Semiconducting layered blue phosphorus: A computational study." *Physical review letters* 112.17 (2014): 176802.

**12:51PM L23.00007 Induced Magnetization and Band Gap in Graphene-Like Materials: Towards Spintronics**, XUAN LUO, National Graphene Research and Development Center, JESSE CAI, Thomas Jefferson High School for Science and Technology, NGRD-TJHSST TEAM — We use first principles calculations incorporated within the ABINIT package to analyze the potential of two dimensional graphene-like materials in spintronics. Spintronics has potential to vastly improve upon and decrease the size of existing silicon based technology. We use four transition metals, Mn, Fe, Co, and Ni, to dope six graphene-like materials: graphene, boron nitride, silicene, molybdenum disulfide, molybdenum diselenide and black phosphorene. With the addition of a transition metal dopant, boron nitride, silicene, molybdenum disulfide, molybdenum diselenide and black phosphorene all displayed magnetization and a band gap in at least one configuration. Doped graphene, however, showed magnetization but no band gap. By using a hybrid graphene/boron nitride surface, or by placing graphene on top of boron nitride, magnetization and a band gap was observed. By altering the surface and the metal dopant, we have the ability to tune the band gap and magnetization. In conclusion, we find that all six graphene-like materials show promise in developing spintronics.

**1:03PM L23.00008 Anisotropic Dirac Fermions in Novel 2D Carbon and Silicon Allotropes**, ZHENHAI WANG, Stony Brook University, MINGWEN ZHAO, Shandong University, XIANG-FENG ZHOU, QIANG ZHU, Stony Brook University, XIAOMING ZHANG, Shandong University, HUAFENG DONG, ARTEM R. OGANOV, Stony Brook University, SHUMIN HE, PETER GRÜNBERG, Nanjing University of Posts and Telecommunications — Graphene, due to its unique Dirac cones with linear dispersion, exhibits a number of novel physics, such as high carrier mobility and quantum hall effect. Successful preparation of graphene in 2004 has inspired further searches for other 2D Dirac materials. Using systematic evolutionary structure searching, here we proposed one interesting type of 2D Dirac allotropes, which were named as 'phagraphene' [Nano. Lett. 15, 6182 (2015)] and 'siliceneet' respectively. Compared with the isotropic energy dispersion in graphene, the Dirac cones in these samples are direction-dependent. Further investigations proved that such anisotropic behaviors and the distorted Dirac cones are robust against external strain with tunable Fermi velocities. These predictions pave a new way to construct novel functional Dirac materials that might have potential applications in future.

**1:15PM L23.00009 Carbon Phosphide Monolayers: Novel 2D Materials**, GAOXUE WANG, RAVINDRA PANDEY, Michigan Technological Univ, SHASHI P. KARNA, US Army Research Laboratory — Monolayers of carbon phosphide are investigated using the particle swarm optimization and first-principles methods. The calculated results for  $\alpha$ -,  $\beta$ -, and  $\gamma$ - phases of carbon phosphide show novel properties including the presence of Dirac cones in the band structure. These configurations are composed of  $sp^2$  hybridized C atoms and  $sp^3$  hybridized P atoms in a hexagonal network with three-fold coordinated atoms.  $\alpha$ - and  $\beta$ - phases are semiconducting with highly anisotropic electronic and mechanical properties whereas  $\gamma$ -CP is semi-metallic with a high electron mobility. Our results suggest that the group IV-V binary monolayers can be considered as a new family of 2D materials for electronics and optoelectronics applications at nanoscale.

**1:27PM L23.00010 Influence of Metal Substrates on the Nucleation of Chemical Vapor Deposition Growth of Graphene<sup>1</sup>**, JIA LI, LIXIANG ZHONG, Graduate School at Shenzhen, Tsinghua University, Shenzhen 518055, People's Republic of China, YUANCHANG LI, National Center for Nanoscience and Technology, Beijing 100190, People's Republic of China — Using *ab initio* calculations, we systematically investigate the graphene nucleation on ten kinds of metal substrates that have been reported for the chemical vapor deposition growth of graphene. Noble metals (Cu, Ag and Au) and Co have a kinetic smallest graphene precursor, corresponding to the structural transition from linear chain to  $sp^2$  compact cluster. Ru, Rh, Ir and Pt have a energetic smallest graphene precursor, which is much larger than that in terms of kinetics. While for Ni and Pd, the carbon atoms trend to immerse inside the metals, resulting in the distinctively different growth mechanism from other metals. The different influence of metals is associated with their characterized carbon-metal and carbon-carbon coupling competition. The incorporation of five-membered rings into the  $sp^2$  compact cluster is the result of the competition between the curvature energy and the edge formation energy of graphene islands, and is suitable for the enlargement of graphene domain. And the effect of experimental conditions such as temperature, step or defects on the nucleation of graphene at different metal substrates is also discussed.

**1:39PM L23.00011 Stability and Superconductivity of N-(B-) Doped Graphene**, JIAN ZHOU, Virginia Commonwealth Univ, QIANG SUN, QIAN WANG, Peking University, PURU JENA, Virginia Commonwealth Univ — Superconductivity of two-dimensional honeycomb lattice has been predicted to possess a wealth of fascinating properties. For example, if graphene is heavily electron/hole doped, it exhibits high-temperature topological superconductivity. However, to achieve this, the carrier concentration will be too high, and graphene will be dynamically unstable. One possible route will be atomic substitution by B or N atoms, which, unfortunately, again is dynamic instability in nature. Using density functional theory combined with a global structural search and phonon dispersion calculations, we show that an ordered 50% N- (B-) doped graphene can be made energetically and dynamically stable by simultaneous doping carriers and applying biaxial tensile strain. By using a simple model, we show that tensile strain reduces the electrostatic interaction and moves imaginary phonon dispersion to be positive. Electron-phonon coupling calculations show that the N- (B-) doped graphene is superconducting with critical temperature reaching 66 K in the case of 50% N-doped graphene.

**1:51PM L23.00012 Next Generation Monolayer Structures of Group V Elements: Nitrogene and Antimonene**, ONGUN OZCELIK, Princeton University, OLCAY AKTURK, ENGIN DURGUN, SALIM CIRACI, Bilkent University — Based on first-principles density functional theory, we predict that nitrogen and antimony atoms can form single-layer, buckled honeycomb structures called nitrogene[1] and antimonene[2], which are rigid and stable even above room temperature. The 2D crystalline phase of nitrogen, which corresponds to a local minimum in the Born-Oppenheimer surface, is a nonmagnetic insulator with saturated pi bonds. When grown on a substrate like Al(111) surface or graphene, nitrogene binds weakly to substrates and hence preserves its free-standing properties, but it can easily be peeled off. Zigzag and armchair nanoribbons have fundamental band gaps derived from reconstructed edge states. These band gaps are tunable with size and suitable for the emerging field of 2D electronics. Nitrogene and antimonene form not only bilayer, but also 3D graphitic multilayer structures. Single-layer nitrogene can nucleate and grow on the armchair edges of hexagonal boron nitride. Starting from the pseudo-layered character of 3D bulk crystals of antimony, we also demonstrate the formation of monolayer antimonene structure which is similar to nitrogene. [1] Phys. Rev. B 92, 125420, 2015. [2] Phys. Rev. B 91, 235446, 2015.

**2:03PM L23.00013 Design of low work function materials using alkali metal-doped transition metal dichalcogenides**, SOL KIM, Pohang Univ of Sci & Tech, MAN YOUNG LEE, SEONG LEE, 4th RD Institute-4, Agency for Defense Development., SEUNG-HOON JHI, Pohang Univ of Sci & Tech — Engineering the work function is a key issue in surface science. Particularly, discovering the materials that have work functions less than 1eV is essential for efficient thermionic energy conversion. The lowest work function of materials, reported so far, is in a range of about 1eV. To design low work function materials, we chose  $\text{MX}_2$  ( $\text{M}=\text{Mo}$  and  $\text{W}$ ;  $\text{X}=\text{S}$ ,  $\text{Se}$  and  $\text{Te}$ ) as substrates and alkali metals ( $\text{Li}$ ,  $\text{Na}$ ,  $\text{K}$ ,  $\text{Rb}$  and  $\text{Cs}$ ) as dopants, and studied their electronic structures, charge transfer, induced surface dipole moment, and work function using first-principles calculations. We found that the charge transfer from alkali metals to  $\text{MX}_2$  substrates decreases as the atomic radius of alkali metals increases. Regardless of the amount of the charge transfer,  $\text{K}$  on  $\text{WTe}_2$  exhibits the biggest surface dipole moment, which consequently makes the surface work function the lowest. Also, we found a correlation between the binding distance and the work function.

**11:15AM L24.00001 Manipulating edge transport in quantum anomalous Hall insulators<sup>1</sup>**, ABHINAV KANDALA, IBM T J Watson Research Center/Pennsylvania State University — The quantum anomalous Hall (QAH) effect provides a path to obtain dissipation-less, one-dimensional (1D) edge states at zero magnetic field. Its recent experimental realization in magnetic topological insulator thin films lies at the overlap of several areas of condensed matter physics: dilute magnetic semiconductors, low dimensional electron transport and topologically non-trivial material systems. In this talk, we demonstrate how careful compositional and electrical tuning of epitaxial films of Cr-doped  $(\text{Bi,Sb})_2\text{Te}_3$  enables access to a robust zero-field quantized Hall effect, despite sample roughness [1] and low carrier mobility. In samples that show near-dissipation-less transport, we manipulate the intermixing between edge states and dissipative channels via a tilted-field crossover from ballistic 1D edge transport to diffusive transport [2]. This crossover manifests in a gate-tunable giant anisotropic magneto-resistance effect that we use as a quantitative probe of dissipation in our systems. Finally, we discuss experiments with mesoscopic channels of QAH insulator thin films, and discuss the effect of their modified magnetic anisotropy on edge transport. This work was carried out in collaboration with A. Richardella, C-X Liu, M. Liu, W. Wang, N. P. Ong, and N. Samarth. [1] A. Richardella, A. Kandala et. al APL Materials 3 (8), 083303 (2015) [2] A. **11:51AM L24.00002 Spin-orbit Josephson  $\phi_0$ -junction in nanowire quantum dots**, DANIEL SZOMBATI, STEVAN NADJ-PERGE, TU Delft, DIANA CAR, ERIK BAKKERS, TU Eindhoven, LEO KOUWENHOVEN, TU Delft — The Josephson effect describes supercurrent flowing through a junction connecting two superconducting leads by a thin barrier[1]. This current is driven by a superconducting phase difference  $\phi$  between the leads and it is strictly zero when  $\phi$  vanishes, due to the chiral and time reversal symmetry of the Cooper pair tunneling process[2]. Only if these underlying symmetries are broken the supercurrent for  $\phi = 0$  may be finite[3]. This corresponds to a ground state of the junction being offset by a phase  $\phi_0$ . Here, for the first time, we report such Josephson  $\phi_0$ -junction. Our realization is based on a nanowire quantum dot. We use a quantum interferometer device in order to investigate phase offsets and demonstrate that  $\phi_0$  can be controlled by electrostatic gating. Our results have possible far reaching implications for superconducting flux and phase defined quantum bits as well as for exploring topological superconductivity in quantum dot systems. 1. Josephson, *Phys. Lett.* 1, 251–253 (1962). 2. Yip, S.-K., De Alcantara Bonfim, O. F. & Kumar, P., *Phys. Rev. B* 41, 11214–11228 (1990). 3. **12:03PM L24.00003 Controlling the magnetic state of a carbon nanotube Josephson junction with the superconducting phase.**, RAPHAELLE DELAGRANGE, R. WEIL, A. KASUMOV, H. BOUCHIAT, R. DEBLOCK, LPS, CNRS, Univ. Paris-Sud, Orsay, France., D. J. LUITZ, LPT-IRSAMC, Universite de Toulouse and CNRS, Toulouse, France., V. MEDEN, Institut für Theorie der Statistischen Physik, RWTH Aachen University and JARA, Aachen, Germany — The Kondo effect is a many-body phenomenon that screens the magnetic moment of an impurity in a metal. The associated singlet state can be probed in a single impurity by electronic transport in a quantum dot (QD), here made of a carbon nanotube (CNT), which provides a localized electron between the two contacts. Using superconducting leads, one can investigate the competition between the Kondo effect and the superconductivity induced in the CNT. The superconductivity can destroy the Kondo singlet in favor of a magnetic doublet, leading to a sign reversal of the supercurrent in the S-CNT-S junction. This singlet-doublet transition depends on the Kondo temperature and the superconducting gap, as well as the position of the impurity level. We demonstrate experimentally that the superconducting phase difference across the QD can also control this magnetic transition. We use the measurement of the relation between the supercurrent and this superconducting phase as a tool to probe the transition. We show that it has a distinctly anharmonic behavior, that reveals the phase-mediated singlet to doublet transition, in good agreement with finite temperature quantum Monte Carlo calculations. We extract as well a phase diagram of the phase-controlled quantum transition at zero temperature.

**12:15PM L24.00004 Majorana fermions in topological Yu-Shiba-Rusinov chains and lattices with or without spin-orbit interaction.**, PANAGIOTIS KOTETES, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark — Recent spin polarized scanning tunneling microscopy (SPSTM) experiments in magnetic chains (S. Nadj-Perge et al., *Science* 2014) opened new routes for detecting the elusive Majorana fermions (MFs). Within the deep Yu-Shiba-Rusinov (YSR) limit we calculate [1] the spatially resolved tunneling conductance of topological ferromagnetic chains [2] measured by means of SPSTM. Our analysis reveals novel signatures of MFs arising from the interplay of their strongly anisotropic spin-polarization and the magnetization content of the tip. We investigate the occurrence and evolution of zero/finite bias peaks for a single or two coupled chains forming a Josephson junction, when a preexisting chiral symmetry controlling the number of MFs per chain edge is preserved or weakly broken. We also reveal alternative pathways for engineering MFs without spin-orbit interaction (SOI). On one hand, we highlight that antiferromagnetic YSR chains become topological by inducing an artificial SOI using external fields [3], while on the other, we pursue mechanisms for stabilizing magnetic textures and topological YSR lattices [4] following the self-organization principle for topological spiral chains [5]. Schön, *PRB* 90, 060507(R) (2014), [4] M. Schechter, P. Kotetes, K. Flensberg, and J. Paaske, [5] M. Schechter et al., arXiv:1509.07399.

**12:27PM L24.00005 Suppressed Conductance From Spin Selection Rules in F-CNT-F Quantum Dots<sup>1</sup>**, NIKOLAUS HARTMAN<sup>2</sup>, TYLER MORGAN-WALL, NINA MARKOVIC<sup>3</sup>, Johns Hopkins University — Conductance through a quantum dot can be suppressed due to spin selection rules governing the hopping of an additional electron onto an already-occupied quantum dot. Measurements of this effect in a carbon nanotube quantum dot with ferromagnetic contacts will be presented. Suppressed conductance peaks are observed in the Coulomb diamond plots at zero field and explained using spin selection rules. The pattern of suppressed peaks is observed to change with applied magnetic field as the spin ground state of the occupied quantum dot changes.

**12:39PM L24.00006 Hybrid Quantum Point Contact-Superconductor Devices Using InSb Nanowires**, STEPHEN GILL, JOHN JEFFREY DAMASCO, University of Illinois at Urbana-Champaign, DIANA CAR, ERIK BAKKERS, Eindhoven University of Technology, NADYA MASON, University of Illinois at Urbana-Champaign — Recent experiments using hybrid nanowire (NW)-superconductor (SC) devices have provided evidence for Majorana quasiparticles in tunneling experiments [1,2]. However, these tunneling experiments are marked by a soft superconducting gap, which likely originates from disorder at the NW-SC interface [3]. Hence, clean NW-SC interfaces are important for future Majorana studies. By carefully processing the NW-SC interface, we have realized quantized conductance steps in quantum point contacts fabricated from InSb NWs and superconducting contacts. We study the length dependence of ballistic behavior and the induced superconductivity in InSb NWs by quantum point contact spectroscopy. Additionally, we discuss how the transport in InSb NW-SC quantum point contacts evolves in magnetic field.

**12:51PM L24.00007 Flat band of midgap rotating surface states in 3D Dirac and Weyl semimetals under circularly polarized radiation**, JOSE GONZALEZ, RAFAEL A. MOLINA, Instituto de Estructura de la Materia (CSIC), Madrid, Spain — We report the investigation of novel surface states which develop when 3D Dirac or Weyl semimetals are placed under circularly polarized electromagnetic radiation. We find that a gap opens up from the hybridization between Floquet side bands, which leads to the appearance of midgap surface states in the form of evanescent waves decaying from the surface exposed to the radiation. We observe a phenomenon reminiscent of Landau quantization by which the midgap surface states get a large degeneracy proportional to the radiation flux traversing the surface of the semimetal. We show that all these surface states carry angular current, leading to a modulation of their charge that rotates with the same frequency of the radiation, which should manifest in the observation of a macroscopic chiral current in the irradiated surface.

**1:03PM L24.00008 Quantum coherence of mesoscopic stadia and wires coupled to the environment**<sup>1</sup>, YUANTAO XIE, J. J. HEREMANS, Virginia Tech, Physics Department, C. LE PRIOL, Ecole Polytechnique (France), Physics Department, S. VIJAYARAGUNATHAN, T. D. MISHIMA, M. B. SANTOS, The University of Oklahoma, Homer L. Dodge Dept. of Physics and Astronomy — Quantum phase coherence was measured in quasi-1D wires and in mesoscopic stadia connected to wide sample regions by wire-like necks, to investigate the effects of environmental and interdevice coupling on decoherence as contrasted to intrinsic materials properties. Measurements of quantum phase coherence lengths used weak-antiloocalization on nanolithographic InGaAs/InAlAs structures at 390 mK. For quantum wires, experiments show that longer wire lengths result in longer phase coherence lengths. The result is understood from the observation that longer wires average out decoherence introduced at the end sections by environmental coupling. For stadia with quantum-wire-like necks, stadium-wire coupling dominates decoherence in the stadia, rather than environmental coupling. Stadia with wider and shorter necks show longer phase coherence lengths. The result is understood from the observation that wider and shorter wires are geometrically similar to stadia, implying a stronger wave function hybridization between stadia and connecting necks and thus weaker decoherence from stadium-wire coupling. The work shows that geometry has to be taken into account in measured mesoscopic coherence.

**1:15PM L24.00009 Spin-polarized conductance anomalies in one-dimensional channels**, ALFREDO SANCHEZ, JEAN-PIERRE LEBURTON, Univ of Illinois - Urbana — We explain the emergence of conductance anomalies ( $\sim 0.3G_0$  and  $\sim 0.7G_0$ ,  $G_0 = 2e^2/h$ ) in one-dimensional channels by using an unrestricted Hartree-Fock approach with a three-dimensional Coulomb interaction. The latter predicts the onset of a pair of degenerate spin-polarized configurations (or channels), with specific conductance above a concentration-dependent threshold. The  $0.3G_0$  anomaly is a consequence of the 1D nature of the carrier density of states at the conductance onset, which weakens with temperature. Meanwhile, the second anomaly manifests itself as shoulders in the quantum conductance at the onset of concentration-dependent spin polarization, and becomes more pronounced as the temperature increases above 0 K, in agreement with experimental results. Our model also explains the dependence of the anomalies on drain and gate biases, longitudinal magnetic field, and channel length.

**1:27PM L24.00010 An interacting adiabatic quantum motor**, SILVIA VIOLA KUSMINSKIY, University Erlangen-Nürnberg, ANTON BRUCH, FELIX VON OPPEN, Freie Universität Berlin — We consider the effect of electron-electron interactions on the performance of an adiabatic quantum motor based on a Thouless pump operating in reverse. We model such a device by electrons in a 1d wire coupled to a slowly moving periodic potential associated with the classical mechanical degree of freedom of the motor. This periodic degree of freedom is set into motion by a bias voltage applied to the 1d electron channel. We investigate the Thouless motor with interacting leads modeled as Luttinger liquids. We show that interactions enhance the energy gap opened by the periodic potential and thus the robustness of the Thouless motor against variations in the chemical potential. We show that the motor degree of freedom can be described as a mobile impurity in a Luttinger liquid obeying Langevin dynamics with renormalized coefficients due to interactions, for which we give explicit expressions.

**1:39PM L24.00011 The Quantum Pinch Effect in Semiconducting Quantum Wires**, M.S. KUSHWAHA, Rice University — We investigate a two-component, cylindrical, quasi-one-dimensional quantum plasma subjected to a *radial* confining harmonic potential and an applied magnetic field in the symmetric gauge. It is demonstrated that such a system as can be realized in semiconducting quantum wires offers an excellent medium for observing the quantum pinch effect at low temperatures. An exact analytical solution of the problem allows us to make significant observations: surprisingly, in contrast to the classical pinch effect, the particle density as well as the current density display a *determinable* maximum before attaining a minimum at the surface of the quantum wire. The effect will persist as long as the equilibrium pair density is sustained. Therefore, the technological promise that emerges is the route to the precise electronic devices that will control the particle beams at the nanoscale<sup>1</sup>. 1. M.S. Kushwaha, Appl. Phys. Lett. 103, 173116 (2013).

**1:51PM L24.00012 Control of Nanofilament Structure and Observations of Quantum Point Contact Behavior in Ni/NiO Nanowire Junctions**<sup>1</sup>, SEAN OLIVER, George Mason University, JESSAMYN FAIRFIELD, SUNGHUN LEE, ALLEN BELLEW, Trinity College Dublin, IRIS STONE, George Mason University, LAURA RUPPALT, Naval Research Laboratory, JOHN BOLAND, Trinity College Dublin, PATRICK VORA, George Mason University — Resistive switching is ideal for use in non-volatile memory where information is stored in a metallic or insulating state. Nanowire junctions formed at the intersection of two Ni/NiO core/shell nanowires have emerged as a leading candidate structure where resistive switching occurs due to the formation and destruction of conducting filaments. However, significant knowledge gaps remain regarding the conduction mechanisms as measurements are typically only performed at room temperature. Here, we combine temperature-dependent current-voltage (IV) measurements from 15 - 300 K with magnetoresistance studies and achieve new insight into the nature of the conducting filaments. We identify a novel semiconducting state that behaves as a quantum point contact and find evidence for a possible electric-field driven phase transition. The insulating state exhibits unexpectedly complex IV characteristics that highlight the disordered nature of the ruptured filament while we find clear signs of anisotropic magnetoresistance in the metallic state. Our results expose previously unobserved behaviors in nanowire resistive switching devices and pave the way for future applications where both electrical and magnetic switching can be achieved in a single device.

**2:03PM L24.00013 Puzzling electron behavior analogous to the Braess paradox in a mesoscopic network<sup>1</sup>**, SÉBASTIEN TOUSSAINT, SÉBASTIEN FANIEL, FREDERICO MARTINS, IMCN/NAPS, Université catholique de Louvain, Belgium, MARCO PALA, IMEP-LAHC, Université Grenoble Alpes and CNRS, France, LUDOVIC DESPLANQUE, XAVIER WALLART, IEMN, UMR CNRS and UST, France, SERGE HUANT, HERMANN SELLIER, Institut Néel, Université Grenoble Alpes and CNRS, France, VINCENT BAYOT, BENOIT HACKENS, IMCN/NAPS, Université catholique de Louvain, Belgium — A counterintuitive behavior analogous to the Braess paradox is encountered in a two-terminal mesoscopic network patterned in a two-dimensional electron system (2DES) [1]. Decreasing locally the electron density of one channel in the network paradoxically leads to an increased network conductance. Our scanning gate microscopy experiments reveals this puzzling conductance variation, thanks to tip-induced localized modifications of electron flow throughout the network's channels at low temperature, in the ballistic and coherent regime of transport. We compare the amplitude of the measured anomalous conductance variation with conductance changes induced by other mechanisms at play in the mesoscopic network, such as interference phenomena between different paths, and Coulomb blockade due to disorder-induced localized states. The robustness of this puzzling behavior is inspected by varying the global 2DES density, magnetic field and temperature. [1] M. G. Pala *et al.*, Phys. Rev. Lett. 108, 076802 (2012).

## Wednesday, March 16, 2016 11:15AM - 2:15PM —

Session L25 DCMP: Superconductivity: Theory II 324 - Alexander Balatsky, Los Alamos National Laboratory

**11:15AM L25.00001 How the Mott and pseudogap states coalesce beneath the superconductor Dome**, ALEJANDRO CABO MONTES DE OCA<sup>1</sup>, ICIMAF, La Habana, Cuba, ALEJANDRO CABO-BIZET, CEADEN, La Habana, Cuba, VICTOR MARTINEZ, YOANDRI VIELZA, Dept. of Physics, University of Pernambuco, Recife, Brasil, COLLABORATION TEAM TEAM — Former results of a Tight-Binding (TB) model of CuO planes in La<sub>2</sub>CuO<sub>4</sub> are reviewed to underline their wider implications. It is noted that physical systems being appropriately described by the TB model can exhibit the main strongly correlated electron system (SCES) properties, when they are solved in the HF approximation, by also allowing crystal symmetry breaking effects and non-collinear spin orientations of the HF orbitals. In particular, it is argued how a simple 2D square lattice system of Coulomb interacting electrons can exhibit insulator gaps and pseudogap states, and quantum phase transitions as illustrated by the mentioned former works. These results allow to understand the nature of the observed quantum phase transition laying “beneath” the superconducting Dome. It corresponds to coalescence under hole doping increase, of an insulator ground state (with a highly degenerated spin order) with an excited pseudogap state, showing a lattice order symmetry breaking. The evolution of the band structure and Fermi surface with doping are determined.

**11:27AM L25.00002 Scattering rates and specific heat jumps in high- $T_c$  cuprates<sup>1</sup>**, JAMES STOREY, Victoria University of Wellington — Inspired by recent ARPES and tunneling studies on high- $T_c$  cuprates, we examine the effect of a pair-breaking term in the self-energy on the shape of the electronic specific heat jump. It is found that the observed specific heat jump can be described in terms of a superconducting gap, that persists above the observed  $T_c$ , in the presence of a strongly temperature dependent pair-breaking scattering rate. An increase in the scattering rate is found to explain the non-BCS-like suppression of the specific heat jump with magnetic field. A discussion of these results in the context of other properties such as the superfluid density and Raman spectra will also be presented.

<sup>1</sup>Supported by the Marsden Fund Council from Government funding, administered by the Royal Society of New Zealand

**11:39AM L25.00003 Skyrmion-induced Bound States in Superconductors<sup>1</sup>**, SHO NAKOSAI, RIKEN, SERGEY PERSHOGUBA, Nordia, ALEXANDER BALATSKY, Nordita, Los Alamos National Laboratory — We consider superconducting systems proximity-coupled to magnetic materials with skyrmion structures. Motivated by the progress in experiments which allows us to control the magnetic textures, we consider the case where a single skyrmion is floating in ferromagnetic background. We predict the skyrmion bound state is formed around the core of it. The results are obtained through the numerical calculation on the spin-polarized local density of states in the vicinity of the skyrmion core, which shows good agreement with T-matrix analysis. The bound states can be recognized as skyrmion-version of well-known Yu-Shiba-Rusinov states.

**11:51AM L25.00004 Theory of quantum fluctuating superconductivity in incoherent metals**, LUCA DELACRETAZ, Department of Physics, Stanford University, RICHARD DAVISON, Department of Physics, Harvard University, BLAISE GOUTERAUX, SEAN HARTNOLL, Department of Physics, Stanford University — Quantum superconducting fluctuations can be important in two-dimensional, disordered thin films. They lead to the appearance of a metallic state characterized by a non-zero resistivity. We construct an effective description of superfluid hydrodynamics where the phase of the order parameter is relaxed, due to Coulomb interactions or the motion of vortices for instance. We predict there should be a Drude-like or a cyclotron-like pole in the spectrum, and corresponding sharp peaks in the optical conductivity. In some cases the finite electrical conductivity in the phase-fluctuating metallic state is found to be related in a novel way to the thermal conductivity of the normal state.

**12:03PM L25.00005 Charge transfer insulators at half-filling in multiband models of cuprates<sup>1</sup>**, PETER MISTARK, CHRISTOPHER LANE, Northeastern University, HSIN LIN, National University of Singapore, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University — Self-consistent mean-field three-band and four-band Hubbard models are used to study the collapse of the Mott gap in doped cuprates. While no set of doping-independent parameters can explain the observed gaps for the entire doping range, the experimental results are consistent with a weakly doping dependent Hubbard U. A key finding is that, when the Cu-O splitting energy  $\Delta$  is large, the cuprates behave as Mott insulators. However, for small  $\Delta$ , the cuprates become charge transfer insulators.

**12:15PM L25.00006 Polar Kerr effect in high temperature cuprate superconductors<sup>1</sup>**, SUMANTA TEWARI, GIRISH SHARMA, Department of Physics and Astronomy, Clemson University, Clemson, SC, PALLAB GOSWAMI, VICTOR YAKOVENKO, Condensed Matter Theory Center, University of Maryland, College Park, MD, SUDIP CHAKRAVARTY, Department of Physics and Astronomy, University of California Los Angeles, Los Angeles, CA — A mechanism is proposed for the tantalizing evidence of polar Kerr effect in a class of high temperature superconductors the signs of the Kerr angle from two opposite faces of the same sample are identical and magnetic field training is non-existent. The mechanism does not break global time reversal symmetry, as in an antiferromagnet, and results in zero Faraday effect. It is best understood in a phenomenological model of bilayer cuprates, such as YBCO, in which intra-bilayer tunneling nucleates a chiral d-density wave such that the individual layers have opposite chirality. Although the presentation is specific to the chiral d-density wave, the mechanism may be more general to any quasi-two-dimensional orbital antiferromagnet in which time reversal symmetry is broken in each plane, but not when averaged macroscopically.

**12:27PM L25.00007 Dirac lines in the superconducting hyper-honeycomb lattice**, ADRIEN BOUHON, ANNICA BLACK-SCHAFER, Uppsala Univ — Motivated by the recent discovery of the hyper-honeycomb  $\beta$ -Li<sub>2</sub>IrO<sub>3</sub> studied in the context of Kitaev spin liquids, we investigate the possibility to realize superconductivity in the hyper-honeycomb lattice. Based on a t-J model we discuss the effect of the band structure and spin-orbit coupling on the most stable superconducting state. Using group theory we construct all symmetry allowed superconducting states and show that we naturally get Dirac line nodes protected by the non-symmorphic symmetries.

**12:39PM L25.00008 Radiation induced oscillating gap states of nonequilibrium superconductors**, HUIYING LIU, JUNREN SHI, Peking Univ — In recent years, non-equilibrium superconducting phenomena induced by light have drawn great interests. We study effects of a light radiation to a BCS superconductor. The phase transition are obtained from the analysis of self-oscillation conditions of the irradiated dynamical systems. We find an oscillating gap phase solution with a frequency not directly related to the radiation frequency but resulting from the asymmetry of electron density of states of the system. When such a superconductor is in contact with another superconductor, it will give rise to an alternating Josephson current. We further discuss the existence conditions and properties of this alternating gap phase solution and its interesting effects on experiments.

**12:51PM L25.00009 Transient Dynamics of d-wave Superconductors after a Sudden Excitation**, MARCO SCHIRO, CNRS, FRANCESCO PERONACI, MASSIMO CAPONE, SISSA — Motivated by recent ultrafast pump probe experiments on high-temperature superconductors, we discuss the transient dynamics of a d-wave BCS model after a quantum quench of the interaction parameter. We find that the existence of gap nodes, with the associated nodal quasiparticles, introduces a dissipation channel which makes the dynamics much faster than in the conventional s-wave model. For every value of the quench parameters, the superconducting gap rapidly converges to a stationary value smaller than the one at equilibrium. Using a sudden approximation for the gap dynamics, we find an analytical expression for the reduction of spectral weight close to the nodes, which is in qualitative agreement with recent experiments.

**1:03PM L25.00010 Chern mosaic: topology of chiral superconductivity in ferromagnetic adatom lattices<sup>1</sup>**, JOEL RONTYNNEN, TEEMU OJANEN, Low Temperature Laboratory, Aalto University — Recent experiments have demonstrated signatures of Majorana bound states in ferromagnetic atomic chains. We show that similar systems, extended to two dimensional geometry, may support chiral topological superconductivity with large Chern numbers. Our observation is based on the fact that magnetic adatoms on an s-wave superconductor bind subgap Shiba states, which can hybridize and form subgap energy bands with nontrivial topology. Such a Shiba lattice supports long-range hopping, leading to a complex, mosaic-like phase diagram with large Chern numbers. We analyze the incidence of different Chern numbers phases and the size of their energy gaps for various lattice geometries. Our findings reveal the studied system as one of the richest platforms of topological matter known to date.

**1:15PM L25.00011 Weak phase stiffness and nature of the quantum critical point in underdoped cuprates<sup>1</sup>**, WEI KU, YUCEL YILDIRIM, Brookhaven National Laboratory — We demonstrate that the zero-temperature superconducting phase diagram of underdoped cuprates can be quantitatively understood in the strong binding limit, using only the experimental spectral function of the “normal” pseudo-gap phase without any free parameter. In the prototypical (La<sub>1-x</sub>Sr<sub>x</sub>)<sub>2</sub>CuO<sub>4</sub>, a kinetics-driven d-wave superconductivity is obtained above the critical doping  $\delta_c \sim 5.2\%$ , below which complete loss of superfluidity results from local quantum fluctuation involving local p-wave pairs. Near the critical doping, a enormous mass enhancement of the local pairs is found responsible for the observed rapid decrease of phase stiffness. Finally, a striking mass divergence is predicted at  $\delta_c$  that dictates the occurrence of the observed quantum critical point and the abrupt suppression of the Nernst effects in the nearby region. \* Phys. Rev. B 92, 180501(R) (2015); Phys. Rev. X 1, 011011 (2011).

**1:27PM L25.00012 p-Orbital Density Wave with d Symmetry in High-Tc Cuprate Superconductors**, MASAHISA TSUCHIIZU, YUICHI YAMAKAWA, HIROSHI KONTANI, Nagoya University — Emergence of the nematic density wave is a fundamental unsolved problem in cuprate superconductors. To understand the origin of the nematicity, we employ the recently-developed functional renormalization-group method with high numerical accuracy, and discover the critical development of the p-orbital-density-wave (p-ODW) instability in the strong-spin-fluctuation region [1]. The obtained p-ODW state possesses the key characteristics of the charge ordering pattern in Bi- and Y-based superconductors, such as the wavevector parallel to the nearest Cu-Cu direction, and the d-symmetry form factor with the antiphase correlation between  $p_x$  and  $p_y$  orbitals in the same unit cell. From the beautiful scaling relation between the spin susceptibility and the p-ODW susceptibility, we conclude that the p-ODW is driven by the strong interference between spin and charge fluctuations. It is clarified that the strong charge-spin interference, which is the origin of the nematicity, is the hidden but significant characteristics of the electronic states in cuprate superconductors. [1] M. Tsuchiizu, Y. Yamakawa, and H. Kontani, arXiv:1508.07218.

**1:39PM L25.00013 Spectral properties of the two-dimensional t-J model near the Mott transition**, MASANORI KOHNO, International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Japan — The single-particle spectral function of the two-dimensional t-J model near the Mott transition is studied using cluster perturbation theory to clarify how the spectral-weight distribution transforms to that of the Mott insulator as the doping concentration decreases. Various anomalous features observed in cuprate high-temperature superconductors are collectively explained in the two-dimensional t-J model near the Mott transition [1] as in the two-dimensional Hubbard model [2]. The results imply that the spectral features are primarily related to the proximity of the antiferromagnetic Mott insulator, which has a low-energy spin-wave mode but no low-energy charge excitation, and to the presence of states characterized by different energy scales rather than to the presence of double occupancy, which is completely removed in the t-J model. The results are confirmed to remain almost unchanged as the cluster size is increased from 4×4 to 6×6 sites in cluster perturbation theory by using the non-Abelian dynamical density-matrix renormalization group method [1]. **1:51PM L25.00014 Monte Carlo Study of Competing Orders in a Nearly Antiferromagnetic Metal**, EREZ BERG, YONI SCHATTNER, Weizmann Institute of Science, MAX GERLACH, SIMON TREBST, University of Cologne — We study a two-dimensional lattice model of a metal on the verge of an antiferromagnetic transition. The model can be simulated using the quantum Monte Carlo technique with no sign problem. We compute the antiferromagnetic, superconducting, charge density wave, and pair density wave susceptibilities, as well as the superfluid density, across the phase diagram. Near the putative antiferromagnetic quantum critical point, we find a dome-shaped d-wave superconducting phase. The electronic density of states displays an opening of a gap at temperatures moderately above the superconducting  $T_c$ . Our results provide insights into the interplay of antiferromagnetism and unconventional superconductivity at intermediate to strong coupling.

**2:03PM L25.00015 TYPICAL MEDIUM DYNAMICAL CLUSTER APPROXIMATION FOR DISORDERED SUPERCONDUCTORS**<sup>1</sup>, ELISHA SIDDIQUI, Louisiana State University, HANNA TERLETSKA, University of Michigan, CHINEDU EKUMA, Naval Research Laboratory, NS VIDHYADHIRAJA, Jawaharlal Nehru Centre for Advanced Scientific Research, JUANA MORENO, MARK JARRELL, Louisiana State University — We study the effect of disorder on a three dimensional attractive Hubbard model using the typical medium dynamical cluster approximation with the Bogoliubov-de Gennes approach as a cluster solver. We explore the effects of disorder for a fixed interaction strength (U) on the diagonal and off-diagonal typical density of states. Using our results we construct a complete phase diagram in the disorder vs interaction (U) parameter space. As the disorder strength is increased, the pairing parameter or the off-diagonal typical density of states decreases and vanishes at a critical disorder strength while the spectral gap remains finite. This indicates the transition from a superconducting to a super-resistive phase. We observe that at small U the superconductor to super-resistive phase line bends down in the disorder vs interaction (U) parameter space. Also, we find that the superconducting order parameter first rises and then falls with increasing disorder in the small U regime. A further increase in the disorder strength causes the diagonal typical density of states to vanish at a critical value, indicating a transition from a super-resistive to the Anderson insulator phase.

**11:15AM L26.00001 First-principles Studies of the Optical Properties of Eu doped Barium Halides: From Storage Phosphor to Bright Scintillator**, ANDREW CANNING, Lawrence Berkeley National Laboratory, UC Davis, BHARAT MEDASANI, MAURO DEL BEN, GREGORY BIZARRI, Lawrence Berkeley National Laboratory — The Eu doped Ba mixed halide family BaBrX (X=F,Cl,Br,I) changes from being a widely used X-ray Storage Phosphor (BaBrF:Eu) to one of the brightest known gamma ray detector scintillators (BaBrI:Eu). To help understand these contrasting optical properties and guide in the design of new and improved scintillator detectors, in collaboration with experimental groups, we have performed first principles theoretical studies of these materials. In particular we have studied their electron and hole trapping mechanisms and how that can explain their very different optical properties.

**11:27AM L26.00002 Direct experimental characterization of photoemission charge-transfer satellites.**, CONAN WEILAND, National Institute of Standards and Technology, ABDUL RUMAIZ, National Synchrotron Light Source II, Brookhaven National Laboratory, JOSEPH WOICK, National Institute of Standards and Technology — Energy-loss satellites in photoelectron spectroscopy often arise due to different charge-transfer states in condensed matter systems. The specific characterization of these satellites, however, has been controversial, and different theoretical approaches may lead to contradictory characterizations. Here we demonstrate the ability of high energy resonant photoelectron spectroscopy to provide direct experimental evidence of the nature of charge transfer satellites. Analysis of the Ti 1s core line in SrTiO<sub>3</sub> reveals two satellites, located approximately 5 eV and 13 eV lower kinetic energy than the main line. High energy resonant photoelectron spectroscopy reveals that these two peaks originate from ligand 2p  $t_{2g}$  to metal 3d  $t_{2g}$  and ligand 2p  $e_g$  to metal 3d  $e_g$  charge-transfer excitations.

**11:39AM L26.00003 High harmonic generation based time resolved ARPES at 30 eV with 50 meV energy resolution**, TIMM ROHWER, EDBERT J. SIE, FAHAD MAHMOOD, NUH GEDIK, MIT — Angle-resolved photoelectron spectroscopy (ARPES) has emerged as a leading technique in identifying equilibrium properties of complex electronic systems as well as their correlated dynamics. By using femtosecond high harmonic generation (HHG) pulses, this technique can be extended to monitor ultrafast changes in the electronic structure in response to an optical excitation [1]. However, the broad bandwidth of the HHG pulses has been a major experimental limitation. In this contribution, we combine the HHG source with an off-axis Czerny-Turner XUV monochromator and a three-dimensional “ARTOF” photoelectron detector to achieve an unrivaled overall energy resolution of 50 meV in multiple harmonic energies. Moreover, the use of a stack of different gratings enables us to fine control both the photon energy and time vs. energy resolution to its particular needs. The performance of our setup is demonstrated by studies on the transition metal dichalcogenide IrTe<sub>2</sub> which undergoes a first-order structural transition and accompanied reconstruction of the band structure upon cooling without the characteristic opening of an energy gap [2]. [1] T. Rohwer et al., Nature 471 (2011) 490, [2] A. F. Fang et al., Scientific Reports 3 (2013) 1153

**11:51AM L26.00004 Resonant inelastic x-ray scattering study at the oxygen K-edge of corner-shared Sr<sub>2</sub>CuO<sub>3</sub> cuprate**, UMESH KUMAR, Department of Physics and Astronomy, University of Tennessee, Knoxville, USA, JUSTINE SCHLAPPA, European X-Ray Free Electron Laser Facility GmbH, Hamburg, Germany, KEJIN ZHOU, Diamond Light Source, Harwell Science and Innovation Campus, Didcot, Oxfordshire, SURJEET SINGH, Indian Institute of Science Education and Research, Pashan, Pune, India, VLADIMIR STROCOV, Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland, ALEXANDRE REVCOLEVSCHI, Universit Paris-Sud, Orsay Cedex, France, HENRIK RNNOW, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, STEVEN JOHNSTON, Department of Physics and Astronomy, University of Tennessee, Knoxville, USA, THORSTEN SCHMITT, Swiss Light Source, Paul Scherrer Institut, Villigen, Switzerland — We present a resonant inelastic x-ray scattering (RIXS) study at the oxygen K-edge of the spin-chain system Sr<sub>2</sub>CuO<sub>3</sub>. We investigate this system using small cluster exact diagonalization calculations for a microscopic model that considers all the orbitals of Cu and O in CuO<sub>3</sub>-unit cell. Using a canonical parameter set, we compute the XAS and RIXS spectra in comparison to the experiment. This allows us to identify the dd- and charge transfer excitations in the observed spectrum. We also infer the presence of several low energy excitations that may be related to phononic and/or magnetic excitations.

**12:03PM L26.00005 ABSTRACT WITHDRAWN —**

**12:15PM L26.00006 Temperature-Induced Electronic Structure Evolution of ZrTe5 Revealed by High resolution & Laser Angle-Resolved Photoemission Spectroscopy (ARPES)** , YAN ZHANG, CHENLU WANG, GUODONG LIU, GENFU CHEN, LI YU, SHAOLONG HE, LIN ZHAO, Institute of Physics, Chinese Academy of Science, CHUANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Science, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Science — The transition metal pentatellurides ZrTe5 have attracted consideration attention since the 70s, due to the unusual transport properties like resistivity peak at ~140K and the sign change of the Hall coefficient and thermopower. The origin of the most peculiar resistivity peak remains controversial. In this talk we will present high resolution angle-resolved photoemission (ARPES) study on the Fermi surface and band structure of ZrTe5, by using our high resolution ARPES system equipped with the VUV laser and the time-of-flight (TOF) electron energy analyzer. Upon cooling down, we found a gradual transition from hole-like band into electron-like band around the Brillouin zone center. Such an electron state transition forms the underlying physics for the abnormal transport properties. We will also comment on the possibility of a Dirac semimetal in ZrTe5.

**12:27PM L26.00007 Material simulation of charge carrier transport properties of polymer dielectrics** , MIKAEL UNGE, ABB Corporate Research SE 72178 Vsters, Sweden, THOMAS CHRISTEN, ABB Corporate Research Baden-Dttwil, Switzerland, CHRISTER TRNKVIST, ABB Corporate Research SE 72178 Vsters, Sweden, ABB CORPORATE RESEARCH TEAM — To understand electron and hole transport in solid material requires to know its electronic properties, i.e. the density of states (DOS) and whether the states are spatially localized or delocalized. The states closest to the band edges may be localized, states further away can be delocalized. This transition from localized to delocalized states determines the mobility edge, above the mobility edge the mobility is expected to be high. A real polymer is never perfect; it contains a number of oxidative states, bonding defects and molecular impurities. These imperfections yield electronic states that can appear in the band gap of the polymer, traps. Traps can be shallow, i.e. close to the band edges, from these states the charge carrier easily can jump to a state in the band edge or another shallow state. Other traps can be deep, in these states it is likely that the charge carrier remains and become immobile. All these properties related to the electronic structure of the polymer, including its defects, affects the conductivity of the polymer. Linear scaling Density Functional Theory has been applied to calculate electronic structure of amorphous polyethylene. In particular DOS, trap levels and mobility edges are studied.

**12:39PM L26.00008 Generality of anomalous broadening in  $\sigma$  peaks of low-Z compounds** , TERENCE JACH, JOHN VINSON, NIST, Gaithersburg, MD, MATTHIAS MUELLER, RAINER UNTERUMSBERGER, BURKHARD BECKHOFF, PTB, Berlin, Germany — X-ray emission spectra originating from N 1s core holes in some nitrates have displayed extreme broadening(> 4 eV) of a feature identified with the NO  $\sigma$  state. Simple band structure calculations of the valence band derived from this bond in a crystal show it to be quite narrow. Calculations of transitions that take into account many-body corrections in the  $GW$  approximation indicate that the final state has a large imaginary self-energy. We have discovered other compounds that demonstrate this effect experimentally, and we are able to show that they display giant lifetime fluctuations of a similar valence state. We have formulated a criterion of compounds for which this effect should be present.

**12:51PM L26.00009 Novel mechanism for displacive distortions in perovskites: On the orbital ordering transition in  $\text{KCuF}_3$**  , HUNTER SIMS, German Research School for Simulation Sciences, EVA PAVARINI, Institute for Advanced Simulation, Forschungszentrum Jülich, ERIK KOCH, German Research School for Simulation Sciences — The Mott insulating perovskite  $\text{KCuF}_3$  is considered the paradigmatic system with long-ranged orbital order and a cooperative Jahn-Teller distortion of the Cu-F octahedra. However, recent experiments have revealed that the JT-like distortions persist and even grow as temperature is increased. We show that neither superexchange nor Jahn-Teller can accurately describe this behavior—even qualitatively. Supported by GGA+U and model calculations, we explain this anomalous result in terms of a volume-driven lattice instability of purely ionic origin. We examine the effect of ionic size on this mechanism through the related systems  $\text{KCu}_{1-x}\text{Mg}_x\text{F}_3$ ,  $\text{KCrF}_3$ , and  $\text{ACuF}_3$ . As a non-electronic effect, this instability should allow for octahedral distortions even in closed-shell systems with cubic ground states, and we propose design guidelines for the realization of this high-temperature broken-symmetry phase experimentally.

**1:03PM L26.00010 Electrical Breakdown in Solids** , HAROLD HJALMARSON, FRED ZUTAVERN, Sandia National Laboratories, KENNETH KAMBOUR, Leidos, CHRIS MOORE, ALAN MAR, Sandia National Laboratories — During electron breakdown of a solid subjected to a large electric field, impact ionization causes growth of an electron-hole plasma. This growth process is opposed by Auger recombination of the electron-hole pairs. In our work, such breakdown is investigated by obtaining steady-state solutions to the Boltzmann equation. In these calculations, the carriers are heated by the electric field and cooled by phonon emission. Our results imply that breakdown may lead to high carrier-density current filaments. Conductive filaments have been observed in optically-triggered, high-power photoconductive semiconductor switch (PCSS) devices being developed at Sandia Labs. The relationship between the steady-state computed solutions to the observed filaments will be discussed in the presentation. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Administration under contract DE-AC04-94AL85000.

**1:15PM L26.00011 Hole conduction pathways in transparent amorphous tin oxides** , MATTHEW WAHILA, ZACHARY LEBENS-HIGGINS, NICHOLAS QUACKENBUSH, LOUIS PIPER, Dept. of Physics, Binghamton University, KEITH BUTLER, CHRISTOPHER HENDON, ARON WALSH, Dept. of Chemistry, University of Bath, GRAEME WATSON, School of Chemistry and CRANN, Trinity College Dublin — P-type transparent amorphous oxide semiconductors (TAOS) have yet to be sufficiently demonstrated or commercialized, severely limiting the possible device architecture of transparent and flexible oxide electronics. The lack of p-type amorphous oxide candidates mainly originates from the directional oxygen  $2p$  character of their topmost valence states. Previous attempts to create p-type oxides have involved hybridization of the O  $2p$  with metal orbitals, such as with  $\text{CuAlO}_2$  and its Cu  $3d$  - O  $2p$  hybridization. However, the highly directional nature of the utilized orbitals means that structural disorder inhibits hybridization and severely disrupts hole-conduction pathways. Crystalline stannous oxide ( $\text{SnO}$ ) and other lone-pair active post-transition metal oxides can have reduced localization at the valence band edge due to complex hybridization between the O  $2p$ , metal  $p$ , and spherical metal  $s$ -orbitals. I will discuss our investigation of structural disorder in  $\text{SnO}$ . Using a combination of synchrotron spectroscopy, and atomistic calculations, our investigation elucidates the important interplay between atomistic and electronic structure in establishing continuous hole conduction pathways at the valence band edge of transparent amorphous oxides.

**1:27PM L26.00012 Topological aspects of nonlinear optical responses** , TAKAHIRO MORIMOTO, University of California, Berkeley, NAOTO NAGAOSA, RIKEN CEMS, University of Tokyo — There are a variety of nonlinear optical effects including higher harmonic generations, photovoltaic effects, and nonlinear Kerr rotations. A recent remarkable progress in the photovoltaic effect is the high efficiency solar cell action in perovskite oxides without inversion symmetry. The crystal structure lacking inversion replaces the role of artificial structures such as p-n junctions in conventional solar cells. One of the proposed mechanisms for this phenomenon is the shift-current which is supported by a band structure lacking inversion and is related to the Berry connection of Bloch wavefunctions. Motivated by these, we explore topological aspects of the nonlinear optical responses. To this end, we employ the Keldysh method combined with the Floquet formalism, where effective band structures can be defined under an electric field periodic in time. This enables us to describe the shift-current, nonlinear Kerr rotation, photovoltaic effect, and the photo-induced change in the order parameters in a unified fashion. We connect these nonlinear optical responses to topological quantities involving the Berry connection and Berry curvature. It is found that vector fields defined with the Berry connections in the space of momentum and/or parameters govern the nonlinear responses.

**1:39PM L26.00013 A compact, low-loss, tunable phase shifter on defect mitigated dielectrics up to 40 GHz**, NATHAN ORLOFF, CHRISTIAN LONG, XIFENG LU, NIST, HARI NAIR, NATALIE DAWLEY, DARRELL SCHLOM, Cornell University, JAMES BOOTH, NIST — With the emergence of the internet-of-things and increased connectivity of modern commerce, consumers have driven demand for wireless spectrum beyond current capacity and infrastructure capabilities. One way the telecommunications industry is addressing this problem is by pushing front-end electronics to higher frequencies, introducing carrier aggregation schemes, and developing spectrum-sharing techniques. Some of these solutions require frequency agile components that are vastly different from what is in today's marketplace. Perhaps the most basic and ubiquitous component in front-end electronics is the phase shifter. Phase shifters are particularly important for compact beam-forming antennas that may soon appear in commercial technology. Here, we demonstrate a compact, tunable phase shifter with very low insertion loss up to 40 GHz on a defect mitigated tunable dielectric. We demonstrate performance compared to barium-doped strontium titanate phase shifters. Such phase shifters could potentially meet the stringent size and performance characteristics demanded by telecommunications industry, readily facilitating massive multiple-input multiple-output antennas in the next-generation of mobile handsets.

**1:51PM L26.00014 Electrode effects in dielectric spectroscopy measurements on (Nb+In) co-doped  $\text{TiO}_2$** <sup>1</sup>, DAVID CRANDLES, SUSAN YEE, Brock University, MAXIM SAVINOV, DIMITRI NUZHNYI, JAN PETZELT, STANISLAV KAMBA, Institute of Physics, Czech Academy of Sciences, JAN PROKES, Charles University in Prague — Recently, several papers reported the discovery of giant permittivity and low dielectric loss in (Nb+In) co-doped  $\text{TiO}_2$ . A series of tests was performed which included the measurement of the frequency dependence of the dielectric permittivity and ac conductivity of co-doped (Nb+In) $\text{TiO}_2$  as a function of electrode type, sample thickness and temperature. The data suggest that the measurements are strongly affected by the electrodes. The consistency between four contact van der Pauw dc conductivity measurements and bulk conductivity values extracted from two contact ac conductivity measurements suggest that the values of colossal permittivity are, at least in part, a result of Schottky barrier depletion widths that depend on electrode type and temperature.

**11:15AM L27.00001 Vestigial nematicity from spin and/or charge order in the cuprates**, LAIMEI NIE, AKASH MAHARAJ, Stanford University, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign, STEVEN KIVELSON, Stanford University — Nematic order (C4 rotation symmetry breaking) has manifested itself in a variety of materials in the cuprates family, yet its origin remains debatable, with possible links to lattice, charge, and spin degrees of freedom across different doping regimes. We propose an effective field theory of a layered system with incommensurate, intertwined spin- and charge-density wave (SDW and CDW) orders, each of which consists of two components related by C4 rotations. Using a variational free energy approach, we study the growth of the associated nematicity from partially melting those density waves by either increasing temperature or adding quenched disorder. Under the assumption that the zero-disorder, zero-interaction SDW transition temperature is higher than CDW at small doping (and vice versa for large doping), we find that for the general case with finite disorder and interactions there is a universal nematic transition across the entire doping range, accompanied by SDW and CDW transitions (or strong fluctuations at large enough disorder) at lower temperatures. We also discuss the issues concerning the difference between La-based materials and the other hole-doped cuprates.

**11:27AM L27.00002 Quantum critical dynamics of a magnetic impurity in a semiconducting host**<sup>1</sup>, NAGAMALLESWARARAO DASARI, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, 560064, India., SWAGATA ACHARYA, Department of Physics, Indian Institute of Technology Kharagpur, Kharagpur 721302, India., A TARAPHDER, Centre for Theoretical Studies, Indian Institute of Technology Kharagpur, Kharagpur 721302, India., JUANA MORENO, MARK JARRELL, Department of Physics & Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, N. S. VIDHYADHIRAJA, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, 560064, India., PROF. N. S. VIDHYADHIRAJA COLLABORATION, PROF. MARK JARRELL COLLABORATION, PROF. A. TARAPHDER COLLABORATION — We have investigated the finite temperature dynamics of the singlet to doublet continuous quantum phase transition in the gapped Anderson impurity model using hybridization expansion continuous time quantum Monte Carlo. Using the self-energy and the longitudinal static susceptibility, we obtain a phase diagram in the temperature-gap plane. The separatrix between the low-temperature local moment phase and the high temperature generalized Fermi liquid phase is shown to be the lower bound of the critical scaling region of the zero gap interacting quantum critical point. We have computed the nuclear magnetic spin-lattice relaxation rate, the Knight shift, and the Korringa ratio, which show strong deviations for any non-zero gap from the corresponding quantities in the gapless Kondo screened impurity case.

**11:39AM L27.00003 Corner entanglement as a probe of quantum criticality**<sup>1</sup>, WILLIAM WITCZAK-KREMPA, Harvard Univ, PABLO BUENO, KU Leuven, ROBERT C. MYERS, Perimeter Institute — The entanglement entropy in many gapless quantum systems in 2+1D receives a contribution from corners in the entangling surface. It is characterized by a universal function  $a(\theta)$  that depends non-trivially on the corner opening angle  $\theta$ . Focusing on a large family of quantum critical theories with emergent Lorentz invariance (CFTs), we argue that the smooth limit  $a(\theta \approx \pi)$  is entirely determined by the energy-density or stress tensor 2-point function coefficient. This explains recent results obtained via cutting edge simulations on the quantum critical Ising, XY and Heisenberg models. We also show how to extract the full thermal entropy of the quantum critical system using corner entanglement of the groundstate alone. \*\* Bueno, Myers, WK, Phys. Rev. Lett. (2015)

**11:51AM L27.00004 Deconfined quantum criticality beyond designer Hamiltonians**, THOMAS C. LANG, University of Innsbruck, RIBHU K. KAUL, University of Kentucky — The  $\text{SU}(6)$  symmetric generalization of the Hubbard model on the square lattice provides the simplest microscopic realization of the quantum phase transition from a Néel to a valence bond solid (VBS) ordered phase. By constructing dimensionless quantities such as ratios of the magnetic structure factor and valence bond correlations we are able to unambiguously determine the existence of weak, but robust antiferromagnetic order in the weak coupling regime and a plaquette VBS in the strong coupling limit. Furthermore these ratios provide a tool to accurately determine the (critical) point from both sides of the phase transition separating the two limits. Preliminary results suggest a direct continuous transition for which we extract estimates for the critical exponents and compare the scaling function with the  $\text{SU}(6)$  designer spin-models to investigate whether this quantum phase transition is compatible with the scenario of deconfined quantum criticality.

**12:03PM L27.00005 Fermion-induced quantum critical points: beyond Landau criterion**, HONG YAO, ZI-XIANG LI, YI-FAN JIANG, SHAO-KAI JIAN, Institute for Advanced Study, Tsinghua University, Beijing — According to Landau criterion, phase transitions must be first-order when cubic terms of order parameters in the Landau-Ginzburg free energy are allowed by symmetry. Here, from both renormalization group analysis and sign-problem-free quantum Monte Carlo simulations, we show that second-order quantum phase transitions can occur at such putatively-first-order quantum phase transitions in strongly-interacting Dirac semimetals in two spatial dimensions. Such type of Landau-criterion-violating quantum critical points are induced by massless fermionic modes at the quantum phase transitions. We call them “fermion-induced quantum critical points”. From Majorana-quantum-Monte-Carlo simulations and renormalization analysis, we find that the critical exponents at the Kekulé valence-bond-solid transition of the Dirac fermions on the honeycomb lattice are highly-nonclassical. We also discuss experimental signatures of the Kekulé quantum critical point which may be realized in graphene-like systems.

**12:15PM L27.00006 Nonlinear I-V Curve at a Quantum Impurity Quantum Critical Point**, HAROLD BARANGER, Duke Univ, CHUNG-HOU CHUNG, CHAO-YUN LIN, Chiao-Tung Univ and Natl Center for Theoretical Sciences, Taiwan, GU ZHANG, CHUNG-TING KE, GLEB FINKELSTEIN, Duke Univ — The nonlinear I-V curve at an interacting quantum critical point (QCP) is typically out of reach theoretically. Here, however, we provide a striking example of an analytical calculation of the full nonlinear I-V curve at the QCP. The system that we consider is a quantum dot coupled to resistive leads — a spinless resonant level interacting with an ohmic EM environment in which a QCP similar to the two-channel Kondo QCP occurs. Recent experiments studied this criticality via transport measurements: the transmission approaches unity at low temperature and applied bias when tuned exactly to the QCP (on resonance and symmetric tunnel barriers) and approaches zero in all other cases. To obtain the current at finite temperature and arbitrary bias, we write the problem as a one-dimensional field theory and transform from electrons in the left/right leads to right-going and left-going channels between which there is weak two-body backscattering. Drawing on dynamical Coulomb blockade theory, we thus obtain an analytical expression for the full I-V curve. The agreement with the experimental result is remarkable.

**12:27PM L27.00007 Finite-temperature Dynamics and Quantum Criticality in a Model for Insulating Magnets**, JIANDA WU, WANG YANG, CONGJUN WU, UC San Diego, QIMIAO SI, Rice University — Theoretical understanding of the finite-temperature dynamics in quantum critical systems is a challenging problem, due to the mixing of thermal and quantum fluctuations. Recently, neutron scattering experiments in the three-dimensional quantum dimer material  $\text{TiCuCl}_3$  under pressure tuning have mapped out the magnetic dynamics at finite temperatures in the quantum critical regime [1], thereby providing the opportunity for systematic understandings. In this work, we calculate the spin spectral function of an  $O(n)$  symmetric field theory using a field-theory procedure to two loops. We calculate the temperature dependence of the energy and damping rate of the spin excitations in the quantum critical regime, demonstrate a good agreement with the experimental results, and determine the parameter regime of the field theory that is appropriate for  $\text{TiCuCl}_3$ . From our calculations we can also suggest further experimental means to test the applicability of the underlying field theory in this and related systems. [1] P. Merchant, B. Normand, K.W. Krmer, M. Boehm, D. F. McMorrow and Ch. Regg, Nat. Phys. 10, 373 (2014).

**12:39PM L27.00008 Competing phases in the single-band Hubbard model on the 1/5-depleted square lattice**, MICHAEL MULANIX, EHSAN KHATAMI, San Jose State University — Using exact diagonalization of small clusters, we study the Hubbard model on the 1/5-depleted square lattice. This geometry, which arises in ordered-vacancy iron selenide superconductors, consists of 2 by 2 plaquettes connected through inter-plaquette bonds. Previous determinantal quantum Monte Carlo simulations have shown that the model at half filling displays multiple quantum phase transitions by tuning the ratio of hoppings for the two types of bonds, or by varying the interaction strength. We extend those results to the region away from half filling and study the magnetic, charge and pairing correlation functions for a wide range of interaction strengths and the hopping ratios. We find an interesting variation of the magnetic ordering wavevector as the density changes, particularly if the hopping ratio is tuned in favor of the intra-plaquette bond. We also find that, for small interaction strengths and at low densities, unexpected charge or pair density waves dominate.

**12:51PM L27.00009 Metallic quantum critical points with finite BCS couplings**, SHAMIT KACHRU, SRINIVAS RAGHU, Stanford University, GONZALO TORROBA, Centro Atómico Bariloche and CONICET, HUAJIA WANG, University of Illinois, Urbana-Champaign — We study the fate of superconductivity in the vicinity of a class of metallic quantum critical points obtained by coupling a Fermi surface to a critical boson. In such systems there is a competition between the enhanced pairing tendency due to the presence of long-range attractive interactions near criticality, and the suppression of superconductivity due to the destruction of the Landau quasiparticles. We show that there are regimes in which these two effects offset one another, resulting in a novel non-Fermi liquid fixed point with *finite*, scale invariant, BCS coupling. While these interactions lead to substantial superconducting fluctuations, they do not drive the system into a superconducting ground state. The metallic quantum critical fixed points are connected to the superconducting regime by a continuous phase transition. These results are established using a controlled expansion in the deviation from  $d = 3$  spatial dimensions, as well as in a large number  $N$  of internal flavors. We discuss the possible relevance of our findings to the phenomenon of superconducting domes condensing out of a non-Fermi liquid normal state near quantum critical points.

**1:03PM L27.00010 Metallic quantum critical ferromagnets: a quantum Monte Carlo calculation of Non-Fermi liquid exponents**, SAM RIDGWAY, CHRIS HOOLEY, St Andrews — We study a lattice field theory describing the quantum ferromagnetic transition of a metal in two spatial dimensions, using a sign-problem free quantum Monte Carlo algorithm. We provide evidence for the continuous nature of the transition, and calculate universal critical exponents that indicate non-Fermi liquid behaviour at the critical point.

**1:15PM L27.00011 Violation of hyperscaling at the Ising-nematic quantum critical point in a two-dimensional metal**, ANDREAS EBERLEIN, Harvard University, IPSITA MANDAL, Perimeter Institute for Theoretical Physics, SUBIR SACHDEV, Harvard University and Perimeter Institute for Theoretical Physics — Spatially isotropic critical quantum states in  $d$  spatial dimensions which have the hyperscaling property have an optical conductivity that scales as  $\omega^{(d-2)/z}$  for high frequencies  $\omega \gg T$ , where  $T$  is the temperature and  $z$  the dynamic critical exponent. We examine the Ising-nematic quantum critical point in  $d = 2$  using the fixed point theory by Dalidovich and Lee (Phys. Rev. B 88, 245106 (2013)) and compute the optical conductivity in an expansion in  $\epsilon = 5/2 - d$ . We show that hyperscaling is violated at this quantum critical point and discuss the scaling behaviour of the optical conductivity at  $T = 0$ .

**1:27PM L27.00012 Rescuing a Quantum Phase Transition with Quantum Noise**<sup>1</sup>, GU ZHANG, Duke Univ, EDUARDO NOVAIS, UFABC, HAROLD BARANGER, Duke Univ — We show that placing a quantum system in contact with an environment can enhance non-Fermi-liquid correlations, rather than destroying quantum effects as is typical. The system consists of two quantum dots in series with two leads; the highly resistive leads couple charge flow through the dots to the electromagnetic environment (noise). The similarity to the two impurity Kondo model suggests that there will be a quantum phase transition between a Kondo phase and a local singlet phase. However, this transition is destabilized by charge tunneling between the two leads. Our main result is that sufficiently strong quantum noise suppresses this charge transfer and leads to stabilization of the quantum phase transition. We present the phase diagram, the ground state degeneracy at the four fixed points, and the leading temperature dependence of the conductance near these points.

**1:39PM L27.00013 Anisotropic Non-Fermi Liquids**, SHOUVIK SUR, National High Magnetic Field Laboratory, and Florida State University, SUNG-SIK LEE, McMaster University, and Perimeter Institute for Theoretical Physics — We study non-Fermi liquids that arise at quantum critical points associated with spin (SDW) and charge density wave (CDW) transitions in metals with twofold rotational symmetry. We use the 'codimensional' regularization scheme, where a one-dimensional Fermi surface is embedded in  $3 - \epsilon$  dimensional momentum space. In three dimensions, quasilocal marginal Fermi liquids arise at the SDW and CDW critical points. Below three dimensions, a perturbative anisotropic non-Fermi liquid state is realized at the SDW critical point, where not only time but also different spatial coordinates develop distinct anomalous dimensions. The stable non-Fermi liquid exhibits an emergent algebraic nesting as the patches of the Fermi surface are deformed into a universal power-law shape near the hot spots. Due to the anisotropic scaling, the energy of spin fluctuations disperse with different power laws in different momentum directions. In contrast, at the CDW critical point, the perturbative expansion breaks down immediately below three dimensions as the interaction renormalizes the speed of charge fluctuations to zero within a finite renormalization group scale.

**1:51PM L27.00014 Universal quantum criticality in Hubbard models with massless Dirac dispersion**, YUICHI OTSUKA, SEIJI YUNOKI, RIKEN Advanced Institute for Computational Science, SANDRO SORELLA, SISSA - International School for Advanced Studies — We investigate the metal-insulator transition of two-dimensional interacting electrons with massless Dirac-like dispersion, describe by the Hubbard models on two geometrically different lattices: honeycomb and  $\pi$ -flux square lattices. By performing large-scale quantum Monte Carlo simulations followed by careful finite-size scaling analyses, we find that the transition from semi-metallic to antiferromagnetic insulating phases is continuous and evaluate the critical exponents with a high degree of accuracy for the corresponding universality class, which is described in the continuous limit by the Gross-Neveu model. We furthermore discuss the fate of the quasiparticle weight and the Fermi velocity across this transition.

**2:03PM L27.00015 Mott Quantum Criticality in the Anisotropic 2D Hubbard Model<sup>1</sup>**, BENJAMIN LENZ, SALVATORE R. MANMANA, THOMAS PRÜSCHKE, Institute for Theoretical Physics, University of Göttingen, FAKHER F. ASSAAD, MARCIN RACZKOWSKI, Institute for Theoretical Physics and Astrophysics, University of Würzburg — We present evidence for Mott quantum criticality in an anisotropic two-dimensional system of coupled Hubbard chains at half-filling. In this scenario emerging from variational cluster approximation and cluster dynamical mean-field theory, the interchain hopping  $t_{\perp}$  acts as control parameter driving the second-order critical endpoint  $T_c$  of the metal-insulator transition down to zero at  $t_{\perp}^c/t \simeq 0.2$ . Below  $t_{\perp}^c$  the volume of hole and electron Fermi pockets of a compensated metal vanishes continuously at the Mott transition. Above  $t_{\perp}^c$  the volume reduction of the pockets is cut off by a first-order transition. We discuss the relevance of our findings to a putative quantum critical point in layered organic conductors whose location remains elusive so far.

## Wednesday, March 16, 2016 11:15AM - 2:15PM – Session L28 DMP: Topological Crystalline Insulators 327 - Liang Fu, Massachusetts Institute of Technology

**11:15AM L28.00001 Searching for ideal topological crystalline insulators and topological superconductors in the Pb-Sn-In-Te system<sup>1</sup>**, GENDA GU, Brookhaven national laboratory — The discovery of 3D topological insulator materials and topological superconductor open up a new research field in the condensed matter physics. In order to search for the ideal topological insulator, topological crystalline insulator and topological superconductor, we have grown a large number of the single crystals of Pb-system (Pb-Sn-In-Te) topological crystalline insulator and their topological superconductor. We have measured the physical properties on these single crystals by various techniques. We have studied the effect of crystal growth condition, impurity and composition on the bulk electrical conductivity of these single crystals. We try to find out which composition and crystal growth condition is the best for the ideal topological insulator, topological crystalline insulator and topological superconductor. We have got the bulk topological superconductor with  $T_c = 5K$ .

**11:51AM L28.00002 Interplay of Dirac Fermions and Structural Deformations in Topological Crystalline Insulators**, ILIJA ZELJKOVIC, Boston College — Topological crystalline insulators (TCIs) are a new class of topological materials which harbor massless Dirac surface states (SS). Theory postulates that these SS are protected by crystalline symmetries, and that SS electrons can acquire a mass if these symmetries are broken. Moreover, this unique crystalline protection has led to a series of intriguing predictions of strain-generated phenomena, such as the appearance of pseudo-magnetic fields and topological phase transitions. In this talk, I will present our scanning tunneling microscopy (STM) investigations of two TCI systems: single crystals of  $Pb_{1-x}Sn_xSe$  and strained thin films of SnTe. Simultaneous imaging of the atomic and electronic structures in TCI single crystals reveals that a fraction of the Dirac electrons acquire mass due to a surface distortion that breaks a crystalline mirror symmetry. Furthermore, we discover that even in the absence of any symmetry breaking, local strain in TCI heteroepitaxial thin films can induce spatially dependent changes in the SS dispersion associated with the momentum-space shift of the Dirac nodes. Our experiments provide the first direct visualization of the effects of strain on the SS band structure in topological materials and suggest a novel pathway for manipulation of Dirac electrons via structural deformations.

**12:27PM L28.00003 Modulation of the surface states of SnTe films by doping impurities<sup>1</sup>**, CHI-HSUAN LEE, CHIH-KAI YANG, National Chengchi University — Electronic structures of SnTe films doped by impurities are investigated using density functional calculations. There are surface states crossing the Fermi level in bulk SnTe, which is a topological crystalline insulator. For thin SnTe films, however, an energy gap is opened due to quantum tunneling. The gap can be reduced and even eliminated by doping impurities at the surfaces of the films, all the while keeping the mirror symmetry associated with bulk SnTe intact. Impurities with magnetic moments, on the other hand, can destroy the mirror symmetry.

**12:39PM L28.00004 Nanomaterials of the topological crystalline insulators,  $Pb_{1-x}Sn_xTe$  and  $Pb_{1-x}Sn_xSe$ .**, MOHAMMED SAGHIR, ANNA SANCHEZ, STEVE HINDMARSH, STEVE YORK, GEETHA BALAKRISHNAN, University of Warwick — The study of topological insulators and their derivatives, in both 1D and 2D forms, has been the subject of great interest which has grown vastly in recent years. Topological insulators (TIs) and Topological Crystalline insulators (TCIs) exhibit exotic surface properties which are thought to be difficult to detect due to the surface signal being overwhelmed by that arising from the bulk of the material. As a result, by increasing the surface area to volume ratio, the signal from the surface states could be easier to investigate. We present results of the growth and characterisation of nanomaterials for the TCIs,  $Pb_{1-x}Sn_xTe$  and  $Pb_{1-x}Sn_xSe$ . Bulk crystals were used as starting materials for the growth, from which various morphologies of these TCIs were obtained. Nanowires of  $Pb_{1-x}Sn_xTe$  have been produced with a Sn composition of  $\sim x = 0.25$ , at which a transition from trivial to non-trivial insulator has been reported for bulk materials. The results obtained on the growth of nanomaterials of  $Pb_{1-x}Sn_xSe$  are also described, all of which were characterised using various x-ray diffraction and electron microscopy techniques.

**12:51PM L28.00005 Anomalous electronic states in  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  induced by hydrostatic pressure<sup>1</sup>**, TIAN LIANG, SATYA KUSHWAHA, QUINN GIBSON, R. J. CAVA, N. P. ONG, Princeton University — Dirac/Weyl semimetals have attracted strong interest. In Dirac semimetals  $\text{Cd}_3\text{As}_2$ ,  $\text{Na}_3\text{Bi}$ , the Dirac nodes split into Weyl states in a magnetic field, which leads to novel phenomena, such as ultrahigh mobility ( $10^7 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ) in  $\text{Cd}_3\text{As}_2$  [1], and the chiral anomaly in  $\text{Na}_3\text{Bi}$  [2]. The chiral anomaly appears as a negative longitudinal magnetoresistance. A new path to realize Weyl states is via the closing of the bulk gap in a system with broken inversion symmetry. As the gap is tuned, a Weyl semimetallic state is predicted to appear between two insulating phases [3]. We performed the hydrostatic pressure measurement for  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  and observed that the gap of the system closes under pressure and the system shows insulator to metal phase transition. Interestingly, in the metallic phase, we observed giant negative magnetoresistance as well as anomalous hall effect which onsets only in the quantum limit. We discuss the implication of these phenomena and their relation with the Berry curvature. [1] Liang, T. et al., *Nature Materials*, **14**, 280 (2015). [2] Xiong, J. et al., *Science*, **350**, 413 (2015). [3] Murakami, S et al., *Phys. Rev. B* **78**, 165313 (2008); *New J. Phys.* **9**, 356 (2007).

<sup>1</sup>Supported by MURI grant (ARO W911NF-12-1-0461), Army Research Office (ARO W911NF-11-1-0379), Gordon and Betty Moore Foundation (EPiQS Initiative GBMF4539)

**1:03PM L28.00006 Topological crystalline semimetals in non-symmorphic lattices without time-reversal symmetry**, YIGE CHEN, HEUNG-SIK KIM, HAE-YOUNG KEE, University of Toronto — Numerous efforts have been devoted to reveal exotic semimetallic phases with topologically non-trivial bulk and surface states in materials with strong spin-orbit coupling. Recent theoretical works on orthorhombic perovskite iridates  $\text{SrIrO}_3$  have indicated that non-symmorphic symmetry is crucial to protect a nodal line Fermi surface (FS) in addition to space-time inversion symmetry [C. Fang *et.al.*, *PRB* **92**, 081201(R) (2015), Y. Chen *et.al.*, *Nat. Commu.* **6**, (2015)]. In this work, we investigate possible topological semimetals in the absence of time-reversal symmetry. In principle, an anti-unitary operator, defined as a product of time-reversal and glide operators, can protect a four-fold or two-fold degenerate nodal FS. Indeed this happens in  $\text{SrIrO}_3$  with the magnetic field along a particular direction. A trivial gapped insulator can also occur due to a lack of such anti-unitary operation. This study shows that non-symmorphic crystals with multiple fractional lattice translations exhibit rich topological properties.

**1:15PM L28.00007  $\text{SU}(3)$  Quantum Hall Ferromagnetism in  $\text{SnTe}$** , CHENG-CHENG LIU, The University of Texas at Dallas, XIAO LI, University of Maryland, FAN ZHANG, The University of Texas at Dallas, A. H. MACDONALD, The University of Texas at Austin — The (111) surface of  $\text{SnTe}$  hosts one isotropic G-centered and three degenerate anisotropic M-centered Dirac surface states. We predict that a nematic phase with spontaneously broken  $C_3$  symmetry will occur in the presence of an external magnetic field when the  $N=0$  M Landau levels are  $1/3$  or  $2/3$  filled. The nematic state phase boundary is controlled by a competition between intravalley Coulomb interactions that favor a valley-polarized state, and weaker intervalley scattering processes that increase in relative strength with magnetic field. An in-plane Zeeman field alters the phase diagram by lifting the three-fold M Landau level degeneracy, yielding a ground state energy with  $2\pi/3$  periodicity as a function of Zeeman-field orientation angle.

**1:27PM L28.00008 Interplay of imperfections and surface states in topological crystalline insulators**, EVGENY PLEKHANOV, CEDRIC WEBER, Kings College, London — The conducting states, recently discovered at the surface of a special class of insulators topological insulators - are distinguished for their insensitivity to local and non-magnetic surface defects. Their behavior in the presence of magnetic impurities and macroscopic imperfections of the surface is puzzling and hard to analyze quantitatively. Here, we present a systematic study of the imperfections (magnetic impurities and deviations from perfect surface cleavage) in topological crystalline insulators of the tin telluride family by using realistic first-principles-derived tight-binding models. The theoretical framework proposed is quite general and easily permits the extensions to other TI families and impurity types. The influence of the strong local correlations of the impurity atoms on the topological states stability is also discussed within the frame of the Dynamical Mean Field Theory.

**1:39PM L28.00009 Space group constraints on weak indices in topological crystalline insulators**, DANIEL VARJAS, FERNANDO DE JUAN, Univ of California - Berkeley, YUAN-MING LU, The Ohio State University — In this work we derive constraints on weak indices of topological insulators and superconductors coming from space group symmetry. Weak indices are topological invariants of lower dimensional slices of the Brillouin zone, notable examples are the Chern numbers in class A and weak  $Z_2$  indices in class AII in 3D. The components of the weak indices form a momentum space vector that transforms in a simple fashion under space group symmetries, using results of momentum space crystallography we find the allowed values for each Bravais lattice. Nonsymmorphic symmetries, such as screw axes and glide planes pose additional constraints. Accounting for both of these we find that most space groups experience some restriction, to the extent that some cannot support nontrivial weak topological insulators and superconductors at all. This result puts a strong constraint on candidates in the experimental and numerical search for topological materials based on the lattice structure alone.

**1:51PM L28.00010 Quantized electric quadrupole moment in Topological Crystalline Insulators**, WLADIMIR A. BENALCAZAR, Department of Physics, Univ of Illinois - Urbana, B. ANDREI BERNEVIG, Department of Physics, Princeton University, TAYLOR HUGHES, Department of Physics, Univ of Illinois - Urbana — We define the quadrupole moment as a bulk topological quantity in 2-dimensional insulators. When protected by spatial symmetries, a non-trivial quadrupole with full open boundaries exhibits robust, quantized and corner-localized half-charges. Alternatively, the non-trivial quadrupole state manifests as an edge-localized non-trivial polarization (i.e. edge-localized 1-dimensional topological insulators) in systems with open boundaries along one direction but closed along the other. We characterize this phase and explore new phenomena, as well as generalizations of this moment to higher dimensions.

**2:03PM L28.00011 Temperature dependence of angle-resolved photoemission of the crystalline topological insulator  $\text{Pb}_{1-x}\text{Sn}_x\text{Se}(111)$** , OLIVER RADER, PARTHA S. MANDAL, Helmholtz-Zentrum Berlin, GUNTHER SPRINGHOLZ, GUNTHER BAUER, VALENTYN VOLOBUIEV, Johannes-Kepler-Universitt Linz, ANDREI VARYKHALOV, EVANGELOS GOLIAS, JAIME SNCHEZ-BARRIGA, Helmholtz-Zentrum Berlin — The system  $\text{Pb}_{1-x}\text{Sn}_x\text{Se}$  is a topological insulator protected by mirror symmetry. Angle-resolved photoemission investigations have so far been concentrating on (100) surfaces of bulk single crystals. Here, we systematically study (111) epitaxial films under variation of the Sn concentration (10

**Wednesday, March 16, 2016 11:15AM - 2:15PM —**  
Session L29 DCMP DMP: Two-Dimensional Topological Insulators: Heterostructures and Beyond 328 - Fan Zhang, University of Texas, Dallas

**11:15AM L29.00001 Topological Phases in Perovskite Oxide Heterostructures**, ROKYEON KIM, CCES, IBS & Seoul National University, JAEJUN YU, Seoul National University, HOSUB JIN, Ulsan National Institute of Science and Technology — Quantum spin Hall (QSH) insulator is a new state of matter characterized by gapless edge states and insulating bulk states. Because the edge states are topologically protected and therefore robust against non-magnetic perturbations, it has a potential to be utilized in spintronics devices. Quantum valley Hall (QVH) phase, on the other hand, is another class of topological state exhibiting valley-contrasting Berry curvature and spin splitting, which could yield novel transport properties, such as valley Hall effect and valley spin Hall effect. We propose a new kind of perovskite (111) heterostructures which can host both QSH and QVH phases with appropriate choices of composing elements. By carrying out first-principles calculations, we demonstrate that a Dirac cone emerges in a particular choice of heterostructure, and a sizable spin-orbit coupling turns the system into the QSH phase. In addition, the QVH phase with different Berry phases and spin textures in each valley is shown to be realized in the heterostructure with broken inversion symmetry. We propose that these perovskite heterostructures can provide a feasible platform for spintronics, valleytronics, and topological engineering of the two-dimensional electron system.

**11:27AM L29.00002 Structure of the Surface States at Topological Insulator-Semiconductor Interfaces<sup>1</sup>**, MAHMOUD M. ASMAR, DANIEL SHEEHY, ILYA VEKHTER, Louisiana State University — Topologically-protected surface states of three-dimensional topological insulators (TIs) are characterized by spin and momentum locking. In the simplest picture the emergent two dimensional semimetal displays opposite helicities around the point of degeneracy. Possible applications of TIs rely on forming interfaces with other materials, such as semiconductors or superconductors. In such heterostructures, the dispersion and quantum numbers of the surface states become not only dependent on bulk properties but also on the specifics of the boundaries between the TI and the material in contact. Making use of the three dimensional  $k \cdot p$  Hamiltonian describing TIs, and taking in to account surface potentials compatible with the symmetries of the TI and the semiconducting material, we find the effects of the latter on the energy-momentum dispersion and spin structure of the surface state and explore the consequences this may have on physical observables.

**11:39AM L29.00003 Interplay of Dirac surface states and magnetic fluctuations in topological insulator heterostructures**, HILARY M. HURST, DMITRY K. EFIMKIN, VICTOR GALITSKI, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland, College Park — We consider the proximity effect between Dirac states at the surface of a topological insulator and a ferromagnet with easy plane anisotropy, which is described by the XY-model and undergoes a Berezinskii-Kosterlitz-Thouless (BKT) phase transition. Classical magnetic fluctuations interacting with the surface states of a topological insulator can be described by an effective gauge field. This model can be mapped onto the problem of Dirac fermions in a random magnetic field, however this analogy is only partial in the presence of electron-hole asymmetry or warping of the Dirac dispersion which results in screening of magnetic fluctuations. We show that this proximity coupling leads to anomalous transport behavior of the surface states near the BKT transition temperature.

**11:51AM L29.00004 Transforming common III-V/II-VI insulating building blocks into topological heterostructure via the intrinsic electric polarization<sup>1</sup>**, ALEX ZUNGER, XIUWEN ZHANG, LEONARDO ABDALLA, QIHANG LIU, University of Colorado, Boulder — Currently known topological insulators (TIs) are limited to narrow gap compounds incorporating heavy elements, thus severely limiting the material pool available for such applications. We show how a heterovalent superlattice made of common semiconductor building blocks can transform its non-TI components into a topological heterostructure. The heterovalent nature of such interfaces sets up, in the absence of interfacial atomic exchange, a natural internal electric field that along with the quantum confinement leads to band inversion, transforming these semiconductors into a topological phase while also forming a giant Rashba spin splitting. We demonstrate this paradigm of designing TIs from ordinary semiconductors via first-principle calculations on III-V/II-VI superlattice InSb/CdTe. We illustrate the relationship between the interfacial stability and the topological transition, finding a “window of opportunity” where both conditions can be optimized. This work illustrates the general principles of co-evaluation of TI functionality with thermodynamic stability as a route of identifying realistic combination of common insulators that could produce topological heterostructures.

**12:03PM L29.00005 Emergence of quantum spin Hall and “half-topological” states at Graphene/TMDC heterostructures<sup>1</sup>**, DENIS KOCHAN, MARTIN GMTIRA, PETRA HÖGL, JAROSLAV FABIAN, University of Regensburg — We discuss orbital and spin-orbital proximity effects emerging in graphene deposited on a monolayer transition-metal dichalcogenides (TMDCs: MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub>, WSe<sub>2</sub>) and analyze the impact on spin transport in such graphene/TMDC heterostructures. First-principles investigations show that graphene on MoS<sub>2</sub>, MoSe<sub>2</sub>, and WS<sub>2</sub> has a topologically trivial band structure, while graphene on WSe<sub>2</sub> exhibits inverted bands. The essential low energy physics can be well described by a symmetry inspired realistic tight-binding Hamiltonian. We predict topologically protected helical edge states for graphene zigzag nanoribbons on WSe<sub>2</sub>, demonstrating the emergence of the quantum spin Hall effect. Our model also features “half-topological states”, which are protected against time-reversal disorder on one edge only. Unlike in pristine graphene, the proximity spin-orbit coupling in graphene on TMDCs is significant (orders of meV), making the predicted effect testable experimentally. References: M. Gmitra, D. Kochan, P. Högl, J. Fabian; Trivial and inverted Dirac bands, and emergence of quantum spin Hall states in graphene on transition-metal dichalcogenides, arXiv:1510.00166

**12:15PM L29.00006 Tunneling spectroscopy in engineered SrTiO<sub>3</sub> heterostructures**, ADRIAN SWARTZ, HISASHI INOUE, TYLER MERZ, Stanford University, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HAROLD HWANG, Stanford University and SLAC National Accelerator Laboratory — Despite decades of intense research on the topic, superconductivity in the dilute high- $k$  semiconductor SrTiO<sub>3</sub> (STO) has posed a long-standing problem. In light of the recent reports of unconventional 2D superconductivity in STO-based heterostructures, this problem deserves renewed attention in the bulk limit. Tunneling spectroscopy, which directly measures the electronic density of states, is a powerful tool to investigate the superconducting ground state as well as the relevant electron-phonon couplings. A limiting obstacle for employing this technique is the long depletion lengths formed when semiconducting SrTiO<sub>3</sub> is contacted with a metal in Schottky junctions, which obstructs access to the intrinsic bulk electronic properties. Here, using band alignment engineered planar tunneling junctions to minimize these long depletion lengths, we experimentally re-examine canonical tunneling experiments in Nb-doped STO. We discuss our results on the extraction of the electron-phonon coupling in SrTiO<sub>3</sub> and its relevance to the superconducting condensate.

**12:27PM L29.00007 Origins of conducting channel at  $\text{LaAlO}_3/\text{SrTiO}_3$  heterointerface investigated by *in situ* ARPES**, HYANGKEUN YOO, LUCA MORESCHINI, AARON BOSTWICK, Advanced Light Source, LBNL, ANDREW WALTER, Brookhaven National Laboratory, NSLS II, TAE WON NOH, Seoul National University, YOUNG JUN CHANG, University of Seoul, ELI ROTENBERG, Advanced Light Source, LBNL — The high-mobility conducting interface (CI) between  $\text{LaAlO}_3$  (LAO) and  $\text{SrTiO}_3$  (STO) has revealed many fascinating phenomena. But the formation mechanism of the CI has not been conclusively explained. Here, we investigated the CI formation between LAO and STO by *in situ* angle-resolved photoemission spectroscopy. By directly imaging the LAO polarity-induced built-in potential ( $V_i$ ) at each step of the LAO growth, we demonstrated that the  $V_i$  is proportional to the LAO thickness and the conducting interface is appeared above 3 unit cells of LAO. However, we found that the  $V_i$  and the critical thickness are strongly dependent on the amount of the surface oxygen vacancies controlled by the synchrotron ultraviolet-irradiation and the oxygen gas exposure. This indicates that the only polar catastrophe, theorized to explain the CI formation above a critical thickness, is not adequate. Instead, our results point to a decisive role played by the oxygen vacancy, and explain why the  $V_i$  and the critical thickness as reported in several works show some variation, rather than being a universal quantity.

**12:39PM L29.00008 Electronic structure study of UV photodoping evolution on the  $\text{TiO}_2$  terminated  $\text{SrTiO}_3$** , CHAOFAN ZHANG, SIMES, Stanford University, ZHONGKAI LIU, ZHUOYU CHEN, Department of Applied Physics, Stanford University, CHUNJING JIA, YAO WANG, SIMES, Stanford University, YANWU XIE, Department of Applied Physics, Stanford University, WEI LI, SIMES, Stanford University, JAMES. -J LEE, TAO JIA, SLAVKO REBEC, ERIC YUE MA, Department of Applied Physics, Stanford University, SUNGKWAN MO, ALS, Lawrence Berkeley National Laboratory, BRIAN MORITZ, ROBERT MOORER, SIMES, Stanford University, RUIHUA HE, Department of Physics, Boston College, T.-P. DEVEREAUX, SIMES, Stanford University, WORAWAT MEEVASANA, School of Physics, Suranaree University of Technology, Thailand, ZHIXUN SHEN, SIMES, Stanford University — The metallic two dimensional electron gas (2DEG) has been observed on the UV light irradiated bare  $\text{SrTiO}_3$  surface of various terminations ((001),(110),(111)) using angular resolved photoemission spectroscopy (ARPES). The study of electronic structure of 2DEG opens a window to study the complex physical properties on the bare  $\text{SrTiO}_3$  surface, such as the superconductivity, the high mobility and ferromagnetism. In this talk, we will show the clear polaron band that due to the electron phonon coupling formed at low carrier density gradually screening out and vanishing as the photodoping increases, instead of that, the quantum well states start appearing at higher doping level. Besides that, the upshifting of both the incoherent in-gap and deep valence states towards the Fermi level suggests a huge gap shrinking, which we believe to be the negative electronic compressibility on the 2DEG surface on  $\text{SrTiO}_3$ . All the properties mentioned above were observed at all the three terminations. We also would like to compare their behavior at similar carrier density range.

**12:51PM L29.00009 Quasi 2D electronic states with high spin-polarization in centrosymmetric  $\text{MoS}_2$  bulk crystals**, L. PLUCINSKI, M. GEHLMANN, PGI-6, FZ Juelich, G. BIHLMAYER, I. AGUILERA, PGI-1, FZ Juelich, E. MLYNCZAK, M. ESCHBACH, S. DÖRING, P. GOSPODARIC, PGI-6, FZ Juelich, B. KARDYNAL, PGI-9, FZ Juelich, S. BLÜGEL, PGI-1, FZ Juelich, C. M. SCHNEIDER, PGI-6, FZ Juelich — Time reversal dictates that nonmagnetic, centrosymmetric crystals cannot be spin-polarized. However, it has been recently shown that the electronic structure in these crystals can in fact show a high spin-polarization, as long as it is probed locally in real and in reciprocal space [1]. We present the first observation of this type of compensated polarization in  $\text{MoS}_2$  bulk crystals. Using spin- and angle-resolved photoemission spectroscopy we directly observed a spin-polarization of more than 65% for distinct valleys in the electronic band structure. By additionally evaluating the probing depth of our method we find that these valence band states at the K point in the Brillouin zone are close to fully polarized for the individual atomic trilayers of  $\text{MoS}_2$ , which is confirmed by our density functional theory calculations. Furthermore, we show that these states are almost completely confined within two dimensions. Our findings prove that these highly desired properties of  $\text{MoS}_2$  can be accessed without thinning it down to the monolayer limit. Our results are accessible at the pre-print server: M. Gehlmann et al., arXiv:1510.04101 (2015). [1] X. Zhang, Q. Liu, J.-W. Luo, A. J. Freeman, and A. Zunger, Nat. Phys. 10, 381 (2014).

**1:03PM L29.00010 Dirac State in Giant Magnetoresistive Materials<sup>1</sup>**, Y. WU, N.H. JO, Ames Laboratory & Iowa State University, M. OCHI, RIKEN Center for Emergent Matter Science & Tohoku University, L. HUANG, D. MOU, T. KONG, E. MUN, L. WANG, Y. LEE, S. L. BUD'KO, P. C. CANFIELD, Ames Laboratory & Iowa State University, N. TRIVEDI, Ohio State University, R. ARITO, RIKEN Center for Emergent Matter Science & Tohoku University, A. KAMINSKI, Ames Laboratory & Iowa State University — We use ultrahigh resolution, tunable, vacuum ultraviolet laser-based angle-resolved photoemission spectroscopy (ARPES) to study the electronic properties of materials that recently were discovered to display titanic magnetoresistance. We find that that several of these materials have Dirac-like features in their band structure. In some materials those features are “ordinary” Dirac cones, while in others the linear Dirac dispersion of two crossing bands forms a linear object in 3D momentum space. Our observation poses an important question about the role of Dirac dispersion in the unusually high, non-saturating magnetoresistance of these materials.

**1:27PM L29.00012 Topological protection from random Rashba spin-orbit backscattering: Ballistic transport in a helical Luttinger liquid<sup>1</sup>**, HONG-YI XIE, Rice Univ, HEQIU LI, Zhejiang University, YANG-ZHI CHOU, MATTHEW FOSTER, Rice Univ — Rashba spin-orbit coupling enables irrelevant backscattering in a time-reversal symmetric helical Luttinger liquid (HLL). We study the Landauer conductance  $G$  of a HLL in the presence of random Rashba coupling as well as the density-density (Luttinger) interaction. We prove that the transport is purely ballistic ( $G = e^2/h$ ) at any temperature due to the topology. The solution involves a unitary transformation that corresponds to a spin-1/2 in a random, two-component time-dependent magnetic field that preserves the projection of the spin along one fluctuating component (integrable dynamics). Our result is exact for a fixed realization of disorder, and avoids difficulties that arise in disorder-averaged perturbative calculations such as bosonization. We compare the HLL with random Rashba coupling to the Dyson model describing an ordinary spinless quantum wire with particle-hole symmetry, which exhibits non-ballistic transport even at zero temperature.

**1:39PM L29.00013 Detection of topological states in two-dimensional Dirac systems by the dynamic spin susceptibility**, MASAAKI NAKAMURA, Department of Physics, Ehime University, AKIYUKI TOKUNO, Centre de Physique Theorique, Ecole Polytechnique/College de France — We discuss dynamic spin susceptibility (DSS) in two-dimensional (2D) Dirac electrons with spin-orbit interactions to characterize topological insulators. The imaginary part of the DSS appears as an absorption rate in response to a transverse AC magnetic field, just like an electron spin resonance experiment for localized spin systems. We found that when the system is in a static magnetic field, the topological state can be identified by an anomalous resonant peak of the imaginary part of the DSS as a function of the frequency of the transverse magnetic field  $\omega$ . This anomalous peak is related to a transition between two Landau levels close to the Fermi level, which is not allowed in the trivial state. In the absence of the static magnetic field, the imaginary part of the DSS becomes a continuous function of  $\omega$  with a threshold frequency  $\omega_c$ . In this case, the topological and the trivial phases can also be distinguished by the values of  $\omega_c$  and by the line shapes. Thus the DSS is an essential and an experimentally observable physical quantity to characterize the topological insulators.

**1:51PM L29.00014 Magnetic moment coupled to a helical edge can make weak correlations seem strong**, JUKKA VAYRYNEN, Yale University, FLORIAN GEISSLER, University of Würzburg, LEONID GLAZMAN, Yale University — We study the effect of a localized magnetic moment on the helical edge electron transport. The spin flips caused by the moment can be effective in the electron backscattering. We evaluate the resulting differential conductance as a function of temperature  $T$  and applied bias  $V$  for any value of  $V/T$ . At temperatures  $T$  above the Kondo temperature, the deviation of the conductance from its quantized value displays a power-law temperature dependence,  $\delta G \propto T^{-\alpha}$ . We show that the Luttinger liquid effects with  $3/4 < K < 1$  may lead to a small exponent  $\alpha < 1/2$ . Values of  $K$  close to 1 correspond to weakly-correlated electrons. Our results provide an alternative interpretation of the recent experiment by Li et al. [1] where a power-law behavior of the conductance was attributed to strong correlation effects with the value of  $K$  fine-tuned close to  $1/4$ .

**2:03PM L29.00015 Chiral exciton in the topological insulator  $\text{Bi}_2\text{Se}_3$** <sup>1</sup>, HSIANG-HSI KUNG, MARYAM SALEHI, XUEYUN WANG, NIKESH KOIRALA, MATTHEW BRAHLEK, ALEXANDER LEE, SANG-WOOK CHEONG, SEONGSHIK OH, GIRSH BLUMBERG, Department of Physics & Astronomy, Rutgers University — Materials with novel band structures can host “chiral excitons”, where the exciton emission preserves the helicity of the excitation photon, as recently demonstrated in transition metal dichalcogenide monolayers<sup>2,3</sup>. Here, we report the observation of a highly polarized photoluminescence peak, which is due to chiral exciton emission in the topological insulator  $\text{Bi}_2\text{Se}_3$ . Surprisingly, the energy of the emission is centered at 2.26 eV, much higher than the 0.3 eV bulk band gap of  $\text{Bi}_2\text{Se}_3$ . The excitation profile shows maximum polarization around 2.60 eV excitation, suggesting the chiral exciton is due to interband transition between the topological surface states and a bulk band. We demonstrate that the polarization of the exciton emission is insensitive to temperature and  $\text{Bi}_2\text{Se}_3$  film thickness, providing a convenient and robust platform for optoelectronic applications.

Session L30 DMP: Functional Defects in Oxide Heterostructures 329 - Hanghui Chen, Columbia University

**11:15AM L30.00001 Structural and electronic response via oxygen vacancy control in  $\text{SrFeO}_3$  heterostructures**, ALEX KRICK, EUN JU MOON, AMANDA HUON, STEVEN MAY, Drexel University — The electronic and structural properties of complex perovskite oxide thin films are often directly influenced by their oxygen vacancy concentration. Here, we investigate epitaxial films of  $\text{SrFeO}_3$ , which exhibits a variety of structural and electronic phases as a function of oxygen content. The ability to control these functional properties via temperature or external fields is not present in conventional semiconductors and is attractive from an application perspective. As-grown films are oxidized using a post-growth anneal in dilute ozone, yielding metallic behavior consistent with bulk  $\text{SrFeO}_3$ . X-ray diffraction and temperature dependent resistivity collected at different stages of oxidation and reduction reveal minute structural transformations that yield large changes in electronic behavior due to oxygen loss.

**11:27AM L30.00002 A new kind of line defect in  $\text{NdTiO}_3$  perovskite**<sup>1</sup>, MEHMET TOPSAKAL, JONG SEOK JEONG, PENG XU, BHARAT JALAN, RENATA WENTZCOVITCH, ANDRE MKHOYAN, University of Minnesota — We report an observation of a new line defect in strained  $\text{NdTiO}_3$  perovskite. Aberration-corrected analytical scanning transmission electron microscopy and first-principles calculations are used to characterize its atomic structure and electronic properties. The defect represents a shift and rotation of the core Ti-O-Nd unit accommodating the deficiency of Ti-O units in neighboring columns and strain. The core of the defect has considerably different electronic properties resulting from Ti being in different oxidation states. This observation closes the dimensionality gap between previously observed point and planar defects in complex oxides needed to accommodate the alterations of stoichiometry and strain. This new line defect should also exist in other multi-valent perovskites, and could open a new avenue for tailoring unexpected and highly-desirable electronic properties.

**11:39AM L30.00003 Interplay of oxygen vacancies and electronic correlations in  $\text{SrVO}_3$** <sup>1</sup>, STEFFEN BACKES, AARAM J. KIM, Institut für Theoretische Physik, Universität Frankfurt, FRANK LECHERMANN, Institut für Theoretische Physik, Universität Hamburg, HARALD O. JESCHKE, Institut für Theoretische Physik, Universität Frankfurt, MARCELO J. ROZENBERG, Laboratoire de Physique des Solides, Université Paris-Sud, ANDRES F. SANTANDER SYRO, CSNSM, Université Paris-Sud and CNRS/IN2P3, ROSER VALENTI, Institut für Theoretische Physik, Universität Frankfurt — We investigate the role of oxygen vacancies in  $\text{SrVO}_3$  within LDA+DMFT (density functional theory combined with dynamical mean-field theory). We show that, in addition to the usual  $t_{2g}$  lower Hubbard band, oxygen vacancies are responsible for an additional peak around  $-1$  eV of V  $3d_{z^2}$  orbital character, which is not present in the bulk system without vacancies. We discuss our results in the light of recent angle-resolved photoemission (ARPES) experiments.

**11:51AM L30.00004 Strain induced defects and charge state transitions in oxides**, ULRICH ASCHAUER, University of Bern — It recently became apparent that bi-axial strain in coherent epitaxial perovskite oxide thin films or heterostructures can not only be accommodated by changes in structural parameters such as bond lengths or octahedral-rotation angles, but also by the formation of point defects. The redox reactions accompanying the formation of anion and cation vacancy defects lead to local volume changes, which facilitate the formation of either defect species under bi-axial strain. In this talk we will, after a general introduction to the phenomenon, use density functional theory (DFT) calculations to explore the generality of this concept for perovskite oxides and binary rock-salt oxides and put an emphasis on defects in different charge states. Moreover we will discuss the interaction of defects with ferroelectric domain walls, leading to novel functionalities in strained thin films.

**12:27PM L30.00005 Antisite defects at oxide interfaces**<sup>1</sup>, HANGHUI CHEN, ANDREW MILLIS, Columbia Univ — We use ab initio calculations to estimate formation energies of cation (transition metal) antisite defects at oxide interfaces and to understand the basic physical effects that drive or suppress the formation of these defects. We find [1] that antisite defects are favored in systems with substantial charge transfer across the interface, while Jahn-Teller distortions and itinerant ferromagnetism can prevent antisite defects and help stabilize atomically sharp interfaces. Our results enable identification of classes of systems that are more and less susceptible to the formation of antisite defects and motivate a range of experimental studies and further theoretical calculations to further explicate the oxide interface systems. [1] H. Chen and A. J. Millis, arXiv:1509.06643, (2015).

**12:39PM L30.00006 Metal-Insulator Transition and Weak Localization in Oxygen Vacancy Doped  $\text{BaSnO}_{3-\delta}$  Thin Films<sup>1</sup>**, KOUSTAV GANGULY, ABHINAV PRAKASH, JONG SEOK JEONG, K. ANDRE MKHOYAN, BHARAT JALAN, CHRIS LEIGHTON, University of Minnesota — We present detailed temperature-dependent electronic transport in oxygen vacancy doped  $\text{BaSnO}_3$  films grown on  $\text{MgO}(001)$ ,  $\text{LaAlO}_3(001)$ , and  $\text{GdScO}_3(110)$  using high pressure oxygen sputter deposition. Various modes of high-resolution X-ray diffraction and scanning transmission electron microscopy confirm phase-pure, close to stoichiometric, smooth, epitaxial  $\text{BaSnO}_3(001)$ . [1] As-grown films are insulating, but can be made conductive with *n*-type carriers via vacuum annealing, resulting in 300 K Hall mobilities up to  $35 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$  at  $510^{19}$  carriers per  $\text{cm}^3$ . [1] Film thickness, reduction temperature, and substrate (*i.e.* lattice mismatch) have been systematically varied, enabling study of the insulator-metal transition, and, in particular, 2D weak localization at low temperatures. The results provide significant insight into the active transport mechanisms in  $\text{BaSnO}_3$  films. [1] Ganguly *et al.* APL Materials 3, 062509 (2015).

**12:51PM L30.00007 Tuning optical absorption and photoexcited recombination dynamics in  $\text{La}_{1-x}\text{Sr}_x\text{FeO}_{3-\delta}$  through A-site substitution and oxygen vacancies<sup>1</sup>**, SERGEY SMOLIN, MARK SCAFETTA, AMBER CHOQUETTE, Drexel Univ, MATTHEW SFEIR, Brookhaven National Lab, JASON BAXTER, STEVEN MAY, Drexel Univ — We study optical absorption and recombination dynamics in  $\text{La}_{1-x}\text{Sr}_x\text{FeO}_{3-\delta}$  thin films, uncovering the effects of tuning nominal Fe valence via A-site substitution and oxygen stoichiometry. Variable angle spectroscopic ellipsometry was used to measure static optical properties, revealing a linear increase in absorption coefficient at 1.25 eV and a red-shifting of the optical absorption edge with increasing Sr fraction. The absorption spectra can be similarly tuned through the introduction of oxygen vacancies, indicating the critical role that nominal Fe valence plays in optical absorption. Dynamic optoelectronic properties were studied with ultrafast transient reflectance spectroscopy, revealing similar nanosecond photoexcited carrier lifetimes for oxygen deficient and stoichiometric films with the same nominal Fe valence. These results demonstrate that while the static optical absorption is strongly dependent on Fe valence tuned through cation or anion stoichiometry, oxygen vacancies do not appear to play a significantly detrimental role in the recombination kinetics.

<sup>1</sup>NSF: ECCS-1201957, MRI DMR-0922929, MRI DMR-1040166. This research used resources of the Center for Functional Nanomaterials, which is a U.S. DOE Office of Science Facility, at Brookhaven National Laboratory under Contract No. DE-SC0012704.

**1:03PM L30.00008 Low Dimensional Oxygen Vacancy Ordering and Diffusion in  $\text{SrCrO}_{3-\delta}$** , PHUONG VU ONG, PETER V. SUSHKO, Physical & Computational Sciences Directorate, Pacific Northwest National Laboratory, Richland, WA 99352, U.S.A., PHYSICAL & COMPUTATIONAL SCIENCES DIRECTORATE, PACIFIC NORTHWEST NATIONAL LABORATORY, RICHLAND, WA 9 TEAM — Oxygen vacancies ( $V_O$ ) are known to strongly affect the structure and electronic properties of complex oxides. An ability to control local concentration and spatial distribution of the vacancies, as well as stability and dimensionality of their aggregates, would enable generating novel materials functionalities, such as fast directional charge and mass transport. We use first-principles simulations to study mechanisms of formation, aggregation and diffusion of oxygen vacancies in  $\text{SrCrO}_{3-\delta}$ . We found that at low concentrations oxygen vacancies have a tendency to aggregate into one-dimensional (1D) structures oriented along a [110] direction. These  $V_O$  clusters induce rearrangements of oxide ions and conversion of Cr-centered perovskite lattice octahedra into tetrahedra. In turn, aggregation of these 1D  $V_O$  clusters enables formation of 2D vacancy aggregates parallel to the (111) plane of the cubic perovskite lattice. We provide a simple physical picture for the formation and growth of such low-dimensional  $V_O$ -structures. Moreover, we found mechanisms of  $V_O$  migration which enable a diffusion and expansion of the  $V_O$ -structures with low activation energies. Our results elucidate the atomic-scale mechanisms of efficient and reversible reduction and oxidation process observed in this material. These mechanisms could be extended to other complex oxides and used in design of high performance electrolytes and cathodes.

**1:15PM L30.00009 Structure and Electronic Transport of Oxygen-Deficient  $\text{SrTiO}_3$  Thin Films Buffered with  $\text{DyScO}_3$** , PURNIMA BALAKRISHNAN, URUSA ALAAN, MATTHEW GRAY, YURI SUZUKI, Stanford Univ — Oxygen deficiency in  $\text{SrTiO}_3$  (STO) induces metallic behavior in bulk and thin film form. Thus far, reports of STO thin film metallicity have been limited to homoepitaxial growth on bulk STO substrates. Growth on other substrates has suppressed metallicity, suggesting the important role of lattice distortions. In this presentation, we report on the metallicity and corresponding structure of oxygen-deficient STO films deposited on  $\text{DyScO}_3$  (DSO) buffered STO substrates and compare to STO films deposited directly on STO substrates. These films are epitaxial, atomically flat, expanded out-of-plane by  $\sim 0.6\%$ , and coherently strained to the STO substrate. Oxygen-deficient STO thin films grown on STO and DSO-buffered STO substrates are metallic, while films deposited on  $\text{LaAlO}_3$ ,  $(\text{LaAlO}_3)(\text{SrTaO}_3)$ , and DSO substrates are insulating. The resistivities of metallic films follow a  $T^3$  dependence near room temperature, transitioning to a  $T^2$  dependence below  $\sim 100$  K, and are increased by the addition of a DSO buffer. Comparison of sheet resistance across films of various thicknesses indicates the presence of an insulating layer around 7 unit cells thick. These properties indicate the importance of both oxygen deficiency and lattice structure in obtaining metallicity.

**1:27PM L30.00010 Non-Fermi liquids in two and three-dimensional doped  $\text{SrTiO}_3$** , EVGENY MIKHEEV, SANTOSH RAGHAVAN, JACK ZHANG, PATRICK MARSHALL, ADAM KAJDOS, Materials Department, University of California, Santa Barbara, CA 93106-5050, USA, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, California 93106-4030, USA, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara, CA 93106-5050, USA — A remarkable feature of transport in doped  $\text{SrTiO}_3$  is the temperature dependence of the electrical resistivity that is proportional to  $T^n$  with  $n \leq 2$ . This power law suggests electron-electron scattering is the dominant scattering mechanism. It extends to room temperature and above in both three-dimensional, uniformly doped  $\text{SrTiO}_3$  and in two-dimensional electron liquids (2DELs) at oxide interfaces. In case of  $n = 2$ , the behavior is traditionally identified as that of a Landau Fermi liquid. Here we argue that Landau Fermi liquid theory does not apply to the electron liquid in  $\text{SrTiO}_3$ , even when  $n = 2$ . Using electrostatic gating and chemical doping, we demonstrate that this regime is associated with a scattering rate and an energy scale that are independent of carrier density. This is in fundamental conflict with the premise of the Fermi liquid theory, where this energy scale is the Fermi energy. This work raises important questions in terms of microscopic scattering mechanism. It appears to be relevant for understanding of transport in many other strongly correlated systems, which also show very robust  $T^n$  regimes with carrier density independent scattering rates.

**1:39PM L30.00011 Understanding the Origin of Surface Depletion in  $\delta$ -doped  $\text{SrTiO}_3$  Structures**, HYEOK YOON, HISASHI INOUE, ADRIAN G. SWARTZ, Stanford Univ, YASUYUKI HIKITA, SLAC National Accelerator Laboratory, HAROLD Y. HWANG, Stanford Univ, SLAC National Accelerator Laboratory — Unlike most of the conventional semiconductors, the large dielectric constant of  $\text{SrTiO}_3$  results in a pronounced surface depletion width [1]. In thin films, the effect of surface depletion is even more dramatic: reduction of mobility and two-dimensional carrier density. To avoid this effect, capping and buffering a narrow channel of *n*-type doped  $\text{SrTiO}_3$ , so called  $\delta$ -doping, is designed to make the channel free from surface scattering, resulting in highly mobile carriers [2-4] We have investigated systematic changes in electronic transport by tuning the thicknesses of the undoped surface buffering cap and the  $\delta$ -doped layer. This has allowed us to map the phase diagram consisting of a three-dimensional metal, two-dimensional metallic behavior, and an insulating phase. We also show the surface depletion width as a function of doping density in order to study the origin of surface depletion of  $\text{SrTiO}_3$  [1] A. Ohtomo and H. Y. Hwang, *Appl. Phys. Lett.* **84**, 1716 (2004). [2] Y. Kozuka *et al.*, *Appl. Phys. Lett.* **97**, 222115 (2010). [3] Y. Kozuka, M. Kim *et al.*, *Nature* **462**, 487 (2009). [4] M. Kim *et al.*, *Phys. Rev. Lett.* **107**, 106801 (2011).

**1:51PM L30.00012 High-mobility SrTiO<sub>3</sub> delta-doped field-effect transistors**, HISASHI INOUE, ADRIAN SWARTZ, GLAM, Stanford University, YASUYUKI HIKITA, SIMES, SLAC National Accelerator Laboratory, HAROLD HWANG, GLAM, Stanford University, SIMES, SLAC National Accelerator Laboratory — Two-dimensional electron systems in SrTiO<sub>3</sub> show intriguing properties such as high mobility transport, magnetism, and possible unconventional superconductivity. A delta-doped structure, sandwiching a narrow two-dimensional conducting SrTiO<sub>3</sub> channel between two insulating SrTiO<sub>3</sub> layers, provides a clean platform to realize such electronic states, with symmetric confining potential in the absence of interface or surface scattering. Electric field gating of the conducting channel in a field-effect transistor (FET) geometry is a powerful method for tuning low-dimensional systems via carrier density modulation. We have synthesized high quality SrTiO<sub>3</sub> delta-doped structures using pulsed laser deposition, and optimized the device processing steps to achieve ideal FET characteristics at room temperature. This progress enabled examination of high-mobility transport in the carrier density regime as low as  $3 \times 10^{12} \text{ cm}^{-2}$  at low-temperatures, opening promising avenues to investigate quantum transport and realization of exotic quantum phases in SrTiO<sub>3</sub> two-dimensional electron systems.

**2:03PM L30.00013 A model of dopant diffusion through a strongly correlated p-n junction.**, JEDRZEJ WIETESKA, Columbia University, RICHARD BRIERLEY, Yale University, GIAN GUZMAN-VERRI, University of Costa Rica and Argonne National Laboratory, GUNNAR MOLLER, University of Cambridge, PETER LITTLEWOOD, Argonne National Laboratory, University of Chicago, LITTLEWOOD GROUP COLLABORATION — The diffusion of charged ions in a solid depends on an equation of state that balances diffusive and screened electrostatic forces, and is well understood in the case of conventional semiconductors and metals. In the case of a strongly-correlated material, the physics is different, and expected to be relevant, for example, in Li-ion battery cathodes. We propose a model of dopant ion motion through a strongly correlated p-n junction. Our approach is to consider diffusive (Nernst-Planck) dynamics of dopants under screened electrostatic interactions computed [1] within a mean-field (Thomas-Fermi) approximation. Dopant profiles as function of time are calculated for a p-n junction held at constant voltage. In the case where filling levels are near a correlation-induced gap, Mott insulating regions can form at the p-n interface and their dynamics is studied. References: 1. Charlebois et al., Phys. Rev. B, 87 035137 (2013)

Session L31 DCP: Advances in Density Functional Theory VI 331 - Marivi Fernandez Serra, SUNY-Stony Brook

**11:15AM L31.00001 Fast RPA and GW calculations: cubic system size scaling**, GEORG KRESSE, Faculty of Physics, Univ. Vienna — The random phase approximation (RPA) to the correlation energy and the related GW approximation are among the most promising methods to obtain accurate correlation energy differences and QP energies from diagrammatic perturbation theory at reasonable computational cost. The calculations are, however, usually one to two orders of magnitude more demanding than conventional density functional theory calculations. Here, we show that a cubic system size scaling can be readily obtained reducing the computation time by one to two orders of magnitude for large systems. Furthermore, the scaling with respect to the number of k points used to sample the Brillouin zone can be reduced to linear order. In combination, this allows accurate and very well-converged single-point RPA and GW calculations, with a time complexity that is roughly on par or better than for self-consistent Hartree-Fock and hybrid-functional calculations [1-2]. Furthermore, the talk discusses the relation between the RPA correlation energy and the GW approximation: the self-energy is the derivative of the RPA correlation energy with respect to the Green's function. The calculated self-energy can be used to compute QP-energies in the GW approximation, any first derivative of the total energy, as well as corrections to the correlation energy from the changes of the charge density when switching from DFT to a many-body description (GW singles energy contribution) [3]. **11:51AM L31.00002 Influence of *xc* functional on thermal-elastic properties of Ceria: A DFT-based Debye-Grüneisen model approach<sup>1</sup>**, JI-HWAN LEE, YOUNGJOO TAK, TAEHUN LEE, ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University — Ceria (CeO<sub>2-x</sub>) is widely studied as a choice electrolyte material for intermediate-temperature (~ 800 K) solid oxide fuel cells. At this temperature, maintaining its chemical stability and thermal-mechanical integrity of this oxide are of utmost importance. To understand their thermal-elastic properties, we firstly test the influence of various approximations to the density-functional theory (DFT) *xc* functionals on specific thermal-elastic properties of both CeO<sub>2</sub> and Ce<sub>2</sub>O<sub>3</sub>. Namely, we consider the local-density approximation (LDA), the generalized gradient approximation (GGA-PBE) with and without additional Hubbard *U* as applied to the 4f electron of Ce, as well as the recently popularized hybrid functional due to Heyd-Scuseria-Ernzerhof (HSE06). Next, we then couple this to a volume-dependent Debye-Grüneisen model to determine the thermodynamic quantities of ceria at arbitrary temperatures. We find an explicit description of the strong correlation (e.g. via the DFT+*U* and hybrid functional approach) is necessary to have a good agreement with experimental values, in contrast to the mean-field treatment in standard *xc* approximations (such as LDA or GGA-PBE).

**12:03PM L31.00003 Catalytic Effects of Oxide Surfaces on Diels-Alder Cycloaddition between Furan and Methyl Acrylate: A DFT Study.**, TAHA SALAVATI-FARD, GLEN JENNESS, STAVROS CARATZOULAS, DOUGLAS DOREN, University of Delaware — Using density functional theory with periodic boundary conditions, we study the catalytic effects of oxide surfaces such as ZrO<sub>2</sub> and HfO<sub>2</sub> on Diels-Alder reaction between furan and methyl acrylate. The cycloadduct can be dehydrated later to produce methyl benzoic which is an important step toward benzoic acid production. The gas-phase and on-surface reaction mechanisms are studied in detail. The surface hydration effects on the reaction mechanism and energy profile are studied as well. Our calculations show that the oxide surfaces catalyze the reaction significantly through the interaction of metal sites with methyl acrylate. The calculations are interpreted by making use of electronic density of states and band structure of the catalyst.

**12:15PM L31.00004 Role of Exchange and Correlation in Predicting Structures and Properties of Fluoride Materials**, NENIAN CHARLES, Drexel University, JAMES RONDINELLI, Northwestern University — The study of fluorine-based inorganic compounds has captured the attention of condensed matter physicists as a route to engineer novel states of matter. Here, we present a density functional theory (DFT) study on fluorides with structures ranging from simple to complex, including KF (rock salt), MnF<sub>2</sub> and VF<sub>2</sub> (rutile), KMnF<sub>3</sub> (perovskite), and Na<sub>3</sub>MnF<sub>6</sub> and Na<sub>6</sub>ScF<sub>6</sub> (cryolite). The focus is on understanding the accuracy of various exchange-correlation functionals for the prediction of structural, electronic, and phonon properties at four different levels of theory, i.e., the local density approximation (LDA), generalized gradient approximation (GGA), meta-GGA, and hybrid functional level with exact exchange. Specifically, we draw attention to the meta-GGA functional MS2 [Sun *et al*, Phys. Rev. Lett., **111**, 106401 (2013)], demonstrating that although it shows improvements over the LDA and GGA functionals in predicting structural properties of fluorides, MS2 generally performs poorer for the electronic and phonon properties. Our study provides useful insights for predictive design of functional halide compounds using computational models based on DFT.

## 12:27PM L31.00005 Bond Breaking in Epoxy Systems: A Combined QM/MM Approach

STEPHEN BARR, UTC, Air Force Research Laboratory, GARY KEDZIORA, Engility Corp., Air Force Research Laboratory, ALLISON ECKER, SOCHE, Air Force Research Laboratory, JAMES MOLLER, Miami University, RAJIV BERRY, TIM BREITZMAN, Air Force Research Laboratory — A novel method to combine molecular mechanics and quantum mechanics (QM/MM) is developed with the intent to accurately and efficiently account for covalent bond breaking in polymer systems. Since classical force fields cannot accurately account for bond breaking, and QM is too demanding to simulate large systems, a hybrid approach is required. In the method demonstrated here, strain is applied to the system using a classical force field. When a bond break is likely, a zone surrounding the bond is used in a QM calculation to determine which, if any, bonds break. The QM result is then used to reconstitute the system to continue the classical simulation until another QM calculation is triggered. In this way a QM calculation is only computed when and where it is needed, allowing for an efficient simulation. A key component of this method is a density functional theory (DFT) method which provides accurate forces as bonds are pulled past their breaking points. To find the best method, a number of functionals are compared with high level QM calculations by pulling various small molecules, representative of epoxies, past a bond breaking event. Appropriate values for the QM zone size and the QM trigger criteria are also determined. The overall QM/MM method is then applied to an epoxy system.

## 12:39PM L31.00006 Bayesian Error Estimation Functionals

KARSTEN W. JACOBSEN, CAMD, Dept. of Physics, Technical University of Denmark — The challenge of approximating the exchange-correlation functional in Density Functional Theory (DFT) has led to the development of numerous different approximations of varying accuracy on different calculated properties. There is therefore a need for reliable estimation of prediction errors within the different approximation schemes to DFT. The Bayesian Error Estimation Functionals (BEEF) have been developed with this in mind. The functionals are constructed by fitting to experimental and high-quality computational databases for molecules and solids including chemisorption and van der Waals systems. This leads to reasonably accurate general-purpose functionals with particular focus on surface science. The fitting procedure involves considerations on how to combine different types of data, and applies Tikhonov regularization and bootstrap cross validation. The methodology has been applied to construct GGA and metaGGA functionals with and without inclusion of long-ranged van der Waals contributions. The error estimation is made possible by the generation of not only a single functional but through the construction of a probability distribution of functionals represented by a functional ensemble. The use of the functional ensemble is illustrated on compound heat of formation and by investigations of the reliability of calculated catalytic ammonia synthesis rates.

## 1:15PM L31.00007 Joint Density Functional Theory for the electrode/electrolyte interface: Benchmarking liquid structure with experiment and *ab initio* molecular dynamics

KENDRA LETCHWORTH-WEAVER, Argonne National Laboratory, Cornell University, CHRISTINE UMBRIGHT, Cornell University, MARIA CHAN, PAUL FENTER, Argonne National Laboratory, T. A. ARIAS, Cornell University — Understanding the physics of the interface between a charged electrode surface and a fluid electrolyte would inform design of electrochemical energy storage and conversion devices. However, such studies require a simultaneously accurate yet inherently multi-scale theory. Joint density-functional theory (JDFT) bridges the relevant length-scales by joining a fully *ab initio* description of the electrode with a low computational cost, yet atomically detailed classical DFT description of the liquid electrolyte structure. Leveraging JDFT within our framework to treat charged systems in periodic boundary conditions, we can predict the voltage-dependent structure and energetics of solvated ions at the interface between graphitic and single-crystalline metallic electrodes and technologically relevant liquid electrolytes. First, we elucidate the physical origin of the experimentally measured voltage-dependent differential capacitance of an Ag(111) electrode in aqueous NaF electrolyte, examining the crucial role of ion de-solvation and physisorption onto the electrode surface. We go on to compare the JDFT-predicted interfacial liquid structure next to a graphitic electrode with results obtained from X-ray reflectivity measurements and *ab initio* molecular dynamics simulations.

## 1:27PM L31.00008 Role of Van der Waals interactions in determining the structure of liquid tellurides<sup>1</sup>

MATTHIEU MICOULAUT, HUGO FLORES-RUIZ, Paris Sorbonne Universités, VANESSA COULET, Universités Aix-Marseille, ANDREA PIARRISTEGUY, Université Montpellier II, MARK JOHNSON, GABRIEL CUELLO, Institut Laue Langevin, ANNIE PRADEL, Université Montpellier II — The simulation of tellurides using standard density functional (DFT) theory based molecular dynamics usually leads to an overestimation of the bond distances and a noticeable mismatch between theory and experiments when e.g. structure functions are being directly compared. Here, the structural properties of several compositions of Ge-Te and Ge-Sb-Te liquids are studied from a combination of neutron diffraction and DFT-based molecular dynamics. Importantly, we find an excellent agreement in the reproduction of the structure in real and reciprocal spaces, resulting from the incorporation of dispersion forces in the simulation. We then investigate structural properties including structure factors, pair distribution functions, angular distributions, coordination numbers, neighbor distributions, and compare our results with experimental findings.

## 1:39PM L31.00009 Ti $\alpha - \omega$ phase transformation and metastable structure, solid-state nudged elastic band method<sup>1</sup>

NIKOLAI ZARKEVICH<sup>2</sup>, DUANE D. JOHNSON<sup>2</sup>, Ames Laboratory — The four most utilized structural metals, and, hence, its structural changes and potential metastable phases under stress are of considerable interest. DFT+U combined with the generalized solid-state nudged elastic band (SS-NEB) method, we consider the pressure-driven transformation of Ti from  $\alpha$  to  $\omega$  phases, and find an intermediate metastable body-centered orthorhombic (bco) structure of lower density. We verify its stability by calculating its electronic structure, and compare computational results to experiment. Interestingly, standard density functional theory (DFT) yields a ground state, in contradiction to the observed  $\alpha$  phase at low pressure and temperature. We correct this by proper consideration of  $d$ -electrons, and utilize DFT+U method in the SS-NEB to obtain the relevant transformation pathway and structures.

**1:51PM L31.00010 The effect of the pair correlation function on dynamic density functional theory<sup>1</sup>**, STEPHEN J. TATE, Department of Chemical Engineering, Imperial College London, BENJAMIN D. GODDARD, School of Mathematics, University of Edinburgh, GRIGORIOS A. PAVLIOTIS, Department of Mathematics, Imperial College London, SERAFIM KALLIADASIS, Department of Chemical Engineering, Imperial College London — In a previous study [1], a general dynamical density functional theory (DDFT) to include hydrodynamic interactions (HI) and inertial effects of colloidal particles was derived and validated with stochastic simulations. But the pair correlation function,  $g$ , was approximated with a simplest possible volume-exclusion function, namely a Heaviside step function. Here we explore what effect more accurate  $g$ 's have on the same DDFT. These include a correction giving the Percus-Yevick solution for hard spheres, which is known analytically. Furthermore, since we typically deal with systems outside of equilibrium, we model non-adiabatic effects to the HI terms in the DDFT, including density and momentum dependence. [1] B.D. Goddard, A. Nold, N. Savva, G.A. Pavliotis and S. Kalliadas, "General dynamical density functional theory for classical fluids," Phys. Rev. Lett. 109 (120603) 2012.

**2:03PM L31.00011 Understanding the spurious DFT fractional charge in the electrochemical double layer**, LEANNE CHEN, MICHAL BAJDICH, ALAN LUNTZ, KAREN CHAN, JENS NORSKOV, SUNCAT Center for Interface Science and Catalysis, SLAC National Accelerator Laboratory and Stanford University — An ongoing challenge in computational electrochemistry is the accurate determination of electrochemical barriers at constant electrode potential. Recently, our group developed an efficient scheme to determine the barriers using a simple extrapolation based on the interfacial charge [1]. However, semilocal DFT calculations have shown that the magnitude of the charge of solvated species ( $\text{H}_3\text{O}^+$ ,  $\text{OH}^-$ ,  $\text{Li}^+$ ,  $\text{Na}^+$ ) in the outer Helmholtz plane is not 1e, but always near 0.6e, which suggests a charge delocalization error in DFT. Furthermore, we frequently observe inaccurate alignment of the metal Fermi and solvent energy levels. Using an increasing amount of exact exchange, we first analyze the charge delocalization error in the dissociation of NaCl molecule, where a large amount of exchange is needed to reproduce the step-like transition of charge from +1 to 0 on the dissociated Na and Cl. Next, we apply the same method to the metal-water interface with solvated ions at varying distances from the surface. The performance of hybrid and other fractional charge-corrected functionals will be discussed together with the possibility of a simple correction scheme. [1] Chan, K.; Nørskov, J. K. Electrochemical Barriers Made Simple. *J. Phys. Chem. Lett.* **2015**, 6 (14), 2663–2668.

**Session L32 DCP: Dynamic Interactions Between Nanostructures** 332 - Todd Krauss, University of Rochester

**11:15AM L32.00001 Efficient Light-driven Long Distance Charge Separation and H<sub>2</sub> Generation in Semiconductor Quantum Rods and Nanoplatelets**, TIANQUAN LIAN, Emory University — Quantum confined semiconductor nanocrystals (0D quantum dots, 1D quantum rods and 2D quantum platelets) have been intensively investigated as light harvesting and charge separation materials for photovoltaic and photocatalytic applications. The efficiency of these semiconductor nanocrystal-based devices depends on many fundamental processes, including light harvesting, carrier relaxation, exciton localization and transport, charge separation and charge recombination. The competition between these processes determines the overall solar energy conversion (solar to electricity or fuel) efficiency. Semiconductor nano-heterostructures, combining two or more material components, offer unique opportunities to control their charge separation properties by tailoring their compositions, dimensions and spatial arrangement. Further integration of catalysts (heterogeneous or homogeneous) to these materials form multifunctional nano-heterostructures. Using 0D, 1D and 2D CdSe/CdS/Pt heterostructures as model systems, we directly probe the above-mentioned fundamental exciton and carrier processes by transient absorption and time-resolved fluorescence spectroscopy. We are examining how to control these fundamental processes through the design of heterostructures to achieve long-lived charge separation and efficient H<sub>2</sub> generation. In this talk, we will discuss a new model for exciton dissociation by charge transfer in quantum dots (i.e. Auger assisted electron transfer), mechanism of 1D and 2D exciton transport and dissociation in nanorods, and key factors limiting H<sub>2</sub> generation efficiency in CdSe/CdS/Pt nanorod heterostructures.

**11:51AM L32.00002 How to harvest solar energy with the photosynthetic reaction center.**, ALEXANDER BALAEFF, JUSTIN REYES, University of Central Florida — Photosynthetic reaction center (PRC) is a protein complex that performs a key step in photosynthesis: the electron-hole separation driven by photon absorption. The PRC has a great promise for applications in solar energy harvesting and photosensing. Such applications, however, are hampered by the difficulty in extracting the photogenerated electric charge from the PRC. To that end, it was proposed to attach the PRC to a molecular wire through which the charge could be collected. In order to find the attachment point for the wire that would maximize the rate of charge outflow from the PRC, we performed a computational study of the PRC from the *R. viridis* bacterium. An ensemble of PRC structures generated by a molecular dynamics simulation was used to calculate the rate of charge transport from the site of initial charge separation to several trial sites on the protein surface. The Pathways model was used to calculate the charge transfer rate in each step of the network of heme co-factors through which the charge transport was presumed to proceed. A simple kinetic model was then used to determine the overall rate of the multistep charge transport. The calculations revealed several candidate sites for the molecular wire attachment, recommended for experimental verification.

**12:03PM L32.00003 Managing photons and carriers for photocatalysis**, ISABELL THOMANN, HOSSEIN ROBATJAZI, SHAH BAHAUDDIN, CHLOE DOIRON, XUEJUN LIU, THEJASWI TUMKUR, WEI-REN WANG, PARKER WRAY, Rice University — While small plasmonic nanoparticles efficiently generate energetic hot carriers, light absorption in a monolayer of such particles is inefficient, and practical utilization of the hot carriers in addition requires efficient charge-separation. Here we describe our approach to address both challenges. By designing an optical cavity structure for the plasmonic photoelectrode [1], light absorption in these particles can be significantly enhanced, resulting in efficient hot electron generation. Rather than utilizing a Schottky barrier to preserve the energy of the carriers, our structure allows for their direct injection into the adjacent electrolyte. On the substrate side, the plasmonic particles are in contact with a wide band gap oxide film that serves as an electron blocking layer but accepts holes and transfers them to the counter electrode. The observed photocurrent spectra follow the plasmon spectrum, and demonstrate that the extracted electrons are energetic enough to drive the hydrogen evolution reaction. A similar structure can be designed to achieve broadband absorption enhancement in monolayer MoS<sub>2</sub> [2]. Time permitting, I will discuss charge carrier dynamics in hybrid nanoparticles composed of plasmonic / two-dimensional materials, and applications of photo-induced force microscopy to study photocatalytic processes. [1] Nano Letters, 2015, 15 (9), p 6155 [2] Photon management strategies for monolayer MoS<sub>2</sub>, submitted

## 12:15PM L32.00004 Charge Transfer Dynamics in Semiconductor Quantum Dots Relevant to Solar Hydrogen Production.

, TODD KRAUSS, University of Rochester — Artificial conversion of sunlight to chemical fuels has attracted attention for several decades as a potential source of clean, renewable energy. For example, in light-driven proton reduction to molecular hydrogen, a light-absorbing molecule (the photosensitizer) rapidly transfers a photoexcited electron to a catalyst for reducing protons. We recently found that CdSe quantum dots (QDs) and simple aqueous  $\text{Ni}^{2+}$  salts in the presence of a sacrificial electron donor form a highly efficient, active, and robust system for photochemical reduction of protons to molecular hydrogen. To understand why this system has such extraordinary catalytic behavior, ultrafast transient absorption (TA) spectroscopy studies of electron transfer (ET) processes from the QDs to the Ni catalysts were performed. CdSe QDs transfer photoexcited electrons to a Ni-dihydrolipoic acid (Ni-DHLA) catalyst complex extremely fast and with high efficiency. Even under high fluence, the relative fraction of TA signal due to ET remains well over 80%, and depopulation from exciton-exciton annihilation is minimal (6%). We also found that increasing QD size and/or shelling the core CdSe QDs with a shell of CdS slowed the ET rate, in agreement with the relative efficiency of photochemical  $\text{H}_2$  generation. The extremely fast ET provides a fundamental explanation for the exceptional photocatalytic  $\text{H}_2$  activity of the CdSe QD/Ni-DHLA system and guides new directions for further improvements.

## 12:51PM L32.00005 Multi-photon Photoemission Dynamics in $\text{TiO}_2$

, ADAM ARGONDISO, University of Pittsburgh, XUEFENG CUI, University of Science and Technology of China, CONG WANG, University of Pittsburgh, HUIJUAN SUN, HONGHUI SHANG, JIN ZHAO, University of Science and Technology of China, HRVOJE PETEK, University of Pittsburgh —  $\text{TiO}_2$  is a material of interest in photocatalytic and photovoltaic applications. Until recently, however, the ability to probe the electron dynamics of this system has been limited to optical experiments. By probing the rutile  $\text{TiO}_2(110)$  surface using two-photon photoemission (2PP) with a tunable ultrashort ( $\sim 20$  fs) laser pulse we investigated the dynamics of electrons excited to its conduction band. Previous 2PP experiments on protic solvent covered  $\text{TiO}_2$  surfaces using 400 nm (3.1 eV) light revealed the presence of an unoccupied surface adsorbate-induced wet electron state. By expanding such measurements at higher photon energy we have found a pair of new nearly degenerate unoccupied states located at 2.7 and 2.8 eV above the Fermi level. Based on the calculated electronic structure and optical transition moments, as well as related spectroscopic evidence, we assign these resonances to transitions between Ti-3d bands of nominally  $t_{2g}$  and  $e_g$  symmetry, which are split by crystal field. A detailed understanding of the  $t_{2g}$ - $e_g$  transitions is essential for the characterization of electron dynamics and adsorbate induced resonances in photocatalytic processes on  $\text{TiO}_2$ .

## 1:03PM L32.00006 ABSTRACT WITHDRAWN —

## 1:15PM L32.00007 Hole transfer dynamics from QDs to tethered ferrocene derivatives

, A. PAUL ALIVISATOS, Department of Chemistry, University of California, Berkeley — Quantum dots (QDs) have shown particular promise in recent years as light absorbers in solar energy conversion schemes. However, in solution junction solar devices such as QD-sensitized solar cells and photocatalytic water splitting systems, efficiencies are often limited by hole transfer from the photoexcited QD. This process is sluggish and can lead to oxidative photocorrosion of the QD material. In order to design highly efficient nanocrystal systems with hole transfer rates that outcompete these undesirable processes, a fundamental understanding of the parameters that control these rates is imperative.

We have developed a model system to study charge transfer from QDs to surface bound acceptors, to fundamentally understand the charge transfer processes for QD systems, namely electronic coupling between the donor and acceptor and the thermodynamic driving force for the hole transfer process. Specifically, we examine hole transfer from the nearly spherical CdSe-core CdS-shell QDs with photoluminescence (PL) quantum yields over 80% to ferrocene derivatives bound to the QD surface via an alkane thiol linker. In this system, we mitigate the ill-defined nonradiative charge dynamic pathways that are intrinsic to native CdSe cores, and then controllably engineer on the surface charge acceptors with well-defined oxidation potentials, spatial distribution, and quantity. By measuring the PL lifetime decay and calibrating the number of hole acceptor ligands per QD via quantitative  $^1\text{H}$  NMR, we extracted the hole transfer rate per acceptor. This rate per acceptor could be varied over four orders of magnitude by changing the coupling between donor and acceptor through modulations in the CdS shell thickness and alkane chain length of the molecule. Furthermore, owing to the large number of acceptors on the surface, we achieve systems in which  $\sim 99\%$  of the photoexcited holes are transferred to these well-defined mediators.

We further mapped the relationship between the thermodynamic driving force and hole transfer rate. We systematically tune the driving force over nearly 1 eV by varying the redox potentials of the ferrocene ligands through functionalization of the cyclopentadiene rings. Our results show a monotonic increase in rate as a function of the increasing driving force with no observed inverted region. This behavior is understood by considering the residual electron in the QD conduction band, which could exhibit intraband excitations coupled to the hole transfer, thus creating a many-state system that would eliminate the inverted region. The resulting relationship between rate and energetic driving force for hole transfer can be used to design QD-molecular systems that maximize interfacial charge transfer rates while minimizing energetic losses associated with the driving force.

## 1:51PM L32.00008 Cooperative Electron-Hole Dynamics at the Organic Donor-Acceptor Interface<sup>1</sup>

, CHEE KONG LEE, SHI LIANG, ADAM WILLARD, Massachusetts Institute of Technology — Charge transfer (CT) excitons are Coulombically bound electron and hole pairs located in spatially separate regions. They play an important role in both light emission of organic light emitting devices and the generation of photocurrent in organic photovoltaic. For some donor/acceptor blends the lowest electronic excitations are triplet CT states, and in these materials the photoluminescence and photocurrent generation exhibit a non-trivial magnetic field dependence due to its effect on singlet-triplet intersystem crossing and reverse intersystem crossing rates. Recent experiments have demonstrated that in these materials bound electron-hole pairs can move geminately over distance of 5-10nm confirming the transport of CT excitons despite strong Coulombic attraction. These experiments can be understood with a numerical model combining kinetic Monte Carlo and the quantum master equation. The model contains a minimal set of physical elements, and yet is able to quantitatively reproduce the experimental results. More importantly, the model provides insights into properties that otherwise cannot be obtained from experiments. Here I present the details of this model along with the physical insights it has provided into this particular class of materials.

<sup>1</sup>Cooperative Electron-Hole Dynamics at the Organic Donor-Acceptor Interface

## 2:03PM L32.00009 Probing of Charge Transfer States at Buried Organic Interfaces with Even-Order Spectroscopy

, RAVINDRA PANDEY, AARON MOON, SEAN ROBERTS, University of Texas at Austin — Organic thin film photovoltaics (OPV) are an emerging economically competitive technology that combines manufacturing adaptability, low-cost processing and a lightweight, flexible device end-product. At junctions formed between organic electron-donating and electron-accepting materials, the abrupt change in the dielectric properties can strongly perturb the density of states of the OPV. This can substantially alter the driving force for charge transfer between these materials. Electronic Sum Frequency Generation (ESFG), owing to its inherent interfacial sensitivity, is ideally suited to probe buried interfaces. Here, we report the ESFG spectra of Copper Phthalocyanine (CuPc) films, deposited on  $\text{SiO}_2$  measured for both reflection and transmission geometries. Three peaks are observed that roughly correlate with resonances that comprise CuPc's Q-band absorption but display slight shifts and amplitude changes with respect to CuPc's bulk absorption spectrum. Experimental results are compared with calculations based on a thin film interference model that accounts for ESFG emitted from both the CuPc:Air and CuPc: $\text{SiO}_2$  interface as well as contributions to the signal from higher order source terms from the bulk. The model reveals a difference in the density of states between the two interfaces and suggests that by combining experimental transmission and reflection data it is possible to separate bulk and interfacial contributions to ESFG spectra.

**Session L33 DMP GMAG: Kitaev Physics in Honeycomb Iridates** 336 - George Jackeli, University of Stuttgart

**11:15AM L33.00001 Evidence for coexisting magnetic order in frustrated three-dimensional honeycomb iridates  $\text{Li}_2\text{IrO}_3$**  , NICHOLAS BREZNAY, ALEJANDRO RUIZ, ALEX FRANO, JAMES ANALYTIS, University of California, Berkeley — The search for unconventional magnetism has found a fertile hunting ground in 5d iridium oxide (iridate) materials. The competition between coulomb, spin-orbit, and crystal field energy scales in honeycomb iridates leads to a quantum magnetic system with localized spin-1/2 moments communicating through spin-anisotropic Kitaev exchange interactions. Although early and ongoing work has focused on layered two-dimensional honeycomb compounds such as  $\text{Na}_2\text{IrO}_3$  and a 4d analog,  $\text{RuCl}_3$ , recently discovered polytypes of  $\text{Li}_2\text{IrO}_3$  take on three-dimensional honeycomb structures. Bulk thermodynamic studies, as well as recent resonant x-ray diffraction and absorption spectroscopy experiments, have uncovered a rich phase diagram for these three-dimensional honeycomb iridates. Low temperature incommensurate and commensurate magnetic orders can be stabilized by tuning the applied magnetic field, displaying a delicate coexistence that signals highly frustrated magnetism.

**11:27AM L33.00002 Vacancies in a 3D-Kitaev model on hyper-honeycomb lattice** , G J SREEJITH, Max Planck Institute for Physics of Complex Systems, Dresden, SUBHRO BHATTACHARJEE, International Centre for Theoretical Sciences, Bangalore, RODERICH MOESSNER, Max Planck Institute for Physics of Complex Systems, Dresden — We study the properties of isolated single and pairs of vacancies in an exactly solvable Kitaev model on a three dimensional hyper-honeycomb lattice. We show that each vacancy in the lattice is associated with a low energy spin like degree of freedom, similar to the case of previously studied honeycomb model. We calculate the contribution from these vacancy spin-moments to the low field magnetization response to a  $z$ -directed field. Isolated vacancies in the gapped phase act as free spins. In the gapless phase, these spins interact with the surrounding spin-liquid suppressing the low-field magnetization to  $\frac{1}{\sqrt{\ln[1/h_z]}}$ . Pair of vacancies have a sublattice-dependent, anisotropic, spin-liquid mediated interaction with each other. In the gapless phase, interaction between vacancies in the same (opposite) sublattice enhances (suppresses) the low-field magnetization, indicating a ferromagnetic (anti-ferromagnetic) nature. We also show that, unlike vacancies in the honeycomb lattice, the vacancies here do not bind a flux at low-energies.

**11:39AM L33.00003 Spin-Peierls instability of three-dimensional Kitaev spin liquids with Majorana Fermi surface** , MARIA HERMANNNS, SIMON TREBST, ACHIM ROSCH, University of Cologne — The Kitaev honeycomb model is one of the paradigmatic examples of a frustrated spin system exhibiting a quantum spin liquid ground state. The emergent low-energy degrees of freedom are Majorana fermions that can form various different (semi-)metallic states. Three-dimensional variants of this model can, in particular, harbor gapless quantum spin liquids with a Majorana Fermi surface. In this talk, we discuss Fermi surface instabilities arising from additional spin exchange terms (such as a Heisenberg coupling), which induce interactions between the emergent Majorana fermion degrees of freedom. We show that independent of the details of the interactions, the Majorana Fermi surface is always unstable. Generically, the system spontaneously dimerizes at exponentially small temperatures and forms a quantum spin liquid with nodal lines. Depending on the microscopic details, further symmetries of the system may be broken at this transition. These spin-Peierls instabilities of a 3D spin liquid are closely related to BCS instabilities of fermions<sup>1</sup>.

**11:51AM L33.00004 Kitaev physics in three dimensional honeycomb iridates<sup>1</sup>** , YONG-BAEK KIM, Univ of Toronto — It has been realized that Mott insulators with strong spin-orbit coupling may allow strongly bond-dependent exchange interactions between local moments. Such interactions may lead to magnetic frustration and possible quantum spin liquid phases. This is in contrast to usual frustrated magnets, where the magnetic frustration comes from the geometry of the underlying lattice structure. Hence, it offers a new avenue to generate exotic phases of matter. Recently, both two-dimensional ( $\alpha$ - $\text{Li}_2\text{IrO}_3$ ) and three-dimensional honeycomb iridates ( $\beta$ - $\text{Li}_2\text{IrO}_3$  and  $\gamma$ - $\text{Li}_2\text{IrO}_3$ ) have been discovered and it has been suggested that the magnetic exchange interactions contain the so-called Kitaev interaction, which depends on bond directions. In particular, the local moments of Ir ions in  $\beta$ - $\text{Li}_2\text{IrO}_3$  and  $\gamma$ - $\text{Li}_2\text{IrO}_3$  reside on the three-dimensional hyper-honeycomb and stripy-honeycomb lattices. The Kitaev model is exactly solvable on these lattices as well as the two-dimensional honeycomb lattice and the ground state is a quantum spin liquid with gapless excitations. We discuss recent progress in theoretical understanding of magnetic exchange interactions, possible presence of quantum spin liquid phases, and unusual magnetic order in  $\beta$ - $\text{Li}_2\text{IrO}_3$  and  $\gamma$ - $\text{Li}_2\text{IrO}_3$ . These theoretical results are used to make connections to recent experimental data.

**12:27PM L33.00005 Detecting Semimetal Surface Modes in Kitaev Spin Liquids** , BRENT PERREAULT, University of Minnesota, JOHANNES KNOLLE, Cavendish Laboratory, NATALIA B. PERKINS, F. J. BURNELL, University of Minnesota — Raman scattering is a useful probe for Kitaev-type spin liquids because it couples only to the dispersing (and potentially gapless) fermionic degrees of freedom in these systems. I will discuss Raman scattering in Kitaev spin liquids on the 3D hyperhoneycomb (H-0) lattice, where these fermionic degrees of freedom realize topologically non-trivial band structures with protected gapless surface states. I will describe Raman signatures both of bulk 3D samples, and thin-film samples of these materials, where the resonant Raman response can detect the protected surface modes.

**12:39PM L33.00006 Large Band Gap of alpha-RuCl<sub>3</sub> Probed by Photoemission and Inverse Photoemission Spectroscopy** , SOOBIN SINN, CHOONG HYUN KIM, LUKE SANDILANDS, IBS-CCES, Seoul National University, KYUNG-DONG LEE, CHOONGJAE WON, IBS-CCES, Inha University, JI SEOP OH, IBS-CCES, Seoul National University, MOONSUP HAN, YOUNG JUN CHANG, University of Seoul, NAMJUNG HUR, Inha University, HITOSHI SATO, Hiroshima Synchrotron Radiation Center, BYEONG-GYU PARK, Pohang Accelerator Laboratory, CHANGYOUNG KIM, HYEONG-DO KIM, TAE WON NOH, IBS-CCES, Seoul National University — The Kitaev honeycomb lattice model has attracted great attention because of its possibility to stabilize a quantum spin liquid ground state. Recently, it was proposed that alpha-RuCl<sub>3</sub> is its material realization and the first 4d relativistic Mott insulator from an optical spectrum and LDA+ $U$ +SO calculations. Here, we present photoemission and inverse photoemission spectra of alpha-RuCl<sub>3</sub>. The observed band gap is about 1.8 eV, which suggests that the previously assigned optical gap of 0.3 eV is misinterpreted, and that the strong peak at about 1.2 eV in the optical spectrum may be associated with an actual optical gap. Assuming a strong excitonic effect of 0.6 eV in the optical spectrum, all the structures except for the peak at 0.3 eV are consistent with our electronic spectra. When compared with LDA+ $U$ +SO calculations, the value of  $U$  should be considerably larger than the previous one, which implies that the spin-orbit coupling is not a necessary ingredient for the insulating mechanism of alpha-RuCl<sub>3</sub>. We also present angle-resolved photoemission spectra to be compared with LDA+ $U$ +SO and LDA+DMFT calculations.

**12:51PM L33.00007 Ab-initio study on crystal structure of  $\alpha$ -RuCl<sub>3</sub>** , HAE-YOUNG KEE, HEUNG-SIK KIM, Univ of Toronto —  $\alpha$ -RuCl<sub>3</sub> was recently proposed as a candidate system for materialization of Kitaev model, but precise structural information of the compound has remained elusive. For the clarification of the full three-dimensional crystal structure of  $\alpha$ -RuCl<sub>3</sub>, we performed ab-initio electronic structure calculations including effects of spin-orbit coupling (SOC) and electron correlations. We found that SOC prevents dimerization between Ru atoms, and keeps the system close to honeycomb lattice. The ground state crystal structure has monoclinic  $C2/m$ -type layer stacking, but trigonal  $P3_112$ -and orthorhombic  $Cmc2_1$ -type stacking orders are comparable to the  $C2/m$  structure in energy, so that stacking faults can be easily introduced. The electronic structure and the  $j_{\text{eff}}=1/2$  pseudospin exchange interactions and possible magnetic states in  $\alpha$ -RuCl<sub>3</sub> will be presented.

**1:03PM L33.00008 Nanoscale structural and electronic characterization of  $\alpha$ -RuCl<sub>3</sub> layered compound**<sup>1</sup> , MAXIM ZIATDINOV, ARTEM MAKSOV, ARNAB BANERJEE, WU ZHOU, TOM BERLIJN, JIAQIANG YAN, STEPHEN NAGLER, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee, ARTHUR BADDORF, SERGEI KALININ, Oak Ridge National Laboratory — The exceptional interplay of spin-orbit effects, Coulomb interaction, and electron–lattice coupling is expected to produce an elaborate phase space of  $\alpha$ -RuCl<sub>3</sub> layered compound, which to date remains largely unexplored. Here we employ a combination of scanning transmission electron microscopy (STEM) and scanning tunneling microscopy (STM) for detailed evaluation of the system's microscopic structural and electronic orders with a sub-nanometer precision. The STM and STEM measurements are further supported by neutron scattering, X-Ray diffraction, density functional theory (DFT), and multivariate statistical analysis. Our results show a trigonal distortion of Cl octahedral ligand cage along the  $C_3$  symmetry axes in each RuCl<sub>3</sub> layer. The lattice distortion is limited mainly to the Cl subsystem leaving the Ru honeycomb lattice nearly intact. The STM topographic and spectroscopic characterization reveals an intra unit cell electronic symmetry breaking in a spin-orbit coupled Mott insulating phase on the Cl-terminated surface of  $\alpha$ -RuCl<sub>3</sub>. The associated long-range charge order (CO) pattern is linked to a surface component of Cl cage distortion. We finally discuss a fine structure of CO and its potential relation to variations of average unit cell geometries found in multivariate analysis of STEM data.

**1:15PM L33.00009 Probing Spin Excitations Using Magneto-Raman Spectroscopy** , K. THIRUNAVUKKUARASU<sup>1</sup>, Z. LU, National High Magnetic Field Laboratory, Tallahassee, FL, J. SIMPSON, Department of Physics, Towson University, MD, A. WALKER, National Institute of Standards and Technology, Gaithersburg MD, J. SEARS, Y.-J. KIM, Department of Physics, University of Toronto, Canada, K. BURCH, Department of Physics, Boston College, MA, D. SMIRNOV, National High Magnetic Field Laboratory, Tallahassee, FL — The presence of a 2D quantum spin liquid state was recently suggested for the spin-orbit coupled Mott insulator  $\alpha$ -RuCl<sub>3</sub> with a honeycomb lattice.[Phys. Rev. 90, 041112 (2014)] Optical spectroscopy, Raman scattering, specific heat as well as magnetic susceptibility measurements on  $\alpha$ -RuCl<sub>3</sub> identified elementary excitations due to electronic correlations and spin-orbit coupling.[arXiv:1503.07593, Phys. Rev. Letters 114, 147201 (2015), and Phys. Rev. 91, 144420 (2015)] These observations appear to be consistent with theoretical expectations for Heisenberg-Kitaev model for QSL.[Phys. Rev. 91, 241110 (2015)] The underlying mechanism for the unconventional magnetism in  $\alpha$ -RuCl<sub>3</sub> was further investigated by probing the effect of external magnetic field on the Raman spectroscopic signatures. Raman scattering experiments were performed at temperatures down to 5 K and magnetic fields up to 10 T. The intensity of strongest  $A_{1g}$  phonon was found to decrease with increasing magnetic field strength suggesting the presence of strong magnetic interactions. The experimental observations and its implications will be presented.

**1:39PM L33.00011 High Pressure Transport and Structural Study on the Honeycomb Lattice Iridates  $A_2\text{IrO}_3$  ( $A = \text{Na, Li}$ )** , YOGESH SINGH, Indian Institute of Science Education and Research (IISER) Mohali, Knowledge City, Sector 81, Mohali 140306, India, SAMAR LAYEK, School of Physics and Astronomy, Tel-Aviv University, 69978, Tel-Aviv, Israel, KAVITA MEHLAWAT, Indian Institute of Science Education and Research (IISER) Mohali, Knowledge City, Sector 81, Mohali 140306, India, ERAN GREENBERG, GREGORY KH. ROZENBERG, MOSHE P. PASTERNAK, School of Physics and Astronomy, Tel-Aviv University, 69978, Tel-Aviv, Israel — The honeycomb lattice iridates  $A_2\text{IrO}_3$  ( $A = \text{Na, Li}$ ) have been predicted and shown to exhibit novel magnetic properties which suggest that these materials could realize bond-directional Kitaev-like magnetic exchange interactions [1 - 5]. We will present high pressure (P) electrical transport ( $P \leq 80$  GPa) and powder X-ray diffraction ( $P \leq 40$  GPa) on these materials. The PXRD data for both materials show a structural transition around  $P \sim 5$  GPa. The transport data show a dramatic reduction of the charge gap for  $\text{Na}_2\text{IrO}_3$ . Lett. **108**, 127203 (2012). [3] F. Ye et al., Phys. Rev. B **85**, 180403 (2012) [5] S. H. Chun et al. Nature Phys. **11**, 462 (2015).

**1:51PM L33.00012 Order by disorder in Kitaev-Heisenberg models on the honeycomb lattice<sup>1</sup>**, NATALIA PERKINS, YURIY SIZYUK, SAMUEL DUCATMAN, Univ of Minnesota, Minneapolis, PETER WOELFLE, Institute for Condensed Matter Theory and Institute for Nanotechnology, Karlsruhe Institute of Technology — Recent diffuse magnetic x-ray scattering data in Na<sub>2</sub>IrO<sub>3</sub> [1] clearly determined the spin orientation in this zigzag state and showed that, unexpectedly, it is along the 44.3 degrees direction with respect to a axis, which is approximately half way in between the cubic x and y axes. This experiment provides an important check of the validity of any model proposed to describe the magnetic properties of Na<sub>2</sub>IrO<sub>3</sub> as the model should correctly predict not only the type of the magnetic order but also its orientation in space. We propose that order by disorder mechanism in quantum J1-K1-J2-K2-J3 model [2] gives the experimentally observed direction along cubic face diagonals. Our findings are based on both the calculation of the contribution of thermal fluctuations of quantum spins into free energy obtained by Hubbard-Stratonovich transformation and the zero-point correction to the ground state energy due to quantum spin fluctuations obtained by the spin-wave expansion at zero temperature. **Session L34 FOEP: Forum on Outreach and Engaging the Public** 337 - Yvan Bruynseraede, University of Leuven

**11:15AM L34.00001 How to interact with Congress about Science**, RAYMOND ORBACH, The University of Texas at Austin — The role of Congress is critical to the success of the scientific enterprise, both in terms of authorization and appropriation. As a consequence, it is very important to make the case for science directly with Congress. Every scientist has a representative in the House of Representatives in whose district he/she lives, and in the Senate. Constituents are especially welcomed in their offices. A personal visit is the most effective means for transmitting the importance of science in general, and physics in particular. The AAAS website lists the "Top Ten Rules for Working With Congress." They are: (1) Know your goal; (2) Understand how Congress works; (3) Conduct detailed background research; (4) Determine the timing of your course of action; (5) Be clear and succinct; (6) Understand Congressional staff and their influence; (7) Provide concrete suggestions; (8) Present support of science as a means to meet national and local goals, not as an entitlement; (9) Be willing to say "I don't know"; and (10) Follow up appropriately. Each of these will be described in more detail during the presentation. The March Meeting is an example of a particularly important time period for meeting with representatives (Rule #4). The President's Budget Request has been submitted to Congress, and the individual appropriation subcommittees are in the process of developing their respective "mark ups." Appointments with members or their staff is now timely, and urgent. Authorization bills are also in play, and can have significant impact on the scientific community. Paying attention to their development in key committees (e.g. the Science, Space, and Technology Committee of the House of Representatives), and providing appropriate and timely input, is the responsibility of every scientist.

**11:51AM L34.00002 How to organize a World Renowned Science Festival**, MARC SCHULMAN, USA Science and Engineering Festival — No abstract available.

**1:03PM L34.00004 How Physics World reaches out in a digital age**, MATIN DURRANI, Editor, Physics World — Physics World is an award-winning international magazine that exists in print and digital formats. Exploiting the opportunities available with digital publishing and apps, our output has expanded hugely in recent years to include technology-linked focus issues, regional special reports on the likes of China, India, Mexico and Brazil, plus audio, video and interactive material too. This growth in content - and new media for presenting physics - reflects wider changes in communication. People increasingly want to access content in a manner and time of their choosing, seeking out information presented in a way that suits them and their needs. That can be challenging for physics communicators because it means tailoring your message to different audiences and the medium they are using. But it's exciting too as you can reach out to many more people into physics - and in many different ways - than was possible in the past. This talk outlines some principles of good communication, including telling a good story, bearing the reader, viewer or listener in mind, using appropriate media, keeping up with social media, and exploiting the power of video. But with new forms of communication constantly emerging, it's worth remembering there is no one "right answer".

**1:39PM L34.00005 Physics in a Brewery**, JEREMIE PALACCI, UC, San Diego — Looking through the glass, and what Physics found there. A story of beer. Bubbles, heads and temperature make for a great pint, and a vast playground for the physicist. We will discuss a variety of aspects of the science of beer and reflect on the rational of the tricks pulled by professional brewers! – In partnership with Mike Hess Brewery, San Diego.

**11:15AM L35.00001 Reversible electron-hole separation in a hot carrier solar cell**, HEINER LINKE, Lund University — Hot-carrier solar cells are envisioned to utilize energy filtering to extract power from photogenerated electron-hole pairs before they thermalize with the lattice, and thus potentially offer higher power conversion efficiency compared to conventional, single absorber solar cells. The efficiency of hot-carrier solar cells can be expected to strongly depend on the details of the energy filtering process, a relationship which to date has not been satisfactorily explored. Here, we establish the conditions under which electron-hole separation in hot-carrier solar cells can occur reversibly, that is, at maximum energy conversion efficiency. We find that, under specific conditions, the energy conversion efficiency of a hot-carrier solar cell can exceed the Carnot limit set by the intra-device temperature gradient alone, due to the additional contribution of the quasi-Fermi level splitting in the absorber. To achieve this, we consider a highly selective energy filter such as a quantum dot embedded into a one-dimensional conductor. We also establish that the open-circuit voltage of a hot-carrier solar cell is not limited by the band gap of the absorber, due to the additional thermoelectric contribution to the voltage. Additionally, we find that a hot-carrier solar cell can be operated in reverse as a thermally driven solid-state light emitter. In addition this theoretical analysis, I will also report on first experimental results in a nanowire-based energy filter device. Ref: S Limpert, S Bremner, and H Linke, New J. Phys 17, 095004 (2015)

**11:51AM L35.00002 Thermionic energy conversion in carbon nanotube networks**, CHEN LI, KEVIN PIPE, University of Michigan - Ann Arbor, KEVIN PIPE'S GROUP TEAM — We investigate whether efficient carrier ballistic transport in CNT networks can overcome the parasitic effects of high CNT thermal conductance to yield thermionic (TI) devices with high energy conversion efficiency and/or high cooling power density. We simulate semiconducting single-walled carbon nanotube (SWCNT) structures in which inter-tube junctions provide the necessary filtering of high-energy electrons. Using energy-dependent transmission functions, we compare the performances of various junction types in selective filtering, and then perform Monte Carlo (MC) simulations to study the subsequent relaxation of hot electrons within the SWCNTs. Finally, we examine the parasitic effects of high thermal conductance, accounting for reductions in phonon mean free path due to scattering at inter-tube junctions. The results of the junction transmission, MC, and phonon transport simulations suggest optimal CNT types, junction types, and inter-junction spacings that maximize energy conversion metrics such as efficiency and cooling power density. While certain aspects of electron transport and phonon transport in CNT networks remain unresolved, our simulations suggest that CNT-based networks show promise for TI energy conversion.

**12:03PM L35.00003 Enhanced Thermoelectric Properties in Tailored Semiconducting SWCNT Networks**, A.D. AVERY, Metropolitan State University of Denver, B.H. ZHOU, National Renewable Energy Laboratory, J. LEE, E. LEE, Korea Advanced Institute of Science and Technology, E.M. MILLER, R. IHL, National Renewable Energy Laboratory, D. WESENBERG, University of Denver, K.S. MISTRY, S.L. GUILLOT, National Renewable Energy Laboratory, B.L. ZINK, University of Denver, Y. KIM, Korea Advanced Institute of Science and Technology, J.L. BLACKBURN, A.J. FERGUSON, National Renewable Energy Laboratory — Single-walled carbon nanotubes (SWCNTs) are a versatile electronic material being explored as cost-effective, high-performance alternative in a variety of renewable energy applications. In this talk, we present a series of experiments designed to probe the thermal and electrical transport through networks of semiconducting SWCNT dispersed in matrices of polyfluorene polymers. We measured electrical transport as a function of hole density to explore the coupling between the electrical conductivity and Seebeck coefficient (thermopower) in the s-SWCNT networks. These networks exhibit large thermopowers  $> 1000 \mu\text{V/K}$  at very low hole densities. Thermopower values remain high at high doping levels, resulting in thermoelectric power factors greater than  $340 \mu\text{W/m K}$ . Finally, we present measurements that demonstrate our doping process significantly reduces the thermal conductivity relative to undoped networks suggesting s-SWCNTs are a viable material for realizing thermally stable room temperature thermoelectric devices fashioned from inexpensive and abundant organic constituents.

**12:15PM L35.00004 Effects of Defects and Strain on Thermoelectric Properties of Single-walled Carbon Nanotubes<sup>1</sup>**, MASATO OHNISHI, TAKUMA SHIGA, JUNICHIRO SHIOMI, Univ of Tokyo — Carbon nanotubes (CNTs) have attracted much attention as a thermoelectric material. Although CNTs have large lattice thermal conductivity, CNT-based composites are promising candidates for thermoelectric material because the phonon transport is suppressed by scattering at contacts between CNTs. Therefore, previous studies have mainly focused on thermoelectric properties at contacts between CNTs. However, understanding the effects of defects and strain on the thermoelectric properties of CNTs themselves are important because they exist inevitably in real systems. In this study, we study the effects of defects, vacancy and Stone-Wales defect, and uniaxial compressive strain on single-walled CNTs (SWNTs) employing nonequilibrium molecular dynamics simulation and Green's function method. We find that the defects and buckling deformation significantly decrease electron conductance, and the effect is much stronger than that on thermal conductivity and Seebeck coefficient, resulting in severe reduction of the figure of merit. In addition, the estimation of thermoelectric performance including a inter-SWNT contact indicates that the effect of defects and strain can deteriorate the figure of merit of the SWNT networks.

**12:27PM L35.00005 Photoinduced thermoelectric transport in solution-processed semiconductors**, NELSON COATES, CSU Maritime, FAN YANG, AYASKANTA SAHU, JEFFREY URBAN, Lawrence Berkeley National Lab — The ability to fabricate semiconductor materials directly from solution offers a number of advantages over traditional semiconductor processing routes. In addition to the generally lower costs of manufacturing and ability to scale device to large areas, solution-based fabrication techniques also easily allow for extensive physical and chemical tuning of the processed materials. Here, we examine ways to tune the photoinduced thermoelectric transport in solution-processed semiconductors, and in particular explore ways to leverage some of the inherent characteristics of solution processed semiconductors (such as electronic inhomogeneity and large trap densities) to improve the photoinduced thermoelectric response in these materials.

**12:39PM L35.00006 Large local temperature gradient induced by surface plasmon heating of periodic metal structure**, RYOKO SHIMADA, HITOMI SAKAI, Japan Women's University — Mixtures of several gas or solution having different concentration can be separated by the gradient of temperature. This is the so-called Soret effect. This phenomenon is quite important for chemical reaction and material condensation/separation. For activating large Soret effect, it would be useful to focus on the surface plasmon heating (SPH) of metal nanostructures that interact with light. In this work, a local temperature gradient was created with the aid of SPH achieved for periodic silver structures in a mesoscopic length scale fabricated by a nanosphere lithography method. Excitation of this periodic structure (by blue laser, for example) could create a localized periodic temperature gradient, as large as  $\sim 1,000 \text{ K}/\mu\text{m}$ , as suggested from preliminary heat-transfer calculation. Experimental and theoretical results will be presented on site

**12:51PM L35.00007 Valley caloritronics and its realization by graphene nanoribbons<sup>1</sup>**, XIAOBIN CHEN, LEI ZHANG, HONG GUO, McGill University — We propose and theoretically investigate a new idea of **valley caloritronics** where quantum transport of the valley degrees of freedom is thermally induced. Valley caloritronics addresses questions such as thermal generation of valley polarized current and more importantly, pure valley current without an accompanying charge current. After establishing a general physical picture, we show that heat-induced pure valley current can be generated by virtue of wedge-shaped graphene nanoribbons in a two-probe device setup. We discover that the quantum transport properties of the valley degree of freedom can be very different when driven by a voltage bias or by a temperature bias. A very surprising result is that an alternating valley current can be *thermally* generated via gate control: namely the heat-induced valley current changes its flow direction in some quasi-periodic manner versus the value of a gate voltage at a fixed polarity. Our results indicate a vast potential for developing valley caloritronic devices.

**1:03PM L35.00008 Theoretical studies on performance evaluation of solar thermoelectronic energy converter with graphene emitter**, OLUKUNLE OLAWOLE<sup>1</sup>, DILIP DE<sup>2</sup>, Department of Physics, Covenant University, Ota, Nigeria — In this paper we consider detailed energy dynamics of solar thermoelectronic energy converter using graphene as the emitter. The emitter is heated by solar energy concentrated by a parabolic mirror concentrator. We study the performance evaluation of the energy conversion using temperature dependent work function of graphene and model the space charge problem by introducing a factor in the emitter and collector current densities. We present computations on power output and efficiency as function of solar insolation, height of emitter from the base of the mirror, reflection coefficient of the mirror, temperature and work function of collector. Effect of molecular doping on the performance of the graphene solar tech is also discussed.

<sup>1</sup>Please schedule our papers so that they are well separated in time for presentations.

**1:15PM L35.00009 Graphene-based vdW heterostructure Induced High-efficiency Thermoelectric Devices.** , SHIJUN LIANG, LAY KEE ANG, Singapore University of Technology and Design — Thermoelectric material (TE) can convert the heat into electricity to provide green energy source and its performance is characterized by a figure of merit (ZT) parameter. Traditional TE materials only give ZT equal to around 1 at room temperature. But, it is believed that materials with  $ZT > 3$  will find wide applications at this low temperature range. Prior studies have implied that the interrelation between electric conductivity and lattice thermal conductivity renders the goal of engineering ZT of bulk materials to reach  $ZT > 3$ . In this work, we propose a high-efficiency van der Waals (vdW) heterostructure-based thermionic device with graphene electrodes, which is able to harvest wasted heat (around 400K) based on the newly established thermionic emission law of graphene electrodes instead of Seebeck effect, to boost the efficiency of power generation over 10% around room temperature. The efficiency can be above 20% if the Schottky barrier height and cross-plane lattice thermal conductivity of transition metal dichalcogenides (TMD) materials can be fine-engineered. As a refrigerator at 260 K, the efficiency is 50% to 80% of Carnot efficiency. Finally, we identify two TMD materials as the ideal candidates of graphene/TMD/graphene devices based on the state-of-art technology.

**1:27PM L35.00010 Printable Graphene-based Thermoelectric Device with High Temperature Capability** , TIAN LI, YANAN CHEN, DENNIS DREW, LIANGBING HU, University of Maryland, College Park, NANOMATERIALS FOR EMERGING DEVICES COLLABORATION — Thermoelectric devices are of particular interest due to their capability to convert heat into electrical power. We demonstrate the use of a Graphene-based thermoelectric device that can generate output voltages of hundreds of millivolts with an illuminating Graphene strip as the blackbody source. Our proposed device is superior for thermoelectric conversion mainly due to its high temperature capability that yields a maximum Carnot efficiency limit of 90% (referenced to room temperature) and a high Seebeck coefficient. Our device is also macroscopic with good mechanical strength and stabilized performance, making it attractive for large scale and reliable thermoelectric devices.

**1:39PM L35.00011 Thermal conductivity and rectification study of restructured Graphene** , ANUJ ARORA, University of Tokyo — Electronics' miniaturization, has led to search for better thermal management techniques and discovery of important transport phenomenon. Thermal rectification, directionally preferential heat transport analogous to electrical diode, is one such technique, garnering tremendous interest. Its possibility has been explored through structural asymmetry, introducing a differential phonon density of states in hot and cold regions. As of now, mass and shape asymmetries have been studied, both experimentally and theoretically. However, strict requirements of material length being shorter than phonon mean free path and phonon coherence preservation at surface, makes connecting two materials with different temperature-dependent thermal conductivities, a more natural approach. To avoid resultant thermal boundary resistance and integration complexities, we achieve the affect in single material, by restructuring a region of Graphene by introducing defects. The asymmetry impedes ballistic phonon transport, modulating temperature dependence of thermal conductivity in the two regions. We perform deviational Monte Carlo simulations based on Energy-based formulation to microscopically investigate phonon transport, possibility and optimal conditions for thermal rectification. The proposed method uses phonon properties obtained from first principle, treat phonon-boundary scattering explicitly with properties drawn from Bose-Einstein Distribution.

**1:51PM L35.00012 Experimental Studies of Graphene Antidot Lattices for Thermoelectric Applications<sup>1</sup>** , QING HAO, DONGCHAO XU, HONGBO ZHAO, Department of Aerospace and Mechanical Engineering, University of Arizona, XU DU, Department of Physics, Stony Brook University — Pristine graphene has low thermoelectric performance due to its ultra-high thermal conductivity and zero band gap that leads to a low Seebeck coefficient ( $S$ ). Both issues can be addressed by patterning periodic nano- or sub-1-nm pores (antidots) across graphene, called graphene antidot lattices (GALs). In GALs, a geometry-dependent band gap can be opened up to dramatically increase  $S$ , with significantly reduced thermal conductivity ( $k$ ) due to phonon scattering by antidots. Above will lead to a high thermoelectric figure of merit ( $\sim 1.0$  at 300 K by computations [1]) in GALs to be used for device cooling. Despite numerous calculations, experimental studies of GALs are restricted to electrical conductivity ( $\sigma$ ) measurements for GALs with  $\sim 10$  nm patterns. The critical  $k$  measurements are still lacking. In this work, all three thermoelectric properties ( $S$ ,  $k$ , and  $\sigma$ ) are measured on suspended GALs with sub-10 nm pores. In comparison, electrical properties are also characterized for GALs on a substrate. The results presented here provide important guidance on how to tailor transport properties of general two-dimensional materials with ALs. **2:03PM L35.00013 Ab initio design of low work function complex oxides for thermionic energy conversion** , STEPHANIE MACK, UC Berkeley, GUO LI, Molecular Foundry, LBNL; Joint Center for Artificial Photosynthesis, JEFFREY NEATON, UC Berkeley; Molecular Foundry, LBNL; Kavli Energy Nanosciences Institute at Berkeley — Understanding and controlling work functions, or band edge energies, is of interest for a variety of applications in optoelectronics and energy conversion. In particular, while recent advances in device design have improved the feasibility of thermionic generators, new low work function materials are needed to enable their widespread use. Perovskite-based oxides ( $ABO_3$ ) are a diverse class of materials that, depending on the transition metal atoms on the A and B sites, can give rise to myriad emergent and collective phenomena. Here, we use density functional theory calculations to examine how the work function of one such oxide, SrRuO<sub>3</sub> (SRO), can be tuned by monolayers of SrTiO<sub>3</sub> (STO) and other polar or near-polar oxides. We find that SRO work functions can be tuned by over 1 eV with one layer of STO, although the calculated reduction in work function is an order of magnitude less than would be expected from the bulk polarization. We understand the variation in work function via a detailed analysis of Born effective charges at the surface, which are as small as 10% of their bulk values, and charge rearrangement at the STO surface and SRO/STO interface.

**11:15AM L40.00001 Hamiltonian formulations in the computation of extremely deformed nano-scale hyper-elastic rods.** , JOHN H. MADDOCKS, EPFL FSB MATHGEOM LCVMM — There has been a recent resurgence of interest in models exploiting elastic filaments and ribbons, motivated in large part by nano-scale applications, including DNA. Such models are frequently nearly inextensible or nearly unsharable. I will describe how such systems can be modelled as a smooth limit within a hierarchy of perturbed Hamiltonian formulations of the governing equations. Examples include a sequence-dependent double-strand birod model of DNA, where a more familiar rod model can be obtained as a smooth limit in which the intra-strand degrees of freedom are frozen..

**11:51AM L40.00002 A conserved quantity in thin body dynamics** , JAMES HANNA, HODJAT PENDAR, Virginia Tech — We use an example from textile processing to illustrate the utility of a conserved quantity associated with metric symmetry in a thin body. This quantity, when combined with the usual linear and angular momentum currents, allows us to construct a four-parameter family of curves representing the equilibria of a rotating, flowing string. To achieve this, we introduce a non-material action of mixed Lagrangian-Eulerian type, applicable to fixed windows of axially-moving systems. We will point out intriguing similarities with Bernoulli's equation, discuss the effects of axial flow on rotating conservative systems, and make connections with 19th- and 20th-century results on the dynamics of cables.

**12:03PM L40.00003 Tearing of thin spherical shells adhered to equally curved rigid substrates**, CONNOR MCMAHAN, ANNA LEE, JOEL MARTHELOT, PEDRO REIS, Massachusetts Institute of Technology — Lasik (Laser-Assisted in Situ Keratomileusis) eye surgery involves the tearing of the corneal epithelium to remodel the corneal stroma for corrections such as myopia, hyperopia and astigmatism. One issue with this procedure is that during the tearing of the corneal epithelium, if the two propagating cracks coalesce, a flap detaches which could cause significant complications in the recovery of the patient. We seek to gain a predictive physical understanding of this process by performing precision desktop experiments on an analogue model system. First, thin spherical shells of nearly uniform thickness are fabricated by the coating of hemispherical molds with a polymer solution, which upon curing yields an elastic and brittle structure. We then create two notches near the equator of the shell and tear a flap by pulling tangentially to the spherical substrate, towards its pole. The resulting fracture paths are characterized by high-resolution 3D digital scanning. Our primary focus is on establishing how the positive Gaussian curvature of the system affects the path of the crack tip. Our results are directly contrasted against previous studies on systems with zero Gaussian curvature, where films were torn from planar and cylindrical substrates.

**12:15PM L40.00004 Cracks in Sheets Draped on Curved Surfaces**, NOAH P. MITCHELL, James Franck Institute, University of Chicago, VINZENZ KONING, VINCENZO VITELLI, Instituut-Lorentz for Theoretical Physics, Universiteit Leiden, WILLIAM T.M. IRVINE, James Franck Institute, University of Chicago — Conforming materials to surfaces with Gaussian curvature has proven a versatile tool to guide the behavior of mechanical defects such as folds, blisters, scars, and pleats. In this talk, we show how curvature can likewise be used to control material failure. In our experiments, thin elastic sheets are confined on curved geometries that stimulate or suppress the growth of cracks, and steer or arrest their propagation. By redistributing stresses in a sheet, curvature provides a geometric tool for protecting certain regions and guiding crack patterns. A simple model captures crack behavior at the onset of propagation, while a 2D phase-field model successfully captures the crack's full phenomenology.

**12:27PM L40.00005 Pick-up, impact, and peeling.**, HARMEET SINGH, JAMES HANNA, Virginia Tech — We consider a class of problems involving a one-dimensional, inextensible body with a propagating discontinuity (shock) associated with partial contact with a rigid obstacle providing steric, frictional, or adhesive forces. This class includes the pick-up and impact of an axially flowing string or cable, and the peeling of an adhesive tape. The dynamics are derived by applying an action principle to a non-material volume. The resulting boundary conditions provide momentum and energy jump conditions at the shock. These are combined with kinematic conditions on velocities and accelerations to obtain families of steady-state solutions parameterized by the shock velocity and momentum and energy sources. We find relationships between the jump in stress, injection of momentum, and dissipation of energy, which we apply to specific cases, and compare with other results in the literature on chain fountains, falling folded chains, and impulsively loaded cables. Time permitting, we will briefly discuss the possibility of using kinematic conditions and information about accelerating or otherwise unsteady forms of the adjoining bulk solutions to construct an equation of motion of the shock.

**12:39PM L40.00006 Effect of boundary conditions on the buckling instabilities of a ribbon under twist<sup>1</sup>**, CASEY TRIMBLE, ARSHAD KUDROLLI, Department of Physics, Clark University — We investigate the buckling instabilities of a thin flat sheet in the shape of a ribbon which is held at its ends and twisted under tension. Recently it was shown that such a system with clamped boundary conditions exhibited a rich variety of buckled shapes with longitudinal and transverse wrinkles as a function of applied twist and tension for a given ribbon aspect ratio and elastic modulus [1], which could be described by a far from threshold analysis of the covariant form of the Foppl-von Karman equations [2]. Here, we focus on the effect of the boundary conditions on the observed buckling patterns by constraining the ends only at the midpoint towards imposing free boundary conditions normal to the ribbon. In particular, we compare and contrast the observed phase diagram and the shape of the longitudinal and transverse buckled modes as a function of applied constraints. [1] J. Chopin and A. Kudrolli, Phys. Rev. Lett. 111, 174302 (2013). [2] J. Chopin, V. Demery, and B. Davidovitch J. Elast. 119, 137 (2015).

**12:51PM L40.00007 Multi-stability and bifurcations of a thin band.**, TIAN YU, JAMES HANNA, Department of Biomedical Engineering and Mechanics, Virginia Tech — Thin band- or strip-like structures are common motifs in flexible and deployable systems, serving as integrated connectors, hinges, and umbilicals. The morphing systems impose variable constraints on these components, inducing complex responses. We experimentally investigate a simple configuration representing the above type, a thin elastic band with end constraints on position and orientation. These constraints correspond to a combination of compression and shear with respect to a flat rectangular rest configuration. We vary the aspect ratio of the band, and the position and clamping angle at its ends. The buckled structure remains developable up to limiting deformations that approach one of two states, each dominated by two singularities. At intermediate deformations, the structure may adopt many distinct stable states. Transitions between these states can be smooth or violent, and depend strongly on constraints such as the clamping angle. Time permitting, we will relate our results to the behavior of anisotropic rods, and of strips subjected to twisting and extension.

**1:03PM L40.00008 Finite and infinite wavelength elastocapillary instabilities with cylindrical geometry**, JOHN BIGGINS, CHEN XUAN<sup>1</sup>, Cambridge University — In an elastic cylinder with shear modulus  $\mu$ , radius  $R_0$  and surface tension  $\gamma$  we can define an emergent elastocapillary length  $l = \gamma/\mu$ . When this length becomes comparable to  $R_0$  the cylinder becomes undergoes a Rayleigh-Plateau type instability, but surprisingly, with infinite wavelength  $\lambda$  rather than with wavelength  $\lambda \sim R_0 \sim l$ . Here we take advantage of this infinite wavelength behaviour to construct a simple 1-D model of the elastocapillary instability in a cylindrical gel which permits a high-amplitude fully non-linear treatment. In particular, we show that the instability is sub-critical and entirely dependent on the elastic cylinder being subject to tension. We also discuss elastocapillary instabilities in a range of other cylindrical geometries, such a cylindrical cavities through a bulk elastic solid, or a solid cylinder embedded in a bulk elastic solid, and show that in these cases instability has finite wavelength. Thus infinite wavelength behaviour is a curiosity of elastic cylinders rather than the generic behaviour or elasto-capillarity.

**1:15PM L40.00009 Sequential buckling of an elastic wall<sup>1</sup>**, JOSE BICO, HADRIEN BENSE, LUDOVIC KEISER, BENOIT ROMAN, PMMH, ESPCI, Paris, France, FRANCISCO MELO, Universidad de Santiago de Chile, MANOUK ABKARIAN, Centre de Biochimie Structurale, Montpellier, France — A beam under quasistatic compression classically buckles beyond a critical threshold. In the case of a free beam, the lowest buckling mode is selected. We investigate the case of a long wall grounded of a compliant base and compressed in the axial compression. In the case of a wall of slender rectangular cross section, the selected buckling mode adopts a nearly fixed wavelength proportional to the height of the wall. Higher compressive loads only increase the amplitude of the buckle. However if the cross section has a sharp shape (such as an Eiffel tower profile), we observe successive buckling modes of increasing wavelength. We interpret this unusual evolution in terms of scaling arguments. At small scales, this variable periodicity might be used to develop tunable optical devices.

<sup>1</sup>We thank ECOS C12E07, CNRS-CONICYT, and Fondecyt Grant No. N1130922 for partially funding this work.

**1:27PM L40.00010 Mechanics of a Knitted Fabric<sup>1</sup>** , SAMUEL POINCLOUX, FREDERIC LECHENAULT, MOKHTAR ADDA-BEDIA, Laboratoire de Physique Statistique, Ecole Normale Supérieure, 24 rue Lhomond, 75005 Paris, France — A simple knitted fabric can be seen as a topologically constrained slender rod following a periodic path. The non-linear properties of the fabric, such as large reversible deformation and characteristic shape under stress, arise from topological features known as stitches and are distinct from the constitutive yarn properties. Through experiments we studied a model stockinette fabric made of a single elastic thread, where the mechanical properties and local stitch displacements were measured. Then, we derived a model based on the yarn bending energy at the stitch level resulting in an evaluation of the displacement fields of the repetitive units which describe the fabric shape. The comparison between the predicted and the measured shape gives very good agreement and the right order of magnitude for the mechanical response is captured. This work aims at providing a fundamental framework for the understanding of knitted systems, paving the way to thread based smart materials.

**1:39PM L40.00011 Crumpling of an Elastic Ring in Two Dimensions** , CARTER VANHUSS, SHENGFENG CHENG, Department of Physics & Macromolecules and Interfaces Institute, Virginia Polytechnic Institute and State University — We use molecular dynamics simulations to study the crumpling of an elastic ring (i.e., a circular elastic line) in two dimensions. The crumpling is triggered by reducing the radius of a circular repulsive wall that is used to confine the ring. The ring is modeled as a bead-spring chain. A harmonic potential describing the bonds between neighboring beads is parameterized to reproduce the Young's modulus of the elastic line in the continuum limit. A modified harmonic angle interaction is used to capture the bending of the elastic line including situations where the line is locally stretched or compressed. We have confirmed that the bead-spring model has the correct continuum limit by comparing results on rings made of different numbers of beads but with parameters derived from the same elastic line. With the computational model, we study the morphological transition of the ring and the local distribution of the bond and bending energies as the ring is compressed at various rates, forced to crumple, and finally confined into a dense-packed structure. We find that the crumpling transition signals a sharp energy transfer from the compression to the bending mode. We further explore the possibility of defining an effective temperature for such crumpled systems.

**1:51PM L40.00012 Natural Curvature as Effective Confinement in Elastic Sheets** , OCTAVIO ALBARRAN, Max Planck Institute for Dynamics and Self-Organization, ELENI KATIFORI, University of Pennsylvania, LUCAS GOEHRING, Max Planck Institute for Dynamics and Self-Organization — The wrinkling and folding transitions of thin elastic sheets have been extensively studied in the last decade. The exchange of energy from stretching to bending acts as a paradigm for a wide range of elastic instabilities, including the wrinkling of the gut, and the crinkling of leaves. In two dimensions this type of problem is typically considered by the model of an Euler-*elastica* in compressive confinement. We show that, even without any external forces, an elastic surface supported by a fluid can bend and wrinkle when it acquires a non-zero natural curvature. Locally, we will demonstrate how a preferential curvature can be related to an effective compression, and hence a confining force that can vary spatially. This suggests a simple experimental setup, where we have characterised a variety of wrinkle patterns that can be generated for different mechanical properties and natural curvatures.

**2:03PM L40.00013 Anomalously soft non-Euclidean spring** , IDO LEVIN, ERAN SHARON, Hebrew Univ of Jerusalem — In this work we study the mechanical properties of a frustrated elastic ribbon spring - the non-Euclidean minimal spring. This spring belongs to the family of non-Euclidean plates: it has no spontaneous curvature, but its lateral intrinsic geometry is described by a non-Euclidean reference metric. The reference metric of the minimal spring is hyperbolic, and can be embedded as a minimal surface. We argue that the existence of a continuous set of such isometric minimal surfaces with different extensions leads to a complete degeneracy of the bulk elastic energy of the minimal spring under elongation. This degeneracy is removed only by boundary layer effects. As a result, the mechanical properties of the minimal spring are unusual: the spring is ultra-soft with rigidity that depends on the thickness,  $t$ , as  $t^{7/2}$ , and does not explicitly depend on the ribbon's width. These predictions are confirmed by a numerical study of a constrained spring. This work is the first to address the unusual mechanical properties of constrained non-Euclidean elastic objects. We also present a novel experimental system that is capable of constructing such objects, along with many other non-Euclidean plates.

**11:15AM L42.00001 Antithetical Polymers: Performance Through Structured Incompatible Elements** , A.P. NOWAK, HRL Laboratories, 3011 Malibu Canyon Rd, Malibu, CA — Modern coating technology is often limited by a complex trade space that leaves many applications poorly served. Next generation coatings able to successfully meet these application challenges typically require multiple and often contradictory properties not easily met with traditional homogenous compositions. This presentation describes our efforts to combine highly incompatible coating elements capable of organizing into discrete regions at mesoscopic length scales (0.1-10  $\mu\text{m}$ ) in order to express multiple undiluted physical properties of individual components at the macroscopic scale. Such a strategy requires understanding and controlling the interactions between composition and processing that ultimately drive microstructure and performance. Specific examples presented will include anti-fouling coatings where we have combined a low surface energy component with a lubricating region or anti-freeze element to mitigate accumulation of insect debris or delay freezing, respectively. In collaboration with the following: A.F. Gross, A.R. Rodriguez, E. Sherman, C. Ro, S. Yang, M. Behroozi, and B. Fong, HRL Laboratories, 3011 Malibu Canyon Rd, Malibu, CA

**11:51AM L42.00002 Predicting the In-Service Lifetime of Polymers: A multi-scale modeling approach.** , OM PRAKASH, Boeing Research & Technology India Centre, Bangalore 560016, India — Recent advances in theoretical chemistry have enabled a predictive approach to assessing polymer behaviors without lifetime testing. We report on progress in this area. In collaboration with the following: Priya Parandekar and Nishant Sinha, Boeing Research & Technology India Centre, Bangalore 560016, India

**12:27PM L42.00003 Understanding network forming reactions and properties through combining computational and experimental methods** , JEANNETTE M. GARCIA, IBM Almaden, San Jose CA — Poly(hexahydrotriazine)s (PHTs) represent a class of synthetically tunable and dynamic materials that exhibits broad scope in thermal and mechanical properties. Depending on monomer choice, these thermosets can range from elastomeric and self-healing to strong and brittle. Highly crosslinked thermosetting networks such as these have limited solubility in organic solvents; thus, solid-state analysis was coupled with *in silico* methods to characterize structure-property relationships. Density functional theory (DFT) on small-molecule model systems and molecular dynamics (MD) simulations on network-formation provided a rationale for observed properties and guided ensuing experiments. This talk will focus on the combination of experimental efforts with computational analysis to develop and design new polymeric materials with targeted properties.

**11:15AM L43.00001 Flexible embedding of networks**, JUAN FERNANDEZ-GRACIA, CAROLINE BUCKEE, JUKKA-PEKKA ONNELA, Harvard T.H. Chan School of Public Health — We introduce a model for embedding one network into another, focusing on the case where network A is much bigger than network B. Nodes from network A are assigned to the nodes in network B using an algorithm where we control the extent of localization of node placement in network B using a single parameter. Starting from an unassigned node in network A, called the source node, we first map this node to a randomly chosen node in network B, called the target node. We then assign the neighbors of the source node to the neighborhood of the target node using a random walk based approach. To assign each neighbor of the source node to one of the nodes in network B, we perform a random walk starting from the target node with stopping probability  $\alpha$ . We repeat this process until all nodes in network A have been mapped to the nodes of network B. The simplicity of the model allows us to calculate key quantities of interest in closed form. By varying the parameter  $\alpha$ , we are able to produce embeddings from very local ( $\alpha = 1$ ) to very global ( $\alpha \rightarrow 0$ ). We show how our calculations fit the simulated results, and we apply the model to study how social networks are embedded in geography and how the neurons of C. Elegans are embedded in the surrounding volume.

**11:27AM L43.00002 Exploring many-body physics with deep networks**, GIACOMO TORLAI, University of Waterloo, JUAN CARRASQUILLA, Perimeter Institute, DAVID SCHWAB, Northwestern University, ROGER MELKO, University of Waterloo — The introduction of neural networks with deep architecture has led to a revolution, giving rise to a new wave of technologies empowering our modern society. Although data science has been the main focus, the idea of generic algorithms which automatically extract features and representations from raw data is quite general and applicable in multiple scenarios. Motivated by the effectiveness of deep learning algorithms in revealing complex patterns and structures underlying data, we are interested in exploiting such tool in the context of many-body physics. In this talk we will focus on how to extract information about the physics of a many-body system from the generative training of a deep network, and ultimately consider discriminative tasks, such as phase diagrams estimation and critical points detection. We will discuss results for different classical spin systems, including models with quenched disorder.

**11:39AM L43.00003 Random walks on networks<sup>1</sup>**, ISAAC DONNELLY, Northeastern — Random walks on lattices are a well used model for diffusion on continuum. They have been to model subdiffusive systems, systems with forcing and reactions as well as a combination of the three. We extend the traditional random walk framework to the network to obtain novel results. As an example due to the small graph diameter, the early time behaviour of subdiffusive dynamics dominates the observed system which has implications for models of the brain or airline networks.

<sup>1</sup>I would like to thank the Australian American Fulbright Association

**11:51AM L43.00004 The Impact of Selectivity on Fitness Evolution in the Multi-Generational Matching Problem<sup>1</sup>**, STEPHEN DIPPLE, TAO JIA, GYORGY KORNISS, BOLESŁAW SZYMANSKI, Rensselaer Polytechnic Institute — The stochastic matching hypothesis has been found to produce self-similar pairing without explicitly requiring self-similarity in the rules for matching. Here, we introduce an added complexity of selectivity in which the relative probability of being matched are modified.<sup>2</sup> This allows for probing in areas between the currently established matching hypothesis, random matching, and the extreme case of super selectivity, where only the very best fitness matches for nodes are created. A higher selectivity parameter has been found to indirectly increase the number of matches in the system monotonically. A fairly simple model is then implemented to produce offspring who inherit fitness based on the inherited fitness distribution which is a function of the parents' fitness. While the results show that the specific distribution used may limit the inherited quality factors to a too narrow range to be broadly applicable, the model does expose some interesting patterns in fitness evolution across multiple generations in the context of selectivity and network degree distribution.

**12:03PM L43.00005 A matrix product algorithm for stochastic dynamics on locally tree-like graphs**, THOMAS BARTHEL, Duke University, Department of Physics, CATERINA DE BACCO, SILVIO FRANZ, Université Paris-Sud, LPTMS — In this talk, I describe a novel algorithm for the efficient simulation of generic stochastic dynamics of classical degrees of freedom defined on the vertices of locally tree-like graphs. Such models correspond for example to spin-glass systems, Boolean networks, neural networks, or other technological, biological, and social networks. Building upon the cavity method and ideas from quantum many-body theory, the algorithm is based on a matrix product approximation of the so-called edge messages – conditional probabilities of vertex variable trajectories. The matrix product edge messages (MPEM) are constructed recursively. Computation costs and accuracy can be tuned by controlling the matrix dimensions of the MPEM in truncations. In contrast to Monte Carlo simulations, the approach has a better error scaling and works for both, single instances as well as the thermodynamic limit. Due to the absence of cancellation effects, observables with small expectation values can be evaluated accurately, allowing for the study of decay processes and temporal correlations with unprecedented accuracy. The method is demonstrated for the prototypical non-equilibrium Glauber dynamics of an Ising spin system. Reference: arXiv:1508.03295.

**12:15PM L43.00006 Percolation transition in dynamical traffic network with evolving critical bottlenecks**, DAQING LI, BeiHang University — A critical phenomenon is an intrinsic feature of traffic dynamics, during which transition between isolated local flows and global flows occurs. However, very little attention has been given to the question of how the local flows in the roads are organized collectively into a global city flow. Here we characterize this organization process of traffic as “traffic percolation,” where the giant cluster of local flows disintegrates when the second largest cluster reaches its maximum. We find in real-time data of city road traffic that global traffic is dynamically composed of clusters of local flows, which are connected by bottleneck links. This organization evolves during a day with different bottleneck links appearing in different hours, but similar in the same hours in different days. A small improvement of critical bottleneck roads is found to benefit significantly the global traffic, providing a method to improve city traffic with low cost. Our results may provide insights on the relation between traffic dynamics and percolation, which can be useful for efficient transportation, epidemic control, and emergency evacuation.

**12:27PM L43.00007 Properties of the networks of same-spin sites in each Ising Model macrostate**, ROBERT HOSKEN, The Aerospace Corporation — An Ising Model macrostate contains all the microstates with the same energy. Each macrostate is labeled in an energy two-space by the two sums in the Hamiltonian, one for the magnetism and the other for the interaction energy. In a single macrostate, a network can be defined for all the up-spin sites and another network for all the down-spin sites. An exact formula has been derived that explicitly provides the total number of connection links (edges) in both of these macrostate networks. This derivation follows from a meticulous analysis of the calculation of the sum of the product of spins in the Hamiltonian. It is applicable to one, two, and three dimension Ising models with periodic boundary conditions. The formula permits calculation of the total number of nearest-neighbor connections for all of the sites, and thus the average number of connections per site. The number of connections can be used to calculate the probability that a nearest neighbor in a particular direction at a spin site has the same spin. This probability can be used to infer the closeness of any macrostate to the ferromagnetic ground states, the paramagnetic region, or the anti-ferromagnetic ground states. Note that these properties of each macrostate do not require knowledge of the number of microstates in the macrostate (the density of states).

**12:39PM L43.00008 Upper Bound for the Ordering Transition on an Ising Model on a Graph**, TIMOTHY DOWNING, LEONID PRYADKO, Univ of California - Riverside — We present an upper bound for the ordering transition of a ferromagnetic Ising model on a graph. Namely, we show that at any given temperature, the magnetic susceptibility per spin cannot exceed that on an infinite tree, the universal cover of the original graph. Exact solution of the Ising model on the tree can be obtained using Bethe-Peierls expansion (also known as Belief Propagation). The corresponding transition point is given by a solution of an eigenvalue problem.

**12:51PM L43.00009 Spectral renormalization group theory on nonspatial networks**, ASLI TUNCER, AYSE ERZAN, Istanbul Tech Univ — We recently proposed a “spectral renormalization group” scheme, for non-spatial networks with no metric defined on them. We implemented the spectral renormalization group on two deterministic non-spatial networks without translational invariance, namely the Cayley tree and diamond lattice. The thermodynamic critical exponents for the Gaussian model are only functions of the spectral dimension,  $\tilde{d}$ . The Gaussian fixed point is stable with respect to a  $\psi^4$  perturbation up to second order on these lattices with  $\tilde{d} = 2$ , the lower critical dimension for the Ising universality class. This is expected for the Cayley tree, but for the diamond lattice it is an indication that the perturbation expansion up to second order breaks down at  $\tilde{d} = 2$ , as it does for the Wilson scheme on the square lattice. On generalized diamond lattices, with  $2 < \tilde{d} < 4$ , we find non-Gaussian fixed points with non-trivial exponents. For  $\tilde{d} > 4$ , the critical behavior is once again mean field.

**1:03PM L43.00010 Real beards and real networks: a spin-glass model for interacting individuals**, DION O'NEALE, University of Auckland — “I want to be different, just like all the other different people” sang the band King Missile. Whether they are the Beatniks of the 1950s, the punks of the 1970s, or the hipsters of today, non-conformists often tend to look the same, seemingly at odds with their goal of non-conformity. The spin-glass model, originally developed to describe the interaction of magnetic spins, and since applied to situations as diverse as the electrical activity of networks of neurons, to trades on a financial market, has recently been used in social science to study populations of interacting individuals comprised of a mix of both conformists and anti-conformists - or hipsters. Including delay effects for the interactions between individuals has been shown to give a system with non-trivial dynamics with a phase transition from stable behaviour to periodic switching between two states (let's call them bushy bearded and clean shaven). Analytic solutions to such a model are possible, but only for particular assumptions about the interaction and delay matrices. In this work we will show what happens when the interactions in the model are based on real-world networks with “small-world” effects and clustering.

**1:15PM L43.00011 Condensation and transport in the totally asymmetric inclusion process (TASIP)**<sup>1</sup>, JOHANNES KNEBEL, MARKUS F WEBER, LMU Munich, TORBEN KRUEGER, IST Austria, ERWIN FREY, LMU Munich — Transport phenomena are often modeled by the hopping of particles on regular lattices or networks. Such models describe, e.g., the exclusive movement of molecular motors along microtubules: no two motors may occupy the same site. In our work, we study inclusion processes that are the bosonic analogues of the fermionic exclusion processes. In inclusion processes, many particles may occupy a single site and hopping rates depend linearly on the occupation of departure and arrival sites. Particles thus attract other particles to their own site. Condensation occurs when particles collectively cluster in one or multiple sites, whereas other sites become depleted. We showed that inclusion processes describe both the selection of strategies in evolutionary zero-sum games and the condensation of non-interacting bosons into multiple quantum states in driven-dissipative systems. The condensation is captured by the antisymmetric Lotka-Volterra equation (ALVE), which constitutes a nonlinearly coupled dynamical system. We derived an algebraic method to analyze the ALVE and to determine the condensates. Our approach allows for the design of networks that result in condensates with oscillating occupations, and yields insight into the interplay between network topology and transport properties.

**1:27PM L43.00012 Multi-frequency and edge localized modes in mechanical and electrical lattices**, LARS ENGLISH, Dickinson College, FAUSTINO PALMERO, University of Seville, PANAYOTIS KEVREKIDIS, University of Massachusetts — We present experimental evidence for the existence of a type of dynamical, self-localized mode called a multi-frequency breather in both a mechanical lattice of pendula and an electrical lattice. These modes were excited and stabilized by subharmonic driving. We also experimentally characterize dynamical modes that are localized on the edges of the pendulum chain, as well as in 2D electrical lattices. In the latter system, we briefly discuss the role of lattice topology in the stability of such modes.

**1:39PM L43.00013 Stokes Trap: Multiplexed particle trapping and manipulation using fluidics**, ANISH SHENOY, CHARLES SCHROEDER, University of Illinois at Urbana-Champaign — We report the development of the Stokes Trap, which is a multiplexed microfluidic trap for control over an arbitrary number of small particles in a microfluidic device. Our work involves the design and implementation of “smart” flow-based devices by coupling feedback control with microfluidics, thereby enabling new routes for the fluidic-directed assembly of particles. Here, we discuss the development of a new method to achieve multiplexed microfluidic trapping of an arbitrary number of particles using the sole action of fluid flow. In particular, we use a Hele-Shaw microfluidic cell to generate hydrodynamic forces on particles in a viscous-dominated flow defined by the microdevice geometry and imposed peripheral flow rates. This platform allows for a high degree of flow control over individual particles and can be used for manufacturing novel particles for fundamental studies, using fluidic-directed assembly. From a broader perspective, our work provides a solid framework for guiding the design of next-generation, automated on-chip assays.

**11:15AM L44.00001 Quantum Speed Limits, coherence and asymmetry**, IMAN MARVIAN, massachusetts institute of technology, ROBERT SPEKKENS, Perimeter Institute for theoretical physics, PAOLO ZANARDI, University of Southern California — The resource theory of asymmetry is a framework for classifying and quantifying the symmetry-breaking properties of both states and operations relative to a given symmetry. In the special case where the symmetry is the set of translations generated by a fixed observable, asymmetry can be interpreted as coherence relative to the observable eigenbasis, and the resource theory of asymmetry provides a framework to study this notion of coherence. We here show that this notion of coherence naturally arises in the context of quantum speed limits. Indeed, the very concept of speed of evolution, i.e., the inverse of the minimum time it takes the system to evolve to another (partially) distinguishable state, is a measure of asymmetry relative to the time translations generated by the system Hamiltonian. Furthermore, the celebrated Mandelstam-Tamm and Margolus-Levitin speed limits can be interpreted as upper bounds on this measure of asymmetry by functions which are themselves measures of asymmetry in the special case of pure states. Using measures of asymmetry that are not restricted to pure states, such as the Wigner-Yanase skew information, we obtain extensions of the Mandelstam-Tamm bound which are significantly tighter in the case of mixed states.

**11:27AM L44.00002 A Strong Loophole-Free Test of Local Realism**, PETER BIERHORST, LYNDEN SHALM, MARTIN STEVENS, THOMAS GERRITS, SCOTT GLANCY, MICHAEL ALLMAN, KEVIN COAKLEY, SHELLEE DYER, CARSON HODGE, ADRIANA LITA, VARUN VERMA, RICHARD MIRIN, EMANUEL KNILL, SAE WOO NAM<sup>1</sup>, National Institute of Standards and Technology, Boulder, CO — We discuss theoretical and statistical aspects of a recent loophole-free violation of local realism using entangled photon pairs. The experiment ensures that all relevant events in the Bell test are spacelike separated by placing the parties far enough apart and using fast random number generators and high-speed polarization measurements. A high-quality polarization-entangled source of photons, combined with high-efficiency, low-noise, single-photon detectors, allows us to make measurements without requiring any fair-sampling assumptions. We collected six data sets, and for each data set we used a hypothesis test to compute the maximum probability (the p-value) that our experiment, if it had been governed by local realism, would produce a violation as large or larger than we observed. The smallest p-value we observed is  $5.9 \times 10^{-9}$ .

**11:39AM L44.00003 Implications of Einstein-Weyl Causality on Quantum Mechanics**, DAVID BENDANIEL, Cornell University — A fundamental physical principle that has consequences for the topology of space-time is the principle of Einstein-Weyl causality. This also has quantum mechanical manifestations. Borchers and Sen have rigorously investigated the mathematical implications of Einstein-Weyl causality and shown the denumerable space-time  $Q^2$  would be implied. They were left with important philosophical paradoxes regarding the nature of the physical real line  $E$ , e.g., whether  $E = R$ , the real line of mathematics. In order to remove these paradoxes an investigation into a constructible foundation is suggested. We have pursued such a program and find it indeed provides a dense, denumerable space-time and, moreover, an interesting connection with quantum mechanics. We first show that this constructible theory contains polynomial functions which are locally homeomorphic with a dense, denumerable metric space  $R^*$  and are inherently quantized. Eigenfunctions governing fields can then be effectively obtained by computational iteration. Postulating a Lagrangian for fields in a compactified space-time, we get a general description of which the Schrodinger equation is a special case. From these results we can then also show that this denumerable space-time is relational (in the sense that space is not infinitesimally small if and only if it contains a quantized field) and, since  $Q^2$  is imbedded in  $R^{*2}$ , it directly fulfills the strict topological requirements for Einstein-Weyl causality. Therefore, the theory predicts that  $E = R^*$ .

**11:51AM L44.00004 Entanglement Entropy and Mutual Information of Circular Entangling Surfaces in 2+1d Quantum Lifshitz Model<sup>1</sup>**, TIANCI ZHOU, XIAO CHEN, EDUARDO FRADKIN, Univ of Illinois - Urbana — We investigate the entanglement entropy (EE) of circular entangling surfaces in the 2+1d quantum Lifshitz model, where the spatially conformal invariant ground state is a Rokhsar-Kivelson state with Gibbs weight of 2d free Boson. We use cut-off independent mutual information regulator [1] to define and calculate the subleading correction in the EE. The subtlety due to the Boson compactification in the replica trick is carefully taken care of. Our results show that for circular entangling surface, the subleading term is a constant on both the sphere of arbitrary radius and infinite plane. For the latter case, it parallels the constancy of disk EE in 2+1d conformal field theory, despite the lack of full space time conformal invariance. In the end, we present the mutual information of two disjoint disks and compare its scaling function in the small parameter regime (radii much smaller than their separation) with Cardy's general CFT results [2]. 1. **12:03PM L44.00005 Monogamy of quantum steering**, ANTONY MILNE, DAVID JENNINGS, Imperial College London, SANIA JEVTIC, Brunel University, TERRY RUDOLPH, Imperial College London, HOWARD WISEMAN, Griffith University — The quantum steering ellipsoid formalism naturally extends the Bloch vector picture for qubits to provide a visualisation of two-qubit systems. If Alice and Bob share a correlated state then a local measurement by Bob steers Alice's qubit inside the Bloch sphere; given all possible measurements by Bob, the set of states to which Alice can be steered form her steering ellipsoid. We apply the formalism to a three-party scenario and find that steering ellipsoid volumes obey a simple monogamy relation. This gives us a novel derivation of the well-known CKW (Coffman-Kundu-Wootters) inequality for entanglement monogamy. The geometric perspective also identifies a new measure of quantum correlation, 'obesity', and a set of 'maximally obese' states that saturate the steering monogamy bound. These states are found to have extremal quantum correlation properties that are significant in the steering ellipsoid picture and for the study of two-qubit states in general.

**12:15PM L44.00006 Conflict between the Uncertainty Principle and wave mechanics**, ANTONY BOURDILLON, retired — The traveling wave group that is defined on conserved physical values is the vehicle of transmission for a unidirectional photon or free particle having a wide wave front. As a stable wave packet, it expresses internal periodicity combined with group localization. Heisenberg's Uncertainty Principle is precisely derived from it. The wave group demonstrates serious conflict between the Principle and wave mechanics. Also derived is the phase velocity beyond the horizon set by the speed of light. In this space occurs the reduction of the wave packet which occurs in measurement and which is represented by comparing phase velocities in the direction of propagation with the transverse plane. The new description of the wavefunction for the stable free particle or antiparticle contains variables that were previously ignored. Deterministic physics must always appear probabilistic when hidden variables are bypassed. Secondary hidden variables always occur in measurement. The wave group turns out to be probabilistic. It is ubiquitous in physics and has many consequences.

**12:27PM L44.00007 Coherence-path-information duality relation for N paths**, MARK HILLERY, Department of Physics, Hunter College of CUNY, EMILIO BAGAN, Fisica Teorica: Informacio i Fenomens Quantics, Universitat Autònoma de Barcelona, JANOS BERGOU, Department of Physics, Hunter College of CUNY — For an interferometer with two paths, there is a duality relation between the information about which path the particle took and the visibility of the interference pattern at the output. The more path information we have, the smaller the visibility, and vice versa. We generalize this relation to a multi-path interferometer, and we substitute a recently defined measure of quantum coherence for the visibility. The path information is provided by attaching a detector to each path and applying the minimum-error state discrimination procedure to the detector states.

**12:39PM L44.00008 Axioms for quantum mechanics: relativistic causality, retrocausality, and the existence of a classical limit<sup>1</sup>**, DANIEL ROHRLICH<sup>2</sup>, Physics Department, Ben-Gurion University of the Negev, Beersheba 8410501 — Y. Aharonov and A. Shimony both conjectured that two axioms – relativistic causality (“no superluminal signalling”) and nonlocality – so nearly contradict each other that only quantum mechanics reconciles them. Can we indeed derive quantum mechanics, at least in part, from these two axioms? No: “PR-box” correlations show that quantum correlations are not the most nonlocal correlations consistent with relativistic causality. Here we replace “nonlocality” with “retrocausality” and supplement the axioms of relativistic causality and retrocausality with a natural and minimal third axiom: the existence of a classical limit, in which macroscopic observables commute. That is, just as quantum mechanics has a classical limit, so must any generalization of quantum mechanics. In this limit, PR-box correlations *violate* relativistic causality. Generalized to all stronger-than-quantum bipartite correlations, this result is a derivation of Tsirelson's bound (a theorem of quantum mechanics) from the three axioms of relativistic causality, retrocausality and the existence of a classical limit. Although the derivation does not assume quantum mechanics, it points to the Hilbert space structure that underlies quantum correlations.

**12:51PM L44.00009 J-holomorphic maps and the uncertainty principle in geometric quantum mechanics** , BARBARA SANBORN, Antioch College — The theory of geometric quantum mechanics describes a quantum system as a Hamiltonian dynamical system, with a complex projective Hilbert space as its phase space. The Kähler structure of the projective space provides quantum mechanics with a Riemannian metric in addition to the symplectic structure characteristic of classical mechanics. By including aspects of the symplectic topology of the quantum phase space, the geometric theory is extended and enriched. In particular, the quantum uncertainty principle is naturally expressed as an inequality from J-holomorphic map theory.

**1:03PM L44.00010 A proposed physical analog for a quantum probability amplitude** , JEFFREY BOYD, retired — What is the physical analog of a probability amplitude? All quantum mathematics, including quantum information, is built on amplitudes. Every other science uses probabilities; QM alone uses their square root. Why? This question has been asked for a century, but no one previously has proposed an answer. We will present cylindrical helices moving toward a particle source, which particles follow backwards. Consider Feynman's book QED. He speaks of amplitudes moving through space like the hand of a spinning clock. His hand is a complex vector. It traces a cylindrical helix in Cartesian space. The Theory of Elementary Waves changes direction so Feynman's clock faces move toward the particle source. Particles follow amplitudes (quantum waves) backwards. This contradicts wave particle duality. We will present empirical evidence that wave particle duality is wrong about the direction of particles versus waves. This involves a paradigm shift; which are always controversial. We believe that our model is the ONLY proposal ever made for the physical foundations of probability amplitudes. We will show that our probability amplitudes in physical nature form a Hilbert vector space with adjoints, an inner product and support both linear algebra and Dirac notation.

**1:15PM L44.00011 Quantum enhanced estimation of a multi-dimensional field.**<sup>1</sup> , ANIMESH DATTA, University of Warwick, TILLMANN BAUMGRATZ, University of Oxford — We present a framework for the quantum-enhanced estimation of multiple parameters corresponding to non-commuting unitary generators. We derive the quantum Fisher information matrix to put a lower bound on the total variance of all the parameters involved. We present the conditions for the attainment of the multi-parameter bound, which is not guaranteed unlike the quantum metrology of single parameters. Our study also reveals that too much quantum entanglement may be detrimental to attaining the Heisenberg scaling in the estimation of unitarily generated parameters. One particular case of our framework is the simultaneous estimation of all three components of a magnetic field. We propose a probe state that demonstrates that the simultaneous estimation of the three components is better than the precision of estimating the three components individually. We provide realistic measurements that come close to attaining the quantum limit, exhibiting the advantage of simultaneous quantum estimation even in the case of non-commuting generators. Our work applies to precision estimation any Hamiltonian, and may be employed in efficient process tomography and verification. Our theoretical proposal can be implemented in any finite dimensional quantum system such as trapped ions and nitrogen vacancy centres in diamond.

**1:27PM L44.00012 Fisher symmetry and the geometry of quantum states** , JONATHAN A. GROSS, HOWARD BARNUM, CARLTON M. CAVES, Univ of New Mexico — The quantum Fisher information (QFI) is a valuable tool on account of the achievable lower bound it provides for single-parameter estimation. Due to the existence of incompatible quantum observables, however, the lower bound provided by the QFI cannot be saturated in the general multi-parameter case. A bound demonstrated by Gill and Massar (GM) captures some of the limitations that incompatibility imposes in the multi-parameter case. We further explore the structure of measurements allowed by quantum mechanics, identifying restrictions beyond those given by the QFI and GM bound. These additional restrictions give insight into the geometry of quantum state space and notions of measurement symmetry related to the QFI.

**1:39PM L44.00013 Information Thermodynamics applied to the MERA quantum circuit.**<sup>1</sup> , VASILIOS PASSIAS, VICTOR CHUA, APOORV TIWARI, SHINSEI RYU, University of Illinois at Urbana-Champaign — We interpret the MERA (Multiscale Entanglement Renormalization Ansatz) tensor network as a unitary quantum circuit to study excited states of quantum spin-chains. Contrary to the common use of MERA as a variational ground state ansatz, the quantum circuit defined by MERA – adapted to a fixed ground state – is employed as a diagnostic tool to study dynamically evolving excited state wavefunctions. Outputs of the quantum computation emanating from the isometry tensors, which are normally approximate tensor product states, now fluctuate strongly. These “bulk” degrees of freedom in the MERA which act as logical qubits are studied using tools from quantum information theory and information thermodynamics. A local temperature scale based on Landauer's information erasure principle is defined to measure their degree of fluctuation. We investigate properties of this temperature against the expectations of Luttinger's theorem which relates weak field gravity to heat flow.

**1:51PM L44.00014 The Dimensions of Emergent Spacetime in the Influence Network** , KEVIN KNUTH, State Univ of NY - Albany — It has been previously demonstrated that the consistent quantification of a causally ordered set of events (influence network) with respect to observers represented by embedded chains results in a unique consistent quantification scheme that reproduces the Minkowski metric in the case of coordinated chains and Lorentz transformations in the case of linearly-related chains (Knuth and Bahreyni 2014). Here we demonstrate that quantification by multiple coordinated chains can only be consistent in the cases of two and four chains resulting in emergent 1+1 and 3+1 dimensional spacetimes, respectively. Odd numbers of chains are specifically ruled out and numbers of chains greater than four lead to a system that is not closed under chain permutation symmetry in a manner consistent with Galois theory. As a result, the spacetime framework that emerges from the consistent quantification of a causally ordered set of events with respect to embedded observers provides a potential foundation for emergent spacetime as well as an explanation as to the significance and nature of 3+1 spacetime dimensions.

**2:03PM L44.00015 Locality and entanglement in bandlimited quantum field theory** , JASON PYE, University of Waterloo, WILLIAM DONNELLY, University of California Santa Barbara, ACHIM KEMPF, University of Waterloo — We consider a model for a Planck scale ultraviolet cutoff which is based on Shannon sampling. Shannon sampling originated in information theory, where it expresses the equivalence of continuous and discrete representations of information. When applied to quantum field theory, Shannon sampling expresses a hard ultraviolet cutoff in the form of a bandlimitation. This introduces nonlocality at the cutoff scale in a way that is more subtle than a simple discretization of space: quantum fields can then be represented as either living on continuous space or, entirely equivalently, as living on any one lattice whose average spacing is sufficiently small. We explicitly calculate vacuum entanglement entropies in 1+1 dimensions and we find a transition between logarithmic and linear scaling of the entropy, which is the expected 1+1 dimensional analog of the transition from an area to a volume law. We also use entanglement entropy and mutual information as measures to probe in detail the localizability of the field degrees of freedom. We find that, even though neither translation nor rotation invariance are broken, each field degree of freedom occupies an incompressible volume of space, indicating a finite information density.

**11:15AM L45.00001 One- and two-qubit logic using silicon-MOS quantum dots<sup>1</sup>**, ANDREW DZURAK, UNSW - Australia — Spin qubits in silicon are excellent candidates for scalable quantum information processing [1] due to their long coherence times and the enormous investment in silicon CMOS technology. While our Australian effort in Si QC has largely focused on spin qubits based upon phosphorus dopant atoms implanted in Si [2,3], we are also exploring spin qubits based on single electrons confined in SiMOS quantum dots [4]. Such qubits can have long spin lifetimes  $T_1 = 2$  s, while electric field tuning of the conduction-band valley splitting removes problems due to spin-valley mixing [5]. In isotopically enriched Si-28 these SiMOS qubits have a control fidelity of 99.6% [6], consistent with that required for fault-tolerant QC. By gate-voltage tuning the electron  $g^*$ -factor, the ESR operation frequency can be Stark shifted by  $>10$  MHz [6], allowing individual addressability of many qubits. Most recently we have coupled two SiMOS qubits to realize a CNOT gate [7] using exchange-based controlled phase (CZ) operations. The speed of the two-qubit CZ-operations is controlled electrically via the detuning energy and over 100 two-qubit gates can be performed within a coherence time of  $8 \mu\text{s}$ . [1] D.D. **11:51AM L45.00002 Silicon quantum processor with robust long-distance qubit coupling**, GUILHERME TOSI, FAHD A. MOHIYADDIN, STEFANIE TENBERG, UNSW Australia, RAJIB RAHMAN, GERHARD KLIMECK, Purdue University, ANDREA MORELLO, UNSW Australia — Recent demonstration of high-fidelity quantum operations using donors in silicon [1] has ignited an urge in scaling up these systems to a multi-qubit device. However, multi-qubit operations and long-distance donor coupling remain a formidable challenge. We will present a novel scalable design for a silicon quantum processor [2] that allows for long-distance fast 2-qubit gates and does not require precise donor placement. Quantum information is encoded into either the nuclear-spin or the flip-flop states of electron and nucleus. It can be manipulated by biasing the electron wavefunction to be shared between donor and interface, in such a way that the hyperfine interaction strongly depends on electric fields. The qubits are spaced by hundreds of nanometers and coupled through direct electric dipole interactions and/or photonic links. All operations are performed at second-order clock transitions, preserving the qubits' outstanding coherence times. A large number of qubits can then be interconnected in a network robust against errors. Prototypical devices are fabricated to demonstrate the processor's basic units. [1] J. T. Muhonen, et.al. Nature Nanotechnol. 9, 986 (2014). [2] G. Tosi, et.al. arXiv:1509.08538 (2015).

**12:03PM L45.00003 Towards optimizing two-qubit operations in three-electron double quantum dots**, ADAM FREES, University of Wisconsin-Madison, Madison, WI 53706, JOHN KING GAMBLE, Center for Computing Research, Sandia National Laboratories, Albuquerque, NM 87123, SEBASTIAN MEHL, JARA-Institute for Quantum Information, RWTH Aachen University, Peter Grünberg Institute (PGI-2), Forschungszentrum Jülich, MARK FRIESEN, S.N. COPPERSMITH, University of Wisconsin-Madison, Madison, WI 53706 — The successful implementation of single-qubit gates in the quantum dot hybrid qubit motivates our interest in developing a high fidelity two-qubit gate protocol. Recently, extensive work has been done to characterize the theoretical limitations and advantages in performing two-qubit operations at an operation point located in the charge transition region. Additionally, there is evidence to support that single-qubit gate fidelities improve while operating in the so-called “far-detuned” region, away from the charge transition. Here we explore the possibility of performing two-qubit gates in this region, considering the challenges and the benefits that may present themselves while implementing such an operational paradigm. This work was supported in part by ARO (W911NF-12-0607) (W911NF-12-R-0012), NSF (PHY-1104660), ONR (N00014-15-1-0029). The authors gratefully acknowledge support from the Sandia National Laboratories Truman Fellowship Program, which is funded by the Laboratory Directed Research and Development (LDRD) Program. Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the US Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

**12:15PM L45.00004 High-Fidelity Entangling Gates for Two-Electron Spin Qubits<sup>1</sup>**, PASCAL CERFONTAINE, JARA-Institute for Quantum Information, RWTH Aachen Univ., SEBASTIAN MEHL, DAVID P. DIVINCENZO, Peter Grünberg Institute (PGI-2), Forschungszentrum Jülich, HENDRIK BLUHM, JARA-Institute for Quantum Information, RWTH Aachen Univ. — High fidelity gate operations for manipulating individual and multiple qubits are a prerequisite for fault-tolerant quantum information processing. Recently, we have shown that single-qubit gates for singlet-triplet qubits in GaAs can be pulse-engineered to reduce systematic errors and mitigate magnetic field fluctuations from the abundant nuclear spins, leading to experimentally demonstrated gate fidelities of 98.5% [1]. We expect that a similar approach will be successful for two-qubit gates. We now describe short gating sequences for exchange-based two-qubit gates, showing that gate infidelities below 0.1% can be reached in realistic quantum dot setups [2]. Additionally, we perform numerical pulse optimization to fully take the experimentally important imperfections into account, minimizing systematic errors and noise sensitivity. Since transferring the optimal control pulses to an experimental setting will inevitably incur systematic errors, we discuss how these errors can be calibrated on the experiment. [1] P. Cerfontaine, T. Botzem, D. Schuh, D. Bougeard, H. Bluhm, in preparation. [2] S. Mehl, H. Bluhm, D. P. DiVincenzo, PRB 90 (2014).

**12:27PM L45.00005 Error-reducing sequence for capacitively coupled singlet-triplet qubits**, FERNANDO CALDERON-VARGAS, JASON KESTNER, Univ of Maryland-Balt County — Two-qubit gates can be implemented by capacitively coupling singlet-triplet qubits, which has been experimentally demonstrated to be capable of generating entangling operations. However, the fidelity of the entangling two-qubit gates is still far from optimum. In this light, we propose a two-qubit entangling echo sequence that reduces drastically the two-qubit decoherence due to the Overhauser field fluctuation and improves the fidelity of two-qubit gates under charge noise.

**12:39PM L45.00006 Decoherence of two electron spin qubit in Si double quantum dot with g-factor modulations**, PEIHAO HUANG, GARNETT BRYANT, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland — The rapid progress in the manipulation and detection of semiconductor spin qubits enables the experimental demonstration of high fidelity two qubit gates that are necessary for universal quantum computing. Here, we consider the decoherence of two electron spin due to phonon emission in a Si double quantum dot (DQD). In the large detuning regime, where the two qubit gate is operated, we find that the decoherence depends strongly on the g-factor modulation and the asymmetry of the two dots. The estimated two qubit decoherence rate is comparable to the experimental measured results. We discuss the impact of the decoherence on the single/two qubit operations and ways to reduce the gate errors for the addressable semiconductor spin qubit.

**12:51PM L45.00007 Valley dependent g-factor anisotropy in Silicon quantum dots**, RIFAT FERDOUS, Purdue University, ERIKA KAWAKAMI, PASQUALE SCARLINO, MICHAŁ NOWAK, QuTech and Kavli Institute of Nanoscience, GERHARD KLIMECK, Purdue University, MARK FRIESEN, SUSAN N. COPPERSMITH, MARK A. ERIKSSON, University of Wisconsin-Madison, LIEVEN M. K. VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, RAJIB RAHMAN, Purdue University — Silicon (Si) quantum dots (QD) provide a promising platform for a spin based quantum computer, because of the exceptionally long spin coherence times in Si and the existing industrial infrastructure. Due to the presence of an interface and a vertical electric field, the two lowest energy states of a Si QD are primarily composed of two conduction band valleys. Confinement by the interface and the E-field not only affect the charge properties of these states, but also their spin properties through the spin-orbit interaction (SO), which differs significantly from the SO in bulk Si. Recent experiments have found that the g-factors of these states are different and dependent on the direction of the B-field. Using an atomistic tight-binding model, we investigate the electric and magnetic field dependence of the electron g-factor of the valley states in a Si QD. We find that the g-factors are valley dependent and show 180-degree periodicity as a function of an in-plane magnetic field orientation. However, atomic scale roughness can strongly affect the anisotropic g-factors. Our study helps to reconcile disparate experimental observations and to achieve better external control over electron spins in Si QD, by electric and magnetic fields.

**1:03PM L45.00008 Strong spin relaxation anisotropy in a single-electron quantum dot**, LIUQI YU, L. C. CAMENZIND, D. E. F. BIESINGER, University of Basel, J. ZIMMERMAN, A. C. GOSSARD, UCSB, D. M. ZUMBHL, University of Basel — Spin coherence and relaxation is of crucial importance in operating spin based qubits. In a magnetic field, spins relax predominately through spin-phonon coupling mediated by spin-orbit interaction (SOI) [1]. Here we present measurements of the spin relaxation rate anisotropy in a gate defined single-electron GaAs quantum dot. The spin relaxation rate  $W$  is measured at applied magnetic fields of 4 T in the plane of the 2D electron gas.  $W$  exhibits strong anisotropy: a sinusoidal dependence on the B-field angle  $\varphi$  with a period of 180 degrees, as reported recently [2]. The extrema are observed at fields pointing nearly along the [110] and [1-10] crystal axes, modulated by a factor of about 14 from minimum to maximum. The periodicity is attributed to the interplay of Rashba and Dresselhaus SOIs. To decipher the role of SOI, we perform pulsed-gate spectroscopy to extract orbital excited-state energies, and obtain very good agreement with theory also for the angular dependence  $W(\varphi)$ , indicating that  $\alpha$  and  $\beta$ , Rashba and Dresselhaus coefficients respectively, have the same relative sign and are within 20% of each other. With controllable manipulations of the dot orbitals by varying gate voltages, it is possible to precisely extract values of  $\alpha$  and  $\beta$ . Meanwhile, top- and back gates have been implemented on the device structure, which allows full electrical control over the Rashba SOI in the 2D electron gas [3]. [1] V. N. Golovach et al., Phys. Rev. Lett. **93**, 016601 (2004). [2] P. Scarlino et al., Phys. Rev. Lett. **113**, 256802 (2014). [3] F. Dettwiler et al., arXiv:1403.3518 (2014).

**1:15PM L45.00009 Electron Spin Resonance Characterization of Damage and Recovery of Si/SiO<sub>2</sub> Interfaces from Electron Beam Lithography**, JIN-SUNG KIM, ALEXEI TYRYSKIN, STEPHEN LYON, Department of Electrical Engineering, Princeton University — Electron beam lithography (EBL) is an essential tool for the fabrication of few electron silicon quantum devices. However, high-energy electrons and photons from the EBL process create shallow traps and other defects at the Si/SiO<sub>2</sub> interface, inhibiting the control of electron populations through electrostatic gating. To reduce defect densities, high temperature and forming gas anneals are commonly used. We studied the effect of these anneals on the reduction of shallow traps created by EBL by fabricating two sets of large area ( $\sim 1\text{cm}^2$ ) MOSFETs and characterizing them using transport and electron spin resonance (ESR) measurements. One set was exposed to a typical EBL dosage (10kV,  $40\mu\text{C}/\text{cm}^2$ ) and the other remained unexposed. All MOSFETs were fabricated from the same commercially grown gate stack (30nm dry thermal oxide, 200nm amorphous silicon gate layer) and were annealed at 900C in N<sub>2</sub> and at 435C in forming gas. Our transport data indicate that these annealing steps recover the EBL exposed sample's low temperature (4.2K) peak mobility to 85% of the unexposed sample's. Additionally, our ESR data indicate that annealing the EBL exposed sample reduces its density of shallow traps (2-4 meV) to the same density as the unexposed sample.

**1:27PM L45.00010 Assessing MOS Interface Quality for Silicon Quantum Dot Device Fabrication**, RYAN STEIN, Joint Quantum Institute, University of Maryland, JIN-SUNG KIM, STEVE LYON, Department of Electrical Engineering, Princeton University, NEIL M. ZIMMERMAN, M. D. STEWART, JR., National Institute of Standards and Technology — Defects at the Si-SiO<sub>2</sub> interface are capable of trapping electrons and degrading the operation of silicon-based quantum dot devices. To improve device performance, we are working to characterize the interface quality in MOSCAPs and MOSFETs fabricated at NIST by comparing industry standard defect measurements, such as capacitance-voltage (CV), conductance, and mobility, to electron spin resonance (ESR) measurements. This comparison will give insight into the relative role of defects near the band edge and those distributed throughout the gap in degrading device performance. We will discuss our progress toward this goal as well as our latest data and interpretations.

**1:39PM L45.00011 First-principles hyperfine tensors for electrons and holes in silicon and GaAs**, PERICLES PHILIPPOPOULOS, McGill University, STEFANO CHESI, Beijing Computational Science Research Center, WILLIAM COISH, McGill University — Knowing (and controlling) hyperfine interactions in silicon and III-V semiconductor nanostructures is important for quantum information processing with electron and nuclear spin states. We have performed density-functional theory (DFT) calculations that fully account for spin structure of the Bloch states (in contrast with approaches that rely on the density alone). Using this method, we confirm the known value for the contact hyperfine coupling in the conduction band of silicon, but find a significant deviation in the value for the conduction band of GaAs relative to the accepted value, estimated in ref. [1]. Moreover, this method can be used to calculate the full hyperfine tensor for the valence band, where spin-orbit effects may be strong, precluding methods that determine hyperfine couplings from the density alone. This general method can be applied to a broad class of materials with strong combined spin-orbit and hyperfine interactions. [1] D. Paget, G. Lampel, B. Sapoval, and V. I. Safarov Phys. Rev. B **15**, 5780 (1977)

**1:51PM L45.00012 Quantum quench dynamics of a central-spin system**, ALESSANDRO RICOTTONE, WILLIAM COISH, McGill Univ, STEFANO CHESI, YINAN FANG, Beijing Computational Science Research Center — Quantum effects can significantly influence equilibration dynamics. In quantum annealing, a local tunneling mechanism may accelerate the approach to equilibrium. Similarly, long-range quantum coherence can allow for rapid transitions between macroscopically distinct states of a quantum system. An experimentally relevant example of this is given by a 'central' electron spin coupled to an ensemble of nuclear spins in a quantum dot. This system admits a superradiance-like burst of current through ferromagnetic leads due to long-range nuclear spin coherence [1] with a simultaneous inversion of the nuclear-spin polarization. Here, we study this system coupled to normal leads. In particular, we study quench dynamics of the nuclear spin polarization after passing through a quantum phase transition controlled by an applied magnetic field. As a function of dephasing controlled by a magnetic field gradient, we find a crossover from rapid equilibration via collective states to slow dynamics described by classical (product-state) spin configurations. This understanding may allow us to better control dynamic nuclear spin polarization processes in quantum dots and to control more general quantum states of nuclear-spin ensembles. [1] S. Chesi and W. A. Coish PRB **91**, 245306 (2015)

**2:03PM L45.00013 Theory of Corner States in Silicon Nanowire Devices<sup>1</sup>**, ANDRE SARAIVA, BELITA KOILLER, Universidade Federal do Rio de Janeiro, M FERNANDO GONZALEZ-ZALBA, Hitachi Cambridge Lab — Nanowire-based transistors, such as FinFETs and Tri-gate FETs, form one and zero dimensional states at the corners. These corner states may be manipulated for quantum electronic applications, such as tunable quantum dot-based spin qubits. We discuss the electronic structure of the electrons bound at the corner, considering the effects due to the anisotropy of the effective mass, the splitting of valleys due to the confinement and the scattering at the interface, generalizing our results to corners of arbitrary angle. Our results indicate the optimal conditions for lifting the valley degeneracy, known to impact quantum coherence and control. We finally mention the expected impacts of this geometry on the tunnel and exchange coupling between dots at opposite corners of a wire.

**11:15AM L46.00001 Quantum oscillation signatures of Fermi arc surface states in Weyl semimetals**, ANDREW POTTER, Univ of California - Berkeley — Weyl semimetal states and their crystalline symmetry protected Dirac- analogs have recently been discovered in a variety of materials. These new phases of matter offer an interesting example of topology in the absence of a protecting band- or correlation- gap. The bulk topological character of these materials is revealed upon the application of a magnetic field, which produces chiral Landau level modes that propagate along the field and which mediate inter-valley charge pumping associated with chiral anomaly physics. At a surface, the bulk topology manifests itself in unusual surface states whose Fermi surface consists of disjoint arcs. In this talk, I will describe magnetic field induced quantum oscillation signatures of both the surface and bulk topological features of these materials. These oscillations are associated with unusual magnetic orbits that start on the Fermi arc of one surface, propagate through the bulk on the chiral Landau level, and complete the orbit on the opposite surface. I also will describe some recent experimental evidence for these orbits in Dirac semimetal thin films.

**11:51AM L46.00002 Optical properties of the perfectly compensated semimetal WTe<sub>2</sub><sup>1</sup>**, C. C. HOMES, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, Upton, New York, M. N. ALI, R. J. CAVA, Department of Chemistry, Princeton University, Princeton, New Jersey — The optical properties of layered tungsten ditelluride have been measured over a wide temperature and frequency range for light polarized in the *a-b* planes. A striking low-frequency plasma edge develops in the reflectance at low temperature where this material is a perfectly compensated semimetal. The optical conductivity is described using a two-Drude model which treats the electron and hole pockets as separate electronic subsystems. At low temperature, one scattering rate collapses by over two orders of magnitude, while the other also undergoes a significant, but less dramatic, decrease; both scattering rates appear to display the quadratic temperature dependence expected for a Fermi liquid. First principles electronic structure calculations reveal that the low-lying optical excitations are due to direct transitions between the bands associated with the electron and hole pockets.<sup>2</sup>

**12:03PM L46.00003 Role of spin-orbit coupling and evolution of the electronic structure of WTe<sub>2</sub> under an external magnetic field<sup>1</sup>**, DANIEL RHODES, SUVADIP DAS, QIU RUN ZHANG, NHMFL, FSU, BIN ZENG, NIHAR PRADHAN, NHMFL, NAOKI KIKUGAWA, NHMFL, NIMS, EFSTRATIOS MANOUSAKIS, NHMFL, FSU, LUIS BALICAS, NHMFL — Here, we present a study on the temperature and angular dependence of the Shubnikov-de Haas (SdH) effect in the semimetal WTe<sub>2</sub>. This compound has been shown to display a large, nonsaturating magnetoresistance which was attributed to nearly perfectly compensated densities of electrons and holes. We observe four fundamental SdH frequencies and attribute them to spin-orbit split, electron-like, and hole-like Fermi-surface (FS) cross-sectional areas. Their angular dependence is consistent with ellipsoidal FSs that suggest a modest excess in the density of electrons with respect to that of the holes. We show that DFT calculations fail to correctly describe the FSs of WTe<sub>2</sub> and find evidence for field-dependent FS cross-sectional areas. We also observe a pronounced field-induced renormalization of the effective masses. Our observations suggest that the electronic structure of WTe<sub>2</sub> evolves with the magnetic field due to the Zeeman splitting. This evolution is likely to contribute to its pronounced magnetoresistivity.

**12:15PM L46.00004 Magneto-optic measurements of the Weyl semimetal NbAs**, NATHAN ARMSTRONG, McMaster University, YINMING SHAO, Univ of California - San Diego, ZHUJUN YUAN, International Center for Quantum Materials, Peking University, SHUANG JIA, International Center for Quantum Materials, Peking University; Collaborative Innovation Center of Quantum Matter, Beijing, D.N. BASOV, Univ of California - San Diego, THOMAS TIMUSK, McMaster University; Canadian Institute for Advance Research — NbAs is among the newly discovered Weyl semimetals that are of great interest because they have the potential to confirm the chiral anomaly predicted by particle physics. It has been theorized that two separated Weyl nodes of opposite chirality can have a chiral current flow between them with the application electric and magnetic fields parallel to the displacement of the nodes. Indeed, magnetoresistance measurements on TaAs and NbAs found a negative magnetoresistance with these fields. ARPES and band structure calculations show that NbAs has two different groups of Weyl nodes with all the node splittings in  $k_x - k_y$  planes. In addition to the Weyl nodes there are other trivial bands that create Fermi pockets elsewhere in the BZ that are also observed in reflectance measurements. We will present magneto-optics results from far infrared optical data of NbAs in Voigt geometry up to 8 Tesla. In the far infrared at large fields there are two strong features that show an 11% and 3% change of reflectance in field at 60 and 480  $cm^{-1}$ , respectively. We evaluate these data with comparison to the above mentioned band structure of NbAs.

**12:27PM L46.00005 Linear magnetoresistance and zero-field anomalies in HfNiSn single crystals<sup>1</sup>**, LUCIA STEINKE, Texas AM Univ., JEDEDIAH J. KISTNER-MORRIS, HAIMING DENG, GAYLE GESCHWIND, Stony Brook Univ., MEIGAN C. ARONSON, Texas AM Univ. — The Half-Heusler compound HfNiSn is probably best known as a candidate material for thermoelectric applications, and studies of its properties have mainly focused on polycrystalline samples and thin films. However, magnetotransport studies of HfNiSn show unusual transport properties like linear magnetoresistance (LMR) [1], where single-crystalline samples of HfNiSn exhibit unexpected LMR at very low fields. In this work, we optimized the solution growth of HfNiSn to obtain high-quality single crystals, where electrical transport measurements show that it is a compensated semimetal below  $\approx 200$  K, where the Hall voltage is zero. At higher temperatures, we see a finite Hall contribution from activated excess carriers. In the semimetallic regime, we observe transport anomalies like resistive signals that strongly depend on contact configuration, and LMR below 5 K. Both low-field DC and low frequency AC magnetization measurements show pronounced diamagnetic behavior and the onset of paramagnetism below 4 K. High-frequency diamagnetic screening may be attributed to a decreased skin depth with decreased resistance, but this scenario seems unlikely in HfNiSn since the measured resistance increases steeply at the lowest temperatures. [1] K. Ahilan et al., PRB 69, 245116 (2004).

**12:39PM L46.00006 Landau level quantization and almost flat modes in three-dimensional semimetals with nodal ring spectra**, JUN-WON RHIM, Max-Planck-Institut für Physik komplexer Systeme, 01187 Dresden, Germany, YONG BAEK KIM, Department of Physics, University of Toronto, Toronto, Ontario, Canada M5S 1A7, CANADIAN INSTITUTE FOR ADVANCED RESEARCH COLLABORATION — We investigate Landau level structures of semimetals with nodal ring dispersions. When the magnetic field is applied parallel to the plane in which the ring lies, there exist almost nondispersive Landau levels at the Fermi level ( $E_F = 0$ ) as a function of the momentum along the field direction inside the ring. We show that the Landau levels at each momentum along the field direction can be described by the Hamiltonian for the graphene bilayer with fictitious interlayer couplings under a tilted magnetic field. Near the center of the ring where the interlayer coupling is negligible, we have Dirac Landau levels which explain the appearance of the zero modes. Although the interlayer hopping amplitudes become finite at higher momenta, the splitting of zero modes is exponentially small and they remain almost flat due to the finite artificial in-plane component of the magnetic field. The emergence of the density of states peak at the Fermi level would be a hallmark of the ring dispersion.

**12:51PM L46.00007 Observation of the Thermal Hall Effect Using Capacitive Thermometers in Bismuth**, COLIN TINSMAN, GANG LI, FAN YU, TOMOYA ASABA, BENJAMIN LAWSON, Univ of Michigan - Ann Arbor, CAROLINE SU, Univ of California - Berkeley, LU LI, Univ of Michigan - Ann Arbor — The thermal Hall effect is the thermal analog of the electrical Hall effect. Rarely observed in normal metals, thermal Hall signals were argued to be a key property for a number of strongly correlated materials, such as high temperature superconductors, correlated topological insulators, and quantum magnets. The observation of the thermal Hall effect requires precise measurement of temperature in intense magnetic fields. Particularly at low temperature, resistive thermometers have a strong dependence on field, which makes them unsuitable for this purpose. We have created capacitive thermometers which instead measure the dielectric constant of strontium titanate ( $\text{SrTiO}_3$ ).  $\text{SrTiO}_3$  approaches a ferroelectric transition, causing its dielectric constant to increase by a few orders of magnitude at low temperature. As a result, these thermometers are very sensitive at low temperature while having very little dependence on the applied magnetic field, making them ideal for thermal Hall measurements. We demonstrate this by making measurements of the thermal Hall effect in Bismuth in magnetic fields of up to 10T.

**1:03PM L46.00008 Gyrotropic magnetic effects in chiral metals**, IVO SOUZA, Universidad del Pais Vasco, San Sebastian, SHUDAN ZHONG, University of California, Berkeley, DAVID VANDERBILT, Rutgers University, JOEL MOORE, University of California, Berkeley — We consider two conjugate transport effects occurring in chiral metals as the low-frequency limit of natural optical activity (optical gyrotropy). One occurs in the clean limit where  $\omega$  is small compared to the minimum energy for interband transitions, but large compared to the scattering rate  $1/\tau$ . It consists of a dissipationless current induced by a magnetic field,  $J_i = \alpha'_{ij} B_j$ , and is different from the chiral magnetic effect requiring a static  $\mathbf{B}$  and an electric-field pulse  $\mathbf{E} \parallel \mathbf{B}$ . In the inverse effect a magnetization is generated by a dissipative current,  $M_i = (1/\omega)\alpha''_{ji} E_j$ , with  $\mathbf{E}$  the field driving the current and  $\omega \ll 1/\tau$ , as discussed by Yoda *et al.*, Sci. Rep. 5, 12024 (2015). The low-frequency gyrotropic responses  $\alpha'$  and  $\alpha''$  in the clean and dirty limits can be combined into a complex tensor  $\alpha = \alpha' + i\alpha''$  given by the Fermi-surface integral of the total (orbital plus spin) intrinsic magnetic moment of the Bloch electrons, with a prefactor proportional to  $1 - i\omega\tau$ . Without spin-orbit coupling, only the orbital moment contributes.

**1:15PM L46.00009 Anomalous optical properties of a multiband metal due to thermal redistribution: The case of  $\text{SrMnSb}_2$** , H. J. PARK, LUKE J. SANDILANDS<sup>1</sup>, CCES-IBS & Dep. of Physics and Astronomy, SNU, J. S. YOU, Dep. of Physics, POSTECH, HYO SEOK JI, Dep. of Chemistry, POSTECH, C. H. SOHN, CCES-IBS & Dep. of Physics and Astronomy, SNU, J. W. HAN, Dep. of Physics and Photon Science, School of Physics and Chemistry, GIST, S. J. MOON, Dep. of Physics, Hanyang Univ., K. W. KIM, Dep. of Physics, Chungbuk National Univ., J. H. SHIM, Dep. of Chemistry & Division of Advanced Nuclear Engineering, POSTECH, JUN SUNG KIM, Dep. of Physics, POSTECH, T. W. NOH<sup>2</sup>, CCES-IBS & Dep. of Physics and Astronomy, SNU — We report an optical spectroscopic study of  $\text{SrMnSb}_2$ , a low carrier density metal. As temperature is decreased, our measurements reveal a large increase in the free carrier plasma frequency, which is unusual for a metal. This seemingly anomalous behavior can be accounted for using a 'three band' model of the multiband electronic structure of  $\text{SrMnSb}_2$  that includes two conduction bands and one valence band close to the Fermi level. The temperature dependence of the low-lying interband optical transitions and the Hall number can also be understood using our model. Our results provide a possible explanation for the puzzling optical properties that have been reported in a number of topical low carrier density metals and semimetals.

**1:27PM L46.00010 Optical Spectroscopy of anomalous Fermi Liquids.**, THOMAS TIMUSK, McMaster Univ — It is customary to classify a metallic conductor as a Fermi liquid if, at low temperatures, the electrical resistivity varies as the square of the absolute temperature. Fermi liquid theory shows that if umklapp scattering dominates then, independent of a particular band structure, this T squared dependence is accompanied by a quadratic frequency dependence where  $\rho(T, \omega) = C(\omega^2 + b(\pi T)^2)$  where the scaling constant  $b = 4$  for a Fermi liquid[1,2]. A survey of literature shows that where spectroscopic data exist,  $b = 4$  has not been generally observed[3]. We find that, surveying the recent literature, that in heavy fermion systems the scaling coefficient  $b = 1$ , pointing to a resonant scattering mechanism [2]. In most other systems an unknown mechanism yields a value of  $b$  of around 2. 1. R. N. Gurzhi, Sov. Phys. JETP 14, 886 (1962). 2. D.L. Maslov and A.V. Chubukov, Phys. Rev. B 86, 155137 (2012). 3. **1:39PM L46.00011 Origin of large electron-phonon coupling in the metallic hydride TiH<sub>2</sub>**<sup>1</sup>, SHANAVAS K. VEEDU, DAVID S. PARKER, Oak Ridge National Laboratory — The recent discovery of large superconducting transition temperature of  $T_c = 190$  K in metallic H<sub>2</sub>S under high pressures of 200 GPa, has renewed the interest in the superconducting properties of metal-hydrogen systems. These materials are expected to be electron-phonon superconductors and hydrogen with its low mass can contribute new optic phonons that may couple with the conduction electrons. Often, though not always, a large electron-phonon coupling parameter  $\lambda$  (and consequently high  $T_c$ ) can result from a high electronic density of states at the Fermi level ( $N(E_F)$ ) and the presence of soft phonons. With the help of first-principles calculations within density functional theory, we studied the cubic TiH<sub>2</sub> which has a large  $3d$   $N(E_F) = 2.8$  states/eV/f.u. Our calculated phonon dispersions show that Ti modes active below frequencies of 10 THz whereas much lighter H modes are active between 32 and 40 THz. Electron-phonon coupling calculations reveal a  $\lambda = 0.98$  which corresponds to a  $T_c = 6.1$  K. However, the large  $N(E_F)$  also leads to a tetragonal instability at low temperatures in TiH<sub>2</sub>, which may be overcome by a uniaxial strain, potentially making it a candidate for electron-phonon superconductor.

**1:51PM L46.00012 Structure and dynamics of bulk liquid iron at pressures up to 58 GPa. A first-principles study**<sup>1</sup>, DAVID GONZALEZ, MIRIAM MARQUES, LUIS ENRIQUE GONZALEZ, Dpt. Fisica Teorica, Atomica y Optica, Facultad de Ciencias, Universidad de Valladolid, 47011 Valladolid — The static and dynamic properties of bulk liquid Fe at several high pressure states, have been studied by using first-principles molecular dynamics simulations based on the density functional theory and the projector augmented wave technique. Results are reported for four thermodynamic states at pressures of 27, 42, 50 and 58 GPa for which x-ray scattering data are available. The calculated static structure shows very good agreement with the available experimental data, including an asymmetric second peak which becomes more marked with increasing pressure. The dynamical structure reveals the existence of propagating density fluctuations and the associated dispersion relation has also been determined. The relaxation mechanisms for the density fluctuations have been analyzed in terms of a model with two decay channels (fast and slow, respectively). We found that the thermal relaxation proceeds along the slow decaying channel whereas the fast one is that of the viscoelastic relaxation. Finally, results are also reported for some transport coefficients.

**2:03PM L46.00013 Thermodynamic properties by Equation of state of liquid sodium under pressure.**<sup>1</sup>, HUAMING LI, Georgia Inst of Tech, YONGLI SUN, XIAOXIAO ZHANG, Taiyuan University of Technology, China, MO LI, Georgia Inst of Tech — Isothermal bulk modulus, molar volume and speed of sound of molten sodium are calculated through an equation of state of a power law form within good precision as compared with the experimental data. The calculated internal energy data show the minimum along the isothermal lines as the previous result but with slightly larger values. The calculated values of isobaric heat capacity show the unexpected minimum in the isothermal compression. The temperature and pressure derivative of various thermodynamic quantities in liquid Sodium are derived. It is discussed about the contribution from entropy to the temperature and pressure derivative of isothermal bulk modulus. The expressions for acoustical parameter and nonlinearity parameter are obtained based on thermodynamic relations from the equation of state. Both parameters for liquid Sodium are calculated under high pressure along the isothermal lines by using the available thermodynamic data and numeric derivations. By comparison with the results from experimental measurements and quasi-thermodynamic theory, the calculated values are found to be very close at melting point at ambient condition. Furthermore, several other thermodynamic quantities are also presented.

**11:15AM L47.00001 Quantum thermodynamics for systems out of equilibrium strongly interacting with their surroundings.**, MAICOL OCHOA, University of Pennsylvania, MASSIMILIANO ESPOSITO, University of Luxembourg, MICHAEL GALPERIN, University of California - San Diego — The performance of molecular and nanoscopic systems as nanodevices capable of transforming some form of energy into work is greatly determined by their interaction with the surroundings. When the interaction is strong, one may redefine the part of the universe that can be regarded as the system in order to achieve a full dynamic as well as thermodynamic description. In this work we study a single level strongly interacting with a fermionic bath that undergoes slow driving. The dynamics of the system is estimated using Nonequilibrium Green's functions NEGF. We explore different alternatives for the system bath separation under driving, identifying the corresponding terms for heat and energy transferred as well as the dissipation term. We also formulate the problem in terms of the renormalized spectral density. Our investigations indicate that none of the alternatives can fully reproduce the laws of thermodynamics suggesting that the notion of heat, expressed as the expectation value of some part of the Hamiltonian, is responsible for the inconsistency.

**11:27AM L47.00002 A Variational Statistical-Field Theory for Polar Liquid Mixtures**<sup>1</sup>, BILIN ZHUANG, ZHEN-GANG WANG, California Institute of Technology — Using a variational field-theoretic approach, we derive a molecularly-based theory for polar liquid mixtures. The resulting theory consists of simple algebraic expressions for the free energy of mixing and the dielectric constant as functions of mixture composition. Using only the dielectric constants and the molar volumes of the pure liquid constituents, the theory evaluates the mixture dielectric constants in good agreement with the experimental values for a wide range of liquid mixtures, without using adjustable parameters. In addition, the theory predicts that liquids with similar dielectric constants and molar volumes dissolve well in each other, while sufficient disparity in these parameters result in phase separation. The calculated miscibility map on the dielectric constant-molar volume axes agrees well with known experimental observations for a large number of liquid pairs. Thus the theory provides a quantification for the well-known empirical like-dissolves-like rule.

**11:39AM L47.00003 Role of solvent environments in single molecule conductance used insulator-modified mechanically controlled break junctions.**<sup>1</sup> , NANDINI MUTHUSUBRAMANIAN<sup>2</sup>, CHANDAN MAITY<sup>3</sup>, ELENA GALAN GARCIA<sup>4</sup>, RIENK EELKEMA<sup>5</sup>, FERDINAND GROZEMA<sup>6</sup>, HERRE VAN DER ZANT<sup>7</sup>, Delft University of Technology, KAVLI INSTITUTE OF NANOSCIENCE COLLABORATION, DEPARTMENT OF CHEMICAL ENGINEERING COLLABORATION — We present a method for studying the effects of polar solvents on charge transport through organic/biological single molecules by developing solvent-compatible mechanically controlled break junctions of gold coated with a thin layer of aluminium oxide using plasma enhanced atomic layer deposition (ALD). The optimal oxide thickness was experimentally determined to be 15 nm deposited at ALD operating temperature of 300C which yielded atomically sharp electrodes and reproducible single-barrier tunnelling behaviour across a wide conductance range between  $1 G_0$  and  $10^{-7} G_0$ . The insulator protected MCBJ devices were found to be effective in various solvents such as deionized water, phosphate buffered saline, methanol, acetonitrile and dichlorobenzene. The yield of molecular junctions using such insulated electrodes was tested by developing a chemical protocol for synthesizing an amphipathic form of oligo-phenylene ethynylene (OPE3-PEO) with thioacetate anchoring groups. This work has further applications in studying effects of solvation, dipole orientation and other thermodynamic interactions on charge transport.

**11:51AM L47.00004 Inferring mixture Gibbs free energies from static light scattering data**<sup>1</sup> , DAVID ROSS, Rochester Institute of Technology, CHRISTOPHER WAHLE, University of Findlay, GEORGE THURSTON, Rochester Institute of Technology — We describe a light scattering partial differential equation for the free energy of mixing that applies to connected, isotropic ternary and quaternary liquid composition domains, including restricted domains which may not touch all binary axes. For restricted domains, contrasting light scattering efficiency patterns obtained at different wavelengths can correspond to the same underlying free energy, and supplement the available information. We discuss well-posed problems for this fully nonlinear, degenerate elliptic partial differential equation. Using Monte Carlo simulations, we provide estimates of the overall system measurement time and sample spacing needed to determine the free energy to a desired degree of accuracy, and indicate how measurement time depends on instrument throughput. These methods provide a way to use static light scattering to measure, directly, mixing free energies of many systems that contain liquid domains.

**12:03PM L47.00005 *In situ/operando* soft x-ray spectroscopy characterization of ion solvation and catalysis.** , YI-SHENG LIU, JINGHUA GUO, Lawrence Berkeley Natl Lab — Many important systems especially in energy-related regime are based on the complexity of material architecture, chemistry and interactions among constituents within. To understand and thus ultimately control the varying applications calls for *in-situ/operando* characterization tools. We will present the recent development of the *in-situ/operando* soft X-ray spectroscopic in the studies of catalytic and alkali ion solvation under bias condition, and reveal how to overcome the challenge that soft X-rays cannot easily peek into the high-pressure catalytic cells or liquid electrochemical cells. Also the different feasible detection approaches can provide surface and bulk sensitivity experimentally from those *in-situ* cells. The unique design of *in-situ/operando* soft X-ray spectroscopy instrumentation and fabrication principle with examples in Ca, Na, Mg based solutions at ambient pressure/temperature and high temperature (~250C) gas catalysis will be shown.

**12:15PM L47.00006 Excited statemolecular dynamics in polarizable environments** , JOSIAH BJORGAARD, KIRILL VELIZHANIN, SERGEI TRETIAK, Los Alamos Natl Lab — Many experimental measurements of molecular systems are performed in solutions, where the solvent forms a polarizable environment around the solute. The effects of this on important molecular processes such as vibrational relaxation or chemical reaction are often significant. In this talk, recent developments in efficiently simulating solvation effects in quantum molecular dynamics for excited electronic states are presented. These methods fall into the category of multiscale quantum mechanics/continuum methods. To adequately describe polarization of the solvent by the electronically excited states of molecules, state-specific methods have been pursued which allow for polarization effects based on the excited state charge density. Variational formulations of solvation models in linear response time-dependent density functional theory are described which allow analytical gradients and efficient molecular dynamics propagation. Further, recently developed simulation methods for nonequilibrium solvation effects are demonstrated.

**12:27PM L47.00007 Evolution of molecular crystal optical phonons near structural phase transitions** , NIGEL MICHKI, KATHERINE NIESSEN, MENG YANG XU, ANDREA MARKELZ, SUNY at Buffalo — Molecular crystals are increasingly important photonic and electronic materials. For example organic semiconductors are lightweight compared to inorganic semiconductors and have inexpensive scale up processing with roll to roll printing[1]. However their implementation is limited by their environmental sensitivity, in part arising from the weak intermolecular interactions of the crystal. These weak interactions result in optical phonons in the terahertz frequency range. We examine the evolution of intermolecular interactions near structural phase transitions by measuring the optical phonons as a function of temperature and crystal orientation using terahertz time-domain spectroscopy. The measured orientation dependence of the resonances provides an additional constraint for comparison of the observed spectra with the density functional calculations [2], enabling us to follow specific phonon modes. We observe crystal reorganization near 350 K for oxalic acid as it transforms from dihydrate to anhydrous form. We also report the first THz spectra for the molecular crystal fructose through its melting point.

**12:39PM L47.00008 Transient ultrafast coherent spectroscopy of 2-propanol** , SETH MEISELMAN, MATTHEW DECAMP, Univ of Delaware, VIRGINIA LORENZ, Univ of Illinois at Urbana-Champaign — We use transient coherent spontaneous Raman spectroscopy to measure the coherence lifetimes of vibrational states in liquid propanol. By creating single-photon-level collective excitations of the vibrational states in the system we observe coherence oscillations due to simultaneous excitation of the  $2885\text{ cm}^{-1}$ ,  $2938\text{ cm}^{-1}$ , and  $2976\text{ cm}^{-1}$  modes. These lifetimes and oscillation frequencies agree with frequency-domain lineshape measurements.

**12:51PM L47.00009 Molecular Level-Crossing Dynamics in Condensed Phase from an Optical Hanle Effect Perspective** , RACHEL GLENN, MARCOS DANTUS, None — The molecular optical Hanle effect typically involves field-induced level-splitting to measure excited state lifetimes. Here I will discuss how curve-crossing dynamics probed with a single shaped pulse in the weak field regime can be understood from a perspective of the molecular optical Hanle effect. I will discuss how pulse shaping can be utilized to investigate the curve-crossing dynamics occurring in a large organic molecule in solution. Both Experimental and theoretical results will be presented.

**1:03PM L47.00010 Femtosecond Heterodyne Transient Grating Studies of Nonradiative Decay of the  $S_2$  ( $1^1B_u^+$ ) State of Peridinin: Detection and Spectroscopic Assignment of an  $S_x$  Intermediate State<sup>1</sup>**, SOUMEN GHOSH, MICHAEL M. BISHOP, JEROME D. ROSCIOLI, Michigan State University, AMY M. LAFOUNTAIN, HARRY A. FRANK, University of Connecticut, WARREN F. BECK, Michigan State University — Femtosecond heterodyne transient grating spectroscopy was employed to investigate the nonradiative relaxation dynamics of peridinin from the  $S_2$  state to the  $S_1$  ( $2^1A_g^-$ ) state in methanol. A global target analysis indicates that  $S_2$  decays in 12 fs to populate an intermediate state,  $S_x$ . The absorption and dispersion components of the transient grating signal exhibit a response that is very similar to that of  $\beta$ -carotene in benzonitrile solution. Numerical simulation of the experimental data indicates that the excited state absorption transition from  $S_x$  has a larger oscillator strength than that of  $S_1$ , which rules out an assignment of  $S_x$  to a vibrationally excited  $S_1$  state. The lifetime of  $S_x$  is found to be strongly dependent on the polar solvation timescale. This result indicates that nonradiative decay from  $S_x$  to  $S_1$  involves large-amplitude torsional motions and a concomitant formation of intramolecular charge transfer character. The present work provides the first evidence that peridinin has an ultrashort  $S_2$  lifetime owing to the onset of torsional motions and shows that the  $S_x$  acts as an active state for excitation energy transfer to chlorophyll in light-harvesting proteins.

**1:15PM L47.00011 Isomerization of one molecule observed through tip enhanced Raman spectroscopy<sup>1</sup>**, YANXING ZHANG, Department of Physics and Astronomy, University of California, JOONHEE LEE, VARTKESS A. APKARIAN, Department of Chemistry, University of California, RUQIAN WU, Department of Physics and Astronomy, University of California, RUQIAN WU, YANXING ZHANG TEAM, JOONHEE LEE, VARTKESS A. APKARIAN TEAM — While exploring photoisomerization of azobenzyl thiols (ABT) adsorbed on Au(111), through joint scanning tunneling microscopy (STM) and tip-enhanced Raman scattering (TERS) studies, the reversible photoisomerization of one molecule is captured in TERS trajectories. The apparently heterogeneously photo-catalyzed reaction is assigned to cis-trans isomerization of an outlier, which is chemisorbed on the silver tip of the STM. In order to clarify the role of the silver tip of the STM, we perform systematic density functional theory (DFT) calculations. The results show that compared with the case on the flat Ag(111) surface, the energy difference between trans and cis states of ABT decrease as we add one silver atom or a tetrahedron silver cluster on Ag(111) surface which mimic the geometry of a silver tip. In particular, the trans stretches away from the surface on the tetrahedral silver cluster, and the energy difference between trans and cis decreases to 0.27 eV, from ~1 eV for ABT on the flat Ag(111) surface. This significantly increases the possibility of cis-trans isomerization, as observed in our experiments.

**1:27PM L47.00012 Femtosecond Carrier Dynamics in Gold-MoS<sub>2</sub> Hybrid Nanostructures**, CHLOE DOIRON, XUEJUN LIU, HOSSEIN ROBATJAZI, ISABELL THOMANN, Department of Electrical and Computer Engineering, Rice University — Small plasmonic nanoparticles are known to efficiently generate energetic hot carriers [1] that can be harnessed by injecting them across a Schottky barrier. To understand the role of plasmon-induced hot carrier generation across Schottky junctions in photocatalytic processes, we synthesized quasi-2D MoS<sub>2</sub> monolayer flakes decorated with Au nanoparticles in ethanol. Our goal is to study ultrafast plasmon induced electron injection from Au nanospheres into MoS<sub>2</sub> monolayer flakes. We will present femtosecond transient absorption measurements on MoS<sub>2</sub>/Au hybrid nanoparticles in ethanol solvent, and compare them with neat MoS<sub>2</sub> flakes in ethanol.

**1:39PM L47.00013 Is DNA a metal, semiconductor or insulator? A theoretical approach<sup>1</sup>**, RAFAEL REY-GONZALEZ, KAREN FONSECA-ROMERO, CARLOS PLAZAS, Universidad Nacional de Colombia, GRUPO DE PTICA E INFORMACIN CUNTICA TEAM — Over the last years, scientific interest for designing and making low dimensional electronic devices with traditional or novel materials has been increased. These experimental and theoretical researches in electronic properties at molecular scale are looking for developing efficient devices able to carry out tasks which are currently done by silicon transistors and devices. Among the new materials DNA strands are highlighted, but the experimental results have been contradictories pointing to behaviors as conductor, semiconductor or insulator. To contribute to the understanding of the origin of the disparity of the measurements, we perform a numerical calculation of the electrical conductance of DNA segments, modeled as 1D disordered finite chains. The system is described into a Tight binding model with nearest neighbor interactions and a s orbital per site. Hydration effects are included as random variations of self-energies. The electronic current as a function of applied bias is calculated using Landauer formalism, where the transmission probability is determined into the transfer matrix formalism. We find a conductor-to-semiconductor-to-insulator transition as a function of the three effects taken into account: chain size, intrinsic disorder, and hydration

**1:51PM L47.00014 Femtosecond Heterodyne Transient Grating Detection of Conformational Dynamics in the  $S_0$  ( $1^1A_g^-$ ) State of Carotenoids After Nonradiative Decay of the  $S_2$  ( $1^1B_u^+$ ) State<sup>1</sup>**, JEROME D. ROSCIOLI, SOUMEN GHOSH, MICHAEL M. BISHOP, Michigan State University, AMY M. LAFOUNTAIN, HARRY A. FRANK, University of Connecticut, WARREN F. BECK, Michigan State University — Transient grating spectroscopy was used to study the dynamics of nonradiative decay of the  $S_1$  ( $2^1A_g^-$ ) state in  $\beta$ -carotene and peridinin after optical preparation of the  $S_2$  state. The kinetics of the recovery of the absorption and dispersion components of the third-order signal exhibit significantly different time constants. For  $\beta$ -carotene in benzonitrile, the absorption and dispersion recovery time constants are 11.6 and 10.2 ps. For peridinin in methanol, the time constants are 9.9 and 7.4 ps. These results indicate that the initial product of the decay of the  $S_1$  state is a conformationally displaced structure. The decay rate for the  $S_1$  state and the conformational relaxation rate are both slowed in peridinin as the polarity of the solvent decreases; in ethyl acetate, the conformational relaxation time constant is 45 ps, which rules out a dominant contribution from vibrational cooling. These results indicate that the  $S_1$  state develops intramolecular charge transfer character owing to distortions along torsional and out-of-plane coordinates, with a pyramidal structure favored as the most stable conformation. Recovery of the photoselected ground state conformation involves a reverse charge-transfer event followed by relaxation to a planar structure.

**Session L48 GQI: Decoherence in Superconducting Qubits: Materials and TLSs** 349 - David Pappas, NIST-Boulder

**11:15AM L48.00001 Characterizing and reducing microfabrication-induced loss in superconducting devices, Part I: Resonators<sup>1</sup>**, ANDREW DUNSWORTH, UC Santa Barbara, A. MEGRANT, Google, Santa Barbara, Z. CHEN, C. QUINTANA, UC Santa Barbara, B. BURKETT, J. KELLY, R. BARENDs, A. FOWLER, E. JEFFREY, T. WHITE, D. SANK, J. MUTUS, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, B. CHIARO, C. NEILL, P.J.J. O'MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, A. VAINSENCER, J. WENNER, UC Santa Barbara, J.M. MARTINIS, University of California and Google, Santa Barbara — Planar and 3D superconducting qubits have previously been shown to be limited by microfabrication induced loss. Using finite element simulations, we have identified a major source of this decoherence in superconducting qubits. Furthermore, we experimentally verified this dominant loss channel using a novel resonator based approach, which we call 'Hydra' resonators. We fully characterized and then substantially reduced this loss channel using these Hydra resonators. I will report on these measurements and their implications on improving the coherence of superconducting qubits.

**11:27AM L48.00002 Characterizing and reducing microfabrication-induced loss in superconducting devices, Part II: Xmon qubits**, ANTHONY MEGRANT, Google, Santa Barbara, A. DUNSWORTH, C. QUINTANA, UC Santa Barbara, J. KELLY, R. BARENDs, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, UC Santa Barbara, A. FOWLER, E. JEFFREY, J. MUTUS, Google, Santa Barbara, C. NEILL, P.J.J. O'MALLEY, UC Santa Barbara, P. ROUSHAN, D. SANK, Google, Santa Barbara, A. VAINSENCER, J. WENNER, UC Santa Barbara, T. WHITE, Google, Santa Barbara, J.M. MARTINIS, University of California and Google, Santa Barbara — Microfabrication-induced loss has previously been shown to limit the coherence times of both planar and 3-D superconducting qubits. Energy loss in these qubits arises from interactions with two-level state defects which are located in thin lossy surface dielectrics. More recently, we have identified a major source of this loss and then substantially improved this decoherence channel using a novel resonator structure for characterization and improvement. I will report on recent measurements of Xmon qubits with substantially improved coherence times due to our new fabrication process.

**11:39AM L48.00003 Supercritical Fluid Assisted Cleaning of Patterned Aluminum Microstructures for Removal of Post-Processing Residue and Surface Contamination**, MARVIN G. WARNER, CHRISTOPHER A. BARRETT, CYNTHIA L. WARNER, Pacific Northwest National Laboratory, CHRISTOPHER J.K. RICHARDSON, NATHAN SIWAK, Laboratory for Physical Sciences, University of Maryland — We report the development of preliminary methods for the supercritical CO<sub>2</sub> assisted removal of post-processing residue and surface contamination from delicate aluminum structures, such as those found in superconducting quantum circuits based on Josephson Junctions. The supercritical CO<sub>2</sub> serves as an effective solvent system to assist in the delivery of various co-solvents, stripping agents, and surfactants to the surface of the patterned devices without introducing harsh chemical reagents that can lead to degradation and etching of the aluminum structures. This work was conducted to determine the feasibility and benefits of inserting a supercritical CO<sub>2</sub> cleaning step into device patterning and cleaning processes. The results presented here will discuss our efforts to determine the optimal formulation, shortest exposure time, and exposure methods (*e.g.*, pulsed versus static) necessary to completely remove surface contamination while preserving the integrity of the underlying patterned aluminum structures. The methods presented here could make great strides in removing fabrication based residue and surface contamination, which has been shown to lead to decoherence in superconducting quantum circuits.

**11:51AM L48.00004 Low temperature internal friction of amorphous silicon<sup>1</sup>**, XIAO LIU, THOMAS METCALF, GLENN JERNIGAN, Naval Research Lab, BATTOGTOKH JUGDERSUREN, Sotera Defense Solutions Inc., BRIAN KEARNEY, NRC Postdoctoral Associate, JAMES CULBERSTON, Naval Research Lab — The ubiquitous low-energy excitations, known as two-level tunnelling systems (TLS), are one of the universal phenomena of amorphous solids. These excitations dominate the acoustic, dielectric, and thermal properties of structurally disordered solids. Using the double-paddle oscillator internal friction measurement technique, we have shown that TLS can be made to almost completely disappear in e-beam deposited amorphous silicon (a-Si) as the growth temperature increased to 400C. However, there is a mysterious broad maximum in internal friction at 2-3K, which we suspect to come from metallic contamination of our oscillators and is not related to a-Si. Our new result of a-Si, deposited in a different UHV system and on oscillators with a different type of metallic electrodes, confirms our suspicion. This lowers the upper bound of possible TLS content in a-Si, in terms of tunnelling strength, to below 10<sup>-6</sup>. Our results offer an encouraging opportunity to use growth temperature to improve the structure order of amorphous thin films and to develop high quality amorphous dielectrics for applications, such as in modern quantum devices.

**12:03PM L48.00005 Elastic measurements of TLSs in amorphous silicon at mK temperatures**, ANDREW FEFERMAN, Institut Néel, CNRS and Université Grenoble Alpes, XIAO LIU, THOMAS METCALF, GLENN JERNIGAN, Naval Research Laboratory, EDDY COLLIN, Institut Néel, CNRS and Université Grenoble Alpes — The low temperature properties of glass are distinct from those of crystals due to the presence of poorly understood low-energy excitations. These are usually thought to be atoms tunneling between nearby equilibria, forming tunneling two level systems (TLSs). Elastic measurements on amorphous silicon films deposited with e-beam evaporation showed that this material contains a variable density of TLSs that decreases as the growth temperature increases from 45 to 400 deg C [1]. We will present an analysis of the elastic properties of these films down to the low mK range in the framework of the standard tunneling model. [1] X. Liu, D. R. Queen, T. Metcalf, J. Karel and F. Hellman, Phys. Rev. Lett., 113, 025503 (2014)

**12:15PM L48.00006 Device Applications for the Tunneling Atom Maser**, YANIV ROSEN, SAMARESH GUCHHAIT, Laboratory for physical sciences, College Park, MD, ALEX BURIN, Tulane university, New Orleans, LA, KEVIN OSBORN, Laboratory for physical sciences, College Park, MD — Random two-level system defects in dielectrics absorb energy and limit the coherence of superconducting qubits and resonators used in quantum computing applications. So far attempts to reduce this loss have been confined to device design and material optimization. We present the ability to control the loss of a dielectric by directly manipulating the population of its two level system defects (TLSs). The defect populations can be controlled and the resonator can pass continuously through regimes of ordinary defect loss, to negligible material dissipation, and finally to coherent amplification. The theory behind the device is discussed and matched to experimental results. Using similar methods, we propose devices that control loss, exhibit reduced noise, and amplify signals.

**12:27PM L48.00007 A qubit designed with a dynamically controlled bath of two-level system defects**, TIM KOHLER, YANIV ROSEN, SAMARESH GUCHHAIT, Univ of Maryland-College Park, KEVIN OSBORN, Laboratory of Physical Science — Although superconducting qubits have made tremendous gains, they still suffer decoherence from two level system (TLS) defects that are found at dielectric films including the native oxides on superconductors. Qubits often minimize TLS effects by choosing optimal device geometries. We have previously investigated methods to electrically sweep the energy of a bath of TLSs and control their excited-state population. Here we discuss a qubit design that incorporates a similar control over the TLSs, and which may prove to minimize TLS decoherence effects. In this device the qubit energy can remain constant while the TLS bath is dynamically controlled. We will discuss experimental progress towards realizing this qubit.

**12:39PM L48.00008 Surface Participation Effects in Titanium Nitride and Niobium Resonators<sup>1</sup>**, ALLISON DOVE, JOHN MARK KREIKEBAUM, WILLIAM LIVINGSTON, REMY DELVA, YANJIE QIU, REINHARD LOLOWANG, VINAY RAMASESH, KEVIN O'BRIEN, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — Improving the coherence time of superconducting qubits requires a precise understanding of the location and density of surface defects. Superconducting microwave resonators are commonly used for quantum state readout and are a versatile testbed to systematically characterize materials properties as a function of device geometry and fabrication method. We report on sputter deposited titanium nitride and niobium on silicon coplanar waveguide resonators patterned using reactive ion etches to define the device geometry. We discuss the impact of different growth conditions (temperature and electrical bias) and processing techniques on the internal quality factor ( $Q$ ) of these devices. In particular, to investigate the effect of surface participation, we use a Bosch process to etch many-micron-deep trenches in the silicon substrate and quantify the impact of etch depth and profile on the internal  $Q$ .

<sup>1</sup>This research was supported by the ARO.

**12:51PM L48.00009 Fabrication and characterization of highly disordered TiN thin films by reactive evaporation for circuit-QED.**, YEN-HSIANG LIN, RAYMOND MENCIA, BAOLONG NGUYEN, VLADIMIR MANUCHARYAN, University of Maryland - College Park — Titanium nitride (TiN) has been identified as one of the potentially new materials for circuit-QED. In particular, disordered TiN films close to superconductor-insulator transition can be beneficial to greatly enhance kinetic inductance due to low superfluid density. Here we report TiN thin films prepared by e-beam evaporation within a nitrogen rich environment. By controlling nitrogen gas flow rate, the normal sheet resistance of TiN film can be tuned higher than 1kOhms while superconductivity still remains above 2K. Here, we present our characterization results and microwave measurement of quality factor  $Q$  and kinetic inductance  $L$ .

**1:03PM L48.00010 TiN superconducting coplanar waveguide resonators with single-photon quality factors of 1.5 million**, GREG CALUSINE, DANNA ROSENBERG, DAVID HOVER, RABINDRA DAS, ALEXANDER MELVILLE, KHOVALIN MILOSHI, WAYNE WOODS, JONILYN YODER, MIT Lincoln Laboratory, WILLIAM OLIVER, MIT Lincoln Laboratory; Research Laboratory of Electronics, MIT — The investigation of loss mechanisms in superconducting coplanar waveguide (CPW) resonator provides an efficient means to elucidate relevant loss mechanisms affecting superconducting qubit circuits. As compared to superconducting qubits, the reduced complexity of CPW fabrication coupled with the straightforward characterization of CPW properties facilitates the deconvolution of the impact of individual fabrication steps on the CPW performance. We assess this impact by characterizing the statistically significant differences in internal quality factors ( $Q_i$ ) at the single-photon level resulting from different fabrication processes in aluminum and titanium nitride (TiN) superconducting thin film CPW resonators on silicon. We demonstrate repeatable  $Q_i$ 's at the single-photon level of approximately  $1.5 \times 10^6$  in TiN CPW resonators with 90 percent of devices showing  $Q_i$ 's above  $1 \times 10^6$  and single  $Q_i$ 's as high as  $3.8 \times 10^6$ . This work is sponsored in part by the Laboratory for Physical Science, IARPA, and the Assistant Secretary of Defense for Research and Engineering under Air Force Contract FA8721-05-0002. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the United States Government.

**1:15PM L48.00011 Anomalous thickness dependence of quality factor in TiN film resonators grown on functionalized Si substrates**, PENG XU, TIM KOHLER, Laboratory for Physical Sciences, EVGENIYA LOCK, Naval Research Laboratory, YANIV ROSEN, ARUNA RAMANAYAKA, SAMARESH GUCHHAIT, KEVIN OSBORN, Laboratory for Physical Sciences — Various properties affect the quality factor of superconducting resonators at millikelvin temperatures including the presence of nanoscale interfacial dielectric films and residual quasiparticles. Superconducting titanium nitride is polycrystalline such that growth phases may also affect the resonator quality. Here, we functionalize Si substrates in different hydrophobic and hydrophilic plasma environments, sputter titanium nitride on top and pattern the latter films into resonators. For each functionalization we study the quality factor dependence on the superconducting film thickness, where the thicknesses are changed only between 25 and 50 nm. As expected, most functionalizations reveal very little quality factor dependence on superconducting film thickness. However, other functionalizations dramatically, and even anomalously, increase or decrease the quality with thickness. For example, oxygen plasma functionalization causes the quality factor to increase by a factor of more than ten at single photon power with increased thickness. We report on the progress towards finding the intrinsic reason for strong quality factor dependences on surface functionalization.

**1:27PM L48.00012 Optimized Shielding and Fabrication Techniques for TiN and Al Microwave Resonators<sup>1</sup>**, JOHN MARK KREIKEBAUM, EUNSEONG KIM, WILLIAM LIVINGSTON, ALLISON DOVE, Univ of California - Berkeley, GREGORY CALUSINE, DAVID HOVER, DANNA ROSENBERG, WILLIAM OLIVER, MIT Lincoln Laboratory, IRFAN SIDDIQI, Univ of California - Berkeley — We present a systematic study of the effects of shielding and packaging on the internal quality factor ( $Q_i$ ) of Al and TiN microwave resonators designed for use in qubit readout. Surprisingly,  $Q_i = 1.3 \times 10^6$  TiN samples investigated at 100 mK exhibited no significant changes in linewidth when operated without magnetic shielding and in an open cryo-package. In contrast, Al resonators showed systematic improvement in  $Q_i$  with each successive shield. Measurements were performed in an adiabatic demagnetization refrigerator, where typical ambient fields of 0.2 mT are present at the sample stage. We discuss the effect of 100 mK and 500 mK Cu radiation shields and cryoperm magnetic shielding on resonator  $Q$  as a function of temperature and input power in samples prepared with a variety of surface treatments, fabrication recipes, and embedding circuits.

**1:39PM L48.00013 Characterizing the performance of waveguide technologies for microwave-frequency quantum communication**, PHILIPP KURPIERS, TOBIAS FREY, ANDREAS WALLRAFF, ETH - Zurich — In circuit quantum electrodynamics (QED) systems quantum communication over distances beyond chip-scale requires low-loss waveguides. We measure the loss per unit length and the phase stability of commercially available waveguide technologies down to Millikelvin temperatures and single photon levels. More specifically, we characterize the frequency dependent attenuation and dispersion properties of a range of semi-rigid microwave cables and waveguides. We study the properties of various, commonly used conducting and dielectric materials with high accuracy in resonant structures to extract the internal quality factor which is inversely proportional to the loss per unit length. Furthermore, we compare our data with corresponding loss models. The results of our characterization are relevant to applications in which quantum communication is needed between nodes of a small network, e.g. between quantum circuits realized on different chips within the same or in distinct cryogenic systems.

**1:51PM L48.00014 Spectrum of a Resonator Coupled to a Driven Superconducting Qubit in the Strong Dispersive Regime of Circuit Quantum Electrodynamics**, YONUK CHONG, HYUN-GUE HONG, DONG-GWANG HA, Korea Research Institute of Standards and Science — The resonator spectrum in the strong dispersive coupling regime of circuit-QED has been a useful nondestructive indicator of a stationary qubit state. Here we present experimental observation of the further modification of the resonator spectrum as the qubit undergoes the dynamic transition by a resonant driving field. The quartet resonance associated with the polarized qubit is observed for the resonant driving at one-photon as well as the multi-photon transition in a 3D transmon qubit. The evolution of the resonance as a function of the driving power and the detuning of the driving field is well understood by a simple model which is based on the analytic diagonalization of Hamiltonian and described in terms of dressed states, Lamb shift, and AC Stark shift.

**2:03PM L48.00015 Characterizing Ensembles of Superconducting Qubits**, ADAM SEARS, JEFF BIRENBAUM, DAVID HOVER, DANNA ROSENBERG, STEVEN WEBER, JONILYN L. YODER, JAMIE KERMAN, MIT Lincoln Laboratory, SIMON GUSTAVSSON, ARCHANA KAMAL, FEI YAN, MIT, WILLIAM OLIVER, MIT Lincoln Laboratory — We investigate ensembles of up to 48 superconducting qubits embedded within a superconducting cavity. Such arrays of qubits have been proposed for the experimental study of Ising Hamiltonians, and efficient methods to characterize and calibrate these types of systems are still under development. Here we leverage high qubit coherence ( $> 70 \mu s$ ) to characterize individual devices as well as qubit-qubit interactions, utilizing the common resonator mode for a joint readout. This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

**11:27AM L50.00002 Atom interferometric measurement of “Big G” on the International Space Station<sup>1</sup>**, ELIZABETH ASHWOOD, DOGA MURAT KURKCUOGLU, MARK EDWARDS, Georgia Southern Univ, CHARLES CLARK, Joint Quantum Institute — Recent measurements of Newton's universal gravitational constant (“Big G”) using atom interferometric methods have increased the uncertainty in the value of this important fundamental constant<sup>2</sup>. We have developed tools for rapid simulation and evaluation of atom interferometer (AI) schemes that can be implemented in the Cold Atom Laboratory to be deployed to the International Space Station (ISS) in 2017. We have approximated the solution of the rotating-frame Gross-Pitaevskii equation in both one and three dimensions by using the Lagrangian Variational Method (LVM). The LVM trial wave function is a sum of  $N_c$  Gaussian clouds and we have derived equations of motion for the centers, widths, and phase parameters of these clouds. These equations of motion can be rapidly solved for many different AI designs enabling the estimation of interferometer sensitivity and the effects of errors. We present two potential schemes for measuring “Big G” on the ISS. These include a Mach-Zehnder-like scheme as well as a design similar to a Foucault Pendulum.

**11:39AM L50.00003 Sensitivity improvements to the YbF electron electric dipole moment experiment**, ISABEL RABEY, JACK DEVLIN, BEN SAUER, JONY HUDSON, MIKE TARBUTT, ED HINDS, Imperial College London — The electron is predicted to have a small electric dipole moment (EDM). The size of this fundamental property is intimately connected to the breaking of time reversal symmetry (T) in nature. The Standard Model, which does include a small amount of T asymmetry, predicts the EDM to be too small to ever detect at  $d_e < 10^{-38}$  e.cm. However, many extensions of the Standard Model that suggest additional T-violation predict the electron's EDM to be within a measurable regime of both current and proposed experiments. This talk describes our YbF electron EDM experiment and introduces some of the technical improvements made to our machine since the last measurement. We have increased the statistical sensitivity of our interferometer by increasing the number of YbF molecules that participate in the experiment and by increasing their detection probability. We demonstrate several hardware developments that combine laser, microwave and rf fields which, when applied to YbF, can pump six times more population into the initial measurement state. In the detection region we have used techniques developed for molecular laser cooling, including resonant polarisation modulation, to dramatically increase the number of scattered photons by a factor of 10. Combining all improvements, the statistical uncertainty of our measurement is expected to be reduced by a factor of ninety, allowing us to search for physics beyond the Standard Model and below the recent upper limit of  $d_e < 8.9 \times 10^{-29}$  e.cm.

**11:51AM L50.00004 Anti-parity-time symmetry via flying atoms**, JIANMING WEN, Yale Univ, LIANG JIANG, Yale University, YANHONG XIAO, PENG PENG, WANXIA CAO, CE SHEN, WEIZHI QU, Fudan University — We report the first experimental demonstration of optical anti-parity-time (anti-PT) symmetry [1], a counterpart of conventional PT symmetry [2], in a warm atomic-vapor cell. By exploiting rapid coherence transport via flying atoms, our scheme illustrates essential features of anti-PT symmetry with an unprecedented precision on phase-transition threshold, and substantially reduces experimental complexity and cost, in contrast to most previous experimental studies relying highly on the advances of nanotechnologies and sophisticated fabrication techniques to synthesize solid-state materials. Of importance, our results represent a significant advance in non-Hermitian physics by bridging a firm connection with the field of atomic, molecular and optical physics, where novel phenomena and applications in quantum and nonlinear optics aided by (anti-)PT symmetry can be anticipated. [1] P. Peng, W. Cao, C. Shen, W. Qu, J. Wen, L. Jiang, and Y. Xiao, arXiv: 1509.07736 (2015). [2] L. Chang, X. Jiang, S. Hua, C. Yang, J. Wen, L. Jiang, G. Li, G. Wang, and M. Xiao, *Nature Photonics* **8**, 524-529 (2014).

**12:03PM L50.00005 Two-dimensional atom localization via phase-sensitive absorption-gain spectra in five-level hyper inverted-Y atomic systems**, ZHONGHU ZHU, WEN-XING YANG<sup>1</sup>, Department of Physics, Southeast University, Nanjing 210096, PR China, AI-XI CHEN, Department of Applied Physics, School of Basic Science, East China Jiaotong University, Nanchang 330013, PR China — High-precision measurement of an atomic position through a standing-wave field has been the subject of active research over the past few decades because of its potential applications in laser cooling and trapping of neutral atoms, such as atom nanolithography, Bose-Einstein condensation, and coherent patterning of matter waves. More recently, two-dimensional atom localization, achieved by applying two orthogonal standing-wave fields, has been studied extensively for its unique properties. For realizing high-precision two-dimensional atom localization, we explore two-dimensional atom localization based on phase-sensitive probe absorption and gain in a microwave-driven five-level hyper inverted-Y atomic system. Because of the spatial position-dependent atom-field interaction, two-dimensional atom localization can be achieved by the measurements of the probe absorption and gain spectra. It was clearly shown that the precision of two-dimensional atom localization is extremely sensitive to the detuning of the weak probe field, the intensities of the two control fields, and the relative phase of the driving fields. The main advantage of our proposed scheme is that the maximum probability of finding the atom at an expected position in one period of the standing-wave fields is 100%.

**12:15PM L50.00006 Three-bosons in 2D with a magnetic field**, SETH RITTENHOUSE, Department of Physics, The United States Naval Academy, ANDREW WRAY, BRAD JOHNSON, Department of Physics and Astronomy, Western Washington University — Systems of interacting particles in reduced dimensions in the presence of external fields can exhibit a number of surprising behaviors, for instance the emergence of the fractional quantum Hall effect. Examining few-body interactions and effects can lead to significant insights within these systems. In this talk we examine a system of three bosons confined to two dimensions in the presence of a perpendicular magnetic field within the framework of the adiabatic hyperspherical method. For the case of zero-range, regularized pseudo-potential interactions, we find that the system is nearly separable in hyperspherical coordinates and that, away from a set of narrow avoided crossings, the full energy eigenspectrum as a function of the 2D s-wave scattering length is well described by ignoring coupling between adiabatic hyperradial potentials. In the case of weak attractive or repulsive interactions, we find the lowest three-body energy states exhibit even/odd parity oscillations as a function of total internal 2D angular momentum and that for weak repulsive interactions, the universal lowest energy interacting state has an internal angular momentum of  $M = 3$ .

**12:27PM L50.00007 Three-Body Effects in a Zero-Scattering-Length Condensate**, LAWRENCE PHILLIPS, Heriot Watt University — When pairwise interactions between ultracold Bosons are set to zero using Feshbach resonance, the resulting condensate is well described by replacing the standard two-body contact interaction with a three-body pseudopotential and proceeding with Hartree-Fock theory in the usual way. We give a prescription for calculating the coupling constant appearing in the three-body pseudopotential, and use it to investigate the dependence of the zero-scattering-length dynamics upon the original two-body potential.

**12:39PM L50.00008 Nonadiabatic calculations on hydrogen molecule**, JACEK KOMASA, Adam Mickiewicz University, Poznan, KRZYSZTOF PACHUCKI, Warsaw University, Poland — Since its infancy quantum mechanics has treated hydrogen molecule as a test bed. Contemporary spectroscopy is able to supply the dissociation energy ( $D_0$ ) of  $H_2$  with the accuracy of  $3.7 \cdot 10^{-4} \text{ cm}^{-1}$ , while current theoretical predictions are  $10^{-3} \text{ cm}^{-1}$  in error. Both the uncertainties are already smaller than the quantum electrodynamic (QED) effects contributing to  $D_0$ , which poses a particular challenge to theoreticians. Undoubtedly, in order to increase the predictive power of theory one has to not only account for the multitude of the tiny relativistic and QED effects but, especially, significantly increase precision of the largest component of  $D_0$ —the nonrelativistic contribution. We approach the problem of solving the Schroedinger equation, equipped with new methodology, with the target precision of  $D_0$  set at the level of  $10^{-7} \text{ cm}^{-1}$ .

**12:51PM L50.00009 s-wave resonant short-range interactions in a d-dimensional finite volume**, SHANGGUO ZHU, SHINA TAN, Georgia Inst of Tech — It has been known that the energy spectra of few or many particles with short-range interactions in a finite periodic box are shifted according to the size of the box. In particular, the two-body interaction in a three-dimensional box is described by the Lüscher's formulas. Here we study the energy of one particle scattered by a resonant s-wave short-range center in a d-dimensional finite volume. When  $d = 6$ , this one-body problem is mapped to the scattering of three particles in a three-dimensional box with a resonant three-body interaction.

**1:03PM L50.00010 The Bosonic Kane-Mele Hubbard model**, RAJBIR NIRWAN<sup>1</sup>, Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt/Main, Germany, IVANA VASIC, Scientific Computing Laboratory, Institute of Physics Belgrade, University of Belgrade, 11080 Belgrade, Serbia, ALEXANDRU PETRESCU, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544, USA, KARYN LE HUR, Centre de Physique Théorique, Ecole Polytechnique and CNRS, Université Paris-Saclay, France, WALTER HOFSTETTER, Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt/Main, Germany — We investigate the bosonic equivalent of the Kane-Mele model on the honeycomb lattice [1] including spin-orbit and interaction effects. This model is a generalization of the interacting bosonic Haldane model introduced in Ref. [2]. We also allow for an on-site conversion (coherent) term between the two species. We analyze the phase diagram using bosonic dynamical mean-field theory and analytical methods. In the Mott phase, a strong-coupling expansion is performed to investigate the magnetism and frustration effects. A connection is drawn with the quantum theory of an antiferromagnet on a triangular lattice in a magnetic field [3]. This model can be realized in ultra-cold atom systems with current technology. **1:15PM L50.00011 Strong correlation effects in a two-dimensional Bose gas with quartic dispersion**, JURAJ RADIC, STEFAN NATU, VICTOR GALITSKI, University of Maryland, College Park — We consider a two-dimensional Bose gas at zero temperature with an underlying quartic single-particle dispersion in one spatial direction. This type of band structure can be realized using the NIST scheme of spin-orbit coupling, in the regime where the lower band dispersion has the form  $\varepsilon_{\mathbf{k}} \sim k_x^4/4 + k_y^2 + \dots$ . We numerically compare the ground state energies of the mean-field Bose-Einstein condensate (BEC) and various trial wave-functions, where bosons avoid each other at short distances. We discover that, at low densities, several types of strongly correlated states have an energy per particle ( $\epsilon$ ), which scales with density ( $n$ ) as  $\epsilon \sim n^{4/3}$ , in contrast to  $\epsilon \sim n$  for the weakly interacting Bose gas. These competing states include a Wigner crystal, quasi-condensates described in terms of properly symmetrized fermionic states, and variational wave-functions of Jastrow type, where the latter has the lowest energy and describes a strongly-correlated condensate. Our results show that even for weakly-interacting bosons in higher dimensions, one can explore the crossover from a weakly-coupled BEC to a strongly-correlated condensate by simply tuning the single particle dispersion or density.

**1:27PM L50.00012 Wave function anatomy of ultracold fermions in a double well: Attractive-pairing, Wigner-molecules, and entanglement**<sup>1</sup>, BENEDIKT B. BRANDT, CONSANTINE YANNOULEAS, UZI LANDMAN, School of Physics, Georgia Institute of Technology — We report on exact benchmark configuration-interaction computational solutions of the many-body Hamiltonian, uncovering the spectral evolution, wave function anatomy, and entanglement properties of a few interacting ultracold fermions in the entire parameter range, including crossover from an single-well to a double-well confinement and a controllable energy imbalance between the wells. According to recent experiments, the two wells are taken as quasi-one-dimensional and both the linear and parallel configurations of them are considered. We demonstrate attractive pairing and formation of repulsive, highly correlated, ultracold Wigner molecules, associated with the emergence of Heisenberg spin chains.<sup>2</sup> For two fermions, the entanglement measure of the von-Neumann entropy is used as a diagnostic tool for identifying maximally entangled two-qubit Bell states.<sup>3</sup>

**1:39PM L50.00013 Solvable Models for a Few Atoms in a Few One-Dimensional Wells**, NATHAN HARSHMAN, Department of Physics, American University — This project identifies networks of one-dimensional, few-particle, few-well models that can be smoothly connected by tuning trap shape and two-body interaction parameters. Solvable models within these networks are identified and analyzed by exploiting symmetries in few-body configuration space and phase space. In one-dimension, ordering permutation symmetry is particularly effective for generating new models. Ordering permutation symmetry is distinct from particle permutation symmetry and arises when there are similar regions in configuration space that are completely disconnected due to unitary interactions and/or infinite well barriers. Realistic experiments with a few atoms or with ultracold gases trapped in effectively one-dimensional wells are analyzed by comparison with nearby solvable models using approximation schemes like perturbation theory or variational methods. The transition from systems with a few particles in a few wells to systems with many particles in large lattices can be explored using these techniques.

**11:15AM L51.00001 Meron deconfinement in the quantum Hall bilayer at intermediate distances**, MILICA MILOVANOVIC, Institute of Physics Belgrade, EDIB DOBARDZIC, Faculty of Physics, University of Belgrade, ZLATKO PAPIC, University of Leeds — Quantum Hall bilayer phase diagram with respect to interlayer distance bears a remarkable similarity with phase diagrams of strongly correlated systems as a function of doping, with magnetic ordering on the one end and Fermi-liquid-like behavior on the other. Moreover, it has been suggested [1] that a BCS correlated state of composite fermions with p-wave pairing may exist in the intermediate region. We discuss features of this state using the composite boson point of view, and exact diagonalization calculations on the torus. Furthermore, we argue that in the same state there is a possibility for meron deconfinement, i.e., the deconfinement of the vortex excitations of the magnetically ordered phase. [1] G. Moller, S. H. Simon, and E. H. Rezayi, Phys. Rev. Lett. 101, 176803 (2008); G. Moller, S. H. Simon, and E. H. Rezayi, Phys. Rev. B 79, 125106 (2009).

**11:27AM L51.00002 Magnetotransport of a Quantum Hall Double Layer at Landau Level Filling  $1/2 + 3/2^1$** , WU XING-JUN, LIU RUIYUAN, MI JIAN, ZHANG CHI, Peking University, PFEIFFER LOREN, WEST KEN, Princeton University, DU RUI-RUI, Rice University — The effect of interlayer-tunneling on electron transport in quantum Hall double layers in the regime of exciton condensation state at Landau level filling factor one ( $1/2+1/2$ ) has been well established, in that the interlayer coherence promotes a huge zero-bias conductance peak due to resonantly-enhanced tunneling (e.g., Phys. Rev. Lett. 84, 5808, 2000). Consequently, an in-plane magnetic field is found to suppress this tunneling. Recent theoretical work, on a similar system consisting of two layers with fillings  $1/2+3/2$ , suggests that here the resonant-enhanced tunneling would be suppressed and an in-plane magnetic field, conversely, would play a promoting role in tunneling. We investigate this regime in high-mobility GaAs/AlGaAs bilayers of suitable parameters and with individually contacted layers. Preliminary results and a brief discussion will be presented.

**11:39AM L51.00003 Probing a Wigner Crystal via Composite Fermion Commensurability Oscillations in an Adjacent Layer**, HAO DENG, INSUN JO, YANG LIU, MANSOUR SHAYEGAN, LOREN N. PFEIFFER, KEN W. WEST, KIRK W. BALDWIN, Department of Electrical Engineering, Princeton University, Princeton, New Jersey 08544 — At high magnetic fields and low temperatures, two-dimensional electrons form a composite fermion (CF) Fermi sea with a well-defined Fermi wave vector when the Landau level fillings factor ( $\nu$ ) is near  $1/2$ . In contrast, when  $\nu \ll 1$ , the Wigner crystal (WC) is the favored ground state. We report measurements of the magneto-resistance in a bilayer electron system with unequal layer densities at high magnetic fields. One layer has a very low density and is in the WC regime ( $\nu \ll 1$ ), while the other (probe) layer is near  $\nu = 1/2$  and hosts a CF sea. As the magnetic field is swept away from  $\nu = 1/2$  of the CF layer, the CFs feel the periodic electric potential of the WC in the other layer and exhibit magneto-resistance maxima whenever their cyclotron orbit encircles certain integer number of the WC lattice points. Via measuring the temperature dependence of strength of these commensurability features, we probe the melting of the WC.

**11:51AM L51.00004 Spin Transition of Composite Fermion Solids in Wide Quantum Wells Observed with Microwave Spectroscopy**, ANTHONY HATKE, LLOYD ENGEL, National High Magnetic Field Laboratory, YANG LIU, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Princeton University — Within a narrow range of Landau filling ( $\nu$ ) near 1, a resonance in the microwave spectrum in high mobility two-dimensional electron systems is known to occur [1]. The resonance is understood as due to a pinning mode of a Wigner solid of quasicarriers and is present in the  $\nu$ -region of vanishing diagonal resistance. In microwave spectroscopy an abrupt jump in the resonance frequency,  $f_{pk}$ , upon decreasing  $\nu$  from 1 was observed in wide quantum wells [2]. This jump was interpreted as a transition between two solid states: S1, which occurred closer to  $\nu = 1$ , and S2 (with enhanced- $f_{pk}$ ), which occurred farther from  $\nu = 1$ . In this talk we discuss microwave measurements using variable carrier density and in plane magnetic field. Typical for a spin-related transition, tilting the sample at fixed  $n$  results in effects similar to those found on increasing  $n$  without tilt. Taken together, the dependencies of the resonance on  $n$  and the tilt angle are consistent with a ground state spin transition between different solids. We discuss our results in terms of interacting two-flux composite fermions. [1] Chen et al., Phys. Rev. Lett. 93, 206805 (2004). [2] Hatke et al., Nat. Commun. 5, 4154 (2014).

**12:03PM L51.00005 Transport Signatures of Dirac Composite Fermions in the  $1/2$ -filled Landau level**, MAKSYM SERBYN, ANDREW C. POTTER, ASHVIN VISHWANATH, Univ of California - Berkeley — The half-filled state plays a special role among the variety of different fractional quantum Hall effect states. Halperin, Lee, and Read (HLR) predicted the existence of compressible state, where gapless excitations consists of electrons bound to a pair of vortices with emergent Fermi surface. There exists ample experimental evidence for this emergent Fermi surface, despite the presence of the strong magnetic field. However, the role of particle hole symmetry of the half-filled Landau level has remained a puzzle. Recently, an alternative, explicitly particle-hole symmetric state was proposed, where composite fermions fill a single Dirac-cone, analogous to the surface state of a topological insulator. These composite Dirac fermions have a quantized  $\pi$  Berry phase due to their spin- $1/2$ , their electric dipole moment, locked to their momentum. In this talk I will consider the experimental probes that can distinguish between HLR and composite Dirac fermions. In particular, I will address the signatures of particle-hole symmetry and Berry phase in the thermoelectric response. In addition, I will discuss other transport experiments which can probe the Fermi surface topology.

**12:15PM L51.00006 Dirac Composite Fermi Liquid in the Half-filled Landau level<sup>1</sup>**, SCOTT GER-AEDTS, Princeton University, MICHAEL ZALETEL, Station Q, Microsoft Research, ROGER MONG, University of Pittsburgh, MAX METLITSKI, Perimeter Institute, ASHVIN VISHWANATH, University of California Berkeley, OLEXEI MOTRUNICH, California Institute of Technology — Quantum Hall fluids at filling fraction one-half exhibit a compressible phase known as the ‘composite Fermi liquid’ (CFL) We use infinite-cylinder density matrix renormalization group to numerically determine that this phase is the ground state of a half-filled Landau level with Coulomb interactions. We find evidence for a Fermi surface of composite fermions, while also probing the non-Fermi liquid character of the phase. It has been recently realized that the traditional theory used to describe the CFL breaks particle-hole symmetry, while the lowest-Landau level projected Hamiltonian does not. We find that the composite Fermi liquid has particle-hole symmetry, inconsistent with the traditional theory but consistent with a recent theory proposed by Son [Phys. Rev. X 5, 031027]. Our results show the Dirac nature of the composite fermions. We also observe the suppression of certain kinds of backscattering processes of the composite fermions, similar to the suppression in topological insulator surface states.

**12:27PM L51.00007 Spontaneous polarization of composite fermions in the  $n = 1$  Landau level of graphene<sup>1</sup>**, AJIT COIMBATORE BALRAM, Pennsylvania State University, CSABA TÖKE, Budapest University of Technology and Economics, ARKADIUSZ WÓJS, Wrocław University of Technology, JAINENDRA JAIN, Pennsylvania State University — Motivated by experiments that reveal expansive fractional quantum Hall states in the  $n = 1$  graphene Landau level and suggest a nontrivial role of the spin degree of freedom [Amet *et al.*, Nat. Commun. 6, 5838 (2014)], we perform accurate quantitative study of the competition between fractional quantum Hall states with different spin polarizations in the  $n = 1$  graphene Landau level. We find that the fractional quantum Hall effect is well described in terms of composite fermions, but the spin physics is qualitatively different from that in the  $n = 0$  Landau level. In particular, for the states at filling factors  $\nu = s/(2s \pm 1)$ ,  $s$  integer, a combination of exact diagonalization and the composite fermion theory shows that the ground state is fully spin polarized and supports a robust spin wave mode even in the limit of vanishing Zeeman coupling. Thus, even though composite fermions are formed, a mean field description that treats them as weakly interacting particles breaks down, and the exchange interaction between them is strong enough to cause a qualitative change in the behavior by inducing full spin polarization. We also find that the fully spin polarized composite fermion Fermi sea has lower energy than the paired Pfaffian state at the relevant half fillings.

<sup>1</sup>Award No. DE-SC0005042 (ACB, JKJ), Hungarian Scientific Research Funds No. K105149 (CT), the Polish NCN grant 2014/14/A/ST3/00654 and the EU Marie Curie Grant PCIG09-GA-2011-294186 (AW)

**12:39PM L51.00008 Anisotropic Composite Fermions and Fractional Quantum Hall Effect**, M A MUEED, DOBROMIR KAMBUROV, SUKRET HASDEMIR, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Princeton University — We study the role of Fermi sea anisotropy on the transport properties of composite Fermions near Landau level filling factor  $\nu = 1/2$  in two-dimensional hole systems confined to GaAs quantum wells. By applying a parallel magnetic field, we tune the Fermi sea anisotropy and monitor the relative change of the transport scattering time along its principal directions. Interpreted in a simple Drude model, our results suggest that the scattering time is longer along the longitudinal direction of the Fermi sea. Furthermore, we find that the measured energy gap for the fractional quantum Hall state at  $\nu = 2/3$  decreases when anisotropy becomes significant.

**12:51PM L51.00009 Spectral properties of center-of-mass conserving two-body Hamiltonians<sup>1</sup>**, AMILA WEERASINGHE, TAHEREH MAZAHARI, ALEXANDER SEIDEL, Washington University in St. Louis — We study the low energy spectral properties of positive center-of-mass conserving two-body Hamiltonians as they arise in models of fractional quantum Hall states. We explore what general constraints can be obtained for such interactions, both in the presence and absence of particle-hole symmetry. We find general bounds that constrain the evolution of the ground state energy with particle number, and in particular constrain the chemical potential at  $T = 0$ . Special attention is given to Hamiltonians with zero modes, in which case similar bounds on the first excited state are also obtained, using a duality property. In this case, in particular an upper bound on the charge gap is also obtained.

<sup>1</sup>This work has been supported by the National Science Foundation under NSF Grant No. DMR-1206781.

**1:03PM L51.00010 Neutral Excitations in the Gaffnian state**, BYUNGMIN KANG, JOEL E. MOORE, UC Berkeley — The Fractional Quantum Hall Effect (FQHE) is one of the most well-studied systems having topological order. Starting with the pioneering work by Laughlin, the model wave function approach has been shown to provide essential information for understanding topological order in gapped incompressible states. We study a model wave function called the Gaffnian state which is believed to represent a gapless, strongly correlated state that is very different from conventional metals. To understand this exotic gapless state better, we provide a representation in which the pairing structure of the Gaffnian state becomes more explicit. We employ the single-mode approximation of the Girvin-MacDonald-Platzman (GMP) mode, which is a neutral collective excitation mode, in order to have a physical picture of the gaplessness of the Gaffnian state. In particular, we discuss how to extract systematically the relevant physics in the long-distance, large electron number limit of the FQH states using a numerical calculation with relatively few electrons.

**1:15PM L51.00011 Beyond the Plasma Analogy: Collective Field Theory for Quantum Hall States**, TANKUT CAN, State Univ of NY- Stony Brook, MICHAEL LASKIN, PAUL WIEGMANN, University of Chicago — We develop a quantum field theory of collective coordinates describing fractional quantum Hall (FQH) states. We show that the familiar properties of Laughlin states are captured by a Gaussian free field theory with a background charge. Gradient corrections to the Gaussian theory arise from ultraviolet regularization, and go beyond the celebrated plasma analogy. They give rise to a gravitational anomaly described by the Liouville theory of 2D quantum gravity. The field theory simplifies the computation of correlation functions in FQH states and makes manifest the effect of quantum anomalies. This talk is based on the preprint arXiv:1412.8716.

**1:27PM L51.00012 Resistively detected high-order magnetoplasmons in a high-quality 2D electron gas**, M.A. ZUDOV, Q. SHI, University of Minnesota, L.N. PFEIFFER, K.W. WEST, Princeton University, J.D. WATSON, M.J. MANFRA, Purdue University — We report on high-order magnetoplasmon resonances detected in photoresistance in high-mobility GaAs quantum wells. These resonances manifest themselves as a series of resistance extrema in the regime of Shubnikov-de Haas oscillations. Extending to orders above 20, the extrema exhibit alternating strength, being less (more) pronounced at even (odd) order magnetoplasmon modes. The lower magnetoplasmon modes reveal the importance of retardation effects.

**1:39PM L51.00013 Zero modes, bosonization, and topological quantum order: The Laughlin state in second quantization**<sup>1</sup>, TAHEREH MAZAHARI, Department of Physics, Washington University, St. Louis, MO 63160, USA, GERARDO ORTIZ, Department of Physics, Indiana University, Bloomington, IN 47405, USA, ZOHAR NUSSINOV, ALEXANDER SEIDEL, Department of Physics, Washington University, St. Louis, MO 63160, USA — We introduce a “second-quantized” representation of the ring of symmetric functions to further develop a purely second-quantized approach to the study of zero modes of frustration-free Haldane-pseudopotential-type Hamiltonians, which in particular stabilize Laughlin ground states. We present three applications of this formalism. We start demonstrating how to systematically construct all zero modes of Laughlin-type parent Hamiltonians in a framework that is free of first-quantized polynomial wave functions, and show that they are in one-to-one correspondence with dominance patterns. Second, as a by-product, we make contact with the bosonization method, and obtain an alternative proof for the equivalence between bosonic and fermionic Fock spaces. Finally, we explicitly derive the second-quantized version of Read’s nonlocal order parameter for the Laughlin state, extending an earlier description by Stone.

**1:51PM L51.00014 Structure of Ground state Wave Functions for the Fractional Quantum Hall Effect: A Variational Approach**<sup>1</sup>, SUTIRTHA MUKHERJEE, SUDHANSU MANDAL, Indian Association for the Cultivation of Science — The internal structure and topology of the ground states for fractional quantum Hall effect (FQHE) are determined by the relative angular momenta between all the possible pairs of electrons. Laughlin wave function is the only known microscopic wave function for which these relative angular momenta are homogeneous (same) for any pair of electrons and depend solely on the filling factor. Without invoking any microscopic theory, considering only the relationship between number of flux quanta and particles in spherical geometry, and allowing the possibility of inhomogeneous (different) relative angular momenta between any two electrons, we develop a general method for determining a closed-form ground state wave function for any incompressible FQHE state. Our procedure provides variationally obtained very accurate wave functions, yet having simpler structure compared to any other known complex microscopic wave functions for the FQHE states. This method, thus, has potential in predicting a very accurate ground state wave function for the puzzling states such as the state at filling fraction 5/2.

**2:03PM L51.00015 Insulating Behavior of Strongly Interacting 2D Electrons in Si MOSFETs**<sup>1</sup>, SHIQI LI, M. P. SARACHIK, City College of New York, CUNY, S. V. KRAVCHENKO, Northeastern University, Boston — Experiments on low disorder strongly-interacting 2D electron systems have shown that in the absence of a magnetic field, the temperature dependence of the resistivity changes from metallic-like to insulating behavior as the electron density  $n_s$  is reduced below a critical density  $n_c$  [1]. It has been shown that a metal to insulator transition also occurs in these systems for fixed electron density  $n_s$  at a critical (density-dependent) in-plane magnetic field which results in complete spin polarization of the electrons [2]. Here we report measurements of the temperature dependence of the resistivity in a high mobility Si-MOSFET sample, where in one case the insulating state is reached by reducing the electron density in zero field, and in the other case it is reached by “quenching” the metallic behavior with an in-plane field of 5 T. We find that the resistivity of the insulating state behaves in very similar ways for both cases, exhibiting Efros-Shklovskii variable range hopping regardless of the degree of polarization of the electron spins. **11:15AM L52.00001 Free-Carrier Absorption in Silicon from First Principles**<sup>1</sup>, GUANGSHA SHI, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — The absorption of light by free carriers in semiconductors such as silicon results in intraband electron or hole excitations, and competes with optical transitions across the band gap. Free-carrier absorption therefore reduces the efficiency of optoelectronic devices such as solar cells because it competes with the generation of electron-hole pairs. In this work, we use first-principles calculations based on density functional theory to investigate direct and phonon-assisted free-carrier absorption in silicon. We determine the free-carrier absorption coefficient as a function of carrier concentration and temperature and compare to experiment. We also identify the dominant phonon modes that contributing to phonon-assisted free-carrier absorption processes, and analyze the results to evaluate the impact of this loss mechanism on the efficiency of silicon solar cells.

**11:27AM L52.00002 Design principles of shift current photovoltaics**<sup>1</sup>, ASHLEY COOK, Department of Physics, University of Toronto, Department of Physics, University of California, Berkeley, BENJAMIN FREGOSO, FERNANDO DE JUAN, Department of Physics, University of California, Berkeley, JOEL MOORE, Department of Physics, University of California, Berkeley, Materials Sciences Division, Lawrence Berkeley National Laboratory — While the basic principles and limitations of conventional solar cells are well understood, relatively little attention has gone toward evaluating and maximizing the potential efficiency of photovoltaic devices based on shift currents. In this work, a sum rule approach is introduced and used to outline design principles for optimizing shift currents for photon energies near the band gap, which depend on wavefunctions via Berry connections as well as standard band structure. Using these we identify two new classes of shift current photovoltaics, ferroelectric polymer films and orthorhombic monochalcogenides, both of which exhibit peak photoresponsivities larger than predictions for previously-known photovoltaics of this type. Using physically-motivated tight-binding models, the full frequency dependent response of these materials is obtained. Exploring the phase space of these models, we find photoresponsivities that can exceed 100 mA/W. These results show that considering the microscopic origin of shift current via effective models allows one to improve the possible efficiency of devices using this mechanism and better grasp their potential to compete with conventional solar cells.

**11:39AM L52.00003 Complete voltage recovery due to suppression of capture to quantum dots**, ANDREI SERGEYEV, KIMBERLY SABLON, U.S. Army Research Laboratory, Adelphi, MD 20783, USA, ALEX VARGHESE, MICHAEL YAKIMOV, VADIM TOKRANOV, SERGE OKTYABRSKY, SUNY Polytechnic Institute, Albany, NY, 12203, VLADIMIR MITIN, University at Buffalo - SUNY, Buffalo, NY 14260 — Decrease of the open circuit voltage in quantum dot (QD) solar cells with respect to the reference cell is an essential drawback of QD devices. Despite numerous efforts, the complete voltage recovery in QD cells has been demonstrated only at low temperatures. We propose and investigate a new approach that combines nanoscale engineering of band structure and potential profile. In this work we (i) fabricated and investigated GaAs solar cells with various nano-engineered InAs QD media, (ii) identified the key photocarrier processes responsible for the voltage reduction, (iii) optimized QD devices and demonstrated the complete voltage recovery with respect to the reference cell together with some improvements in the short circuit current.

**11:51AM L52.00004 Enhancing photovoltaic efficiency through radiative cooling of solar cells below ambient temperature.**, TAQIYAH SAFI, JEREMY MUNDAY, University of Maryland — Sunlight heats up solar cells and the resulting elevated solar cell temperature adversely effects the photovoltaic efficiency and the reliability of the cell. Currently, a variety of active and passive cooling strategies are used to lower the operating temperature of the solar cell. Passive radiative cooling requires no energy input, and is ideal for solar cells; however, previously demonstrated devices still operate above the ambient, leading to a lower efficiency as compared to the ideal Shockley-Queisser limit, which is defined for a cell in contact with an ideal heat sink at ambient temperature (300 K). In this talk, we will describe the use of radiative cooling techniques to lower the cell temperature below the ambient temperature. We show that by combining specifically designed radiative cooling structures with solar cells, efficiencies higher than the limiting efficiency achievable at 300 K can be obtained for solar cells in both terrestrial and extraterrestrial environments. We show that these structures yield an efficiency 0.87% higher than a typical PV module at operating temperatures in a terrestrial application. We also demonstrate an efficiency advantage of 0.4-2.6% for cells in an extraterrestrial environment in near-earth orbit.

**12:03PM L52.00005 Tin alloyed acanthite  $\text{Cu}_2\text{S}$  using cluster expansion method and their stability analysis using density functional theory<sup>1</sup>**, SAJIB BARMAN, MUHAMMAD HUDA, Univ of Texas, Arlington, DR. HUDA'S GROUP TEAM —  $\text{Cu}_2\text{S}$  is a widely known semiconductor which has the potential to be used as an efficient solar absorber material. However, complex phase structures and phase instabilities due to spontaneous Cu vacancy formation are big issues which need to be addressed. Based on a recent theoretical study which has predicted acathite like  $\text{Cu}_2\text{S}$  to be more favorable than other known crystal structures, we have used cluster expansion method to look for the most favorable tin alloyed acanthite  $\text{Cu}_2\text{S}$ . We have used density functional theory systematically to assess the stabilities of those tin alloyed acanthite  $\text{Cu}_2\text{S}$  structures. In addition, effect of Cu vacancies in Sn alloying has also been investigated.

**12:15PM L52.00006 The Upper Bound on Solar Power Conversion Efficiency Through Photonic Engineering<sup>1</sup>**, YUNLU XU, JEREMY MUNDAY, Univ of Maryland-College Park — The power conversion efficiency is a key parameter by which different photovoltaic devices are compared. The maximum value can be calculated under steady-state conditions where the photon flux absorbed by the device equals the outgoing flux of particles (also known as the principle of detailed balance). The photonic engineering of a solar cell offers a new alternative for boosting efficiency. We show that, for an ideally photonic engineered solar cell, its efficiency is subject to an upper bound dictated by a generalized form of detailed balance equation where nano-concentration is taken into account. Results under realistic operating conditions and recent experimental studies will also be discussed.

**12:27PM L52.00007 Nonlinear Response in Silicon Solar Cells<sup>1</sup>**, BEHRANG HAMADANI, JOHN ROLLER, ANDREW SHORE, HOWARD YOON, National Institute of Standards and Technology, NIST COLLABORATION — A light emitting diode (LED)-based system utilizing a combinatorial flux addition method was used to measure the nonlinear relationship in silicon solar cells between the output current of the cell and the incident irradiance level. The light flux was controlled by the supplied current to two sets of LEDs, of either monochromatic light or a combination of various wavelengths. The (non)linearity of a variety of cells were measured over many orders of magnitude of light intensity and various trends were observed, including a transition from nonlinear to linear behavior for some cells as a function of intensity or a complete nonlinear response throughout the probed range. Furthermore, nonlinearity was found to be spectral dependent. An explanation for the observed behavior based on fundamental physics will be provided.

<sup>1</sup>Nonlinear Response in Silicon Solar Cells

**12:39PM L52.00008 Contactless Spectral-dependent Charge Carrier Lifetime Measurements in Silicon Photovoltaic Materials**, JOHN ROLLER, BEHRANG HAMADANI, NIST - Natl Inst of Stds & Tech, MARIO DAGENAIS, University of Maryland - College Park — Charge carrier lifetime measurements in bulk or unfinished photovoltaic (PV) materials allow for a more accurate estimate of power conversion efficiency in completed solar cells. In this work, carrier lifetimes in PV-grade silicon wafers are obtained by way of quasi-steady state photoconductance measurements. These measurements use a contactless RF system coupled with varying narrow spectrum input LEDs, ranging in wavelength from 460 nm to 1030 nm. Spectral dependent lifetime measurements allow for determination of bulk and surface properties of the material, including the intrinsic bulk lifetime and the surface recombination velocity. The effective lifetimes are fit to an analytical physics-based model to determine the desired parameters. Passivated and non-passivated samples are both studied and are shown to have good agreement with the theoretical model.

**12:51PM L52.00009 Effect of Long-Range Polar Electron-Phonon Interaction on the Hot Carrier Dynamics of GaAs**, CHIN SHEN ONG, University of California, Berkeley, MARCO BERNADI, California Institute of Technology, STEVEN G. LOUIE, University of California, Berkeley — Hot carrier dynamics plays an important role in the functionality of electronic and photovoltaic devices. Recent interest in harvesting the energy of hot electrons before it is lost through thermalization has led to renewed interest in the microscopic details of hot electron energy loss mechanisms. Gallium arsenide (GaAs) is of particular interest because amongst its many advantages, it is a direct-gap semiconductor, has high electron mobility and is a high-performing candidate for electronic and photovoltaic applications. GaAs is a polar material, and long-range polar (Frölich) electron-phonon interaction has non-trivial effects on the carrier dynamics in the material. In this work, we investigate the effect of this interaction on the hot carrier dynamics of GaAs. This work is supported by NSF grant No. DMR15-1508412 and the DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility.

**1:03PM L52.00010 Nano-scale Characteristics of Copper poor ordered defect compound at grain boundary of  $\text{CuInGaSe}_2$** , YAPING MA, Chinese Univ of Hong Kong — This work investigates the copper poor ordered defect compound (ODC) layer at grain boundaries (GB) for  $\text{Cu}_x(\text{Ga}_{0.3}\text{In}_{0.7})\text{Se}_2$  with different Cu composition ratio ( $x = 0.9$  and  $0.68$ ). Same chemical composition while widened ODC layer at GBs with lower Cu ratio were first reported determined by the energy dispersive spectroscopy in scanning transmission microscopy mode. Band structure of the ODC layer was directly measured by scanning tunneling spectroscopy showing a downward offset for conduction band and valence band of 200 eV and 350 eV, respectively. This result was further confirmed by photocurrent accumulation and higher Schottky barrier at GBs measured by the conducting probe atomic force microscopy (CP-AFM). Local photovoltaic performance measurements of individual grain boundaries with different ODC width were investigated, using CP-AFM and the disappearance of the differences of open circuit voltage and shunt resistance between grain interior and grain boundary at low illumination provides a direct evidence for the reduced recombination at widened ODC grain boundary which greatly supports the hole barrier theory for the high efficiency of the Copper Indium Ga Selenide solar cells.

**1:15PM L52.00011 Employing Time-Resolved Terahertz Spectroscopy to Analyze Carrier Dynamics in  $\text{Cu}_2\text{ZnSn}(\text{S},\text{Se})_4$  Absorber Layers**<sup>1</sup>, JASON BAXTER, GLENN GUGLIETTA, SIMING LI, Drexel University, KAUSHIK ROY CHOUDHURY, JONATHAN CASPAR, DuPont Central Research and Development, DOUGLAS BISHOP, MICHAEL LLOYD, BRIAN MCCANDLESS, University of Delaware — We report the application of time-resolved terahertz spectroscopy (TRTS) to measure photoexcited carrier lifetimes and mobility, and to determine recombination mechanisms in  $\text{Cu}_2\text{ZnSn}(\text{S},\text{Se})_4$  (CZTSSe) thin films and single crystals. Ultrafast time resolution permits tracking the evolution of carrier density to determine recombination rates and mechanisms. The carrier generation profile was manipulated by varying the photoexcitation wavelength and fluence to distinguish between surface, Shockley-Read-Hall (SRH), radiative, and Auger recombination mechanisms and determine rate constants. Surface and SRH recombination are the dominant mechanisms for the air/CZTSSe/ $\text{SiO}_2$ /Si film stack. Diffusion to, and then recombination at, the air-CZTSSe interface occurred on the order of 100 picoseconds, while SRH recombination lifetimes were 1 - 2 nanoseconds. Analogous measurements on single crystals reveal the effects of eliminating grain boundaries, reducing point defects and secondary phases, and applying surface treatments to reduce surface recombination velocity. TRTS measurements can provide information that is complementary to conventional time-resolved photoluminescence measurements and can direct the design of efficient thin film photovoltaics. **1:27PM L52.00012 Surfactant Antimony enhanced Indium incorporation on InGaN -C plane**<sup>1</sup>, YIOU ZHANG, JUNYI ZHU, Chinese Univ of Hong Kong — InGaN is an ideal alloy system for optoelectronic devices due to its tunable band gap. Yet high-quality InGaN with high In concentration is still a challenging issue that limits its use in green-light LEDs and other devices. In this presentation, we report the surfactant effect of Sb on the In incorporation on InGaN (000-1) surface via first-principles approaches. We constructed surface phase diagram to determine surface structures under different growth conditions. By analyzing surface stress under different structures, we found that Sb adatom can induce tensile sites in the cation layer, enhancing the In incorporation. These findings may provide fundamental understandings and guidelines for the growth of InGaN with high In concentration.

**1:39PM L52.00013 Probing the Surface Defect States of Gallium Nitride Nanowires**, LAUREN SIMONSEN, YUCHEN YANG, Department of Physics and Astronomy, University of Utah, NICHOLAS BORYS, Molecular Foundry, Lawrence Berkeley National Laboratory, ANIL GHIMIRE, Department of Physics and Astronomy, University of Utah, JAMES SCHUCK, SHAUL ALONI, Molecular Foundry, Lawrence Berkeley National Laboratory, JORDAN GERTON, Department of Physics and Astronomy, University of Utah — In this work, we investigate gallium nitride nanowires (NWs) as a potential system for solar-driven water splitting. Although bulk GaN has a UV bandgap, the synthesized NWs exhibit strong absorption and fluorescence emission across the visible spectrum. Density functional theory calculations suggest that this visible fluorescence originates from mid-gap surface-defect states along the triangular facets of the NWs. The orientation of the NWs can be controlled during MOCVD growth, leading to different exposed crystallographic surface terminations with different electronic structures. High resolution microscopy techniques using AFM and confocal hyper-spectral imaging show spectral inhomogeneity across the widths of the NWs, providing evidence that various crystallographic terminations produce different surface states. These NWs also exhibit wave guiding properties, leading to Fabry-Perot fringes and high intensity spectra and the ends of the wires. Photoluminescence excitation spectroscopy reveals a non-linear dependence of the emission spectral features on excitation wavelength, indicating a complex distribution of mid-gap defect states. Time-resolved spectroscopy reveals non-exponential decay dynamics through a complicated manifold of mid-gap states.

Session L53 DFD GSOFD DPOLY: Flow of Complex Fluids, Polymers, Gels Hilton Inner Harbor Holiday Ballroom 4 -

**11:15AM L53.00001 Anomalous response of nematic platelets under LAOStress and Strain revealed by 3D RheoSAXS**, O. KORCULANIN, ICS-3, Forschungszentrum Juelich, Germany, H. HIRSEMANN, B. STRUTH, DESY, Hamburg, Germany, G. PORTALE, Uni. of Groningen and Dubble, ESRF, Grenoble, France, M. P. LETTINGA, ICS-3, Forschungszentrum Juelich, Germany and KU Leuven, Belgium — Dispersions of colloidal Gibbsite platelets in the nematic phase display a complex response to Large Amplitude Oscillatory Shear (LAOS) flow that strongly depends on the strain amplitude. [1] In this work we applied LAOStress and LAOStrain to the nematic dispersion and probed the structure with time-resolved SAXS measurements. By using plate-plate and couette geometry, we had access to both the flow-vorticity and flow-gradient plane, respectively, thus obtain full 3D rotational motion of the director. For LAOStress, we observe strong asymmetrical behavior both in the rheological and the microscopic response. This asymmetry is connected to the yielding behavior of the platelets. By increasing the stress amplitude we observed that the response becomes more symmetric; however, this strongly depends on the frequency, hence the time necessary for the system to yield. Softening of the response towards the center of the gap was observed by scanning the gap while performing LAOStrain. The structural response at low strain amplitude does not propagate throughout the gap, whereas at high strain amplitudes the response in the bulk emerges as erratic. [1] M. P. Lettinga, et al., Non-linear behavior of colloidal platelets in shear flow. Phys. Rev. Lett.(2012) Vol. 109, 246001

**11:27AM L53.00002 Distinctive viscoelastic and viscoplastic nanomechanics of ionically cross-linked polyelectrolyte complexes under intermittent relaxation and creep**, BIAO HAN, TIANZHU MA, Drexel University School of Biomedical Eng., Sci. and Health Systems, DAEYEON LEE, VIVEK SHENOY, University of Pennsylvania, School of Engineering and Applied Science, LIN HAN, Drexel University School of Biomedical Eng., Sci. and Health Systems — This study aims to reveal unique nanoscale viscoelastic and viscoplastic properties of ionically linked polyelectrolyte networks. Layer-by-layer PAH/PAA complexes were tested by four continuous loading cycles in aqueous solutions. In each cycle, AFM-nanoindentation via a microspherical tip ( $R=5\mu\text{m}$ ) was applied up to  $1\mu\text{N}$  force, followed by a 30-60 sec hold at either a constant indentation depth to measure relaxation, or a constant force to measure creep. At a highly cross-linked, net neutral state (0.01M, pH 5.5), instantaneous modulus increased by 2.7-fold from first to last cycle, while the degree of relaxation ( $>95\%$ ) remain consistent. These results indicate repeated loading increases local cross-link density, while relaxation is consistently dominated by cross-link breaking and re-formation. In contrast, under creep, modulus increased by a similar 3.5-fold, and degree of creep is significantly attenuated from  $\approx 50\%$  to  $45\%$  from first to last cycle. Results from creep suggest constant viscous flow of polymer chains in the absence of permanent anchorage. As a result, an irreversible deformation ( $\approx 370\text{nm}$ ) was observed after multiple creep cycles, suggesting the presence of viscoplasticity.

**11:39AM L53.00003 Non-equilibrium Stokes-Einstein relation via active microrheology of hydrodynamically interacting suspensions**, HENRY CHU, ROSEANNA ZIA, Cornell University — In our recently developed non-equilibrium Stokes-Einstein relation, we showed that, in the absence of hydrodynamic interactions, the stress in a suspension is given by a balance between fluctuation and dissipation. Here, we generalize our theory for systems of hydrodynamically interacting colloids, via active microrheology, where motion of a Brownian probe through the medium reveals rheological properties. The strength of probe forcing compared to the entropic restoring force defines a Peclet number,  $Pe$ . In the absence of hydrodynamics, the first normal stress difference and the osmotic pressure scale as  $Pe^4$  and  $Pe^2$  respectively when probe forcing is weak, and uniformly as  $Pe$  for strong probe forcing. As hydrodynamics become important, interparticle forces give way to lubrication interactions. Hydrodynamic coupling leads to a new low- $Pe$  scaling of the first normal stress difference and the osmotic pressure as  $Pe^2$ , and high- $Pe$  scaling as  $Pe^\delta$ , where  $0.799 \leq \delta \leq 1$  as hydrodynamics vary from strong to weak. For the entire range of the strength of hydrodynamic interactions and probe forcing, the new phenomenological theory is shown to agree with standard micromechanical definitions of the stress. We further draw a connection between the stress and the energy storage in a suspension, and the entropic nature of such storage is identified.

**11:51AM L53.00004 Sticky-probe active microrheology**, DEREK HUANG, ROSEANNA ZIA, Cornell University — We study the strongly nonlinear flow behavior of a sticky colloidal dispersion via active microrheology, where the motion of a Brownian probe driven by external forces through the suspension is tracked to infer material properties. Most prior work focused on repulsive hard spheres and the influence of Brownian and hydrodynamic forces on rheological behavior, but in many biological suspensions, particles exert attractive forces on one another. Previous attempts to model the effects of particle attractions on sheared suspensions show that interparticle attractions increase suspension stress and viscosity, but these results are limited to weak shearing flows in macroscopic systems. In our microrheological model, probe motion through the suspension distorts the configuration of particles; the Peclet number, probe forcing compared to thermal forces, gives the extent of this distortion. The equilibrium microstructure and its distortion under probe forcing are also influenced by the strength of interparticle attractions relative to thermal forces. We determine the equilibrium and non-equilibrium microstructure and examine the forcing and attraction contributions to particle motion and suspension stress.

**12:03PM L53.00005 Stress diffusion in models for shear banding**, ELIAN MASNADA, PETER OLMSTED, Georgetown Univ — Understanding shear banding is of utmost importance from both theoretical and experimental point of view and consequently it has been studied for several decades [1]. Despite this study numerous aspects of shear banding remains poorly understood. Because of the intrinsic inhomogeneity in the shear banded state, applicable constitutive models must include spatial inhomogeneities, leading to a so-called 'diffusive' term in the equation of motion for the slow variables that carry stress [2,3]. Such terms are also vital in describing the interaction of bulk shear banding flows with walls and incorporation of wall slip. In this work, we consider different sources of 'diffusion' in polymer models in which concentration degrees of freedom are negligible. The simplest models used are consistent with diffusive terms whose origin is intrinsically dissipative, such as due to hydrodynamic interactions. By contrast, models in which elastic effects such as finite chain stiffness contribute to stress diffusion are inconsistent with simple diffusive models, and we propose alternative consistent models. [1] P. D. Olmsted, Rheol. Acta, 47, 283-300 (2008). [2] C.-Y. D. Lu et al, Phys. Rev. Lett., 84, 642 (2000). [3] A. W. El-Kareh and L. G. Leal, J. Non-Newton. Fluid Mech., 33, 257 (1989).

**12:15PM L53.00006 Strength of self-pinning in coffee drops.**, ANDRZEJ LATKA, KIMBERLY KAWCZINSKI, SIDNEY NAGEL, James Franck Institute, University of Chicago — The equilibrium contact angle  $\theta_e$  of a liquid drop placed on a solid surface is uniquely determined by a balance of surface tension forces according to Young's Equation, yet is rarely observed in real systems. Due to contact angle hysteresis, liquids can make contact with a surface at any angle between the receding and advancing contact angle:  $\theta_R < \theta_e < \theta_A$ . A particularly striking example of this phenomenon is the familiar coffee stain. For coffee  $\theta_R = 0$ , thus as the drop evaporates the contact line remains pinned at its initial location. This results in the majority of the coffee being deposited in a characteristic ring at the drop's original boundary. We investigate how solid particles suspended in a liquid could so strongly influence contact angle hysteresis, by measuring the receding contact angle of a drop at various times during the evaporation process. For low solute concentrations,  $\theta_R$  slowly decreases as the drop evaporates, but remains positive. Surprisingly, we find that increasing the solute concentration results in  $\theta_R = 0$  and a fully pinned contact line almost immediately after the drop is deposited.

**12:27PM L53.00007 Microfluidics of soft granular gels**, RYAN NIXON, Univ of Florida - Gainesville, TAPOMOY BHATTACHARJEE, W. GREGORY SAWYER, THOMAS E. ANGELINI, University of Florida — Microfluidic methods for encapsulating cells and particles typically involve drop making with two immiscible fluids. The main materials constraint in this approach is surface tension, creating inherent instability between the two fluids. We can eliminate this instability by using miscible inner and outer phases. This is achieved by using granular micro gels which are chemically miscible but physically do not mix. These microgels are yield stress materials, so they flow as solid plugs far from shear gradients, and fluidize where gradients are generated – near an injection nozzle for example. We have found that tuning the yield stress of the material by varying polymer concentration, device performance can be controlled. The solid like behavior of the gel allows us to produce infinitely stable jets that maintain their integrity and configuration over long distances and times. These properties can be combined and manipulated to produce discrete particulate bunches of an inner phase, flowing inside of an outer phase, well enough even to print a Morse code message suspended within flow chambers about a millimeter in diameter moving at millimeters a second.

**12:39PM L53.00008 Lift-enhanced Electrical Pinched Flow Fractionation for Particle and Cell Separation.**<sup>1</sup>, CORY THOMAS, ANDREW TODD, XINYU LU, XIANGCHUN XUAN, Clemson University — Pinched flow fractionation (PFF) is a microfluidic technique that utilizes the laminar flow profile in microchannels to continuously separate particles or cells by size. The flow can be either pressure-driven or electric field-driven. We demonstrate in this work that the wall-induced electrical lift force can be exploited to significantly increase the particle or cell displacement in electrical PFF due to its strong size dependence. This enhanced particle and cell separation is implemented by a simple elongation of the pinched segment in electrical PFF. It is demonstrated through both a binary and a ternary separation of polymer particles and biological cells based on surface charge and/or size. We also develop a numerical model to predict and understand this lift-enhanced electrical PFF.

**12:51PM L53.00009 Particle Size Effect on Wetting Kinetics of a Nanosuspension Drop: MD Simulations**, BAIYOU SHI, EDMUND WEBB, Lehigh University — The behavior of nano-fluids, or fluid suspensions containing nanoparticles, has garnered tremendous attention recently for applications in advanced manufacturing. In our previous results from MD simulations, for a wetting system with different advancing contact angles, cases where self-pinning was observed were compared to cases where it was not and relevant forces on particles at the contact line were computed. To advance this work, the roles of particle size and particle loading are examined. Results presented illustrate how particle size affects spreading kinetics and how this connects to dynamic droplet morphology and relevant forces that exist nearby the contact line region. Furthermore, increased particle size in simulations permits a more detailed investigation of particle/substrate interfacial contributions to behavior observed at the advancing contact line. Based on changes in spreading kinetics with particle size, forces between the particle and liquid front are predicted and compared to those computed from simulations. At high loading, particle/particle interactions become relevant and forces computed between particles entrained to an advancing contact line will be presented.

**1:03PM L53.00010 Numerical Computation of Mass Transport in Low Reynolds Number Flows and the Concentration Boundary Layer**, NICHOLAS A. LICATA, NATHANIEL J. FULLER, University of Michigan-Dearborn — Understanding the physical mechanisms by which an individual cell interacts with its environment often requires detailed information about the fluid in which the cell is immersed. Mass transport between the interior of the cell and the external environment is influenced by the flow of the extracellular fluid and the molecular diffusivity. Analytical calculations of the flow field are challenging in simple geometries, and not generally available in more realistic cases with irregular domain boundaries. Motivated by these problems, we discuss the numerical solution of Stokes equation by implementing a Gauss-Seidel algorithm on a staggered computational grid. The computed velocity profile is used as input to numerically solve the advection-diffusion equation for mass transport. Special attention is paid to the case of two-dimensional flows at large Péclet number. The numerical results are compared with a perturbative analytical treatment of the concentration boundary layer.

**1:15PM L53.00011 Cell mechanics through analysis of cell trajectories in microfluidic channel**, SAMUEL BOWIE, ALEXANDER ALEXEEV, TODD SULCHEK, Georgia Institute of Technology — The understanding of dynamic cell behavior can aid in research ranging from the mechanistic causes of diseases to the development of microfluidic devices for cancer detection. Through analysis of trajectories captured from video of the cells moving in a specially designed microfluidic device, insight into the dynamic viscoelastic nature of cells can be found. The microfluidic device distinguishes cells viscoelastic properties through the use of angled ridges causing a series of compressions, resulting in differences in trajectories based on cell stiffness. Trajectories of cell passing through the device are collected using image processing methods and data mining techniques are used to relate the trajectories to cell properties obtained from experiments. Furthermore, numerical simulation of the cell and microfluidic device are used to match the experimental results from the trajectory analysis. Combination of the modeling and experimental data help to uncover how changes in cellular structures result in changes in mechanical properties.

**1:27PM L53.00012 New analysis method for passive microrheology**, KENGO NISHI, CHRISTOPH SCHMIDT, Univ Goettingen, FRED MACKINTOSH, Vrije Universiteit — Passive microrheology is an experimental technique used to measure the mechanical response of materials from the fluctuations of micron-sized beads embedded in the medium. Microrheology is well suited to study rheological properties of materials that are difficult to obtain in larger amounts and also of materials inside of single cells. In one common approach, one uses the fluctuation-dissipation theorem to obtain the imaginary part of the material response function from the power spectral density of bead displacement fluctuations, while the real part of the response function is calculated using a Kramers-Kronig integral. The high-frequency cut-off of this integral strongly affects the real part of the response function in the high frequency region. Here, we discuss how to obtain more accurate values of the real part of the response function by an alternative method using autocorrelation functions.

**1:39PM L53.00013 Effect of droplet shape on ring stains from dried liquid**, MELVIN SANTIAGO, Department of Physics, Case Western Reserve University, Cleveland, Ohio 44106-7079, KATHERINE BROWN, Department of Physics, Hamilton College, Clinton NY 13323, HARSH MATHUR, Department of Physics, Case Western Reserve University, Cleveland, Ohio 44106-7079 — A landmark experimental paper on coffee stains by Deegan et al included a simple theoretical analysis of circular droplets [1]. The analysis was based on a model informally called the Maxwell House equations. It describes the evolving height profile of the droplet, the evaporation of the solvent and the outflow of solute to the rim of the droplet. Since typical droplets are not circles, here we extend the analysis to more general shapes. We find that for thin droplets the height profile may be determined by solving Poisson's equation in a domain corresponding to the footprint of the droplet. Evaporation is treated in a simple approximation via an electrostatic analogy and is dominated by the sharp edges of the droplet. Assuming zero vorticity allows us to analyze the solvent flow in droplets of arbitrary shape. We compare circular droplets to other shapes including long linear droplets, ring shaped droplets and droplets with an elliptical footprint. [1] R.D. Deegan et al, Nature 389, 827 (1997).

**1:51PM L53.00014 Lie Algebraic Analysis of Thin Film Marangoni Flows: Multiplicity of Self-Similar Solutions**, ZACHARY NICOLAOU, SANDRA TROIAN, California Institute of Technology, 1200 E. California Blvd., MC 128-95, Pasadena, CA — The rapid advance of an insoluble surfactant monolayer on a thin liquid film of higher surface tension is controlled by distinct flow regimes characterized by the relative strength of viscous, Marangoni and capillary forces. Such flows play a critical role in human pulmonary and ocular systems. During the past quarter century, researchers have focused exclusively on self-similar solutions to the governing pair of nonlinear PDEs for the film thickness,  $H(r/t^a)$ , and surface concentration,  $\Gamma(r/t^a)/t^b$ , in the limit where the Marangoni or capillary terms vanish, where  $r$  denotes the spatial variable,  $t$  is time, and  $a$  and  $b$  are fractional exponents. Using Lie algebraic techniques, we demonstrate for the first time the existence of several embedded symmetries in this system of equations which yield multiple self-similar solutions describing more complex scaling behavior, even when all three forces are incorporated. A special and previously unrecognized subset of these solutions reveals the dynamical behavior of film thinning and surfactant distribution near the origin, which ultimately meters the downstream flow. Finite element simulations confirm the suite of scaling exponents obtained analytically.

**2:03PM L53.00015 Convective flows generated by evaporation: experiments, linear stability analysis and numerical simulations**, JOCELYN DUNSTAN, Postdoc, KYOUNG JIN LEE, Professor, SIMON PARK, Senior Lecturer, RAYMOND E. GOLDSTEIN, Professor — A novel form of convection was observed in a suspension of non-motile *Photobacterium phosphoreum* bacteria. The pattern resembles classical bioconvection, however this strain has limited if any motility, which excludes this possible explanation. After performing a series of control experiments we found that the convection was actually driven by the evaporation of the salty bacterial medium, and the same kind of plumes were observed using polystyrene beads suspended in water with salt added. A mathematical model was formulated for the process and studied using a linear stability analysis and finite element method simulations, reproducing most of the observed experimental features. From the linear stability analysis, a threshold in salt concentration to observe convective motion was obtained, as well as the wavelength of the pattern at the onset of the instability. This was complemented by finite element simulations, which produced plume dynamics remarkably similar to the experimental observations. Evaporation-driven convection on the millimeter scale has not been studied extensively, and its effect may have been underestimated in other experiments.

**Session L54 DCMP: Supersolids and Band Structure in Strongly Correlated Systems** Hilton  
Baltimore Holiday Ballroom 5 - William Cannon, Texas AM University

**11:15AM L54.00001 Re-investigating Solid Helium under DC Rotation with a Rigid Torsional Oscillator** , JAEWON CHOI, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea, TOMOYA TSUIKI, Department of Physics, Keio University, Yokohama, Kanagawa, Japan, DAISUKE TAKAHASHI, Department of General Education, Ashikaga Institute of Technology, Ashikaga, Tochigi, Japan, KEIYA SHIRAHAMA, Department of Physics, Keio University, Yokohama, Kanagawa, Japan, KIMITOSHI KONO, Quantum Condensed Phase Research Team, RIKEN, Wako, Saitama, Japan, HYOUNGSOON CHOI, EUNSEONG KIM, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea — The resonant period drop observed in a torsional oscillator (TO) containing solid helium first interpreted as the signature of supersolid is now generally accepted as the shear modulus change of solid helium at low temperature. However, there are still several aspects in solid helium that remain unresolved. For instance, the striking DC rotation effect on the TO experiments was observed without altering the shear modulus of solid helium. The DC rotation is not expected to change the elastic property of solid helium while it can destroy superfluidity. Therefore, the DC rotation effect was considered as the strong evidence of superfluidity in solid helium. Here, we re-examine the effect of DC rotation by utilizing a rigidly constructed TO. Previous DC rotation experiments were performed with a TO exhibiting high reduction ratio of the period, which can be attributed to non-ideal construction of the TO. It is plausible that the resonance period and dissipation of non-ideal TO can be more susceptible to environmental vibration caused by the DC rotation. The response of the rigid TO under DC rotation will be reported to test the validity of the previous interpretation thoroughly.

**11:27AM L54.00002 Mass Flux Measurements in Solid  $^4\text{He}$** <sup>1</sup> , VALENTYN RUBANSKYI, YEGOR VEKHOV<sup>2</sup>, ROBERT HALLOCK, Univ of Mass - Amherst — There has been considerable attention given to solid helium over the past decade. Our approach to study the solid has been to sandwich solid helium between two reservoirs of superfluid helium. With this approach, we found and explored the characteristics of mass flux that takes place from one reservoir to the other<sup>3</sup>. We observed flow that has the characteristics of one-dimensional conductivity<sup>4</sup> and we have documented the effects that various concentrations of  $^3\text{He}$  impurity have on the temperature dependence of the flow<sup>5</sup>. These experiments continue and we will report on this work and new results that may be available.

**11:39AM L54.00003 Mass flow in bulk solid  $^4\text{He}$** <sup>1</sup> , ZHI GANG CHENG, JOHN BEAMISH, University of Alberta — Experiments with solid  $^4\text{He}$  and liquid confined in vycor pores have shown an unexpected mass flow in both liquid-solid-liquid and solid-liquid-solid junctions. In both configurations, non-thermally activated flow emerges below 600 mK. The flow rate increases as the temperature decreases, then drops suddenly at a temperature around 100 mK. This drop in flow rate is related to the  $^3\text{He}$  impurity concentration in the samples and prevents us from studying the flows intrinsic behavior at the lowest temperatures. We have now modified our measurement technique, in which solid helium is compressed at one end of a cell and flow is observed as a pressure response at the opposite end. By removing the vycor from our cell, we have eliminated liquid  $^4\text{He}$  and the liquid-solid interfaces which complicated the interpretation of earlier experiments. We find that similar mass flow occurs with only bulk solid  $^4\text{He}$  present. When we reduced the  $^3\text{He}$  concentration to the level of a few parts per trillion, we were able to measure the intrinsic flow rate down to lower temperatures, with no evidence of a drop in flow down to at least 25 mK.

**11:51AM L54.00004 Superclimbing instability in solid Helium-4**<sup>1</sup> , ANATOLY KUKLOV, CSI and the Graduate Center, CUNY — The accumulation of matter in solid  $^4\text{He}$  observed in the UMASS group and dubbed as the syringe effect is discussed within the model of dislocations with superfluid core beyond the linear approximation. Such dislocations are found to be unstable with respect to the syringe effect if biased by chemical potential above a threshold  $\mu_c \approx Gb^4/L$ , where  $G$  is the shear modulus,  $b$  - Burgers vector and  $L$  - free length of a dislocation. In almost perfect crystals, where  $L$  can be as long as several  $\mu\text{m}$  or even longer, the threshold is *macroscopically* small - corresponding to overpressures smaller than few mbar. This effect for edge dislocations has its high temperature analog - Bardeen-Herring instability of dislocations due to diffusive high temperature vacancy transport. For screw dislocations the instability develops through helix formation first observed in Si at high temperatures by W. C. Dash (1958). In solid  $^4\text{He}$  the vacancy diffusion is replaced by the supertransport along dislocation cores. The instability should cause formation of the superfluid dislocation forest leading to the superflow-through-solid effect first observed in the UMASS group. Several testable predictions with respect to the bias and time dependence for the syringe dynamics are made.

**12:03PM L54.00005 Analysis of recent observations of ultrasound propagation in solid  $^4\text{He}$**  , HARRY KOJIMA, Rutgers University, IZUMI IWASA, Kanagawa University, JOHN GOODKIND, UCSD — Extensive measurements have been made on the propagation of 10 MHz ultrasound in solid  $^4\text{He}$ . When the sound excitation level is low, sudden shifts in both the sound propagation velocity and attenuation are observed below 100 mK but the sudden shifts disappear when the excitation level is sufficiently high. The detailed response depends on the ultrasound excitation level and thermal history. The observations are analyzed in terms of the Granato-Lücke theory on the effects of dislocation line motion on the propagation of sound. The effects of pinning of dislocation lines by  $^3\text{He}$  impurities are included in the analysis. Parameters such as the average dislocation length, the dislocation line density, the dissipation coefficient and the impurity binding energy that are extracted by fitting the data to theory will be discussed.

**12:15PM L54.00006  $^4\text{He}$  adsorption on a  $^3\text{He}$ -plated graphite surface** , YONGKYUNG KWON, JEONGHWAN AHN, Konkuk University — Path-integral Monte Carlo (PIMC) calculations have been performed for  $^4\text{He}$  atoms on top of the  $^3\text{He}$  first layer on graphite. For this we ignore Fermi statistics of solidified  $^3\text{He}$  adatoms while Bose statistics of  $^4\text{He}$  atoms are fully incorporated. We first find that the first  $^3\text{He}$  layer exhibits a 7/12 commensurate solid structure at the areal density of  $0.111 \text{ \AA}^{-2}$ , which turns out to be identical to the experimental value for its completion density. Additional adsorption of  $^4\text{He}$  atoms above the complete first  $^3\text{He}$  layer is found to sustain the underlying  $^3\text{He}$  commensurate structure and the second  $^4\text{He}$  layer is observed to display the 4/7 commensurate structure with respect to the first-layer commensurate  $^3\text{He}$  solid at the areal density of  $0.0636 \text{ \AA}^{-2}$ . Furthermore, it is found that the 4/7 commensurate structure of the second-layer  $^4\text{He}$  atoms can be formed above a mixture of the first-layer  $^3\text{He}$  and  $^4\text{He}$  atoms on graphite. These PIMC results suggest that the 4/7 commensurate structure of the second-layer  $^4\text{He}$  atoms on graphite, whose existence on top of the first  $^4\text{He}$  layer has long been in dispute, may be realized on a  $^3\text{He}$ -plated graphite surface. This could lead to a new approach to observe two-dimensional supersolidity in  $^4\text{He}$  on graphite.

**12:27PM L54.00007 Thermodynamics of the Noninteracting Bose Gas in a Two-Dimensional Box**, HEQIU LI, QIUJIANG GUO, JI JIANG, Zhejiang University, DAVID C. JOHNSTON, Iowa State Univ — Bose-Einstein condensation (BEC) of a noninteracting Bose gas of  $N$  particles in a two-dimensional (2D) box with Dirichlet boundary conditions is studied. Confirming previous work, we find that BEC occurs at finite  $N$  at low temperatures  $T$  without the occurrence of a phase transition. We further show that the crossover temperature between weak and strong increases in BEC upon cooling is  $T_E \sim 1/\log(N)$  at fixed area per boson, so in the thermodynamic limit there is no significant BEC in 2D at finite  $T$ . Calculations of thermodynamic properties versus  $T$  and area  $A$  are presented, including Helmholtz free energy, entropy  $S$ , pressure  $p$ , ratio of  $p$  to the energy density  $U/A$ , heat capacity at constant area  $C_V$  and at constant pressure  $C_p$ , isothermal compressibility  $\kappa_T$  and thermal expansion coefficient  $\alpha_p$ , obtained using both the grand canonical ensemble (GCE) and canonical ensemble (CE) formalisms. The GCE formalism gives acceptable predictions for  $S$ ,  $p$ ,  $p/(U/A)$ ,  $\kappa_T$  and  $\alpha_p$  at large  $N$ ,  $T$  and  $A$ , but fails when  $N$  is small or BEC is significant, whereas the CE formalism gives accurate results even at low  $T$  and/or  $A$  where BEC occurs.

**12:39PM L54.00008 Characterizing Featureless Mott Insulating State by Quasiparticle Interferences - A DMFT Prospect<sup>1</sup>**, SHANTANU MUKHERJEE, WEI-CHENG LEE, State Univ of NY - Binghamton — In this talk we discuss the quasiparticle interferences (QPIs) of a Mott insulator using a T-matrix formalism implemented with the dynamical mean-field theory (T-DMFT). In the Mott insulating state, the DMFT predicts a singularity in the real part of electron self energy  $s(w)$  at low frequencies [1], which completely washes out the QPI at small bias voltage. However, the QPI patterns produced by the non-interacting Fermi surfaces can appear at a critical bias voltage in Mott insulating state. The existence of this non-zero critical bias voltage is a direct consequence of the singular behavior of  $\text{Re}[s(w)]/\sim n/w$  with  $n$  behaving as the 'order parameter' of Mott insulating state. We propose that this reentry of non-interacting QPI patterns could serve as an experimental signature of Mott insulating state, and the 'order parameter' can be experimentally measured [2]. [1] A. Georges et al, Rev. Mod. Phys. 68, 13 (1996). [2] Shantanu Mukherjee, and Wei-Cheng Lee, Arxiv: 1504.05214 (2015).

**12:51PM L54.00009 Band Theory for the Electronic and Magnetic Properties of VO<sub>2</sub> Phases<sup>1</sup>**, XIAO SHEN, Vanderbilt University, University of Memphis, SHENG XU, Jiangsu University of Science and Technology, KENT HALLMAN, RICHARD HAGLUND, Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University, Oak Ridge National Lab — VO<sub>2</sub> is widely studied for the insulator-metal transition between the monoclinic M1 (insulator) and rutile R (metal) phases. Recent experiments show that in addition to the M1 and R phases, VO<sub>2</sub> has a rich phase diagram including a recently identified metallic monoclinic phase, making the material particularly intriguing. The origin of the band gap in the insulating phase of VO<sub>2</sub> has been a subject of debate. It was suggested that the insulating phase cannot be described by band theory and thus strong correlations must be invoked. However, recent band calculations using density functional theory (DFT) with a hybrid functional and standard pseudopotentials correctly obtains a band gap for the M1 insulating phase. Subsequent calculations, however, found that the magnetic properties of VO<sub>2</sub> phases are not correctly described by such calculations. Here we present DFT calculations using a tuned hybrid functional and hard pseudopotentials that reproduce both the band gaps and the magnetic properties of the known VO<sub>2</sub> phases. Thus, it is appropriate to use band theory to describe VO<sub>2</sub> phases without invoking strong correlations. Furthermore, using the band theory treatment, we identify a candidate for the metallic monoclinic phase.

**1:03PM L54.00010 A minimal model for the structural energetics of VO<sub>2</sub><sup>1</sup>**, CHANUL KIM, CHRIS MARIANETTI, Columbia Univ, THE MARIANETTI GROUP TEAM — Resolving the structural, magnetic, and electronic structure of VO<sub>2</sub> from the first-principles of quantum mechanics is still a forefront problem despite decades of attention. Hybrid functionals have been shown to qualitatively ruin the structural energetics. While density functional theory (DFT) combined with cluster extensions of dynamical mean-field theory (DMFT) have demonstrated promising results in terms of the electronic properties, structural phase stability has not yet been addressed. In order to capture the basic physics of the structural transition, we propose a minimal model of VO<sub>2</sub> based on the one dimensional Peierls-Hubbard model and parameterize this based on DFT calculations of VO<sub>2</sub>. The total energy versus dimerization in the minimal model is then solved numerically exactly using density matrix renormalization group (DMRG) and compared to the Hartree-Fock solution. We demonstrate that the Hartree-Fock solution exhibits the same pathologies as DFT+U, and spin density functional theory for that matter, while the DMRG solution is consistent with experimental observation. Our results demonstrate the critical role of non-locality in the total energy, and this will need to be accounted for to obtain a complete description of VO<sub>2</sub> from first-principles.

**1:15PM L54.00011 Ab Initio Infrared Spectra and Electronic Response Calculations for the Insulating Phases of VO<sub>2</sub><sup>1</sup>**, CHRISTOPHER HENDRIKS, TYLER HUFFMAN, ERIC WALTER, MUMTAZ QAZILBASH, HENRY KRAKAUER, William and Mary College — Previous studies have shown<sup>2</sup> that, under doping or tensile strain and upon heating, the well-known vanadium dioxide (VO<sub>2</sub>) transition from an insulating monoclinic (M1) to a metallic rutile (R) phase progresses through a triclinic symmetry (T) phase and a magnetic monoclinic phase (M2), both of which are insulating. Structurally, this progression from M1 to R through T and M2 can be characterized by the progressive breaking of the V dimers. Investigation of the effect of these structural changes on the insulating phases of VO<sub>2</sub> may help resolve questions surrounding the long-debated issue of the respective roles of electronic correlation and Peierls mechanisms in driving the MIT. We investigated electronic and vibrational properties of the insulating phases of VO<sub>2</sub> in the framework of DFT+U. We will present *ab initio* calculations of infrared spectra and optical electronic responses for the insulating phases and compare these to available experimental measurements<sup>3,4,5,6</sup>.

### 1:27PM L54.00012 Role of non-local exchange in the electronic structure of correlated oxides

, FEDERICO IORI, Université Paris Sud - CNRS, MATTEO GATTI, Theoretical Spectroscopy Group LSI - CNRS Ecole Polytechnique & Synchrotron SOLEIL, ANGEL RUBIO SECADES, Theory Department, Max Planck Institute for the Structure and Dynamics of Matter, Max Planck Society — Transition-metal oxides (TMO) with partially filled d or f shells are a prototype of correlated materials. They exhibit very interesting properties, like metal-insulator phase transitions (MIT) [1]. In this work we consider several TMO insulators in which Kohn-Sham LDA band structures are metallic: VO<sub>2</sub>, V<sub>2</sub>O<sub>3</sub>, Ti<sub>2</sub>O<sub>3</sub>, LaTiO<sub>3</sub> and YTiO<sub>3</sub>. In the past, this failure of LDA has been explained in terms of its inadequacy to capture the strong interactions taking place between correlated electrons. In the spirit of the Hubbard model, possible corrections to improve onsite correlation are the LDA+U [2] and LDA+DMFT [3] approaches. Here we make use of the HSE06 hybrid functional [4]. We show that, without invoking strong-correlation effects, the contribution of the non-local Fock exchange is essential to correct the LDA results, by curing its delocalization error. In fact, HSE06 provides insulating band structures and correctly describes the MIT in all the considered compounds [5]. We further discuss the advantages and the limitations of the HSE06 hybrid functional in correlated TMO [1] M. Imada et al., Rev. Mod. Phys. 70, 1039 (1998) [2] V.I. Anisimov, et al., Phys. Rev. B 44, 943 (1991). [3] A. Georges et al., Rev. Mod. Phys. 68, 13 (1996). [4] J. Heyd et al., J. Chem. Phys. 118, 8207 (2003); J. Heyd et al., J. Chem. Phys. , 219906(E) (2006). [5] F. Iori, M. Gatti, and A. Rubio Phys. Rev. B , 115129 (2012)

### 1:39PM L54.00013 The electronic structure of the Mott insulator VO<sub>2</sub>: the strongly correlated metal state is screened by impurity band.

, HYUN-TAK KIM, MIT Center in ETRI — A Mott insulator VO<sub>2</sub> (3d<sup>1</sup>) has a direct gap ( $\Delta_{direct} \propto V_{direct}$ ) of 0.6 eV and an indirect gap of  $\Delta_{act} \propto V_{direct} \approx 0.15$  eV coming from impurity indirect band. At T<sub>c</sub>,  $\Delta_{direct} = \Delta_{act} = 0$  is satisfied and the insulator-to-metal transition (IMT) occurs. The metallic carriers near core region can be trapped when a critical onsite Coulomb U<sub>c</sub> exists. Then, a potential energy is defined as

$$V_g = (V_{direct} + U_c) + V_{indirect} \\ = -(2/3)E_F(1 + e(N_{tot}/n_{tot})(1 - \exp(-\Delta_{act}/k_B T))) + U_c, \quad (2)$$

where  $V_{direct} = -(2/3)E_F$  is the screened Coulomb pseudopotential at K = 0.  $\Delta\rho = N_{tot}/n_{tot} \approx 0.018\%$  [1] is defined as the critical doping quantity, where  $n_{tot}$  is the carrier density in the direct band and  $N_{tot}$  is the carrier density in the impurity band. In  $U_c < (2/3)E_F$  case, it sustains the insulator state. However, when both  $U_c > (2/3)E_F$  and  $\Delta_{act} = 0$  by excitation are satisfied, the IMT occurs in  $V_g \geq 0$ . This indicates that the excitation ( $\Delta_{act} = 0$ ) breaks the Coulomb equilibrium ( $V_g < 0$  and insulator sustaining  $U_c$ ) in Eq. (1); the Coulomb energy changes from  $U_c$  to a  $U < U_c$ . The IMT can be switched by the doping (excitation;  $\Delta_{act} = 0$ ) and the de-doping (de-excitation;  $\Delta_{act} = 0.15$  eV) of  $\Delta\rho = N_{tot}/n_{tot}$  to the conduction band, by applying external parameters such as heat, pressure, doping etc. The direct band gap (semiconductor gap) in the Mott insulator smaller than that of dielectric insulators can be explained by  $U_c$ . [1] NewJ.Phys.6(2004)52.

### 1:51PM L54.00014 Two-dimensional quantum percolation with binary non-zero hopping integrals

, BRIANNA DILLON THOMAS, HISAO NAKANISHI, Purdue Univ — In a previous work [Dillon and Nakanishi, Eur.Phys.J B 87, 286 (2014)], we calculated the transmission coefficient of the two-dimensional quantum percolation problem and mapped out in detail the three regimes of localization, i.e., exponentially localized, power-law localized, and delocalized which had been proposed earlier [Islam and Nakanishi, Phys.Rev. E 77, 061109 (2008)]. We now consider a variation on quantum percolation in which the hopping integral ( $V_{diluted}$ ) associated with bonds that connect to at least one diluted site is non-zero but a fraction of the hopping integral ( $V_{full}=1$ ) between non-diluted sites. We study the latter model by calculating quantities such as the transmission coefficient and the inverse participation ratio and find the original quantum percolation results to be stable over a wide range of energy. In particular, except in the immediate neighborhood of the band center (where increasing  $V_{diluted}$  to just  $0.02*V_{full}$  appears to eliminate localization effects), increasing  $V_{diluted}$  only shifts the boundaries between the 3 regimes but does not eliminate them until the  $V_{diluted}$  reaches 20

### 2:03PM L54.00015 Angle resolved photoemission study of the strongly correlated metal V<sub>2</sub>O<sub>3</sub><sup>1</sup>

, IRENE LO VECCHIO, Lawrence Berkeley National Laboratory, JONATHAN D. DENLINGER, OLEG KRUPIN, Advanced Light Source (Berkeley), BUMJOON KIM, Max Planck Institut for Solid State Research (Stuttgart), PATRICIA METCALF, Purdue University (Indiana), STEFANO LUPI, University of Rome "Sapienza" (Italy), JAMES W. ALLEN, University of Michigan, ALESSANDRA LANZARA, University of California Berkeley and LBNL — V<sub>2</sub>O<sub>3</sub> is often considered as the textbook example for the Mott metal-insulator transition. It has been the playground for multiple theoretical approaches and attempts to describe its metallic ground state for half a century. However, the experimental electronic structure is still unknown because of difficulties related to the three-dimensional character of the Fermi surface and the inhomogeneous cleavage of single crystals. Here we reveal for the first time the band structure of V<sub>2</sub>O<sub>3</sub> using angle resolved photoemission spectroscopy. Direct comparison with theory is presented highlighting the important role of electron correlation for the physics of this material.

<sup>1</sup>Experiments at the Advanced Light Source were supported by the U.S. DOE Basic Energy Sciences (DE-AC02-05CH11231)

Session L55 GQI: 20 Years of Quantum Error Correction Hilton Baltimore Holiday Ballroom 6 - Steve Flammia, University of Sydney

### 11:15AM L55.00001 Stability, topology, holography: The many facets of quantum error correction

, JOHN PRESKILL, Caltech — Quantum error correction is a surprising and far-reaching concept, with many implications for science and technology. The theory of quantum error-correcting codes has bolstered our confidence that quantum computing is scalable, deepened our understanding of topological phases of matter, and spawned novel insights into the quantum structure of spacetime.

### 11:51AM L55.00002 Fault Tolerance in Small Experiments

, DANIEL GOTTESMAN, Perimeter Inst for Theo Phys — Experiments are finally reaching the size and level of precise control where we can hope to see a truly fault-tolerant experiment within the next few years. I will give a proposal for a 5-qubit fault-tolerant experiment and discuss how to evaluate if an experiment has successfully demonstrated fault tolerance. I will also consider the possibility of using future fault-tolerant experiments to answer important questions about the interaction of fault-tolerant protocols with real experimental errors.

**12:27PM L55.00003 Quantum Error Correction and the Future of Solid State Quantum Computing<sup>1</sup>**, DAVID DIVINCENZO, Forschungszentrum Juelich and RWTH Aachen — Quantum error correction (QEC) theory has provided a very challenging but well defined goal for the further development of solid state qubit systems: achieve high enough fidelity so that fault-tolerant, error-corrected quantum computation in networks of these qubits becomes possible. I will begin by touching on some historical points: initial work on QEC is actually more than 20 years old, and the landmark work of Kitaev in 1996 which established 2D lattice structures as a suitable host for effective error correction, has its roots in theoretical work in many-body theory from Wegner in the 1970s. I will give some perspective on current developments in the implementation of small fragments of the surface code. The surface-code concept has driven a number of distinct requirements, beyond the reduction of error rates below the 1% range, that are actively considered as experiments are scaled beyond the 10-qubit level.

<sup>1</sup>Support of JARA FIT is acknowledged.

**1:03PM L55.00004 Quantum error correction with trapped ions**, PHILIPP SCHINDLER, University of Innsbruck — Quantum computers promise exponential speed-up compared to their classical counterparts for certain problems. Unfortunately, the states required for quantum computation are fragile and lose their quantum properties with growing system size. In a milestone work, it has been shown that quantum error correction can overcome this problem and enable arbitrary long and arbitrary high quality quantum algorithms. However, current experiments are not able to fulfill the requirements to employ useful quantum error correction procedures. In this talk, I will first review past proof-of-principle experiments in trapped ion quantum information processors. Building on that, I will sketch a way towards a medium-sized trapped ion system that will be capable of running an error correction procedure that outperforms its constituents.

**1:39PM L55.00005 Quantum error correction in superconducting circuits<sup>1</sup>**, MICHEL DEVORET, Yale University — Can we prolong the coherence of a two-state manifold in a complex quantum system beyond the coherence of its longest-lived component? This question is the starting point of the main challenges in the construction of a scalable quantum computer, namely the implementation of quantum error correction. The presentation will review the experimental progress that recently occurred in the field of superconducting quantum circuits towards the correction, for a full logical qubit memory, of the combinations of bit flip and phase flip errors.

## **M1.00001 POLYMER PHYSICS –**

**M1.00002 Morphology Evolution and Dynamic Viscoelastic Behavior of Ternary Elastomer Blends under Shear<sup>1</sup>**, XIA DONG, XIANGGUI LIU, CHARLES C HAN, DUJIN WANG, Beijing National Laboratory for Molecular Sciences, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry CAS — The influence of nanoparticle geometry, such as size and shape, on the phase morphology of partially miscible binary polymer blends under and after shear has been examined by rheological and rheo-optical techniques. The phase morphologies of the solution-polymerized styrene-butadiene rubber and low vinyl content polyisoprene (SSBR/LPI) blend systems were affected by the dispersion status of fillers which were determined by filler shapes and shear strength. Under weak shear flow, the domain morphology of the OMMT filled blend was much thinner than that of the SiO<sub>2</sub> filled blend. Under strong shear flow, the string-like phase interface of the OMMT filled blend was much blurred compared with that of the SiO<sub>2</sub> filled blend. After shear cessation, the orientation status of OMMT sheets determined the orientation of newborn domains. Combined morphology observation and rheological analysis showed that the anisotropic structure and the unfavorable bending energy of OMMT sheets played important roles on phase morphology and its evolution process during or after shear.

**M1.00003 Selective crystallization of regioregularity controlled polythiophene for enhancing mechanical stability and electronic performance**, HYEONG JUN KIM, KAIST, HOJEONG YU, POESTECH, JAE-HAN KIM, JIN-SUNG KIM, TAEK SOO KIM, KAIST, JOON HAK OH, POESTECH, BUMJOON KIM, KAIST — Considering the many potential applications of organic electronics in portable electronic devices, it is of great importance to develop an electro-active material that possesses mechanical stability and high electronic performance. Coexistence of both properties, however, is very difficult to achieve because good electronic performance is associated with long conjugation length, and high crystallinity often results in stiffness and brittleness. Herein, we utilize P3HT with two different regioregularities: high RR (98) P3HT has high electronic properties but poor mechanical resilience, and low RR P3HT (68) exhibits high elasticity and ductility but poor electronic performance. Selective crystallization of high RR P3HT induced by solution assembly allows construction of percolated networks of high RR P3HT nanowires (NWs) embedded in low RR P3HT matrix. Only 5 wt high RR P3HT is required to reach a hole mobility comparable to that of high RR P3HT, and high RR NWs embedded in film exhibits 20 times higher elongation at break. Selective self-assembly allows us to overcome the fragile nature of highly crystalline conjugated polymers without losing their electronic properties.

**M1.00004 Development of flash nanoprecipitation as a scalable platform for production of hybrid polymer-inorganic Janus particles<sup>1</sup>**, VICTORIA E. LEE, ROBERT K. PRUD'HOMME, RODNEY D. PRIESTLEY, Princeton University — Polymer Janus particles, containing two or more distinct domains, can act as supports for inorganic nanoparticles, stabilizing them against aggregation and templating anisotropic functionalization of the microparticles. This anisotropy can be advantageous for applications such as biofuel upgrading, bionanosensors, and responsive materials. Here, we introduce flash nanoprecipitation (FNP) as a scalable, fast process to create hybrid polymer-inorganic Janus particles with control of particle size and anisotropy. During FNP, polymer Janus particles form by rapid intermixing of a polymer solution with a poor solvent, inducing polymer precipitation and phase separation. Inorganic nanoparticles are then adsorbed selectively onto one domain of the polymer support by exploiting electrostatic interactions between the charged particles. By tuning polymer concentration and ratio in the feed stream, the particle size and anisotropy can be controlled. We further demonstrate that these hybrid particles can simultaneously stabilize emulsions and selectively catalyze the degradation of dye in one phase.

<sup>1</sup>With support from the Princeton Imaging Analysis Center

**M1.00005 Control of dynamical self-assembly of strongly Brownian nanoparticles through convective forces induced by ultrafast laser.** , SERIM ILDAY, GURSOY B. AKGUC, ONUR TOKEL, GHAITH MAKEY, OZGUN YAVUZ, KORAY YAVUZ, IHOR PAVLOV, F. OMER ILDAY, OGUZ GULSEREN, Bilkent Univ — We report a new dynamical self-assembly mechanism, where judicious use of convective and strong Brownian forces enables effective patterning of colloidal nanoparticles that are almost two orders of magnitude smaller than the laser beam. Optical trapping or tweezing effects are not involved, but the laser is used to create steep thermal gradients through multi-photon absorption, and thereby guide the colloids through convective forces. Convective forces can be thought as a positive feedback mechanism that helps to form and reinforce pattern, while Brownian motion act as a competing negative feedback mechanism to limit the growth of the pattern, as well as to increase the possibilities of bifurcation into different patterns, analogous to the competition observed in reaction-diffusion systems. By steering stochastic processes through these forces, we are able to gain control over the emergent pattern such as to form-deform-reform of a pattern, to change its shape and transport it spatially within seconds. This enables us to dynamically initiate and control large patterns comprised of hundreds of colloids. Further, by not relying on any specific chemical, optical or magnetic interaction, this new method is, in principle, completely independent of the material type being assembled.

**M1.00006 Amphiphilic Soft Janus Particles as Interfacial Stabilizers** , WENDA WANG, SUNNY NIU, CHRIS SOSA, ROBERT PRUD'HOMME, RODNEY PRIESTLEY, Princeton Univ, PRIESTLEY POLYMER GROUP TEAM, PRUD'HOMME RESEARCH GROUP TEAM — Janus particles, which incorporate two or more “faces” with different chemical functionality, have attracted great attention in scientific research. Amphiphilic Janus particles have two faces with distinctly different hydrophobicity. This can be thought of as colloidal surfactants. Theoretical studies on the stabilization of emulsions using Janus particles have confirmed higher efficiency. Herein we synthesize the narrow distributed amphiphilic polymeric Janus particles via Precipitation-Induced Self-Assembly (PISA). The efficiency of the amphiphilic Janus particles are tested on different oil/water systems. Biocompatible polymers can also be used on this strategy and may potentially have wide application for food emulsion, cosmetics and personal products.

**M1.00007 Time-resolved SANS studies on block copolymer micelles with varying core-solvent interactions** , TYLER COOKSEY, AVANTIKA SINGH, MARIA MARQUEZ, MEGAN ROBERTSON, University of Houston — The self-assembly of block copolymer micelles occurs through a relaxation process dominated by the exchange of individual polymer chains. The objective of this work is to probe the single chain exchange of block copolymer micelles with varying core-solvent interactions, utilizing time-resolved neutron scattering (TR-SANS). The interactions between the core-forming polymer and the solvent has many implications for the micelle structure, including the aggregation number, micelle size, and interfacial tension. However, few studies have investigated the effect of the core polymer-solvent interactions on the dynamics of micelle formation. We will focus our study on poly(epsilon-caprolactone-block-ethylene oxide) block copolymers forming micelle structures in mixtures of water and tetrahydrofuran (THF). It was observed that changing the THF concentration, which varies the degree of repulsion between the core and solvent, greatly influences the single chain exchange rate in this system.

**M1.00008 Spectroscopic Analysis of 10MAG/LDAO Reverse Micelles to Determine Characteristic Properties and Behavioral Extrema** .<sup>1</sup> , JOSHUA BERG<sup>2</sup>, CARA MAWSON<sup>3</sup>, ZACH NORRIS, NATHANIEL NUCCI, Rowan University — Reverse micelles are spontaneously organizing complexes of surfactant that encapsulate a nanoscale pool of water in a bulk non-polar solvent. Reverse micelle (RM) mixtures have a wide range of applications, including biophysical investigation of protein systems. A new RM mixture composed of decyl-1-mono glycerol (10MAG) and lauryldimethylammonium-N-oxide (LDAO) was recently described. This mixture has the potential to prove more widely applicable for use of RMs in applications that involve encapsulation of macromolecules, yet little is known about the phase behavior or size of reverse micelles created by this mixture. Data describing such behaviors for this mixture are presented here. We have used dynamic light scattering (DLS) and fluorescence spectroscopy to investigate the size and partitioning behavior of RMs in varying mixtures of 10MAG, LDAO, water, pentane, and hexanol. These data demonstrate that the 10MAG/LDAO RM mixture exhibits markedly different phase and RM size behavior than that of commonly used RM surfactant mixtures. The implications of these findings for use of the 10MAG/LDAO mix for RM applications will also be addressed.

**M1.00009 Photolithography and Fluorescence Correlation Spectroscopy used to examine the rates of exchange in reverse micelle systems** .<sup>1</sup> , ZACH NORRIS, CARA MAWSON, KYRON JOHNSON, SARAH KESSLER, ANNE REBECCA, NATHAN WOLF, MICHAEL LIM, NATHANIEL NUCCI, Rowan University — Reverse micelles are molecular complexes that encapsulate a nanoscale pool of water in a surfactant shell dissolved in non-polar solvent. These complexes have a wide range of applications, and in all cases, the degree to which reverse micelles (RM) exchange their contents is relevant for their use. Despite its importance, this aspect of RM behavior is poorly understood. Photolithography is employed here to create micro and nano scale fluidic systems in which mixing rates can be precisely measured using fluorescence correlation spectroscopy (FCS). Micro-channel patterns are etched using reactive ion etching process into a layer of silicon dioxide on crystalline silicon substrates. Solutions containing mixtures of reverse micelles, proteins, and fluorophores are placed into reservoirs in the patterns, while diffusion and exchange between RMs is monitored using a FCS system built from a modified confocal Raman spectrometer. Using this approach, the diffusion and exchange rates for RM systems are measured as a function of the components of the RM mixture.

**M1.00010 Self-assembly of mixed lipids into bicelles and vesicles: molecular dynamics simulations.** , HARI SHARMA, ZILU WANG, ELENA DORMIDONTOVA, Department of Physics and Institute of Materials Science, University of Connecticut, Storrs, CT — Formation of complex supramolecular nanostructures, such as micelles, bicelles, vesicles (liposomes) etc. via self-assembly of simple molecules has provided a new pathway for the design and development of effective drug carriers. Solid nanoparticles or functional biopolymers, such as RNA, DNA, peptides can be encapsulated into these carriers for controlled delivery or selective targeting. We performed coarse grained molecular dynamics simulation using the MARTINI force field to study the self-assembly of a binary surfactant mixture composed of long and short phospholipids, DPPC and DHPC, in the ratio 3:1. We found that at low temperature lipids self-assemble into a bicelle (nanodisc) with the longer lipid mainly forming the interior and short lipid the rim of the bicelle. At higher temperature the nanodisc transforms into a vesicle with homogeneously distributed lipids. The structural changes of these nanodiscs and vesicles imposed by gold nanoparticle encapsulation and pegylation will be addressed.

**M1.00011 Directed Assembly of Gold Nanoparticles via Polymer Single Crystals** , SHAN MEI, HAO QI, TIAN ZHOU, CHRISTOPHER LI, None, SOFT MATERIAL LAB TEAM — Gold nanoparticles (AuNPs) have attracted great attention due to their unique properties and potential applications. In recent years, more efforts have been made to the assembly of AuNP into various of ordered structures such as AuNP wires and sheets in order to transfer their properties from nanoscale to macroscale, as well as exploring new properties. In this work we report a method to assemble AuNP into well defined, free standing frame structure using poly(ethylene oxide) (PEO) lamellar single crystal as the template. By controlling the single crystal size and functioning pattern, we are able to tune the width and size of the AuNP frame. We consider this approach to be an efficient and precise way to assemble AuNP and this methodology could be applied to other metal or semiconductor NPs.

**M1.00012 Synthesis of Poly(N-isopropylacrylamide) Microcapsules for Drug Delivery Applications via UV Aerosol Photopolymerization.**<sup>1</sup>, NICOLE ROBERSON, DANIEL DENMARK, SARATH WITANACHCHI, University of South Florida — Hybrid drug delivery systems composed of thermoresponsive polymers and magnetic nanoparticles have been developed using chemical methods to deliver controlled amounts of a biotherapeutic to target tissue. These methods can be expensive, time intensive, and produce impure composites due to the use of surfactants during polymer synthesis. In this study, UV aerosol photopolymerization is used to synthesize N-isopropylacrylamide (NIPAM) monomers, N,N-methylenebisacrylamide (MBA) crosslinker, and irgacure 2959 photoinitiator into the transporting microcapsule for drug delivery. The method of UV aerosol photopolymerization allows for the continuous, cost effective, and time efficient synthesis of a high concentration of pure polymers in a short amount of time; toxic surfactants are not necessary. Optimal NIPAM monomer, MBA crosslinker, and irgacure 2959 photoinitiator concentrations were tested and analyzed to synthesize a microcapsule with optimal conditions for controlled drug delivery. Scanning Electron Microscope (SEM) imaging reveals that synthesis of polymer microcapsules of about 30 micrometers in size is effective through UV aerosol photopolymerization. Findings will contribute greatly to the field of emergency medicine.

**M1.00013 Tertiary phase diagram of cellulose, ionic liquid and organic solvent**, XIN ZHANG, DOUG HENDERSON, Department of Materials Science and Engineering, University of Maryland, MADHUSUDAN TYAGI, YIMIN MAO, NCNR, NIST, Gaithersburg, MD, ROBERT M. BRIBER, HOWARD WANG, Department of Materials Science and Engineering, University of Maryland — Cellulose is the most abundant natural polymer on earth, and widely used in products from clothing to paper. Fundamental understanding of molecular solutions of cellulose is the key to realize advanced technologies beyond cellulose fibers. It has been reported that certain ionic liquid/organic solvent mixtures dissolve cellulose. In this study, the tertiary phase diagram of microcrystalline cellulose, 1-Ethyl-3-methylimidazolium acetate (EMIMAc), and dimethylformamide (DMF) mixtures has been determined using optical cloud point method and small angle neutron scattering (SANS). Data indicate that a molar ratio of EMIMAc to cellulose repeating unit equal or greater than 3 is necessary but not sufficient in forming one-phase homogeneous solutions. A miscibility gap exists in the dilute regime, where a minimum of 5 mol% of EMIM Ac in DMF is needed to form homogenous solutions. SANS show that cellulose chains adopt Gaussian-like conformation in homogenous solutions. The solutions exhibit the characteristics of upper critical solution temperature. Clustering of cellulose chains occurs at low EMIMAc/DMF or EMIMAc/cellulose ratio, or at low temperatures. The mechanism of cellulose dissolution in tertiary mixture is discussed.

**M1.00014 Thin blend films of cellulose and polyacrylonitrile**, RUI LU, XIN ZHANG, Department of Materials Science and Engineering, University of Maryland, College Park, MD, YIMIN MAO, NCNR, NIST, Gaithersburg, MD, ROBERT BRIBER, HOWARD WANG, Department of Materials Science and Engineering, University of Maryland, College Park, MD — Cellulose is the most abundant renewable, biocompatible and biodegradable natural polymer. Cellulose exhibits excellent chemical and mechanical stability, which makes it useful for applications such as construction, filtration, bio-scaffolding and packaging. To further expand the potential applications of cellulose materials, their alloying with synthetic polymers has been investigated. In this study, thin films of cotton linter cellulose (CLC) and polyacrylonitrile (PAN) blends with various compositions spanning the entire range from neat CLC to neat PAN were spun cast on silicon wafers from common solutions in dimethyl sulfoxide / ionic liquid mixtures. The morphologies of thin films were characterized using optical microscopy, atomic force microscopy, scanning electron microscopy and X-ray reflectivity. Morphologies of as-cast films are highly sensitive to the film preparation conditions; they vary from featureless smooth films to self-organized ordered nano-patterns to hierarchical structures spanning over multiple length scales from nanometers to tens of microns. By selectively removing the PAN-rich phase, the structures of blend films were studied to gain insights in their very high stability in hot water, acid and salt solutions.

**M1.00015 Process Dependence of Cellulose Nanofiber Fabrication**, DOUG HENDERSON, XIN ZHANG, Department of Materials Science and Engineering, University of Maryland-College Park, MD, YIMIN MAO, NCNR, NIST, Gaithersburg, MD, SOO-HWAN JANG, LIANGBING HU, ROBERT BRIBER, HOWARD WANG, Department of Materials Science and Engineering, University of Maryland-College Park, MD — Cellulose nanofibers (CNF) are the most abundant natural nanomaterial on earth with potential applications in renewable energy, polymer nanocomposites and flexible electronics. CNF can be produced through TEMPO oxidation which separates the hierarchical structure of cellulose fibers into smaller micro- and nanofibers by altering their surface chemistry, inducing a repulsive electrostatic charge on the fibers. This work will examine the structural evolution of CNF during production. Samples were prepared by removing and quenching aliquots during the TEMPO reaction. The fibers were washed, filtered and re-dispersed into D2O for small angle neutron scattering (SANS) measurements. The SANS data was analyzed to track the changes in the CNF structure as a function of reaction time.

**M1.00016 Multi-scale Characterization of Cellulose TEMPO-Nanofiber Suspension**, YIMIN MAO, Dept. of Materials Sci. and Eng., Univ. of Maryland, College Park; NIST Center for Neutron Research, National Institute of Standards and Technology, KAI LIU, BENJAMIN HSIAO, Chemistry Department, Stony Brook University — Cellulose nanofiber (CNF) suspensions were characterized at multiple length scales. CNF suspension was prepared by applying 2,2,6,6-tetramethyl-1-piperidinyloxy (TEMPO) oxidation method to dry wood pulp. TEMPO method was able to produce fine fibers with a cross section dimension being in the order of magnitude of several nanometers, and length being several hundred nanometers. The surface was negatively charged. Charge density was characterized by Zeta-potential measurement. Both small-angle X-ray (SAXS) and small-angle neutron (SANS) methods were employed to examine fiber dimensions in solution. Data fitting indicated that newly-developed ribbon model was able to capture the essence of CNFs geometry, which is also computationally economic. The rectangular-shaped cross section was consistent to cellulose's crystal structure; and was able to provide insights into how cellulose crystals were biologically synthesized and packed in nature. Multi-angle dynamic light scattering (DLS) was used to study CNF's diffusion properties. A strong scattering-angle dependence of auto-correlation function was observed. The characterization is useful to understanding suspension quality of CNF, and can provide guideline for follow-up research aimed for a variety of applications.

**M1.00017 Controlling the structure and rheology of TEMPO-oxidized cellulose in zinc chloride aqueous suspensions for fabricating advanced nanopaper**, SHA WANG, XIN ZHANG, LIANGBING HU, ROBERT BRIBER, HOWARD WANG, Dept. Materials Science and Engineering, University of Maryland, College Park, LINXIN ZHONG, State Key Laboratory of Pulp and Paper Engineering, South China University of Technology — Due to its abundance, low-cost, biocompatibility and renewability, cellulose has become an attractive candidate as a functional material for various advanced applications. A key to novel applications is the control of the structure and rheology of suspensions of fibrous cellulose. Among many different approaches of preparing cellulose suspensions, zinc chloride addition to aqueous suspensions is regarded an effective practice. In this study, effects of ZnCl<sub>2</sub> concentration on TEMPO-oxidized cellulose (TOC) nanofiber suspensions have been investigated. Highly-transparent cellulose nanofiber suspension can be rapidly obtained by dissolving TOC in 65 wt.% zinc chloride aqueous solutions at room temperature, whereas a transparent zinc ion cross-linked TOC gel could be obtained with zinc chloride concentration as low as 10 wt. %. The structural and rheological characteristics of TOC/ZnCl<sub>2</sub> suspensions have been measured to correlate to the performance of transparent and flexible nanocellulose paper subsequently produced via vacuum filtration or wet-casting processes.

**M1.00018 All-or-none folding of a polymer in confinement<sup>1</sup>** , MARK TAYLOR, Hiram College — A flexible homopolymer chain with sufficiently short-range interactions undergoes a discontinuous transition from an expanded coil to a compact crystallite analogous to the all-or-none folding transition exhibited by fast-folding proteins. One anticipates that geometric confinement will reduce the entropy of the unfolded chain, thereby stabilizing the folded state and shifting the transition to higher temperature. In this work we study a flexible square-well N-mer chain (monomer diameter  $d$ ) located between two hard walls forming a slit-like pore (width  $W$ ) with the chain end-tethered to one wall. We carry out Monte simulations with Wang-Landau sampling to construct the single-chain density of states and use both microcanonical and canonical analyses to characterize phase transitions. When the slit width is similar to the size of the folded chain we observe a modest stabilization effect. Further reduction of the slit width geometrically prohibits the chain from folding into the free-chain ground state. However, a discontinuous all-or-none folding transition still occurs to a flattened crystallite that spans the pore. All-or-none folding persists even to the limit of a very narrow pore ( $W \rightarrow d$ ) where the ground-state structure is a quasi-two-dimensional crystal.

**M1.00019 Exploring the existence of two T<sub>g</sub>s in thin, supported polymer films<sup>1</sup>** , ERIC CHEN, ETHAN GLOR, GABRIEL ANGRAND, ZAHRA FAKHRAAI, Univ of Pennsylvania, FAKHRAAI GROUP TEAM — Ellipsometry has commonly been used to characterize the glass transition temperature ( $T_g$ ) and other properties of nanoscale thin films. In some ultra-thin films the glass transition broadens and even becomes two distinct transitions, as previously observed in free-standing polystyrene, thin films. However, for most polymers, the second, lower  $T_g$  is located below the condensation temperature of water, generating large errors in determining the lower  $T_g$ , which is associated with the layer close to the free interface. Here we designed a vacuum stage with a base pressure of  $<1E-4$  torr, equipped with a Linkam temperature stage with a temperature range of 153 K-873 K to study the properties of thin polymer films, supported on a substrate, in a broad temperature range and explore the existence of two  $T_g$ s in these systems. The stage was machined from aluminum and used infrasil quartz windows to allow the transmission of polarized light without distortion. The vacuum allows for accurate ellipsometry measurements of the properties of thin polymer films, such as expansion coefficient and  $T_g$ , at temperatures well below room temperature, without artifacts due to water condensation.

**M1.00020 Limits of single-molecule super-resolution microscopy in thin polymer films** , MUZHOU WANG, MARCELO DAVANCO, JAMES M. MARR, J. ALEXANDER LIDDLE, JEFFREY W. GILMAN, National Institute of Standards and Technology — Structural characterization by super-resolution microscopy has become increasingly widespread, particularly in the biological community. The technique is powerful because it can produce real-space images with resolutions of tens of nanometers, while sample preparation is relatively non-invasive. Previous studies have applied these techniques to important scientific problems in the life sciences, but relatively little work has explored the attainable limit of resolution using samples of known structure. In this work, we apply photo-activated localization microscopy (PALM) to polymer films that have been nanopatterned using electron-beam lithography. Trace amounts of a rhodamine spiroamide dye are dispersed into nanostructured poly(methyl methacrylate), and UV-induced switching of the fluorophores enables nanoscale localization of single molecules to generate a final composite super-resolution image. Features as small as 50 nm are clearly resolvable. To determine the ultimate resolution limit, we investigate sources of error in the system, particularly from systematic mislocalizations due to the effect of fluorophore orientation on the single-molecule point-spread function.

**M1.00021 Phase separated microstructure and dynamics of polyurethane elastomers under strain** , CIPRIAN IACOB, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802 USA, AJAY PADALGIKAR, Implantable Electronic Systems Division, St. Jude Medical, Rogers, MN, USA, JAMES RUNT, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802 USA — The molecular mobility of polyurethane elastomers is of the utmost importance in establishing physical properties for uses ranging from automotive tires and shoe soles to more sophisticated aerospace and biomedical applications. In many of these applications, chain dynamics as well as mechanical properties under external stresses/strains are critical for determining ultimate performance. In order to develop a more complete understanding of their mechanical response, we explored the effect of uniaxial strain on the phase separated microstructure and molecular dynamics of the elastomers. We utilize X-ray scattering to investigate soft segment and hard domain orientation, and broadband dielectric spectroscopy for interrogation of the dynamics. Uniaxial deformation is found to significantly perturb the phase-separated microstructure and chain orientation, and results in a considerable slowing down of the dynamics of the elastomers. Attenuated total reflectance Fourier transform infrared spectroscopy measurements of the polyurethanes under uniaxial deformation are also employed and the results are quantitatively correlated with mechanical tensile tests and the degree of phase separation from small-angle X-ray scattering measurements.

**M1.00022 Phase behavior of the thermoresponsive polymer Poly(N-isopropyl acrylamide) at variable pressure** , ALFONS SCHULTE, Department of Physics and College of Optics and Photonics, University of Central Florida, Orlando, FL 32817-2385, KORA-LEE CLAUDE, SIMON PINZEK, PETER MLLER-BUSCHBAUM, CHRISTINE PAPADAKIS, TU Munchen, Physik-Department, LS Funktionelle Materialien, James-Frank-Str. 1, 85748 Garching — Stimuli-responsive such as Poly(N-isopropyl acrylamide) (PNIPAM) exhibit lower critical solution temperature (LCST) behaviour. At ambient pressure it is associated with the release of water and coil to globule transition of the polymer chains, leading to phase separation. Using turbidimetry we measure the P-T phase diagram over an extended range of pressure (0.1–400 MPa) and temperature (-10–40 °C). The phase boundary shows an elliptic profile, i.e. the cloud point temperature first increases and then decreases with pressure. This is reflected in the change in Gibbs free energy, isothermal compressibility, and isobaric heat capacity. The role of solvent-solvent interaction and addition of co-solvents is discussed.

**M1.00023 Complex Cure Kinetics of the Hydroxyl-Epoxy Reaction in DGEBA Epoxy Hardened with Diethanolamine** , WINDY ANCIPIK, JOHN MCCOY, New Mexico Institute of Mining and Technology, JAMIE KROPKA, MATHIAS CELINA, Sandia National Laboratories — The curing of a diglycidyl ether of bisphenol-A Epoxy (Epon 828) with diethanolamine (DEA) involves a fast amine-epoxide reaction followed by a slower hydroxyl-epoxide reaction. At curing temperatures below 100°C, the time scales of these two reactions are well separated, and the hydroxyl addition can be studied as an "isolated" reaction. The hydroxyl-epoxide reaction is of great interest due to the complex kinetics involved, which are brought about by competing reactions. The reaction kinetics are believed to be tertiary amine catalyzed and are well fit to a modified form of the Kamal-type equation. Here we study the complex long term reaction kinetics at various temperatures, by using isothermal modulated differential scanning calorimetry, micro calorimetry, and infrared spectroscopy. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**M1.00024 Relaxation Characteristics of 828 DGEBA Epoxy Over Long Time Periods** , JASMINE HOO, RILEY C. REPROGLE, BRIAN WISLER, GABRIEL K. ARECHEDERRA, JOHN D. MCCOY, New Mexico Institute of Mining and Technology, JAMIE M. KROPKA, KEVIN N. LONG, Sandia National Laboratories — The mechanical relaxation response in uniaxial compression of a diglycidyl ether of bisphenol-A epoxy was studied over long time periods. The epoxy, 828DEA, was Epon 828 cured with diethanolamine (DEA). A sample was compressed at constant strain rate and held at various strain levels for days to allow the sample to relax. The sample was then compressed further and held once more. The relaxation curves were fit with a stretched exponential function. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**M1.00025 Effect of Structure on Charge Mobility in Partially Ordered Polymeric Systems**, WAYLON LUO, KIRAN KHANAL, JUTTA LUETTNER-STRATHMANN, University of Akron — The performance of thin film organic semiconductor devices depends on the mobility of the charge carriers, which is strongly affected by the structure of the material. Accounting for these effects in device simulations is difficult since the size of the active layer is too large to generate realistic morphologies from molecular simulations of the constituents. In this work, we present Monte Carlo simulations of a coarse-grained lattice model for dense polymeric systems with a semiflexible component that undergoes a transition to (partially) ordered states at low temperatures. To investigate charge transport, the lattice polymer configurations become part of a model device, which consists of a layer of the material between two electrodes at different potentials. We determine the mobility from Monte Carlo simulations of charge carriers. To model the effect of polymer chain connectivity on charge transport we include an energetic barrier to hopping between sites on different chains; energetic disorder is taken into account by averaging over many polymer configurations. We find that ordering in the material leads to strong mobility anisotropies with increased mobility for transport parallel to the ordered domains and reduced mobility for perpendicular transport.

**M1.00026 Improved electrospinning processing of PU/PEDOT:PSS for electronic textile applications**<sup>1</sup>, ERIN EVKE<sup>2</sup>, Materials Engineering, AARON CLIPPINGER<sup>3</sup>, Biomedical Engineering, CLAYSON SPACKMAN, JOHN-SAMUEL, Mechanical, Aerospace and Nuclear Engineering, RAHMI OZISIK, Materials Engineering; Rensselaer Polytechnic Institute — Poly(3,4-ethylenedioxythiophene)/poly(4-styrenesulfonate), PEDOT:PSS, is an electrically conductive polymer used in electronic textile (e-textile) applications, such as electrochromic textiles, strain sensors, and resistive heaters. In the current study, PEDOT:PSS is blended with varying concentrations of polyurethane (PU) to investigate the flexibility of PU/PEDOT:PSS fibers that are produced via a modified electrospinning process where the jet is collected close to the tip of the needle, thereby, enabling the collection of straight fibers by a rotating spool. The electrical conductivity and mechanical properties of PU/PEDOT:PSS fibers are characterized to understand the effect of PU concentration and the processing parameters.

**M1.00027 Monte-Carlo simulations of a coarse-grained model for  $\alpha$ -oligothiophenes**, AMANI AL-MUTAIRI, JUTTA LUETTNER-STRATHMANN, Department of Physics, University of Akron — The interfacial layer of an organic semiconductor in contact with a metal electrode has important effects on the performance of thin-film devices. However, the structure of this layer is not easy to model. Oligothiophenes are small,  $\pi$ -conjugated molecules with applications in organic electronics that also serve as small-molecule models for polythiophenes.  $\alpha$ -hexithiophene (6T) is a six-ring molecule, whose adsorption on noble metal surfaces has been studied extensively (see, e.g., Ref. [1]). In this work, we develop a coarse-grained model for  $\alpha$ -oligothiophenes. We describe the molecules as linear chains of bonded, discotic particles with Gay-Berne potential interactions between non-bonded ellipsoids. We perform Monte Carlo simulations to study the structure of isolated and adsorbed molecules. [1] M. Kiel et al. Phys. Rev. B 75, 195439 (2007).

**M1.00028 Conductance Thin Film Model of Flexible Organic Thin Film Device using COMSOL Multiphysics**, CAROLYN CARRADERO-SANTIAGO, JOSEE VEDRINE-PAULUS, University of Puerto Rico at Humacao — We developed a virtual model to analyze the electrical conductivity of multilayered thin films placed above a graphene conducting and flexible polyethylene terephthalate (PET) substrate. The organic layers of poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) as a hole conducting layer, poly(3-hexylthiophene-2,5-diyl) (P3HT), as a p-type, phenyl-C61-butyric acid methyl ester (PCBM) and as n-type, with aluminum as a top conductor. COMSOL Multiphysics was the software we used to develop the virtual model to analyze potential variations and conductivity through the thin-film layers. COMSOL Multiphysics software allows simulation and modeling of physical phenomena represented by differential equations such as heat transfer, fluid flow, electromagnetism, and structural mechanics. In this work, using the AC/DC, electric currents module we defined the geometry of the model and properties for each of the six layers: PET/graphene/PEDOT:PSS/P3HT/PCBM/aluminum. We analyzed the model with varying thicknesses of graphene and active layers (P3HT/PCBM). This simulation allowed us to analyze the electrical conductivity, and visualize the model with varying voltage potential, or bias across the plates, useful for applications in solar cell devices.

**M1.00029 Photopatterned surface relief gratings in azobenzene-amorphous polycarbonate thin films**<sup>1</sup>, MORTEN VOLLMANN, Technical University Berlin, PETER GETEK, University of Applied Sciences Berlin, KELLIE OLEAR, CODY COMBS, BENJAMIN CAMPOS, EDMUND WITKOWSKI, The College of New Jersey, ERIN CAIN, Temple University, DAVID MCGEE, The College of New Jersey — Photoinduced orientation of azobenzene chromophores in polymeric host materials has been broadly explored for optical processing applications. Illumination of the chromophore with polarized light rotates the trans isomer perpendicular to the polarization, resulting in spatially modulated birefringence. The photoinduced anisotropy may also drive mass transport, with surface relief patterns being observed in a wide variety of systems. Here we report photoinduced birefringence in a guest-host system of Disperse Red 1- amorphous polycarbonate (DR1-APC). Birefringence was induced with a 490 nm laser and probed at 633 nm, with typical values of  $\Delta n = 0.01$  in 2 micron thick films. Illumination of DR1-APC with intensity and/or polarization gratings also resulted in sinusoidal surface relief patterns with periodicity 1- 3 micron as controlled by the interbeam crossing angle of the 490 nm writing beams; the surface modulation was  $\pm 20$  nm as measured by atomic force microscopy. Photopatterned DR1-APC is advantageous for applications given the ease of thin-film fabrication and the high glass transition temperature of APC, resulting in robust optically-induced surface gratings.

**M1.00030 Morphology of conjugated polymer/insulating polymer blends from inkjet printing and its correlation to the function of field-effect transistors**, HUIPENG CHEN, GUOCHEN ZHENG, LIQIN HU, HUIHUANG YANG, TAILIANG GUO, Fuzhou University — Printed electronics is a rapidly developing field of research which covers any electronic devices or circuits that can be processed using direct printing techniques. Among those printing techniques, inkjet printing is a technique of increasing interest for organic field-effect transistors (FETs) due to its fully data driven and direct patterning. In this work, the morphology of conjugated polymer/insulating polymer blends from inkjet printing and their FET properties has been investigated. The crystallinity and packing of conjugated polymer has been examined by synchrotron x-ray diffraction. The detailed information about the interface and domains of polymer blends were investigated by small angle neutron scattering. It is found that the domains and polymer interface were crucial to the FET properties. Finally, the relationship between morphology and function has been established for polymer blends FET from inkjet printing.

**M1.00031 Solvent-vapor concentration imparts selectivity on the propagation front during polymorphic transformation in molecular-semiconductor thin films**, GEOFFREY PURDUM, Dept. of Chemical and Biological Engineering, Princeton University, THOMAS GESSNER, R. THOMAS WEITZ, BASF SE, GMV 67056, Germany, YUEH-LIN LOO, Dept. of Chemical and Biological Engineering, Princeton University — Post-deposition processing allows precise control over the structural development of molecular-semiconductor thin films. In particular, solvent-vapor annealing converts thin films of a core-chlorinated naphthalene diimide from its triclinic polymorph to its monoclinic polymorph. By tuning the concentration of solvent vapor, we can simultaneously impact the morphology of the resulting monoclinic thin film. At low solvent-vapor concentrations, transformation in-plane is isotropic; we observe comparable transformation rates along the b- and c-axes, resulting in plate-like domains. At high solvent-vapor concentrations, transformation along the c-axis is instead favored, resulting in the formation of needle-like domains. Extended solvent-vapor annealing at these conditions can lead to isolated needles in the active channels of field-effect transistors; these devices exhibit electron mobilities exceeding  $1 \text{ cm}^2/\text{Vs}$ .

**M1.00032 Charge conduction in partially fluorinated discotic liquid crystals**, MITCHELL POWERS, ZHE LI, ROBERT TWIEG, BRETT ELLMAN, Kent State University — Motivated by the role of electrostatic interactions on stacking of partially fluorinated conjugated compounds, we present mobility measurements of, e.g., 1,4-difluoro-2,3,6,7,10,11-hexakis(pentaoxytriphenylene) (2F-HAT5) in discotic mesophases across a wide range of temperature and applied electric field. Charge conduction in this case is well described by a disorder driven hopping model. 2F-HAT5 exhibits a mobility of approximately  $2 \times 10^{-3} \text{ cm}^2/\text{Vs}$ , similar to the parent triphenylene, and has a weak temperature dependence throughout its discotic mesophase, which extends below room temperature. We compare results on this and related compounds to various theoretical models.

**M1.00033 Gated Seebeck Using Polymerized Ionic Liquid Gate Dielectrics**, ELAYNE THOMAS, BHOOSHAN POPPER, HAIYU FANG, MICHAEL CHABINYC, RACHEL SEGALMAN, Univ of California - Santa Barbara — Thermoelectric materials have the ability to convert a temperature gradient into usable electrical power via the Seebeck effect. This phenomenon is directly related to the material's Seebeck coefficient and electrical conductivity, which are in turn linked to its electron (or hole) mobility and carrier concentration. Organic semiconductors show promise for thermoelectric applications due to their flexibility and low-temperature manufacturing techniques; however, the role of ionized dopants on charge transport in these materials remains poorly understood. In this work, we use polymerized ionic liquids (PILs) as a gate dielectric in organic field-effect transistors to directly control the concentration of charges in the conducting channel. We report a method to tune the carrier concentration in the transistor channel via electrostatic gate modulation. We observe carrier concentration levels that are comparable to traditional doping methods with the added ability to precisely tune the concentration of charges induced. With this process, we aim to gather new information on the effect of ions on the performance of organic semiconductors in hopes of better understanding charge transport in conducting polymers on a molecular level.

**M1.00034 Electrospun Composite Nanofibers of Semiconductive Polymers for Coaxial PN Junctions**, WILLIAM SERRANO, SYLVIA THOMAS, University of South Florida at Tampa — The objective of this research is to investigate the conditions under P3HT and Activink, semiconducting polymers, form 1 dimension (1D) coaxial p-n junctions and to characterize their behavior in the presence of UV radiation and organic gases. For the first time, fabrication and characterization of semiconductor polymeric single fiber coaxial arrangements will be studied. Electrospinning, a low cost, fast and reliable method, with a coaxial syringe arrangement will be used to fabricate these fibers. With the formation of fiber coaxial arrangements, there will be investigations of dimensionality crossovers e.g., from one-dimensional (1D) to two-dimensional (2D). Coaxial core/shell fibers have been realized as seen in a recent publication on an electrospun nanofiber p-n heterojunction of oxides ( $\text{BiFeO}_3$  and  $\text{TiO}_2$ , respectively) using the electrospinning technique with hydrothermal method. In regards to organic semiconducting coaxial p-n junction nanofibers, no reported studies have been conducted, making this study fundamental and essential for organic semiconducting nano devices for flexible electronics and multi-dimensional integrated circuits.

**M1.00035 A novel Graphene Oxide film: Synthesis and Dielectric properties**, BETUL CANIMKURBEY, SAIT EREN SAN, Gebze Technical University, MUHAMMAD YASIN, National University of Science and Technology, MUHAMMET ERKAN KSE, Gebze Technical University — In this work, we used Hummers method to synthesize Graphene Oxide (GO) and its parallel plate impedance spectroscopic technique to investigate dielectric properties. Graphene Oxide films were coated using drop casting method on ITO substrate. To analyze film morphology, atomic force microscopy was used. Dielectrics measurements of the samples were performed using impedance analyzer (HP-4194) in frequency range (100 Hz to 10MHz) at different temperatures. It was observed that the films' AC conductivity  $\sigma_{ac}$  varied with angular frequency,  $\omega$  as  $\omega^S$ , with  $S < 1$ . The electrical properties of GO showed changes depending on both frequency and temperature. We observed GO film contains direct current (DC) and Correlated Barrier Hopping (CBH) conductivity mechanisms at low and high frequency ranges, respectively. Using solution processed Graphene Oxide will provide potential for organic electronic applications through its photon absorption and transmittance capability in the visible range and excellent electrical parameters.

**M1.00036 Synthesis and Characterization of Plant based Polythiophene Copolymers for Light Harvesting Applications**<sup>1</sup>, UDARI KODITHUWAKKU, PRASHANTHA MALAVI ARACHCHI, DILRU RATNAWEERA, University of Sri Jayewardenepura, Sri Lanka — Polythiophenes became more attractive in diverse applications due to some of their inherent properties including thermal and environmental stability as well as optical and electronic conductive properties. Commonly thiophene monomers are obtained from byproducts of crude oils. The current study discuss for the first time the synthesis and characterization of light harvesting polythiophenes copolymers from thiophene derivatives extracted from *Tagetes* species. There were mainly two thiophenes derivatives, 5-(3-buten-1-ynyl)-2, 2-bithienyl and 2, 2', 5, 2'-terthienyl (terthiophene), in the roots of the plant. Chemical oxidative radical polymerization was followed during the synthesis of copolymers with various block compositions of plant based terthiophenes and 3-hexyl terthiophenes. Structural characterization of the synthetic products was done using FTIR, NMR, Uv-vis, XRD and DSC techniques. Polythiophene homopolymers obtained from plant based terthiophenes have limited processability of solar cells due to poor solubility in common organic solvents. A significant solubility improvement was observed with copolymers having minor contributions of 3-hexylthiophenes.

**M1.00037 Synthesis and Photoelectrochemistry Characterization of Polymer based on 4,7-Di(thiophen-2-yl)-benzo[c][1,2,5]thiadiazole, (DTBT).** , LUZ MARIA LAZO JIMENEZ<sup>1</sup>, Instituto de Ciencias Nucleares, UNAM., BERNARDO ANTONIO FRONTANA-URIBE<sup>2</sup>, Centro Conjunto de Investigación en Química Sustentable, CCIQS-UNAM-UAEM. — Poly[4,7-di-(thiophen-2-yl)-benzo[c]-[1,2,5] thiadiazole], P(DTBT), is used in polymer:PCMB blends as active layer on organic photovoltaic devices, (OPV); DTBT-based copolymers show well-reversible oxidation and reduction electrochemical processes. These processes indicate their high electrochemical stability suitable for n- and p-doping. This is a typical feature benzothiadiazole containing molecules. In the present study the synthesis conditions of the monomer, 4,7-di-(thiophen-2-yl)-benzo[c]-[1,2,5]-thiadiazole based on Stille coupling reactions has been investigated and its respectively polymer P(DTBT) was prepared by repetitive potential-sweep anodic oxidation of the corresponding monomer DTBT onto Pt disk or indium tin oxide (ITO) electrodes. Electrochemical cyclic voltammetry (CV) was performed to determine the HOMO and the LUMO energy levels of the conjugated DTBT and P(DTBT), both exhibit amphoteric redox properties, n- and p- doping process. The optical gap estimated from electrochemical measurements of the polymer P(DTBT) was found to be 1.77 eV, which is close to the reported band gap (1.1-1.2eV) determined by optical absorption technique . Photoelectrochemical characterization of P(DTBT) was realized from UV-Vis-NIR spectra recorded at different applied potentials. These result are correlated with the charge-transfer phenomena in the polymers applied as active layer on OPV's.

**M1.00038 Electrospinning Nanofiber Based Organic Solar Cell**<sup>1</sup> , ZHENHUA YANG, YING LIU, STONY BROOK UNIVERSITY, MARIA MOFFA, CNR-Istituto Nanoscienze, CHANG-YONG NAM, Brookhaven National lab, DARIO PISIGNANO, CNR-Istituto Nanoscienze, MIRIAM RAFAILOVICH, STONY BROOK UNIVERSITY — Bulk heterojunction (BHJ) polymer solar cells are an area of intense interest due to their potential to result in printable, inexpensive solar cells which can be processed onto flexible substrates. The active layer is typically spin coated from the solution of polythiophene derivatives (donor) and fullerenes (acceptor) and interconnected domains are formed because of phase separation. However, the power conversion efficiency (PCE) of BHJ solar cell is restricted by the presence of unfavorable morphological features, including dead ends or isolated domains. Here we MEH-PPV:PVP:PCBM electrospun nanofiber into BHJ solar cell for the active layer morphology optimization. Larger interfacial area between donor and acceptor is obtained with electrospinning method and the high aspect ratio of the MEH-PPV:PVP:PCBM nanofibers allow them to easily form a continuous pathway. The surface morphology is investigated with atomic force microscopy (AFM) and scanning electron microscopy (SEM). Electrospun nanofibers are discussed as a favorable structure for application in bulk-heterojunction organic solar cells.

<sup>1</sup>Electrospinning Nanofiber Based Bulk Heterojunction Organic Solar Cell

**M1.00039 Asymmetric Zinc Phthalocyanines as Dye-Sensitized Solar Cells.** , GULENAY TUNC, YUNUS YAVUZ, AYSEGUL GUREK, BETUL CANIMKURBEY, ARIF KOSEMIN, SAIT EREN SAN, VEFA AHSEN, Gebze Technical University — Dye-sensitized solar cells (DSSCs) have received increasing attention due to their high incident to photon efficiency, easy fabrication and low production cost . Tremendous research efforts have been devoted to the development of new and efficient sensitizers suitable for practical use. In TiO<sub>2</sub>-based DSSCs, efficiencies of up to 11.4% under simulated sunlight have been obtained with ruthenium polypyridyl complexes. However, the main drawback of ruthenium complexes is the lack of absorption in the red region of the visible light and the high cost. For this reason, dyes with large and stable p-conjugated systems such as porphyrins and phthalocyanines are important classes of potential sensitizers for highly efficient DSSCs. Phthalocyanines (Pcs) have been widely used as sensitizers because of their improved light-harvesting properties in the far red- and near-IR spectral regions and their extraordinary robustness [1]. In this work, a series of asymmetric Zn(II) Pcs bearing a carboxylic acid group and six hexylthia groups either at the peripheral or non-peripheral positions have been designed and synthesized to investigate the influence of the COOH group and the positions of hexylthia groups on the dye-sensitized solar cell (DSSC) performance.

**M1.00040 Highly conductive polymer electrolyte membranes modified with polyethylene glycol-bis-carbamate**<sup>1</sup> , GUOPENG FU, Univ of Akron, JANEL DEMPSEY, John Carroll University, THEIN KYU, Univ of Akron — By virtue of its non-flammability and chemical stability, polyethylene glycol (PEG) networks have shown potential application in all solid-state polymer electrolyte membranes (PEM). However, room temperature ionic conductivity of these PEG based PEMs is inherently low. Plasticization of these PEMs is needed to improve the ionic conductivity. It was demonstrated by this group that small-molecule plasticizers such as succinonitrile, ethylene carbonate, or urea-carbamate can boost ionic conductivity of solid-state polymer electrolyte membranes. Polyethylene glycol bis-carbamate (PEGBC) was synthesized via condensation reaction of polyethylene glycol diamine and ethylene carbonate. The PEGBC modified PEM has shown higher ionic conductivity relative to the unmodified PEM. Moreover, PEGBC modified PEM has a better thermal stability relative to ethylene carbonate based liquid electrolyte with enhanced ionic conductivity.

**M1.00041 Neutron Vibrational Spectroscopy and modeling of polymer/dopant interactions** , ADAM MOULE, THOMAS HARRELSON, University of California, Davis, YONGQIANG CHENG, ANIBAL RAMIREZ-CUESTA, Oak Ridge National Lab, ROLAND FALLER, University of California, Davis, DAVID HUANG, University of Adelaide, Australia — Neutron vibrational spectroscopy (VISION and ORNL) is a powerful technique to determine the configurations of organic species in amorphous samples. We apply this technique to samples of the semiconducting polymer regio-regular P3HT to determine the molecular configurations outside of the crystalline domains, which have never been investigated. Application of density functional theory modeling using crystal field theory and for the single molecule approach yield a variety of configurations of the polymer backbone and side chains. These results demonstrate that only 1% of the volume corresponds to the assumed crystal structure solved using x-ray diffraction. In addition we investigate the configurations of P3HT doped with the molecular dopant F4TCNQ and determine that the charging of the polymer backbone leads to increased side chain stiffness. These results have significant implications for design of organic electronic devices based on thiophenes.

**M1.00042 Single- and Multilayered Nanostructures via Laser-Induced Block Copolymer Self-Assembly**<sup>1</sup> , PAWEŁ MAJEWSKI, KEVIN YAGER, ATIKUR RAHMAN, CHARLES BLACK, Brookhaven Natl Lab — We present a novel method of accelerated self-assembly of block copolymer thin films utilizing laser light, called Laser Zone Annealing (LZA). In our approach, steep temperature transients are induced in block copolymer films by rastering narrowly focused laser line over the light-absorbing substrate. Extremely steep temperature gradients accelerate the process of self-assembly by several orders-of-magnitude compared to conventional oven annealing, and, when coupled to photo-thermal shearing, lead to global alignment of block copolymer domains assessed by GISXAS diffraction studies and real-space SEM imaging. We demonstrate monolithic alignment of various block-copolymer thin films including PS-b-PMMA, PS-b-PEO, PS-b-P2VP, PS-b-PI and observe different responsiveness to the shearing rate depending on the characteristic relaxation timescale of the particular material. Subsequently, we use the aligned polymeric films as templates for synthesis of single- and multi-layered arrays of inorganic, metallic or semiconducting nanowires and nanomeshes and investigate their anisotropic electro-optical properties.

<sup>1</sup>Research carried out in part at the Center for Functional Nanomaterials, Brookhaven National Laboratory, which is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

**M1.00043 Temperature dependent structural, elastic, and polar properties of ferroelectric polyvinylidene fluoride (PVDF) and trifluoroethylene (TrFE) copolymers**, FU-CHANG SUN, AVINASH DON-GARE, ALEXANDRU ASANDEI, University of Connecticut, PAMIR ALPAY, University of Connecticut, SERGE NAKHMANSON, University of Connecticut, UNIVERSITY OF CONNECTICUT TEAM — We use molecular dynamics to calculate the structural, elastic, and polar properties of crystalline ferroelectric  $\beta$ -poly(vinylidene fluoride), PVDF ( $-\text{CH}_2\text{-CF}_2-$ )<sub>n</sub> with randomized trifluoroethylene TrFE ( $-\text{CHF-CF}_2-$ )<sub>n</sub> as a function of TrFE content (0-50%) in the temperature range of 0-400 K. There is a very good agreement between the experimentally obtained and the computed values of the lattice parameters, thermal expansion coefficients, elastic constants, polarization, and pyroelectric coefficients. A continuous decrease in Young's modulus with increasing TrFE content was observed and attributed to the increased intramolecular and intermolecular repulsive interactions between fluorine atoms. The computed polarization displayed a similar trend, with the room temperature spontaneous polarization decreasing by 44% from 13.8  $\mu\text{C}/\text{cm}^2$  (pure PVDF) to 7.7  $\mu\text{C}/\text{cm}^2$  [50/50 poly(VDF-co-TrFE)]. Our results show that molecular dynamics can be used as a practical tool to predict the mechanical and polarization-related behavior of ferroelectric poly(VDF-co-TrFE). Such an atomistic model can thus serve as a guide for practical applications of this important multifunctional polymer.

**M1.00044 Understanding Nonlinear Dielectric Properties in a Biaxially Oriented Poly(vinylidene fluoride) Film at Both Low and High Electric Fields<sup>1</sup>**, YUE LI, College of Polymer Science and Engineering, Sichuan University, LEI ZHU, Department of Macromolecular Science and Engineering, Case Western Reserve University, CASE WESTERN RESERVE UNIVERSITY TEAM, SICHUAN UNIVERSITY TEAM — Understanding nonlinear dielectric behavior in polar polymers is crucial to their potential application as next generation high energy density and low loss dielectrics. In this work, we studied nonlinear dielectric properties of a biaxially oriented poly(vinylidene fluoride) (BOPVDF) film under both low and high electric fields. It was observed that the low-field dielectric nonlinearity for the BOPVDF disappeared above 10 Hz at room temperature, suggesting that the low-field dielectric nonlinearity originated from ionic migration of impurity ions rather than dipolar relaxation of the amorphous segments. Above the coercive field (EC  $\sim 70$  MV/m), bipolar electric displacement-electric field (D-E) loop tests were used to extract the nonlinear behavior for pure PVDF crystals, which had a clear origin of ferroelectric switching of polar crystalline dipoles and domains and nonpolar-to-polar ( $\alpha \rightarrow \delta \rightarrow \beta$ ) phase transformations. Using HVBDS, it was observed that the ferroelectric switching of polar crystalline dipoles and domains in BOPVDF above the EC always took place between 20 and 500 Hz, regardless of a broad range of temperature from -30 to 100 C. This behavior was drastically different from the amorphous PVDF dipoles, which had a strong dependence on frequency over orders of magnitude.

**M1.00045 Correlating Thin-Film Radical Density with Charge Transport in Open-Shell Conducting Macromolecules**, MARTHA HAY, ELIZABETH JERGENS, BRYAN BOUDOURIS, Purdue University — Within the class of radical polymers, stable open-shell species serve as the medium for charge transport by undergoing oxidation-reduction (redox) reactions. The kinetics of these reactions are rapid enough that they are not considered rate-limiting in the electronic interactions of these materials. Rather, the proximity of these radical sites is paramount as a synthetic handle. Unfortunately, controlling the density of radicals has proven challenging in radical polymer systems. Often radical functionality is imparted to a polymer, rather than polymerizing a radical-containing monomer unit. This can prove troublesome as longer reaction times, in the interest of higher radical functionality, can lead to the elimination of radicals. Thus, the consequential altering of the radical electronic interactions is not well understood. We have synthesized a series of polynorbornene-based radical monomers at controlled radical loadings such that the radical density was preserved from monomer to polymer synthesis. As such, we attribute any change in the macroscopic transport properties to a change in the spacing between radical sites. These results elucidate the role of radical site distribution on the electronic performance of nitroxide-based radical polymers.

**M1.00046 Polyvinylidene fluoride molecules in nanofibers, imaged at atomic scale by aberration corrected electron microscopy<sup>1</sup>**, DARRELL RENEKER, JOSEPH GORSE, DINESH LOLLA, The University of Akron, CHRISTIAN KISIELOWSKI, Lawrence Berkeley National Laboratory, JIAYUAN MIAO, PHILIP TAYLOR, Case Western Reserve University, GEORGE CHASE, The University of Akron — Atomic scale features of polyvinylidene fluoride molecules (PVDF) were observed. Electron micrographs of thin, self-supporting PVDF nanofibers showed conformations and relative locations of atoms in segments of polymer molecules. Rows of CF<sub>2</sub> atomic groups, at 0.25 nm intervals, marked the paths of segments of the PVDF molecules. The fact that an electron microscope image of a segment of a PVDF molecule depended upon the particular azimuthal direction, along which the segment was viewed, enabled observation of twist around the molecular axis. The 0.2 nm side-by-side distance between the two fluorine atoms attached to the same carbon atom was clearly resolved. Morphological and chemical changes produced by energetic electrons, ranging from no change to fiber scission, over many orders of magnitude of electrons per unit area, provide quantitative new insights into radiation chemistry. Relative movements of segments of molecules were observed. Synergism between high resolution electron micrographs and images created by molecular dynamic modeling was demonstrated. This paper is at the threshold of growing usefulness of electron microscopy to the science and engineering of polymer and other molecules.

**M1.00047 Design of Free-Standing Microstructured Conducting Polymer Films for Enhanced Particle Removal from Non-uniform Surfaces**, JENNIFER LASTER, NICHOLAS DEOM, BRYAN BOUDOURIS, STEPHEN BEAUDOIN, Purdue University — Particle removal from surfaces is important for a wide range of industrial applications (e.g., microelectronics fabrication). One of the main forces of particle adhesion to a surface is the van der Waals attraction force, which will be the focus of this effort. The surface features of interacting bodies can play a controlling role in the adhesion of particles by increasing or decreasing the amount of mass within the range of strong van der Waals forces. In order to control these interactions, specific geometries can be designed in order to manipulate the micro- and nanostructure of a material, which can conform to the features of a corresponding substrate increasing the overall contact area between the two surfaces. In this work, microstructured films of the conducting polymer polypyrrole (PPy) were synthesized through template-assisted electropolymerization techniques. The removal of fluorescently-labeled polystyrene beads from aluminum surfaces of varying roughness was measured and compared for microstructured and flat PPy films. The microstructured films were found to have an overall increase in the amount of particles removed from the aluminum surfaces; this demonstrates the ability to manipulate particle adhesion through advanced nanostructured polymer templating.

**M1.00048 Out-of-plane Block Copolymer Microdomains in High Aspect-Ratio Templates**, KARIM GADELRAH, WUBIN BAI, ALFREDO ALEXANDER-KATZ, CAROLINE ROSS, Massachusetts Inst of Tech-MIT — Directed self-assembly DSA of block copolymers BCP proved to be a power approach for nanoscale fabrication. In addition, BCP with highly incompatible blocks (high Flory-Huggins interaction parameter ( $\chi$ )) offer improvement in resolution of the BCP patterns. Unfortunately, high- $\chi$  BCPs usually exhibit large differences in surface affinity between the two blocks, forming a surface layer of the lower surface energy block and favoring in-plane orientation of lamellae or cylindrical microdomains. Here, we explore the conditions under which a high  $\chi$  BCP creates an out-of-plane lamellar structure using high aspect ratio trenches with preferential walls. We employ self-consistent field theory SCFT and single mode expansion of Ginzburg-Landau free energy expression in the weak segregation limit to analytically construct a phase diagram of the in- and out-of-plane lamellae as a function of aspect ratio and surface affinity. It is found that achieving an out of plane lamellar structure necessitates a coupling between aspect ratio and surface functionality. In particular, strong side wall attraction results in out-of-plane lamellae when the trench aspect ratio is greater than unity. The results are validated for a polystyrene-block-polydimethylsiloxane (PS-b-PDMS) system within trenches made using interference lithography.

**M1.00049 Vertically Aligned Nanoplate Particles Directed by Block Copolymer Domains for Anisotropic Properties**, NADIA KROOK, University of Pennsylvania, JEFFREY METH, DuPont, CHRISTOPHER MURRAY, ROBERT RIG-  
GLEMAN, RUSSELL COMPOSTO, University of Pennsylvania — During common processing methods, anisotropic fillers in polymer nanocomposites align in the direction of flow, parallel to the surfaces, thus enhancing properties in the plane of the substrate. This research aims to create thin film nanocomposites with perpendicularly aligned anisotropic particles to improve properties in the out-of-plane direction. The demonstrated work explores vertical orientation of rare-earth fluoride nanoplates in lamellar-forming poly(styrene-*b*-methyl methacrylate) to establish a platform that controls the alignment of any planar particle. Currently, gadolinium fluoride (GdF<sub>3</sub>) rhombus nanoplates with the longest and shortest diagonal dimensions of ~30 nm and ~25 nm, respectively, have been specially synthesized with the potential to intercalate the block copolymer (BCP) domains. By employing a ternary brush blend layer to neutralize silicon substrates to both BCP domains, vertical lamellae orientation has been enabled with an optimum film thickness of ~110 nm. The GdF<sub>3</sub> surfaces are chemically modified to drive the plates to a specific BCP domain. After surface modification, the dispersion of GdF<sub>3</sub> in homopolymer will first be shown followed by morphology results from integrating GdF<sub>3</sub> into the BCP using scanning and transmission electron microscopy.

**M1.00050 The role of ultra-fast solvent evaporation on the directed self-assembly of block polymer thin films**, CHLOE DRAPES, G. NELSON, M. GRANT, J. WONG, A. BARUTH, Creighton University — The directed self-assembly of nano-structures in block polymer thin films *via* solvent vapor annealing is complicated by several factors, including evaporation rate. Solvent vapor annealing exposes a disordered film to solvent(s) in the vapor phase, increasing mobility and tuning surface energy, with the intention of producing an ordered structure. Recent theoretical predictions reveal the solvent evaporation affects the resultant nano-structuring. In a competition between phase separation and kinetic trapping during drying, faster solvent removal can enhance the propagation of a given morphology into the bulk of the thin film down to the substrate. Recent construction of a purpose-built, computer controlled solvent vapor annealing chamber provides control over forced solvent evaporation down to 15 ms. This is accomplished using pneumatically actuated nitrogen flow into and out of the chamber. Furthermore, *in situ* spectral reflectance, with 10 ms temporal resolution, monitors the swelling and evaporation. Presently, cylinder-forming polystyrene-*block*-polylactide thin films were swollen with 40% (by volume) tetrahydrofuran, followed by immediate evaporation under a variety of designed conditions. This includes various evaporation times, ranging from 15 ms to several seconds, and four unique rate trajectories, including linear, exponential, and combinations. Atomic force microscopy reveals specific surface, free and substrate, morphologies of the resultant films, dependent on specific evaporation conditions. Funded by the Clare Boothe Luce Foundation and Nebraska EPSCoR.

**M1.00051 Towards ultra-fast solvent evaporation, the development of a computer controlled solvent vapor annealing chamber**, GUNNAR NELSON, J. WONG, C. DRAPES, M. GRANT, A. BARUTH, Creighton Univ, Omaha, NE — Despite the promise of cheap and fast nanoscale ordering of block polymer thin films *via* solvent vapor annealing, a standardized, scalable production scheme remains elusive. Solvent vapor annealing exposes a nano-thin film to the vapors of one or more solvents with the goal of forming a swollen and mobile state to direct the self-assembly process by tuning surface energies and mediating unfavorable chain interactions. We have shown that optimized annealing conditions, where kinetic and thermal properties for crystal growth are extremely fast (<1s), exist at solvent concentrations just below the order-disorder transition of the film. However, when investigating the propagation of a given morphology into the bulk of a film during drying, the role of solvent evaporation comes under great scrutiny. During this process, the film undergoes a competition between two fronts; phase separation and kinetic trapping. Recent results in both theory and experiment point toward this critical element in controlling the resultant morphologies; however, no current method includes a controllable solvent evaporation rate at ultra-fast time scales. We report on a computer-controlled, pneumatically actuated chamber that provides control over solvent evaporation down to 15 ms. Furthermore, *in situ* spectral reflectance monitors solvent concentration with 10 ms temporal resolution and reveals several possible evaporation trajectories, ranging from linear to exponential to logarithmic. Funded by Dr. Randolph Ferlic Summer Research Scholarship and NASA Nebraska Space Grant.

**M1.00052 Directed Self-Assembly of Block Copolymers in Thin Films on Polymer Nano-Stripes**, DONG-EUN LEE, HO-JONG KANG, DONG HYUN LEE, Dankook University, NANO FUNCTIONAL MATERIALS LAB. TEAM — In this study, we report directed self-assembly (DSA) of block copolymers in thin films on nano-stripes of polymers. Unique nano-stripes of poly(tetrafluoro ethylene) (PTFE) having ~20 nm of amplitude and ~200 nm of pitch were simply generated by physically rubbing a PTFE bar on various substrates like Si wafers, glass, and polyimide due to its low friction coefficient and high wear rate. The resulting nano-stripes were extremely oriented along the rubbing direction. Then, various asymmetric polystyrene-*block*-poly(2-vinylpyridine) copolymers (PS-*b*-P2VP) were directly self-assembled on the nano-stripes of PTFE by solvent-annealing in vapor of tetrahydrofuran (THF). As a result, PS-*b*-P2VP exhibited extremely ordered P2VP cylinders oriented normal to the surface in large area on the underlying nano-stripes of PTFE. In addition, as utilizing the BCPs as templates, hexagonal arrays of metal nanoparticles were generated in large area for further application. BCP thin films and arrays of metal nanoparticles were characterized by atomic force microscopy (AFM) and scanning electron microscopy (SEM).

**M1.00053 Perpendicular Orientation of Nanodomains on Versatile Substrates through Self-Neutralization Induced by Star-Shaped Block Copolymers**, MOOSEONG KIM, SANGSHIN JANG, KYU SEONG LEE, HONG CHUL MOON, JONGHEON KWAk, JICHEOL PARK, GUMHYE JEON, JIN KON KIM, POSTECH — A novel self-neutralization concept is introduced by designing molecular architecture of a block copolymer. Star-shaped 18 arm poly(methyl methacrylate)-*block*-polystyrene copolymers ((PMMA-*b*-PS)<sub>18</sub>) exhibiting lamellar and PMMA cylindrical nanodomains are synthesized. When a thin film of (PMMA-*b*-PS)<sub>18</sub> is spin-coated on a substrate, vertically aligned lamellar and cylindrical nanodomains are obtained without any pre- or post-treatment, although thermal annealing for a short time (less than 30 min) is required to improve the spatial array of vertically aligned nanodomains. This result is attributed to the star-shaped molecular architecture that overcomes the difference in the surface affinity between PS and PMMA chains. Moreover, vertical orientations are observed on versatile substrates, for instance, semiconductor (Si, SiO<sub>x</sub>), metal (Au), PS or PMMA-brushed substrate, and a flexible polymer sheet of polyethylene naphthalate.

**M1.00054 The morphology of A2B miktoarm polymer in thin film**, HYEYOUNG KIM, Univ of Mass - Amherst, BEOM-GOO KANG, University of Tennessee, ZHIWEI SUN, JAEWON CHOI, THOMAS RUSSELL, Univ of Mass - Amherst — The morphologies of A2B mikto-arm polymer consisted of poly(2-vinyl pyridine) and polystyrene ((P2VP)2PS) in thin film were examined. Solvent vapor annealing produces films with lamellae perpendicular to the substrate within a very short time. The change in the morphology for different periods of time, corresponding to different swelling ratios was observed by grazing incidence small angle x-ray scattering and scanning force microscopy. This morphology showed the smaller height difference between PS and P2VP microdomains, when compared to the corresponding diblock copolymer. We also observed the long-range ordering formed on the saw-tooth pattern. Thermal annealing, on the other hand, resulted in the lamellae being oriented parallel to the substrate, where unusual behavior was depending on the film thickness and surface energy of substrate.

**M1.00055 Simple, generalizable route to highly aligned block copolymer thin films<sup>1</sup>**, ZHE QIANG, KEVIN CAVICCHI, BRYAN VOGT, University of Akron, UNIVERSITY OF AKRON TEAM — Macroscopic alignment of block copolymer domains in thin films is desired for many applications, such as cell responsive surfaces or optical polarizers. Alignment generally requires specialized tools that apply external fields, shear force gradient, or produce topological patterned substrates. This requirement limits the broad academic application of aligned BCPs. Here, we describe a simple modification of commonly utilized solvent vapor annealing (SVA) process for macroscopic alignment of BCPs. Adhering a flat, crosslinked elastomer pad to the BCP film leads to differential swelling between the elastomer pad and BCP to produce a shear force that aligns the ordered BCP domains. The role of elastomer properties, solvent quality, drying rate and degree of segregation of the block copolymer will be discussed to provide generalized rules for alignment with this technique. Cylindrical nanostructures formed in polystyrene-block-polydimethylsiloxane can be transformed into arrays of silica lines and increasing the thickness from a monolayer to bilayer can effectively halve the spacing of the lines. These results illustrate a generalized method for BCP alignment and a potential route for the generation of complex hierarchical assembled structures.

<sup>1</sup>A generalized method for block copolymer thin film alignment: solvent vapor annealing with shear

**M1.00056 Sulfation effect on levan polysaccharide chains structure with molecular dynamics simulations<sup>1</sup>**, BINNAZ COSKUNKAN, Yeditepe University, DENIZ TURGUT, DENIZ RENDE, Rensselaer Polytechnic Institute, SEYDA MALTA, Yeditepe University, NIHAT BAYSAL, RAHMI OZISIK, Rensselaer Polytechnic Institute, EBRU TOKSOY-ONER, Marmara University — Diversity in conformations and structural heterogeneity make polysaccharides the most challenging biopolymer type for experimental and theoretical characterization studies. Levan is a biopolymer chain that consists of fructose rings with  $\beta(2-6)$  linkages. It is a glycan that has great potential as a functional biopolymer in foods, feeds, cosmetics, pharmaceutical and chemical industries. Sulfated polysaccharides are group of macromolecules with sulfated groups in their hydroxyl parts with a range of important biological properties. Sulfate groups and their positions have a major effect on anticoagulant activity. It is reported that sulfate modified levan has anticoagulant activity such as heparin. In the current study, the effect of sulfation on the structure and dynamics of unmodified and sulfate modified levan are investigated via fully atomistic Molecular Dynamics simulations in aqueous media and varying salt concentrations at 310 K.

**M1.00057 The Effects of pH and Temperature on the Nanostructure of Chitosan Films<sup>1</sup>**, RAMONA LUNA, AHMED TOUHAMI, University of Texas Rio Grande Valley — Developing a matrix that can mimic tissue-like environment for cell cultures and molecular studies can help reduce the loss of some cell functions that occur when investigations are performed in vitro. Of particular interest is chitosan (CS): abundant and renewable biopolymer that is also biodegradable and non-toxic. The present study focuses on synthesizing CS films under various conditions and for multiple applications. We are using several techniques to characterize the physicochemical properties of the synthesized films. The contact angle technique is used to determine the hydrophobicity, hydrophilicity, and the surface free energy. The atomic force microscopy is used to determine the nanostructure, and nanomechanical properties. Here we specifically investigated the effect of the pH and the temperature on the nanostructure of the CS films. AFM images showed remarkable changes in the surface nanostructures that increase the roughness of the films when the pH of the solution increases. However, the surface free energy of these films has not shown any significant changes with the pH. By investigating the properties of these films, the needed biomaterial platform for a specific biological system can be designed and manipulated to increase its performance and lifetime.

**M1.00058 Characterization of Nanoparticle Aggregation in Biologically Relevant Fluids**, KATHLEEN MCENNIS, JOERG LAHANN, University of Michigan — Nanoparticles (NPs) are often studied as drug delivery vehicles, but little is known about their behavior in blood once injected into animal models. If the NPs aggregate in blood, they will be shunted to the liver or spleen instead of reaching the intended target. The use of animals for these experiments is costly and raises ethical questions. Typically dynamic light scattering (DLS) is used to analyze aggregation behavior, but DLS cannot be used because the components of blood also scatter light. As an alternative, a method of analyzing NPs in biologically relevant fluids such as blood plasma has been developed using nanoparticle tracking analysis (NTA) with fluorescent filters. In this work, NTA was used to analyze the aggregation behavior of fluorescent polystyrene NPs with different surface modifications in blood plasma. It was expected that different surface chemistries on the particles will change the aggregation behavior. The effect of the surface modifications was investigated by quantifying the percentage of NPs in aggregates after addition to blood plasma. The use of this characterization method will allow for better understanding of particle behavior in the body, and potential problems, specifically aggregation, can be addressed before investing in in vivo studies.

**M1.00059 Ring Structure of Center of Spacetime, DNA, and Extraterrestrial Being**, DAYONG CAO, AEEA — There is a balance of the flat universe between the stellar matter and the dark massenergy (include dark matter and dark energy) which make of dark hole which has the center of the spacetime. The Einstein's equation has the other formula of the structure of the center of spacetime. There are also balance system between the solar system and its companion dark hole, and between the Milky Way galaxy and its center of the huge dark hole. The model of stellar matter can explain of the structure of molecule by electromagnetic interaction (of the spacetime effect). The ring structure both the nucleic acid and protein is like the structure of the center of the spacetime. It produced by an interaction of double helix between dark massenergy and stellar matter when the companion dark hole of sun seasonal impacted near solar system, and took dark comets and dark massenergy on the earth, and made extinctions while they were producing new DNA of lives, broke the old one to the petroleum, natural gas, and coal. DNA of extraterrestrial being who live on system of the companion dark hole maybe have special ring structure with the double helix. A new big extinction is coming for human being and extraterrestrial being. <http://meetings.aps.org/link/BAPS.2015.APR.H14.8> <http://meetings.aps.org/link/BAPS.2012.APR.K1.79>

**M1.00060 Coacervate Core Micelles for the Dispersion and Stabilization of Organophosphate Hydrolase in Organic Solvents.**, CAROLYN MILLS, ALLIE OBERMEYER, XUEHUI DONG, BRADLEY D. OLSEN, Massachusetts Institute of Technology — Bulk organophosphate (OP) nerve agents are difficult to decontaminate on site and dangerous to transport. The organophosphate hydrolase (OPH) enzyme is an efficient catalyst for hydrolyzing, and thus decontaminating, these compounds, but suffers from poor stability in the hydrophobic bulk OP environment. Here, we exploit the complex coacervation phase separation phenomenon to form complex coacervate core micelles (C3Ms) that can protect this OPH enzyme under these conditions. Stable C3Ms form when mixing a charged-neutral block copolymer methyl-quaternized poly(4-vinylpyridine)-*block*-poly(oligo(ethylene glycol) methacrylate) (Qp4vp-*b*-POEGMA), a homopolymer poly(acrylic acid) (PAA), and OPH under a certain conditions. The C3Ms are then transferred into two organic solvents, ethanol and dimethyl methylphosphonate (DMMP), which is a good simulant for the physical properties of the OP compounds. The C3Ms retain their nanostructures in the organic solvents. The activity test of OPH indicates that the C3Ms successfully protect OPH activity in organic solvents.

**M1.00061 Fluorescence Recovery after Photobleaching in Confined Polymer Thin Films**, LAURA A. G. GRAY, CLIFFORD P. BRANGWYNNE, RODNEY D. PRIESTLEY, Princeton Univ, Dept. of Chemical and Biological Engineering — Over the past twenty years many studies have shown a reduction in the glass transition temperature ( $T_g$ ) of thin polymer films confined on the nanoscale when supported on non-attractive substrates or free-standing. The depth dependence of  $T_g$  has been measured using thin layers of fluorescently tagged polymer to localize the dye within a larger polymer film stack, revealing a decrease in local  $T_g$  tens of nanometers into the film. These results have been explained by the propagation of enhanced mobility from the free-surface into the polymer film. Fewer direct measurements of molecular mobility have been made in confined polymer systems. Here, we present the results of fluorescence recovery after photobleaching (FRAP) experiments investigating the mobility of fluorescently doped and labeled methacrylate-based polymers confined in thin film geometries. Bleaching and recovery was monitored using a laser-scanning confocal microscope that enabled us to bleach arbitrary micron-sized shapes to monitor diffusion in polymer melts.

**M1.00062 Using Atomistic Molecular Dynamics Simulations to Guide Development of Coarse-Grained Models of Polyethylene glycol (PEG), Elastic-like peptides (ELP) and Collagen-like peptides (CMP) For Biomaterial Design**, FRANCESCA STANZIONE, Department of Chemical and Biomolecular Engineering, University of Delaware, Newark, DE 19716., ARTHI JAYARAMAN, Department of Chemical and Biomolecular Engineering, Department of Materials Science and Engineering, University of Delaware, Newark, DE 19716. — Molecular dynamics (MD) is a well established technique to study the structure and dynamics of biomolecular systems. While atomistic simulations maintain chemical details, they are computationally intensive, thus limiting the accessible time, the length scales and the sampling. To overcome these limitations, coarse-grained (CG) models have proven to be successful in reproducing experimentally relevant length and time scales with reasonable computational expense. CG models can be developed to be phenomenological by effectively reproducing experimental results or can be developed by mapping rigorously to structural information provided by atomistic MD simulations. The latter method is recommended for biomolecules and biomaterials since atomistic simulations capture the detailed effect of the medium on interactions that affect the structure, dynamics and functional properties of the biomolecules, and that can be programmed into the CG models. In this poster we highlight three different cases where atomistic MD simulations provide such essential information to guide CG models: Polyethylene glycol, Elastic-like peptides and Collagen-like peptides based biomaterials.

**M1.00063 The influence of ionic strength on DNA diffusion in gel networks<sup>1</sup>**, YUANXI FU, AH-YOUNG JEE, HYEONG-JU KIM, STEVE GRANICK, Institute for Basic Science — Cations are known to reduce the rigidity of the DNA molecules by screening the negative charge along the sugar phosphate backbone. This was established by optical tweezer pulling experiment of immobilized DNA strands. However, little is known regarding the influence of ions on the motion of DNA molecules as they thread through network meshes. We imaged in real time the Brownian diffusion of fluorescent labeled lambda-DNA in an agarose gel network in the presence of salt with monovalent or multivalent cations. Each movie was analyzed using home-written program to yield a trajectory of center of the mass and the accompanying history of the shape fluctuations. One preliminary finding is that ionic strength has a profound influence on the slope of the trace of mean square displacement (MSD) versus time.

<sup>1</sup>The influence of ionic strength on DNA diffusion in gel networks

**M1.00064 Active microrheology of entangled blends of DNA and Actin link polymer flexibility to induced molecular deformations and stress propagation**, ROBERT FITZPATRICK, RAE ROBERTSON-ANDERSON, University of San Diego, ANDERSON RESEARCH TEAM — Actin is a ubiquitous structural protein in the cytoskeleton that gives cells shape and rigidity, and plays important roles in mechanical processes such as cell motility and division. Actins diverse roles stem from its ability to polymerize into semiflexible filaments that are less than one persistence length ( $\sim 17$  nm) in length, and form entangled networks that display unique viscoelastic properties. We previously found that entangled actin networks propagate microscale forces over several persistence lengths ( $\sim 60$  nm) and takes minutes to relax. DNA, oppositely, has thousands of persistence lengths (50 nm) per chain, exhibits minimal force propagation, and takes only seconds to re-equilibrate. To directly determine the role of flexibility in mechanical response and force propagation of entangled networks, we use optical tweezers and fluorescence microscopy to investigate blends of actin and DNA. We use optically driven microspheres to perturb the network far from equilibrium and measure the force the network creates in response to the induced force. We simultaneously track partially labeled actin filaments during the perturbation and subsequent relaxation period. We characterize filament deformation and show explicitly how induced microscale forces propagate through the network.

**M1.00065 Deep image analysis of entangled ring-shaped DNA**, HYEONGJU KIM, AH-YOUNG JEE, STEVE GRANICK, Institute for Basic Science — Ring-shaped DNA entangled in aqueous actin networks and observed by super-resolution microscopy (STED; stimulated emission depletion) offers rich data for comparison with unresolved questions of polymer physics. Using home-written software, we calculated not only the center of mass (CoM) and CoM trajectories of hundreds of molecules, but also analyzed conformation dynamics with statistical analysis including wavelet transformation and a correlation matrix approach. The analysis reveals some surprising aspects unanticipated by classical theories.

**M1.00066 Quantifying the effects of cyclic defects on the mechanical properties of polymer gels**, RUI WANG, MINGJIANG ZHONG, KEN KAWAMOTO, JEREMIAH JOHNSON, BRADLEY OLSEN, Massachusetts Institute of Technology — Understanding the correlation between the topology and properties of polymer gels is an outstanding challenge in polymer science. Classical theories of gel elasticity assume acyclic tree-like network topology; however, all polymer gels inevitably possess cyclic defects: loops that have profound, yet previously unpredictable, effect on gel properties. Here, we develop a modified phantom network theory that describes the effects of loops on the modulus of polymer gels. We demonstrate that small loops (primary and secondary loops) have vital effect on the modulus; whereas this negative impact decreases rapidly as the loop order increases, especially for networks with higher junction functionalities. Loop effect is non-local, which can propagate to its neighborhood strands. We show that adjacent loops weaken the network cooperatively, resulting in the nonlinear decrease of the dimensionless modulus ( $G/vkT$ , where  $v$  is the total density of polymer strands) with the loop fraction. The theory is in good agreement with the experimental data without any fitting parameters.

**M1.00067 Degrafting of polymer brushes from substrates enables insight about the brush structure and facilitates surface patterning.**, ROHAN PATIL, North Carolina State Univ, SALOMON TURGMAN-COHEN, Kettering University, JIRI SROGL, North Carolina State Univ, DOUGLAS KISEROW, US Army Research Office, JAN GENZER, North Carolina State Univ — Polymers end-grafted to surfaces or interfaces, commonly referred to as polymer brushes, enable tailoring physico-chemical properties of material surfaces. Many applications of polymer brushes require information about the molecular weight (MW) and grafting density (GD) of polymer brushes. For brushes synthesized by surface initiated polymerization (SIP) determining these attributes was always a challenge. We have developed a simple method of measuring MW and GD of these systems by degrafting SIP from silica-based surfaces by using tetrabutyl ammonium fluoride (TBAF), which attacks selectively Si-O bonds and enables complete degrafting of poly(methyl methacrylate) (PMMA) brushes from silica based substrates without damaging the backbone. The rate of PMMA degrafting decreases with reaction time and depends on the concentration of TBAF, temperature, and the initial GD of the system. The molecular weight distribution of the degrafted PMMA was measured using size exclusion chromatography. The GD was calculated from known MW and dry thickness of the PMMA brush. Spatial patterns of degrafted regions on the substrate can be prepared by either localizing the TBAF to certain regions or by gradually immersing homogeneous samples into TBAF solution.

**M1.00068 Driving Organic Molecule Crystallization with Surface Reconstructions**, JESSICA BICKEL, GIANFRANCO TROVATO, Cleveland State University — This work examines how surface reconstructions can drive crystallization of organic molecules via self-assembly. Organic electronic molecules have low conductivities compared to inorganic materials, but crystallizing these polymers increases their conductivity. This project uses surface reconstructions with periodically repeating topographies to drive the crystallization process. The samples are grown by placing a drop of a dilute PEDOT solution on the clean Si(001)-(2x1) or Si(111)-(7x7) surface reconstruction and heating the surface up to both evaporate the solvent and promote diffusion of the polymer to the thermodynamically defined lowest energy position. The resulting samples are characterized by scanning tunneling microscopy (STM) with respect to their crystallinity and electronic properties. Of particular interest is whether there is a preferential location for the PEDOT molecule to adsorb and whether there are any conformational changes upon adsorption that modify the HOMO-LUMO gap. This work is being done in a new pan-style RHK-STM enclosed in a glovebox at Cleveland State University. The glovebox has O<sub>2</sub> and H<sub>2</sub>O levels of less than 1ppm. This allows for sample preparation and imaging in a controlled environment that is free from contamination.

**M1.00069 The Study of Interpenetration Length between dPS Films and PS-grafted Layers**, HOYEON LEE, SEONGJUN JO, Yonsei University, TOYOAKI HIRATA, Kyushu University, NORIFUMI L. YAMADA, J-PARC, KEIJI TANAKA, Kyushu University, DU YEOL RYU<sup>1</sup>, Yonsei University — In polymer thin film system, the type of interfacial interaction is a critical parameter to determining the thermal and physical properties of polymer films. Interestingly, the interfacial energy of grafted substrates with polymer chains is remarkably altered by simply controlling grafting density, which has been referred to as autophobicity. In this study, we investigated the interpenetrating interfaces between deuterated polystyrene (dPS) and grafted substrates with the same chemical identity. PS-grafted substrates were prepared using a grafting-to approach with hydroxyl end-functionalized polystyrene (PSOH) in a dry brush regime, where the brush thickness and grafting density were determined based on the chain length (or molecular weight,  $M_n$ ) of PSOHs. The interpenetration lengths ( $\xi$ ) at interfaces between dPS and PS-grafted layers were characterized using neutron reflectivity (NR) measurements (performed at the SOFIA beam-line at J-PARC, Japan).

**M1.00070 Glass transition dynamics and charge carrier mobility in conjugated polyfluorene thin films**, HUI QIN, DAN LIU, TAO WANG, Wuhan University of Technology — Conjugated polymers are commonly used in organic optoelectronic devices, e.g. organic photovoltaics (OPVs), light-emitting diodes (LEDs) and field effect transistors (FETs). In these devices, the conjugated polymers are prepared as thin films with thicknesses in the range of tens to hundreds of nanometers, and are interfaced with different function layers made from organic or inorganic materials. We have studied the glass transition temperature ( $T_g$ ) of poly(9, 9-dioctylfluorene)-co-N-(1, 4-butylphenyl)diphenylamine (TFB) thin films supported on different substrates, as well as their SCLC charge carrier mobility in photodiodes. Both Monotonic and non-monotonic  $T_g$  deviations are observed in TFB thin films supported on Si/SiO<sub>2</sub> and PEDOT:PSS, respectively. With low to moderate thermal crosslinking, the thickness dependent  $T_g$  deviation still exists, which diminishes in TFB films with a high crosslinking degree. The vertical charge carrier mobility of TFB thin films extracted from the SCLC measurements is found increase with film thickness, a value increases from 1 to 50  $\times 10^{-6}$  cm<sup>2</sup> V<sup>-1</sup> s<sup>-1</sup> in the thickness range from 15 to 180 nm. Crosslinking was found to reduce the carrier mobility in TFB thin films. The  $T_g$  deviations are also discussed using the classic layered models in the literature. Our results provide a precise guide for the fabrication and design of high performance optoelectronic devices.

**M1.00071 Bending and Fracture in Thin Polymer Films during Capillary Origami Assembly.**, TIMOTHY TWOHIG, ANDREW CROLL, North Dakota State Univ — Capillary origami uses liquid tension to bend thin films into useful shapes and structures. The ability to scale this process to the microscopic range has led to growing interest in capillary origami and many potential applications. Clearly, the creation of three dimensional structures from flat sheets depends deeply on a combination of properties: fluid tensions, film thickness, film modulus and importantly the films fracture properties. Fractures in a film are a critical component of macroscopic origami but macroscopic methods for creating these fractures are not possible at the microscopic scale. We present an experimental investigation of the interplay of capillary forces and material properties in the creation of controlled fractures in thin polymer films. Specifically, we use capillary forces to lift and bend a thin polymer film to the point of fracture using a variety of film thicknesses and material properties and attempt to model the basic underlying physics. We observe the creation of delaminations and fractures at pre-determined sites that can be tailored to specific shapes to be utilized in capillary origami.

**M1.00072 Confinement Effect on the Effective Viscosity of Plasticized Polymer Films**<sup>1</sup>, FEI CHEN, D. PENG, Boston University Physics Department, Y. OGATA, K. TANAKA, Kyushu University Department of Applied Chemistry, Z. YANG, Soochow University Department of Polymer Science and Engineering, Y. FUJII, National Institute for Materials Science (Japan), N. L. YAMADA, Neutron Science Laboratory High Energy Accelerator Research Organization (Japan), C. H. LAM, Hong Kong Polytechnic University Department of Applied Physics, OPHELIA K. C. TSUI, Boston University Physics Department — We have measured the effective viscosity of polystyrene films with a small (4 wt%) added amount of dioctyl phthalate (DOP) deposited on silica. A broad range of molecular weights,  $M_w$ , from 13.7 to 2,100 kg/mol was investigated. Our result shows that for the thin films with  $M_w < 100$  kg/mol, the addition of DOP causes the effective viscosity to decrease by a factor of ~4, independent of  $M_w$ . But for the higher  $M_w$  films, the effective viscosity of the DOP added films creeps towards that of the neat films with increasing  $M_w$ . A model assuming the effective viscosity to be dominated by enhanced surface mobility for the lower  $M_w$  films, but surface-promoted interfacial slippage for the higher  $M_w$  films is able to account for the experimental observations.

**M1.00073 Adhesion and Wetting in Soft Polymeric Systems**<sup>1</sup>, ANDREY DOBRYNIN, ZHEN CAO, Univ of Akron, MARK STEVENS, Sandia National Laboratories — We have developed a generalized model of particle/surface interactions describing adhesion and wetting phenomena. We show that for an elastic nanoparticle with radius  $R_p$  and shear modulus  $G_p$  interacting with an elastic substrate having shear modulus  $G_s$  the crossover between adhesion and wetting-like behavior is determined by a dimensionless parameter  $\beta \propto \gamma^*(G^*R_p)^{-2/3}W^{-1/3}$ . In the limit of small values of the parameter  $\beta \ll 1$ , our model reproduces JKR model for particle adhesion on elastic substrates (adhesion regime). However, in the opposite limit,  $\beta \gg 1$ , the capillary forces play a dominant role and determine particle/substrate interactions (wetting regime). We extended our approach to describe the detachment of rigid nanoparticles from elastic surfaces. Simulation results confirm that the detachment force,  $f^*$ , depends on a dimensionless parameter  $\delta \propto \gamma_s(G_sR_p)^{-1/3}W^{-2/3}$ , which corresponds to the ratio of the surface energy of the neck and the substrate elastic energy. In the case when  $\delta \ll 1$ , the critical detachment force approaches a critical value calculated in the framework of the JKR model,  $f^* = 1.5\pi WR_p$  (JKR regime). However, in the opposite limit, the critical detachment force scales as  $f^* \propto \gamma_s^{3/2}R_p^{1/2}G_s^{-1/2}$  (necking regime). All simulation data can be described by a crossover function  $f^* \propto \gamma_s^{3/2}R_p^{1/2}G_s^{-1/2}\delta^{-1.89}$ .

**M1.00074 Novel adhesion properties of irreversibly adsorbed polymer chains<sup>1</sup>**, ZHIZHAO CHEN, MANI SEN, JUSTIN CHEUNG, DEBORAH BARKLEY, NAISHENG JIANG, WENDUO ZENG, MAYA K. ENDOH, TADANORI KOGA, Stony Brook University — The stability of thin polymer films on solids is of vital interest in traditional technologies and in new emerging nanotechnologies. We recently found that nanoscale structures of polymer chains adsorbed onto a silicon (Si) substrate (“adsorbed nanolayers”) play a crucial role in the thermal stability of the film. To understand the adhesion mechanism at the adsorbed polymer-free polymer interface, we mimicked the interface by preparing bilayers where a 200 nm-thick polymer film and an adsorbed nanolayer, both prepared on Si, were pressed together at high temperature. The bilayers were then subjected to an adhesion test by measuring the critical normal force required to separate the two films. Polystyrene was used as a model. The results are intriguing as they show an absence of adhesion between the “flattened” adsorbed chains, which lie flat on the solid, and the chemically identical free chains. On the other hand, the “loosely adsorbed” polymer chains, which are formed as a result of limited adsorption space on the solid surface, do display a degree of adhesion with the bulk polymer. We postulate that the loosely adsorbed chains act as “connectors” which promote adhesion effectively across the solid-polymer interface.

<sup>1</sup>We acknowledge the financial support from NSF Grant No. CMMI-1332499.

**M1.00075 Entropic Segregation of Short Polymers to the Surface of a Polydisperse Blend<sup>1</sup>**, PENDAR MAHMOUDI, MARK MATSEN, University of Waterloo — Surface effects become particularly important for micro-sized and even more so for nano-sized objects. Naturally, enthalpic preferences will cause certain components of a multi-component material to segregate to a surface, but in polymeric materials this can also happen as a result of purely entropic reasons. To demonstrate this, we consider the effect of a surface on a binary blend of chemically identical long and short polymers, using self-consistent field theory. Despite the absence of any enthalpic preference, the short polymers are found to segregate to the surface. We investigate how the amount of the surface excess and its decay length depends on the polymeric model, the molecular weights of the two polymers and the blend composition.

**M1.00076 Effect of tacticity on the structure and glass transition temperature of polystyrene thin films**, YERGOU TATEK, SOLOMON NEGASH, Addis Ababa University, MESFIN TSIGE, The University of Akron — Detailed atomistic Molecular Dynamics simulations are performed to explore the effect of tacticity on the glass transition temperature as well as other pertinent structural properties of films of polystyrene (PS) chains adsorbed onto two distinct types of solid substrates. The investigated systems consist of thin films made of isotactic, syndiotactic and atactic PS chains adsorbed on graphite and hydroxylated silica surfaces. The structure of the films is investigated in terms of film density profiles and side chains and backbone orientations. Simulations results reveal a marked dependence of the film structure on substrate type while the absence of a strong correlation between structure and tacticity is observed. Moreover, it is found that the glass transition temperature is also substrate dependent and takes larger values for films adsorbed on graphite surface, irrespective of chain tacticity.

**M1.00077 Capillary wrinkling of thin bilayer polymeric sheets<sup>1</sup>**, JOOYOUNG CHANG, NARAYANAN MENON, THOMAS RUSSELL, Univ of Mass - Amherst — We have investigated capillary force induced wrinkling on a floated polymeric bilayer thin sheet. The origin of the wrinkle pattern is compressional hoop stress caused by the capillary force of a water droplet placed on the floated polymeric thin sheet afore investigated. Herein, we study the effect of the differences of surface energy arising from the hydrophobicity of Polystyrene (PS Mw: 97 K, Contact Angle: 88 °) and the hydrophilicity of Poly(methylmethacrylate) (PMMA Mw: 99K, Contact Angle: 68 °) on two sides of a bilayer film. We measure the number and the length of the wrinkles by broadly varying the range of thicknesses of top (9 nm to 550 nm) and bottom layer (25 nm to 330 nm). At the same, there is only a small contrast in mechanical properties of the two layers (PS E = 3.4 GPa, and PMMA E = 3 GPa). The number of the wrinkles is not strongly affected by the composition (PS(Top)/PMMA(Bottom) or PMMA(Top)/PS(Bottom)) and the thickness of each and overall bilayer system. However, the length of the wrinkle is governed by the contact angle of the drop on the top layer of bilayer system. We also compare this to the wrinkle pattern obtained in monolayer systems over a wide range of thickness from PS and PMMA (7 nm to 1 μm).

**M1.00078 Role of monomer sequence and backbone structure in polypeptoid and polypeptide polymers for anti-fouling applications**, ANASTASIA PATTERSON, GEORGIOS RIZIS, UC Santa Barbara, BRANDON WENNING, Cornell University, JOHN FINLAY, Newcastle University, CHRISTOPHER OBER, Cornell University, RACHEL SEGALMAN, UC Santa Barbara — Polymeric coatings rely on a fine balance of surface properties to achieve biofouling resistance. Bioinspired polymers and oligomers provide a modular strategy for the inclusion of multiple functionalities with controlled architecture, sequence and surface properties. In this work, polypeptoid and polypeptide functionalized coatings based on PEO and PDMS block copolymers were compared with respect to surface presentation and fouling by *Ulva linza*. While polypeptoids and polypeptides are simple isomers of each other, the lack of backbone chirality and hydrogen bonding in polypeptoids leads to surprisingly different surface behavior. Specifically, the polypeptoids surface segregate much more strongly than analogous polypeptide functionalized polymers, which in turn affects the performance of the coating. Indeed, polypeptoid functionalized surfaces were significantly better both in terms of anti-fouling and fouling release than the corresponding polypeptide-bearing polymers. The role of specific monomer sequence and backbone chemistry will be further discussed in this poster.

**M1.00079 Conformation and hydration of surface grafted and free polyethylene oxide chains in solutions.<sup>1</sup>**, UDAYA DAHAL, Department Dept. of Physics and Institute of Materials Science, Univ. of Connecticut, ZILU WANG, Dept. of Physics and Institute of Materials Science, Univ. of Connecticut, ELENA DORMIDONTOVA, DDept. of Physics and Institute of Materials Science, Univ. of Connecticut — Due to the wide application of polyethylene oxide (PEO), ranging from biomedicine to fuel cells, it is one of the most studied polymers in the scientific world. In order to elucidate detailed molecular-level insights on the impact of surface grafting on PEO conformation, we performed atomistic molecular dynamics simulations of PEO chains in solution and grafted to a flat gold surface in different solvents. We examined the hydration as well as conformation of the free chain compared to the grafted polymer in pure water and mixed solvents. We find that grafted chains are stiffer and have a stronger tendency to form helical structures in isobutyric acid or mixture of isobutyric acid and water solution than the free chains in corresponding solutions. For grafted chains exposed to pure water the random coil conformation is retained at low grafting density, but becomes stretched and more dehydrated as the grafting density or temperature increases.

**M1.00080 Charge transport and structural dynamics in ultra-thin films of polymerized ionic liquids**<sup>1</sup>, MAXIMILIAN HERES, TYLER COSBY, Univ of Tennessee, Knoxville, STEFAN BERDZINSKI, VERONICA STREHMEL, Department of Chemistry and Institute for coatings and surface chemistry, Hochschule Niederrhein University of Applied Sciences, ROBERTO BENSON, JOSHUA SANGORO, Univ of Tennessee, Knoxville — Ion conduction and structural dynamics in a series of ultra-thin films of imidazolium based polymerized ionic liquids are investigated using broadband dielectric spectroscopy, atomic force microscopy, and ellipsometry. No alteration in the characteristic charge transport rate is observed between bulk sample and films as thin as 12nm. These results are discussed within the recent approaches proposed to explain the confinement effects on structural dynamics in polymers and low molecular weight ionic liquids.

<sup>1</sup>NSF DRM Polymers Program

**M1.00081 Molecular dynamics simulations and morphology analysis of TEM imaged PVDF nanofibers**<sup>1</sup>, JIAYUAN MIAO, Case Western Reserve University, DARRELL RENEKER, MESFIN TSIGE, University of Akron, PHILIP TAYLOR, Case Western Reserve University — With the goal of elucidating the structure of polyvinylidene fluoride (PVDF) nanofibers, all-atom molecular dynamics simulations were performed, and the results compared with structures observed in high resolution transmission electron microscopy (TEM) at the molecular level. Simulation shows that the stability of the  $\beta$ -phase component in a PVDF nanofiber is influenced by its thickness and processing history. When exposed to irradiation, as in a TEM observation, the structure is then further modified by the effects of chain scission. The transformation from the  $\beta$  phase into a paraelectric phase can explain the spindle formation and serpentine motion of molecular segments observed by Zhong et al. (Polymer, 54, 2013, 3745-3756) in irradiated PVDF nanofibers. From a comparison between simulated and experimental TEM images it was possible to identify numerous features that are useful in unveiling the inherent structure of PVDF nanofibers. The experimental TEM images appear to match well with those predicted by a model based on  $\alpha$ -phase PVDF, while also being consistent with an alternative model (Nanoscale 2015, DOI: 10.1039/c5nr01619c).

**M1.00082 Processing and characterization of natural fiber reinforced thermoplastic composites using micro-braiding technique**, SATOSHI KOBAYASHI, Tokyo Metropolitan Univ, SHINJI OGIHARA, Tokyo University of Science — In the present study, we investigate fatigue properties of green composites. A hemp fiber yarn reinforced poly(lactic acid) composite was selected as a green composite. Unidirectional (UD) and textile (Textile) composites were fabricated using micro-braiding technique. Fatigue tests results indicated that fatigue damages in UD composites was splitting which occurred just before the final fracture, while matrix crack and debonding between matrix and fiber yarn occurred and accumulated stably in Textile composites. These results were consistent with modulus reduction and acoustic emission measurement during fatigue tests.

**M1.00083 Deformation Behavior during Processing in Carbon Fiber Reinforced Plastics**, SHINJI OGIHARA, Tokyo University of Science, SATOSHI KOBAYASHI, Tokyo Metropolitan University — In this study, we manufacture the device for measuring the friction between the prepreg curing process and subjected to pull-out tests with it. The prepreg used in this study is a unidirectional carbon/epoxy, produced by TORAY designation of T700SC/2592. When creating specimens 4-ply prepreps are prepared and laminated. The 2-ply prepreps in the middle are shifted 50mm. In order to measure the friction between the prepreg during the cure process, we simulate the environment in the autoclave in the device, and we experiment in pull-out test. Test environment simulating temperature and pressure. The speed of displacement should be calculated by coefficient of thermal expansions (CTE). By calculation, 0.05mm/min gives the order of magnitude of displacement speed. In this study, 3 pull-out speeds are used: 0.01, 0.05 and 0.1mm/min. The specimen was heated by a couple of heaters, and we controlled the heaters with a temperature controller along the curing conditions of the prepreg. We put pressure using 4 bolts. Two strain gages were put on the bolt. We can understand the load applied to the specimen from the strain of the bolt. Pressure was adjusted the tightness of the bolt according to curing conditions. By using such a device, the pull-out test performed by tensile testing machine while adding temperature and pressure. During the 5 hours, we perform experiments while recording the load and stroke. The shear stress determined from the load and the stroke, and evaluated.

**M1.00084 Localized Memory Effect of Elastomers Filled with Nanoparticles**, SHOUBO LI, XIAORONG WANG, Chemical Engineering, Tongji University, Shanghai — When a filler-reinforced elastomer compound is oscillatory sheared or pressed at a small fixed strain (e.g., 2%) for a period of time, it can produce a localized memory perturbation in its dynamic spectrum. Typically, a localized memory appears near the applied strain amplitude in the loss modulus spectrum. Sequential holding the system at two strains can produce one or two holes depending on the deformation histories. While this discovery of localized memory effect seems to be significant and compelling, its generality in vulcanized elastomers containing various fillers has not yet been tested extensively. In this work, we intend to expand on our previous work of a colloidal silica-filled model system to carbon black-filled real rubbers. We also examine the effect of filler volume fraction in rubber compounds on the spectral memory phenomenon.

**M1.00085 Mechanical Properties of Cellulose Microfiber Reinforced Polyolefin**, SATOSHI KOBAYASHI, HIROYUKI YAMADA, Tokyo Metropolitan Univ — Cellulose microfiber (CeF) has been expected as a reinforcement of polymer because of its high modulus and strength and lower cost. In the present study, mechanical properties of CeF/polyolefin were investigated. Tensile modulus increased with increasing CeF content. On the other hand, tensile strength decreased. Fatigue properties were also investigated with acoustic emission measurement. Stiffness of the composites gradually decreased with loading. Drastic decrease in stiffness was observed just before the final fracture. Based on the Mori-Tanaka's theory, the method to calculate modulus of CeF were proposed to evaluate dispersion of CeF.

**M1.00086 Soft composites with the twisted plywood microstructure, a lesson from nature.**<sup>1</sup>, YONGJIN KIM, ALFRED CROSBY, Univ of Mass - Amherst, CROSBY RESEARCH GROUP TEAM — The twisted plywood microstructure, consisting of rigid structural units within a continuous matrix, is known to be prevalent in many natural materials, including exoskeletons of crustacean, scales of fish, and even bones of mammals. Although it is yet to be resolved whether this structure is a product of evolution or an inevitable consequence of chirality of building blocks, nature utilizes the structure extensively to create various components. Previous studies have focused on fabricating and characterizing synthetic composites with similar structures; however, these composites have been based on a rigid matrix, e.g. an epoxy resin, and hard fibers, e.g. carbon fibers. For this combination of materials, it has been difficult to deconvolute the specific roles of each component. For a better understanding of the advantage of the structure, we have developed flexible composites, comprising a soft matrix and hard fiber bundles at two different size scales. Macroscopic engineered samples were created by combining elastomer and hard fibers, while sub-micron composites are fabricated from self-assembled nanoparticle ribbons and hydrogel matrices. The advantageous mechanical response of these flexible twisted plywood composites is characterized and presented.

**M1.00087 Modeling heterogeneous polymer-grafted nanoparticle networks having biomimetic core-shell structure**, BADEL L. MBANGA, VICTOR V. YASHIN, Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA 15261, USA, NIELS HOLTEN-ANDERSEN, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA 15261, USA — Inspired by the remarkable mechanical properties of such biological structures as mussel adhesive fibers, we use 3D computational modeling to study the behavior of heterogeneous polymer-grafted nanoparticle (PGN) networks under tensile deformation. The building block of a PGN network is a nanoparticle with grafted polymer chains whose free ends' reactive groups can form both permanent and labile bonds with the end chains on the nearby particles. The tunable behavior of cross-linked PGN networks makes them excellent candidates for designing novel materials with enhanced mechanical properties. Here, we consider the PGN networks having the core-shell structures, in which the type and strength of the inter-particle bonds in the outer shell differ from those in the core. Using the computer simulations, we obtain and compare the ultimate tensile properties (strength, toughness, ductility) and the strain recovery properties for the uniform samples and various core-shell structures. We demonstrate that the core-shell structures could be designed to obtain highly resilient self-healing materials

**M1.00088 Effects of Dimensionality and Flexibility of Conductive Fillers in Nanocomposites on Percolating Network Formation and Electrical Conductivity**, SEULKI KWON, HYUN WOO CHO, BONG JUNE SUNG, Department of Chemistry, Sogang University, Seoul 121-742, Republic of Korea — We conduct extensive Langevin dynamics (LD) simulation to explore how the dimensionality and flexibility of conductive fillers in polymer nanocomposites influence their percolation network formation and electrical conductivity. The percolation network formation of nanoparticles in polymer matrices is critical to obtaining desired properties of polymer nanocomposites. Some nanofillers such as carbon nanotubes (CNTs) and graphene nanosheets, are so flexible that they become either wavy or crumpled. Such a variability in nanofiller conformation brings a change to the percolation network, but has been often ignored in the theoretical and computational investigation. We consider three kinds of nanofillers of different dimensionality: zero-dimensional (0D) nanospheres, one-dimensional (1D) nanorods, and two-dimensional (2D) nanoplates. We estimate the percolation network concentration ( $\varphi_c$ ) and electrical conductivity with careful finite-size scaling. When the sizes of nanofillers are comparable, the dimensionality of nanofillers influences on  $\varphi_c$  and electrical conductivity of nanocomposites significantly. The effect of flexibility of nanofillers is less significant than that of dimensionality.

**M1.00089 Structure, Nanomechanics and Dynamics of Dispersed Surfactant-Free Clay Nanocomposite Films**, XIAO ZHANG, JING ZHAO, University of Akron, CHAD SNYDER, National Institute of Standards and Technology, ALAMGIR KARIM, University of Akron, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY COLLABORATION — Natural Montmorillonite particles were dispersed as tactoids in thin films of polycaprolactone (PCL) through a flow coating technique assisted by ultra-sonication. Wide angle X-ray scattering (WAXS), Grazing-incidence wide angle X-ray scattering (GI-WAXS), and transmission electron microscopy (TEM) were used to confirm the level of dispersion. These characterization techniques are in conjunction with its nanomechanical properties via strain-induced buckling instability for modulus measurements (SIEBIMM), a high throughput technique to characterize thin film mechanical properties. The linear strengthening trend of the elastic modulus enhancements was fitted with Halpin-Tsai (HT) model, correlating the nanoparticle geometric effects and mechanical behaviors based on continuum theories. The overall aspect ratio of dispersed tactoids obtained through HT model fitting is in reasonable agreement with digital electron microscope image analysis. Moreover, glass transition behaviors of the composites were characterized using broadband dielectric relaxation spectroscopy. The segmental relaxation behaviors indicate that the associated mechanical property changes are due to the continuum filler effect rather than the interfacial confinement effect.

**M1.00090 Influence of Surface Coating of Magnetic Nanoparticles on Mechanical Properties of Polymer Nanocomposites<sup>1</sup>**, ECEM YARAR, GIZEM KARAKAS, Yeditepe University, DENIZ RENDE, RAHMI OZISIK, Rensselaer Polytechnic Institute, SEYDA MALTA, Yeditepe University — Polymer nanocomposites have emerged as promising materials due to improved properties when compared with conventional bulk polymers. Nanofillers are natural or synthetic organic/inorganic particles that are less than 100 nm in at least one dimension. Even the addition of trace amounts of nanofillers to polymers may lead to unique combinations of properties. Among variety of inorganic nanofillers, iron oxide magnetic nanoparticles are of great interest due to their unique physical and chemical properties, such as low toxicity, biocompatibility, large magnetization and conductivity, owing to their extremely small size and large specific surface area. In this study, approximately 8-10 nm magnetic nanoparticles coated with either citric acid or oleic acid are synthesized and blended with poly(methyl methacrylate) (PMMA) or poly(ethylene oxide) (PEO). The hydrophobicity/hydrophilicity of the polymer and the surface coating on the iron oxide nanoparticles are exploited to control the dispersion state of nanoparticles, and the effect of dispersion on mechanical and thermal properties of the nanocomposite are investigated via experimental methods such as dynamic mechanical analysis and differential scanning calorimetry.

**M1.00091 Wide Angle X-Ray Scattering Investigations on Irradiated iPP-VGCF Nanocomposites.**, ARNOLD FONSECA, DORINA CHIPARA, KAREN LOZANO, MIRCEA CHIPARA, The University of Texas Rio Grande Valley — Isotactic Polypropylene (iPP) has been loaded by various amounts of Vapor Grown Carbon Nanofiber (VGCF), ranging between 0 and 20 % wt., via melt mixing. The as obtained nanocomposites were gamma irradiated in air, at room temperature, at a dose rate of about 1 kGy/h and various integral doses ranging between 0 and 28 kGy. by using a <sup>60</sup>Co source. Wide Angle X-Ray Spectroscopy has been used to quantify the changes in the crystalline structure and the degree of crystallinity of iPP-VGCF nanocomposites. The measurements have been carried out by a Bruker Discover 8 spectrometer. Additional measurements have been performed by Raman spectroscopy using a Renishaw InVia microscope system operating at 532 and 785 nm. The experimental spectra of the nanocomposite were fitted by assuming a superposition of extended Breit-Wigner-Fano line shapes. It is concluded that the observed modifications noticed in these nanocomposites are dominated by the radiation-induced degradation of the polymeric matrix. Differential Scanning calorimetry data provided additional information regarding the effect of the nanofiller on the degree of crystallinity.

**M1.00092 Designing a gel-fiber composite to extract nanoparticles from solution**, YA LIU, University of Pittsburgh, OLGA KUKSENOK, Clemson University, ANNA BALAZS, University of Pittsburgh — Using DPD simulations, we proposed the design of a gel-fiber coating where the components of the system act in concert to extract particles from solution and localize these solids in the underlying gel layer. We model an array of flexible fibers that are embedded in a lower critical solution temperature (LCST) thermo-responsive gel, which swells at lower temperatures and collapses at higher temperatures. The system is immersed in a solution containing dispersed nanoparticles and this fluid is driven to flow by an imposed shear. When the gel is heated, it collapses to expose the fibers, and thereby, triggers the "catch" process. Namely, the fibers can act like "arms" that wrap around the nanoparticle and bring it from the outer solvent into the gel layer. Moreover, we show that depending on the flexibility and hydrophobicity of the fibers, as well as the imposed shear, we can position the nanoparticles at the desired height within the gel layer. Our approach can be utilized for the detection and separation of components in fluids and for the controlled insertion of nanoparticles within a hydrogel at a particular distance from the gel interface

**M1.00093 ABSTRACT WITHDRAWN —**

**M1.00094 Viscoelastic Analysis of Thermally Stiffening Polymer Nanocomposites<sup>1</sup>**, ANDREW EHLERS\*, DENIZ RENDE, Rensselaer Polytechnic Institute, ERKAN SENSES, PINAR AKCORA, Stevens Institute of Technology, RAHMI OZISIK, Rensselaer Polytechnic Institute — Poly(ethylene oxide), PEO, filled with silica nanoparticles coated with poly(methyl methacrylate), PMMA, was shown to present thermally stiffening behavior above the glass transition temperature of both PEO and PMMA. In the current study, the viscoelastic behavior of this nanocomposite system is investigated via nanoindentation experiments to complement on going rheological studies. Results were compared to neat polymers, PEO and PMMA, to understand the effect of coated nanoparticles.

<sup>1</sup>This material is based upon work supported by the National Science Foundation under Grant No. CMMI-1538730. \*Undergraduate student.

**M1.00095 Controlling the Degradation of Bioresorbable Polymers<sup>1</sup>**, ISTVAN MORITZ, BRIAN CROWLEY\*, ELIZABETH BRUNDAGE\*, Materials Science and Engineering, Rensselaer Polytechnic Institute, DENIZ RENDE, Center for Materials, Devices and Integrated Systems, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Bioresorbable polymers play a vital role in the development of implantable materials that are used in surgical procedures, controlled drug delivery systems; and tissue engineering scaffolds. The half-life of common bioresorbable polymers ranges from 3 to over 12 months and slow bioresorption rates of these polymers restrict their use to a limited set of applications. The use of embedded enzymes was previously proposed to control the degradation rate of bioresorbable polymers, and was shown to decrease average degradation time to about 0.5 months. In this study, electromagnetic actuation of iron oxide magnetic nanoparticles embedded in an encapsulant polymer, poly(ethyleneoxide), PEO, was employed to initiate enzyme assisted degradation of bioresorbable polymer poly(caprolactone), PCL. Results indicate that the internal temperature of iron oxide magnetic nanoparticle doped PEO samples can be increased via an alternating magnetic field, and temperature increase depends strongly on nanoparticle concentration and magnetic field parameters. The temperature achieved is sufficient to relax the PEO matrix and to enable the diffusion of enzymes from PEO to a surrounding PCL matrix. Current studies are directed at measuring the degradation rate of PCL due to the diffused enzyme.

**M1.00096 Interfacial slip in nano filled polymer blends**, JOHN MIKHAIL, DI XU, JOSEPH ORTIZ, DILIP GERSAPPE, Stony Brook University — The ability to control the interfacial slip in polymer blends is key to strengthening the material. Here, we look at how nano fillers can be used to strengthen the interface. By designing nano fillers with the appropriate surface energy we show how nano fillers can localize at the interface between the two polymer blends. We examine the role that the aspect ratio of the nano filler has on its ability to reduce the interfacial slip, and look to understand the mechanisms by which the slip is reduced. We look for network formation near the interface as a possible strengthening mechanism.

**M1.00097 Nanocellulose Composite Materials Synthesizes with Ultrasonic Agitation**, TIMOTHY KIDD, ANDREW FOLKEN, BYRON FRITCH, DEREK BRADLEY, University of Northern Iowa — We have extended current techniques in forming nanocellulose composite solids, suspensions and aerogels to enhance the breakdown of cellulose into its molecular components. Using only mechanical processing which includes ball milling, using a simple mortar and pestle, and ultrasonic agitation, we are able to create very low concentration uniform nanocellulose suspensions in water, as well as incorporate other materials such as graphite, carbon nanotubes, and magnetic materials. Of interest is that no chemical processing is necessary, nor is the use of nanoparticles, necessary for composite formation. Using both graphite and carbon nanotubes, we are able to achieve conducting nanocellulose solids and aerogels. Standard magnetic powder can also be incorporated to create magnetic solids. The technique also allows for the creation of an extremely fine nanocellulose suspension in water. Using extremely low concentrations, less than 1% cellulose by mass, along with careful control over processing parameters, we are able to achieve highly dilute, yet homogenous nanocellulose suspensions. When air dried, these suspensions have similar hardness and strength properties to those created with more typical starting cellulose concentrations (2-10%). However, when freeze-dried, these dilute suspensions form aerogels with a new morphology with much higher surface area than those with higher starting concentrations. We are currently examining the effect of this higher surface area on the properties of nanocellulose aerogel composites and how it influences the impact of incorporating nanocellulose into other polymer materials.

**M1.00098 Predicting  $\chi$  for polymers with stiffness mismatch from simulations**, DANIEL KOZUCH, WENLIN ZHANG, ENRIQUE GOMEZ, SCOTT MILNER, Department of Chemical Engineering, Penn State University — The Flory-Huggins  $\chi$  parameter describes the excess free energy of mixing and governs phase behavior for polymer blends and block copolymers. For chemically distinct polymers, the value of  $\chi$  is dominated by the mismatch in cohesive energy densities of the monomers. For blends of chemically similar polymers, the entropic portion of  $\chi$ , arising from non-ideal local packing, becomes more significant. Using polymer field theory, Fredrickson, Liu, and Bates predict that a difference in backbone stiffness can result in a positive  $\chi$  for chains consisting of chemically identical monomers. To quantitatively investigate this phenomenon, we perform molecular dynamic (MD) simulations for bead-spring chains which differ only in stiffness. From the simulations, we apply a novel thermodynamic integration to extract  $\chi$  as low as  $10^{-3}$  per monomer for blends with mild stiffness mismatch. By introducing a standardized effective monomer, we map real polymers to our bead-spring chains and show that the predicted entropic portion of  $\chi$  are consistent with experimental data.

**M1.00099 Comparative Study of Silk-Silk Alloy Materials**, YE XUE, Rowan University; Nanjing University, DAVE JAO, Rowan University, WENBING HU, Nanjing University, NATHAN WOLF, EVA-MARIE ROCKS, XIAO HU, Rowan University — Silk fibroin materials can be used for various kinds of biomedical applications. We report a comparative study of silk-silk blend materials using thermal analysis and infrared spectroscopy. Four groups of silk-silk blend films: Mori-Tussah, Mori-Muga, Mori-Eri and Mori-Thai, were fabricated from aqueous solutions and blended at different weight ratios, respectively. These silk-silk blend systems exploit the beneficial material properties of both silks. DSC and temperature-modulated DSC were used to measure the transition temperatures and heat capacity of these water-based silk-silk blend films. Fourier transform infrared spectrometer was used to characterize secondary structures of silk-silk blends. This study demonstrates that Mori silk are fully miscible with Tussah, Muga, Eri and Thai silk at different weight ratios without phase separation. Glass transition temperatures, degradation temperatures and the contents of alpha-helix and random coils of those silk-silk blend films can be controlled by changing the contents of different silks in the blend system. The features of Mori silk combined with the attributes of Tussah, Muga, Eri and Thai silk offer a useful suite of materials for a variety of applications in the future.

**M1.00100 Compatibility and Impact Resistance of Biodegradable Polymer Blends Using Clays and Natural Nanotubes**, YICHEN GUO, XUE YUAN, XIANGHAO ZUO, MIRIAM RAFAILOVICH, Stony Brook University — Montmorillonite clays and Halloysite nanotubes (HNTs) were modified by surface adsorption of resorcinol di (phenyl phosphate) (RDP) oligomers. Biodegradable poly (lactic acid) (PLA) and poly (butylene adipate-co-butylene terephthalate) (PBAT) polymers were blended together with RDP coated clays and tubes. TEM images of thin sections indicated that even though both RDP coated clay nanotubes and platelets located on the interfacial region between two immiscible polymers, only the platelets, having the larger aspect ratio, were able to reduce the PBAT domain sizes. The ability of clay platelets to partially compatibilize the blend was further confirmed by the dynamic mechanical analysis (DMA) which showed that the glass transition temperatures of two polymers tend to shift closer. Izod impact testing demonstrated that the rubbery PBAT phase greatly increased the impact strength of the unfilled blend, but addition of only 5% of clay filler decrease the impact strength by nearly 50% while a small increase was observed with nanotubes at that concentration. A simple model is proposed. The clay platelets are observed to cover the interfacial area. Although they are effective at reducing the interfacial tension, they block the entanglements between two polymer phase and increase the overall brittleness. On the other hand, the HNTs are observed to lie perpendicular to the interface, which makes them less effective in reducing interfacial tension, but far more effective at retarding micro-crack propagation.

**M1.00101 Hybrid Simulation Strategy for Simulating Self-Assembled Morphologies at the Atomistic Length Scales<sup>1</sup>**, VAIDYANATHAN SETHURAMAN, VENKAT GANESAN, Univ of Texas, Austin — In the context of Lithium-ion batteries, an enhancement in both ionic conductivity and mechanical properties, were observed for block copolymer electrolytes with increasing MW. On the contrary, when homopolymers were used as electrolytes, the ionic conductivity decreased with increasing MW. However, the origins of such increase in conductivity are unclear and are speculated to be tied to both the morphology and the atomistic details of the copolymer themselves. Motivated by such issues, we present a strategy to create ordered morphologies of block copolymers at the atomistic level using a combination of coarse-graining and inverse coarse-graining techniques. A mapping which is developed using the long-ranged structural mapping in the disordered phases will be utilized to generate self-assembled morphologies. In particular we focus on generating self-assembled morphologies of PS-PEO at the atomistic length scales. Statics and dynamics of such self-assembled morphologies will be presented and the effect of self assembly on the transport properties of ions will also be explored.

**M1.00102 Controlling Miscibility in Polyethylene-Polynorbornene Block Copolymers via Side-Group Chemistry.**, WILLIAM MULHEARN, RICHARD REGISTER, Princeton University — Block copolymers containing a crystallizable block, such as polyethylene (PE), and an amorphous block with high glass transition temperature ( $T_g$ ) are an interesting class of materials since the rigid glassy block can improve the mechanical response of the article under strain by reinforcing the crystal fold surface. However, to prepare an easily processable PE-containing block copolymer it is necessary to avoid microphase separation in the melt by selection of amorphous blocks with weak repulsive interactions against PE (low Flory interaction parameter  $\chi$  or interaction energy density  $X$ ). Most such low- $\chi$  polymers are chemically similar to PE, such as copolymers of ethylene and a small amount of an  $\alpha$ -olefin, and therefore exhibit similarly low glass transition temperatures. This work investigates a series of low- and high- $T_g$  polymers based on substituted norbornene monomers, polymerized via ring-opening metathesis polymerization (ROMP). Hydrogenated polynorbornene derivatives possess a wide range of glass transition temperatures, and miscibility with PE can be readily tuned by the choice of substituents on the monomers (e.g. aromatic vs. aliphatic groups). Two species investigated, hydrogenated poly(cyclohexyl norbornene) and hydrogenated poly(norbornyl norbornene), have high  $T_g$  and also remain miscible with polyethylene to high molecular weight. Furthermore, we develop a set of mixing rules to qualitatively predict the solubility behavior of substituted ROMP polynorbornenes as a function of their side-groups.

**M1.00103 Influence of Homopolymers on the Microdomain Behavior of Block Copolymers in 2D Confinement**, YOUNGKEOL KIM, SUNGYOUL HWANG, GUIDUK YU, KOOKHEON CHAR, Seoul Natl Univ — Constraints imposed by nanometer scale confinement lead to changes in bulk equilibrium behavior of block copolymers (BCPs). Cylindrical pores with diameters corresponding to the length equivalent of several copolymer chains have been employed to investigate the influence of two-dimensional confinement on the behavior of BCPs. In this study, we expand the scope to homopolymer-BCP binary blends. Given fraction of homopolymers, the phase behavior of blends is dependent on molecular weight ( $M_w$ ) of homopolymers. Lamella- and cylinder-forming poly(styrene-*b*-butadiene) (PS-*b*-PBD) and PS homopolymers (hPS) were drawn into the pores of anodized aluminum oxide (AAO) membranes in the melt by capillary forces. Based on the detailed observation of the morphologies within porous columns, we analyzed the structural transition of BCPs induced by the presence of hPS and confinement. The effect of hPS on the micro-domain of BCPs is greatly accentuated in nanoscale confinement compared to the bulk state due to the entropic loss of polymer chains. Pore diameters of AAO and  $M_w$  of the PS-*b*-PBD are also controlled so as to examine the effects of confinement on the phase transition of PS-*b*-PBD/hPS blends.

**M1.00104 Tunable Surface Energy Interlayer Coating to Control the Phase Behavior of Block Copolymers in 2D Confinement**, SUNGYOUL HWANG, YOUNGKEOL KIM, DOKYEONG KWON, KOOKHEON CHAR, Seoul Natl Univ — There have been many studies to investigate the phase behavior of block copolymers (BCPs) in cylindrical confinement. In the nanometer scale 2D confinement, the phase behavior of BCPs is mainly dependent upon commensurability and interfacial interaction. However, most studies have focused only on the effects of commensurability on the microdomains of BCP. In this study, we employed organosilicate (OS) which has tunable surface energy upon adjusting curing temperature as interlayer to examine the phase behavior of BCPs as a function of interfacial energy. The OS interlayer was coated in the inner surface of anodized aluminum oxide (AAO) pores by template-wetting method and cured in a range of temperature to control the surface energy of the interlayer. Lamellae-forming poly(styrene-*b*-methyl methacrylate) (PS-*b*-PMMA) (SMA) in the melt was injected into the OS-coated AAO pores by capillary forces. With the detailed analysis, we note that the self-assembly of SMA within 2D confinement is competitively affected by both entropic and enthalpic effects as the contact interfacial energy is varied. Simply by controlling the curing temperature of the OS interlayer, various morphologies arising from both preferential and neutral wetting were identified.

**M1.00105 Bottlebrush Copolymer Morphology Transition: Influence of Side Chain Length and Block Volume Fraction<sup>1</sup>**, YUE GAI, DONG-PO SONG, JAMES WATKINS, Univ of Mass - Amherst — Brush block copolymers synthesized via living ring-opening metathesis polymerization (ROMP) offer unique advantages as templates for functional hybrid materials. Unlike linear block copolymer, the bottlebrush polymer phase transition not only depends on volume fractions of the two blocks but also on side chain length. Here we report the morphology transitions of PS-*b*-PEO bottlebrush copolymer (BBCP) as a function of PEO side chain length and block volume fraction. For the BBCPs with similar side chain lengths, highly ordered lamellar morphologies were observed with PEO volume fractions in a wide range from 32 vol% to 72 vol%, which is significantly different from that of traditional linear block copolymers. This study will lay the groundwork for nanostructure fabrications using the BBCPs and provides new insights into the phase behavior of the new type of materials.

**M1.00106 Microwave Irradiation on Graphene Dispersed Within Polymeric Matrices.**, JORGE CISNEROS, BRIAN YUST, MIRCEA CHIPARA, Univ of Texas Rio Grande Valley — Graphene is a two dimensional nanomaterial with high thermal and electric conductivity and Young modulus. These features make graphene an ideal reinforcement for polymeric matrices. However, the mechanical features of polymer-carbon nanostructured composites are limited by the dispersion of the filler and by the delamination or microcracks initiated at the interface between the polymeric matrix and nanofiller. This last weakness can be addressed by improving the interface via chemical and physical methods. Microwave heating of graphite is a very efficient approach if the polymeric matrix does not also have a strong absorption. During the irradiation, the nanofiller is preferentially heated; the local melting of the polymer at the interface improves the interface by filling the microcracks and delaminations. Nanocomposites of polystyrene-poly(ethylene-*ran*-butylene)-polystyrene loaded by various amounts of graphene ranging from 0 % to 20 % wt. have been prepared by solution mixing using chloroform as solvent. The as obtained nanocomposites have been subjected to microwave irradiation in an Anton Paar Monowave 300 system operating at 75 W, for various irradiation times 5, 10, 15, 30, 45, and 60 minutes. The effect of microwave irradiation has been studied by Raman spectroscopy.

**M1.00107 Acoustic and Ultrasonic Spectral Evolution in Pre- and Post-Damage Self-Healing Poly (Ethylene Co-Methacrylic Acid) Ionomer Samples** , JONATHAN BUCKLEY, KENNETH PESTKA II, Longwood University, STEPHEN KALISTA, Department of Biomedical Engineering, Rensselaer Polytechnic Institute — We measured the pre- and post-damage resonant spectra of several self-healing ionomer samples composed of poly (ethylene co-methacrylic acid) (EMAA). The post-damage results indicate significant time-dependent variation in the acoustic and ultrasonic resonant spectral waveforms of these self-healing samples. These results are consistent with other recent experiments that demonstrate time evolution of resonant frequencies and associated quality factors within samples of post-damage EMAA ionomers. However, in our experiments it was found that, in some circumstances, the quality factors and associated resonant frequencies can exhibit time-dependent variation both before and after external damage. By quantifying time-dependent variations in the spectra of undamaged samples, including quality factor, resonant frequency and spectral waveform, we demonstrate a method to isolate changes in the resonant spectra that are present solely due to the post-damage healing behavior of these EMAA ionomers.

**M1.00108 Effect of charge density in chain extension reactions involving complexes of 4, 4'-diaminodiphenylmethane and various alkali metal salts** , SUBRAJEET DESHMUKH, KATHERINE CARRASQUILLO , FANG CHANG TSAI, LINA WU, SHAW LING HSU, University of Massachusetts Amherst, UNIVERSITY OF MASSACHUSETTS AMHERST TEAM — Controlling the reaction of methylene diphenyl diisocyanate (MDI)-terminated polyester prepolymer and 4, 4'-diaminodiphenylmethane (MDA) is extremely important in many large scale applications. The ion-diamine complex has the advantage of blocking the instantaneous reaction between the diamine and isocyanate from taking place until it is released at elevated temperatures. We synthesized complexes of MDA with various alkali metal salts. These complexes create a barrier between the diamine and isocyanate thus preventing the premature reaction. We compared the complexes in terms of their dissociation and the subsequent curing with the prepolymer. Charge density had a tremendous effect. DSC showed that Na complexes dissociated at a lower temperature and needed less energy to dissociate than the Li complexes. The effect of change in cation on complex dissociation was more pronounced compared to the change in anion. Also, the ionic liquid introduced greatly altered the dissociation behavior. Temperature and time resolved IR spectroscopy was used to monitor the urea and NH band. By DSC and IR, we showed that NaCl complex is best suited for the curing of prepolymer with regards to curing temperature and energy.

**M1.00109 Structural dynamics in polystyrene-b-polyisoprene copolymers with varying molecular architectures** , THOMAS KINSEY, MAXIMILIAN HERES, JIMMY MAYS, ROBERTO BENSON, JOSHUA SANGORO, Univ of Tennessee, Knoxville — A series of polystyrene-polyisoprene block copolymers with different molecular architectures are investigated by broadband dielectric spectroscopy and temperature modulated differential scanning calorimetry. The influence of copolymer composition on segmental and normal mode relaxation dynamics is analyzed. These results are discussed with respect to the current understanding of copolymer dynamics and interactions.

**M1.00110 How to Improve Ion Transport in Polymer Nanocomposites? Insights from Atomistic Simulations** , SANTHOSH MOGURAMPALLY, VENKAT GANESAN, Univ of Texas, Austin — We present different strategies to enhance ion conducting properties of polymer nanocomposite electrolytes and their implications by varying the surface chemistries of the nanoparticles and interactions between nanoparticle and components of polymer-salt mixture. Our molecular dynamics simulations suggest that the ionic mobilities and conductivities correlate with the combined effects of the changes in polymer segmental dynamics and the modifications in the local environment of ionic species arising from the introduction of nanoparticles. In the presence of  $\alpha$ ,  $\beta$  and  $\gamma$ - $\text{Al}_2\text{O}_3$  nanoparticles, we observe a monotonic decrease of ionic conductivities and mobilities with the nanoparticle loading due to the corresponding slowing of polymer dynamics. However, with the introduction of the repulsive interactions between nanoparticle and components of polymer-salt mixture, we find an increase in the mobility and conductivity of the polymer nanocomposites. However, the repulsive interactions seem to decrease the elastic moduli in contrast to the moduli enhancing effects by attractive interactions.

**M1.00111 STRUCTURE OF ANION-CONDUCTING POLYMERS FROM WAXS AND MD SIMULATIONS** , BARBARA FRISKEN, SEPEHR TAHMASEBI, ERIC SCHIBLI, STEVEN HOLDCROFT, Simon Fraser University — The structure of novel polymers for anion exchange membranes (AEMs) is investigated using wide angle X-ray scattering (WAXS) combined with molecular dynamics (MD) simulations using a united-atom force field model based on the DREIDING force field. The polymers being studied are poly(benzimidazole) (PBI) derivatives including poly(dimethylbenzimidazole) (PDMBI), mesitylene poly(benzimidazole) (mes-PBI), and mesitylene poly(dimethylbenzimidazole) (mes-PDMBI). WAXS reveals an amorphous structure with two main length scales. By comparing simulation results to WAXS data, we attribute features observed in the scattering data to side-to-side spacing between polymer chains and to the parallel-ring stacking of the benzimidazole rings. Overall, we are able to validate the interpretation of scattering data by combining MD simulations and scattering experiments.

**M1.00112 Charge Transport and Dynamics in Confined Phosphonium-based Ionic Liquids<sup>1</sup>** , TYLER COSBY, University of Tennessee, Knoxville, KATSUHIKO TSUNASHIMA, National Institute of Technology, Wakayama College, JOSHUA SANGORO, University of Tennessee, Knoxville — Charge transport and structural dynamics in a homologous series of phosphonium-based ionic liquids confined in silica nanopores are investigated by broadband dielectric spectroscopy and Fourier transform infrared spectroscopy. The impact of alkyl chain length and hydrophobic aggregation on the physicochemical properties as well as the interplay between confinement effects and pore-wall interactions through silica surface silanization are investigated. The results are discussed within the framework of current understanding of confinement effects in ionic liquid systems, especially in comparison to imidazolium-based ionic liquids.

<sup>1</sup>NSF DMR Polymers Program

**M1.00113 Charge Transport and Dynamics in Confined Ammonium and Phosphonium-based Ionic Liquids** , MATTHEW HARRIS, TYLER COSBY, Univ of Tennessee, Knoxville, KATSUHIKO TSUNASHIMA, National Institute of Technology, Wakayama College, JOSHUA SANGORO, Univ of Tennessee, Knoxville — Charge transport and structural dynamics in a homologous series of ammonium and phosphonium ionic liquids confined in silica nanopores are investigated by broadband dielectric spectroscopy and Fourier transform infrared spectroscopy. The impact of the central atom of the cation on the physicochemical properties as well as the interplay between confinement effects and pore-wall interactions through silica surface silanization are investigated. The results are discussed within the framework of current understanding of confinement effects in ionic liquid systems, especially in comparison to imidazolium-based ionic liquids.

**M1.00114 Amphiphilic Zwitterionic Coatings for Marine Anti-Biofouling Applications.** , EDWIN WALKER JR, C. K. PANDIYARAJAN, KIRILL EFIMENKO, JAN GENZER, North Carolina State Univ — Marine biofouling is a problem plaguing the surfaces of cargo ships, military ships and submarines. Previous approaches have relied primarily on the use of Cu-based coatings, which have deleterious effects on aquatic life. Recently, the vast majority of research efforts have focused on the use of polymer brushes synthesized by controlled radical polymerization to create either, the commonly used PEG/PEO materials, amphiphilic alternatives or promising zwitterionic-based moieties. Our approach is based on copolymerizing N, N'-2-dimethylaminoethyl methacrylate (DMAEMA) and propargyl methacrylate (PgMA) in different molar ratios (typically, 1:1 and 3:1) using AIBN-based free radical initiator. The copolymers are then benzitized with 1, 3- propane sultone to obtain zwitterionic macromolecules. We create substrate-anchored hydrogels by casting the copolymers as films onto polystyrene-based substrates and crosslink them using a photo-active reagent benzophenone. We investigate the cross-linking reaction with IR, the thickness and swelling as a function of ionic strength and electrolyte using spectroscopic ellipsometry and the wettability using water contact angle. We study the resistance of the coatings towards non-specific protein adsorption using fibrinogen and BSA.

### M1.00115 How does the molecular network structure influence PDMS elastomer wettability?

, MATTHEW MELILLO, JAN GENZER, North Carolina State University — Poly(dimethylsiloxane) (PDMS) is one of the most common elastomers, with applications ranging from medical devices to absorbents for water treatment. Fundamental understanding of how liquids spread on the surface of and absorb into PDMS networks is of critical importance for the design and use of another application - microfluidic devices. We have systematically studied the effects of polymer molecular weight, loading of tetra-functional crosslinker, end-group chemical functionality, and the extent of dilution of the curing mixture on the mechanical and surface properties of end-linked PDMS networks. The gel and sol fractions, storage and loss moduli, liquid swelling ratios, and water contact angles have all been shown to vary greatly based on the aforementioned variables. Similar trends were observed for the commercial PDMS material, Sylgard-184. Our results have confirmed theories predicting the relationships between modulus and swelling. Furthermore, we have provided new evidence for the strong influence that substrate modulus and molecular network structure have on the wettability of PDMS elastomers. These findings will aid in the design and implementation of efficient microfluidics and other PDMS-based materials that involve the transport of liquids.

### M1.00116 The effects of elastocapillary length on the surface creasing instability of hydrogels

, TETSU OUCHI, Univ of Mass - Amherst, QIHAN LIU, ZHIGANG SUO, Harvard University, RYAN HAYWARD, Univ of Mass - Amherst — Creasing is a mode of surface instability induced by compressing elastomers or gels. Formation of creases is known to proceed by a nucleation and growth process, and the critical nucleus size is thought to be determined by the elastocapillary length (defined by the ratio of surface tension to elastic modulus). Here, we vary the elastocapillary length over the range of 0.008 to 0.4 mm by preparing a series of soft hydrogels with different compositions and contacting them with humidified air. By rapidly applying compression, we are able to achieve strains that exceed the Maxwell strain (where creases become favorable compared to a flat surface) by more than 0.10, and which approach Biot's prediction for linear instability of a compressed half-space. Regardless of the conditions, however, we observe formation of creases only by nucleation and growth, although the density of nucleation sites is found to be sensitive to elastocapillary length. Interestingly, fast propagation of creases (at velocities similar to the speed of sound in the material) are found at strains approaching Biot's point.

### M1.00117 Computer Simulations of Bottlebrush Melts and Soft Networks<sup>1</sup>

, ZHEN CAO, Univ of Akron, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, SERGEI SHEIKO, Univ of NC - Chapel Hill, ANDREY DOBRYNIN, Univ of Akron — We have studied dense bottlebrush systems in a melt and network state using a combination of the molecular dynamics simulations and analytical calculations. Our simulations show that the bottlebrush macromolecules in a melt behave as ideal chains with the effective Kuhn length  $b_K$ . The bottlebrush induced bending rigidity is due to redistribution of the side chains upon backbone bending. Kuhn length of the bottlebrushes increases with increasing the side-chain degree of polymerization  $n_{sc} \propto b_K \propto n_{sc}^{0.46}$ . This model of bottlebrush macromolecules is extended to describe mechanical properties of bottlebrush networks in linear and nonlinear deformation regimes. In the linear deformation regime, the network shear modulus scales with the degree of polymerization of the side chains as  $G_0 \propto (n_{sc} + 1)^{-1}$  as long as the ratio of the Kuhn length to the size of the fully extended bottlebrush backbone between crosslinks,  $R_{max}$ , is smaller than unity,  $b_K/R_{max} \ll 1$ . Bottlebrush networks with  $b_K/R_{max} \propto 1$  demonstrate behavior similar to that of networks of semiflexible chains with  $G_0 \propto n_{sc}^{0.5}$ . In the nonlinear deformation regime, the deformation dependent shear modulus is a universal function of the first strain invariant  $I_1$  and bottlebrush backbone deformation ratio  $\beta$  describing stretching ability of the bottlebrush backbone between crosslinks.

### M1.00118 Modeling polymer gel that strengthen under tension

, SANTIDAN BISWAS, VICTOR V. YASHIN, ANNA C. BALAZS, Univ of Pittsburgh — We develop a constitutive model of a responsive polymer gel, which can reversibly form additional crosslinks when under tension. We assume that the polymer chains incorporate the folded domains encompassing the reactive functional groups (cryptic sites). Under extension of the network, the domains unfold and expose the cryptic sites, which can then form labile bonds with the linker chains grafted to the network. Once the deformation is removed, the linkers detach from the cryptic sites, and unfolded domains go back to the folded configuration thus hiding the cryptic sites. The gel behavior under applied force is described by the equations of elasticity of the polymer network coupled to the kinetic equations for the folding and binding transitions. The developed model could be used for designing new polymer gel-based materials that exhibit self-strengthening in response to a mechanical action.

### M1.00119 Modeling thermal-mechanical behavior of networks with reconfigurable crosslinks<sup>1</sup>

, JE-CHANG YANG, YUAN MENG, MITCHELL ANTHAMATTEN, University of Rochester — Actively moving polymers nearly always involve the storage or release of mechanical energy using external stimuli. Thermomechanical experiments were conducted on well-defined chemical networks bearing both permanent and light-reconfigurable covalent junctions. Experimental data include stress relaxation and mechanical creep during photoinduced network reconfiguration as well as equilibrium stress-strain behavior of reprogrammed networks. Physical models of elastic networks were applied to describe thermomechanical behavior during and after bond re-formation while under external stress. The role of dangling ends in influencing competitive network mechanics is evaluated to explain observed phenomena and discrepancies between theory and data. Understanding how process path is related to the equilibrium thermomechanics of such reprogrammed networks is important to engineering shape actuator driven by crystallization.

### M1.00120 Imparting large macroscopic changes with small changes in polypeptide composition

, MICHELLE SING, GARETH MCKINLEY, BRADLEY OLSEN, Massachusetts Institute of Technology — Block copolymers composed of polypeptides provide an excellent platform for exploring the underlying physics surrounding macroscopic associative network behavior. Previous work in our group has elucidated a difference in the mechanical properties of two nearly identical elastin-like polypeptide (ELP) endblocks. In poly(ELP)s, this substitution is known to result in tighter beta turns. These beta turns exhibit slower responses to changes in temperature within the material. Under shear, the modulus for the alanine-containing ELP triblock is almost three times higher than the glycine-containing ELP. Additionally, preliminary tensile tests show higher stress and strain at break for the alanine ELP triblock. We are able to explain the reasons for this behavior using a variety of spectroscopic and analytical techniques. Small angle neutron and x-ray scattering indicate differences in ordering between the alanine and glycine containing ELP materials both in shear and in stagnant flow.

### M1.00121 Effect of Temperature and Strain on a Self-assembled Gel

, SATISH MISHRA, SANTANU KUNDU, Mississippi State University — Gels are widely used in food industry and biomedical field. For physically associating gels, mechanical properties depend on the nature of association between the polymer and the solvent. A thermoreversible, physically associating gel is considered here, which consists of 10% (v/v) poly (methyl methacrylate) - poly (n-butyl acrylate) - poly (methyl methacrylate) in butanol, a midblock selective solvent. Below gelation temperature, the end blocks collapse and form aggregates, and the mid-blocks act as bridges between those aggregates. Rheo-SANS experiments were conducted on these samples where small angle neutron scattering (SANS) and shear-rheology experiments are combined. SANS data were collected over a wide temperature range, from 65C to -10C with and without strain. Near the gelation temperature, SANS data can be fitted with hard sphere model. However, with decrease of temperature, structural changes, due to clustering of aggregates, are observed. The SANS and rheological results in combination provide insight in structural changes of the gel with strain and temperature, respectively.

**M1.00122 Rubber Elasticity for percolation network consisting of Gaussian Chains**, KENGO NISHI, Georg-August-Universitt Gttingen, MITSUHIRO SHIBAYAMA, TAKAMASA SAKAI, The University of Tokyo — A theory describing the elastic modulus for percolation networks of Gaussian chains on general lattices such as square and cubic lattices is proposed and its validity is examined with simulation and mechanical experiments on well-defined polymer networks. The theory was developed by generalizing the effective medium approximation for Hookian spring network (EMA) to Gaussian chain networks. From EMA theory, we found that the ratio of the elastic modulus at  $p, G$  to that at  $p = 1, G_0$ , must be equal to  $G/G_0 = (p - 2/f)/(1 - 2/f)$  if the position of sites can be determined so as to meet the force balance, where  $p$  is the degree of cross-linking reaction. However, the EMA prediction cannot be applicable near its percolation threshold because EMA is a mean field theory. Thus, we combine real-space renormalization and EMA, and propose a theory called real-space renormalized EMA, i.e., REMA. The elastic modulus predicted by REMA is in excellent agreement with the results of simulations and experiments of near-ideal diamond lattice gels.

Please set this talk on Mon, Tue, or Wed (March 14-16) just after its accompanying talk, MAR16-2015-000773.

**M1.00123 Nonlinear Stress Relaxation of “Quasi-monodisperse Polyisoprene and Poly(*ptert*-butylstyrene)**, HIROSHI WATANABE, YUMI M.

Viscoelastic relaxation was examined for entangled miscible blends of *cis*-polyisoprene (PI) and poly(*ptert*-butylstyrene) (PtBS) therein,  $\tau_{PI}$  and  $\tau_{PtBS}$ , changed with the composition  $w_{PI}$  and the molecular weights  $M_{PI}$  and  $M_{PtBS}$ .  $w_{PI}$ ,  $M_{PI}$ , and  $M_{PtBS}$  values were chosen adequately. For example, in a blend with  $w_{PI} = 0.75$ ,  $M_{PI}/\tau_{PtBS} = 1$  and  $M/M_e = 55$  and  $8.3$  for PI and PtBS. Under small strains, this blend exhibited a single relaxation peak, thereby behaving as a “quasi-monodisperse” material. Under large step strains, the blend showed two relaxation peaks, known as the type-A damping for entangled monodisperse homopolymers. Nevertheless, PI had  $M/M_e = 55$  and PtBS had  $M/M_e = 8.3$ . Large  $M/M_e$  ratio exhibit very strong type-C damping. Thus, as compared to homopolymers, the nonlinear relaxation of the blend with large  $M/M_e$  ratio. This suppression is discussed in relation to the slow Rouse retraction of the coexisting PtBS chains.

(I have to take off on Thursday).

**M1.00124 Bidirectional Control of Flow in Thin Polymer Films by Photochemically Manipulating Surface Tension**, CHAE BIN KIM, DUSTIN JAMES, SUNSHINE ZHOU, AUSTIN DULANEY, CHRISTOPHER ELLISON, The University of Texas at Austin — The Marangoni effect causes transport of liquids in response to surface tension gradients. In a thin polymer film, such flow results in formation of topographic features that could be exploited as a practically useful route to manufacture patterned surfaces. An especially versatile material for this application should be able to be spatially programmed to possess regions of higher or lower relative surface tension so that the direction of flow into or out of those regions can be directed with precision. To this end, we describe here a photopolymer whose melt-state surface tension can be selectively raised or lowered in light exposed regions depending on the wavelength and dose of applied light. The direction of Marangoni flow into or out of irradiated regions agrees with expected surface tension changes associated with each photochemical transformation. We believe this patterning methodology will be potentially useful for high throughput fabrication environments such as roll-to-roll processing that can exploit contact-free and solvent-free topography development.

**M1.00125 Dynamics of associating polymers and the sticky Rouse model: a study by combined dielectric and dynamic mechanical techniques**, YANGYANG WANG, Oak Ridge National Laboratory, TYLER COSBY, JOSHUA SANGORO, University of Tennessee, Knoxville — Reversible association through non-covalent bonding is ubiquitous in the soft matter world. Despite decades of studies, the dynamics of associating polymers have not been well understood. Here we examine the dynamics of butadiene- and isoprene-based polymeric systems with pairwise association through hydrogen bonding. Compared to ionomers, where reversible crosslinks are typically not well defined, these hydrogen bonding polymers are associated through strictly binary contacts and thus provide a better opportunity to test theoretical ideas. By combining dielectric spectroscopy and dynamic mechanical measurement, we are able to identify both chain and junction dynamics and analyze their motional coupling mechanism. The results are discussed in the context of the sticky Rouse model.

**M1.00126 Evolution of Yield Stress during Structural Relaxation for the Epoxy 828DEA<sup>1</sup>**, GABRIEL ARECHEDERRA, JOHN MCCOY, New Mexico Tech, JAMIE KROPKA, Sandia National Laboratories — The evolution of yield stress from structural relaxation of diethanolamine cured diglycidyl ether of bisphenol-A, 828DEA, was tracked using uniaxial compression experiments. Samples were aged isothermally for up to 3 months at 5 temperatures ranging from deep in the glass to above  $T_g$ . Since 828DEA has remaining reactive potential, it is anticipated that the  $T_g$  will continue to evolve throughout the course of the study as new chemical crosslinks are formed. Consequently, it is important to track the evolution of  $T_g$  as well as the progression of the fictive temperature in order to interpret the evolution of yield stress.

**M1.00127 Can Stress Relaxation Experiments be Used to Assess Deformation Induced Mobility in Glassy Polymers?**, JAMIE KROPKA, KEVIN LONG, Sandia National Laboratories — The observance of an increase in glassy polymer relaxation rates under a mechanical deformation is often referred to as deformation induced mobility (DIM). It has been argued that stress relaxation experiments can provide indirect evidence of this phenomenon. Recently, stress relaxation experiments have been interpreted as demonstrating a mobility decrease with increased deformation when very slow strain rates,  $1.2 \times 10^{-5} \text{ s}^{-1}$ , are used to apply the deformation. This would suggest against generality of DIM and would have significant implications to constitutive models founded on this principle. Here, a mathematical exercise is performed to evaluate the implications of DIM on stress relaxation response. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Administration under contract DE-AC04-94AL85000.

**M1.00128 Chain networking revealed by molecular dynamics simulation**, YEXIN ZHENG, MESFIN TSIGE, SHI-QING WANG, Department of Polymer Science, University of Akron — Based on Kremer-Grest model for entangled polymer melts, we demonstrate how the response of a polymer glass depends critically on the chain length. After quenching two melts of very different chain lengths (350 beads per chain and 30 beads per chain) into deeply glassy states, we subject them to uniaxial extension. Our MD simulations show that the glass of long chains undergoes stable necking after yielding whereas the system of short chains is unable to neck and breaks up after strain localization. During ductile extension of the polymer glass made of long chain significant chain tension builds up in the load-bearing strands (LBSs). Further analysis is expected to reveal evidence of activation of the primary structure during post-yield extension. These results lend support to the recent molecular model<sup>1</sup> and are the simulations to demonstrate the role of chain networking. This work is supported, in part, by a NSF grant (DMR-EAGER-1444859)

**M1.00129 How plasticizer makes a ductile polymer glass brittle?**<sup>1</sup>, YUE ZHAO, XIAOXIAO LI, SHI-QING WANG, Univ of Akron — During uniaxial extension, a polymer glass of high molecular weight is ductile at high temperatures (still below  $T_g$ ) and turns brittle when the temperature is sufficiently lowered. Incorporation of small-molecular additives to polymer glasses can speed up segmental relaxation considerably. The effect of such plasticization should be to make the polymers more ductile. We examined the effect of blending a few weight percent of either triphenyl phosphate (TPP) or a mineral oil to a commercial-grade PS and PMMA. Our Instron tests show that the plasticized PS is less ductile. Specifically, at 70 °C, the original PS is ductile at an extensional rate of 0.02 s<sup>-1</sup> [1] whereas the PS with 4 wt. % TPP turns brittle. Mechanical spectroscopic measurements show that the alpha relaxation time is shortened by more than two orders of magnitude with 4 wt. % TPP. On the other hand, such anomalous behavior did not occur in PMMA. We need to go beyond the conventional description to rationalize these results. [1] Li, X.; Wang, S. Q. ACS Macro Letters 2015, 1110-1113.

**M1.00130 Surface diffusion of molecular glasses: Material dependence and impact on physical stability**<sup>1</sup>, SHIGANG RUAN, WEI ZHANG, LIAN YU, University of Wisconsin-Madison — Surface diffusion coefficients have been measured for molecular glasses tris-naphthylbenzene (TNB) and PMMA oligomers by surface grating decay. Surface diffusion on TNB is vastly faster than bulk diffusion, by a factor of  $10^7$  at  $T_g$ , while the process is very slow on PMMA. Along with the previous results on *o*-terphenyl, nifedipine, indomethacin, and polystyrene oligomers, we find that surface diffusion slows down with increasing molecular size and intermolecular forces, whereas bulk diffusion has a weaker material dependence. The molecular glasses studied show fast crystal growth on the free surface. A general correlation is observed between the coefficient of surface diffusion and the velocity of surface crystal growth, indicating surface crystallization is supported by surface mobility. (Zhu, L., et al. *Phys. Rev. Lett.* 106 (2011): 256103; Zhang, W., et al. *J. Phys. Chem. B* 119 (2015): 5071-5078)

**M1.00131 Liquid Crystalline Phases of Polymer Brushes**<sup>1</sup>, KIANA AMINI, NASSER ABUKHDEIR, MARK MATSEN, University of Waterloo — The phase behavior of liquid-crystal polymeric brushes in solvent are investigated using self-consistent field theory. The polymers are modeled as freely-jointed chain consisting of  $N$  rigid segments. The isotropic interactions between the polymer and the solvent are treated using the standard Flory-Huggins theory, while the anisotropic liquid-crystalline (LC) interactions between rigid segments are taken into account using the Mayer-Saupe theory. For weak LC interactions, the brush exhibits the conventional parabolic-like profile, while for strong LC interactions, the polymers crystallize into a dense brush with a step-like profile. At intermediate interaction strengths, we find the microphase-segregated phase observed previously for lattice-model calculations.<sup>2</sup> In this phase, the brush exhibits a crystalline layer next to the grafting surface with an external layer similar to the conventional brush.

**M1.00132 Thermal Characterization of Thermotropic Nematic Liquid-Crystalline Elastomers**, DAVID THOMAS, MATT CARDARELLI, Tufts University, ANTONI SANCHEZ-FERRER, ETH Zurich, BADEL L. MBANGA, TIMOTHY J. ATHERTON, PEGGY CEBE, Tufts University — Nematic Liquid-Crystalline Elastomers (LCEs) are weakly crosslinked polymeric networks that exhibit rubber elasticity and liquid-crystalline orientational order due to the presence of mesogenic groups. Three end-on side-chain nematic LCEs were investigated using real-time synchrotron wide-angle X-ray scattering (WAXS), differential scanning calorimetry (DSC), and thermogravimetry (TG) to correlate thermal behavior with structural and chemical differences among them. The elastomers differed in crosslinking density and mesogen composition. Thermally reversible glass transition temperature,  $T_g$ , and nematic-to-isotropic transition temperature,  $T_{ni}$ , were observed upon heating and cooling for all samples. By varying the heating rate,  $T_g^0$  and  $T_{ni}^0$  were determined at zero heating rate. The temperature dependence of the orientational order parameter was determined from the anisotropic azimuthal angular distribution of the equatorial reflection seen during real-time WAXS experiments. Our results show that the choice of crosslinking unit, its shape, density, as well as the structure of co-monomers, all influence the temperature range over which the thermal transitions take place.

**M1.00133 Crystal Growth Theory for Random Copolymers of Crystallizable and Non-crystallizable Units**, HERVE MARAND, HADI MOHAMMADI, Virginia Tech, Department of Chemistry — While the presence of randomly distributed non-crystallizable units (e.g. short branches in metallocene linear low density polyethylene) has been carefully considered in the thermodynamics of copolymers crystallization, it has been mostly ignored in the analysis of crystal growth rate data. In this work, we present an extension of the Lauritzen-Hoffman (LH) secondary nucleation theory that considers crystal growth processes for random copolymers of crystallizable and non-crystallizable units. Concentrating on the distribution of crystallizable unit sequence lengths rather than the whole polymer chain, rate equations in the LH theory are modified to account for the population of crystallizable sequences able to form a specific number of folds. We then calculate the flux over the nucleation barrier for each lamellar thickness, the secondary nucleation rate,  $i$ , the substrate completion rate,  $g$ , and derive the crystal growth rate,  $G$ , as a function of crystallization temperature. The model also allows prediction of the lamellar thickness distribution as a function of crystallization temperature. In qualitative agreement with literature data, our model predicts lower crystal growth rates and higher average lamellar thicknesses for m-LLDPE than for linear polyethylene at the same undercooling.

**M1.00134 Flow-induced Crystallization of Long Chain Aliphatic Polyamides under a Complex Flow Field**<sup>1</sup>, XIA DONG, YUNYUN GAO, LILI WANG, DUJIN WANG, Beijing National Laboratory for Molecular Sciences, CAS Key Laboratory of Engineering Plastics, Institute of Chemistry CAS — The present work deals with the flow-induced multiple orientations and crystallization structure of polymer melts under a complex flow field. This complex flow field is characteristic of the consistent coupling of extensional pulse and closely followed shear flow in a narrow channel. Utilizing an ingenious combination of an advanced micro-injection device and long chain aliphatic polyamides, the flow-induced crystallization morphology was well preserved for ex-situ synchrotron micro-focused wide angle X-ray scattering as well as small angle X-ray scattering. The experimental results clearly indicate that the effect of extensional pulse on the polymer melt is restrained and further diminished due to either the transverse tumble of fountain flow or the rapid retraction of stretched high molecular weight tails. However, the residual shish-kebab structures in the core layer of the far-end of channel suggest that the effect of extensional pulse should be considered in the small-scaled geometries or under the high strain rate condition.

**M1.00135 Effects of mechanical strain and heat on the strain-induced crystalline  $\beta$  to  $\alpha$  structural transition of syndiotactic polystyrene.** , FUYUAKI ENDO, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University — The polymorphic behavior of syndiotactic polystyrene (sPS) during the  $\beta$  to  $\alpha$  form transition was investigated. sPS presents complex polymorphism with five crystalline forms. Quite a few crystalline structural transitions have also been reported, including our recent discovery of the structural transition from  $\beta$  to  $\alpha$  forms induced by tensile deformation at around 200C. In this study, we analyzed the individual effects of mechanical strain and heat on the  $\beta$  to  $\alpha$  crystalline structural transformation caused by the mechanical deformation. sPS film samples containing  $\beta$  form crystals were prepared and stretched at 130C (near the glass transition temperature of sPS), followed by the annealing process of the samples below the melting temperature. X-ray analyses revealed that the stretched sample possessed mesomorphic  $\alpha$  forms, indicating that the mechanical strain could invoke the destruction of  $\beta$  form crystals by producing mesomorphic  $\alpha$  forms. Interestingly, the annealed samples exhibited sharp X-ray reflections typical of  $\alpha$  forms, which became even sharper by the increase in the annealing temperature. It was therefore concluded that the heat could induce the structural transitions from mesomorphic  $\alpha$  forms to perfect  $\alpha$  forms.

**M1.00136 Tracing Poly(ethylene-oxide) Crystallization using Atomic Force Microscopy<sup>1</sup>** , XAVIER CAPALDI, SAMUEL AMANUEL, None — The early stages of nucleation and crystallization of Poly(ethylene-oxide) have been studied using Atomic Force Microscopy equipped with a heating and cooling stage. Effects of molecular weight and sample preparation techniques were studied using amplitude and frequency modulation. Mapping the viscoelastic behavior at different temperatures and has enabled the development of a relatively new technique for following the evolution of crystallization and melting of a semi-crystalline polymer.

<sup>1</sup>Tracing Poly(ethylene-oxide) Crystallization using Atomic Force Microscopy

**M1.00137 Viscoelastic Properties of Fluorinated Ethylene-Propylene (FEP) Random Copolymers<sup>1</sup>** , MEGAN CURTIN\*, BENJAMIN WRIGHT\*, Chemical and Biological Engineering, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Fluorinated ethylene-propylene (FEP) random copolymers contain tetrafluoroethylene (TFE) and hexafluoropropylene (HFP) repeat units. FEP is an excellent alternative to poly(tetrafluoroethylene), PTFE, which cannot be melt processed due to its high molecular weight and extensive crystallinity. On the other hand, FEP is a melt processible polymer and offers similar if not the same properties as PTFE. Many studies have been performed on FEP over the years, however, the properties of these polymers strongly depend on the HFP concentration and molecular weight (distribution). Just like PTFE, FEP cannot be dissolved in many solvents, therefore, obtaining molecular weight distribution of these polymers is not possible with commonly used methods. In the current study, we perform rheological analysis of various FEPs and obtain their molecular weight distributions by employing the Tuminello method.

**M1.00138 Thermal Properties of Trogamid by Conventional and Fast Scanning Calorimetry<sup>1</sup>** , PEGGY CEBE, JOHN MERFELD, BIN MAO, Tufts University, ANDREAS WURM, EVGENY ZHURAVLEV, CHRISTOPH SCHICK, University of Rostock — We use conventional slow scan rate differential scanning calorimetry, and fast scanning chip-based calorimetry (FSC), to investigate the crystallization and melting behavior of Trogamid, a chemical relative of nylon. Fundamental thermal properties of Trogamid were studied, including the melt crystallization kinetics, heat of fusion, and the solid and liquid state heat capacities. Using slow scan DSC (at 5 K/min), Trogamid displays a glass transition relaxation process at ~133 C, melting endotherm peak at 250 C, and is stable upon repeated heating to 310 C. When using slow scan DSC, the isothermal melt crystallization temperatures were restricted to 225 C or above. Trogamid crystallizes rapidly from the melt and conventional calorimetry is unable to cool sufficiently fast to prevent nucleation and crystal growth prior to stabilization at lower crystallization temperatures. Using FSC we were able to cool nano-gram sizes samples at 2000 K/s to investigate a much lower range of melt crystallization temperatures, from 205-225 C. The experimental protocol for performing FSC on semicrystalline polymers to obtain liquid state heat capacity data will be presented.

**M1.00139 Polymer crystallization in thin films: morphology and physical properties** , GIOVANNI KELLY, JULIE ALBERT, Tulane University — Polymer crystallization has been studied both computationally and experimentally for decades, elucidating many of the mysteries surrounding crystallization kinetics and thermodynamics. However, many unanswered questions remain pertaining to the relationships between crystallization phenomena and material properties needed for specific applications that range from drug delivery and tissue engineering to optical devices and mechanically robust membranes. One of the especially interesting facets of polymer crystallization is the behavior observed when these long chain molecules are spatially confined in thin and ultrathin films. Confined geometry leads to chain configurations, and therefore thermal, mechanical, and optical properties, sometimes far removed from reported bulk values. This project aims to study the phenomena exhibited by linear semi-crystalline polymers in thin films as well as the way in which blending with homopolymers, block copolymers, and novel polymer chain architectures affect morphology, biodegradation, optical, thermal, and mechanical properties.

**M1.00140 Morphological Evolution During Tensile Deformation in Semi-Crystalline Precise Functional Copolymers via Fitting of *In Situ* Xray Scattering** , EDWARD B. TRIGG, L. ROBERT MIDDLETON, University of Pennsylvania, BRIAN S. AITKEN, University of Florida, JASON AZOULAY, DUSTIN MURTAGH, Sandia National Laboratories, KENNETH B. WAGENER, University of Florida, JOSEPH CORDARO, Sandia National Laboratories, KAREN I. WINEY, University of Pennsylvania — Morphological evolution during tensile deformation of semi-crystalline polymers is often described qualitatively. The layered crystal structures of precise copolymers, in which functional groups are bonded at precise intervals along the polymer backbone, allow for quantitative fitting of oriented X-ray scattering peaks to provide additional information. The crystallites in precise poly(ethylene-co-acrylic acid) align with the acid group layers' normal vector *parallel* to the tensile direction, while those in precise poly(ethylene-co-imidazolium bromide) align with the layers' normal vector *perpendicular* to the tensile direction. We present fits of *in situ* X-ray scattering during tensile deformation of semi-crystalline precise copolymers, to quantify the size, shape, and degree of orientation of the crystallites during the deformation process. Mathematical descriptions of the X-ray scattering in these two cases is explored, and a physical explanation for the difference in alignment direction is proposed.

**M1.00141 Probing polyethylene crystallization via simultaneous Raman scattering, rheology and microscopy** , KALMAN MIGLER, ANTHONY KOTULA, ANGELA HIGHT WALKER, NIST — The structure and rheology of polyolefins during crystallization is of critical importance to the polymer processing industry. Here we present simultaneous Raman scattering, rheological and optical microscopy measurements of crystallizing high density polyethylenes during quiescent and slow flow conditions. Raman scattering measurements during quiescent crystallization allow us to quantify three different mass fractions of chain conformers: an amorphous fraction, an orthorhombic crystalline fraction, and a fraction of chains that contain many consecutive trans bonds but are not part of the orthorhombic crystal. These non-crystalline consecutive trans (NCCT) conformers are generated as a precursor to crystallinity. Slow steady shear rates ( $1 \leq \dot{\gamma} \leq 1$ ) applied during isothermal crystallization experiments dramatically increase the crystallization rate as well as the amount of NCCT conformers produced. Optical measurements of sheared samples during crystallization reveal the formation of fiber structures that compositionally contain more NCCT conformers than the surrounding melt. The increase in the complex shear modulus commonly measured for crystallizing polyethylenes correlates with the growth of chain conformers and the appearance of spherulites within the melt.

**M1.00142 Molecular simulations of the formation of semi-crystalline structure from super-cooled polyethylene melt**, PENG YI, Johns Hopkins Univ — Formation of semi-crystalline structure is important for industrial processing, but it is scientifically poorly understood due to the strong anisotropy and the conformational flexibility of polymer chains. In this work we report the results of molecular dynamics simulations of homogeneous crystallization from polyethylene melts. A realistic united atom model was used. At room temperature (~30% supercooling), the crystal nucleation and growth lead to a stable semi-crystalline structure, with crystal lamellae separated by amorphous regions. Entanglement in the amorphous region prevents further crystal growth. The crystal-amorphous interface migrates with changing annealing temperature. Chain segments in the amorphous region adopt loop, bridge and tail conformations. Their populations and lengths were calculated and analyzed.

**M1.00143 Engineering Multi-scale Electrospun Structure for Integration into Architected 3-D Nanofibers for Cimex Annihilation: Fabrication and Mechanism Study.**, SHAN HE, LINXI ZHANG, stony brook university, YING LIU, Advanced Energy Research and Technology Center, MIRIAM RAFAILOVICH, Stony Brook University, GARCIA CENTER FOR POLYMERS AT ENGINEERED INTERFACES TEAM — In this study, engineered electrospun scaffolds with fibers oriented with designed curvature in three dimensions (3D) including the looped structure were developed based on the principle of electrostatic repulsion. Here we illustrate that 3D electrospun recycled polystyrene fibers could closely mimic the unique architectures of multi-direction and multi-layer nano-spiderweb. In contrast to virgin PS, the recycled PS (Dart Styrofoam) are known to contain zinc stearate which acts as a surfactant resulting in higher electrical charge and larger fiber curvature, hence, lower modulus. The surfactant, which is known to decrease the surface tension, may have also been effective at decreasing the confinement of the PS, where chain stretching was shown to occur, in response to the high surface tension at the air interface. Three dimensional flexible architecture with complex structures are shown to be necessary in order to block the motion of Cimex lectularius. Here we show how an engineered electrospun network of surfactant modified polymer fibers with calculated dimensions can be used to immobilize the insects. The mechanical response of the fibers has to be specifically tailored so that it is elastically deformed, without fracturing or flowing. Carefully controlling and tailoring the electrospinning parameters we can now utilize architected 3D nanofiber to create an environmental-friendly Cimex immobilization device which can lead to annihilation solution for all the other harmful insects.

**M1.00144 From Non-equilibrium to Equilibrium: Micellar Kinetics seen by Time-resolved Small-angle Scattering**, REIDAR LUND, Department of Chemistry, University of Oslo — The kinetic pathways of self-assembled nanostructures are not fully understood. Time-resolved small-angle X-ray/neutron scattering (TR-SAXS/SANS) is powerful technique<sup>1</sup> that allows kinetics processes such as nucleation processes<sup>2,3</sup> and morphological transitions<sup>4,5</sup> to be followed with structural resolution over time scales starting from milliseconds. Neutrons offer the additional advantage of facile contrast variation through H/D substitution schemes, which also allow equilibrium processes such as molecular exchange and diffusion to be studied<sup>1,6,7</sup>. Here we will highlight the current capabilities of TR-SAS and show results on the kinetics of polymeric micelles. We will address how the understanding of kinetic pathways can be used control the nanostructure.

**M1.00145 Characterization and Molecular Simulation of Poly(p-phenylene/m-phenylene) Copolymers.**<sup>1</sup>, ROBERT BUBECK, Michigan State University, STEVEN KEINATH, Michigan Molecular Institute - Retired — Characterization and molecular simulation of the molecular structure and microstructure of poly(p-phenylene/m-phenylene) copolymers were carried out. Tensile modulus, yield stress, and entanglement molecular weight were modeled as amorphous polymers as a function of m-phenylene content. Significant biphasic character, however, was observed for two copolymers in the melt near 300°C using variable temperature synchrotron-based WAXS. The biphasic nature of the melt may be a contributor to difficulty in melt processing. Precise experimental determinations of entanglement molecular weights were frustrated by the occurrence of significant amounts of nematic mesophasic order in the rubbery and melt regimes of two commercial poly(p-phenylene/m-phenylene) examples. Nonetheless, entanglement molecular weights obtained by molecular modeling can be useful for experimental guidance because the level of order in the glassy phase near ambient temperature was found to be low (5 %) regardless of melt processing history. Based on both the modeling and WAXS measurements, it is believed that increasing m-phenylene content reduces modulus, and improves toughness and processibility.

**M1.00146 Thermal Conductivity behavior of MWCNT based PMMA and PC composites**, GIRIJA DUBEY, York College-CUNY, NY11451, PRASHANT JINDAL, University Institute of Engineering & Technology, Panjab University, 160014, India, RAJIV BHANDARI, NEHA DHIMAN, CHETAN BAJAJ, VIJAY JINDAL, Department of Physics, Panjab University, Chandigarh 160014, India — Poly methyl methacrylate (PMMA) and Polycarbonate (PC) are low cost polymer materials which can be easily transformed into desired shapes for various applications. However they have poor mechanical, thermal and electrical properties which are required to be enhanced to widen their scope of applications specifically where along with high strength, rapid heat transfer is essential. Multi Walled Carbon nanotubes (MWCNTs) are excellent new materials having extraordinary mechanical and transport properties. We will report results of fabricating composites of varying compositions of MWCNTs with PMMA and PC and their thermal conductivity behaviour using simple transient heat flow methods. The samples in disk shapes of around 2 cm diameters and 0.2 cm thickness with MWCNT compositions varying up to 10 wt% were fabricated. We found that both PMMA and PC measured high thermal conductivity with increase in the composition of CNTs. The thermal conductivity of 10wt% MWCNT/PMMA composite increased by nearly two times in comparison to pure PMMA.

**M1.00147 Rheological Properties of a Polybutadiene/Clay Nano-Composite Crosslinked via Thiol-ene Click Chemistry** , VIJESH TANNA, H. HENNING WINTER, Univ of Mass - Amherst — We have created an industrially feasible processing method to create a novel polybutadiene/clay nanocomposite. The fabrication step was designed such the final composite would be chemically crosslinked with exfoliated clay sheets dispersed randomly throughout the polymer matrix. Due to the polybutadiene's high functionality, the composite's storage modulus was shown to increase by several orders of magnitude due to crosslinking. In addition, the effect of reinforcements due to clay was shown to double the storage modulus of the composite due to the high elasticity of individual clay sheets. Surprisingly, we observed a critical crossover frequency,  $w_c$ , below which the mechanical properties, complex modulus, of the neat crosslinked polymer slightly exceed that of the composite. This transition may be due to the large lateral dimensions of the individual clay sheets, hundreds of microns, preventing a small number of crosslinks from forming. We have shown that reinforcement from both chemical crosslinks and clay significantly improves the mechanical properties of the polybutadiene/clay composite and have quantified this reinforcement over a wide range of temperatures and frequencies.

**M1.00148 Quantum Molecular Dynamics Validation of Nanocarbon Synthesis by High-Temperature Oxidation of Nanoparticles<sup>1</sup>** , CHUNYANG SHENG, KENICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, Collaboratory for Advanced Computing and Simulations, KOHEI SHIMAMURA, FUYUKI SHIMOJO, Department of Physics, Kumamoto University, PRIYA VASHISHTA, Collaboratory for Advanced Computing and Simulations, DEPARTMENT OF PHYSICS, KUMAMOTO UNIVERSITY COLLABORATION, CACS USC COLLABORATION — High-temperature oxidation of silicon-carbide nanoparticles (nSiC) underlies a wide range of technologies from high-power electronic switches for efficient electrical grid, thermal protection of space vehicles, to self-healing ceramic nanocomposites. Here, multimillion-atom reactive molecular dynamics simulations validated by *ab initio* quantum molecular dynamics simulations predict unexpected condensation of large graphene flakes during high-temperature oxidation of nSiC. In the validation process Small nSiC in oxygen environment is chosen to perform QMD simulation, then the QMD results provide the number of Si-O and C-O bonds as a function of time and high temperature. Same RMD simulation is simultaneously performed. We compare the time evolution of different bonds, and observe the condensation of large number of C-cluster nuclei into larger carbon clusters. We further provide the QMD simulation results as an input to a genetic algorithm, which trains the RMD force field parameters, the output force field produce results that are closer to the ground truth QMD simulation results.

**M1.00149 Role of Entropic Barriers in Controlling Polymer Diffusion in Polystyrene Nanocomposites** , PHILIP GRIFFIN, WEI-SHAO TUNG, University of Pennsylvania, JEFFREY METH, Dupont, NIGEL CLARKE, University of Sheffield, RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — Polymer diffusion in polymer nanocomposites (PNCs) is significantly modified relative to the neat state. While it is suspected that nanoparticle-induced confinement plays a key role in the diffusion process, a detailed understanding of this process remains nonetheless elusive. We present recent studies of the temperature dependent polymer center-of-mass tracer diffusion coefficient in an athermal PNC comprising polystyrene and phenyl-capped, spherical silica NPs using elastic recoil detection. We find that the polymer tracer diffusion coefficient in the PNC relative to the bulk decreases with increasing nanoparticle concentration and is unexpectedly more strongly reduced at higher temperatures. This unusual temperature dependence of polymer diffusion in PNCs cannot be explained by the reptation model or a modified version incorporating an effective tube diameter, but instead it is the direct result of entropic free energy barriers imposed on polymer chains under confinement.

**M1.00150 Morphology and Transport Properties of Novel Polymer Nanocomposites Resulted from Melt Processing of Polyvinylacetate Substrates Coated with Layer-by-Layer Assemblies** , IMAN SOLTANI, RICHARD J. SPONTAK, North Carolina State Univ — Novel polymer nanocomposites (PNCs) were processed through layer-by-layer (LBL) deposition of clay and polyethylene terephthalate ionomer layers on polyvinylacetate (PVAc) substrates, followed by repetitive melt pressing of coated samples to crush LBL assemblies into the polymeric matrix. The increase in the clay content in resulted PNCs prepared through similar LBL coatings, relative to previously studied hydrophobic polystyrene-based nanocomposites, postulated superiority of PVAc, with relatively higher hydrophilicity, to interact with LBL assemblies. Also, these PNCs showed relatively good barrier improvement against transport of oxygen and carbon dioxide gases, proposing the scavenging effect of LBL assemblies crushed portions as highly tortuous labyrinths with high aspect ratios, comprising edge-edge flocculated exfoliated clay platelets, observed through transmission electron micrographs. However, combinative morphological investigations through optical microscopy, x-ray diffractometry, and transmission electron microscopy proposed low global dispersion of clay throughout polymeric matrix, conjecturing insufficient intensity of stress applied through cyclic melt pressing, and/or slight thermal degradation of samples via extended times of processing at high temperatures.

**M1.00151 Polymer Dynamics by Dielectric Spectroscopy** , JENNIFER ZEHNER, KARIN BICHLER, GERALD SCHNEIDER, Louisiana State University Chemistry Department — Theoretical modeling of polymer dynamics is fundamentally important to describe experimental results and to develop new materials. There are many different processes in polymers covering a very broad time range. Dielectric spectroscopy is able to cover a broad frequency range, around 10 decades. Thus many different processes can be studied and it provides a unique means to explore the processes and the time-scales. In our presentation, we emphasize how the line-shape permits to derive information on certain mechanisms. We use entangled melts and demonstrate the influence of entanglements, contour length-fluctuations and constraint release on the spectra and describe it by a theory. Furthermore, we compare it to rheology experiment and demonstrate those parts which are complimentary. We use this knowledge to achieve an advanced understanding of polymer dynamics in nanocomposites.

**M1.00152 Polymer Dynamics in Blends** , KARIN BICHLER, JENNIFER ZEHNER, GERALD SCHNEIDER, Louisiana State University Chemistry Department — Depending on their miscibility mixtures of polymers or polymers and nanoparticles tend to phase separate. Such systems are of fundamental interest. For example, in case of a blend of two polymer melts a dynamic asymmetry may be generated. It could slow down the chains in one phase or accelerate the chains in the other phase. Due to their heterogeneity these systems are of fundamental interest. Using a certain technique it is very challenging to access all of the information necessary to understand the materials and the interplay between different phases. In order to enhance our understanding, we apply dielectric spectroscopy, scattering experiments and atomic force microscopy to reveal both structure and dynamics and to unravel the fascinating processes.

**M1.00153 Nonadiabatic Dynamical Studies of Lead Chalcogenide Quantum Dots (Pb<sub>16</sub>X<sub>16</sub>; X = S, Se, Te) Passivated with thin Cadmium Chalcogenide Shells** , PATRICK TAMUKONG, SVETLANA KILINA, North Dakota State University — DFT and TDDFT studies of Pb<sub>16</sub>X<sub>16</sub>/Cd<sub>52</sub>Y<sub>52</sub> (X, Y = S, Se, Te) Core/Shell quantum dots (QDs) have been performed to assess their ground (i.e., the optimized geometries, density of states, projected density of states, and optical absorption spectra), and excited state properties. Most of the heterostructures were analyzed for the first time (e.g., Pb<sub>16</sub>S<sub>16</sub>/Cd<sub>52</sub>Te<sub>52</sub> and Pb<sub>16</sub>Te<sub>16</sub>/Cd<sub>52</sub>Se<sub>52</sub>). The thin shell core/shell QDs proved to be largely borderline type II with much similarity between QDs containing Cd<sub>52</sub>S<sub>52</sub> and Cd<sub>52</sub>Se<sub>52</sub> shells, whereas core/shell QDs with a Cd<sub>52</sub>Te<sub>52</sub> shell appeared to be borderline type-I. Nonadiabatic DFT-based dynamics, coupled with the surface hopping method, have been done to investigate fates of excited electrons or holes in these systems.

**M1.00154 Emergent Magnetism in Mesoporous Materials**, SHER ALAM, KEK Accelerator Lab, AJAYAN VINU, University of Queensland — We discuss the emergence of magnetism in Mesoporous Materials. We have obtained experimental results showing a variety of magnetic behaviors arising, by using different types of mesoporous or nanoporous templates. Since the templates allow different magnetic properties to arise naturally we have dubbed this as dynamic templating method. Our procedure and realization incidentally demonstrates the idea of Nanoarchitectonics proposed by Aono, as a MANA concept. Which, simply means to allow different nano-blocks to interact to obtain a certain desired structure and properties.

**M1.00155 Using Self-Similarity to Simulate Meniscus Evolution Around TMV Due to Surface Diffusion**<sup>1</sup>, RICHARD POTTER, YUE ZHANG<sup>2</sup>, ZAHRA FAKHRAAI<sup>3</sup>, Univ of Pennsylvania — It has been hypothesized that enhanced surface diffusion allows the formation of stable molecular glasses during physical vapor deposition. The improved properties of these glasses, such as increased density and kinetic stability can help improve material properties in pioneering fields of technology such as organic electronics and pharmaceutical drug delivery. While surface diffusion has been measured previously on the surfaces of organic glasses, direct measurements on the surface of vapor-deposited stable glasses has proven more challenging. This research focuses on a straightforward method for measuring the surface diffusion coefficients of molecular glasses through the use of tobacco mosaic virus (TMV) nanorods as probe particles. In conjunction, mathematical models based on the thin film equation were used to simulate fast meniscus formation around the nanorods on the glassy surface. The evolution of the meniscus is self-similar, which allows quick quantification of the diffusion coefficient, by solving the time evolution for a single experiment. Experimental data were compared and fit to these simulations to derive a quantity for the surface diffusion coefficient,  $D_s$ .

**M1.00156 Interfacial damping properties of polymeric composites: Effect of interfacial strength**, YAPING HUANG, Nanyang Institute of Technology — Experimental studies on interfacial properties of polymeric composites, such as glass transition temperature, showed that the interfacial strength was critical. Numerical studies could also predict interfacial properties based on interfacial strength. In this study, interfacial damping properties and interfacial strength of fiber based polymeric composites were measured by dynamic mechanical tests and micro-bond tests, respectively, with the objective of quantitative analysis. Properties of polymers, varying from polar to non-polar, from amorphous to semi-crystalline, from low molecular weight to high molecular weight, were investigated. The results showed supportive predictions about interfacial damping properties of fiber based polymeric composites.

**M1.00157 Equilibrium flattening process of irreversibly adsorbed polymer chains on a solid**<sup>1</sup>, MANI SEN, Materials Science and Engineering (MSE), Stony Brook University (SBU), NY, NAISHENG JIANG, MAYA ENDOH, TADANORI KOGA, MSE, SBU, DAISUKE KAWAGUCHI, KEIJI TANAKA, Kyushu University, Japan — We here report the equilibrium process of adsorbed polymer chains on a solid by sum frequency generation (SFG) spectroscopy. Polystyrene (PS,  $M_w = 290$  kDa) thin films prepared onto quartz prisms (a weakly attractive system) were used as a model system. Spin-cast PS 50 nm films on quartz surface (QS) were annealed at  $150\text{ }^\circ\text{C} > T_g$  for up to 100 h and subsequently rinsed with chloroform to derive the “flattened chains” that lie flat onto the substrate surface. The SFG results for the “matured” flattened chains after annealing for 96 h revealed the strong interfacial orientation of the backbone chains and weak orientation of PS phenyl rings at the QS which is in contrast to a PS spin-cast film annealed at  $150\text{ }^\circ\text{C}$  for 1 h: the phenyl rings were strongly directed toward the QS, while the backbone chains were weakly orientated at the QS. We postulate that the increase in the number of solid/segment contacts of the backbone chains is the driving force for this equilibrium flattening process. We will also discuss the generality of this flattening process by using solvent-cast PS thin films where the chains are randomly oriented near the QS.

**M1.00158 Phase Transitions of 2-Decanol in Nano Pores**<sup>1</sup>, SAMUEL AMANUEL, JASON TURNER, CALEB NOVINS, ALEXANDER CLAIN, Dept. of Phys & Astro., Union College — We studied the melting of 2-decanol confined in nano pores, 10-100 nm, using a power-compensated Differential Scanning Calorimeter (DSC). The melting temperature of the nano confined 2-decanol decreases as pore size decreases and a linear relationship is observed between the melting temperature and the inverse of the pore size. This is in agreement with the Gibbs-Thomson prediction. In addition, the apparent heat of fusion of the 2-decanol confined in the nano pores appears to decrease as the size of the pores decreases. However, the apparent heat of fusion of the nano confined 2-decanol may not necessarily be its true heat of fusion. Annealing, for instance, increases the apparent heat of fusion by as much as 26%. A correction or alternate procedure should be employed to extract the true heat of fusion from DSC measurements, especially when the physical size of the sample is in nano scale or the sample possesses a large surface area to volume ratio.

<sup>1</sup>This work was partially supported by NSF-DMR: 1229142.

**M1.00159 Heat of fusion of primary alcohol confined in Nano pores.**<sup>1</sup>, HARRISONN GRIFFIN, SAMUEL AMANUE, Dept. of Phys. & Astro., Union College — Melting behavior of physically confined 1-decanol in nano porous silica was probed using a Differential Scanning Calorimeter (DSC). In agreement with the Gibbs-Thompson prediction, we observe that the melting temperature of the confined 1-decanol scales inversely with the physical size of the pores. Contrary to the assumption used in developing the Gibbs-Thompson equation, however, the apparent heat of fusion decreases as the pore size decreases. Previously, several models have been proposed where the interfacial layer/s of molecules do not participate in the phase transition and thereby would not contribute to the heat of fusion. While these could reconcile the seeming contradiction, annealing the nano confined materials enables some of the interfacial layers to be incorporated into an existing crystal. This leads to an increase in the apparent heat of fusion and a systematic relationship exists between the annealing temperature and the increase in the apparent heat of fusion.

**M1.00160 Structure and Dynamics of Polymers in Cylindrical Nanoconfinement: A Molecular Dynamics Study**, JAMES PRESSLY, ROBERT RIGGLEMAN, KAREN WINEY, Univ of Pennsylvania — The structure and dynamics of polymers under nanoconfinement is critical for understanding how polymers behave in applications from hydraulic fracking to fabricating integrated circuits. We previously used simulations to explore the effect of the diameter of cylindrical pores ( $d = 10-40\sigma$ , where  $\sigma$  is the unit length in reduced units) on polymer end-to-end distance ( $R_{ee,perp}$ ,  $R_{ee,par}$ ), entanglement density, melt diffusion coefficient ( $D$ ), and local relaxation time ( $\tau_{perp}$ ,  $\tau_{par}$ ) at fixed polymer chain length ( $N = 350$ ). These studies found  $D$ ,  $R_{ee,par}$ , and  $\tau_{perp}$  increased with increasing confinement while entanglement density,  $R_{ee,perp}$ , and  $\tau_{par}$  decreased. Experiments also found that  $D$  increased but to a lesser extent. Here, we examine the molecular weight dependence of these properties using  $N = 25, 50, 100, 200, 350$ , and 500 confined to pores of diameter  $14\sigma$  to examine a range of confinements. Our preliminary results show that as  $N$  increases  $D$  and  $R_{ee,par}$  increase as well, relative to the unconfined state, while entanglement density and  $R_{ee,perp}$  decrease, consistent with our previous work. Interestingly,  $\tau$  is shown to be independent of chain length indicating the impact of confinement imposed by reducing pore diameter is distinct from that imposed by increasing chain length.

## **M1.00161 Man-made Earthquakes & Multifractals in Neutral Fluid Turbulence/Injection<sup>1</sup>**

WH- MAKSOED<sup>2</sup>, Prodi of Physics UI, Depok 16424- INDONESIA — Man-made earthquakes coincides with induced seismicity: "typically minor earthquakes & tremors that are caused by human activity that alters the stresses & Strains on the earth crust" [Wikipedia: "induced seismicity"]. For these, RD Andrews wrote: "Based on observed seismicity rate & geographical trends following major oil & gas plays with large amounts of produced water, the rates & trends in seismicity are very unlikely to represent a naturally occurring process". "The Prague, Oklahoma, earthquake sequence of 2011, along the Wilzetta faults zone, included the significant foreshock, a main shock of magnitude 5.7, it has been suggested that this sequence represent earthquakes triggered by fluid injection/natural fluid turbulence shows multifractal characteristics, of [405]-325-7968 of Dr. G. ## **M1.00162 FLUIDS —**

### **M1.00163 Chemically generated convective transport in microfluidic system**

OLEG SHKLYAEV, Department of Chemical Engineering, The University of Pittsburgh, SAMBEETA DAS, ALICIA ALTEMOSE, Department of Chemistry, The Pennsylvania State University, HENRY SHUM, ANNA BALAZS, Department of Chemical Engineering, The University of Pittsburgh, AYUSMAN SEN, Department of Chemistry, The Pennsylvania State University — High precision manipulation of small volumes of fluid, containing suspended micron sized objects like cells, viruses, and large molecules, is one of the main goals in designing modern lab-on-a-chip devices which can find a variety of chemical and biological applications. To transport the cargo toward sensing elements, typical microfluidic devices often use pressure driven flows. Here, we propose to use enzymatic chemical reactions which decompose reagent into less dense products and generate flows that can transport particles. Density variations that lead to flow in the assigned direction are created between the place where reagent is fed into the solution and the location where it is decomposed by enzymes attached to the surface of the microchannel. When the reagent is depleted, the fluid motion stops and particles sediment to the bottom. We demonstrate how the choice of chemicals, leading to specific reaction rates, can affect the transport properties. In particular, we show that the intensity of the fluid flow, the final location of cargo, and the time for cargo delivery are controlled by the amount and type of reagent in the system.

### **M1.00164 Flow reversal in enzymatic microfluidic pumps**

HENRY SHUM, University of Pittsburgh, ISAMAR ORTIZ-RIVERA, ARJUN AGRAWAL, AYUSMAN SEN, Pennsylvania State University, ANNA BALAZS, University of Pittsburgh — A chemical reaction occurring at an enzyme-covered patch in a closed fluid chamber generates local solute concentration gradients and, hence, fluid density gradients. This has recently been shown to drive fluid flows with speeds of the order of microns per second. We develop and analyze a model that accounts for fluid density changes due to consumption of the reaction substrate and accumulation of products for such a fluid pump based on the enzyme urease. Hydrolysis of urea by urease produces ammonium bicarbonate, which leads to a net increase in solution density. Higher density fluid is expected to sink and spread horizontally away from the pump. Modeling reveals, however, that the local fluid density is not necessarily greatest near the pump and fluid flow can even reverse in direction after some time. The qualitative behavior depends on two dimensionless parameters, the ratio of solutal expansion coefficients and the ratio of diffusion coefficients for the reaction substrate and product. The predicted reversal of pumping direction is experimentally verified and we show that the direction of pumping also depends on the amount of enzyme present on the patch. A better understanding of these pumps will aid in the design of responsive, chemically powered microfluidic flow control.

### **M1.00165 Phase transitions analogy for cavity flows.**

PETRU FODOR, MIRON KAUFMAN, Physics, Cleveland State University — The fluid flow in cavity type systems, in which one of the walls is moving while the others are stationary, is analyzed using computational modeling, under the assumption of no-slip boundary conditions. By iteratively adapting the mesh used, we are able to map with high spatial resolution the complex flow structures that form at the two types of corners of the cavity, i.e. (i) corners defined by stationary walls, and (ii) corners defined by a stationary and the moving wall, respectively. For the structures that form in the vicinity of the fixed points defined by the corners, we observe that the flow magnitudes and spatial distributions follow scaling laws similar with critical phenomena. In particular, the behavior at the first type of corner is analogous to a first-order transition (discontinuity) point, while the behavior at the second one is analogous to a thermodynamic critical point (second-order transition). These results provide a unique insight into the solution to Navier-Stokes equations for cavity flows.

### **M1.00166 A Statistical investigation of sloshing parameters for multiphase offshore separators**

MD MAHMUD<sup>1</sup>, Lamar University, RAFIQU KHAN<sup>2</sup>, Cameron Corp, QIANG XU<sup>3</sup>, Lamar University — Liquid sloshing in multiphase offshore separators has been the subject of intense investigations for last several decades both by experiments and simulations. Large number scientists have worked to minimize sloshing impacts and others have developed new methods to describe the sloshing patterns. In addition, complex mathematical models are developed to characterize sloshing phenomenon. However, a comprehensive statistical study of the input parameters and output results is yet to be done. In this study, statistical approaches will be considered to determine the significant parameters for liquid sloshing. The factor analysis and principal component analysis techniques are considered to identify the significant parameters for liquid sloshing. Numerical experiments are carried out through Computation Fluid Dynamics (CFD) technique using ANSYS Fluent software. The input parameters considered here are liquid depth/length ratio, acceleration, wave frequencies, amplitudes in various sea state conditions. The measured variables include hydrodynamic force, pressure, moments, turbulent kinetic energy, height of interfaces. Mathematical correlations may be developed from the data analysis.

### **M1.00167 Efficient Combustion Simulation via the Adaptive Wavelet Collocation Method**

KEVIN LUNG, ERIC BROWN-DYMKOSKI, VICTOR GUERRERO, ERIC DORAN, KEN MUSETH, JO BALME, BOB URBERGER, ANDRE KESSLER, STEPHEN JONES, BILLY MOSES, ANTHONY CROGNALE, Space Exploration Tech (SpaceX) — Rocket engine development continues to be driven by the intuition and experience of designers, progressing through extensive trial-and-error test campaigns. Extreme temperatures and pressures frustrate direct observation, while high-fidelity simulation can be impractically expensive owing to the inherent multi-scale, multi-physics nature of the problem. To address this cost, an adaptive multi-resolution PDE solver has been designed which targets the high performance, many-core architecture of GPUs. The adaptive wavelet collocation method is used to maintain a sparse-data representation of the high resolution simulation, greatly reducing the memory footprint while tightly controlling physical fidelity. The tensorial, stencil topology of wavelet-based grids lends itself to highly vectorized algorithms which are necessary to exploit the performance of GPUs. This approach permits efficient implementation of direct finite-rate kinetics, and improved resolution of steep thermodynamic gradients and the smaller mixing scales that drive combustion dynamics. Resolving these scales is crucial for accurate chemical kinetics, which are typically degraded or lost in statistical modeling approaches.

**M1.00168 Dual-Mode Measurement and Theoretical Analysis of Evaporation Kinetics of Binary Mixtures**<sup>1</sup>, HANYU SONG, Mechanical Engineering, University of Connecticut, CHI-RUEI HE, Chemical Engineering, National Chung Hsing University, CARL BASDEO, JI-QIN LI, DEZHUANG YE, Mechanical Engineering, University of Connecticut, DEVENDRA KALONIA, School of Pharmacy, University of Connecticut, SI-YU LI, Chemical Engineering, National Chung Hsing University, TAI-HSI FAN, Mechanical Engineering, University of Connecticut — Theoretical and experimental investigations are presented for the precision measurement of evaporation kinetics of binary mixtures using a quartz crystal resonator. A thin layer of light alcohol mixture including a volatile (methanol) and a much less volatile (1-butanol) components is deployed on top of the resonator. The normal or acoustic mode is to detect the moving liquid-vapor interface due to evaporation with a great spatial precision on the order of microns, and simultaneously the shear mode is used for in-situ detection of point viscosity or concentration of the mixture near the resonator. A one-dimensional theoretical model is developed to describe the underlying mass transfer and interfacial transport phenomena. Along with the modeling results, the transient evaporation kinetics, moving interface, and the stratification of viscosity of the liquid mixture during evaporation are simultaneously measured by the impedance response of the shear and longitudinal waves emitted from the resonator. The system can be used to characterize complicated evaporation kinetics involving multi-component fuels.

## **M1.00169 SOFT CONDENSED MATTER —**

**M1.00170 Spin-resolved conductance of Dirac electrons through multibarrier arrays**, DIPENDRA DAHAL, Graduate Center and Hunter College of City University of New York, 695 Park Avenue, New York, NY 10065, USA, GODFREY GUMBS, Hunter College of City University of New York, 695 Park Avenue, New York, NY 10065, USA, ANDRII IUROV, Center for High Technology Materials, University of New Mexico, Albuquerque, NM 87106, USA — We use a transfer matrix method to calculate the transmission coefficient of Dirac electrons through an arbitrary number of square potential barrier in gapped monolayer graphene (MLG) and bilayer graphene (BLG). The widths of barriers may not be chosen equal. The shift in the angle of incidence and the width of the barrier required for resonance are investigated numerically for both MLG and BLG. We compare the effects due to energy gap on these two transmission coefficient for each of these two structures (MLG and BLG). We present our results as functions of barrier width, height as well as incoming electron energy as well as band gap and examine the conditions for which perfect reflection or transmission occurs. Our transmission data are further used to calculate conductivity.

**M1.00171 Dielectric Screening Response of a Plasmonic "Sandwich"**, N.J.M. HORING, Department of Physics and Engineering Physics, Stevens Institute of Technology, Hoboken, NJ 07030, GODFREY GUMBS, DIPENDRA DAHAL, Department of Physics and Astronomy, Hunter College, CUNY, New York, NY 10065, ANDRII IUROV, Center for High Technology Materials, University of New Mexico, Albuquerque, NM 87106 — We have formulated the RPA integral equation for a system composed of two identical semi-infinite metallic plasmas with planar bounding surfaces at  $z = \pm d/2$ . The gap between the two metallic bulk plasmas contains a two-dimensional semiconductor plasma at  $z=0$ . This equation for the inverse dielectric function is solved analytically in position representation for a narrow gap, yielding an explicit formula for the inverse dielectric screening function in terms of the nonlocal 2D semiconductor polarizability and the bulk metallic polarizability, the latter well approximated in the local limit. Based on this solution, we have evaluated the nonlocal plasmon dispersion relation computationally, taking Graphene as the 2D semiconductor plasma. The associated nonlocal Graphene plasmon spectrum coupled to the sandwich system is exhibited in 3D plots, which show a linear mode and another displaced from the bulk plasma frequency.

**M1.00172 EM Wave Transmission through a Nano-hole in a Plasmonic Layer**, DESIRE DESIRE MIESSEIN, NORMAN J. MORGENSTERN HORING, HARRY LENZING, Department of Physics and Engineering Physics, Stevens Institute of Technology, Hoboken, NJ 07030, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College, CUNY, New York, NY 10065 — We examine the role of the angle of incidence of an incoming EM wave in its transmission through a subwavelength nano-hole in a thin semiconductor plasmonic layer. Fully detailed calculations and results are exhibited for p- and s-polarizations of the incident wave for a variety of incident angles in the near, middle and far zones of the transmitted radiation. Our dyadic Greens function formulation includes both (1) the electromagnetic field transmitted directly through the 2D plasmonic layer and (2) the radiation emanating from the nano-hole. Interference fringes due to this superposition are explicitly exhibited. Based on an integral equation formulation, this dyadic Greens function approach does not involve any appeal to metallic boundary conditions. It incorporates the role of the 2D plasmon of the semiconductor layer, which is smeared due to its lateral wave number dependence. We find that the interference fringes, which are clustered near the nano-hole, flatten to a uniform level of transmission directly through the sheet alone at large distances from the nano-hole.

**M1.00173 Modeling heterogeneous polymer-grafted nanoparticle networks**, TAO ZHANG, BADEL MBANGA, VICTOR YASHIN, ANNA BALAZS, Chemical Engineering Department, University of Pittsburgh, Pennsylvania 15261, USA — Via a dynamic 3D computational approach, we simulate the heterogeneous polymer-grafted nanoparticle networks. The nanoparticles rigid cores are decorated with a corona of grafted polymers, which contain reactive functional groups at the chain ends. With the overlap of grafted polymers, these reactive groups can form weak labile bonds, which can reform after breakage, or stronger bonds, which rupture irreversibly and thus, the nanoparticles are interconnected by dual cross-links. Previous work has been done on homogeneous networks, while we introduce the heterogeneity by considering two types of particles having different reactive functional groups, so that the labile bond energy varies depending on types of the two end reactive groups. We study the effect of tensile and rotational deformations on the network morphology, and observe, in particular, the phase separation of two types of particles. Our results will provide guidelines for designing transformable material that can controllably change structure under mechanical action.

**M1.00174 Adhesion of Particulate Materials to Mesostructured Polypyrrole**, DARBY HOSS, Purdue University, ROBERT KNEPPER, PETER HOTCHKISS, ALEXANDER TAPPAN, Sandia National Laboratories, BRYAN BOUDOURIS, STEPHEN BEAUDOIN, Purdue University — Interactions based on van der Waals (vdW) forces will influence the performance and reliability of mesostructured polypyrrole swabs used for the collection and detection of trace particles. The vdW adhesion force between materials is described by the Hamaker constant, and these constants are measured via optical and dielectric properties (i.e., according to Lifshitz theory), inverse gas chromatography (IGC), and contact angle measurements. Here, contact angle measurements were performed on films of several common materials and used to estimate Hamaker constants. This, in turn, will allow for the tuning of the design properties associated with the polypyrrole swabs. A comparison of these results to Hamaker constants estimated using Lifshitz Theory and IGC reveals the fundamental behavior of the materials. The Hamaker constants were then used in a new computational vdW adhesion model. The idealized model describes particle adhesion to an array of mesostructures. This model elucidates the importance of where the particle makes contact with the mesostructure and the independence of vdW forces generated by each mesostructure. These results will facilitate the rational design of polypyrrole swabs optimized for harvesting microscale particles of trace materials.

**M1.00175 Droplet Dynamics of a Flowing Emulsion System**, OLIVIA CYPULL, KLEBERT FEITOSA, James Madison University — The inner workings of glassy systems have long been a topic of interest for soft material scientists. Similarities between the jamming behavior of emulsions and the glass transition of glassy systems have prompted the conjecture that they might share the same underlying mechanism. Here we study a dense oil-in-water emulsion system forced to flow through a narrow microchannel. By matching the index of refraction of the two phases, we image the internal dynamics of the droplets in a confocal microscope. At low velocity speeds, we find that the velocity along the edge of the microchannel was not significantly different than then the average droplet velocity in the bulk suggesting a near plug flow. By contrast the droplets near the edge experienced more movement perpendicular to the flow indicating the fluidization effect of the confining walls.

**M1.00176 Self-assembly in Dipolar Fluids<sup>1</sup>**, MICHELA RONTI, SOFIA KANTOROVICH, Univ of Vienna — We are studying low temperature structural transitions in dipolar hard spheres (DHS), combining grand-canonical Monte Carlo simulations and direct analytical theoretical calculations. DHS is characterized by long-range anisotropic interactions: it consists of a point dipole at the center of a hard sphere. We are interested in low temperature and low density phase behaviour of DHS systems. From a theoretical point of view the process of self-assembly is not responsible for a phase transition; this belief was completely reverted by theoretical studies showing that the process of self-assembly is alone capable to induce phase transition. On the other hand in the last years it was proved that no sign of critical behaviour is observed, implementing efficient and tailored Monte Carlo algorithms. Moreover a theoretical approach based on Density Functional Theory was developed: a series of structural transitions were discovered providing evidence of a hierarchy in the structures on cooling. We are performing free-energy calculations in order to draw the phase diagram of DHS model. Comparing the numerical results with the theoretical ones shed light on the scenario of temperature induced structural transitions in magnetic nanocolloids.

**M1.00177 Deconvolution of the role of metal and pH in metal coordinating polymers.<sup>1</sup>**, SETH CAZZELL, NIELS HOLTEN-ANDERSEN, Massachusetts Inst of Tech-MIT — Nature uses metal binding amino acids to engineer both mechanical properties and structural functionality. Some examples of this metal binding behavior can be found in both mussel foot protein and DNA binding protein. The mussel byssal thread contains reversible intermolecular protein-metal bonds, allowing it to withstand harsh intertidal environments. Zinc fingers form intramolecular protein-metal bonds to stabilize the tertiary structure of DNA binding proteins, allowing specific structural functionality. Inspired by both these metal-binding materials, we present mechanical and spectroscopic characterization of a model polymer system, designed to mimic this bonding. Through these studies, we are able to answer fundamental polymer physics questions, such as the role of pH and metal to ligand ratio, illuminating both the macroscopic and microscopic material behavior. These understandings further bio-inspired engineering techniques that are used to design viscoelastic soft materials.

**M1.00178 Optically induced thermal response of Chlorophyll for biomedical applications**, CHIAWEI TU, SADAT MD EHSAN, YUAN ZHAO, DONGLU SHI, DAVID MAST, Univ of Cincinnati — The heating behavior of Chlorophyll was investigated for possible use in hyperthermia cancer treatments. One measure of hyperthermia effectiveness is the Specific Absorption Rate (SAR) defined as the initial slope of the sample heating behavior, however, for nanoparticle (NP) loaded samples, this initial heating rate is often limited by heat transfer mechanisms from the NPs to the surrounding material and not the initial NP heating. This is especially true for water-based, NP loaded tissue surrogates. Organic solvent dispersed NP loaded samples face the additional problem of heating rate variations due to solvent evaporation effects. We report on measurements of the initial optical heating rates of Chlorophyll and deposited directly on small, Pt thin film resistance temperature detectors (RTDs). Solid state lasers (638 nm and 655 nm) were used to illuminate these samples at different intensities and at specific wavelengths associated with peaks (662 nm) in Chlorophyll's UV-VIS optical absorption spectra while recording the RTD resistance at 0.1 second intervals. This technique significantly reduce evaporation errors we had experienced and has the potential to directly measure the heating behavior of Chlorophyll based NP materials.

**M1.00179 Directed percolation identified as equilibrium pre-transition towards non-equilibrium arrested gel states**, MARCO LAURATI, RONJA CAPELLMANN, MATTHIAS KOHL, STEFAN EGELHAAF, MICHAEL SCHMIEDEBERG, University of Düsseldorf — The macroscopic properties of gels arise from their slow dynamics and load bearing network structure, which are exploited by nature and in numerous industrial products. However, a link between these structural and dynamical properties has remained elusive. Here we present confocal microscopy experiments and simulations of gel-forming colloid-polymer mixtures with competing interactions. They reveal that gel formation is preceded by continuous and directed percolation. Both transitions lead to system spanning networks, but only directed percolation results in extremely slow dynamics, ageing and a shrinking of the gel that resembles syneresis. Therefore, dynamical arrest in gels is found to be linked to a structural transition, namely directed percolation, which is quantitatively associated with the mean number of bonded neighbours. Directed percolation is a universality class of transitions out of equilibrium, our study hence connects gel formation to a well-developed theoretical framework which now can be exploited to achieve a detailed understanding of arrested gels.

**M1.00180 Novel coarse-graining approach for Star polymer and linear Homopolymer mixtures**, EMANUELE LOCATELLI, CHRISTOS LIKOS, University of Vienna — We present a novel coarse-graining approach, suitable for star polymer mixtures. The approach is based on the calculation of the effective interaction between a star polymer and a single monomer, which can be used to coarse-grain the interaction between a star and a complex object. The effective interaction has been calculated numerically for star polymers of different functionalities  $f$  and for different degrees of polymerization  $N$ . We find that these potentials can be scaled following the star polymer scaling laws. We test our approach, calculating the effective interaction between a star polymer and a linear homopolymer, comparing the results obtained from coarse graining and monomer resolved simulations. We employ this technique to study star - linear homopolymer mixtures, focusing on the limit of very long homopolymers.

**M1.00181 A simple depth-averaged model for dry granular flow**, CHI-YAO HUNG, National Taiwan University, COLIN P. STARK, Lamont-Doherty Earth Observatory, Columbia University, HERVÉ CAPART, National Taiwan University — Granular flow over an erodible bed is an important phenomenon in both industrial and geophysical settings. Here we develop a depth-averaged theory for dry erosive flows using balance equations for mass, momentum and (crucially) kinetic energy. We assume a linearized GDR-Midi rheology for granular deformation and Coulomb friction along the sidewalls. The theory predicts the kinematic behavior of channelized flows under a variety of conditions, which we test in two sets of experiments: (1) a linear chute, where abrupt changes in tilt drive unsteady uniform flows; (2) a rotating drum, to explore steady non-uniform flow. The theoretical predictions match the experimental results well in all cases, without the need to tune parameters or invoke an ad hoc equation for entrainment at the base of the flow. Here we focus on the drum problem. A dimensionless rotation rate (related to Froude number) characterizes flow geometry and accounts not just for spin rate, drum radius and gravity, but also for grain size, wall friction and channel width. By incorporating Coriolis force the theory can treat behavior under centrifuge-induced enhanced gravity. We identify asymptotic flow regimes at low and high dimensionless rotation rates that exhibit distinct power-law scaling behaviors.

**M1.00182 A Computational Study of the Growth of Hexagonal Ice.**, MAXWELL FULFORD, King's College London, UK, MATTEO SALVALAGLIO, UCL, UK, MICHELE PARRINELLO, ETH Zurich; USI Lugano, CARLA MOLTENI, King's College London, UK — Hexagonal ice (Ih) has two distinct crystallographic surfaces; a basal and prism surface. At low vapour pressures, Ih forms thin plates and elongated prisms, depending on the temperature. The macroscopic shape depends on the relative rate of growth of the basal and prism surfaces. The aim of our research is to estimate the relative rate of growth of the two surfaces for a range of temperatures and ultimately predict the shape of Ih, using computer simulations. Our simulations show the well-known phenomenon that the surface of ice lowers its interfacial free energy by forming a stable quasi-liquid layer (QLL). The QLL mediates crystal growth and has a thickness which varies with temperature and crystallographic surface. We use a combination of Molecular Dynamics and Metadynamics to study how the interfacial structure at the ice/quasi-liquid and quasi-liquid/vapour interfaces influence the adsorption potential, surface transport properties and growth shape..

**M1.00183 The mystery of Coulomb friction in sediment transport**<sup>1</sup>, THOMAS PHTZ, Ocean College, Zhejiang University, ORENCIO DURAN, MARUM-Center for Marine Environmental Sciences, University of Bremen — Nearly all analytical models of sediment transport in Newtonian fluid (e.g., air or water) are based on Bagnold's assumption of a constant Coulomb friction coefficient (particle-shear-pressure-ratio,  $\mu$ ) at the interface ( $z_b$ ) between sediment bed and transport layer. In fact, this assumption is the main reason why these models predict the sediment load (and subsequently the sediment transport rate) to be proportional to the excess shear stress ( $\tau - \tau_t$ ), a scaling which has been confirmed in many wind-tunnel and flume experiments. Attempts to explain why  $\mu(z_b)$  is constant have usually been based on the sliding-friction analogy or rheology arguments. However, here we analytically derive  $\mu(z_s) \approx \sqrt{3} - 1$ , where  $z_s$  is the location at which the production rate of particle fluctuation energy is maximal. Our derivation is based on the assumption that the rate of collisional transfer of horizontal into vertical kinetic energy is typically much larger than the rate of energy dissipation. Using state-of-the-art numerical simulations of sediment transport in Newtonian fluid, we validate all assumptions and approximation involved in our derivation. Interestingly, the location  $z_s$  can significantly deviate from  $z_b$  depending on the simulated conditions.

**M1.00184 Core formation by porous flow allowed by hysteresis in melt network topology**, SOHEIL GHANBARZADEH, MARC HESSE, MASHA PRODANOVIC, The University of Texas at Austin — The formation of the core via percolation is an attractive process to form planetary cores early in the planets evolution. There is currently a debate whether the ratio of interfacial forces between solid-solid and solid-liquid interfaces, imposing the dihedral angle between the solid grains and the pore fluid, in an olivine-melt matrix allows the formation of a percolating network. We present first computations of equilibrium melt distributions in realistic irregular grains and show that the percolation threshold at dihedral angles above 60 degrees is significantly larger than those previously reported for simple geometries. However, given typical compositions of the terrestrial planets initial porosities after the onset of melting of iron are large, 20-40threshold to form a connected melt network. As the porosity decreases due to melt segregation the network remains connected and allows core formation by porous flow. Only as the porosities approach 1and the iron become isolated in pockets along triple junctions. This residual iron may provide an explanation for the formation of dense layers near the core mantle boundary such as "

**M1.00185 Spontaneous Pattern Formation of Surface Nanodroplets from Competitive Growth**, DETLEF LOHSE, University of Twente, SHUHUA PENG, XUEHUA ZHANG, RMIT, Melbourne — Nanoscale droplets on a substrate are of great interest because of their relevance for droplet-based technologies for light manipulation, lab-on-chip devices, miniaturised reactors, encapsulation and many others. In this work, we establish a basic principle for the symmetrical arrangement of surface nanodroplets during their growth under simple flow conditions. In our model system, nanodroplets nucleate at the rim of spherical cap microstructures on a substrate, due to a pulse of oversaturation is supplied by a solvent exchange process. We find that, while growing at the rim of the microcap, the nanodroplets self-organise into highly symmetric arrangements, with respect to position, size, and mutual distance. The angle between the neighbouring droplets is four times the ratio between the base radii of the droplets and the spherical caps. We show and explain how the nanodroplets acquire the symmetrical spatial arrangement during their competitive growth and why and how the competition enhances the overall growth rate of the nucleated nanodroplets. This mechanism behind the nanodroplet self-organisation promises a simple approach for the location control of droplets with a volume down to attoliters.

**M1.00186 Decoupling between Diffusivity and Effective Viscosity in Poly(isobutyl methacrylate) Films with a Thickness-Independent Glass Transition**<sup>1</sup>, KUN GENG, Boston University Physics Department, REIKA KATSUMATA, University of Texas at Austin, McKetta Department of Chemical Engineering, XUANJI YU, Boston University Division of Materials Science and Engineering, HEONJOO HA, AUSTIN R. DULANEY, CHRISTOPHER J. ELLISON, University of Texas at Austin, McKetta Department of Chemical Engineering, OPHELIA K.C. TSUI, Boston University Physics Department, Division of Materials Science and Engineering — We report measurements of self-diffusion ( $D$ ) and effective viscosity ( $\eta_{\text{eff}}$ ) on silica-supported poly(isobutyl methacrylate) (PiBMA) thin films. These films had been found to exhibit thickness ( $h_0$ ) independence in the glass transition temperature,  $T_g$  ( $= 58^\circ\text{C}$ ). At  $T = 106^\circ\text{C}$ ,  $D$  was independent of  $h_0$ , consistent with  $T_g$ . On the other hand,  $\eta_{\text{eff}}$  decreased with decreasing  $h_0$ , indicating decoupling between  $D$  and  $\eta_{\text{eff}}$ . We contemplate that the decoupling is caused by dynamic heterogeneity in the film and that  $D$  and  $\eta_{\text{eff}}$  are different dynamic averages. Specifically, by using a layer model, where the film is divided into sub-layers with thickness  $h_i$  and local viscosity  $\eta_i$ , and assuming that  $D \sim k_B T / \langle \eta_i \rangle$  and  $\eta_{\text{eff}} \sim \langle h_i^3 / (3\eta_i) \rangle$ , we are able to account for all the measurements.

<sup>1</sup>We are grateful to the support of NSF through the project DMR-1310536 and DMR-1053293.

**M1.00187 Interfacial Bubble Deformations**<sup>1</sup>, BRIAN SEYMOUR, James Madison University, PARVIS SHABANE, Virginia Tech, OLIVIA CYPULL, James Madison University, SHENGFENG CHENG, Virginia Tech, KLEBERT FEITOSA, James Madison University — Soap bubbles floating at an air-water experience deformations as a result of surface tension and hydrostatic forces. In this experiment, we investigate the nature of such deformations by taking cross-sectional images of bubbles of different volumes. The results show that as their volume increases, bubbles transition from spherical to hemispherical shape. The deformation of the interface also changes with bubble volume with the capillary rise converging to the capillary length as volume increases. The profile of the top and bottom of the bubble and the capillary rise are completely determined by the volume and pressure differences.

**M1.00188 Temperature-dependent neutron diffraction measurements from D<sub>2</sub>O hydrating single-supported lipid bilayers of DMPC**<sup>1</sup>, Z. N. BUCK, J. TORRES, A. MAZZA, H. KAISER, H. TAUB, Univ. of Missouri - Columbia, F. Y. HANSEN, Technical University of Denmark, A. MISKOWIEC, Oak Ridge National Lab, M. TYAGI, NIST Center for Neutron Research — The freezing point depression of water associated with biological membranes, studied principally by NMR, has been of interest for decades. Here we have used neutron diffraction measurements at the University of Missouri Research Reactor (MURR) to investigate the freezing behavior of water associated with single-supported zwitterionic lipid bilayers composed of DMPC. Diffraction patterns obtained as a function of temperature reveal that water freezes abruptly into its hexagonal phase at 270 K with no evidence of amorphous ice. Following the initial crystallization of the membrane-associated water there is a region of continuous hexagonal crystal growth, which is believed to occur in the interfacial water closest to the membrane. The temperature-dependent intensity of the observed Bragg peaks have been compared with that of incoherently elastically-scattered neutrons collected on the High-Flux Backscattering Spectrometer at NIST from an identical sample hydrated with H<sub>2</sub>O [2]. We find excellent agreement between the two data sets, suggesting the absence of amorphous solid water and that all the water hydrating a DMPC membrane eventually freezes into the hexagonal crystalline phase. <sup>2</sup>M. Bai *et al.*, Europhys. Lett. **98**, 48006 (2012).

**M1.00189 Elasticity and Extensibility Determine Printability and Spinnability of Polymer Solutions** , JELENA DINIC, LEIDY JIMENEZ, VIVEK SHARMA, Univ of Illinois - Chicago — Many advanced manufacturing technologies like inkjet and 3D printing, nano-fiber spinning involve complex free-surface flows, and the formation of columnar necks that undergo spontaneous capillary-driven thinning and pinch-off. The progressive self-thinning of neck is often characterized by self-similar profiles and scaling laws that depend on the relative magnitude of capillary, inertial and viscous stresses for simple (Newtonian and inelastic) fluids. Stream-wise velocity gradients that arise within the thinning columnar neck create an extensional flow field that can orient and stretch macromolecules, contributing extra elastic stresses and extensional viscosity that change thinning and pinch-off dynamics for polymeric complex fluids. Characterizing the filament thinning and break-up kinetics in jetting, dripping and stretching liquid bridge provides invaluable insight into the interplay of elastic, viscous, capillary and inertial stresses relevant for these applications. We elucidate how polymer composition, flexibility and molecular weight determine the thinning and pinch-off kinetics in our experiments. Both effective relaxation time and transient extensional viscosity are found to be strongly concentration dependent even for dilute solutions.

**M1.00190 Patterns, Instabilities, Colors, and Flows in Vertical Foam Films** , SUBINUER YILIXIATI , YIRAN ZHANG , EWELINA WOJCIK , VIVEK SHARMA , Univ of Illinois - Chicago — Understanding and controlling the drainage kinetics of thin films is an important problem that underlies the stability, lifetime and rheology of foams and emulsions. We follow the drainage kinetics of vertical foam films using imaging and color science. Interference between light reflected from two surfactant-laden surfaces that are 100 nm - 10 micron apart leads to thickness-dependent iridescent colors in the visible region. Below 50 nm the thin films appear as black. In this study, we utilize the thin film interference colors as markers for identifying patterns, instabilities and flows within vertical foam films. We study the emergence of thickness fluctuations near the borders (i.e. marginal regeneration) and within thinning films. Finally, we elucidate how buoyancy, capillarity, convection and gravity-driven instabilities and flows, are affected by the choice and concentration of constituents. We find fascinating examples of two-dimensional hydrodynamics and unexplained, if not unprecedented, drainage kinetics.

**M1.00191 Effects of aspect ratio on the phase diagram of spheroidal particles<sup>1</sup>** , SONGUL KUTLU, JASON HAAGA, JEFFREY RICKMAN, JAMES GUNTON, Lehigh University — Ellipsoidal particles occur in both colloidal and protein science. Models of protein phase transitions based on interacting spheroidal particles can often be more realistic than those based on spherical molecules. One of the interesting questions is how the aspect ratio of spheroidal particles affects the phase diagram. Some results have been obtained in an earlier study by Odriozola (J. Chem. Phys. 136:134505 (2012)). In this poster we present results for the phase diagram of hard spheroids interacting via a quasi-square-well potential, for different aspect ratios. These results are obtained from Monte Carlo simulations using the replica exchange method. We find that the phase diagram, including the crystal phase transition, is sensitive to the choice of aspect ratio.

**M1.00192 Coarse-grained simulation of dynamin-mediated fission** , MARCUS MULLER, GUOJIE ZHANG, MARC FUHRMANS, Georg-August University, Goettingen, Germany — Fission is a process in which a region of a lipid bilayer is deformed and separated from its host membrane, so that an additional, topologically independent compartment surrounded by a continuous lipid bilayer is formed. It is a fundamental process in the compartmentalization of living organisms and carefully regulated by a number of membrane-shaping proteins. An important group within these is the dynamin family of proteins that are involved in the final severance of the hourglass-shaped neck, via which the growing compartment remains connected to the main volume until the completion of fission. We present computer simulations testing different hypotheses of how dynamin proteins facilitate fission by constriction and curvature. Our results on constraint-induced fission of cylindrical membrane tubes emphasize the importance of the local creation of positive curvature and reveal a complex picture of fission, in which the topological transformation can become arrested in an intermediate stage if the proteins constituting the fission machinery are not adaptive.

**M1.00193 Coarse grained modeling of transport properties in monoclonal antibody solution** , JAMES SWAN, GANG WANG, Massachusetts Inst of Tech-MIT — Monoclonal antibodies and their derivatives represent the fastest growing segment of the bio pharmaceutical industry. For many applications such as novel cancer therapies, high concentration, sub-cutaneous injections of these protein solutions are desired. However, depending on the peptide sequence within the antibody, such high concentration formulations can be too viscous to inject via human derived force alone. Understanding how heterogeneous charge distribution and hydrophobicity within the antibodies leads to high viscosities is crucial to their future application. In this talk, we explore a coarse grained computational model of therapeutically relevant monoclonal antibodies that accounts for electrostatic, dispersion and hydrodynamic interactions between suspended antibodies to predict assembly and transport properties in concentrated antibody solutions. We explain the high viscosities observed in many experimental studies of the same biologics.

**M1.00194 Hierarchical Cluster Formation in Concentrated Monoclonal Antibody Formulations** , P. DOUGLAS GODFRIN, University of Delaware, JONATHAN ZARZAR, ISIDRO (DAN) ZARRAGA, Genentech, Inc., LIONEL PORCAR, PETER FALUS, Institute Laue-Langevin, NORMAN WAGNER, University of Delaware, YUN LIU, NIST Center for Neutron Research, University of Delaware — Reversible cluster formation has been identified as an underlying cause of large solution viscosities observed in some concentrated monoclonal antibody (mAb) formulations. As high solution viscosity prevents the use of subcutaneous injection as a delivery method for some mAbs, a fundamental understanding of the interactions responsible for high viscosities in concentrated mAb solutions is of significant relevance to mAb applications in human health care as well as of intellectual interest. Here, we present a detailed investigation of a well-studied IgG1 based mAb to relate the short time dynamics and microstructure to significant viscosity changes over a range of pharmaceutically relevant physiochemical conditions. Using a combination of experimental techniques, it is found that upon adding Na<sub>2</sub>SO<sub>4</sub>, these antibodies dimerize in solution. Proteins form strongly bounded reversible dimers at dilute concentrations that, when concentrated, interact with each other to form loosely bounded, large, transient clusters. The combined effect of forming strongly bounded dimers and a large transient network is a significant increase in the solution viscosity. Strongly bounded, reversible dimers may exist in many IgG1 based mAb systems such that these results contribute to a more comprehensive understanding of the physical mechanisms producing high viscosities in concentrated protein solutions.

**M1.00195 Probing matrix and tumor mechanics with *in situ* calibrated optical trap based active microrheology** , JACK RORY STAUNTON, WILFRED VIEIRA, KANDICE TANNER, NIH, TISSUE MORPHODYNAMICS UNIT TEAM — Aberrant extracellular matrix deposition and vascularization, concomitant with proliferation and phenotypic changes undergone by cancer cells, alter mechanical properties in the tumor microenvironment during cancer progression. Tumor mechanics conversely influence progression, and the identification of physical biomarkers promise improved diagnostic and prognostic power. Optical trap based active microrheology enables measurement of forces up to 0.5 nN within a sample, allowing interrogation of *in vitro* biomaterials, *ex vivo* tissue sections, and small organisms *in vivo*. We fabricated collagen I hydrogels exhibiting distinct structural properties by tuning polymerization temperature T<sub>p</sub>, and measured their shear storage and loss moduli at frequencies 1-15k Hz at multiple amplitudes. Lower T<sub>p</sub> gels, with larger pore size but thicker, longer fibers, were stiffer than higher T<sub>p</sub> gels; decreasing strain increased loss moduli and decreased storage moduli at low frequencies. We subcutaneously injected probes with metastatic murine melanoma cells into mice. The excised tumors displayed storage and loss moduli 40 Pa and 10 Pa at 1 Hz, increasing to 500 Pa and 1 kPa at 15 kHz, respectively.

**M1.00196 Dynamics of Micropipette Vibration During Piezo-assisted Microinjection<sup>1</sup>**, MEHDI KARZAR-JEDDI<sup>2</sup>, NEJAT OLGAC, TAI-HSI FAN, Department of Mechanical Engineering, University of Connecticut, Storrs, Connecticut 06269-3139, USA — Microinjection is a well-accepted method to introduce materials such as sperm, DNA materials, or nucleus into a living cell for biomedical applications. The conventional microinjection procedure consists of immobilizing the cell by applying suction through a holding pipette, and then an injecting micropipette penetrates through the cell membrane and introduces the materials into the cell. To assist the penetration process a piezo-generated pulse train is applied to the injecting pipette, which causes an undesirable lateral vibration at the injecting pipette tip. In this research we provide an analytical model to study the response of micropipette to the piezo-pulse train using the Duhamel integral method. Our results show that filling the micropipette tip with mercury causes a larger amplitude stroke vibration in micropipette tip than that of empty micropipette when it is submerged in the viscous medium surrounding the cell. The mercury introduced larger stroke vibration can cause a larger shear force and assist the penetration of micropipette through the cell membrane.

**M1.00197 Characterizing the mechanical behavior of the zebrafish germ layers**, DAVID KEALHOFER, FRIEDHELM SERWANE, ALESSANDRO MONGERA, PAYAM ROWGHANIAN, ADAM LUCIO, OTGER CAMPÀS, University of California, Santa Barbara — Organ morphogenesis and the development of the animal body plan involve complex spatial and temporal control of tissue- and cell-level mechanics. A prime example is the generation of stresses by individual cells to reorganize the tissue. These processes have remained poorly understood due to a lack of techniques to characterize the local constitutive law of the material, which relates local cellular forces to the resulting tissue flows. We have developed a method for quantitative, local in vivo study of material properties in living tissue using magnetic droplet probes. We use this technique to study the material properties of the different zebrafish germ layers using aggregates of zebrafish mesendodermal and ectodermal cells as a model system. These aggregates are ideal for controlled studies of the mechanics of individual germ layers because of the homogeneity of the cell type and the simple spherical geometry. Furthermore, the numerous molecular tools and transgenic lines already developed for this model organism can be applied to these aggregates, allowing us to characterize the contributions of cell cortex tension and cell adhesion to the mechanical properties of the zebrafish germ layers.

**M1.00198 A finite element study of the stability of spontaneous curling of thin shells**, XIAOMIN HAN, Thayer School of Engineering, Dartmouth College, QIAOHANG GUO, College of Material Science and Engineering, Fuzhou University, KEVIN CHU, Serendipity Research, IAN TRASE, NAN HU, ZI CHEN, Thayer School of Engineering, Dartmouth College — Thin shells are of great interest in engineering due to their ubiquity in nature. The mechanical instabilities of thin shells are a key factor in understanding many real world phenomena, such as the closure of a Venus flytrap or the curling of a dried leaf. Given the analytical theory that quantitatively described the stability of thin shells subject to surface stress, we are able to identify a dimensionless parameter that controls the stability of thin shells. Finite element analyses are employed to numerically examine the predictions. Bi-layer plates are fabricated where one layer is pre-stretched and has much smaller Young's modulus than the other layer to examine mechanical instability. By measuring the two principle curvatures on the plate, the onset of bifurcation can be determined. Different initial conditions and material properties are taken into account in the FEA, including initial curvature, Poisson's ratio, and the magnitude of surface stress. The numerical experiments agree well with the theory.

**M1.00199 Diffusion of micrometer-sized soft particles in confinement<sup>1</sup>**, BENJAMIN JORDAN, KEVIN APTOWICZ, West Chester University — We investigate the diffusion of micrometer sized poly(N-isopropylacrylamide) (PNIPAM) gel particles in confinement. The influence of confinement on the transport of small particles is becoming increasingly important for microfluidics and bio-fluidics. Analytical solutions to this problem are limited to very unique geometries or gross approximations. Computational methods have provided more insight into the problem as well as experimental investigations. However, most research has focused on the hard-sphere problem. In this work, we will explore the diffusion of soft particles in confinement. The dynamics of the particles confined between two parallel walls is captured with video-microscopy. In addition, we use a recently developed technique to measure confinement of particles in-situ with a precision of 1%. This poster will present some preliminary results of how confinement affects the diffusion of these soft particles.

**M1.00200 Electric Double Layer electrostatics of spherical polyelectrolyte brushes with pH-dependent charge density**, HAO LI, GUANG CHEN, SHAYANDEV SINHA, SIDDHARTHA DAS, Univ of Maryland-College Park, SOFT MATTER, INTERFACES, AND ENERGY LABORATORY (SMIEL) TEAM — Understanding the electric double layer (EDL) electrostatics of spherical polyelectrolyte (PE) brushes, which are spherical particles grafted with PE layers, is essential for appropriate use of PE-grafted micro-nanoparticles for targeted drug delivery, oil recovery, water harvesting, emulsion stabilization, emulsion breaking, etc. Here we elucidate the EDL electrostatics of spherical PE brushes for the case where the PE exhibits pH-dependent charge density. This pH-dependence necessitates the consideration of explicit hydrogen ion concentration, which in turn dictates the distribution of monomers along the length of the grafted PE. This monomer distribution is shown to be a function of the nature of the sphere (metallic or a charged or uncharged dielectric or a liquid-filled sphere). All the calculations are performed for the case where the PE electrostatics can be decoupled from the PE elastic and excluded volume effects. Initial predictions are also provided for the case where such decoupling is not possible.

**M1.00201 Unraveling the Nanostructure and Chain Conformation of Peptide-polymer Conjugates in Solution using Small-angle X-ray Scattering**, REIDAR LUND, Department of chemistry, University of Oslo, TING XU, UC-Berkeley, HE DONG, Clarkson University — For therapeutics, polymer functionalization, often by poly(ethylene glycol), PEG ("PEGylation"), is an effective method to improve the solubility, increase the life time and protect the proteins from the immune system[1]. However it is essential that the proteins maintain their structural integrity in solution- thus the role of the polymer and their interactions with proteins needs to be understood. In this work we show how small-angle X-ray scattering (SAXS) can be used as a powerful technique to characterize the structural components of peptide-polymer conjugates in solution [2,3]. We specifically show that by applying detailed modelling very detailed structural features can be revealed, including the PEG chain conformation. In the presentation we will provide an overview of the methodology, specifically addressing peptides that form either alpha-helical bundles [2,3] or beta-sheet structures [4,5] and relate their structure in solution to their crystal structure.

**M1.00202 Geometric Frustration Selects Morphology in Chiral Filament Bundles<sup>1</sup>**, DOUGLAS HALL, ISAAC BRUSS, UMass Amherst, JUSTIN BARONE, Virginia Tech, GREGORY GRASON, UMass Amherst — Assemblies of twisted filaments appear in a range of biological contexts, from extracellular filament bundles to amyloid fibrils. Owing to numerous distinctions in molecular structures and interactions underlying these diverse assemblies, a framework to predict and classify the basic mechanisms of structure formation in twisted filament assemblies is still lacking. In this study, we model how the size and shape of self-assembled fibers are controlled by competition between the elastic costs of inter-filament frustration, bending deformation of filaments and bundle surface energy. Exploiting a geometric mapping between inter-filament packing in twisted bundles and packing on positively-curved 2D surfaces, we show that the anisotropy of the bundle cross-section is determined by a single parameter describing the competition between elastic and bending costs. We compare the continuum model's predictions for stability of cylindrical and tape-like twisted morphologies to numerical simulations of cohesive filament bundles and observations of micron-scale amyloid fibers assembled from hydrolyzed protein fragments.

**M1.00203 Controlling the Size and Shape of the Elastin-Like Polypeptide based Micelles**, KIRIL STRELETZKY, HANNAH SHUMAN, ADAM MARASCHKY, NOLAN HOLLAND, Cleveland State University — Elastin-like polypeptide (ELP) trimer constructs make reliable environmentally responsive micellar systems because they exhibit a controllable transition from being water-soluble at low temperatures to aggregating at high temperatures. It has been shown that depending on the specific details of the ELP design (length of the ELP chain, pH and salt concentration) micelles can vary in size and shape between spherical micelles with diameter 30-100 nm to elongated particles with an aspect ratio of about 10. This makes ELP trimers a convenient platform for developing potential drug delivery and bio-sensing applications as well as for understanding micelle formation in ELP systems. Since at a given salt concentration, the headgroup area for each foldon should be constant, the size of the micelles is expected to be proportional to the volume of the linear ELP available per foldon headgroup. Therefore, adding linear ELPs to a system of ELP-foldon should result in changes of the micelle volume allowing to control micelle size and possibly shape. The effects of addition of linear ELPs on size, shape, and molecular weight of micelles at different salt concentrations were studied by a combination of Dynamic Light Scattering and Static Light Scattering. The initial results on 50 M ELP-foldon samples (at low salt) show that Rh of mixed micelles increases more than 5-fold as the amount of linear ELP raised from 0 to 50 M. It was also found that a given mixture of linear and trimer constructs has two temperature-based transitions and therefore displays three predominant size regimes.

**M1.00204 Directed Assembly of Hierarchically Ordered Clusters from Anisotropic Microparticles<sup>1</sup>**, KOOHEE HAN, BHUVNESH BHARTI, North Carolina State Univ, C. WYATT SHIELDS IV, GABRIEL P. LOPEZ, Duke University, ORLIN D. VELEV, North Carolina State Univ — The directed assembly of colloidal particles with specific connectivity, symmetry, and directional response requires controlled interactions and means of programmable binding force. We will show how patchy microparticles can be hierarchically assembled into ordered clusters, resulting from directional interactions between metal-coated facets. First, we introduce lipid mediated capillary bridging as a new class of binding force for directed assembly of metallo-dielectric patchy microspheres. Iron oxide surface patches on latex microspheres were selectively wetted with liquid lipids, guiding the particle assembly into well-defined 2D and 3D clusters. The temperature driven fluid-to-gel phase transition of the fatty acids acts as a thermal switch for cluster assembly and disassembly. Secondly, we used external fields to bind patchy microcubes based on their polarization configuration and interparticle interaction. We present assembled clusters of cobalt-coated patchy microcubes that can be dynamically reconfigured using external magnetic field. The residual polarization of ferromagnetic cobalt patches allows for preserving the assembled sequence even in the absence of the field and drives dynamic reconfiguration of assembled clusters.

**M1.00205 Aging and nonlinear rheology of thermoreversible colloidal gels**, NORMAN WAGNER, MELISSA GORDON, CHRISTOPHER KLOXIN, University of Delaware — Colloidal dispersions are found in a wide variety of consumer products such as paint, food and pharmaceuticals. We investigate gel formation and aging in a thermoreversible gel consisting of octadecyl-coated silica nanoparticles suspended in n-tetradecane. In this system, the octadecyl brush can undergo a phase change allowing the attractions between particles to be tuned by temperature (1,2). By probing the system with steady shear and large amplitude oscillatory shear, we have studied the effect of thermal history and shear history on gel formation and gel mechanical properties during aging. Gels were formed by approaching a common temperature from above and below to determine a reference state from which creep tests were conducted. Creep ringing was observed as expected for the viscoelastic gel. The rheological aging is interpreted in terms of the gel microstructure formed with differing thermal and shear histories to determine how processing affects structure. Recently proposed scaling laws for the rheology and structure under flow are explored within the context of gel aging (3). Through rheological and microstructural measurements, we will further the understanding of gel formation and aging in this model system which may be applied to processing conditions in an industrial setting. 1. **M1.00206 Dissolution of a Colloidal Particle in an Oscillatory Fluid Medium**, DEZHUANG YE, JI-QIN LI, Mechanical Engineering, University of Connecticut, ROBIN BOGNER, Pharmaceutical Sciences, University of Connecticut, TAI-HSI FAN, Mechanical Engineering, University of Connecticut — Understanding dissolution kinetics of a colloidal particle in an aqueous solution is of great importance in many pharmaceutical and biochemical applications. We present theoretical analysis of low Reynolds number transient dynamics and mass transfer of a dissolving spherical particle in a unidirectional oscillatory flow. The coupling of fluid flow and passive motion of the particle are resolved analytically, and the transient mass transfer associated with the oscillation of the particle is numerically computed. The flow patterns, diffusive and convective transport phenomena, and the dissolution kinetics under various saturation concentrations and flow conditions are characterized by the frequency parameter, Schmidt number, and Peclet number. The result serves as a basic case in determining the efficiency of drug dissolution or reconstitution that depends on various shaking methods.

**M1.00207 Effective temperatures and the breakdown of the Stokes-Einstein relation for particle suspensions<sup>1</sup>**, CARLOS MENDOZA, Materials Research Institute UNAM, IVAN SANTAMARA-HOLEK, UMDI-J Facultad de Ciencias UNAM, AGUSTIN PREZ-MADRID, Departament de Física Fonamental, Universitat de Barcelona — The short- and long-time breakdown of the classical Stokes-Einstein relation for colloidal suspensions at arbitrary volume fractions is explained here by examining the role that confinement and attractive interactions play in the intra- and inter-cage dynamics executed by the colloidal particles. We show that the short-time diffusion coefficient is larger than the one predicted by the classical Stokes-Einstein relation due to a non-equilibrated energy transfer between kinetic and configuration degrees of freedom. This transfer can be incorporated in an effective temperature that replaces the bath temperature in a Generalized Stokes-Einstein relation (GSER). This relation then allows to obtain the diffusion coefficient once the viscosity is known. On the other hand, the temporary cluster formation induced by confinement and attractive interactions of hydrodynamic nature, makes the long-time diffusion coefficient to be smaller than the corresponding one obtained from the classical Stokes-Einstein relation. Additionally, we provide a simple expression based on a differential effective medium theory (DEMT) that allows to calculate the diffusion coefficient at short and long times. Comparison of our results with experiments and simulations for suspensions of hard and porous spheres shows an excellent agreement in all cases.

**M1.00208 Hydrodynamic interactions in colloidal systems confined to linear geometries with a singular corner.**<sup>1</sup> , BINHUA LIN, RYAN ZARCONI, STUART A. RICE, University of Chicago — Here we investigate the question of whether or not the requirement that particles diffuse around a corner affects their hydrodynamic coupling. We report the results of studies of the collective diffusion coefficients of particles in quasi-one-dimensional linear channels of widths 3 and 5  $\mu\text{m}$ , each with a singular central corner of angle: 60-, 90-, 120-, and 180-degrees. We find that for large angles, the channels are so close in their geometry to 180-degrees that the corner has very little to no effect on the hydrodynamic coupling of particles on opposite sides of the apex. For small angles, the corner's effect is to increase the particle separation at which the maximum hydrodynamic coupling occurs.

**M1.00209 Effect of Salts on Drainage of Foam** , SOUMYADIP SETT, University of Illinois at Chicago, STOYAN KARAKASHEV, University of Sofia, Bulgaria, STOYAN SMOUKOV, University of Cambridge, UK, ALEXANDER YARIN, University of Illinois at Chicago — Gravitational drainage from thin planar vertical sodium dodecyl sulfate (SDS) films in the presence of inorganic salts was experimentally studied. Strong ion-specific effects of the counter ions were found to affect the stability and the rate of drainage of the planar foam films as a function of concentration of the inorganic salts. The counter-ions can either stabilize (below the critical concentration) or destabilize the foam films. We found that the strongest foam stabilizer salt became the strongest foam destabilizer beyond its critical concentration.

**M1.00210 The role of the anchoring conditions in the electro rheological behavior of a nematic constrained by two coaxial cylinders and submitted by a pressure drop** , DANIEL MARTNEZ SNCHEZ, Universidad Autonoma de la Ciudad de Mxico, JUAN ADRIN REYES CERVANTES, Universidad Nacional Autonoma de Mxico — We study a nematic liquid crystal (LC) filling the region between two coaxial cylinders subjected to the simultaneous action of both a pressure gradient applied parallel to the axis of the cylinders and a radial low frequency electric field. For the LC 4'-n-pentyl-4-cyanobiphenyl (5CB), we consider soft anchoring boundary conditions to obtain the configuration of the director and the velocity profile and the pressure gradient for nonslip boundary conditions. Finally, we calculate the effective viscosity, the first normal stress difference, and the dragging forces on the cylinders.

**M1.00211 Colloidal particles embedded in liquid crystal droplets** , DREW MELCHERT, MONIRO SADAT, YE ZHOU, JUAN J. DE PABLO<sup>1</sup>, Institute for Molecular Engineering, University of Chicago — In this work, we encapsulate polystyrene and silica particles in nematic liquid crystal (LC) droplets dispersed in water using microfluidic glass capillary devices. While polystyrene particles induce planar anchoring on the surface, silica particles, treated with DMOAP, create homeotropic anchoring of the LC molecules at their surface. Sodium dodecyl sulfate (SDS) is added to the aqueous phase to stabilize LC droplets and promote a radial configuration with point defect in the center of LC droplet. Our experimental and computational studies show that, when trapped inside the LC droplets, particles with both anchoring types become mostly localized at the defect point (at the center) and interact with the radial configuration. Interestingly, a twisting structure is observed for polystyrene particle with strong planar anchoring. Although localization of the particles at the droplet center is the most stable state and with the lowest free energy, off-center positions also emerge, displacing the defect point from the center to near the surface of a radial droplet.

**M1.00212 Coarse-Grained Molecular Monte Carlo Simulations of Liquid Crystal-Nanoparticle Mixtures**<sup>1</sup> , RYAN NEUFELD, GRIGORIY KIMAEV, FRED FU, NASSER M. ABUKHDEIR, University of Waterloo — Coarse-grained intermolecular potentials have proven capable of capturing essential details of interactions between molecule molecules, while substantially reducing the number of degrees of freedom of the system under study. In the domain of liquid crystals, the Gay-Berne (GB) potential has been successfully used to model the behavior of rod-like and disk-like mesogens. However, only ellipsoid-like interaction potentials can be described with GB, making it a poor fit for many real-world mesogens. In this work, the results of Monte Carlo simulations of liquid crystal domains using the Zewdie-Corner (ZC) potential are presented. The ZC potential is constructed from an orthogonal series of basis functions, allowing for potentials of essentially arbitrary shapes to be modeled. We also present simulations of mixtures of liquid crystalline mesogens with nanoparticles. Experimentally these mixtures have been observed to exhibit microphase separation and formation of long-range networks under some conditions. This highlights the need for a coarse-grained approach which can capture salient details on the molecular scale while simulating sufficiently large domains to observe these phenomena. We compare the phase behavior of our simulations with that of a recently presented continuum theory.

**M1.00214 Magnetic domains and defects in ferromagnetic liquid crystal colloids realized with optical patterning**<sup>1</sup> , ANDREW HESS, QINGKUN LIU, IVAN SMALYUKH, University of Colorado Boulder — A promising approach in designing composite materials with unusual physical behavior combines solid nanostructures and orientationally ordered soft matter at the mesoscale. Such composites not only inherit properties of their constituents but also can exhibit emergent behavior, such as ferromagnetic ordering of colloidal metal nanoparticles forming mesoscopic magnetization domains when dispersed in a nematic liquid crystal. Here we demonstrate the optical patterning of domain structures and topological defects in such ferromagnetic liquid crystal colloids which allows for altering their response to magnetic fields. Our findings reveal the nature of the defects in this soft matter system which is different as compared to non-polar nematic and ferromagnetic systems alike.

<sup>1</sup> This research was supported by the NSF grant DMR-1420736.

**M1.00215 Conformation of charged vesicles: the Debye Huckel and the low curvature limit** , KUMARI PRITI SINHA, PROF. ROCHISH M. THAKKAR, Indian Inst of Tech-Bombay — The shape as well as tension and pressure inside an uncharged vesicle are determined by the reduced volume. These parameters are important for a vesicle or a biological cell, since it can affect bio-physical processes such as osmosis and permeation, interaction with external agents such as bio- macromolecules and thermal fluctuations of the bilayer membrane of a vesicle. Charged membranes are ubiquitous in nature, most biological cell bio-membranes are charged, and therefore the knowledge of shape, tension and pressure of charged vesicles is critical. Additionally, the distribution of charges in the inner and outer leaflets is also important as it can affect the spatial interaction of a bilayer membrane with proteins. This work addresses these issues in the low charge and curvature limit. Our analysis indicates that despite a very strong two-way coupling between the charge and the curvature, the shapes of charged vesicles remain similar to that of uncharged vesicles at comparable reduced volumes, even for reasonable values of total charge. However, the tension and pressure values are higher, and are accurately estimated. Similarly the charge distribution on the outer and inner leaflet is strongly affected by the curvature. The value of spontaneous curvature due to charge redistribution is estimated. The insensitivity of the shape to charges persists even when only the outer leaflet is charged instead of charged inner and outer leaflets

**M1.00216 Emergence of DNA-encapsulating liposomes from a DNA-lipid blend film<sup>1</sup>**, SHUN-SUKE SHIMOBAYASHI, Department of Physics, Kyoto University, MAFUMI HISHIDA, Department of Chemistry, Tsukuba University, TOMO KURIMURA, MASATOSHI ICHIKAWA, Department of Physics, Kyoto University — A Micro-scale giant unilamellar vesicle (GUV) densely encapsulating molecular systems is one of the simplest life-mimicking model systems. The dehydration-rehydration process proposed by Deamer et al. more than 30 years ago generates vesicles to satisfy the constraints of micro-scale size, unilamellarity and densely polymer-encapsulation [1]. Nevertheless, the physico-chemical mechanism of a set of dehydration-rehydration process has been poorly understood. The present study reveals crucial factors on the process through fluorescent microscopic observation [2] and small angle x-ray scattering. From the results, we propose a plausible physical mechanism for the process, making it possible to optimize the encapsulation of any agent. [1] D. W. Deamer, G. L. Barchfield, J. Mol. Evol, 18, 203-206 (1982). [2] S. F. Shimobayashi and M. Ichikawa, J. Phys. Chem. B 118, 10688-10694 (2014).

<sup>1</sup>This work was supported by Grant-in-Aid for JSPS Fellows Grant (No. 25-1270) and by KAKENHI (Nos. 26707020, 25103012, and 26115709).

**M1.00217 Lipid transfer energetics between free-standing and solid supported membranes: reconciling discrepancies.**, BENNY WAH, JOSEPH ADAMS, JEFFREY BREIDIGAN, LI GE, PIOTR HORBAL, Univ of Illinois - Chicago, LIONEL PORCAR, University of Delaware, SUMIT GARG, URSULA PEREZ-SALAS, Univ of Illinois - Chicago — The membranes of animal cells have significant variation in the lipid and protein composition. If it weren't for the active work of proteins that maintain most of these variations, membranes would ultimately homogenize throughout by mixing. It has been long been recognized that the study of the passive movement of lipids between and within membranes can provide insight into this energetic toll. Using small angle neutron scattering, a non-invasive in situ technique, we recently demonstrated that tags or small structure changes in the lipids can have a huge effect on their transport characteristics. In the present study we compare lipid transfer and energetics between supported free standing membranes. We find that exchange and flipping process are comparable while the presence of the surface slightly increases inter and intra-membrane transport rates. The activation energies for exchange appear to be nearly unaffected by the presence of the surface while for flip-flop it slightly increases. The increase in the rates due to the presence of the surface may possibly explain the apparent contradicting behavior previously reported on supported flat membrane systems and in free-standing membranes.

**M1.00218 Photo-Regeneration of Severed Gel Using Photo-Controlled Radical Polymerization**, AWANEESH SINGH, Univ of Pittsburgh, OLGA KUKSENOK, Clemson University, JEREMIAH A. JOHNSON, Massachusetts Institute of Technology, ANNA C. BALAZS, Univ of Pittsburgh — Using the framework of dissipative particle dynamics (DPD) simulation, we developed a novel computational model that enables photo-regeneration of the gel matrix when a significant portion of the material is severed. We considered photo-controlled radical polymerization (photo-CRP) within polymer networks with embedded iniferters (initiators for the photo-CRP reaction). These iniferters turn on the polymerization process in the presence of light with monomers and cross-linkers in the solution. This "photo-growth" allow us to effectively regenerate severed gels under the application of light. The growth process can be turned off once the polymerization is near completion, which forms a new cross-linked gel that resembles the uncut material. The polymerization rate can be modulated by altering the light intensity.

**M1.00219 Frictional Properties of UV illuminated ZnO Thin Films Grown by Pulsed Laser Deposition<sup>1</sup>**, HSIANG-CHIH CHIU, HUAN-PU CHANG, FANG-YU LO, YU-TING YEH, Department of Physics, National Taiwan Normal University, DEPARTMENT OF PHYSICS, NATIONAL TAIWAN NORMAL UNIVERSITY COLLABORATION — Zinc Oxide (ZnO) nanostructures have potential applications in nano-electro-mechanical systems (NEMS) due to their unique physical properties. ZnO is also an excellent lubricant and hence a promising candidate for protective coatings in NEMS. By means of atomic force microscopy (AFM), we have investigated the frictional properties of ZnO thin films prepared by pulsed laser deposition technique. In addition, UV illumination is used to convert the surface wettability of ZnO thin films from being more hydrophobic to superhydrophilic via the photo-catalyst effect. We found that the frictional properties of the UV illuminated, superhydrophilic ZnO surface are strongly dependent on the environment humidity. While for hydrophobic ZnO, no such dependence is found. The observed frictional behaviors can be explained by the interplay between the surface roughness, environmental humidity and the presence of nanoscale capillary condensation forming between surface asperities at the tip-ZnO contact. Our results might find applications in future ZnO related NEMS.

<sup>1</sup>Frictional Properties of UV illuminated ZnO Thin Films Grown by Pulsed Laser Deposition

**M1.00220 Fracture of molecular glasses under tension and fracture-induced crystallization**, YINSHAN CHEN, TRAVIS POWELL, LIAN YU, University of Wisconsin-Madison — Molecular glasses are formed and fractured by cooling a liquid on a less thermally expansive substrate. In-plane tension is created by the mismatch of thermal expansion coefficients and accumulates to cause catastrophic network fracture. This simple experiment allowed the measurement of fracture toughness and the heat of fracture of molecular glasses for the first time. For the systems studied (*o*-terphenyl, indomethacin, and sucrose benzoate), the fracture condition is well described by recent theories and a material-specific energy release rate (fracture toughness) approximately 1 J/m<sup>2</sup>. The heat of fracture was found to be anomalously high relative to the value expected for the energy release rate and the surface area created. The large release of heat is caused by the reduction of heat capacity for a glass film constrained on a rigid substrate. Rapid crystal growth was observed along fracture surfaces. (Ref.: Powell, C. T.; Chen, Y.; Yu, L. J. Non-Crystalline Solids 2015, 429, 122–128)

**M1.00221 Supramolecular Hydrogels from Self-Assembly of di-Fmoc-L-lysine**, SEYED MEYSAM HASHEMNEJAD, KINSEY NAAS, SANTANU KUNDU, Mississippi State University — Mechanical properties and nanostructure of a supramolecular hydrogel formed by self-assembly of di-fluorenylmethyloxycarbonyl-lysine (di-Fmoc-L-lysine) are reported here. Hydrogels were prepared by solvent switch technique in which water was added to a solution of di-Fmoc-L-lysine in dimethyl sulfoxide (DMSO). Mechanical properties of the gels were investigated using shear and cavitation rheology. The gels display strain-softening behavior at moderate strain values. Morphological investigations of the samples were conducted using FTIR and CD spectroscopy, electron microscopy, and atomic force microscopy (AFM). Self-assembled fibers with lateral dimensions ranging from 10 to 50 nm were captured in microscopy studies. FTIR results indicate  $\beta$ -sheet-like conformation of the peptides in the hydrogel.

**M1.00222 Predicting out-of-Equilibrium Phase Behavior in the Dynamic Self-Assembly of Colloidal Crystals**, JAMES SWAN, ZACHARY SHERMAN, Massachusetts Inst of Tech-MIT — Crystals self-assembled from colloidal particles are useful in an array of well demonstrated applications. During fabrication however, gelation and glassification often leave these materials arrested in defective or disordered metastable states. We show how time-dependent, pulsed interparticle interactions can avoid kinetic barriers and yield well-ordered crystalline domains for a suspension of hard, spherical colloidal particles interacting through short-range attractions. This dynamic self-assembly process is analogous to the flashing Brownian ratchet. Although this is an inherently unsteady, out-of-equilibrium process, we can predict its outcome using appropriate time averages of equilibrium equations of state. The predicted phase behavior is tested and validated by examining the fluid/crystal coexistence of such dynamically self-assembling dispersions in Brownian dynamics simulations of sedimentation equilibrium and homogeneous nucleation. We also show that our dynamic self-assembly scheme offers control and tunability over the crystal growth kinetics and can even stabilize nonequilibrium structures.

**M1.00223 Achieving synchronization with active hybrid materials: Coupling self-oscillating gels and piezoelectric films.** , VICTOR V. YASHIN, Department of Chemical Engineering, University of Pittsburgh, STEVEN P. LEVITAN, Department of Electrical and Computer Engineering, University of Pittsburgh, ANNA C. BALAZS, Department of Chemical Engineering, University of Pittsburgh — Our goal is to develop materials that compute by using non-linear oscillating chemical reactions to perform spatio-temporal recognition tasks. The material of choice is a polymer gel undergoing the oscillatory Belousov-Zhabotinsky reaction. The novelty of our approach is in employing hybrid gel-piezoelectric micro-electro-mechanical systems (MEMS) to couple local chemo-mechanical oscillations over long distances by electrical connection. Our modeling revealed that (1) interaction between the MEMS units is sufficiently strong for synchronization; (2) the mode of synchronization depends on the number of units, type of circuit connection (serial or parallel), and polarity of the units; (3) each mode has a distinctive pattern in phase of oscillations and generated voltage. The results indicate feasibility of using the hybrid gel-piezoelectric MEMS for oscillator based unconventional computing.

**M1.00224 Rheological Characterization of Bioinspired Mineralization in Hydrogels** , ABIGAIL REGITSKY, NIELS HOLTEN-ANDERSEN, Massachusetts Institute of Technology — With increasing amounts of CO<sub>2</sub> in the atmosphere linked to potentially catastrophic climate change, it is critical that we find methods to permanently sequester and store CO<sub>2</sub>. Inspired by the natural biomineralization of calcium carbonate (CaCO<sub>3</sub>), one future goal of this project is to understand the mechanisms of CaCO<sub>3</sub> mineralization in order to ultimately optimize a bioinspired hydrogel system, which produces high value industrial powders that consume CO<sub>2</sub> as a feedstock. Along the way, we are developing a rheological technique to study mineral nucleation and growth events by measuring the modulations in mechanical properties of a hydrogel system during mineralization. Our initial system consists of a gelatin hydrogel matrix, which is preloaded with calcium ions, and an aqueous solution of carbonate ions, which are allowed to diffuse through the gel to initiate the mineralization process. In order to monitor how the growth of minerals affects the mechanical properties of the gel network, we measure the storage (G') and loss (G'') moduli of the system in situ. Future work will focus on modifying the properties of the minerals formed by changing the polymer used in the hydrogel network and adding other organic molecules into the system.

**M1.00225 Hardening and yielding in colloidal gels** , EMANUELA DEL GADO, JADER COLOMBO, MEHDI BOUZID, Georgetown University — Attractive colloidal gel networks are disordered elastic solids that can form even in extremely dilute particle suspensions. With interaction strengths comparable to the thermal energy, their stress-bearing network can locally restructure via breaking and reforming inter-particle bonds. We use molecular dynamics simulations of a model system to investigate the strain hardening and the yielding process. During shear start up protocol, the system exhibits strong localization of tensile stresses that may be released through the breaking and formation of new bonds. In this regime, the small amplitude oscillatory shear analysis shows that the storage and the loss modulus follow a power law behavior that are closely reminiscent of experimental observations. At large accumulated strains, the strain-induced reorganization of the gel may trigger flow heterogeneities and eventually lead to the yielding of the gel via a quasi brittle damage of its structure.

**M1.00226 Agglomerate Breakdown in Shear Thickening Fluids by Large Amplitude Oscillatory Shear (LAOS)** , RAN TAO, KIRK D. RICE, GALE A. HOLMES, NIST - Natl Inst of Stds & Tech — Amorphous fumed silica and polypropylene glycol (PPG) suspensions were investigated using both steady shear and oscillatory shear rheology. As-mixed and sonicated silica/PPG suspensions show different shear thickening behavior with different critical shear rates as analyzed by the MITLAOS framework as well as the Fourier Transform approach. The as-mixed suspensions show a pronounced decrease in viscosity or modulus over the course of measurement, which is ascribed to an irreversible breakdown of silica-PPG agglomerates induced by shear. We also extend research to study colloidal silica/PPG dispersions under the same LAOS framework. In particular, we seek to understand the impact of the nanoparticle's structure, i.e., fractal vs. non-fractal, on the oscillatory STF response.

## M1.00227 STATISTICAL AND NONLINEAR PHYSICS —

**M1.00228 Three Dimensional Observations of Quantum Vortex Dynamics in Superfluid Helium** , PETER MEGSON, DANIEL LATHROP, University of Maryland, College Park — Liquid helium, when cooled below 2.17 K, becomes a superfluid with exotic physical properties such as flow without friction. Superfluid flow is irrotational except about line-like topological phase defects with quantized circulation, known as quantum vortices. The dynamics of these vortices include events such as reconnection, wherein vortices meet and exchange tails, and Kelvin wave propagation, a possible mechanism for energy dissipation. We observe the dynamics of fluorescent nanoparticles trapped on the vortices using a newly developed 3D stereographic system. This talk will present new observations of reconnection events and analysis comparing vortex reconnection behavior in three dimensions to previous work that observed such events in two-dimensional projection. In particular, we discuss the power law scaling of vortex separation as a function of time and the effect of the initial angle of separation between the vortex filaments.

**M1.00229 Tension-induced tunable corrugation in bio-inspired two-phase soft composite materials: mechanisms and implications** , AHMED ELBANNA, QIANLI CHEN, University of Illinois Urbana Champaign — We numerically investigate the elastic deformation response of a two-phase bio-inspired soft composite material under externally applied concentric tension using the finite element method. We show that by carefully designing the inclusion pattern it is possible to induce corrugations normal to the direction of stretch. By stacking 1D composite fibers to form 2D membranes, these corrugations collectively lead to the formation of membrane channels with shapes and sizes that are tunable by the level of stretch. Furthermore, we show that by using specific inclusion patterns in laminated plates, it is possible to create pop-ups and troughs enabling the development of complex 3D geometries from planar construction. We have found that the corrugation amplitude increases with the stiffness of inclusion and its eccentricity from the tension axis. We discuss the mechanisms leading to the development of corrugations as well as its different implications. We discuss applications for this design in a variety of fields including tunable band gap formation, surface roughness controllability, auxetic materials and toughness enhancement via programmable evolving geometrical effects..

**M1.00230 Phase correlation in the eigenfunctions of a class of quantum chaotic systems** , JIAOZI WANG, WENGE WANG, Univ of Sci & Tech of China — The random matrix theory predicts vanishing correlation function for eigenfunctions. In this work, we study an important class of quantum chaotic systems, whose Hamiltonians have a sparse structure in unperturbed bases. It is shown that, contrary to the prediction of the random matrix theory, components of the eigenfunctions in such systems have interesting phase correlations, giving non-vanishing correlation functions. Explicit expressions for some of the correlation functions are derived and checked by numerical simulations. As an application, a relation between a type of transition probability and a survival probability amplitude is derived.

**M1.00231 Harnessing geometric and magnetic nonlinearities in phononic meta-plates** , OSAMA BILAL, ANDRE FOEHR, CHIARA DARAIO, Department of Mechanical and Process Engineering, ETH-Zurich — Owing to their physical realization, locally resonant metamaterials retain narrow subwavelength band gaps. Moreover, the fixed geometry and dimensions of the unit cell set a hardbound on the central frequency of the operational bandwidth. Real-time tunable metamaterials extend the range of applications and further enable the realization of new sensors, filters, and switches. Our work harnesses the interaction between geometric nonlinearity and nonlinear magnetic potentials to engineer frequency-agile subwavelength band gaps. The concept is general and applicable to various metamaterials systems. Both numerical simulations and experimental realization of the proposed concept will be presented.

**M1.00232 Propagation of mechanical waves through a stochastic medium with spherical symmetry** , CARLOS AVENDANO, Universidad Autonoma de la Ciudad de Mexico, ADRIAN REYES, Universidad Nacional Autonoma de Mexico — We analyze the propagation of mechanical waves through an anisotropic and inhomogeneous medium with spherical symmetry. We assume that both its elastic and density properties, are random functions of spatial coordinates with specific statistical properties, which allow us to represent media whose properties are not completely determined. We compute the expected value of this system.

**M1.00233 A network model of human aging: Limits, errors, and information** , SPENCER FARRELL, ARNOLD MITNITSKI, KENNETH ROCKWOOD, ANDREW RUTENBERG, Dalhousie University — The Frailty Index (FI) quantifies human aging using the fraction of accumulated age-related deficits. The FI correlates strongly with mortality and accumulates non-linearly and stochastically with age. Clinical data shows a nearly universal limit of  $FI \leq 0.7$ . We computationally model an aging population using a network model of interacting deficits. Deficits damage and repair at rates that depend upon the average damage of connected nodes. The model is parametrized to fit clinical data. We find that attribution errors, especially false negative, allow the model to recover the frailty limit. Mutual information allows us to assess how well the FI can predict mortality. Mutual information provides a non-parametric measure of how the FI predicts mortality. We find that attribution errors have a small effect on the mutual information when many deficits are included in the model. The mutual information of our model and of the clinical data are comparable.

**M1.00234 Changes in the Distribution of Avalanches on a Conical Bead Pile with Cohesion<sup>1</sup>** , JUSTINE WALKER, SUSAN LEHMAN, College of Wooster, KARIN DAHMEN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, JONATHAN UHL, Retired — The probability distributions for avalanches of varying size are experimentally determined for a slowly driven, conical bead pile. The pile is composed of roughly 20 000 steel spheres, 3 mm in diameter, atop a circular base; it is driven by adding one bead at a time to the apex of the pile. We investigate the dynamic response of the pile by recording avalanches off the pile over the course of tens of thousands of bead drops. The avalanching behavior is studied at different drop heights and different amounts of cohesion between the beads. The level of cohesion is tuned through use of an applied uniform magnetic field. Smaller, local avalanches are distinguished from larger, non-local avalanches and the moments of the avalanche distribution are calculated separately for these different populations. The resulting moments scale with cohesion differently, and the results are compared to the scaling predictions from an analytic mean-field model and corresponding simulation of slip avalanches in a shear system [Dahmen, Nat Phys 7, 554 (2011)].

<sup>1</sup>Research supported by NSF CBET 1336116 and 1336634

**M1.00235 Improving detection of avalanches on a conical bead pile<sup>1</sup>** , AVI VAJPEYI, SUSAN LEHMAN, College of Wooster, KARIN DAHMEN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, JONATHAN UHL, Retired — A conical bead pile subject to slow driving and an external magnetic field is used as a simple system to investigate the variations in the avalanche size probability distribution function. Steel beads are dropped onto the pile from different heights and at different strengths of applied magnetic field. Avalanches are recorded by the change in mass as beads fall off the pile. Experimentally we observe an increasing deviation from power law behavior as the field and thus cohesion between the beads increases. We compare our experimental results for the probability distribution function to the results of an analytic theory from a mean-field model of slip avalanches [Dahmen, Nat Phys 7, 554 (2011)]. The model also makes predictions for avalanche duration, which is not measurable with the existing system. To more fully characterize the avalanching behavior of the pile over time, a high-speed camera has been added to the system to record the largest avalanches and allow more detailed analysis. The conical pile geometry presents a challenge for observation and particle tracking over the full pile. Our implementation scheme and preliminary results from the video analysis are presented.

**M1.00236 Effects of sudden density changes in disordered superconductors and semiconductors<sup>1</sup>** , HIBA ASSI, HARSHWARDHAN CHATURVEDI, MICHEL PLEIMLING, UWE TÄUBER, Department of Physics, Virginia Tech — Vortices in type-II superconductors in the presence of extended, linear defects display the strongly pinned Bose glass phase at low temperatures. This disorder-dominated thermodynamic state is characterized by suppressed lateral flux line fluctuations and very slow structural relaxation kinetics: The vortices migrate between different columnar pinning centers to minimize the mutual repulsive interactions and eventually optimize the system's pinning configuration. To monitor the flux lines' late-time structural relaxations, we employ a mapping between an effectively two-dimensional Bose glass system and a modified Coulomb glass model, originally developed to describe disordered semiconductors at low temperatures. By means of Monte Carlo simulations, we investigate the effects of the introduction of random bare site energies and sudden changes in the vortex or charge carrier density on the soft Coulomb gap that appears in the density of states due to the emerging spatial anticorrelations. The non-equilibrium relaxation properties of the Bose and Coulomb glass states and the ensuing aging kinetics are studied through the two-time density autocorrelation function and its various scaling forms.

**M1.00237 Autonomous Brownian motors driven by nonadiabatic variation of internal parameters** , ALEX PLYUKHIN, Saint Anselm College — We study a family of autonomous motors based on a Brownian particle driven from thermal equilibrium by periodic in time variation of the internal potential through which the particle interacts with molecules of the surrounding thermal bath. We demonstrate for such motors the absence of a linear response regime: The average driving force and drift velocity are shown to be quadratic in both the frequency and amplitude of the variation. The adiabatic approximation (of an infinitely slow variation) and the leading correction to it (linear in the variation's frequency) lead to zero drift and are insufficient to describe the motor's operation.

**M1.00238 Modeling the Earth: Climate on an Icosphere** , STEPHANIE FOUTS, Washington and Lee University, L. JONATHAN COOK, Roanoke College — The totally asymmetric simple exclusion process with Langmuir kinetics is a one-dimensional transport model used to study the motion of particles through a lattice. Its applications include systems in the fields of biology, climatology, mathematics, civil engineering, and physics. In our research, we examine the temporal dynamics through the power spectra, as well as the time-averaged particle distribution on the lattice via Monte Carlo simulations. We have applied our particle transport model to an icosahedron in an attempt to model Earth's changing climate. In our research, we examine the temporal dynamics of the particle distribution on the lattice, as they correspond to seasonal heat fluctuations in the polar and equatorial regions of the globe. Using Monte Carlos simulations, we alter the input parameters of the system to explore the resultant actions of the Earth-system model. Our findings include seasonal oscillations consistent with those seen in reality. We also built a mathematical framework for our model which, when solved numerically, matches the oscillations seen in our physical system.

**M1.00239 Directed Nanopatterning with Nonlinear Laser Lithography** , ONUR TOKEL, OZGUN YAVUZ, EMRE ERGECEN, IHOR PAVLOV, GHAITH MAKEY, FATIH OMER ILDAY, Bilkent University — In spite of the successes of maskless optical nanopatterning methods, it remains extremely challenging to create any isotropic, periodic nanopattern. Further, available optical techniques lack the long-range coverage and high periodicity demanded by photonics and photovoltaics applications. Here, we provide a novel solution with Nonlinear Laser Lithography (NLL) approach [1]. Notably, we demonstrate that self-organized nanopatterns can be produced in all possible Bravais lattice types. Further, we show that carefully chosen defects or structured noise can direct NLL symmetries. Exploitation of directed self-organization to select or guide to predetermined symmetries is a new capability. Predictive capabilities for such far-from-equilibrium, dissipative systems is very limited due to a lack of experimental systems with predictive models. Here we also present a completely predictive model, and experimentally confirm that the emergence of motifs can be regulated by engineering defects, while the polarization of the ultrafast laser prescribes lattice symmetry, which in turn reinforces translational invariance. Thus, NLL enables a novel, maskless nanofabrication approach, where laser-induced nanopatterns can be rapidly created in any lattice symmetry. [1] Nature Photonics, 7, 897 (2013)

**M1.00240 purohit@seas.upenn.edu** , XIAOJUN LIANG, PRASHANT PUROHIT, University of Pennsylvania — The thermal fluctuations of lipid bilayer membranes are key to their interaction with cellular components as well as the measurement of their mechanical properties. Typically, membrane fluctuations are analyzed by decomposing into normal modes or by molecular simulations. Here we propose a new approach to calculate the partition function of a membrane. We view the membrane as a fluctuating von Karman plate and discretize it into triangular elements. We express its energy as a function of nodal displacements, and then compute the partition function and covariance matrix using Gaussian integrals. We recover well-known results for the dependence of the projected area of the membrane on the applied tension and recent simulation results on the dependence of membrane free energy on geometry, spontaneous curvature and tension. As new applications we compute the fluctuations of the membrane of a malaria infected cell and analyze the effects of boundary conditions on fluctuations. We also compare our calculation with some simulation method to show our time efficiency as well as accuracy.

**M1.00241 Back-and-forth micromotion of aqueous droplets in a dc electric field** , TOMO KURIMURA, MASATOSHI ICHIKAWA, Kyoto University, MASAHIRO TAKINOUE, Tokyo Institute of Technology, KENICHI YOSHIKAWA, Doshisha University — Recently, it was reported that an aqueous droplet in an oil phase exhibited rhythmic back-and-forth motion under stationary dc voltage on the order of 100 V. Here, we demonstrate that the threshold voltage for inducing such oscillation is successfully decreased to the order of 10 V through downsizing of the experimental system [1]. Notably, the threshold electric field tends to decrease with a nonlinear scaling relationship accompanied by the downsizing. We derive a simple theoretical model to interpret the system size dependence of the threshold voltage. This model equation suggests the unique effect of additional noise, which is qualitatively characterized as a coherent resonance by an actual experiment as a kind of coherent resonance. Our result would provide insight into the construction of micrometer-sized self-commutating motors and actuators in microfluidic and micromechanical devices. [1] TK, MI, MT and KY, Phys.Rev.E 88, 042918 (2013).

**M1.00242 Phase Transitions in a Model of Y-Molecules Abstract** , DANIELLE HOLZ, DONOVAN RUTH, Lehigh University, RAUL TORAL, Institute for Cross-Disciplinary Physics and Complex Systems, JAMES GUNTUN, Lehigh University — Immunoglobulin is a Y-shaped molecule that functions as an antibody to neutralize pathogens. In special cases where there is a high concentration of immunoglobulin molecules, self-aggregation can occur and the molecules undergo phase transitions. This prevents the molecules from completing their function. We used a simplified model of 2-Dimensional Y-molecules with three identical arms on a triangular lattice with 2-dimensional Grand Canonical Ensemble. The molecules were permitted to be placed, removed, rotated or moved on the lattice. Once phase coexistence was found, we used histogram reweighting and multicanonical sampling to calculate our phase diagram.

## M1.00243 ABSTRACT WITHDRAWN —

**M1.00244 Social Network Influence and Personal Financial Status** , SHAOJUN LUO, FLAVIANO MORONE, City College of CUNY, CARLOS SARRAUTE, Grandata, Buenos Aires, Argentina, HERNAN MAKSE, City College of CUNY — Networks of social ties emerging from individual economic needs display a highly structured architecture. In response to socio-economic demands, people reshape their circle of contacts for maximizing their social status, and ipso facto, the pattern of their interconnections is strongly correlated with their personal financial situation. In this work we transform this qualitative and verbal statement into an operative definition, which allows us to quantify the economic wellness of individuals through a measure of their collective influence. We consider the network of mobile phone calls made by the Mexican population during three months, in order to study the correlation of person's economic situation with her network location. Notably, we find that rich people tend to be also the most influential nodes, i.e., they self-organize to optimally position themselves in the network. This finding may be also raised at the level of a principle, a fact that would explain the emergence of the phenomenon of collective influence itself as the result of the local optimization of socio-economic interactions. Our method represents a powerful and efficient indicator of socio-economic robustness, which may be applied to maximize the effect of large scale economic intervention and stimulus policies

**M1.00245 Statistical Mechanics of Japanese Labor Markets** , HE CHEN<sup>1</sup>, Hokkaido University — We introduce a probabilistic model to analyze job-matching processes of recent Japanese labor markets, in particular, for university graduates by means of statistical physics. To make a model of the market efficiently, we take into account several hypotheses. Namely, each company fixes the (business year independent) number of opening positions for newcomers. The ability of gathering newcomers depends on the result of job matching process in past business years. This fact means that the ability of the company is weakening if the company did not make their quota or the company gathered applicants too much over the quota. All university graduates who are looking for their jobs can access the public information about the ranking of companies. By assuming the above essential key points, we construct the local energy function of each company and describe the probability that an arbitrary company gets students at each business year by a Boltzmann-Gibbs distribution. We evaluate the relevant physical quantities such as the employment rate and Gini index. We discuss social inequalities in labor markets, and provide some ways to improve these situations, such as the informal job offer rate, the job-worker mismatch between students and companies.

**M1.00246 Agitated granular rod monolayers: Tetratic or uniaxial nematic?**<sup>1</sup> , THOMAS MUELLER, Experimentalphysik V, University of Bayreuth, DANIEL DE LAS HERAS, Theoretische Physik II, University of Bayreuth, INGO REHBERG, KAI HUANG, Experimentalphysik V, University of Bayreuth — The ordering of granular rod monolayers under vertical agitations against gravity is investigated experimentally and compared quantitatively with equilibrium Monte Carlo simulations and density functional theory. At sufficiently high number density, short rods form a tetratic state and long rods form a uniaxial nematic state. The ordering transitions are found to be independent of the agitation frequency and strength, suggesting that the detailed nature of energy injection into such a nonequilibrium system does not play a crucial role. Interestingly, the length-to-width ratio at which the order changes from tetratic to uniaxial is around 7.3 in both experiments and simulations. This quantitative agreement indicates that, despite of driven far from thermodynamic equilibrium, agitated granular systems may share similar features with corresponding equilibrium systems. Finally, we summarize the universal and non-universal aspects between nonequilibrium granular rod and equilibrium liquid crystal systems in a state diagram.

**M1.00247 Buckling of Patterned Top Films**, DOKYEONG KWON, Seoul Natl Univ, HYO SEON SUH, University of Chicago, KOOKHEON CHAR, Seoul Natl Univ — Buckling of thin films on elastomeric substrates such as polydimethylsiloxane (PDMS) is the well-known phenomenon in buckling instability originating from the moduli mismatch between a substrate and a thin film placed on the top. Recently, many studies on the microstructure created by the buckling with flat top films have been reported and physics behind them has almost been well received. However, only a few work has been done for the buckling structure with micro- or nano-patterned top films and buckling mechanics for patterned top film-PDMS bilayers has not yet been established in detail. Here, we present the buckling of various patterned top films placed on top of elastomeric PDMS substrates. Geometrical patterns were prepared by unconventional lithography techniques such as thermal imprinting of polystyrene (PS) films. Buckling instability was induced by applying mechanical stress to the patterned top surface-PDMS bilayers. Resulting buckled structures showed different mechanical structures as shape and structural parameters of the top thin films were varied. The structural changes were analyzed by introducing a beam theory or a plate theory for the simple modeling of the top surfaces, giving insights on the buckling mechanics of top films with complicated patterns placed on PDMS substrates.

**M1.00248 Triggered Snap-Through of Bistable Shells**<sup>1</sup>, YIJIE CAI, Wuhan University of Technology, SHICHENG HUANG, IAN TRASE, NAN HU, ZI CHEN, Dartmouth College — Elastic bistable shells are common structures in nature and engineering, such as the lobes of the Venus flytrap or the surface of a toy jumping poppers. Despite their ubiquity, the parameters that control the bistability of such structures are not well understood. In this study, we explore how the geometrical features of radially symmetric elastic shells affect the shape and potential energy of a shell's stable states, and how to tune certain parameters in order to generate a snap-through transition from a convex semi-stable state to concave stable state. We fabricated a series of elastic shells with varying geometric parameters out of silicone rubber and measured the resulting potential energy in the semi-stable state. Finite element simulations were also conducted in order to determine the deformation and stress in the shells during snap-through. It was found that the energy of the semi-stable state is controlled by only two geometric parameters and a dimensionless ratio. We also noted two distinct transitions during snap-through, one between monostability and semi-bistability (the state a popper toy is in before it snaps-through and jumps), and a second transition between semi-bistability and true bistability. This work shows that it is possible to use a set of simple parameters to tailor the energy landscape of an elastic shell in order to generate complex trigger motions for their potential use in smart applications.

**M1.00250 Thermodynamics and Phase Transitions of Ising Model on Inhomogeneous Stochastic Recursive Lattice**<sup>1</sup>, RAN HUANG, Shanghai Jiao Tong Univ — As one of the few exactly solvable thermodynamic models, the Ising model on recursive lattice is featured by its impressive advantages and successful applications in various thermodynamic and statistical researches. However this model was considered that, since the recursive calculation demands homogeneous structure, it can only describe the bulk and even systems with narrow utilization. In this work we figured out a practical methodology to extend the conventional homogeneous structure of single-unit Husimi lattice to be random inhomogeneous lattices with variable units and structures, while keeping the feature of exact calculation. Three designs of inhomogeneous recursive lattices: the random-angled rhombus lattice, the Husimi lattice of variable units, and the randomly multi-branched Husimi square lattice; and the corresponding exact recursive calculations based on the partial partition function algorithm, which is derived from the Bethe Cavity method, have been investigated and developed. With the "total-symmetry assumption" and the "iterative-replica trick" we were able to exactly solve the classical ferromagnetic spin-1 Ising models on these lattices, to describe the complex systems that can only be solved by approximations or simulations on regular lattices. Our work may enhance the application of the exact calculation on recursive lattices in various fields of materials science and applied physics, especially it may serve as a powerful tool to explore the cross-dimensional thermodynamics and phase transitions.

**M1.00251 Nonlinear dynamics of Bohmian trajectories in a double-well potential**, O. F. DE ALCAN-TARA BONFIM, Univ of Portland, JOAO FLORENCIO, Universidade Federal Fluminense, RJ-Brazil — We investigate the dynamics of a quantum particle in a one-dimensional double-well potential within the framework of Bohm's quantum mechanics. We find that the behavior of the trajectories is linked to the degree of complexity of the initial wave packet. By increasing the complexity of the wave packet we obtain trajectories that are either periodic, quasiperiodic, or chaoticlike.

**M1.00252 Nematic-columnar phase transition in oriented hard rectangles**, TRISHA NATH, The Institute of Mathematical Sciences, C.I.T. Campus, Taramani, Chennai 600113, India, DEEPAK DHAR, Department of Theoretical Physics, Tata Institute of Fundamental Research, Homi Bhabha Road, Mumbai, 400005, India, R. RAJESH, The Institute of Mathematical Sciences, C.I.T. Campus, Taramani, Chennai 600113, India — We consider an assembly of monodispersed hard rectangles of size  $2 \times d$  on a square lattice with only hard core interactions amongst them. The long axes of the rectangles can be oriented along the horizontal or vertical directions. For large enough aspect ratio, it is known that this system undergoes three phase transitions as the density ( $\rho$ ) of rectangles is increased: first an isotropic-nematic transition (at  $\rho_1^*$ ), second a nematic-columnar transition (at  $\rho_2^*$ ), and third a columnar-sublattice transition (at  $\rho_3^*$ ). In the nematic phase, only the orientational symmetry is broken. The columnar and sublattice phases correspond to additional broken translational symmetries along one (perpendicular to the nematic orientation) and both directions respectively. Interestingly, the critical value  $\rho_2^*$  remains finite, approximately 0.73, even as  $d \rightarrow \infty$ . We develop a systematic high density expansion for the surface tension between two differently-ordered columnar phases. Keeping only the first order perturbative correction term and setting this surface tension to zero, we get an estimate of  $\rho_2^*$  in excellent agreement with estimates from Monte Carlo simulations, for all  $d \geq 2$ .

**M1.00253 BIOLOGICAL PHYSICS** —

**M1.00254 Single-molecule studies of collagen mechanics** , NANCY FORDE, NAGHMEH REZAEI, Department of Physics, Simon Fraser University, MICHAEL KIRKNESS, Department of Molecular Biology and Biochemistry, Simon Fraser University — Collagen is the fundamental structural protein in vertebrates. Its triple helical structure at the molecular level is believed to be strongly related to its mechanical role in connective tissues. However, the mechanics of collagen at the single-molecule level remain contentious. Estimates of its persistence length span an order of magnitude, from 15-180 nm for this biopolymer of 300 nm contour length. How collagen responds to applied force is also controversial, with different single-molecule studies suggesting one of three different responses: extending entropically, overwinding, or unwinding, all at forces below 10 pN. Using atomic force microscopy to image collagens deposited from solution, we find that their flexibility depends strongly on ionic strength and pH. To study force-dependent structural changes, we are performing highly parallelized enzymatic cleavage assays of triple helical collagen in our new compact centrifuge force microscope. Because proteolytic cleavage requires a locally unwound triple helix, these experiments are revealing how local collagen structure changes in response to applied force. Our results can help to resolve long-standing debates about collagen mechanics and structure at the molecular level.

**M1.00255 Population Dynamics of Viral Inactivation<sup>1</sup>** , KRISTA FREEMAN, DONG LI, Carnegie Mellon University, MANJA BEHRENS, Lund University, KIRIL STRELETZKY, Cleveland State University, ULF OLSSON, Lund University, ALEX EVILEVITCH, Carnegie Mellon University — We have investigated the population dynamics of viral inactivation *in vitro* using time-resolved cryo electron microscopy combined with light and X-ray scattering techniques. Using bacteriophage  $\lambda$  as a model system for pressurized double-stranded DNA viruses, we found that virions incubated with their cell receptor eject their genome in a stochastic triggering process. The triggering of DNA ejection occurs in a non synchronized manner after the receptor addition, resulting in an exponential decay of the number of genome-filled viruses with time. We have explored the characteristic time constant of this triggering process at different temperatures, salt conditions, and packaged genome lengths. Furthermore, using the temperature dependence we determined an activation energy for DNA ejections. The dependences of the time constant and activation energy on internal DNA pressure, affected by salt conditions and encapsidated genome length, suggest that the triggering process is directly dependent on the conformational state of the encapsidated DNA. The results of this work provide insight into how the *in vivo* kinetics of the spread of viral infection are influenced by intra- and extra cellular environmental conditions.

**M1.00256 Theory of sequence-dependent scaling and confinement of viral RNA molecules<sup>1</sup>** , JOSHUA KELLY, Univ of California - Los Angeles — We present a general theory for the fractal dimensions of the genomic viral RNA molecules of small RNA viruses and apply the theory as well to RNA encapsidation competition experiments.

<sup>1</sup>Work supported by NSF

**M1.00257 Convex Lens-induced Confinement to Visualize Biopolymers and Interaction Parameters** , FRANK STABILE, DANIEL BERARD, GIL HENKIN, MARJAN SHAYEGAN, FRANOIS MICHAUD, SABRINA LESLIE, McGill University — In this poster, we present a versatile CLiC (Convex Lens-induced Confinement) microscopy system to access a broad range of biopolymer visualization and interaction parameters. In the CLiC technique, the curved surface of a convex lens is used to deform a flexible coverslip above a glass substrate, creating a nanoscale gap that can be tuned during an experiment to load and confine molecules into nanoscale features, both linear and circular, embedded in the bottom substrate. We demonstrate and characterize massively parallel DNA nanochannel-based stretching, building on prior work. Further, we demonstrate controlled insertion of reagent molecules within the CLiC imaging chamber. We visualize real-time reaction dynamics of nanoconfined species, including dye/DNA intercalation and DNA/DNA ligation reactions, demonstrating the versatility of this nanoscale microscopy platform.

**M1.00258 Slow Domain Motions of an Oligomeric Protein from Deep-Sea Hyperthermophile probed by Neutron Spin Echo** , DEBSINDHU BHOWMIK, UTSAB SHRESTHA, GURPREET DHINDSA, Wayne State University, MELISSA SHARP, European Spallation Source, LAURA R. STINGACIU, Oak Ridge National Laboratory, XIANG-QIANG CHU, Wayne State University, XIANG-QIANG CHU TEAM — Deep-sea microorganisms have the ability to survive under extreme conditions, such as high pressure and high temperature[1]. In this work, we used the combination of the neutron spin-echo (NSE) and the small angle neutron scattering (SANS) techniques to study the inter-domain motions of the inorganic pyrophosphate (IPPase) enzyme derived from thermostable microorganisms *Thermococcus thioreducens*. The IPPase has hexameric quaternary structure with molecular mass of approx. 120kDa (each subunit of 20kDa), which is a large oligomeric structure. The understanding of its slow inter-domain motions can be the key to explain how they are able to perform catalytic activity at higher temperature compared to mesophilic enzymes, thus leading to adapt to extreme environment present at the seabed [1]. The NSE can probe these slow motions directly in the time domain up to several tens of nanoseconds at the nanometers length scales, while the corresponding structural change can be explored by the SANS [2]. Our results provide a better picture of the local flexibility and conformational substates unique to these types of proteins, which will help us better understand the relation between protein dynamics and their biological activities. **M1.00259 Replica-exchange Wang-Landau simulations of the HOP lattice protein model<sup>1</sup>** , GUANGJIE SHI, Center for Simulation Physics, The University of Georgia, THOMAS WÜST, ID Scientific IT Services, ETH Zürich, Switzerland, YING WAI LI, National Center for Computational Sciences, Oak Ridge National Laboratory, DAVID P. LANDAU, Center for Simulation Physics, The University of Georgia — The hydrophobic-polar (HP) lattice protein model has been the subject of intensive investigation in an effort to aid our understanding of protein folding. However, the high ground state degeneracies caused by its simplification stands in contrast to the generally unique native states of natural proteins. Here we proposed a simple modification, by introducing a new type of “neutral” monomer, 0, i.e. neither hydrophobic nor polar, thus rendering the model more realistic without increasing the difficulties of sampling significantly<sup>2</sup>. With the replica exchange Wang-Landau (REWL) scheme<sup>3</sup> we investigated several widely studied HP proteins and their HOP counterparts. Dramatic differences in both ground state and thermodynamic properties have been found. For example, the HOP version of Crambin shows more clear two-step folding and 3 order of magnitudes less ground state degeneracy than its HP counterpart.

**M1.00260 Identifying paths of allosteric communication in the protein BirA through simulations** , GREGORY CUSTER, DOROTHY BECKETT, SILVINA MATYSIAK, University of Maryland — Biotin ligase/repressor (BirA) is a bifunctional enzyme which adenylates biotin and transfers the product, biotinyl-5-AMP (bio-5-AMP) to biotin carboxyl carrier protein (BCCP). In the absence of BCCP, bio-5-AMP promotes the dimerization of BirA. In dimer form, the BirA bio-5-AMP complex is able to bind to the biotin operator and prevents further synthesis of biotin. The bio-5-AMP binds away from the dimer interface, so it is acting as an allosteric activator. We perform all-atom molecular dynamics simulations with BirA to look at fluctuations within the protein at equilibrium. We simulate apoBirA, liganded BirA, as well as two mutants, M211A and V219A. In agreement with experimental observations, several loops of the protein become stabilized for the liganded BirA when compared to the apo protein. In addition, changes in the dimer interface are observed for the M211A and V219A mutations, which are located in the ligand binding region. Using inter-residue correlation coefficients and pair energies a communication network through the protein is constructed. With this network we have identified paths which have the potential to be important in allosteric activation of BirA. These paths and the methods we use to identify them will be presented.

**M1.00261 Modeling Hand-Over-Hand and Inchworm Steps in Myosin VI**, AMANDA JACK, Denison University, IAN LOWE, University of Pennsylvania, RIINA TEHVER, Denison University — Myosin VI is a molecular motor protein that moves along actin filaments to transport cargo within a cell. There is much experimental evidence that the myosin VI dimer moves “hand-over-hand” along actin; however, recent experiments suggest that the protein can also move via an “inchworm” mechanism. We created a mechanochemical kinetic model to predict myosin VI's behavior under different ATP, ADP, and force conditions, taking these alternative mechanisms into account. Our model's calculations agree well with experimental results and can also be used to predict myosin VI's behavior outside experimentally tested regimes, such as under forward force. We also predict an optimized motor function for the protein around physiological (-2 pN) load and anchoring under -3 pN load. By using our model to predict myosin VI's response to environmental change, we can gain insight into the behavior of a protein that can be difficult to observe experimentally.

**M1.00262 Synchrotron radiation circular dichroism spectroscopy study of recombinant T $\beta$ 4 folding**<sup>1</sup>, YUNG-CHIN HUANG, HSUEH-LIANG CHU, PENG-JEN CHEN, CHIA-CHING CHANG, Natl Chiao Tung Univ — Thymosin beta 4 (T $\beta$ 4) is a 43-amino acid small peptide, has been demonstrated that it can promote cardiac repair, wound repair, tissue protection, and involve in the proliferation of blood cell precursor stem cells of bone marrow. Moreover, T $\beta$ 4 has been identified as a multifunction intrinsically disordered protein, which is lacking the stable tertiary structure. Owing to the small size and disordered character, the T $\beta$ 4 protein degrades rapidly and the storage condition is critical. Therefore, it is not easy to reveal its folding mechanism of native T $\beta$ 4. However, recombinant T $\beta$ 4 protein (rT $\beta$ 4), which fused with a 5-kDa peptide in its amino-terminal, is stable and possesses identical function of T $\beta$ 4. Therefore, rT $\beta$ 4 can be used to study its folding mechanism. By using over-critical folding process, stable folding intermediates of rT $\beta$ 4 can be obtained. Structure analysis of folding intermediates by synchrotron radiation circular dichroism (SRCD) and fluorescence spectroscopies indicate that rT $\beta$ 4 is a random coil major protein and its hydrophobic region becomes compact gradually. Moreover, the rT $\beta$ 4 folding is a two state transition. Thermal denaturation analysis indicates that rT $\beta$ 4 lacks stable tertiary structure. These results indicated that rT $\beta$ 4, similar to T $\beta$ 4, is an intrinsically disordered protein.

**M1.00263 Structural Properties of Human CaMKII Ca<sup>2+</sup>/Calmodulin-Dependent Protein Kinase II using X-ray Crystallography**, YUMENG MELODY CAO, Smith College, ETHAN MCSPADDEN, JOHN KURIYAN, U.C. Berkeley, DEPARTMENT OF MOLECULAR AND CELL BIOLOGY AND DEPARTMENT OF CHEMISTRY TEAM — To this day, human memory storage remains a mystery as we can at most describe the process vaguely on a cellular level. Switch-like properties of Calcium/Calmodulin-Dependent Protein Kinase II make it a leading candidate in understanding the molecular basis of human memory. The protein crystal was placed in the beam of a synchrotron source and the x-ray crystallography data was collected as reflections on a diffraction pattern that undergo Fourier transform to obtain the electron density. We observed two drastic differences from our solved structure at 2.75Å to a similar construct of the mouse CaMKII association domain. Firstly, our structure is a 6-fold symmetric dodecamer, whereas the previously published construct was a 7-fold symmetric tetradecamer. This suggests the association domain of human CaMKII is a dynamic structure that is triggered subunit exchange process. Secondly, in our structure the N-terminal tag is docked as an additional beta-strand on an uncapped beta-sheet present in each association domain protomer. This is concrete evidence of the involvement of the polypeptide docking site in the molecular mechanism underlining subunit exchange. In the future, we would like to selectively inhibit the exchange process while not disrupting the other functionalities of CaMKII.

**M1.00264 Nanomechanics of Protein Unfolding outside Protease Nanopores**, BINQUAN LUAN, RUHONG ZHOU, IBM T J Watson Res Ctr — Protein folding and unfolding have been the subject of active research for decades. Most of previous studies in protein unfolding were focused on temperature, chemical and/or force (such as in AFM) induced denaturations. Recent studies on the functional roles of proteasomes (such as ClpXP) revealed a novel unfolding process in cell, during which a target protein is mechanically unfolded and pulled into a confined, pore-like geometry for degradation. While the proteasome nanomachine has been extensively studied, the mechanism for unfolding proteins with the proteasome pore is still poorly understood. Here, we investigate the mechanical unfolding process of ubiquitin with (or really outside) an idealized proteasome pore, and compare such process with that in the AFM pulling experiment. Unexpectedly, the required force by a proteasome can be much smaller than that by the AFM. Simulation results also unveiled different nanomechanics, tearing fracture vs. shearing friction, in these two distinct types of mechanical unfoldings.

**M1.00265 Coarse Graining to Investigate Membrane Induced Peptide Folding of Anticancer Peptides**, SAI GANESAN, HONGCHENG XU, SILVINA MATYSIAK, Univ of Maryland-College Park — Information about membrane induced peptide folding mechanisms using all-atom molecular dynamics simulations is a challenge due to time and length scale issues. We recently developed a low resolution Water Explicit Polarizable PROtein coarse-grained Model by adding oppositely charged dummy particles inside protein backbone beads. These two dummy particles represent a fluctuating dipole, thus introducing structural polarization into the coarse-grained model. With this model, we were able to achieve significant  $\alpha$ - $\beta$  secondary structure content de novo, without any added bias. We extended the model to zwitterionic and anionic lipids, by adding oppositely charged dummy particles inside polar beads, to capture the ability of the head group region to form hydrogen bonds. We use zwitterionic POPC and anionic POPS as our model lipids, and a cationic anticancer peptide, SVS1, as our model peptide. We have characterized the driving forces for SVS1 folding on lipid bilayers with varying anionic and zwitterionic lipid compositions. Based on our results, dipolar interactions between peptide backbone and lipid head groups contribute to stabilize folded conformations. Cooperativity in folding is induced by both intra peptide and membrane-peptide interaction.

**M1.00266 Group transfer theory of single molecule imaging experiments in the F-ATPase biomolecular motor**<sup>1</sup>, SANDOR VOLKAN-KACSO, RUDOLPH MARCUS, California Institute of Technology — I describe a chemo-mechanical theory to treat single molecule imaging and “stalling” experiments on the F-ATPase enzyme. This enzyme is an effective stepping biomolecular rotary motor with a rotor shaft and a stator ring. Using group transfer theoretical approach the proposed structure-based theory couples the binding transition of nucleotides in the stator subunits and the physics of torsional elasticity in the rotor. The twisting of the elastic rotor domain acts as a perturbation upon the driving potential, the Gibbs free energy. In the theory, without the use of adjustable parameters, we predict the rate and equilibrium constant dependence of steps such as ATP binding and phosphate release as a function of manipulated rotor angle. Then we compare these predictions to available data from stalling experiments. Besides treating experiments, the theory can provide guides for atomistic simulations, which could calculate the reorganization parameter and the torsional spring constant. The framework is generic and I discuss its application to other single molecule experiments, such as controlled rotation and other biomolecular motors, including motor-DNA complexes and linear motors. [PNAS, Early Edition, Oct. 19, 2015, doi: 10.1073/pnas.1518489112]

**M1.00267 Molecular Dynamics Simulation and Statistics Analysis Reveals the Defense Response Mechanism in Plants**, ZHICHAO LIU, YUNJIE ZHAO, CHEN ZENG, Department of Physics, The George Washington University, COMPUTATIONAL BIOPHYSICS LAB TEAM — As the main protein of the bacterial flagella, flagellin plays an important role in perception and defense response. The newly discovered locus, FLS2, is ubiquitously expressed. FLS2 encodes a putative receptor kinase and shares many homologies with some plant resistance genes and even with some components of immune system of mammals and insects. In Arabidopsis, FLS2 perception is achieved by the recognition of epitope flg22, which induces FLS2 heteromerization with BAK1 and finally the plant immunity. Here we use both analytical methods such as Direct Coupling Analysis (DCA) and Molecular Dynamics (MD) Simulations to get a better understanding of the defense mechanism of FLS2. This may facilitate a redesign of flg22 or de-novo design for desired specificity and potency to extend the immune properties of FLS2 to other important crops and vegetables.

**M1.00268 Multiscale modeling of three-dimensional genome**, BIN ZHANG, PETER WOLYNES, Rice University — The genome, the blueprint of life, contains nearly all the information needed to build and maintain an entire organism. A comprehensive understanding of the genome is of paramount interest to human health and will advance progress in many areas, including life sciences, medicine, and biotechnology. The overarching goal of my research is to understand the structure-dynamics-function relationships of the human genome. In this talk, I will be presenting our efforts in moving towards that goal, with a particular emphasis on studying the three-dimensional organization, the structure of the genome with multi-scale approaches. Specifically, I will discuss the reconstruction of genome structures at both interphase and metaphase by making use of data from chromosome conformation capture experiments. Computationally modeling of chromatin fiber at atomistic level from first principles will also be presented as our effort for studying the genome structure from bottom up.

**M1.00269 Quantifying the DNA binding characteristics of ruthenium based threading intercalator  $\Lambda\text{-}\Lambda$ -P with optical tweezers**, NICHOLAS BRYDEN, Bridgewater State University, MA, MICAH MCCAULEY, Northeastern University, MA, FREDRIK WESTERLUND, PER LINCOLN, Chalmers University of Technology, Sweden, IOULIA ROUZINA, Ohio State University, OH, MARK WILLIAMS, Northeastern University, MA, THAYAPARAN PARAMANATHAN, Bridgewater State University, MA — Utilizing optical tweezers, biophysics researchers have been able to study drug-DNA interactions on the single molecule level. Binuclear ruthenium complexes are a particular type of drug molecule that have been found to have potential cancer-fighting qualities, due to their high binding affinity and low dissociation rates. These complexes are threading intercalators, meaning that they must thread their bulky side chains through DNA base pairs to allow the central planar moiety to intercalate between the bases. In this study, we explored the binding properties of the binuclear ruthenium complex,  $\Lambda\Lambda$ -P ( $\Lambda\Lambda$ -[ $\text{bidppz}(\text{phen})_4\text{Ru}_2$ ] $^{4+}$ ). A single DNA molecule is held at a constant force and the  $\Lambda\Lambda$ -P solution introduced to the system in varying concentrations until equilibrium is reached. DNA extension data at various concentrations of  $\Lambda\Lambda$ -P recorded as a function of time provide the DNA binding kinetics and equilibrium binding affinity. Preliminary data analysis suggests that  $\Lambda\Lambda$ -P exhibits fast binding kinetics compared to the very similar  $\Delta\Delta$ -P. These complexes have the same chemical structure and only differ in their chirality, which suggests that the left handed ( $\Lambda\Lambda$ ) threading moieties require less DNA structural distortion for threading compared with the right handed ( $\Delta\Delta$ ) threading moieties.

**M1.00270 Temperature Dependent Rotational Correlation in Lipids<sup>1</sup>**, CHRISTINA OTHON, NEDA DADASH-VAND, EDUARDO VEGA LOZADA, Wesleyan University — The lateral heterogeneity of lipid dynamics is explored in free standing lipid monolayers. As the temperature is lowered the lipids exhibit increasingly broad and heterogeneous rotational correlation. This increase in heterogeneity appears to exhibit a critical onset, similar to those observed for glass forming fluids. We explore this heterogeneous relaxation by measuring the rotational diffusion of a fluorescent probe (NBD-PC) using wide-field time-resolved fluorescence anisotropy microscopy, in single constituent lipid monolayer of DMPC. The observed relaxation exhibits a narrow, liquid-like distribution at high temperatures ( $\tau \sim 2.4$  ns), consistent with previous experimental measures by different methods. However, as the temperature is quenched, the distribution broadens, and we observe the appearance of a long relaxation population (16.5 ns). This demonstrates that the nanoscale diffusion and reorganization in lipid structures can be significantly complex, even in the simplest unstructured architectures. This result can have a significant impact on the organization, permeability and energetics of natural membrane structures.

**M1.00271 A study of the eigenvectors of low frequency vibrational modes in crystalline cytidine via high pressure infrared absorption and molecular dynamics simulations.**, CARL STARKEY, University of Toledo, KRISTINA WOODS, Carnegie-Mellon University, SCOTT LEE, University of Toledo — High-pressure infrared absorption experiments and molecular dynamics simulations have been used to study the eigenvectors and eigenvalues of the vibrational modes of crystalline cytidine at 295 K by evaluating the logarithmic derivative of the vibrational frequency with respect to pressure:  $\frac{1}{\omega} \frac{d\omega}{dP}$ . Crystalline samples of molecular materials such as cytidine have vibrational modes that are localized within a molecular unit ("internal" modes) as well as modes in which the molecular units vibrate against each other ("external" modes). The value of the logarithmic derivative is a diagnostic probe of the nature of the eigenvector of the vibrational modes, making high pressure experiments a very useful probe for such studies. Internal stretching modes have low logarithmic derivatives while external as well as internal torsional and bending modes have higher logarithmic derivatives. Modes at about 503, 757, 795, 3093 and 3351  $\text{cm}^{-1}$  are found to have negative logarithmic pressure derivatives, indicating a weakening of the effective force constants associated with those modes. The two modes above 3000  $\text{cm}^{-1}$  are hydrogen-bond-stretching modes. The identity of all of these modes will be determined via molecular dynamical simulations.

**M1.00272 Computational Study of Pseudo-phosphorylation of the Microtubule associated Protein Tau**, DMITRIY PROKOPOVICH, LUCA LARINI, Rutgers University-Camden — This computational study focuses on the effect of pseudo-phosphorylation on the aggregation of the microtubule associated protein tau. In the axon of the neuron, tau regulates the assembly of microtubules in the cytoskeleton. This is important for both stabilization of and transport across the microtubules. One of the hallmarks of the Alzheimer's disease is that tau is hyper-phosphorylated and aggregates into neurofibrillary tangles that lay waste to the neurons. It is not known if hyper-phosphorylation directly causes the aggregation of tau into tangles. Experimentally, pseudo-phosphorylation mimics the effects of phosphorylation by mutating certain residues of the protein chain into charged residues. In this study, we will consider the fragment called PHF43 that belongs to the microtubule binding region and has been shown to readily aggregate.

**M1.00273 Quantum Computational Calculations of the Ionization Energies of Acidic and Basic Amino Acids: Aspartate, Glutamate, Arginine, Lysine, and Histidine.**<sup>1</sup>, C. P. DE GUZMAN, M. ANDRIANARI-JAONA, Y. S. LEE, V. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA, 94508 — An extensive knowledge of the ionization energies of amino acids can provide vital information on protein sequencing, structure, and function. Acidic and basic amino acids are unique because they have three ionizable groups: the C-terminus, the N-terminus, and the side chain. The effects of multiple ionizable groups can be seen in how Aspartate's ionizable side chain heavily influences its preferred conformation (*J Phys Chem A*. 2011 April 7; 115(13): 2900–2912). Theoretical and experimental data on the ionization energies of many of these molecules is sparse. Considering each atom of the amino acid as a potential departing site for the electron gives insight on how the three ionizable groups affect the ionization process of the molecule and the dynamic coupling between the vibrational modes. In the following study, we optimized the structure of each acidic and basic amino acid then exported the three dimensional coordinates of the amino acids. We used ORCA to calculate single point energies for a region near the optimized coordinates and systematically went through the x, y, and z coordinates of each atom in the neutral and ionized forms of the amino acid. With the calculations, we were able to graph energy potential curves to better understand the quantum dynamic properties of the amino acids.

<sup>1</sup>The authors thank Pacific Union College Student Association for providing funds.

**M1.00274 Aggregation propensity of critical regions of the protein Tau**, MICAH MUTHEE, AZKA AHMED, LUCA LARINI, Rutgers University-Camden — The Alzheimer's disease is an irreversible, progressive brain disorder that slowly destroys memory and thinking skills, which eventually leads to the inability to carry out the simplest tasks. The Alzheimer's disease is characterized by the formation of protein aggregates both within and outside of the brain's cells, the neurons. Within the neurons, the aggregation of the protein tau leads to the destruction of the microtubules in the axon of the neuron. Tau belongs to a group of proteins referred to as Microtubule-Associated Proteins. It is extremely flexible and is classified as an intrinsically unstructured protein due to its low propensity to form secondary structure. Tau promotes tubulin assembly into microtubules thereby stabilizing the cytoskeleton of the axon of the neurons. The microtubule binding region of tau consists of 4 pseudo-repeats. In this study, we will focus on the aggregation propensity of two fragments. In this study we will focus on the PHF43 fragment that contains the third pseudo-repeat and has been shown experimentally to aggregate readily. Another fragment that contains the second pseudo-repeat will be considered as well. Mutations in this region are associated with various forms of dementia and for this reason we will consider the mutant P301L.

**M1.00275 A Novel Approach for Computing Cross-Sections in Ion-Mobility Measurements**, LUCA LARINI, OSCAR MARIN, Rutgers University - Camden — Mass spectrometry allows the identification of molecules based on their mass to charge ratio. One of the advantages of this technique is that it is able to distinguish molecules that differ for a small value of the mass. In addition, once the molecule of interest has been selected by the mass spectrometer, it can be further analyzed in an ion mobility tube that can characterize the conformations adopted by the molecule. This is extremely useful when dealing with unstructured proteins that populate multiple conformations. However, ion mobility distinguishes structures based on their cross-section. In order to associate a well-defined tridimensional structure to a specific cross-section, molecular dynamics simulations must be performed first, and then the theoretical cross-section compared to the experimental one. Computing a cross-section starting from molecular dynamics data is extremely computationally expensive. For this reason, we have developed a software that takes advantage of the multicore and multimode architecture of modern computer clusters.

**M1.00276 Single molecule fluorescence studies of transition paths in DNA hairpin folding**, KATHERINE TRUEX, HOI SUNG CHUNG, JOHN LOUIS, WILLIAM EATON, National Institutes of Health — DNA hairpins are the simplest structures for investigating fundamental aspects of nucleic acid folding mechanisms. For two-state hairpins, all of the mechanistic information on how the hairpin folds is contained in the transition path (TP), the rare event in single molecule trajectories when the free energy barrier between folded and unfolded states is actually crossed. The only previous experimental study of TPs in nucleic acids used optical tweezer measurements and Szabo's analytical theory for diffusive barrier crossing to reconstruct the free energy surface for an indirect determination of average TP times (Neupane *et al.* *PRL* 2012). We used confocal single molecule FRET and maximum likelihood analysis of photon trajectories to determine an upper bound of 2.5  $\mu$ s for the average TP time of a DNA hairpin (Truex *et al.*, *PRL* 2015), compared to the value of 4  $\mu$ s predicted by Neupane *et al.*, providing an important test of energy landscape theory. Current experiments are aimed at eventually characterizing structural changes during TPs, which will provide a very demanding test of mechanisms predicted by both theoretical models and simulations.

**M1.00277 Electrical Heart Defibrillation with Ion Channel Blockers**, ERIN FEENEY, COURTNEY CLARK, STEFFAN PUWAL, Oakland University — Heart disease is the leading cause of mortality in the United States. Rotary electrical waves within heart muscle underlie electrical disorders of the heart termed fibrillation; their propagation and breakup leads to a complex distribution of electrical activation of the tissue (and of the ensuing mechanical contraction that comes from electrical activation). Successful heart defibrillation has, thus far, been limited to delivering large electrical shocks to activate the entire heart and reset its electrical activity. In theory, defibrillation of a system this nonlinear should be possible with small electrical perturbations (stimulations). A successful algorithm for such a low-energy defibrillator continues to elude researchers. We propose to examine in silico whether low-energy electrical stimulations can be combined with antiarrhythmic, ion channel-blocking drugs to achieve a higher rate of defibrillation and whether the antiarrhythmic drugs should be delivered before or after electrical stimulation has commenced. Progress toward a more successful, low-energy defibrillator will greatly minimize the adverse effects noted in defibrillation and will assist in the development of pediatric defibrillators.

**M1.00278 Dynamics of driven transitions between minima of a complex energy landscapes**, SAI TEJA PUSULURI, Department of physics, Ohio University, ALEX H LANG, Computational Neurobiology Laboratory, Salk Institute, PANKAJ MEHTA, Department of physics, Boston University, HORACIO E CASTILLO, Department of physics, Ohio University — We recently modeled cellular interconversion dynamics[1] by using an epigenetic landscape model[2] inspired by neural network models. Given an arbitrary set of patterns, the model can be used to construct an energy landscape in which those patterns are the global minima. Here we study the transitions between stable states of the landscapes thus constructed, under the effect of an external driving force. We consider three different cases: i) choosing the patterns to be random and independently distributed ii) choosing a set of patterns directly derived from the experimental cellular transcription factor expression data for a representative set of cell types in an organism and iii) choosing randomly generated trees of hierarchically correlated patterns, inspired by biology. For each of the three cases, we study the stability of the global minima against thermal fluctuations and external driving forces, and the dynamics of the driven transitions away from global minima. We compare the results obtained in the three cases defined above, and in particular we explore to what degree the correlations between patterns affect the transition dynamics.

**M1.00279 Anomalous motor mediated cargo transport in microtubule networks**, STEVEN VANDAL, Worcester Polytechnic Institute, Dept of Physics, DANIEL MACVEIGH-FIERRO, ZHIYUAN SHEN, Worcester Polytechnic Institute, Dept of Biology and Biotechnology, KYLE LEMOI, Worcester Polytechnic Institute, Dept of Physics, LUIS VIDALI, Worcester Polytechnic Institute, Dept of Biology and Biotechnology, JENNIFER ROSS, University of Massachusetts Amherst, Dept of Physics, ERKAN TUZEL, Worcester Polytechnic Institute, Dept of Physics — Cargo transport is an important biological mechanism by which cells locomote, self-organize, and actively transport organelles. This transport is mediated by the cytoskeletal network and molecular motors; however, it is not known how network self-organization and dynamics affect these transport processes. In order to develop a mechanistic understanding of cargo transport, we use a coarse-grained Brownian dynamics model that incorporates the dynamics of these networks, as well as experimentally determined motor properties. We will test these models with two experimental systems: (1) in vitro microtubule networks with kinesin-1 motors, and quantum dot cargos on recreated microtubule networks, and (2) an excellent model organism, the moss *Physcomitrella patens*, in which chloroplasts are transported via the microtubule network by means of kinesin-like proteins. Phenomenological network characterizations are made, both in vivo and in vitro, and cargo motility is characterized using Mean Squared Displacement (MSD) measurements. Our simulations shed light on the role of network density and motor properties on the observed transport behavior, and improve our understanding of cargo transport in cells.

**M1.00280 Water - Based  $\text{TiO}_2$  Suspensions: A Raman Study**, ROBERTO RANGEL, DORINA CHIPARA, BRIAN YUST, DESIREE PADILLA, MIRCEA CHIPARA, The University of Texas Rio Grande Valley — The antibacterial features of  $\text{TiO}_2$  are under scrutiny due to the UV radiation, which contributes to the generation of reactive oxygen species, mainly in water environments. A study of  $\text{TiO}_2$  suspensions in water and broth is reported.  $\text{TiO}_2$  has a low solubility in water.  $\text{TiO}_2$  (anatase), with average diameter of 15 nm from Nanostructured & Amorphous Materials, Inc. has been added to the fluid (water, broth) and the mixture was stirred for 1-10 h, followed by a 10-60 minutes sonication. The suspension was left to sediment for 1 day before measurements. Quasistable suspensions of  $\text{TiO}_2$  in water and broth were investigated by Raman spectroscopy using a Renishaw InVia spectrometer operating at 532 and 785 nm. The spectra of the nanofiller have been simulated by a collection of Breit-Wigner Fano line shapes and the effect of the preparation conditions (stirring and sonication time) on the parameters of Raman lines are reported. The differences are explained by observing that the sonication destroys the agglomerates of anatase resulting in a better dispersion of nanoparticles and consequently a longer sedimentation time. Sample preparation/storage have been done both under dark and UV light conditions.

**M1.00281 The broadcasting mechanism of master regulator  $NF\kappa B$  switches.**, DAVIT POTOYAN, Rice University — The transcription factor  $NF\kappa B$  is involved in many cellular responses. Therefore there is a large number of sites in the genome to which  $NF\kappa B$  binds thereby activating myriad of genes as a response to various environmental stimuli. Kinetics becomes an important feature to reckon with in eukaryotic regulatory networks with many targets like the  $NF\kappa B$  system. In particular models based on the classical picture of genetic switches predict slow down regulation of  $NF\kappa B$  which can lead to wasteful over-expression of genes. A way to resolve this difficulty is to evolve faster ways of deactivating  $NF\kappa B$ . There is evidence from experiments and our simulations that this is done by an  $IkB$  induced process of stripping  $NF\kappa B$  off directly from its genetic sites instead of waiting for autonomous dissociation. The broadcasting mechanism proposed in this work solves the time scale problem inherent in the classical picture. Using combination of stochastic and deterministic models we show how such a mechanism results in efficient regulation of  $NF\kappa B$  network.

**M1.00282 Processing oscillatory signals by incoherent feedforward loops<sup>1</sup>**, CAROLYN ZHANG, FEILUN WU, RYAN TSOI, IGOR SHATS, LINGCHONG YOU, Duke University — From the timing of amoeba development to the maintenance of stem cell pluripotency, many biological signaling pathways exhibit the ability to differentiate between pulsatile and sustained signals in the regulation of downstream gene expression. While networks underlying this signal decoding are diverse, many are built around a common motif, the incoherent feedforward loop (IFFL), where an input simultaneously activates an output and an inhibitor of the output. With appropriate parameters, this motif can generate temporal adaptation, where the system is desensitized to a sustained input. This property serves as the foundation for distinguishing signals with varying temporal profiles. Here, we use quantitative modeling to examine another property of IFFLs, the ability to process oscillatory signals. Our results indicate that the system's ability to translate pulsatile dynamics is limited by two constraints. The kinetics of IFFL components dictate the input range for which the network can decode pulsatile dynamics. In addition, a match between the network parameters and signal characteristics is required for optimal "counting". We elucidate one potential mechanism by which information processing occurs in natural networks with implications in the design of synthetic gene circuits for this purpose.

**M1.00283 Shock wave irradiations avoiding fluid flow evoke intracellular  $\text{Ca}^{2+}$  signaling**, TORU TAKAHASHI, AKIRA TSUKAMOTO, SHIGERU TADA, National Defense Academy of Japan — Shock wave irradiation accelerates therapeutic effects including angiogenesis. One mechanism underlying those effects is cellular responses evoked by shock wave irradiation. Fluid flow is one of major physical phenomena induced by shock wave irradiation. Cellular responses evoked by fluid flow are similar to those evoked by shock wave irradiation. Thus, fluid flow could be responsible for cellular responses evoked by shock wave irradiation. However, it is obscure whether fluid flow is required for the cellular responses evoked by shock wave irradiation. In this study, intracellular  $\text{Ca}^{2+}$  signaling was observed in cells seeded in down-sized chambers. In the down-sized chambers, fluid flow was supposed to be suppressed because size of chambers (6 mm in diameter, 1 mm in thickness) was analogous to size of shock wave focus region (3mm in diameter). Dynamics of polystyrene microbeads suspended in the chambers were visualized with a CCD camera and analyzed with a particle image velocimetry (PIV) method to quantify fluid flow in the chamber. As a result, shock wave irradiation evoked intracellular  $\text{Ca}^{2+}$  signaling. However, fluid flow was not observed in the chamber due to shock wave irradiation. Thus, it was suggested that physical mechanics, not fluid flow, are further required for evoking intracellular  $\text{Ca}^{2+}$  signaling following to shock wave irradiation.

**M1.00284 Dynamics of phenotypic reversibility of bacterial cells with oscillating hydrostatic pressure**, SUDIP NEPAL, Univ of Arkansas-Fayetteville, PRADEEP KUMAR, Department of Physics, Univ of Arkansas-Fayetteville — Bacterial cells encounter and respond to physiochemical fluctuations. The response depends on the extent and type of the stresses applied. The response of bacterial cells to the fluctuating stress is relatively unknown. Here, we have studied the response of wild type *Escherichia coli* (*E. coli*) under fluctuating hydrostatic pressures ranging from 1 atm to 500 atm. High pressure acts as a stress to *E. coli* since these bacteria are adapted to grow optimally at atmospheric pressure. Cell division of *E. coli* is inhibited at high pressures resulting in increase in the length of the cells. Cell-length is reversible in nature and bacterial cells revert back to normal size on a time scale that is proportional to the strength and time of continuous pressure applied upon relaxing the high pressure condition. We have studied the dynamics of cellular reversibility of *E. coli* under the conditions in which continuous pressure is applied and subsequently relaxed over different time scales. We have quantified the dynamics of cellular reversibility with different relaxation times. Furthermore, we propose a model to describe the reversibility of the bacterial cell with the relaxation time. Our theoretical model fits well to the experimental data. We further

**M1.00285 Chiral pattern formation in compact microbial colonies**, KIRILL KOROLEV, ASHISH BINO GEORGE, Boston University — Chirality is ubiquitous in biology from single molecules to entire populations. Yet, we are still lacking a detailed understanding of how chiral patterns emerge from cell competition and growth, even in simple microbial colonies. Although many microbes grow as dense colonies with no apparent chirality, recent experiments with *Escherichia coli* have demonstrated that internal dynamics in such populations can be in fact chiral. We show that there is a unique way to extend the commonly-used reaction-diffusion models of colony growth to account for the emergent chirality. This new model connects microscopic and macroscopic chirality and explains the origin of logarithmic spirals separating different sub-populations in a colony. We also show that chirality is substantially enhanced by the cooperation among the cells at the expansion frontier. In heterogeneous populations composed of strains with different chiralities and growth rates, our model predicts a very rich set of possible dynamics. For example, different chiralities can result in either sharp boundaries between the strains or promote their intermixing depending on the preferred twisting directions of the strains.

**M1.00286 Adhesion of Mycobacterium smegmatis to Charged Surfaces and Diagnostics Implications.**<sup>1</sup> , DIANE GORSE, ALI DHINOJWALA, Univ of Akron, FRANCISCO MOORE, Univ of Akron, NSF — Pulmonary tuberculosis (PTB) causes more than 1 million deaths annually. Smear microscopy is a primary rapid detection tool in areas where 95 % of PTB cases occur. This technique, in which the sputum of a symptomatic patient is stained and examined using a light microscope for Mycobacterium tuberculosis (MTB) shows sensitivity between 20 and 60 %. Insufficient bacterial isolation during sample preparation may be a reason for low sensitivity. We are optimizing a system to capture bacteria on the basis of electrostatic interactions to more thoroughly isolate bacteria from suspension and facilitate more accurate detection. Silica supports coated with positively-charged polyelectrolyte, poly(diallyldimethylammonium chloride), captured approximately 4.1 times more Mycobacterium smegmatis, a model organism for MTB, than was captured on negatively-charged silica substrates. Future experimentation will employ branched polymer systems and seek to justify the use of colloidal stability theories to describe initial capture.

**M1.00287 Cell motility and antibiotic tolerance of bacterial swarms** , WENLONG ZUO<sup>1</sup>, Shenzhen Research Institute, The Chinese University of Hong Kong; Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong — Many bacteria species can move across moist surfaces in a coordinated manner known as swarming. It is reported that swarm cells show higher tolerance to a wide variety of antibiotics than planktonic cells. We used the model bacterium *E. coli* to study how motility affects the antibiotic tolerance of swarm cells. Our results provide new insights for the control of pathogenic invasion via regulating cell motility.

**M1.00288 The Effect of Graphene Oxide/Reduced Graphene Oxide Functionalized with Metal Nanoparticles on Dermal, Bacterial, and Cancerous/Non-Cancerous Epithelial Cells**<sup>1</sup> , ARTHUR CHEN, MIRIAM RAFAILOVICH, MARCIA SIMON, State Univ of NY- Stony Brook, REBECCA ISSEROFF, Lawrence Public High School, STEPHEN WALKER, State Univ of NY- Stony Brook, JAE HEE CHO, Boston University, JOHN JEROME, Suffolk University — Graphene and metal nanoparticles are permeating health products but their effects individually and combined on human skin are uncertain. This project studied the effect of graphene oxide (GO) and reduced graphene oxide (rGO) functionalized with Ag or Pt nanoparticles (Ag/PtNPs) on bacterial, dermal (DFBC's), and cancerous (SCC13's) and non-cancerous (DO33's) epidermal cells. GO was functionalized with AgNPs or PtNPs, forming metallized-GO; then reduced with NaBH<sub>4</sub>. FTIR and SEM confirmed the synthesis and composition. Confocal and SEM showed that Ag-rGO, depending on nanoparticle size, killed either *S. Aureus* or *K. Pneumoniae*, while Pt-rGO and rGO had no effect. Rhodamine staining revealed that Ag-rGO was very toxic to SCC13's, but only slightly toxic to DO33's. Pt-rGO and rGO had little effect on SCC13's and DO33's. At high concentrations all GO solutions inhibited cell growth but were not cytotoxic. Optical microscopy displayed that every GO/rGO solution adhered to DFBC's and influenced their direction of growth, making GO/rGO potentially applicable for wound healing.

**M1.00289 The functional consequences of non-genetic diversity in cellular navigation**<sup>1</sup> , THIERRY EMONET, ADAM J WAITE, NICHOLAS W FRANKEL, YANN DUFOUR, JESSICA F JOHNSTON, Yale University — Substantial non-genetic diversity in complex behaviors, such as chemotaxis in *E. coli*, has been observed for decades, but the relevance of this diversity for the population is not well understood. Here, we use microfluidics to show that non-genetic diversity leads to significant structuring of the population in space and time, which confirms predictions made by our detailed mathematical model of chemotaxis. We then use genetic tools to show that altering the expression level of a single chemotaxis protein is sufficient to alter the distribution of swimming behaviors, which directly determines the performance of a population in a gradient of attractant, a result also predicted by our model.

**M1.00290 Allosteric Small-Molecule Inhibitors of the AKT Kinase** , D. S. DALAFAVE, The College of New Jersey — This research addresses computational design of small druglike molecules for possible anticancer applications. AKT and SGK are kinases that control important cellular functions. They are highly homologous, having similar activators and targets. Cancers with increased SGK activity may develop resistance to AKT-specific inhibitors. Our goal was to design new molecules that would bind both AKT and SGK, thus preventing the development of drug resistance. Most kinase inhibitors target the kinase ATP-binding site. However, the high similarity in this site among kinases makes it difficult to target specifically. Furthermore, mutations in this site can cause resistance to ATP-competitive kinase inhibitors. We used existing AKT inhibitors as initial templates to design molecules that could potentially bind the allosteric sites of both AKT and SGK. Molecules with no implicit toxicities and optimal drug-like properties were used for docking studies. Binding energies of the stable complexes that the designed molecules formed with AKT and SGK were calculated. Possible applications of the designed putative inhibitors against cancers with overexpressed AKT/SGK is discussed.

**M1.00291 Effects of Chemotherapy-Induced Alterations in Cell Mechanical Properties on Cancer Metastasis** , SRUTI PRATHIVADHI, ANDREW EKPENYONG, MICHAEL NICHOLS, CAROLYN TAYLOR, JIANHAO NING, Creighton University — Biological cells can modulate their mechanical properties to suit their functions and in response to changes in their environment. Thus, mechanical phenotyping of cells has been employed for tracking stem cell differentiation, bacterial infection, cell death, etc. Malignant transformation of cells also involves changes in mechanical properties. However, the extent to which mechanical properties of cancer cells contribute to metastasis is not well understood. Yet, more than 90% of all cancer deaths are directly related to metastasis. Transit of cells through the microcirculation is one of the key features of metastasis. We hypothesize that cancer treatment regimens do inadvertently alter cell mechanical properties in ways that might promote cancer metastasis. We use a microfluidic microcirculation mimetic (MMM) platform which mimics the capillary constrictions of the pulmonary and peripheral microcirculation to determine if *in-vivo*-like mechanical stimuli can evoke different responses from cells subjected to various cancer drugs. In particular, we show that cancer cells treated with chemotherapeutic drugs such as daunorubicin, become more deformable at short timescales (0.1 s) and transit faster through the device. Our results are first steps in evaluating the pro- or anti-metastatic effects of chemotherapeutic drugs based on their induced alterations in cell mechanical properties.

**M1.00292 Collective motion in Proteus mirabilis swarms** , XU HAORAN<sup>1</sup>, Shenzhen Research Institute, The Chinese University of Hong Kong; Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong — *Proteus mirabilis* is a Gram-negative, rod-shaped bacterium. It is widely distributed in soil and water, and it is well known for exhibiting swarming motility on nutrient agar surfaces. In our study, we focused on the collective motility of *P. mirabilis* and uncovered a range of interesting phenomena. Here we will present our efforts to understand these phenomena through experiments and simulation.

**M1.00293 Swimming and transport of bacteria in time-periodic flows<sup>1</sup>** , REBECCA WINTER, ALISON PATTESON, DAVID GAGNON, PAULO ARRATIA, Univ of Pennsylvania — The transport of bacteria can be highly influenced by external flows in oceans, rivers, and intestinal tracts. This has implications in biological systems for the performance of major biological processes, such as biofilm formation. In this study, we experimentally investigate the aggregation and transport of swimming *Vibrio cholerae* bacteria in time-periodic flows. Bacteria are placed in a well-characterized flow, and bacterial concentrations are recorded for a range of Reynolds numbers (Re) that spans two orders of magnitude, from 0.1 to 10. It is generally found that bacteria deplete from regions of high deformation rate and accumulate near vortices. This phenomenon seems to be dictated by a combination of bacterial activity and background flow vorticity.

**M1.00294 Emergence of collective motion in bacterial suspensions** , SONG LIU<sup>1</sup>, Shenzhen Research Institute, The Chinese University of Hong Kong; Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong — It is well known that bacterial suspensions will exhibit collective motion at high concentrations, in which both steric and hydrodynamic interactions play important roles. We aim to investigate whether steric and hydrodynamic interactions are of equal importance to the emergence of collective motion. Here we will present our efforts to experimentally tune the relative strength of these interactions in bacterial suspensions. Our preliminary results suggest that the transition to collective motion may depend on the interplay between steric and hydrodynamic interactions.

<sup>1</sup>Mailing address: Room 306 Science Centre North Block, The Chinese University of Hong Kong, Shatin, N.T. Hong Kong SAR. Phone: +852-3943-6354. Fax: +852-2603-5204. E-mail: songliuphy@gmail.com

**M1.00295 Effect of microemulsions on cell viability of human dermal fibroblasts** , JUYI LI, TATSIANA MIRONAVA, MARCIA SIMON, MIRIAM RAFILOVICH, NISSIM GARTI, State Univ of NY- Stony Brook — Microemulsions are optically clear, thermostable and isotropic mixture consisting of water, oil and surfactants. Their advantages of ease preparation, spontaneous formation, long-term stability and enhanced solubility of bioactive materials make them great potentials as vehicles in food and pharmaceutical applications. In this study, comparative in vitro cytotoxicity tests were performed to select a best formulation of microemulsion with the least toxicity for human dermal fibroblasts. Three different kinds of oils and six different kinds of surfactants were used to form microemulsions by different ratios. The effect of oil type and surfactant type as well as their proportions on cell proliferation and viability were tested.

**M1.00296 Experimental evolution of *E. coli*** , MENGSHI ZHANG<sup>1</sup>, Shenzhen Research Institute, The Chinese University of Hong Kong; Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong — The evolution from unicellular to multicellular behavior is an essential step in the history of life. Our aim is to investigate the emergence of collective behavior in the model organism *Escherichia coli* (*E. coli*) and its selection advantages, such as better utilization of public goods. Our preliminary results suggest that the evolution of collective behavior may be a natural response to stressed conditions.

<sup>1</sup>Mailing address: Room 306 Science Centre North Block, The Chinese University of Hong Kong, Shatin, N.T. Hong Kong SAR. Phone: +852-3943-6354. Fax: +852-2603-5204. E-mail: mengshi0928@gmail.com

**M1.00297 Centrosome Positioning in 1D Cell Migration** , KATRINA ADLERZ, HELIM ARANDA-ESPINOZA, Univ of Maryland-College Park — During cell migration, the positioning of the centrosome and nucleus define a cell's polarity. For a cell migrating on a two-dimensional substrate the centrosome is positioned in front of the nucleus. Under one-dimensional confinement, however, the centrosome is positioned behind the nucleus in 60% of cells. It is known that the centrosome is positioned by CDC42 and dynein for cells moving on a 2D substrate in a wound-healing assay. It is currently unknown, however, if this is also true for cells moving under 1D confinement, where the centrosome position is often reversed. Therefore, centrosome positioning was studied in cells migrating under 1D confinement, which mimics cells migrating through 3D matrices. 3 to 5  $\mu\text{m}$  fibronectin lines were stamped onto a glass substrate and cells with fluorescently labeled nuclei and centrosomes migrated on the lines. Our results show that when a cell changes directions the centrosome position is maintained. That is, when the centrosome is between the nucleus and the cell's trailing edge and the cell changes direction, the centrosome will be translocated across the nucleus to the back of the cell again. A dynein inhibitor did have an influence on centrosome positioning in 1D migration and change of directions.

**M1.00298 Active microrheology reveals molecular-level variations in the viscoelastic properties of *Chaetopterus mucus*** , WILLIAM WEIGAND, Univ of San Diego, ASHLEY MESSMORE, University of California, San Diego, RAE ANDERSON, Univ of San Diego — The sea annelid, *Chaetopterus Variopedatus*, secretes a bioluminescent mucus that also exhibits complex viscoelastic properties. The constituents of the mucus are relatively unknown but it does play an important role in the development of the worms' parchment-like housing tubes. In order to determine how and why this mucus can exhibit material properties ranging from fluidity to rigidity we perform microrheology experiments. We determine the microscale viscoelastic properties by using optical tweezers to produce small oscillations in the mucus which allow us to determine both the linear storage and loss moduli ( $G'$ ,  $G''$ ) along with the viscosity of the fluid. By varying the size of the microspheres (2-10  $\mu\text{m}$ ) and oscillation amplitude (.5-10  $\mu\text{m}$ ) we are able to determine the dominant intrinsic length scales of the molecular mesh comprising the mucus. By varying the oscillation frequency (1-15Hz) we determine the crossover frequency at which  $G'$  surpasses  $G''$ , to quantify the longest relaxation time of the mesh network. Initial results show a strong dependence on bead size which indicate that the dominant entanglement lengthscale of the mucus mesh is  $\sim 5 \mu\text{m}$ . Microspheres of this size exhibit a wide variety of stress responses in different regions of the mucus demonstrating the substantial microscale heterogeneity of the mucus. We carry out measurements on a population of worms of varying size and age to determine mucus variability between worms.

**M1.00299 Regulation of muscle contraction by Drebrin-like protein 1 probed by atomic force microscopy.** , RENATA GARCES, EUGENIA BUTKEVICH, MITJA PLATEN, CHRISTOPH F. SCHMIDT, Third Institute of Physics - Biophysics, Georg August University, Göttingen, BIOPHYSICS TEAM — Sarcomeres are the fundamental contractile units of striated muscle cells. They are composed of a variety of structural and regulatory proteins functioning in a precisely orchestrated fashion to enable coordinated force generation in striated muscles. Recently, we have identified a *C. elegans* drebrin-like protein 1 (DBN-1) as a novel sarcomere component, which stabilizes actin filaments during muscle contraction. To further characterize the function of DBN-1 in muscle cells, we generated a new *dbn-1* loss-of-function allele. Absence of DBN-1 resulted in a unique worm movement phenotype, characterized by hyper-bending. It is not clear yet if DBN-1 acts to enhance or reduce the capacity for contraction. We present here an experimental mechanical study on *C. elegans* muscle mechanics. We measured the stiffness of the worm by indenting living *C. elegans* with a micron-sized sphere adhered to the cantilever of an atomic force microscope (AFM). Modeling the worm as a pressurized elastic shell allows us to monitor the axial tension in the muscle through the measured stiffness. We compared responses of wild-type and mutant *C. elegans* in which DBN-1 is not expressed..

**M1.00300 Quantifying Microtentacle Dynamics for Non-adherent Tumor Cells<sup>1</sup>**, ELEANOR ORY, DESU CHEN, University of Maryland, College Park, KRISTI CHAKRABARTI, STUART MARTIN, University of Maryland School of Medicine, WOLFGANG LOSERT, University of Maryland, College Park, UNIVERSITY OF MARYLAND, COLLEGE PARK COLLABORATION, UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE COLLABORATION — In current cancer medicine, metastasis is still responsible for 90

**M1.00301 Measuring shear force transmission across a biomimetic glycocalyx**, ISABEL BRAY, DYLAN YOUNG, JAN SCRIMGEOUR, Department of Physics, Clarkson University, Potsdam NY 13699 — Human blood vessels are lined with a low-density polymer brush known as the glycocalyx. This brush plays an active role in defining the mechanical and biochemical environment of the endothelial cell in the blood vessel wall. In addition, it is involved in the detection of mechanical stimuli, such as the shear stress from blood flowing in the vessel. In this work, we construct a biomimetic version of the glycocalyx on top of a soft deformable substrate in order to measure its ability to modulate the effects of shear stress at the endothelial cell surface. The soft substrate is stamped on to a glass substrate and then enclosed inside a microfluidic device that generates a controlled flow over the substrate. The hydrogel chemistry has been optimized so that it reliably stamps into a defined shape and has consistent mechanical properties. Fluorescent microbeads embedded in the gel allow measurement of the surface deformation, and subsequently, calculation of the shear force at the surface of the soft substrate. We investigate the effect of the major structural elements of the glycocalyx, hyaluronic acid and charged proteoglycans, on the magnitude of the shear force transmitted to the surface of the hydrogel.

**M1.00302 Micro-mechanical model for the tension-stabilized enzymatic degradation of collagen tissues**, THAO NGUYEN, Mechanical Engineering, Johns Hopkins University, JEFFERY RUBERTI, Department of Bioengineering, Northeastern University — We present a study of how the collagen fiber structure influences the enzymatic degradation of collagen tissues. Experiments of collagen fibrils and tissues show that mechanical tension can slow and halt enzymatic degradation. Tissue-level experiments also show that degradation rate is minimum at a stretch level coincident with the onset of strain-stiffening in the stress response. To understand these phenomena, we developed a micro-mechanical model of a fibrous collagen tissue undergoing enzymatic degradation. Collagen fibers are described as sinusoidal elastica beams, and the tissue is described as a distribution of fibers. We assumed that the degradation reaction is inhibited by the axial strain energy of the crimped collagen fibers. The degradation rate law was calibrated to experiments on isolated single fibrils from bovine sclera. The fiber crimp and properties were fit to uniaxial tension tests of tissue strips. The fibril-level kinetic and tissue-level structural parameters were used to predict tissue-level degradation-induced creep rate under a constant applied force. We showed that we could accurately predict the degradation-induced creep rate of the pericardium and cornea once we accounted for differences in the fiber crimp structure and properties.

**M1.00303 Mechanical model of kinesin moving on microtubule**, KIWING TO, Institute of Physics, Academia Sinica, YA-CHANG CHOU, YI-FENG HSIAO, KUAN-HUA CHEN, Department of Physics, National Tsing Hua University — Kinesins are biomolecules that serve as intercellular motors for carrying cellular cargos along microtubules. Although the mechanism of converting the chemical energy of ATP to mechanical work is not fully understood, the motion of a kinesin on a microtubule has been measured and two different mechanisms, namely the hand-over-hand and inchworm, has been proposed. The particular shape of kinesin and microtubules suggest a possible mechanism for force generation similar to Brownian ratchet. Using a bead chain connected to two heads that are attracted to a vibrated ratchet plate as a scaled up analog of the kinesin-microtubule system, we manage to simulate both handoverhand and inchworm motion [Chou, et. al., Physica A443, 66 (2015)]. In addition, we find that chain, which play the role of the stalk in a kinesin molecule, can also generate force by interacting with the ratchet plate [Chen, et. al. Phys. Rev. E87, 012711 (2013)].

**M1.00304 Food category consumption and obesity prevalence across countries: an application of Machine Learning method to big data analysis.**, JOCELYN DUNSTAN, Johns Hopkins Bloomberg Public Health School, SAEIDEH FALLAH-FINI, Cal Poly Pomona, CLAUDIA NAU, THOMAS GLASS, Johns Hopkins Bloomberg Public Health School, GLOBAL OBESITY PREVENTION CENTER TEAM — The applications of sophisticated mathematical and numerical tools in public health has been demonstrated to be useful in predicting the outcome of public intervention as well as to study, for example, the main causes of obesity without doing experiments with the population. In this project we aim to understand which kind of food consumed in different countries over time best defines the rate of obesity in those countries. The use of Machine Learning is particularly useful because we do not need to create a hypothesis and test it with the data, but instead we learn from the data to find the groups of food that best describe the prevalence of obesity.

**M1.00305 An analytically tractable model for community ecology with many species<sup>1</sup>**, BENJAMIN DICKENS, Department of Physics, Boston University, CHARLES FISHER, Bayesian Inference Group, Pfizer, Cambridge, MA, PANKAJ MEHTA, Department of Physics, Boston University, PANKAJ MEHTA BIOPHYSICS THEORY GROUP TEAM — A fundamental problem in community ecology is to understand how ecological processes such as selection, drift, and immigration yield observed patterns in species composition and diversity. Here, we present an analytically tractable, presence-absence (PA) model for community assembly and use it to ask how ecological traits such as the strength of competition, diversity in competition, and stochasticity affect species composition in a community. In our PA model, we treat species as stochastic binary variables that can either be present or absent in a community: species can immigrate into the community from a regional species pool and can go extinct due to competition and stochasticity. Despite its simplicity, the PA model reproduces the qualitative features of more complicated models of community assembly. In agreement with recent work on large, competitive Lotka-Volterra systems, the PA model exhibits distinct ecological behaviors organized around a special ("critical") point corresponding to Hubbell's neutral theory of biodiversity. Our results suggest that the concepts of "phases" and phase diagrams can provide a powerful framework for thinking about community ecology and that the PA model captures the essential ecological dynamics of community assembly.

**M1.00306 Speeding up evolution**, WOUTER HOFF, Oklahoma State University — Proteins and cells offer great opportunities for green chemistry and renewable energy. However, few of these possible applications have been put into practice because of details that turn out to be major barriers to cost-efficient implementation and that prove difficult to solve by genetic engineering. A better understanding of molecular evolution promises a novel approach to addressing these important challenges. While major advances have been made, major gaps remain in understanding the evolution of proteins. Different approaches to accelerating molecular evolution into targeted directions will be discussed, including recent progress on evolution in non-homogeneous environments.

**M1.00307 Population heterogeneity promotes a preference for blind cooperation**<sup>1</sup>, ALFONSO PEREZ-ESCUERO, JONATHAN FRIEDMAN, JEFF GORE, Massachusetts Institute of Technology — Game theory—and common sense—recommend to carefully weigh costs and benefits before deciding on a course of action. Yet we often disapprove of people who do so, even when their actual decision benefits us. For example, we prefer people who directly agree to do us a favor over those who agree only after securing enough information to ensure that the favor will not be too costly. Why should we care about how people make their decisions, rather than just focus on the decisions themselves? Hoffman et al. (2015) have shown that such aversion to information gathering may be beneficial when it is strong enough to increase the level of cooperation. Here we show that the same type of aversion arises in heterogeneous populations, but for a different reason: individuals who seek additional information may reveal themselves to be undesirable partners, since they are less likely to cooperate in the future when conditions change. Aversion to information gathering thus facilitates preferential interactions with blind cooperators, who are more favorable partners. Due to this new mechanism the prevalence of such aversion rapidly increases with population diversity, because partner discrimination is more useful in populations which harbor partners of a more varied quality.

**M1.00308 Complex sound stimuli representation by small neural groups in subcortical auditory structure**<sup>1</sup>, DOMINIKA LYZWA, Institute of Neuroscience, Newcastle University & Institute for Nonlinear Dynamics, University of Goettingen — The neural representation of complex natural sound stimuli in higher auditory structures is not yet well understood. Based on neurophysiological recordings from the mammalian auditory midbrain, neural responses to complex (natural and also artificial) sounds are investigated and mapped with respect to temporal and spectral neural tuning in the subcortical structure. The mapping includes spiking activity of single neurons and small neural clusters and local field potential activity. A neural model is presented which captures the mapping and also the similarity of responses across the auditory structure, and is used to predict responses to novel sound.

**M1.00309 A phylogenetic study of the section moduli of the humerus in bipedal theropod dinosaurs.**, SCOTT LEE, ZACHARY RICHARDS, University of Toledo — The section modulus of a bone is a measure of its ability to resist bending torques. Carnivorous dinosaurs including Tyrannosauroidae and Allosauroidae had strong humeri, presumably to hold struggling prey during hunting. The herbivorous dinosaurs of Ornithomimosauria had weak arm bones. This is believed to reflect the fact that their arms were never subjected to large bending torques. The unusual dinosaurs of Therizinosauria had arms as strong as found in the carnivorous dinosaurs. This is consistent with the hypothesis that their manus suggests a digging lifestyle. Other groups including Oviraptorosauria, Troodontidae, Dromaeosauridae and Compsognathidae are also examined.

**M1.00310 Physics of the Brain: Interaction of the Optical-Fiber-Guided Multi-Ultraviolet-Photon Beams with the Epilepsy Topion, (the Seizure Onset Area)**<sup>1</sup>, V. ALEXANDER STEFAN, Institute for Advanced Physics Studies, Stefan University, La Jolla, California 92037 — A novel method for the possible prevention of epileptic seizures is proposed, based on the multi-ultraviolet-photon beam interaction<sup>2</sup> with the epilepsy topion, (nonlinear coupling of an ultra high frequency mode to the brain beta phonons). It is hypothesized that epilepsy is a chaotic-dynamics phenomenon: small electrical changes in the epilepsy-topion lead, (within the 10s of milliseconds), to the onset of chaos, (seizure—excessive electrical discharge), and subsequent cascading into adjacent areas.<sup>3</sup> The ultraviolet photons may control the imbalance of sodium and potassium ions and, consequently, may prove to be efficient in the prevention of epileptic seizures.

**M1.00311 Asynchronous electrical activity in epileptic seizures**<sup>1</sup>, KATHERINE HOLMAN, Towson University, EUGENE LIM, Ohio Wesleyan University, STEPHEN GLISKE, WILLIAM STACEY, University of Michigan, CHRISTIAN FINK, Ohio Wesleyan University — High-frequency oscillations (HFOs) have been postulated to be potential biomarkers for focal epileptic seizures, with fast ripples (>250 Hz) as the most interesting candidate. The mechanisms underlying the generation of fast ripples, however, are not well understood. In this study, we draw upon results from previous computational studies on HFOs to develop a new mathematical model from first principles describing the generation of HFOs through asynchronous neuronal firing. Asynchrony in the model is obtained with the introduction of two parameters of heterogeneity: variability in the inter-spike interval (ISI) and jitter. The model predicts the generation of harmonic narrow-band oscillations if the heterogeneity-governing parameters do not differ from the predefined ISI by more than 20%. Comparisons against results from a separately constructed computational model verify the accuracy of the model in study. These results provide us with a rigorous framework in which we may investigate the mechanisms driving the generation of abnormal HFOs, and may serve as groundwork for future research in epileptogenesis.

**M1.00312 Columnar organization of orientation domains in V1**, JOSCHA LIEDTKE, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — In the primary visual cortex (V1) of primates and carnivores, the functional architecture of basic stimulus selectivities appears similar across cortical layers (Hubel & Wiesel, 1962) justifying the use of two-dimensional cortical models and disregarding organization in the third dimension. Here we show theoretically that already small deviations from an exact columnar organization lead to non-trivial three-dimensional functional structures. We extend two-dimensional random field models (Schnabel et al., 2007) to a three-dimensional cortex by keeping a typical scale in each layer and introducing a correlation length in the third, columnar dimension. We examine in detail the three-dimensional functional architecture for different cortical geometries with different columnar correlation lengths. We find that (i) topological defect lines are generally curved and (ii) for large cortical curvatures closed loops and reconnecting topological defect lines appear. This theory extends the class of random field models by introducing a columnar dimension and provides a systematic statistical assessment of the three-dimensional functional architecture of V1 (see also (Tanaka et al., 2011)).

**M1.00313 A Topological Perspective of Neural Network Structure**, ANN SIZEMORE, CHAD GIUSTI, University of Pennsylvania, MATTHEW CIESLAK, SCOTT GRAFTON, University of California Santa Barbara, DANIELLE BASSETT, University of Pennsylvania — The wiring patterns of white matter tracts between brain regions inform functional capabilities of the neural network. Indeed, densely connected and cyclically arranged cognitive systems may communicate and thus perform distinctly. However, previously employed graph theoretical statistics are local in nature and thus insensitive to such global structure. Here we present an investigation of the structural neural network in eight healthy individuals using persistent homology. An extension of homology to weighted networks, persistent homology records both circuits and cliques (all-to-all connected subgraphs) through a repetitive thresholding process, thus perceiving structural motifs. We report structural features found across patients and discuss brain regions responsible for these patterns, finally considering the implications of such motifs in relation to cognitive function.

**M1.00314 Automated Region of Interest Detection of Fluorescent Neurons for Optogenetic Stimulation**, JONATHAN MISHLER, DIETMAR PLENZ, Natl Inst of Mental Health - NIMH — With the emergence of optogenetics, light has been used to simultaneously stimulate and image neural clusters *in vivo* for the purpose of understanding neural dynamics. Spatial light modulators (SLMs) have become the choice method for the targeted stimulation of neural clusters, offering unprecedented spatio-temporal resolution. By first imaging, and subsequently selecting the desired neurons for stimulation, SLMs can reliably stimulate those regions of interest (ROIs). However, as the cluster size grows, manually selecting the neurons becomes cumbersome and inefficient. Automated ROI detectors for this purpose have been developed, but rely on neural fluorescent spiking for detection, requiring several thousand imaging frames. To overcome this limitation, we present an automated ROI detection algorithm utilizing neural geometry and stationary information from a few hundred imaging frames that can be adjusted for sensitivity.

**M1.00315 An in vivo analysis of facial muscle change treated with botulinum toxin type A using digital image speckle correlation**, YAN XU, SAMANTHA PALMACCIO PALMACCIO, DUC BUI, ALEXANDER DAGUM, MIRIAM RAFILOVICH, State Univ of NY- Stony Brook — Been famous for clinical use from early 1980s, the neuromuscular blocking agent Botulinum toxin type A (BTX-A), has been used to reduce wrinkles for a long time. Only little research has been done to quantify the change of muscle contraction before and after injection and most research paper depend on subjective evaluation from both patients and surgeons. In our research, Digital Image Speckle Correlation (DISC) was employed to study the mechanical properties of skin, contraction mode of muscles (injected) and reaction of neighbor muscle group (un-injected). At the same time, displacement patterns (vector maps) generated by DISC can predict injection locus for surgeons who normally handle it depending only on visual observation.

**M1.00316 Learning physical biology via modeling and simulation: A new course and textbook for science and engineering undergraduates**<sup>1</sup>, PHILIP NELSON, Univ Pennsylvania — To a large extent, undergraduate physical-science curricula remain firmly rooted in pencil-and-paper calculation, despite the fact that most research is done with computers. To a large extent, undergraduate *life-science* curricula remain firmly rooted in descriptive approaches, despite the fact that much current research involves quantitative modeling. Not only does our pedagogy not reflect current reality; it also creates a spurious barrier between the fields, reinforcing the narrow silos that prevent students from connecting them. I'll describe an intermediate-level course on "Physical Models of Living Systems." The prerequisite is first-year university physics and calculus. The course is a response to rapidly growing interest among undergraduates in a broad range of science and engineering majors. Students acquire several research skills that are often not addressed in traditional undergraduate courses: •Basic modeling skills; •Probabilistic modeling skills; •Data analysis methods; •Computer programming using a general-purpose platform like MATLAB or Python; •Pulling datasets from the Web for analysis; •Data visualization; •Dynamical systems, particularly feedback control.

**M1.00317 Light, Imaging, Vision: An interdisciplinary undergraduate course**<sup>1</sup>, PHILIP NELSON<sup>2</sup>, Univ Pennsylvania — The vertebrate eye is fantastically sensitive instrument, capable of registering the absorption of a single photon, and yet generating very low noise. Using eyes as a common thread helps motivate undergraduates to learn a lot of physics, both fundamental and applied to scientific imaging and neuroscience. I'll describe an undergraduate course, for students in several science and engineering majors, that takes students from the rudiments of probability theory to the quantum character of light, including modern experimental methods like fluorescence imaging and Frster resonance energy transfer. After a digression around color vision, we then see how the Feynman principle explains the apparently wavelike phenomena associated to light, including applications like diffraction, subdiffraction imaging, total internal reflection and TIRF microscopy. Then we see how scientists documented the single-quantum sensitivity of the eye seven decades earlier than 'ought' to have been possible, and finally close with the remarkable signaling cascade that delivers such outstanding performance. Course materials are available upon request.

**M1.00318 A Comparative Study Environmental and Radiological Causes Of Cancer In River Nile State, Sudan**, EYAD HAMID, International University of Africa, HATIM KHAIR, King Mohamed ibn saud University — The causes of cancer in River Nile state are differ between environmental and radiological, this paper tried to make comparison between the two causes, to determine the real cause behind the large rising of cancer cases in this state, considering the daily habits for the patients and the possible contamination in the natural resources around them. The noticeable thing that most of cancer cases are might be due to the high concentration of nitrate pollutant detected in natural resources such as drinking water; also by looking to the radioactive elements we see there's high concentration of some radioactive elements specially the K-40 which found in Portulaca Oleracea.

**M1.00319 Dissociative Electron Attachment**, ESMERALDA ARREOLA, None, ESMERALDA ARREOLA COLLABORATION, LEIGH HARGREAVES COLLABORATION — Since the pioneering work of Boudiffa et al. [1], it has been understood that electrons, even with energies near or below the ionization threshold, are capable of initiating strand-breaks in human DNA. This discovery raised important questions for cancer treatments, since sub-ionizing electrons are known to be the most copiously produced secondary product of radiation therapy. But even to date these factors are largely excluded from dosimetry calculations. This lack of inclusion is, at least in part, certainly due to the dearth of fundamental data describing low-energy electron interactions with nucleotide molecules that form the basis of DNA. Understanding of how such slow electrons are able to damage DNA remains incomplete, but the strongly peaked nature of Boudiffa et al.'s data gives strong hints at resonantly driven collision processes. DNA damage is therefore most likely driven by "dissociative electron attachment" (DEA). DEA is a rather complicated process to model due to the coupling of electronic and nuclear degrees of freedom in the molecule. At the California State University Fullerton, we are currently commissioning a new spectrometer to study dissociation channels, reaction rates and orientation effects in DEA collisions between slow electrons and nucleotide molecules. At the meeting we will present design parameters and commissioning data for this new apparatus. -/abstract- [1] Boudiffa et al., Science, 8

**M1.00320 ENERGY RESEARCH AND APPLICATIONS** —

**M1.00321 Photocurrent Enhancement in the ICG Dye Sensitized ZnO Nanowire Device<sup>1</sup>**, GEN LONG, MICHAEL BEATTIE, HUIZHONG XU, MOSTAFA SADOQI, Department of Physics, St John's University — In this presentation, we report a systematic study of photocurrent in ICG dye sensitized ZnO nanowire/FTO devices. ZnO nanowire is grown by hydrothermal method, with length of ~200nm to 1  $\mu$ m and diameter of ~30 to 60nm. ICG dye is incorporated by immersing ZnO grown FTO substrate. Different concentrations, solvents of ICG dye, sizes of ZnO nanowires and annealing temperatures and atmosphere after immersion were studied. The synthesized nanostructures and devices were characterized by XRD, UV-VIS absorption, SEM, AFM, solar simulator, etc. And an enhancement in the photocurrent due to ICG is observed.

**M1.00322 DFT+U Modeling of Hole Polarons in Organic Lead Halide Perovskites**, ERIC WELCH, Texas State Univ-San Marcos, PAUL ERHART, Chalmers Institute of Technology, LUISA SCOLFARO, ALEX ZAKHIDOV, Texas State Univ-San Marcos — Due to the ever present drive towards improved efficiencies in solar cell technology, new and improved materials are emerging rapidly. Organic halide perovskites are a promising prospect, yet a fundamental understanding of the organic perovskite structure and electronic properties is missing. Particularly, explanations of certain physical phenomena, specifically a low recombination rate and high mobility of charge carriers still remain controversial. We theoretically investigate possible formation of hole polarons adopting methodology used for oxide perovskites. The perovskite studied here is the ABX<sub>3</sub> structure, with A being an organic cation, B lead and C a halogen; the combinations studied allow for A<sub>1-x</sub>A<sub>2,1-x</sub>BX<sub>1-x</sub>X<sub>2,3-x</sub> where the alloy convention is used to show mixtures of the organic cations and/or the halogens. Two organic cations, methylammonium and formamidinium, and three halogens, iodine, chlorine and bromine are studied. Electronic structures and polaron behavior is studied through first principle density functional theory (DFT) calculations using the Vienna Ab Initio Simulation Package (VASP). Local density approximation (LDA) pseudopotentials are used and a +U Hubbard correction of 8 eV is added; this method was shown to work with oxide perovskites. It is shown that a localized state is realized with the Hubbard correction in systems with an electron removed, residing in the band gap of each different structure. Thus, hole polarons are expected to be seen in these perovskites.

**M1.00323 Photovoltaic conversion via hot electron induced thermionic emission from quantum dots**, ANDREI SERGEEV, KIMBERLY SABLON, U.S. Army Research Laboratory, Adelphi, MD 20783, USA — Quantum dot (QD) nanomaterials provide numerous possibilities for nanoscale engineering of photoelectron processes for specific applications, such as lighting, sensing, and energy conversion. It has been found that QDs may increase the photovoltaic conversion efficiency due to enhanced coupling with electromagnetic radiation, multiple exciton generation, and two-step light absorption. The hot electron induced thermionic emission from QDs is a novel mechanism, which may be significantly enhanced due to optimization of QD parameters. In this two-step process the photoelectrons excited from the valence band to localized quantum dot states are extracted from QDs via thermionic emission, which may be initiated by thermal phonons, hot phonons, and hot electrons. Strong interaction between the localized quantum dot electrons and hot photoelectrons excited by high energy photons substantially increases the conversion efficiency due to use of energy of sub-bandgap photons and energy of hot photoelectrons, which otherwise would be lost in relaxation processes. Here we present the theoretical model of the conversion via thermionic emission from quantum dots, results of optimization of photoelectron processes, and experimental data, which evidence in favor of this mechanism.

**M1.00324 Strain-induced tuning of surface energetics, electron conductivity and reduction drive in spinel LiMn<sub>2</sub>O<sub>4</sub> cathodes<sup>1</sup>**, IVAN SCIVETTI, GILBERTO TEOBALDI, University of Liverpool — LiMn<sub>2</sub>O<sub>4</sub> (LMO) implementation in cathodes of rechargeable Li-ion batteries (LIBs) is hampered by the limited lifetime of the material and the stability of its interfaces, starting from the Solid Electrolyte Interphase [1,2]. Recent experiments [2] and Density Functional Theory (DFT) simulations [3] indicate that the formation and effectiveness of the SEI on LMO are related to the surface orientation. In this context, we analyse the role of geometrical strain for the relative energy, magnetic ordering and the reduction drive of several LMO surfaces. DFT simulations reveal LMO surfaces to be markedly sensitive to geometrical strain. Strain lower than 10% can lead to insulator-metal and ferromagnetic-antiferromagnetic transitions, alter the relative energy of LMO surfaces, and induce changes as large as 1.0 eV in the surface chemical potential, thence the reduction drive. Prompted by advances in the synthesis of metal-oxide core-shell nanostructures [4], the use of strained LMO coating to enhance SEI-formation is put forward as a potential nano-engineered strategy for longer lived SEI on LMO substrates.

**M1.00325 Defect physics vis-à-vis electrochemical performance in layered mixed-metal oxide cathode materials**, KHANG HOANG, North Dakota State University, MICHELLE JOHANNES, Naval Research Laboratory — Layered mixed-metal oxides with different compositions of (Ni,Co,Mn) [NCM] or (Ni,Co,Al) [NCA] have been used in commercial lithium-ion batteries. Yet their defect physics and chemistry is still not well understood, despite having important implications for the electrochemical performance. In this presentation, we report a hybrid density functional study of intrinsic point defects in the compositions LiNi<sub>1/3</sub>Co<sub>1/3</sub>Mn<sub>1/3</sub>O<sub>2</sub> (NCM<sub>1/3</sub>) and LiNi<sub>1/3</sub>Co<sub>1/3</sub>Al<sub>1/3</sub>O<sub>2</sub> (NCA<sub>1/3</sub>) which can also be regarded as model compounds for NCM and NCA. We will discuss defect landscapes in NCM<sub>1/3</sub> and NCA<sub>1/3</sub> under relevant synthesis conditions with a focus on the formation of metal antisite defects and its implications on the electrochemical properties and ultimately the design of NCM and NCA cathode materials.

**M1.00326 Modified Graphene Oxide for Long Cycle Sodium-Ion Batteries<sup>1</sup>**, MUHAMED SHAREEF, Kansas State University, HARRISON GUNN, Syracuse University, VICTORIA VOIGT, GURPREET SINGH, Kansas State University — Hummer's process was modified to produce gram levels of 2-dimensional nanosheets of graphene oxide (GO) with varying degree of exfoliation and chemical functionalization. This was achieved by varying the weight ratios and reaction times of oxidizing agents used in the process. Based on Raman and Fourier transform infra red spectroscopy we show that potassium permanganate (KMnO<sub>4</sub>) is the key oxidizing agent while sodium nitrate (NaNO<sub>3</sub>) and sulfuric acid (H<sub>2</sub>SO<sub>4</sub>) play minor role during the exfoliation of graphite. Tested as working electrode in sodium-ion half-cell, the GO nanosheets produced using this optimized approach showed high rate capability and exceptionally high energy density of ~500 mAh/g for up to at least 100 cycles, which is among the highest reported for sodium/graphite electrodes. The average Coulombic efficiency was approximately 99 %.

<sup>1</sup>NSF Grant No. 1454151

**M1.00327 Use of TiO<sub>2</sub> nano particles in Sulfur electrodes to enhance cyclability of Li-S batteries**<sup>1</sup>, RUCHIRA DHARMASENA, GAMINI SUMANASEKERA, Department of Physics- University of Louisville, JACEK JASINSKI, ARJUN THAPA, MAHENDRA SUNKARA, Conn center-University of Louisville — Herein we investigate a novel and facile technique to fabricate Sulfur cathode for Li-S batteries with better cyclability and higher stable gravimetric capacity of around 750 mAh/g over 50 cycles. In this study we have experimented the use of TiO<sub>2</sub> nano particles to prevent polysulfide dissolution into the electrolyte. Absorption and adsorption properties of TiO<sub>2</sub> nano particles are used to trap Lithium Polysulfides. Excellent electrical conductivity property of carbonized polyacrylonitrile (PAN) carbon fibers is effectively used in this technique to establish better electrical connection to Sulfur in the bulk electrode. The thermal annealing technique we use in this work introduces a facile way to load Sulfur into the electrode. Mechanical properties of the Sulfur electrode is improved using a relatively easy way to sustain expansion and contraction at stable coulombic capacity with almost 100 % efficiency. The mechanism of the said Sulfur electrode is discussed in detail using cyclic voltammetry and Impedance spectrum analysis.

**M1.00328 Incorporation of Platinum and Gold Partially Reduced Graphene Oxide in Polymer Electrolyte Membrane Fuel Cells for Increased Carbon Monoxide Tolerance**<sup>1</sup>, LEE BLACKBURN, REBECCA ISSEROFF, MIRIAM RAFILOVICH, State Univ of NY- Stony Brook, JAYMO KANG, University of California, Berkeley, HONGFEI LI, MOLLY GENTLEMAN, State Univ of NY- Stony Brook, QIAO QIAO, Brookhaven National Laboratory — Polymer Electrolyte Membrane Fuel Cells (PEMFCs) can potentially provide “green” energy but the platinum catalyst’s susceptibility to carbon monoxide (CO) poisoning reduces output power. This project hypothesized that gold and platinum-partially reduced graphene oxide (Au/Pt-prGO) catalysts, incorporated into the electrodes and Nafion membrane of a PEMFC, will increase CO tolerance. Aliquots of graphene oxide (GO) were functionalized with platinum and/or gold nanoparticles. Partial reduction with NaBH<sub>4</sub> prevented precipitation. Raman Spectroscopy and HRTEM verified the chemical identity, structure, and presence of the materials. Setups were tested in a PEM fuel cell with a gas feed containing 1000 ppm of CO, and averaged an output power >200% over the control, with the most effective sample, Pt-prGO Electrode + Membrane, yielding an output power ~250% greater than the control. Additionally, each setup’s poisoned output power (P<sub>P</sub>) was compared to its highest possible output power (P<sub>M</sub>). AuPt-prGO Electrode + Membrane produced 100% of its highest possible output power when poisoned, displaying 100% resistance to all CO poisoning at the resistances tested.

**M1.00329 Harvesting Energy from the Flow-Induced Flutter of a ‘Piezoleaf’**, ANDRE RUAS, SANTIAGO ORREGO, KYLE DORAN, AARON RIPS, KOUROSH SHOELE, SUNG HOON KANG, RAJAT MITTAL, Johns Hopkins University — The objective of our research is to examine energy harvesting from the flow-induced flutter of a small piezoelectric membrane, which we call a ‘Piezoleaf’. Piezoleaves are small, low-cost, low-maintenance devices capable of powering small portable electronics or wireless sensors in remote areas. It is well known that piezoelectric membranes subjected to time-varying strains generate electrical energy that can be harvested. In the current project, we have designed and constructed a new, low-speed wind-tunnel (1’x1’, cross-section) to analyze the flow-induced flutter and energy harvesting performance of a small (approximately 1”x2”) piezoleaf. One of the novel features of this research is that the membrane is fixed at its trailing-edge (i.e. an inverted flag) since this is expected to generate more energy than a regular flag configuration. Guided by numerical simulation, we are conducting tests of this configuration in our wind tunnel for various wind speeds (maximum speeds of about 10 m/s) to examine the effect of wind-speed on the flutter and energy harvesting. High-speed videography is also being used to examine the dynamics of the flag and results from this project will be presented.

**M1.00330 High Temperature Concentrated Solar Power Using Liquid Metal**, ASEGUN HENRY, Georgia Institute of Technology — One of the most attractive ways to try and reduce the cost of concentrated solar power (CSP) is to increase the system efficiency and the biggest loss in the system occurs in the conversion of heat to electricity via heat engine. Heat engines that utilize turbomachinery currently operate near their thermodynamic limitations and thus one of the only ways to improve heat engine efficiency is to increase the turbine inlet temperature. Significant effort is being devoted to the development of supercritical CO<sub>2</sub> heat engines, but the most efficient heat engines are combined cycles, which reach efficiencies as high as 60%. However, such heat engines require turbine inlet temperatures ~1300-1500C, which is far beyond what is currently feasible with the state of the art molten salt infrastructure. In working towards the development of a system that can operate in the 1300-1500C temperature range, the most significant challenges lie in the materials and forming functional and reliable components out of new materials. One of the most attractive options from a cost and heat transfer perspective is to use liquid metals, such as tin and aluminum-silicon alloys along with a ceramic based infrastructure. This talk will overview ongoing efforts in the Atomistic Simulation and Energy (ASE) research group at Georgia Tech to develop prototype components such as an efficient high temperature cavity receiver, pumps and valves that can make a liquid metal based CSP infrastructure realizable.

**M1.00331 Cadmium Telluride Solar Cells with PEDOT:PSS Back Contact**<sup>1</sup>, MICHAEL MOUNT, FERNANDA DUARTE, Seton Hall University, NABA PAUDEL, YANFA YAN, University of Toledo, WEINING WANG, Seton Hall University — Cadmium Telluride (CdTe) solar cell is one of the most promising thin film solar cells and its highest efficiency has reached 21%. To keep improving the efficiency of CdTe solar cells, a few issues need to be addressed, one of which is the back contact. The back contact of CdTe solar cells are mostly Cu-base, and the problem with Cu-based back contact is that Cu diffuses into the grain boundary and into the CdS/CdTe junction, causing degradation problem at high temperature and under illumination. To continue improving the efficiency of CdTe/CdS solar cells, a good ohmic back contact with high work function and long term stability is needed. In this work, we report our studies on the potential of conducting polymer being used as the back contact of CdTe/CdS solar cells. Conducting polymers are good candidates because they have high work functions and high conductivities, are easy to process, and cost less, meeting all the requirements of a good ohmic back contact for CdTe. In our studies, we used poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) with different conductivities and compared them with traditional Cu-based back contact. It was observed that the CdTe solar cell performance improves as the conductivity of the PEDOT:PSS increase, and the efficiency (9.1%) is approaching those with traditional Cu/Au back contact (12.5%).

<sup>1</sup>Cadmium Telluride Solar Cells with PEDOT:PSS Back Contact

**M1.00332 Interface Conductance Modal Analysis**, ASEGUN HENRY, Georgia Institute of Technology — A formalism termed the interface conductance modal analysis (ICMA) method will be presented, which allows for calculations of the modal contributions to thermal interface conductance within the context of molecular dynamics (MD) simulations, which inherently include anharmonicity to full order. The eigen modes of vibration are calculated from harmonic lattice dynamics (LD) calculations, however the generality of ICMA formalism also allows for incorporation of anharmonic LD results into the calculations. The formalism itself is based on a modal decomposition of the heat flow across an interface, which is then substituted into expressions for the conductance either based on equilibrium or nonequilibrium MD. Several example cases will be covered and the interesting insights that emerge from the ICMA analyses will be discussed in detail. The ICMA method enables more in-depth study of various effects such as temperature, anharmonicity, interdiffusion, roughness, imperfections, dislocations, stress, changes in crystal structure through a single unified model, as it can essentially treat any material or object where the atoms vibrate around equilibrium sites (e.g., ordered or disordered solids and molecules).

**M1.00333 Transport and thermoelectric properties of hot-pressed  $\text{SnSe}_2$** , NGUYEN VAN QUANG<sup>1</sup>, NGUYEN THI MINH HAI, DUONG ANH TUAN, DUONG VAN THIET, CHO SUNGLAE<sup>2</sup>, University of Ulsan, SONG JAE YONG, PARK HYUNMIN, Korea Research Institute of Standards and Science, JAE YONG SONG COLLABORATION, HYUN-MIN PARK COLLABORATION — Recently,  $\text{SnSe}$  has been reported as ultralow thermal conductivity material which make it become a very high thermoelectric figure of merit ZT material, up to 2.6 at 923 K. But, it is hard to use  $\text{SnSe}$  for applications in high temperature range because  $\text{SnSe}$  decomposes at 700 K. Therefore, searching for crystalline materials with high ZT value at lower temperature is still an attracted field of research.  $\text{SnSe}_2$  is also 2D material which is expected to have low lattice thermal conductivity. However, less is known about thermoelectric property of  $\text{SnSe}_2$ . Eutectic  $\text{SnSe}_2\text{-Bi}_2\text{Se}_3$  has been repoted as a promising low-temperature thermoelectric material with  $\text{ZT}=0.56$  at 593 K. Here, we prepared the polycrystalline  $\text{SnSe}_2$  using hot pressure method. At temperature range up to 573 K, it exhibited an anisotropic n-type charge carrier. Ultra low thermal conductivity is achieved along parallel direction, however, ZT value is still very low whose maximum was 0.045 at 573 K due to low electrical conductivity, and increased with temperature. Our work showed the possibility to enhance ZT of  $\text{SnSe}_2$  polycrystalline via n- and p-type doping experiments.

**M1.00334 Correlation between dimensional crossover and thermoelectric performance in conducting polymer**, JUNHYEON JO, IN-SEON OH, MI-JIN JIN, JUNG-WOO YOO, Ulsan National Institute of Science and Technology (UNIST) — Conjugated polymers are emerging as attractive thermoelectric materials, resulting from low thermal conductivity, easy process and variable potentials for change. Recently, there are significant improvements of the Seebeck coefficient ( $S$ ) and electric conductivity ( $\sigma$ ) in the conjugated polymers by adding chemical additives to reform its ordinary disordered structure system. However, the relation between thermoelectricity and charge transport in the system is not well understood, which gives us a new challenge to improve thermoelectricity in the organic system. Here, we studied thermoelectric performance of dimethyl sulfoxide (DMSO) doped poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) (PEDOT:PSS) with adding variable amounts of fluorosurfactant Zonyl. The charge transport in this disordered system was analyzed within variable range hopping (VRH), which showed the change of hopping dimensionality with further molecular dopants. The morphological change and its effect on charge transport and thermoelectric performance were further investigated through AFM, XPS, etc. As a result, we found the optimal condition for increasing both the Seebeck coefficient and electric conductivity, resulting in a significant improvement for the power factor ( $S^2\sigma$ ).

**M1.00335 ABSTRACT WITHDRAWN** —

**M1.00336 Structural And Magnetic Properties In Off-Stoichiometric  $\text{MnNiGe}$  Based Thin Film And Bulk Compounds**, ANIL ARYAL, ABDIEL QUETZ, SUDIP PANDEY, SIUC, USA, IGOR RODIONOV, VALERII PRUDNIKOV, Moscow State Univ,Russia, TAPAS SAMANTA, LSU, USA, ALEXANDER GRANOVSKY, Moscow State Univ,Russia, ANDREI SOKOLOV, UNL, USA, IGOR DUBENKO, SIUC,USA, SHANE STADLER, LSU, USA, NAUSHAD ALI, SIUC,USA — The crystal structure, magnetic properties and magnetocaloric effect in  $\text{NiMnGe}$  based thin film and bulk compounds are studied by room temperature XRD and magnetization measurements. The bulk compounds  $\text{Ni}_{0.895}\text{Cr}_{0.105}\text{MnGe}_{1.05}$  and  $\text{Ni}_{0.93}\text{Cr}_{0.07}\text{MnGe}_{1.05}$  were prepared by arc melting process. Thin film was obtained from  $\text{Ni}_{0.895}\text{Cr}_{0.105}\text{MnGe}_{1.05}$  target using Pulsed Laser Deposition technique on  $\text{MgO}$  substrate. Both bulk and thin film crystalizes into hexagonal structure. For bulk  $\text{Ni}_{0.895}\text{Cr}_{0.105}\text{MnGe}_{1.05}$  a first order magnetostructural transition from antiferromagnetic orthorhombic to ferromagnetic hexagonal structure was observed near transition temperature 134 K followed by the second order transition (SOT) from ferromagnetic to paramagnetic near Curie temperature  $T_c = 204$  K. In case of thin film only the presence of SOT was observed near  $T_c$ . For  $\text{Ni}_{0.93}\text{Cr}_{0.07}\text{MnGe}_{1.05}$ ,  $\Delta T = 0.65\text{K}$  near  $T_c = 209$  K for  $\Delta H = 1.8$  T was observed. Sokolov acknowledges support from NSF DMR-1310542 grant.

**M1.00337 Efficiency, Power and Period of a model quantum heat engine working in a finite time**<sup>1</sup>, MULUGETA BEKELE, Associate Professor of Physics, AAU, TOLASA A DIMA, Graduate student, MEKUANNENT ALEMYE, Lecturer: Debre Tabor University, WARGA CHEGENO, Lecturer: Wolkite University — We take a spin-half quantum particle undergoing Carnot type cyclic process in a finite time assisted by two heat reservoirs and an external magnetic field. We find that the power of the heat engine is maximum at a particular period of the cyclic process and efficiency at the maximum power is at least half of the Carnot efficiency. We further apply the Omega-criterion for a figure of merit representing a compromise between useful power and lost power determining the corresponding efficiency for the optimization criterion to be at least three fourth of the Carnot efficiency.

**M1.00338 Enhancing photovoltaic efficiency through radiative cooling of solar cells below ambient temperature.**, TAQIYYAH SAFI, JEREMY MUNDAY, University of Maryland, College Park — Sunlight heats up solar cells and the resulting elevated solar cell temperature adversely effects the photovoltaic efficiency and the reliability of the cell. Currently, a variety of active and passive cooling strategies are used to lower the operating temperature of the solar cell. Passive radiative cooling requires no energy input, and is ideal for solar cells; however, previously demonstrated devices still operate above the ambient, leading to a lower efficiency as compared to the ideal Shockley-Queisser limit, which is defined for a cell in contact with an ideal heat sink at ambient temperature (300 K). In this talk, we will describe the use of radiative cooling techniques to lower the cell temperature below the ambient temperature. We show that by combining specifically designed radiative cooling structures with solar cells, efficiencies higher than the limiting efficiency achievable at 300 K can be obtained for solar cells in both terrestrial and extraterrestrial environments. We show that these structures yield an efficiency 0.87% higher than a typical PV module at operating temperatures in a terrestrial application. We also demonstrate an efficiency advantage of 0.4-2.6% for cells in an extraterrestrial environment in near-earth orbit.

**M1.00339 Li-air, rechargeable, solid-state batteries using graphene and boron nitride aerogel matrices.**<sup>1</sup>, ONUR ERGEN, THANG THOAN PHAM, SALLY DEMAIO-TURNER, ALEX ZETTL, University of California at Berkeley — The recent explosion of research on Li-Air batteries has provided new insights into developing more efficient air cathodes. Graphene and boron nitride aerogel matrix is anticipated to be an ideal candidate to produce a high throughput air-breathing system. We developed a Li-Air battery model that accounts for efficient  $\text{O}_2$  throughput. These unique aerogel matrices exhibit the ability to orient the  $\text{O}_2$  passing through and keep out  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , and  $\text{N}_2$ . Thus, the solid-state cells demonstrate a long cycle life, thermal stability, and high rechargeable characteristics. These cells also show an explicit discharge capacity with a constant discharge current density of  $0.1\text{mA}/\text{cm}^2$ .

**M1.00340 Experimental characterization of a small custom-built double-acting gamma-type stirling engine.**<sup>1</sup> , PETER INTSIFUL, Prairie View A & M University, Prairie View, TX, FRANCIS MENSAH, Virginia Union University, Richmond, VA, ARTHUR THORPE, Howard University, Washington, DC — This paper investigates characterization of a small custom-built double-acting gamma-type stirling engine. Stirling-cycle engine is a reciprocating energy conversion machine with working spaces operating under conditions of oscillating pressure and flow. These conditions may be due to compressibility as well as pressure and temperature fluctuations. In standard literature, research indicates that there is lack of basic physics to account for the transport phenomena that manifest themselves in the working spaces of reciprocating engines. Previous techniques involve governing equations: mass, momentum and energy. Some authors use engineering thermodynamics. None of these approaches addresses this particular engine. A technique for observing and analyzing the behavior of this engine via parametric spectral profiles has been developed, using laser beams. These profiles enabled the generation of pv-curves and other trajectories for investigating the thermos-physical and thermos-hydrodynamic phenomena that manifest in the exchangers. The engine's performance was examined. The results indicate that with current load of 35.78A, electric power of 0.505 kW was generated at a speed of 240 rpm and 29.50 percent efficiency was obtained.

**M1.00341 Effects of pH on the characteristics of ZnS thin films grown by using the CBD method**<sup>1</sup> , HEEJIN AHN, DONGCHAN LEE, SUJUNG PARK, YOUNGHO UM, Univ of Ulsan — In CIGS-based thin film solar cells, a chemically deposited ZnS buffer layer with high resistivity is generally used between the absorber layer and transparent conducting oxide layer. In this work, we report a chemical process to prepare ZnS films by the CBD technique based on the typical bath deposition. The influences of ammonia (NH<sub>4</sub>OH) and Na<sub>2</sub>EDTA (Na<sub>2</sub>C<sub>10</sub>H<sub>16</sub>N<sub>2</sub>O<sub>8</sub>) as complexing agents on structural, morphological, and optical properties of ZnS thin films are investigated ranging pH concentration from 5 to 10. To investigate effects of pH on the characteristics of ZnS thin films, by using UV-visible transmittance, atomic force microscopy, and optical absorption were investigated. With changing the pH range, the ZnS thin films demonstrate high transmittance of 75~80% in the visible region, indicating the films are potentially useful in photovoltaic applications. The results will be presented in detail.

**M1.00342 Silicon and phosphorus dual doped graphene as the promising metal-free catalysts for oxygen reduction reaction**<sup>1</sup> , ZHANSHENG LU, SHUO LI, ZONGXIAN YANG, Henan Normal University, RUQIAN WU, University of California Irvine — The pathways of oxygen reduction reaction (ORR) on the metal-free silicon and phosphorus dual doped graphene (Si-P-G) catalyst are systematically investigated based on the dispersion-corrected density functional theory (DFT-D) method. It is found that the Si-P-G can be stable at high temperature from the first-principles molecular dynamics simulation and the local region of dopants displays an important role in the adsorption and reduction of oxygen. Both of the four-electron O<sub>2</sub> direct dissociation and the two-electron OOH dissociation pathways are probable for ORR on the Si-P-G, while the latter pathway is mainly followed by the pathway of the OH hydrogenation into H<sub>2</sub>O. For the OOH dissociation pathway, the hydrogenation of O<sub>2</sub> to OOH is the rate-limiting step with a rather small barrier energy of 0.66 eV. The current results indicate that the Si-P-G is a novel metal-free catalyst for ORR, and which is comparable to that of the Pt catalyst.

<sup>1</sup>Work was supported by the National Science Foundation Center for Chemical Innovation on Chemistry at the Space-Time Limit (CaSTL) under Grant No. CHE-1414466, and the National Natural Science Foundation of China (Grant Nos. 51401078, and 11474086)

**M1.00343 Lattice-Boltzmann-based Simulations of Diffusiophoresis** , JOSHUA CASTIGLIEGO, JENNIFER KREFT PEARCE, Roger Williams University — We present results from a lattice-Boltzmann-based Brownian Dynamics simulation on diffusiophoresis and the separation of particles within the system. A gradient in viscosity that simulates a concentration gradient in a dissolved polymer allows us to separate various types of particles by their deformability. As seen in previous experiments, simulated particles that have a higher deformability react differently to the polymer matrix than those with a lower deformability. Therefore, the particles can be separated from each other. This simulation, in particular, was intended to model an oceanic system where the particles of interest were zooplankton, phytoplankton and microplastics. The separation of plankton from the microplastics was achieved.

**M1.00344 Electro-responsive supramolecular graphene oxide hydrogels for active bacteria adsorption and removal**<sup>1</sup> , BIN XUE, YI CAO, WEI WANG, Nanjing Univ — Bacteria are major contaminations in drinking water and healthcare products. Bacteria contamination may cause severe health problems, including food poisoning and diseases. Currently water sterilization and purification methods to remove contaminated bacteria are mainly based on the size-exclusion mechanism. In order to completely remove all bacteria in water, the pore sizes of the membranes or cartilages should be comparable to the size of bacteria, which inevitable leads to high cross-membrane water pressure and slow purification speed. Moreover, the membranes can easily get clogged. Therefore it is highly demanded to develop efficient methods and novel materials for water purification. Recently, Cui and coworker have introduced a bacteria inactivation method with high efficiency and fast purification speed based on a kind of complex materials made of silver nanofibers, carbon nanotubes and cotton, operating in an electric field. With the help of electric field, the bacteria can be efficiently kill when passing through the membrane even the pore sizes are larger than bacteria. Inspired by their work, here we report a proof-of-principle demonstration of bacteria removal using electro-responsive hydrogels.

**M1.00345 From Compartmentalized to Agent-based Models of Epidemics**<sup>1</sup> , CHARLES MACAL, Argonne National Laboratory — Supporting decisions in the throes of an impending epidemic poses distinct technical challenges arising from the uncertainties in modeling disease propagation processes and the need for producing timely answers to policy questions. Compartmental models, because of their relative simplicity, produce timely information, but often do not include the level of fidelity of the information needed to answer specific policy questions. Highly granular agent-based simulations produce an extensive amount of information on all aspects of a simulated epidemic, yet complex models often cannot produce this information in a timely manner. We propose a two-phased approach to addressing the tradeoff between model complexity and the speed at which models can be used to answer to questions about an impending outbreak. In the first phase, in advance of an epidemic, ensembles of highly granular agent-based simulations are run over the entire parameter space, characterizing the space of possible model outcomes and uncertainties. Meta-models are derived that characterize model outcomes as dependent on uncertainties in disease parameters, data, and structural relationships. In the second phase, envisioned as during an epidemic, the meta-model is run in combination with compartmental models, which can be run very quickly. Model outcomes are compared as a basis for establishing uncertainties in model forecasts.

**M1.00346 Analytical vacuum force, atmospheric pressure dispute**, HAN YONGQUAN, 15611860790 — Typically, the gap gas molecules is  $10^{-9}$  m, since the center speed of the tornado is over 100 m / sec, it divided by the speed of a tornado, the gap of the gas molecules becomes  $10^{-11}$  m. Equivalent to the gap when there is no tornado that the gas molecules allow radiation to pass through, equivalent to the gap is reduced gas molecules 100 times by a tornado. There is no change in the Earth's radiate, the Earth's radiation is reduced to one percent of the original intensity by the radiation through the tornado periphery into the center of the tornado. According to the APS Division of Nuclear Physics in APS -2013 Fall Meeting - Event - Gravitational radiation theory <http://meetings.aps.org/Meeting/DNP13/Session/FB.8>, which I published, the gravity will be reduced to the original gravity percentage one. Waterspout by the Earth's gravity to become the original one percent. Cause the external of the tornadoes atmospheric pressure is constant, the height waterspout should support column height atmospheric pressure is 100 times, that height waterspout may reach nearly kilometers.

**M1.00347 Observation of anomalous dielectric properties in low-dimensional spin 1/2  $\alpha$ - $\text{Cu}_2\text{V}_2\text{O}_7$  magnetic system**, YU-JEN CHEN, KAKARLA-DEVI CHANDRASEKHAR, KO-JUNG FAN, Department of Physics, National Sun Yat-Sen University, JIUNN-YUAN LIN, Institute of Physics, National Chiao Tung University, JENN-MIN LEE, JIN-MING CHEN, National Synchrotron Radiation Research Center, HUNG-DUEN YANG, Department of Physics, National Sun Yat-Sen University — Recently, low-dimensional magnetic systems have received much attention from both theoretical and experimental physics point of view due to their fascinating physical properties. In general,  $\text{Cu}_2\text{V}_2\text{O}_7$  can stabilize at least two sibling polymorphs named as  $\alpha$  and  $\beta$  phases. In  $\alpha$  phase,  $\text{Cu}_2\text{V}_2\text{O}_7$  crystallized in orthorhombic with  $Fdd2$  space groups. The complex magnetic exchange interaction between the Cu-O-Cu ion within the intra and interchain creates the Dzyaloshinskii-Moriya interaction that leads to weak ferromagnetism below the magnetic transition temperature  $T_N = 34$  K. In this study, we present the results of multiple dielectric anomalies observed in the low dimensional spin 1/2  $\alpha$ - $\text{Cu}_2\text{V}_2\text{O}_7$  magnetic system. The observed dielectric signatures can be ascribed to the complex magnetic interaction  $\alpha$ - $\text{Cu}_2\text{V}_2\text{O}_7$  system. Further, the chemical doping effect on the magnetic and multiferroic properties of  $\alpha$ - $\text{Cu}_2\text{V}_2\text{O}_7$  is underway.

**M1.00348 Quantum antiferromagnetic Heisenberg half-odd integer spin model as the entanglement Hamiltonian of the Affleck-Kennedy-Lieb-Tasaki valence bond solid states**, GUANG-MING ZHANG, Tsinghua University, Beijing — Applying a symmetric bulk bipartition to the one-dimensional Affleck-Kennedy-Lieb-Tasaki valence bond solid (VBS) states for the integer spin-S Haldane gapped phase, we can create an array of fractionalized spin-S/2 edge states with the super unit cell  $l$  in the reduced bulk system, and the topological properties encoded in the VBS wave functions can be revealed. The entanglement Hamiltonian (EH) with  $l = \text{even}$  corresponds to the quantum antiferromagnetic Heisenberg spin-S/2 model. For the even integer spins, the EH still describes the Haldane gapped phase. For the odd integer spins, however, the EH just corresponds to the quantum antiferromagnetic Heisenberg half-odd integer spin model with spinon excitations, characterizing the critical point separating the topological Haldane phase from the trivial gapped phase. Our results thus demonstrate that the topological bulk property not only determines its fractionalized edge states, but also the quantum criticality associated with the topological phase, where the elementary excitations are precisely those fractionalized edge degrees of freedom *confined* in the bulk of the topological phase.

**M1.00349 The flexibility of Daubechies wavelets for Linear Scaling DFT calculations**, LUIGI GENOVESE, STEPHAN MOHR, Commissariat l'nergie Atomique et aux nergies Alternatives, LAURA ELISABETH RATCLIFF, Argonne National Laboratory, DAMIEN CALISTE, THIERRY DEUTSCH, Commissariat l'nergie Atomique et aux nergies Alternatives, STEFAN GOEDECKER, Basel University — In recent works, we presented the linear scaling version of the BigDFT code [1] based on Daubechies wavelets, where a minimal set of localized support functions is optimized in situ. Our linear scaling approach is able to generate support functions for systems in various boundary conditions, like isolated, surface and periodic [2], and it is based on a algorithm which is universally applicable, requiring only moderate amount of computing resources. We will present how the flexibility of this approach is helpful in providing a basis set that is optimally tuned to the chemical environment surrounding each atom. In addition than providing a basis useful to project Kohn-Sham orbitals informations like atomic charges and partial density of states, it can also be reused as-is, i.e. without reoptimization, for charge-constrained DFT calculations within a fragment approach [3]. We demonstrate the interest of this approach to express highly precise and efficient calculations for preparing diabatic states and for the computational setup of systems in complex environments [4]. [1] J. Chem. Phys. 140, 204110 (2014) [2] Phys. Chem. Chem. Phys., 2015, DOI: 10.1039/C5C P00437C [3] J. Chem. Phys. 142, 23, 234105 (2015) [4] J.Chem. Theory Comput. 2015, 11, 2077

**M1.00350 Interdependent Lattice Networks in High Dimensions**, STEVEN LOWINGER, GABRIEL CWILICH, SERGEY BULDYREV, Yeshiva University — We study the mutual percolation of two interdependent lattice networks following the procedure outlined by Buldyrev *et al*<sup>1</sup>. We studied lattices of dimensions 2, 3, 4, 5 and 6. We imposed that the length of interdependent links connecting the nodes from one lattice to the other be less than a certain value,  $r$ . We find that for each dimension,  $D < 6$ , there is a value of  $r = r_I > 1$  such that for  $r \geq r_I$ , the cascading failures occur as a discontinuous first order transition, while for  $r < r_I$ , the system undergoes a continuous second order transition, as in the classical percolation theory.  $r_I$  decreases when the dimension of the lattice increases. For  $D = 6$ ,  $r_I = 1$ , which is the same as in random regular (RR) graphs with the same degree (coordination number) of nodes.  $D = 6$  is the upper critical dimension for classical percolation, the point at which the critical exponents of the lattice model become identical to those of RR graphs. We found that in all dimensions the maximal vulnerability of the networks, as a function of  $r$ , is achieved at a distance of  $r = r_{max} > r_I$ , but for  $r > r_{max}$  the vulnerability starts to decrease as  $r \rightarrow \infty$ . However, the decrease becomes less significant as the dimension increases and becomes negligible for  $D = 6$ . Results on how the parameters of the transition scale with the size of the system will be presented. [1] Catastrophic cascade of failures in interdependent networks, Buldyrev, Parshani, Paul, Stanley & Havlin, **Nature** 464, 1025-1028 (15 April 2010)

**M1.00351 Behavioral analysis of the escape response in larval zebrafish**, RUOPEI FENG, KIRAN GIRDHAR, YANN CHEMLA, MARTIN GRUEBELE, Univ of Illinois - Urbana — The behavior of larval zebrafish is of great interest because the limited number of locomotor neurons in larval zebrafish couples with its rich repertoire of movements as a vertebrate animal. Current research uses a priori-selected parameters to describe their swimming behavior while our lab has built a parameter-free model based on singular value decomposition analysis to characterize it. Our previous work has analyzed the free swimming of larval zebrafish and presented a different picture from the current classification of larval zebrafish locomotion. Now we are extending this work to the studies of their escape response to acoustic stimulus. Analysis has shown intrinsic difference in the locomotion between escape response and free swimming.

**M1.00352 Synchronization modulation of Na/K pumps on Xenopus oocytes**, PENGFEI LIANG, JASON MAST, WEI CHEN, Univ of South Florida — We developed a new technique named synchronization modulation to electrically synchronize and modulate the Na/K pump molecules by a specially designed oscillating electric field. This technique is based on the theory of energy-trap in quantum physics as well as the concept of electronic synchrotron accelerator. As a result, the Na-transporters are all entrapped into the positive half-cycle of the applied electric field and consequently, all of the K-transporters are entrapped into the negative half cycle of the field. To demonstrate the process of the pump synchronization and modulation, we use Xenopus oocytes as a platform and introduce two-electrode whole-cell voltage clamp in measurement of pump current. Practically, we first synchronize the pump molecules running at the same pace (rate and phase) by a specially designed oscillation electric field. Then, we carefully maintain the pump synchronization status and gradually change the field frequency (decrease and increase) to modulate the pump molecules to newer pumping rate. The result shows a separation of the inward K current from the outward Na current, and about 10 time increase of the total (inward plus outward) pump current from the net outward current from the random paced pump molecules. Also, the ratio of the modulated total pump current with synchronized total pump current is consistent with the ratio of their field frequencies.

**M1.00353 Kinetic inductance parametric up-converter**, ADITYA KHER, California Institute of Technology, PETER DAY, NASA Jet Propulsion Laboratory, BYEONG HO EOM, JONAS ZMUIDZINAS, California Institute of Technology, H. G. LEDUC, NASA Jet Propulsion Laboratory — We describe a novel class of devices based on the nonlinearity of the kinetic inductance of a superconducting thin film. By placing a current-dependent inductance in a microwave resonator, small currents can be measured through their effect on the resonator's frequency. By using a high-resistivity material for the film and nanowires as kinetic inductors, we can achieve a large coefficient of nonlinearity to improve device sensitivity. We demonstrate a current sensitivity of  $8 \text{ pA/Hz}^{1/2}$ , making this device useful for transition edge sensor readout and other cutting-edge applications. An advantage of these devices is their natural ability to be multiplexed in the frequency domain, enabling large detector arrays for TES-based instruments. A traveling-wave version of the device, consisting of a thin-film microwave transmission line, is also sensitive to small currents as they change the phase length of the line due to their effect on its inductance. We demonstrate a current sensitivity of  $5 \text{ pA/Hz}^{1/2}$  for this version of the device, making it also suitable for TES readout and other applications. It has the advantage of multi-GHz bandwidth and greater dynamic range, offering a different approach to the resonator version of the device.

**M1.00354 Atomistic study on the generation and gliding properties of pyramidal dislocations in magnesium**, HIDEO KABURAKI, MITSUHIRO ITAKURA, MASATAKE YAMAGUCHI, Japan Atomic Energy Agency — Plastic deformation of magnesium and its alloys is attracting great interest as one of the candidate materials for energy-conserving lightweight structural metals. The generation of non-basal pyramidal dislocations near the c-axis direction is the key to enhancing plasticity in these highly anisotropic hcp magnesium materials. However, the fundamental understanding of the generation and gliding properties of pyramidal dislocations is still not clear because of the large Burgers vector. Using the molecular dynamics method, we have successfully generated  $\langle c+a \rangle$  type I and II screw dislocations from the crack set in the perfect magnesium crystal by applying the shear stress. Visualization of these dislocations is important because the core structures are complex and largely extended. Comparing the results by first-principles calculations, we have found that the core of the type I screw dislocation is smoothly extended while that of the type II screw dislocation has a corrugated structure. We also found that both dislocations can easily cross-slip to other slip planes. In particular, it is observed that the core of the gliding pyramidal type I screw dislocation cross-slips to other slip planes. The detailed processes of cross-slip are elucidated in the presentation.

**M1.00355 Outdoor concert hall sound design: idea and possible solutions**, YANG-HANN KIM, JUNG-MIN LEE, Korea Adv Inst of Sci & Tech, WANJUNG KIM, HWAN KIM, NARU-EMS co. Ltd., JUNG-WOO CHOI, Korea Adv Inst of Sci & Tech, SEMYUNG WANG, Gwangju Inst of Sci & Tech — Sound design of outdoor concert halls needs to satisfy two contradictory objectives: good sound reproduction within the hall, as well as the minimization of external sound radiation. Outdoor concert hall usually has open space, therefore good sound for the listeners can be bad sound for its neighborhood. It would be a good attempt to have a virtual sound wall that can reflect all sound, therefore making a relatively quiet zone in the outside. This attempt can be possible if we could produce invisible but very high impedance mismatch around the hall, for a selected frequency band. This can be possible if we can generate an acoustically bright zone inside and a dark (quite) zone outside. Earlier work [Choi, J.-W. and Kim, Y.-H. (2002). J. Acoust. Soc. Am. 111, 1695–1700], at least, assures it is possible for a selected region and frequencies. Simulations show that it is possible for a two-dimensional case. Experimental verification has been also tried. The discrepancies have been explained in terms of the number of loudspeakers, their spatial distributions, spacing with regard to wavelength. The dependency of its performances with respect to the size of bright and dark zone scaled by wavelength of interest has also been explained.

**M1.00356 Multiscale modeling of nanostructured ZnO based devices for optoelectronic applications: Dynamically-coupled structural fields, charge, and thermal transport processes.**<sup>1</sup>, ABDULMUIN ABDULLAH, SAAD ALQAHTANI, MD REZAU KARIM NISHAT, SHAIKH AHMED, Southern Illinois University at Carbondale, SIU NANO-ELECTRONICS RESEARCH GROUP TEAM — Recently, hybrid ZnO nanostructures (such as ZnO deposited on ZnO-alloys, Si, GaN, polymer, conducting oxides, and organic compounds) have attracted much attention for their possible applications in optoelectronic devices (such as solar cells, light emitting and laser diodes), as well as in spintronics (such as spin-based memory, and logic). However, efficiency and performance of these hybrid ZnO devices strongly depend on an intricate interplay of complex, nonlinear, highly stochastic and dynamically-coupled structural fields, charge, and thermal transport processes at different length and time scales, which have not yet been fully assessed experimentally. In this work, we study the effects of these coupled processes on the electronic and optical emission properties in nanostructured ZnO devices. The multiscale computational framework employs the atomistic valence force-field molecular mechanics, models for linear and non-linear polarization, the 8-band  $sp^3s^*$  tight-binding models, and coupling to a TCAD toolkit to determine the terminal properties of the device. A series of numerical experiments are performed (by varying different nanoscale parameters such as size, geometry, crystal cut, composition, and electrostatics) that mainly aim to improve the efficiency of these devices.

<sup>1</sup>Supported by the U.S. National Science Foundation Grant No. 1102192

**M1.00357 ZnO nanowire-based CO sensor**, MON-SHU HO, Physics Department, National Chung Hsing University, WEI-HAO CHEN, Institute of Electronics Engineering, National Tsing Hua University, YU-LIN CHEN, Physics Department, National Chung Hsing University, MENG-FAN CHANG, Institute of Electronics Engineering, National Tsing Hua University — This study applied ZnO nanowires to the fabrication of a CO gas sensor operable at room temperature. Following the deposition of a seed layer by spin coating, an aqueous solution method was used to grow ZnO nanowires. This was followed by the self-assembly of an electrode array via dielectrophoresis prior to the fabrication of the CO sensing device. The material characteristics were analyzed using FE-SEM, EDS, GIXRD, FE-TEM, and the measurement of photoluminescence (PL). Our results identified the ZnO nanowires as a single crystalline wurtzite structure. Extending the growth period from 30 min to 360 min led to an increase in the length and diameter of the nanowires. After two hours, the ZnO presented a preferred crystal orientation of [002]. Sensor chips were assembled using 60 pairs of electrodes with gaps of  $2 \mu\text{m}$ , over which were laid nanowires to complete the sensing devices. The average sensing response was 48.37 s and the average recovery time was 65.61 s, with a sensing response magnitude of approximately 6.8% at room temperature.

**M1.00358 Neutron Imaging Studies of In Situ Growth of Neutron and Gamma Detector Materials**, NICHOLAS STRANGE, CHRISTOPHER CRAIN, FATEMA WAHIDA, ZACH STROUPE, J.Z. LARESE, University of Tennessee — The studies described here are aimed at addressing the critical need to develop dependable crystal growth techniques of solid-state materials used as radiation detectors for both national security and medical applications. We present our activities using pulsed neutron, radiographic imaging and simultaneous diffraction techniques to examine the synthesis of both CZT and CLYC with the goal of identifying the conditions that favor the production of defect free materials. Using a pulsed neutron beam and time of flight detection methods, we exploit the penetrating power and wavelength dependence of neutron absorption to perform measurements during crystal growth. Furthermore, solid boules can be examined either inside the furnace or free standing. The objective of these studies include the validation/improvement of the modeling studies of CLYC and CZT growth behavior, the development of new/improved furnace design, and the identification of optimum growth techniques that enable the production of large boules of defect free, single crystalline materials in a timely/cost effective manner. We provide our preliminary results that include the experiential setup at LANSCE and sample neutron radiographic and synchrotron based IR images of CZT flat solid plates.

**M1.00359 Investigation of Natural *Bombyx mori* Silk Fibroin Proteins Using INS**, CHRISTOPHER CRAIN, NICHOLAS STRANGE, J.Z. LARESE, Univ of Tennessee, Knoxville — The mechanical properties of many protein comprised biomaterials are a direct reflection of non-covalent (i.e. weak) interacting ions such as F-actin in muscles, tubulin in the cytoskeleton of cells, viral capsids, and silk. Porter and Vollrath underscored the two main factors that are critical for understanding the high mechanical strength of silks: the nanoscale semi-crystalline folding structure, which gives it exceptional toughness and strength, and the degree of hydration of the disordered fraction, which acts to modify these properties. Understanding and controlling these two principal factors are the key to the functionality of protein elastomers, and render silk an ideal model protein for (bio)material design. We will describe our investigation of electrospun silk of the *Bombyx mori* (silk worm), using Inelastic Neutron Scattering (INS). These techniques were used to investigate the microscopic dynamics of the dry and hydrated protein.

**M1.00360 Study of the nanosurface properties by analyzing its absorption and scattering cross-section.**, IRINA BARIAKHTAR, Boston College — The interest to study the nanoparticles absorbed on the dielectric or semiconductor substrate is caused by the multiple practical applications of these systems such as nanosensors, electronic devices and lately in PV elements for improving of their efficiency [1, 2]. The author suggests a method of examining the properties of the nanosurface with the absorbed nanoparticle by calculating the absorption and scattering of the electromagnetic field by such system based on construction of its effective electric susceptibility. It was built based on the Green's function approach [3]. The computer simulations show good correspondence with the theory. It was shown that this approach can be applied to investigate the optical absorption and scattering on the nanoparticles on the substrate to be used in PV engineering. 1. Schaad, D. M., Feng, B., Yu, E. Appl. Phys. Lett. 86 (6): 063106 (2005) 2. K. R. Catchpole and A. Polman, Opt. Express 16, 21793-21800 (2008) 3. I. Bariatkhar, Y. Demidenko, S. Kriuchenko, V. Lozovski, Surf. Sci. 323 (1995).

**M1.00361 Controlling Spin State of Magnetic Molecules by Oxygen Binding Studied Using Scanning Tunneling Microscopy**, SOON-HYEONG LEE, Korea University, YUN HEE CHANG, KAIST, HOWON KIM, KYUNG MIN KIM, Korea University, YONG-HYUN KIM, KAIST, SE-JONG KAHNG, Korea University — Binding and unbinding between molecular oxygen and metallo-porphyrin is a key process for oxygen delivery in respiration. It can be also used to control spin state of magnetic metallo-porphyrin molecules. Controlling and sensing spin states of magnetic molecules in such reactions at the single molecule level is essential for spintronic molecular device applications. Here, we demonstrate that spin states of metallo-porphyrin on surfaces can be controlled over by binding and unbinding of oxygen molecule, and be sensed using scanning tunneling microscopy and spectroscopy. Kondo localized state of metallo-porphyrin showed significant modification by the binding of oxygen molecule, implying that the spin state was changed. Our density functional theory calculation results explain the observations with the hybridization of unpaired spins in d and  $\pi^*$  orbitals of metallo-porphyrin and oxygen, respectively. Our study opens up ways to control molecular spin state and Kondo effect by means of molecular binding and unbinding reactions on surfaces.

**M1.00362 Spotting the Gel Point of Photopolymers by Examining NMR Relaxation**, JACK LEE, GRETCHEN HOFMEISTER, MARTHA-ELIZABETH BAYLOR, Carleton College — Spotting when a polymer goes from liquid to solid during polymerization is necessary when working with certain optically cured polymers used to fabricate optofluidic devices that contain both optical and microfluidic features. Through the use of nuclear magnetic resonance (NMR) it may be possible to determine when the transition from liquid to solid, called the gel point, occurs. In examining the proton longitudinal relaxation time for one species of monomers in our polymer mix, our data shows as the polymer cures the relaxation time increases. By examining this data we were able to extract a time to gel point that was within the margin of error of the theoretical gel point of our materials. Outlined here is evidence of why we think longitudinal relaxation is applicable to studying polymerization, and how we are using it to attempt to extract the gel point.

**M1.00363 Observation of Voltage Oscillations in VO<sub>2</sub> with Negative Differential Resistance**, DAE-JOON KANG, HYOUNG WOO YANG, GARAM BAE, Department of Physics, Sungkyunkwan University, Republic of Korea — Many strongly correlated electron systems exhibit complex nonlinear behaviors with electric fields. The origin of the electrical instabilities is closely related to a negative differential resistance (NDR). Here, we report electrical characteristics of two-terminal devices based on vanadium dioxide (VO<sub>2</sub>) thin films fabricated on c-cut sapphire substrates, exhibiting NDR behavior in their I-V characteristics that may work as a voltage oscillator of high efficiency. We show that the NDR behavior can be better understood in the context of metal-insulator phase transition. Furthermore, we found that the source voltage and frequency affect greatly the NDR behaviors, which is indicated by an evident shift of oscillation voltage from 10 V to 1 V. Based on the experimental results, with the source voltage and the frequency systematically varied, the mechanism of the oscillation was found to be the ascribed to an alternate occurrence of an electric-field-induced resistance switching in the MIT of VO<sub>2</sub>. We discuss herein, the origin and potential applications of NDR based devices in detail and investigated the voltage oscillation behaviors of VO<sub>2</sub> to elucidate the underlying physics of its metal insulator transition behavior.

**M1.00364 Cloisite 30B as Nanoclay Compatibilizer for Polysulfone/Polyimide Blend Films.**, ALI AMMAR, Akron Univ, AHMED ELZATAHRY, MARIAM AL-MAADEED, Qatar Univ, ABDULLAH ALLENIZI, King Saud Univ, KARIM ALAMGIR, Akron Univ — Polysulfone (PSF) and polyimide (PI) are used in many applications including membranes for gas separation and water purification. The phase separation issues limit the blend application of these polymers. We studied the effect of nanoclay and Cloisite 30B had on (PSF/PI) films. This was done in order to examine the compatibility effects of clay on phase separation behavior, mechanical strength, and structure properties. The addition of weight percentage of organoclay strongly compatibilized the blend phases for all compositions, decreasing the scale of blend phase separation by a factor of 5-10. Interestingly, the net phase separated domain area converged to the 50% blend composition in all cases. This is attributed to a high degree of exfoliation and degradation of nanoclay particles within the PSF/PI matrix as well as interfacial regions, independent of the blend composition. AFM confirmed these optically observed compatibilization effects by quantitative reduction of aspect ratio (width/height) of surface phase separated domains. The surface free energies of the films decreased by adding C30B. This has led us to conclude that there is a changing of surface topography, which conformed to the contact angle. PSF/PI films showed decreasing in thermal stability due to the surfactant modification of C30B.

**M1.00365 Electronic state modulation of iron selenide by intercalating copper**, KAYA KOBAYASHI, Y ITO, F NAGAI, S MATSUMOTO, T KAMBE, Y BENINO, T NAMBA, Okayama University — FeSe is one of the iron-based superconductors that have the simplest structure. Its superconducting properties are easily modulated by chemical and mechanical method, such as alkali metal intercalation and thinning down to monolayer. The synthesis of copper intercalation by melt method brought the structural change of the system in increasing the copper amount. To investigate the superconducting property of the system, we have synthesized copper intercalated FeSe single crystal. The decrease of superconducting transition temperature observed here is discussed in relation to its modulation on to electronic state of irons.

**M1.00366 Boson Sampling with Trapped Ions**, KATHERINE COLLINS, Univ of Maryland-College Park, KENNETH WRIGHT, CHRISTOPHER RICKERD, CHRISTOPHER MONROE, Univ of Maryland-College Park and Joint Quantum Institute — A classical computer is limited in its ability to solve certain types of problems. A quantum computer might be able to solve some of these problems more efficiently. Calculating the permanent of an  $N \times N$  matrix is an example of a problem that cannot be efficiently solved by a classical computer. Computing the permanent of an  $N \times N$  matrix can be related to the probability of finding a given occupation distribution for  $M$  bosonic modes populated with  $N$  identical bosons. This type of experiment is known as boson sampling. Classically, the computation time required to evaluate the permanent of an  $N \times N$  matrix scales on the order of  $2^N N^2$ .<sup>1</sup> A quantum device that is able to compute an  $N \times N$  permanent through boson sampling represents a physical device that can evaluate a problem not efficiently solvable by a classical system. Some experiments have already demonstrated boson sampling with photons for a small number of bosonic modes, but it is difficult to increase the number of bosons in such experiments. One way to demonstrate a larger-scale boson sampling problem is to use the phonon excitations of a trapped ion chain. We present our progress towards experimentally demonstrating boson sampling with trapped ions.

**M1.00367 Block Copolymer-Based Supramolecular Elastomers with High Extensibility and Large Stress Generation Capability**<sup>1</sup>, ATSUSHI NORO, MIKIHIRO HAYASHI, Nagoya University — We prepared block copolymer-based supramolecular elastomers with high extensibility and large stress generation capability. Reversible addition fragmentation chain transfer polymerizations were conducted under normal pressure and high pressure to synthesize several large molecular weight polystyrene-*b*-[poly(butyl acrylate)-*co*-polyacrylamide]-*b*-polystyrene (S-Ba-S) block copolymers. Tensile tests revealed that the largest S-Ba-S with middle block molecular weight of 3140k achieved a breaking elongation of over 2000% with a maximum tensile stress of 3.6 MPa and a toughness of 28 MJ/m<sup>3</sup> while the reference sample without any middle block hydrogen bonds, polystyrene-*b*-poly(butyl acrylate)-*b*-polystyrene with almost the same molecular weight, was merely viscous and not self-standing. Hence, incorporation of hydrogen bonds into a long soft middle block was found to be beneficial to attain high extensibility and large stress generation capability probably due to concerted combination of entropic changes and internal potential energy changes originating from the dissociation of multiple hydrogen bonds by elongation.

**M1.00368 Continued Growth on Graphene Edges**, ZHENG TANG LUO, Hong Kong Univ of Sci & Tech — Previously, we have shown that the large-size single crystal graphene can be obtained by suppressing the nucleation density during Chemical Vapor Deposition (CVD) growth. Here we demonstrate that the graphene single crystal can be amplified by a continued growth method. In this process, we used a mild oxidation step after the first-growth, which lead to the observed formation of oxides at the vicinity of graphene edges, which allows the graphene growth at seed edges due to reduced activation energy. Consequently, we successfully grown a secondary single-crystal graphene structures with the same lattice structure, orientation on the graphene edges. This amplification method would enable the production of graphene electronics with controlled properties.

**M1.00369 Nonlinear Transport and Noise Properties of Acoustic Phonons**.<sup>1</sup>, KAMIL WALCZAK, Pace University — We examine heat transport carried by acoustic phonons in molecular junctions composed of organic molecules coupled to two thermal baths of different temperatures. The phononic heat flux and its dynamical noise properties are analyzed within the scattering (Landauer) formalism with transmission probability function for acoustic phonons calculated within the method of atomistic Green's functions (AGF technique). The perturbative computational scheme is used to determine nonlinear corrections to phononic heat flux and its noise power spectral density with up to the second order terms with respect to temperature difference. Our results show the limited applicability of ballistic Fourier's law and fluctuation-dissipation theorem to heat transport in quantum systems. We also derive several noise-signal relations applicable to nanoscale heat flow carried by phonons, but valid for electrons as well. We also discuss the extension of the perturbative transport theory to higher order terms in order to address a huge variety of problems related to nonlinear thermal effects which may occur at nanoscale and at strongly non-equilibrium conditions with high-intensity heat fluxes.

**M1.00370 Spectroscopic study of some diatomic molecules via the proper quantization rule**, B. FALAYE, IPN, Mexico City, Mexico — Spectroscopic techniques are very essential tools in studying electronic structures, spectroscopic constants and energetic properties of diatomic molecules. These techniques are also required for parametrization of new method based on theoretical analysis and computational calculations. In this research, we apply the proper quantization rule in spectroscopic study of some diatomic molecules by solving the Schrödinger equation with two solvable quantum molecular systems-Tietz-Wei and shifted Deng-Fan potential models for their approximate nonrelativistic energy states via an appropriate approximation to the centrifugal term. We show that the energy levels can be determined from its ground state energy. The beauty and simplicity of the method applied in this study is that, it can be applied to any exactly as well as approximately solvable models. The validity and accuracy of the method is tested with previous techniques via numerical computation for H<sub>2</sub> and CO diatomic molecules. The result also include energy spectrum of 5 different electronic states of NO and 2 different electronic state of ICl.

**M1.00374 Can we judge an oxide by its cover? The case of the metal/oxide interface from first principles<sup>1</sup>**, MAYTAL CASPARY TOROKER, Department of Materials Science and Engineering — Metal/metal-oxide interfaces appear in a wide variety of disciplines including electronics, corrosion, electrochemistry, and catalysis. Specifically, covering a metal-oxide with a metal is often thought to enhance solar energy absorption and to improve photocatalytic activity. For example, the platinum/hematite (Pt/ $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>) interface has demonstrated improved functionality. In order to advance our understanding of how metal coverage over an oxide helps performance, we characterize the geometry and electronic structure of the Pt/ $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> interface. We investigate the interface using density functional theory +U, and find a stable crystallographic orientation relationship that agrees with experiment. Furthermore, there are significant changes in the electronic structure of  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> as a result of Pt coverage. We therefore suggest the concept of “judging” the electronic properties of an oxide only with its cover. Specifically, covering Fe<sub>2</sub>O<sub>3</sub> with Pt reduces carrier effective mass and creates a continuum of states in the band gap. The former could be beneficial for catalytic activity, while the latter may cause surface recombination. In order to circumvent this problem, we suggest putting metal coverage behind the oxide and far from the electrolyte in a photoelectrochemical device in order to quickly collect electron carriers and avoid recombination with vulnerable holes accumulating as a result of catalysis at the surface. Reference: O. Neufeld and M. Caspary Toroker, “Can we judge an oxide by its cover? The case of platinum over  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub> from first principles”, Phys. Chem. Chem. Phys. 17, 24129 (2015).

**M1.00375 Carbon nanotube transistor based high-frequency electronics**, MICHAEL SCHROTER, Technical University Dresden — At the nanoscale carbon nanotubes (CNTs) have higher carrier mobility and carrier velocity than most incumbent semiconductors. Thus CNT based field-effect transistors (FETs) are being considered as strong candidates for replacing existing MOSFETs in digital applications. In addition, the predicted high intrinsic transit frequency and the more recent finding of ways to achieve highly linear transfer characteristics have inspired investigations on analog high-frequency (HF) applications. High linearity is extremely valuable for an energy efficient usage of the frequency spectrum, particularly in mobile communications. Compared to digital applications, the much more relaxed constraints for CNT placement and lithography combined with already achieved operating frequencies of at least 10 GHz for fabricated devices make an early entry in the low GHz HF market more feasible than in large-scale digital circuits. Such a market entry would be extremely beneficial for funding the development of production CNTFET based process technology. This talk will provide an overview on the present status and feasibility of HF CNTFET technology will be given from an engineering point of view, including device modeling, experimental results, and existing roadblocks.

**M1.00376 Gate Opening Transition of Zeolitic Imidazolate Framework – 8 in Xenon adsorption and Carbon Monoxide Adsorption.**, DINUKA H GALLABA, ALDO D MIGONE, Department of Physics, Southern Illinois University, Carbondale IL 62901, KARIM SAPAG, JHONNY VILLAROEL, Universidad Nacional de San Luis, San Luis 5700, Argentina. — Zeolitic Imidazolate Framework – 8 (ZIF-8) is a porous metal-organic framework material that shows flexibility in adsorbing larger molecules. We have investigated Xe adsorption on ZIF-8 for temperatures in the range between 95K and 157.5 K and we are exploring CO adsorption between 80K and 110K. ZIF-8 is known to undergo a structural (“gate-opening”) transition when sorbent loading increases. We report on this gate-opening phenomenon for Xe and CO on ZIF-8. The gate-opening transition appears as a sub-step at higher loadings in the adsorption isotherm data. For Xe the sub-step disappeared for temperatures above 145 K. All isotherms below this temperature clearly show the extra step. Gate-opening occurs as a result of the re-orientation of the organic linkers in ZIF-8. This re-orientation increases the size of the apertures in the structure, consequently allowing more molecules or atoms to adsorb into the ZIF -8 (which produces the additional sub-step). The isosteric heat of adsorption as a function of loading, and, the energy associated with the structural transition were determined from the adsorption data. We also report on the kinetics of sorption for Xe on ZIF-8: there are two rates that dominate the sorption kinetics on ZIF-8. We report on the values of the rates as a function of sorbent loading.

**M1.00377 Majorana fermion mean field study of two-dimensional inequivalent bipartite kondo lattice**, SAYED ALI AKBAR GHORASHI, Department of physics and Texas center for superconductivity, University of Houston, RUI WANG, Texas center for superconductivity, university of Houston, CHIN-SEN TING, Department of physics and Texas center for superconductivity, University of Houston — We study the antiferromagnetic kondo lattice in a bipartite square lattice using Majorana fermion representation mean field theory. In different sublattice, we introduce different kondo coupling interaction between the local moment and the conduction electrons, and discuss the possible phases of ground state. It is shown that for weak coupling regime there is more competition between two sublattices local moment interactions. Next, we turn on an equal ferromagnetic Heisenberg interaction for both sublattices and we show possible competition and cooperation between these three interactions. Finally, to gain more physical insights we investigate static magnetic susceptibility for different ratios of couplings.

**M1.00378 A universal scaling law for the evolution of granular gases**, MATHIAS HUMMEL, JAMES CLEWETT, MARCO G. MAZZA, Max Planck Institute for Dynamics and Self-Organization — Dry, freely evolving granular materials in a dilute gaseous state coalesce into dense clusters only due to dissipative interactions. This clustering transition is important for a number of problems ranging from geophysics to cosmology. Here we show that the evolution of a dilute, freely cooling granular gas is determined in a universal way by the ratio of inertial flow and thermal velocities, that is, the Mach number. Theoretical calculations and direct numerical simulations of the granular Navier–Stokes equations show that irrespective of the coefficient of restitution, density or initial velocity distribution, the density fluctuations follow a universal quadratic dependence on the system's Mach number. We find that the clustering exhibits a scale-free dynamics but the clustered state becomes observable when the Mach number is approximately of  $O(1)$ . Our results provide a method to determine the age of a granular gas and predict the macroscopic appearance of clusters.

**M1.00379 Development, Selection, and Validation of Tumor Growth Models**, AMIR SHAHMORADI<sup>1</sup>, ERNESTO LIMA<sup>2</sup>, J. TINSLEY ODEN<sup>3</sup>, The University of Texas at Austin — In recent years, a multitude of different mathematical approaches have been taken to develop multiscale models of solid tumor growth. Prime successful examples include the lattice-based, agent-based (off-lattice), and phase-field approaches, or a hybrid of these models applied to multiple scales of tumor, from subcellular to tissue level. Of overriding importance is the predictive power of these models, particularly in the presence of uncertainties. This presentation describes our attempt at developing lattice-based, agent-based and phase-field models of tumor growth and assessing their predictive power through new adaptive algorithms for model selection and model validation embodied in the Occam Plausibility Algorithm (OPAL), that brings together model calibration, determination of sensitivities of outputs to parameter variances, and calculation of model plausibilities for model selection.

**M1.00380 Evidence for quantization and topological states in spin Hall conductivity of low-dimensional systems**, SEBASTIAN KUEFNER, LARS MATTHES, JUERGEN FURTHMUELLER, FRIEDHELM BECHSTEDT, FSU Jena — *Ab initio* relativistic band structure calculations are performed for the frequency-dependent spin Hall conductivity of two-dimensional atomically thin crystals and one-dimensional nanoribbons. We study the influence of topology, quantization and topological edge states. As model systems, fully halogenated germanene, Gel, and its zigzag nanoribbons are investigated. Gel represents a topological insulator due to strong spin-orbit interaction and, hence, band inversion. We demonstrate the quantization of the static spin Hall conductivity. It is hardly influenced by temperature variation but significantly by Fermi level shift. The frequency dependence of the conductivity is governed by the band-structure details. Topological edge states influence the conductivity mainly for vanishing frequencies.

**M1.00381 Ultrafast spectroscopy of exciton and exciton dynamics in mono and few layers of WS<sub>2</sub>**, SUDIKSHA KHADKA, SHROUQ ALEITHAN, MAX LIVSHITS, JEFFREY J. RACK, MARTIN KORDESCH, ERIC STINAFF, Ohio University — Single layer of Transitional metal dichalcogenides (MX<sub>2</sub>) are 2D semiconductors that have a direct band gap in visible spectrum and fill the gap in between 2D metallic and insulating materials. They have possible application in optoelectronic devices, photovoltaics and photodetection, molecular sensing, 'valleytronics', and flexible transparent electronics. Tungsten Disulphide (WS<sub>2</sub>), one of the member of MX<sub>2</sub> family, has a direct band gap of 2.2 eV and a large valley splitting of about 0.4 eV. Here, we present a detailed study of exciton states and their decay mechanisms in mono and few layer WS<sub>2</sub> using femto-second transient absorption spectroscopy. We report a new peak at 3.010.1 eV whose origin in k space is believed to be at or around K point and further investigation is under way. The exponential fitting of decay curve of the exciton A reveals three time components as 1.70.3 ps, 33.510 ps and 67015 ps, most likely corresponding to carrier-carrier scattering, carrier-phonon scattering, and radiative relaxation respectively.

**M1.00382 Enhanced  $T_C$  in granular and thin film Al-Al<sub>2</sub>O<sub>3</sub> nanostructures<sup>1</sup>**, J. S. HIGGINS, R. L. GREENE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland — It is known since the 1970s that the superconducting transition temperature of granular aluminum films can be as high as two to three times the transition temperature of bulk aluminum, depending on the grain size and how strongly the nanometer size grains are connected<sup>1,2</sup>. As the strength of the grain connectivity becomes increasingly weak, the enhanced  $T_C$  is suppressed. The mechanism behind this enhancement is still under debate. Recently, work on larger aluminum nanoparticles (18nm) embedded in an insulating Al<sub>2</sub>O<sub>3</sub> matrix showed an onset of the superconducting transition as high as three times that of bulk aluminum<sup>3</sup>. In this situation, the Al grains are electrically disconnected and in a regime far removed from that of the granular films. Here we compare the two situations through electronic and thermal measurements in order to help elucidate the mechanism behind the enhancements. <sup>1</sup>S. Pracht, *et al.*, arXiv:1508.04270v1 [cond-mat.supr-con] (2015). <sup>2</sup>G. **M1.00383 Substitution and “site-decoupled doping” in iron pnictides**, M. MERZ, P. SCHWEISS, P. NAGEL, M.-J. HUANG, A. PLOG, R. EDER, TH. WOLF, H. V. LÖHNESEN, S. SCHUPPLER, Karlsruhe Institute of Technology, Germany — The composition-dependent electronic structure of iron pnictides, in particular the question if and how charge carriers are introduced to the system upon substitution – by Sr or alkali metals, *AM*, for Ba; by transition metals, *TM*, for Fe; and/or by P for As – continues to provide surprises. Our ongoing systematic study of spatial structure and electronic states by x-ray diffraction and x-ray absorption, performed on a large number of compositions in the (Ba,Sr,*AM*)(Fe,*TM*)<sub>2</sub>(As,P)<sub>2</sub> family of compounds, shows, for instance, that valences are rarely as expected, that doping can be “effective” or “slow” depending on substituent, and that most doping effects are completely “site decoupled”, meaning that they occur *either* on the Fe site or on the As site but not on both simultaneously. Furthermore, the energy-level schemes derived from electronic and spatial structure differ from the present “standard” assumptions. In all, it appears that substitutional effects may be more crucial to magnetism and superconductivity in iron pnictides than direct doping effects.

**M1.00384 ABSTRACT WITHDRAWN —**

**M1.00385 STM imaging of vortex cores states in superconducting graphene**, YU JI, MAOZ OVADIA, Harvard University, JENNIFER HOFFMAN, University of British Columbia, GIL-HO LEE, PHILIP KIM COLLABORATION<sup>1</sup>, WENJING FANG COLLABORATION<sup>2</sup> — Graphene becomes superconducting via the proximity effect when it comes in good contact with a superconductor. In the presence of a magnetic field, superconducting vortices will form and will each contain Andreev bound states. If the normal electrons in the vortices have a Dirac dispersion and they are surface bound states, the zero modes of the Dirac dispersion are then Majorana fermions. We investigate the electronic properties of graphene on superconducting NbN and search for these vortex bound states using our home built low temperature scanning tunneling microscope.

**M1.00386 Singular manifestation of square-planar coordination of an iridate  $\text{Na}_4\text{IrO}_4$** <sup>1</sup>, SUDIPTA KANUNGO, BINGHAI YAN, PATRICK MERZ, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MARTIN JANSEN, Max-Planck-Institut für Solid State Research, Stuttgart, Germany — Local environments and valence electron counts primarily determine the electronic states and physical properties of transition metal complexes. For example, square-planar surroundings found in transition oxometalates such as cuprates, nickelates are usually associated with the  $d^8$  or  $d^9$  electron configuration. In this work, we address an experimentally observed exotic square-planar mono-oxoanion  $[\text{IrO}_4]^{4-}$  in  $\text{Na}_4\text{IrO}_4$  with Ir(IV) in  $d^5$  ( $S=\frac{3}{2}$  state) configuration, using ab-initio calculations. On contrary, in its 3d counterpart,  $\text{Na}_4\text{CoO}_4$ , Co(IV) is in tetrahedral coordination with  $S=\frac{5}{2}$  high spin state. Our ab-initio calculations reveal that the on-site Coulomb interaction  $U$  is the essential factor for determining the stability of the local coordination as well as spin state. We find that due to weak Coulomb repulsion of Ir-5d electrons,  $\text{Na}_4\text{IrO}_4$  form in a square-planar coordination whereas for  $\text{Na}_4\text{CoO}_4$ , Co(IV) is in tetrahedral coordination, due to strong electron correlation at 3d Co site. Following the trend from 5d to 3d, we predict that the intermediate 4d material  $\text{Na}_4\text{RhO}_4$ , if synthesized, may favor tetrahedral coordination but with an  $S=\frac{1}{2}$  low spin state.

**M1.00387 Local electronic structure and ferromagnetic interaction in  $\text{La}(\text{Co,Ni})\text{O}_3$** , MENG-JIE HUANG, PETER NAGEL, DIRK FUCHS, HILBERT VON LOEHNEISEN, MICHAEL MERZ, STEFAN SCHUPPLER, Karlsruhe Institute of Technology, Germany — Perovskite-related transition-metal oxides exhibit a wide range of properties from insulating to superconducting as well as many peculiar magnetic phases, and cobaltites, in particular, have been known for their proximity to spin-state transitions. How this changes with partial substitution by Ni is the topic of the present study. The local electronic structure and the ferromagnetic interaction in  $\text{La}(\text{Co}_{1-x}\text{Ni}_x)\text{O}_3$  has been studied by x-ray absorption (XAS) and x-ray magnetic circular dichroism (XMCD). XAS clearly indicates a mixed-valence state for both Co and Ni, with both valences changing systematically with Ni content,  $x$ . While the gradual spin-state transition of  $\text{Co}^{3+}$  from low-spin (LS) to high-spin (HS) is preserved for low  $x$  it is suppressed in the high Ni-content samples. Regarding the spin configuration of Ni we find it stabilized in a “mixed” spin state, unlike the purely LS state of Ni in  $\text{LaNiO}_3$ . XMCD identifies the element-specific contributions to the magnetic moment and interactions. In particular, we find that it must be the coexistence of the HS state in both  $\text{Co}^{3+}$  and  $\text{Ni}^{3+}$  that induces  $t_{2g}$ -based ferromagnetic interaction via the double-exchange mechanism.

**M1.00388 Tuning band gap of monolayer and bilayer  $\text{SnS}_2$  by strain effect and external electric field : A first principles calculations**<sup>1</sup>, ABEERA RAHMAN, YOUNG-HAN SHIN, University of Ulsan — Recently many efforts have been paid to two-dimensional layered metal dichalcogenides (LMDs). Among them  $\text{MoS}_2$  has become a prototype LMD, and recent studies show surprising and rich new physics emerging in other van der Waals materials such as layered  $\text{SnS}_2$  [1-4].  $\text{SnS}_2$  is a semiconducting earth-abundant material and Sn is a group IV element replacing the transition metal in  $\text{MoS}_2$ .  $\text{SnS}_2$  shows new possibilities in various potential applications. However, the knowledge on basic properties of layered  $\text{SnS}_2$  is still not well understood. In this study, we consider two types of structures; 1T with  $P\bar{3}m1$  (164) space group and 1H with  $P6_3/mmc$  (194) space group. Our first principles calculations show that the 1T structure for  $\text{SnS}_2$  is more stable than the 1H structure whereas latter is more stable for  $\text{MoS}_2$ . Moreover, in contrast to  $\text{MoS}_2$ ,  $\text{SnS}_2$  shows an indirect band gap both for 1T and 1H structures while 1T  $\text{MoS}_2$  is metallic and 1H has a direct band gap. We also study strain effect in the range of 0-10% on the band structure for monolayer and bilayer  $\text{SnS}_2$  (both for 1T and 1H structures). We find significant change in their band gaps. We also investigate the bilayer  $\text{SnS}_2$  with and without out-of-plane stress.

<sup>1</sup>This research was supported by Brain Korea 21 Plus Program and Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Science, ICT and future Planning (NRF-2014M3A7B4049367, NRF-2014R1A2A1A1105089).

**M1.00389 Manipulating individual defects in graphene/BN heterostructures: a first-principles study**, LEDE XIAN, ANGEL RUBIO, Univ of the Basque Country — Recent experiments have demonstrated the possibility of manipulating defects in insulating hexagonal boron nitride (hBN) within a graphene/hBN heterostructure using scanning tunneling microscopy, opening a new pathway of manipulating individual defects of insulators at the nanoscopic scale. With first principle calculations, we are able to simulate this process and elucidate the relevant physics in experiments. Moreover, we calculate the band level alignments between graphene and possible defects states in hBN. Thus, we identify different defects observed in experiments and provide important reference for future experiments and applications.

**M1.00390 CVD-based, photolithographically patterned, highly-sensitive graphene Hall element on hexagonal BN**, JOONGGYU KIM, Center for Integrated Nanostructure Physics, Institute for Basic Science, DOES, Sungkyunkwan University, MIN-KYU JOO, JI-HOON PARK, Center for Integrated Nanostructure Physics, Institute for Basic Science, Sungkyunkwan University, VAN LUAN NGUYEN, Center for Integrated Nanostructure Physics, Institute for Basic Science, DOES, Sungkyunkwan University, KI KANG KIM, Department of Energy and Materials Engineering, Dongguk University, YOUNG HEE LEE, DONGSEOK SUH, Center for Integrated Nanostructure Physics, Institute for Basic Science, DOES, Sungkyunkwan University — Graphene is known to have a high carrier mobility, and the carrier density can be minimized at the charge neutrality point (CNP). Because such features are suitable for Hall sensor measuring magnetic field, we examined the possibility of graphene Hall element (GHE) as a highly sensitive magnetic sensor. For the high-throughput production of GHE in the future, the material synthesized by a chemical-vapor-deposition (CVD) method and the fabrication processes based on photolithography were adopted to show its mass-production feasibility. Specifically, the CVD synthesized hexagonal BN (hBN) was tested as a protection layer of graphene from extrinsic doping driven by  $\text{SiO}_2$  substrate, which causes the shift of CNP. In addition, post annealing sequences were also included between each step, such as the hBN attachment on  $\text{SiO}_2$  and the graphene transfer on hBN/ $\text{SiO}_2$  substrate followed by the PMMA removal. From this work, we can get minimum magnetic resolution around 10 mG/Hz<sup>0.5</sup> at 300 Hz.

**M1.00391 Study of correlations from Ab-Initio Simulations of Liquid Water**<sup>1</sup>, ADRIAN SOTO, MARIVI FERNANDEZ-SERRA, Stony Brook University, DEYU LU, SHINJAE YOO, Brookhaven National Lab — An accurate understanding of the dynamics and the structure of  $\text{H}_2\text{O}$  molecules in the liquid phase is of extreme importance both from a fundamental and from a practical standpoint. Despite the successes of Molecular Dynamics (MD) with Density Functional Theory (DFT), liquid water remains an extremely difficult material to simulate accurately and efficiently because of fine balance between the covalent O-H bond, the hydrogen bond and the attractive van der Waals forces. Small errors in those produce dramatic changes in the macroscopic properties of the liquid or in its structural properties. Different density functionals produce answers that differ by as much as 35% in ambient conditions, with none producing quantitative results in agreement with experiment at different mass densities [*J. Chem Phys.* 139, 194502(2013)]. In order to understand these differences we perform an exhaustive scanning of the geometrical coordinates of MD simulations and study their statistical correlations with the simulation output quantities using advanced correlation analyses and machine learning techniques.

**M1.00392 Improved methods for determining the secondary structure of proteins using FTIR spectroscopy** , DAVID NETO, Oklahoma State University — The determination of the secondary structure is vitally important in the study of proteins. An oft overlooked and underused method to probe the secondary structure of a protein is Fourier transform infrared (FTIR) spectroscopy. A great compliment to both X-ray and NMR techniques, the speed and relatively low cost of FTIR measurements provide a wealth of information about the structure of a protein. To enhance the accuracy of secondary structure calculations, improved methods in the fitting of absorbance spectra are needed. In this talk, we will explore the development of these methods and apply them to a few well studied proteins.

**2:30PM P1.00001 New perspectives on quantum simulation with ultra-cold atoms** , ANA MARIA REY, University of Colorado, Boulder — Understanding the behavior of interacting electrons in solids or liquids is at the heart of modern quantum science and necessary for technological advances. However, the complexity of their interactions generally prevents us from coming up with an exact mathematical description of their behavior. Precisely engineered ultracold gases are emerging as a powerful tool for unraveling these challenging physical problems. In this talk, I will present recent ideas on using alkaline-earth atoms —currently the basis of the most precise atomic clock in the world— for the investigation of complex many-body phenomena and magnetism. I will also discuss a new research direction of using atomic clocks not only as precise time keepers but also as unique quantum laboratories for the investigation of new forms of matter with no known counterpart in nature.

**3:06PM P1.00002 Illuminating biology at the nanoscale with single-molecule and super-resolution fluorescence microscopy** , XIAOWEI ZHUANG, Harvard University — Dissecting the inner workings of a cell requires imaging methods with molecular specificity, molecular-scale resolution, and dynamic imaging capability such that molecular interactions inside the cell can be directly visualized. Fluorescence microscopy is a powerful imaging modality for investigating biological systems largely owing to its molecular specificity and dynamic imaging capability. However, the diffraction-limited resolution of light microscopy is substantially larger than molecular length scales in cells, making many sub-cellular structures difficult to resolve. We developed a super-resolution fluorescence microscopy method, stochastic optical reconstruction microscopy (STORM), which overcomes the diffraction limit by using photo-switchable fluorescent probes to temporally separate the spatially overlapping images of individual molecules. This approach has allowed multicolor and three-dimensional imaging of living cells with nanometer-scale resolution and enabled discoveries of novel sub-cellular structures. In this talk, I will present to concept and technological advances of STORM, as well as some of the recent biological discoveries enabled by STORM. I will also describe a new single-cell transcriptome imaging method multiplexed error-robust fluorescent in situ hybridization (MERFISH), which allows numerous RNA species to be imaged and quantified in single cells. This approach enables unique analyses based on copy numbers and spatial distributions of many RNA species within single cells, facilitating the delineation of gene regulatory networks and in situ identification of cell types.

**3:42PM P1.00003 Making New Particles One By One** , DAVID A. WEITZ, Dept. of Physics and SEAS, Harvard University, Cambridge MA — This talk will describe the use of microfluidic devices to create new structures with unusual properties and enormous potential for technological applications. The particles are formed using fluid drops as templates, and take advantage of the exquisite control afforded by the use of microfluidic devices to very simply create complex structures. These new structures facilitate the study of new properties of materials. It is also feasible to use these methods to very easily create nanoparticles of almost any material through a microfluidic spray drier. Remarkably, if these nanoparticles are small enough, they are amorphous, even if the material is otherwise always crystalline. For example, it is even feasible to produce amorphous nanoparticles of table salt (NaCl). The talk will also describe how it is feasible to produce large quantities of these materials, despite making the particles one at a time. This makes the particles valuable for both fundamental studies and for technological applications

**4:18PM P1.00004 Plasmons, hot electrons and nanoscale heat transfer** , NAOMI HALAS, Rice University — TBD

**4:54PM P1.00005 The Observation of Gravitational Waves from a Binary Black Hole Merger** , DUNCAN BROWN, Syracuse University — On September 14, 2015 the the two detectors of the Laser Interferometer Gravitational-Wave Observatory (LIGO) simultaneously observed gravitational waves from a binary black hole merger. The gravitational waves observed match the waveform predicted by general relativity for the inspiral and merger of a pair of black holes and the ringdown of the resulting single black hole. This is the first direct detection of gravitational waves and the first observation of a binary black hole merger. I will discuss the discovery of this event, the properties of the source, and the future of the new field of gravitational-wave astronomy.

### **2:30PM P5.00001 Homoepitaxial graphene tunnel barriers for spin transport**, ADAM FRIEDMAN,

Naval Research Laboratory — Tunnel barriers are key elements for both charge-and spin-based electronics, offering devices with reduced power consumption and new paradigms for information processing. Such devices require mating dissimilar materials, raising issues of heteroepitaxy, interface stability, and electronic states that severely complicate fabrication and compromise performance. Graphene is the perfect tunnel barrier. It is an insulator out-of-plane, possesses a defect-free, linear habit, and is impervious to interdiffusion. Nonetheless, true tunneling between two stacked graphene layers is not possible in environmental conditions (magnetic field, temperature, etc.) usable for electronics applications. However, two stacked graphene layers can be decoupled using chemical functionalization. We demonstrate successful tunneling, charge, and spin transport with a fluorinated graphene tunnel barrier on a graphene channel. We show that while spin transport stops short of room temperature, spin polarization efficiency values are the highest of any graphene spin devices. We also demonstrate that hydrogenation of graphene can also be used to create a tunnel barrier. We begin with a four-layer stack of graphene and hydrogenate the top few layers to decouple them from the graphene transport channel beneath. We demonstrate successful tunneling by measuring non-linear IV curves and a weakly temperature dependent zero-bias resistance. We demonstrate lateral transport of spin currents in non-local spin-valve structures and determine spin lifetimes with the non-local Hanle effect to be commensurate with previous studies. The measured spin polarization efficiencies for hydrogenated graphene are higher than most oxide tunnel barriers on graphene, but not as high as with fluorinated graphene tunnel barriers. However, here we show that spin transport persists up to room temperature. Our results for the hydrogenated graphene tunnel barriers are compared with fluorinated tunnel barriers and we discuss the possibility that magnetic moments in the graphene tunnel barriers affect the spin transport of our devices.

### **3:06PM P5.00002 Tight-binding description of spin-orbit coupling in graphene due to adatoms<sup>1</sup>**

SUSANNE IRMER, DENIS KOCHAN, KLAUS ZOLLNER, MARTIN GMITRA, TOBIAS FRANK, JAROSLAV FABIAN, University of Regensburg — We present realistic effective tight-binding models for proximity spin-orbit coupling in graphene due to adatoms at top, bridge, and hollow positions. The models are built from symmetry arguments and fitted to ab initio calculations for a variety of adsorbants, such as H [1], F [2], Cu, and CH<sub>3</sub> [3]. For each of these adatoms we provide magnitudes for orbital couplings to the adsorbants, as well as the intrinsic Rashba, and pseudospin-inversion asymmetry (PIA) couplings. Our models can be used to study spin relaxation, spin Hall effect, and spin transport using quantum transport models. [1] M. Gmitra, D. Kochan, J. Fabian, Phys. Rev. Lett. 110, 246602 (2013). [2] S. Irmer, T. Frank, S. Putz, M. Gmitra, D. Kochan, J. Fabian, Phys. Rev. B 91, 115141 (2015). [3] K. Zollner, T. Frank, S. Irmer, M. Gmitra, D. Kochan, J. Fabian, arXiv:1507.02820

### **3:18PM P5.00003 Spintronics with Graphene and van der Waals heterostructures**, SAROJ DASH,

M.VENKATA KAMALAKAR, ANDR DANKERT, Chalmers University of Technology, QUANTUM DEVICE PHYSICS LABORATORY TEAM — Two-dimensional (2D) atomic crystals provide a large class of materials proposed to be important for nanoelectronics and spintronic. Here we present two important advancements in graphene spintronics by employing 2D materials and heterostructures. Graphene is considered to be an ideal material for spin transport due to the high mobility and long spin lifetime of the carriers. We realized spin transport over a long distance of 16  $\mu$ m and spin lifetimes up to 1.2 ns in large area CVD graphene on SiO<sub>2</sub>/Si substrate at room temperature [1]. Subsequently, using the h-BN tunnel barrier/graphene van der Waals heterostructure; we observe an enhancement in the tunnel spin polarization [2], and a negative spin signal for thicker h-BN barriers. These findings open a platform for exploring novel spin functionalities in 2D crystal heterostructures and understanding the basic science that control their behavior. [1] M. V. Kamalakar et al., Long Distance Spin Communication in Chemical Vapor Deposited Graphene, Nature Communications 6, 6766 (2015). [2] M. V. Kamalakar et al., Enhanced Tunnel Spin Injection into Graphene using Hexagonal Boron Nitride; Scientific Reports 4, 61446 (2014).

### **3:30PM P5.00004 Proximity Anisotropic Magnetoresistance in Graphene**, JEONGSU LEE, JAROSLAV

FABIAN, Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — We theoretically investigate charge transport in graphene that is on a ferromagnetic-insulator substrate. The substrate induces spin polarization in graphene—ferromagnetic proximity effect—as demonstrated recently experimentally [1]. We show, using realistic models [2, 3], that the presence of spin-orbit coupling in proximity ferromagnetic graphene leads to anisotropic magnetoresistance whereby graphene's resistance changes with varying magnetic field orientation (both in and out of plane). We evaluate the magnitude as well as the angular dependence of this novel effect using conventional transport models [4] and propose specific experimental schemes to measure it. This work is supported by DFG SFB 689. References [1] Z. Wang, C. Tang, R. Sachs, Y. Barlas, and J. Shi, Phys. Rev. Lett. 114, 016603, (2015) [2] M. Gmitra, D. Kochan, and J. Fabian, Phys. Rev. Lett. 110, 246602 (2013). [3] M. Gmitra, S. Konschuh, C. Ertler, C. Ambrosch-Draxl, and J. Fabian, Phys. Rev. B 80, 235431, (2009) [4] S. Adam, E. H. Hwang, V. M. Galitski, and S. Das Sarma, Proc. ### **3:42PM P5.00005 Stoner-like theory of Magnetism in Silicon MOSFETs<sup>1</sup>**, DENIS GOLOSOV, Bar-

Ilan University — We consider quasi-two-dimensional gas of electrons in a typical Si-MOSFET, assuming contact repulsive interaction between electrons. Magnetisation and susceptibility are evaluated within the mean-field approach. The finite thickness of inversion layer results in an interaction-induced electron wave function change, not found in both purely two-dimensional and three-dimensional (bulk) cases. Taking this self-consistent change into account leads to an increased susceptibility and ultimately to a ferromagnetic transition deep in the high-density metallic regime. We further find that in the paramagnetic state, magnetisation increases sublinearly with increasing in-plane magnetic field. In the opposite limit of low carrier densities, the effects of long-range interaction become important and can be included phenomenologically via bandwidth renormalisation. Our treatment then suggests that with decreasing density, the metal-insulator transition is preceded by a ferromagnetic instability. We discuss the validity of our mean-field scheme, and relate the results to the available experimental data.

### **3:54PM P5.00006 Rashba scattering in the dilute limit**, JOEL HUTCHINSON, JOSEPH MACIEJKO, University of

Alberta — In two-dimensional (2D) noncentrosymmetric crystals, the spin degeneracy of the electronic band structure may be lifted by Rashba spin-orbit coupling. The resulting spin-split dispersion is responsible for the spin Hall effect and has desirable applications to spintronics. This spin-split dispersion is described in terms of two distinct helicity bands, but below a threshold energy, electrons are confined to one of these. At the bottom of this lower band, the density of states exhibits a van Hove singularity. This is the relevant regime for a dilute spin-orbit coupled 2D electron gas, which has been shown to host a variety of exotic phases in the presence of electron-electron interactions. In this talk we investigate scattering of Rashba electrons off a circular potential barrier in this dilute limit, which is relevant both for impurity scattering in the noninteracting limit as well as for short-range two-particle scattering in the interacting problem. The S matrix and scattering cross section are determined, and it is found that scattering becomes effectively one-dimensional at the band bottom.

**4:06PM P5.00007 Edge spin accumulation in a two-dimensional electron gas with two subbands<sup>1</sup>**, ALEXANDER KHAETSKII, State Univ of NY - Buffalo, J. CARLOS EGUES, Instituto de Física de Sao Carlos, Brazil — We have studied the edge spin accumulation in 2D electron gas due to the intrinsic mechanism of spin-orbit interaction for the case of a two-subband structure. This study is strongly motivated by recent experiments [1] which observed the spin accumulation near the edges of a high mobility 2D electron system in a bilayer symmetric GaAs structure in contrast to zero effect in a single-layer configuration. Our theoretical explanation is based on the Rashba-like spin-orbit interaction which arises as a result of the coupling between two subband states of opposite parities in a symmetric quantum well [2]. Following the method developed in [3], we have calculated the edge spin density in a quasi-ballistic regime, and explained the experimental results, in particular, a large magnitude of the edge spin density. We showed that one can easily proceed from the regime of strong spin accumulation to the regime of weak one. It opens up a possibility to construct an interesting new spintronic device. [1]. F. Hernandez et al., Phys. Rev. B **88**, 161305(R) (2013). [2]. E. Bernardes et al., Phys. Rev. Lett. **99**, 076603 (2007). [3]. A. Khaetskii, Phys. Rev. B **89**, 195408 (2014).

**4:18PM P5.00008 Dynamical spin injection into a two-dimensional electron gas in an Al-GaAs/GaAs structure**, KENRO OHTOMO, YUICHIRO ANDO, TERUYA SHINJO, Kyoto University, TETSUYA UEMURA, Hokkaido University, MASASHI SHIRAIISHI, Kyoto University — A two-dimensional electron system in a GaAs-based heterostructure is the attractive platform for spintronics since it has high mobility and spin-orbit interaction can be modulated by the gate voltage<sup>1</sup>. Thus, it is a possible platform to realize electric gate-controlled spin transistor<sup>2</sup>. However, room-temperature spin transport through GaAs-based heterostructure has yet to be shown. We report first spin transport through the quantum well at GaAs/AlGaAs interface at room temperature. We used spin pumping under ferromagnetic resonance to inject spins from the Ni<sub>80</sub>Fe<sub>20</sub> to the GaAs/AlGaAs quantum well. Generated spin current propagated through the 1  $\mu$ m channel and was detected using spin-charge conversion inverse spin Hall effect in the Pt electrode. In agreement with spin pumping theory, polarity of the spin transport signal was reversed together with magnetization of the Ni<sub>80</sub>Fe<sub>20</sub>. This first demonstration of spin transport through a quantum well at a semiconductor heterostructure interface at room temperature opens a way to realize Datta-Das spin-based transistor.

**4:30PM P5.00009 Hole spin coherence in coupled GaAs/AlAs quantum wells<sup>1</sup>**, CHRISTIAN GRADL, MICHAEL KEMPF, JOHANNES HOLLER, DIETER SCHUH, DOMINIQUE BOUGEARD, CHRISTIAN SCHUELLER, TOBIAS KORN, University of Regensburg — Due to its p-like character, the valence band in GaAs-based heterostructures offers rich and complex spin-dependent phenomena. Especially for some low-symmetry growth directions, a strong anisotropy of the hole g factor with respect to the in-plane magnetic field direction is theoretically predicted. Therefore, we perform time-resolved Kerr rotation measurements on an undoped [113]-grown double quantum well (QW) structure to resolve the spin dynamics of hole ensembles at low temperatures. Our gated system consists of two QWs with different well widths, which we use for the spatial separation of the optically excited electron-hole pairs. Thus, we are able to create hole ensembles with spin lifetimes of several hundreds of picoseconds in the broader QW without any doping. This allows the observation of a strong hole g factor anisotropy by varying the magnetic field direction in the QW plane. The experimental g factor values are in very good agreement with theoretical predictions. Furthermore, we observe an unexpected additional non-precessing component in the Kerr signal for certain in-plane magnetic field directions. This might have its origin in a precession axis that is tilted relative to the magnetic field due to the crystal structure of this low-symmetry growth direction.

**4:42PM P5.00010 Investigation and direct mapping of the persistent spin helix in confined structures<sup>1</sup>**, MARKUS SCHWEMMER, MATTHIAS WEINGARTNER, ROLAND VÖLKL, MARTIN OLTSCHER, DIETER SCHUH, DOMINIQUE BOUGEARD, TOBIAS KORN, CHRISTIAN SCHÜLLER, University Regensburg — The spin-orbit field in GaAs-based quantum well (QW) structures typically consists of two different contributions: Dresselhaus and Rashba field. The geometry of the Dresselhaus field, which arises due to the bulk inversion asymmetry, is mostly determined by the growth direction of the quantum well. The Rashba field instead is caused by a structure inversion asymmetry, which can be controlled, e.g. by the modulation doping. For the specific case of a (001)-grown GaAs quantum well with equal strength of Dresselhaus and Rashba fields, the effective spin-orbit field is oriented along the in-plane [110] direction for all  $k$  values and the spin splitting for this direction vanishes. For optically injected spins, which are initially oriented perpendicular to the QW plane, a persistent spin helix (PSH) state forms. We use a femtosecond pulsed TiSa-Laser system combined with a magneto-optical Kerr effect microscope for time- and space-resolved mapping of the PSH. With this technique, we investigate the PSH behavior in confined structures, e.g., thin channels along the helix direction. Hence we find that lateral confinement increases the effective PSH lifetime drastically. In more complex structures, we observe that PSH formation is even stable under a forced direction change.

<sup>1</sup>Financial support by the DFG via SFB 689 and SPP 1285 is gratefully acknowledged.

**4:54PM P5.00011 Role of contact resistance in the effective spin relaxation rate in graphene spin valves<sup>1</sup>**, GORDON STECKLEIN, YOSKA ANUGRAH, JING LI, STEVEN J. KOESTER, PAUL CROWELL, University of Minnesota — Recent experiments (Maassen et al., PRB **86** 235408 (2012), Idzuchi et al., PRB **91** 241407(R) (2015)) have identified the role of finite contact resistances in determining the spin lifetime in graphene based on Hanle measurements of lateral spin valves. We have investigated this effect in spin valves fabricated using Co/AIOx tunnel barriers and graphene grown by chemical vapor deposition. By carrying out non-local spin valve and Hanle measurements over a wide range of gate voltages, we observe a variation in the spin signal that can be explained by the role of the contacts. Using the measured interface resistance, we quantify the degree of contact-induced spin sinking as the ratio of the contact resistance to the channel spin resistance and show that the variation in spin signal is explained by variation in this spin sinking parameter. By properly accounting for the effect of the contact resistance, we measure a spin lifetime that varies between 150-500 picoseconds.

**5:06PM P5.00012 Boundary conditions for transition-metal dichalcogenide monolayers in the continuum model**, CSABA G. PÉTERFALVI, ANDOR KORMÁNYOS, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78464 Konstanz, Germany — We derive the boundary conditions for MoS<sub>2</sub> and similar transition-metal dichalcogenide honeycomb (2H polytype) monolayers with the same type of  $k \cdot p$  Hamiltonian within the continuum model around the K points. [1] In an effective 2-band description, the electron-hole symmetry breaking quadratic terms are also taken into account. We model the effect of the edges with a linear edge constraint method that has been applied previously to graphene. Focusing mainly on zigzag edges, we find that different reconstruction geometries with different edge-atoms can generally be described with one scalar parameter varying between 0 and  $2\pi$ . We analyze the edge states and their dispersion relation in MoS<sub>2</sub> in particular, and we find good agreement with the results of previous density functional theory calculations for various edge types. [1] Cs. G. Péterfalvi, A. Kormányos, G. Burkard, arXiv:1509.00184 (2015).

## Wednesday, March 16, 2016 2:30PM - 5:30PM –

Session P6 GMAG DMP: Magnetic Complex Oxides I 302 - Gian Guzman-Verri, University of Costa Rica / Argonne National Lab

**2:30PM P6.00001 High antiferromagnetic transition temperature for a layered hexagonal compound:  $\text{SrRu}_2\text{O}_6$** <sup>1</sup>, JIAQIANG YAN, Oak Ridge National Laboratory and University of Tennessee — 4d or 5d transition metal oxides (TMOs) are less correlated and have a larger bandwidth than 3d TMOs. A high magnetic ordering temperature for 4d/5d TMOs is not expected. It was therefore a surprise when a perovskite,  $\text{SrTcO}_3$ , was reported to order magnetically around 1000 K. Unfortunately, the radioactive nature of Tc prevented further investigation of the underlying mechanism for the high magnetic ordering temperature. Here we report antiferromagnetic order of  $\text{SrRu}_2\text{O}_6$  at 565 K. Two features distinguish this compound from  $\text{SrTcO}_3$ : (1)  $\text{SrRu}_2\text{O}_6$  is not radioactive, which allows the study of the underlying physics by a large variety of techniques as well as the possible fine tuning of the magnetic ground state; and (2)  $\text{SrRu}_2\text{O}_6$  crystallizes into a quasi-two-dimensional structure with layers of edge-sharing  $\text{RuO}_6$  octahedra separated by nonmagnetic Sr layers. Our density functional calculations and Monte Carlo simulations suggest an origin of the reduced moment size and the high Neel temperature.

<sup>1</sup>Work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division and by the CEM and NSF MRSEC under Grant No. DMR-1420451.

**3:06PM P6.00002 Molecular orbitals vs. relativistic orbitals in  $t_{2g}$  honeycomb lattices:  $\text{SrRu}_2\text{O}_6$  as compared to  $\text{Na}_2\text{IrO}_3$ ,  $\text{RuCl}_3$ , and  $\text{Li}_2\text{RuO}_3$ .**<sup>1</sup>, IGOR MAZIN, Naval Research Laboratory, SERGEY STRELTISOV, Institute of Metal Physics, Ekaterinburg, Russia, KATERYNA FOYEVTSEVA, University of British Columbia, Canada —  $t_{2g}$  states on a honeycomb lattice tend to form non-dispersive localized states even if large intersite hopping is present. In the nonrelativistic case, these are molecular orbitals (MO) localized on metal hexagons, if the ligand-assisted nearest and next nearest neighbor hoppings,  $t'_1$  and  $t'_2$ , dominate, or dimers (DO), if the direct overlap,  $t_1$ , dominates. In the ultrarelativistic limit  $t_{2g}$  form effective relativistic orbitals (RO),  $j_{eff} = 3/2$ , which are atomically localized if  $t'_1$  is the dominant hopping. On the first glance, the three regimes are defined by the conditions  $t'_1 \gg t_1, \lambda$  or  $t_1 \gg t'_1, \lambda$  or  $\lambda \gg t_1, t'_1$ . In reality, the latter condition is never fulfilled, especially in ruthenates, yet not only  $\text{Na}_2\text{IrO}_3$ , but also  $\text{RuCl}_3$  appear to be in a regime dominated by RO, even though the residual effect of MO critically influences magnetic interactions, while  $\text{Li}_2\text{RuO}_3$ , not far removed from  $\text{RuCl}_3$  in the parameter space, is firmly in the DO regime. Most surprisingly,  $\text{SrRu}_2\text{O}_6$ , which is even closer to  $\text{RuCl}_3$ , happens to be fully in the MO regime, with negligible spin-orbit effects. In this talk, we will show that an additional, decisive factor is the doping level per site. The principal difference between  $\text{Na}_2\text{IrO}_3$  or  $\text{RuCl}_3$ ,  $\text{Li}_2\text{RuO}_3$ , and  $\text{SrRu}_2\text{O}_6$  is that the first two have one  $t_{2g}$  hole per site, the second one two holes, and the last three electrons. In particular, the total dominance of MO in the latter compound fully explains its unique and unexpected magnetic properties.

**3:18PM P6.00003 Magnetization reversal and negative volume thermal expansion in Fe doped  $\text{Ca}_2\text{RuO}_4$** <sup>1</sup>, T. F. QI, S. J. YUAN, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA, F. YE, S. CHI, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, J. TERZIC, H. ZHANG, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA, Z. ZHAO, Department of Geological and Environmental Sciences, Stanford University, Stanford, CA 94305, USA, X. LIU, Institute of Physics, Chinese Academy of Sciences, Beijing, 100190, China, S. PARKIN, Department of Chemistry, University of Kentucky, Lexington, KY 40506, USA, W. L. MAO, Department of Geological and Environmental Sciences, Stanford University, Stanford, CA 94305, USA, G. CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA — We report structural, magnetic, transport and thermal properties of single-crystal  $\text{Ca}_2\text{Ru}_{1-x}\text{Fe}_x\text{O}_4$  ( $0 \leq x \leq 0.2$ ) as functions of pressure, magnetic field and temperature. The central findings of this work are a pronounced magnetization reversal and a negative thermal expansion that are induced by Fe doping. Our results including neutron diffraction data suggest that the magnetization reversal is primarily a result of different temperature dependences of two antiparallel, competing Ru and Fe sublattices and that the negative thermal expansion is achieved via magnetic and metal-insulator transitions. We will present and discuss our results with comparison drawn with relevant systems.

<sup>1</sup>This work was supported by the NSF via Grant No. DMR-1265162

**3:30PM P6.00004 NMR study of new ruthenates with high magnetic ordering**, P.L. PAULOSE, TANMOY CHAKRABARTY, Tata Institute of Fundamental Research, Mumbai, India — The Ru based compounds,  $\text{Ca}_3\text{LiRuO}_6$  and  $\text{Ca}_3\text{NaRuO}_6$  show unusually high magnetic ordering temperature. Extended super exchange model is invoked to explain the magnetic behavior in the isostructural compound  $\text{Ca}_3\text{LiOsO}_6$ . We have carried out NMR investigation on these two Ru-based compounds.  $\text{Ca}_3\text{LiRuO}_6$  is a weak ferromagnet with a magnetic ordering temperature ( $T_C$ ) of 115 K which is explored by the temperature dependence of  $^7\text{Li}$  NMR line shift, line-width and spin-lattice relaxation rate ( $1/T_1$ ). Above  $T_C$ , a broad maximum is observed in the evolution of line-width of the spectra. We speculate that this feature might be attributed to some low-dimensional magnetic behavior. Contrastingly,  $\text{Ca}_3\text{NaRuO}_6$  with similar structure and local geometry of the  $\text{Ru}^{5+}$  ions is a conventional antiferromagnet with a transition temperature of 90 K. The temperature dependence of  $^{23}\text{Na}$  NMR line shift and  $1/T_1$  is studied across magnetic transition in  $\text{Ca}_3\text{NaRuO}_6$ . The temperature variation of line-width is found to be different compared to  $\text{Ca}_3\text{LiRuO}_6$ . In both these systems,  $1/T_1$  decreases significantly below ordering temperature, characteristic of many antiferromagnetic systems.

**3:42PM P6.00005 Spin-orbit dimers in double perovskites**, GEORGE JACKELI, University of Stuttgart and Max Planck Institute for Solid State Research, Stuttgart, Germany — In Mott insulators, unquenched orbital degrees of freedom often frustrate the magnetic interactions and lead to a plethora of interesting phases with unusual spin patterns or non-magnetic states without long-range order. Here, we present a theoretical study of interplay of spin and orbital degrees in double-perovskite compounds with  $d^1$  ions occupying the fcc sublattice. We show that the ground state of such a system is non-magnetic dimer pseudo-spin singlet with extensive orientational degeneracy of dimers. We discuss how the pseudo-spin state forming the singlet is altered upon increasing the strength of the relativistic spin-orbit coupling and show that the dimer 'gas' phase remains the ground state throughout. Our theoretical findings support and explain the experimentally observed non-magnetic amorphous valence bond state in  $\text{Ba}_2\text{YMoO}_6$  and in related compounds.

**4:18PM P6.00006 Doping an antiferromagnetic insulator : A route to an antiferromagnetic metallic phase**, PRIYA MAHADEVAN, SHISHIR PANDEY, S.N.Bose National Centre for Basic Sciences, D.D. SARMA, SSCU, Indian Institute of Science, Bangalore — Usually antiferromagnetism is accompanied by an insulating character of the ground state, while ferromagnetism is accompanied by metallicity. In the limit of half-filling, the Hubbard model yields an antiferromagnetic insulator as the ground state. From the Nagaoka theorem we expect ferromagnetism at any finite electron doping of this half filled state. Numerical studies on the other hand, have however shown, that at low doping concentrations one has a narrow region of an antiferromagnetic metallic phase. The question is whether this is realizable in real materials. Among the 3d transition metal oxides, this antiferromagnetic metallic phase has remained elusive as strong electron-phonon coupling results in a different phase diagram. The 5d transition metal oxides are therefore more suitable. In this work we solve a multiband Hubbard model relevant for a 5d transition metal oxide within a mean-field approach and show that the large bandwidth and the small intra-atomic Hund's exchange associated with this limit gives us a robust AFM-M ground state for 25% electron doping. The conclusions are supported by ab-initio electronic structure calculations for NaOsO<sub>3</sub>.

**4:30PM P6.00007 Excitations and enhanced coupling at the magnetic metal-insulator transition in NaOsO<sub>3</sub> and Cd<sub>2</sub>Os<sub>2</sub>O<sub>7</sub>**, S. CALDER, J. H. LEE, M. B. STONE, ORNL, J. G. VALE, C. DONNERER, UCL, N. A. BOGDANOV, IFW Dresden, J. LANG, APS, M. FEYGENSON, ORNL, X. LIU, CAS, M. H. UPTON, D. CASA, APS, M. D. LUMSDEN, Z. ZHAO, J.-Q. YAN, ORNL, Y.G. SHI, Y.S. SUN, Y. TSUJIMOTO, K. YAMAURA, NIMS, D. MANDRUS, University of Tennessee, S. NISHIMOTO, J. VD BRINK, IFW Dresden, J. P. HILL, BNL, D. F. MCMORROW, UCL, A. D. CHRISTIANSON, ORNL — 5d oxides provide new paradigms of cooperative interactions that drive novel emergent behavior. This is exemplified in the osmates NaOsO<sub>3</sub> and Cd<sub>2</sub>Os<sub>2</sub>O<sub>7</sub> that host MITs where magnetic order appears intimately entwined. However, unlike the iridates where spin-orbit coupling (SOC) behavior dominates, in the 5d<sup>3</sup> osmates an orbital singlet is expected and reduced effect of SOC. We measure the inelastic spectra with neutrons and RIXS. Our results uncover the 5d-manifold splitting to reveal a suppressed role of SOC in the creation of the electronic ground state but dominant behavior in the creation of the magnetic state. Moreover at the MIT in NaOsO<sub>3</sub> we find a giant spin-phonon coupling and in Cd<sub>2</sub>Os<sub>2</sub>O<sub>7</sub> a magnetic excitation corresponding to a superposition of multiple spin-flips.

**4:42PM P6.00008 Terahertz Spectroscopy of Osmate Double Perovskites<sup>1</sup>**, MATTHEW T. WARREN, Department of Physics, The Ohio State University. Columbus OH 43210, R. MORROW, Department of Chemistry, The Ohio State University. Columbus OH 43210, T. T. MAI, Department of Physics, The Ohio State University. Columbus OH 43210, J. XIONG, P. M. WOODWARD, Department of Chemistry, The Ohio State University. Columbus OH 43210, R. VALDÉS AGUILAR, Department of Physics, The Ohio State University. Columbus OH 43210 — Double perovskites containing 5d transition metal elements allow study of the interplay of spin-orbit coupling and electronic correlations due to the heavy nuclei and large electronic wavefunctions. Here we have studied polycrystalline Sr<sub>2</sub>MOsO<sub>6</sub> (M = Mg, Fe, Co; with Os electronic configuration of d<sup>2</sup>, d<sup>3</sup>, d<sup>2</sup>, respectively) with time-domain terahertz spectroscopy. Terahertz electrodynamics seem to be decoupled from observed magnetic and structural phase transitions in M=Mg, Co. A strong absorption is measured in M=Mg, Co around 1.5 THz, which softens with temperature, as expected for an optical phonon. The effectiveness of the variable-range hopping model and the origin of higher temperature conductivity are examined. Work at OSU supported by the NSF MRSEC Center for Emergent Materials under Grant DMR-1420451.

<sup>1</sup>Work supported by the Center for Emergent Materials: an NSF MRSEC under award DMR-1420451.

**4:54PM P6.00009 Numerical Implementation of a General Spinwave Model to Simulate Spin-wave Excitations Found in Inelastic Neutron Scattering Data**, D. CASAVANT, I. BRODSKY, G. J. MACDOUGALL, Dept. of Physics, Univ. of Illinois at Urbana-Champaign — Many important details regarding magnetism in a material can be inferred from the magnetic excitation spectrum, and in this context, general calculations of the classical spinwave spectrum are often necessary. Beyond the simplest of lattices, however, it is difficult to numerically determine the full spinwave spectrum, due primarily to the non-linearity of the problem. In this talk, I will present MATLAB code, developed over the last few years at the University of Illinois, that calculates the dispersions of spinwave excitations out of an arbitrarily defined ordered spin system. The calculation assumes a standard Heisenberg exchange Hamiltonian with the incorporation of a single-ion anisotropy term which can be varied site-by-site and can also simulate the application of an applied field. An overview of the calculation method and the structure of the code will be given, with emphasis on its general applicability. Extensions to the code enable the simulation of both single-crystal and powder-averaged neutron scattering intensity patterns. As a specific example, I will present the calculated neutron scattering spectrum for powders of CoV<sub>2</sub>O<sub>4</sub>, where good agreement between the simulated and experimental data suggests a self-consistent picture of the low-temperature magnetism.

**5:06PM P6.00010 Unusual behaviour of thermal conductivity in vanadium dioxide across the metal-insulator transition<sup>1</sup>**, KEDAR HIPPALGAONKAR, Institute of Materials Research and Engineering, SANGWOOK LEE, CHANGHYUN KO, University of California, Berkeley, FAN YANG, Lawrence Berkeley National Lab, JOONKI SUH, KAI LIU, KEVIN WANG, XIANG ZHANG, CHRIS DAMES, JUNQIAO WU, University of California, Berkeley — In an electrically conductive solid, the Wiedemann-Franz (WF) law requires the electronic contribution to thermal conductivity to be proportional to the product of electrical conductivity and absolute temperature, where the ratio is the Lorenz number, typically not much different from the Sommerfeld value  $L_0 = 2.44 \times 10^{-8}$  W-ohm-K<sup>-2</sup> at room temperature. The WF law reflects a basic property of metals where charge and heat are both carried by the same quasiparticles that both experience elastic scattering. At temperatures below the Debye temperature, the WF law has been experimentally shown to be robust in conventional conductors, with violations theoretically predicted or experimentally observed in strongly correlated electron systems or Luttinger liquids. However, the experimentally observed violations are at very low temperatures. Here we report breakdown of the WF law in a strongly correlated metal, in which the electronic thermal conductivity and L nearly vanish at temperatures above room temperature, where the electronic thermal conductivity amounts to only <~5% of the value expected from the WF law.

<sup>1</sup>Unusual behaviour of thermal conductivity in vanadium dioxide across the metal-insulator transition

**5:18PM P6.00011 Effects of Paramagnetism and Electron Correlations on the Electronic Structure of MnO: *Ab Initio* Study**, SANGMOON YOON, KYOUNGSUK JIN, Seoul Natl Univ, SEOUNG-HUN KANG, Kyung Hee Univ, KI TAE NAM, MIYOUNG KIM, Seoul Natl Univ, YOUNG-KYUN KWON, Kyung Hee Univ — Manganese oxide nanoparticles have attracted a lot of attentions as a promising candidate for next-generation catalyst. Therefore, understanding the electronic structure of manganese oxide in room temperature is highly required for the rational design of catalysts. We study the effects of paramagnetism and electron correlations on the electronic structure of MnO using *ab initio* density functional theory. Spin configurations of paramagnetism are postulated as the ensemble average of various spin disorders. Each initial disordered spin configuration is randomly generated with two constraints on magnetic local moments. We first investigate the influence of magnetic ordering on the electronic structure of MnO using noncollinear spin calculations and find that the magnetic disorders make valence band maximum more delocalized. Moreover, we examine the role of electron correlations in the electronic structure of paramagnetic MnO using DFT+U calculations. Strong electron correlations modify not only the size of band gap but also the magnitude of local moments as in the antiferromagnetic MnO. Besides, the initialized spin disorder remains almost unchanged as electron correlation gets stronger. Furthermore, our results obtained by considering both strong electron correlation and paramagnetism confirm experimentally-observed oxygen K edge X-ray emission spectra <sup>[1]</sup> reflecting the feature of valence bands. <sup>[1]</sup> E. Z. Kurmaev et al., Phys. Rev. B. **77**, 165127 (2008).

**2:30PM P7.00001 Magnetic resonance studies of the Mg acceptor in thick free-standing and thin-film GaN<sup>1</sup>**, MARY ELLEN ZVANUT, University of Alabama at Birmingham — Mg, the only effective p-type dopant for the nitrides, substitutes for Ga and forms an acceptor with a defect level of about 0.16 eV. The magnetic resonance of such a center should be highly anisotropic, yet early work employing both optically detected magnetic resonance (ODMR) and electron paramagnetic resonance (EPR) spectroscopies revealed a defect with a nearly isotropic g-tensor. The results were attributed to crystal fields caused by compensation and/or strain typical of the heteroepitaxially grown films. The theory was supported by observation of the expected highly anisotropic ODMR signature in homoepitaxially grown films in which dislocation-induced non-uniform strain and compensation are reduced. The talk will review EPR measurements of thin films and describe new work which takes advantage of the recently available thick free-standing GaN:Mg substrates grown by hydride vapor phase epitaxy (HVPE) and high nitrogen pressure solution growth (HNPS). Interestingly, the films and HVPE substrates exhibit characteristically different types of EPR signals, and no EPR response could be induced in the HNPS substrates, with or without illumination. In the heteroepitaxial films, a curious angular dependent line-shape is observed in addition to the nearly isotropic g-tensor characteristic of the Mg-related acceptor. On the other hand, the free-standing HVPE crystals reveal a clear signature of a highly anisotropic shallow acceptor center. Comparison with SIMS measurements implies a direct relation to the Mg impurity, and frequency-dependent EPR studies demonstrate the influence of the anisotropic crystal fields. Overall, the measurements of the thick free-standing crystals show that the Mg acceptor is strongly affected by the local environment.

<sup>1</sup>The ODMR was performed by Evan Glaser, NRL and the free-standing Mg-doped HVPE crystals were grown by Jacob Leach, Kyma Tech. The work at UAB is supported by NSF Grant No. DMR-1308446.

**3:06PM P7.00002 Unusual electronic phase transition in hydrogenated TiO<sub>2</sub> thin layer**, CHUNLEI YUE, JIN HU, XUE LIU, ZHIQIANG MAO, JIANG WEI, Tulane University — Hydrogenated TiO<sub>2</sub> has been studied intensively in recently years for its effectiveness of engineering band gap by introducing the hydrogen doping level close to the conduction band edge. Consequently, significant improvement of solar absorption efficiency has been achieved and has been successfully showcased in the photovoltaic and photocatalytic applications. Although the room temperature optical enhancement is fascinating, the comprehensive electronic properties of such hydrogenated TiO<sub>2</sub> have hardly been investigated. Here we report our electric transport measurement of hydrogenated TiO<sub>2</sub> thin layer in the temperature range from 400K to 3.5K. We observed a stabilized metallic behavior of hydrogenated TiO<sub>2</sub>, which persists down to 50K, and then a surprising transition to an insulating phase between 50K and 20K. Furthermore, the insulating phase of hydrogenated TiO<sub>2</sub> shows a photocurrent response up to 4 orders magnitude. We interpret the possible mechanism as the transition of O-H vibrational modes, which leads to the freezing of electrons donated by the intercalated hydrogen.

**3:18PM P7.00003 Dynamics of H<sub>i</sub><sup>+</sup> in Indium Oxide<sup>1</sup>**, W. B. FOWLER, M. STAVOLA, YING QIN, P. WEISER, WEIKAI YIN, Lehigh University — Studies of IR absorption[1] under uniaxial stress[2] and diffusion[3] of H<sub>i</sub><sup>+</sup> as well as the dynamics of positively charged muonium[4] in In<sub>2</sub>O<sub>3</sub> provide an experimental framework to understand these processes in detail. While the bixbyite structure[5] of In<sub>2</sub>O<sub>3</sub> has overall cubic symmetry, its remarkable internal asymmetries lead to a number of candidate locations for H<sub>i</sub><sup>+</sup>. Furthermore, the unique topology of In<sub>2</sub>O<sub>3</sub> leads to constraints on possible H diffusion paths. We have used the CRYSTAL06 code[6] with a hybridized DFT Hamiltonian to determine equilibrium positions and vibrational frequencies for possible sites for H<sub>i</sub><sup>+</sup> and have analyzed candidate diffusion paths and processes for H<sub>i</sub><sup>+</sup> and Mu<sup>+</sup>. **3:30PM P7.00004 Gd-Doped BaSnO<sub>3</sub> Thin Films: High Mobility in a Magnetically-Doped Transparent Conducting Oxide<sup>1</sup>**, URUSA ALAAN, Stanford University, PADRAIC SHAFER, ALPHA N'DIAYE, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, YURI SUZUKI, Stanford University — It has recently been shown that when the perovskite-structure BaSnO<sub>3</sub> (BSO) is doped with La<sub>Ba</sub><sup>'</sup>, the result is a transparent conducting oxide with room-temperature electron mobilities that are much higher than conventional ternary oxides. The ability to achieve high carrier mobilities in BSO is promising for future perovskite-structure devices. We have used pulsed laser deposition to grow epitaxial thin films of Ba<sub>0.96</sub>Gd<sub>0.04</sub>SnO<sub>3</sub> (Gd:BSO) and Ba<sub>0.96</sub>La<sub>0.04</sub>SnO<sub>3</sub> (La:BSO) on (001) SrTiO<sub>3</sub> and (001) MgO substrates. At 300 K, Gd:BSO films have  $\rho \sim 2$  m $\Omega$ ·cm,  $\mu_e \sim 28$  cm<sup>2</sup>/V·s and  $n \sim 1.0 \times 10^{20}$  cm<sup>-3</sup>. At the same temperature, La:BSO films have  $\rho \sim 0.4$  m $\Omega$ ·cm,  $\mu_e \sim 58$  cm<sup>2</sup>/V·s and  $n \sim 2.5 \times 10^{20}$  cm<sup>-3</sup>. While La:BSO is diamagnetic, Gd:BSO is paramagnetic with a clear magnetic response that saturates at  $\sim 7\mu_B/\text{Gd}^{3+}$ , and a negative ordinary magnetoresistance at low temperatures. Like La:BSO, Gd:BSO is transparent and colorless in the visible regime. Thus, we have shown that Gd is good dopant for BSO in order to achieve transparency and metallicity that is coincident with a magnetic response.

<sup>1</sup>We acknowledge support from the Army Research Office under grant W911NF-14-1-0611, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and the National Science Foundation Graduate Research Fellowship Program.

**3:42PM P7.00005 Links in Superconducting, ferroelectric & antiferrodistortive instabilities in pristine & ion implanted SrTiO<sub>3</sub> by studying JT lattice distortions, Cubic-Tetragonal phase transition, incoherent lattice fluctuations & Phonons using RBS-Ion Channeling, XPS & Raman Scattering.**, KALYAN SASMAL, VIKTOR HADJIEV, QUARK CHEN, WEI-KAN CHU, Texas Center for Superconductivity & Dept of Physics, University of Houston, TX, USA — Perovskite SrTiO<sub>3</sub> is quantum paraelectric. Cubic-tetragonal phase transition at 105K, driven by condensation of zone corner phonon involving rotation of oxygen octahedra. Jahn-Teller centers allows dynamical charge transfer & polaron-bipolaron formation. Dynamical covalency elicit structural instability in layered superconductor approach ferroelectric. MeV He<sup>+</sup> RBS-Axial Ion Channeling, ultrafast real-space probe of sub-picometre atomic displacement is used to probe JT effect & incoherent lattice fluctuations as a function of temperature in ion implanted STO lattice. Critical channeling angle  $\psi_c$  & ratio of minima of Angular ICh-RBS spectral yield  $\chi_{\min}$  for Sr & Ti sub lattices determine lattice distortion. Cr & Fe impurities mostly distort Ti sublattice. Displacements of Ti<sup>4+</sup> are calculated. Similar values of  $\psi_{1/2}$  for Sr sublattice indicates no displacement of Sr. Actually Cr/Fe located in Ti positions. JT Cr<sup>4+</sup>, Cr<sup>5+</sup> & Fe<sup>4+</sup> impurity could induce Raman-active localized oxygen vibrational mode, which doesn't involve motion of nearest Fe or Ti ions. Displacive phase transition provides direct evidence of changes with temperature in thermal vibrational amplitude of lattice atoms across structural phase transition. Interplay of ferroelectric, antiferrodistortive distortions & superconducting order are discussed.

**3:54PM P7.00006 Collapse of electrons to a donor cluster in SrTiO<sub>3</sub>**, HAN FU, KONSTANTIN REICH, BORIS SHKLOVSKII, University of Minnesota — It is known that when a nucleus has charge  $Ze$  where  $Z > 137$ , electrons collapse onto the nucleus resulting in a net charge  $Z_n < Z$ . This effect is due to the relativistic dispersion law. Here a similar effect is found for a donor cluster in SrTiO<sub>3</sub> (STO), but with a different origin (see Phys. Rev. B 92, 035204 (2015)). At low temperatures, STO has an enormously large dielectric constant and the nonlinear dielectric response becomes dominant when the electric field is still small. This leads to the collapse of electrons into a charged spherical donor cluster with radius  $R$  when its total charge number  $Z$  exceeds a critical value  $Z_c \simeq R/a$  where  $a$  is the lattice constant. The net charge  $Z_n e$  grows with  $Z$  until  $Z$  exceeds  $Z^* \simeq (R/a)^{9/7}$ . After this point, the charge of the compact core  $Z_n$  remains  $\simeq Z^*$ , while the rest  $Z^*$  electrons form a sparse Thomas-Fermi electron atmosphere around it. We show that the thermal ionization of such two-scale atoms easily strips the outer atmosphere while the inner core remains preserved. We extend our results to the case of long cylindrical clusters. We discuss how our predictions can be tested by measuring conductivity of chain of discs of charge on the STO surface.

**4:06PM P7.00007 Point defects and band alignment in strontium cerate<sup>1</sup>**, MICHAEL SWIFT, CHRIS G. VAN DE WALLE, Univ of California - Santa Barbara — Strontium cerate (SrCeO<sub>3</sub>) is a well-known ionic conductor of both hydrogen and oxygen. In applications, it is frequently doped (for instance with yttrium or neodymium) to increase stability and promote diffusion. However, the microscopic effects of doping and native defects are not fully understood. Building on previous computational work in barium cerate (BaCeO<sub>3</sub>), we use density functional theory with a hybrid functional to study impurities, electronic structure, and band alignments in these systems. We establish trends that we expect to hold across the perovskite cerates. We also discuss the alignment of the thermodynamic charge-state transition levels of hydrogen, and applications to this class of materials.

<sup>1</sup>This work was supported by DOE.

**4:18PM P7.00008 Ferromagnetism in ZnO doped with alkaline elements**, YIREN WANG, JINGYUAN PIAO, GUOZHONG XIN, Univ of New South Wales, YUNHAO LU, Zhejiang University, ZHIMIN AO, University of Technology Sydney, NINA BAO, JUN DING, National University of Singapore, SEAN LI, JIABAO YI, Univ of New South Wales — We have observed room temperature ferromagnetism (RTFM) in ZnO doped with alkaline elements. Using first-principles calculations we found the magnetization in these systems is originated from the O2p hole states around Zn vacancies. Calculations indicate that the formation energy of Zn vacancies alone is rather high while further investigation indicates the formation can be much stabilized by the alkaline dopants in the form of defect complexes. By calculating the formation energy of concerned defects and complexes, we found the role of the dopants that under a certain doping concentration: Zn vacancy, substitutional and interstitial dopants can form a defect complex, which can lower formation energy, therefore stabilizing Zn vacancies. Moreover K dopants have shown unique functions on the ferromagnetism since the substitutional K can induce magnetic moments to the system by forming partial zinc vacancy via lattice distortion. Hence K doped ZnO can be magnetic at low doping concentrations. Experimentally, Li, Na doped ZnO films and K doped ZnO nanorods with different doping levels are synthesized, RTFM can be observed in all these systems. The magnetization is found to be greatly influenced by the doping concentrations. The experimental results have shown good consistence with our theoretical calculations. Our studies can inspire the defect induced ferromagnetism as a new route for the fabrication of new diluted magnetic semiconductors.

**4:30PM P7.00009 Oxygen vacancies in amorphous-Ta<sub>2</sub>O<sub>5</sub> from first-principles calculations<sup>1</sup>**, JIHANG LEE, EMMANOUIL KIOUPAKIS, Materials Science and Engineering, University of Michigan, WEI LU, Electrical Engineering and Computer Science, University of Michigan — Oxygen vacancies are thought to play a crucial role in the electrical and optical properties of tantalum pentoxide (Ta<sub>2</sub>O<sub>5</sub>) devices. Even though numerous experimental studies on oxygen vacancies in Ta<sub>2</sub>O<sub>5</sub> exist, experimentally detected defects are ambiguously identified due to the absence of an accurate and conclusive theoretical analysis. We investigate oxygen vacancies in amorphous Ta<sub>2</sub>O<sub>5</sub> with first-principles calculations based on hybrid density functional theory. The calculated thermodynamic and optical transition levels of stable oxygen vacancies are in good agreement with measured values from a variety of experimental methods, providing conclusive clues for the identification of the defect states observed in experiments. We determine the concentration of oxygen vacancies and their dominant oxidation state as a function of growth conditions. We analyze the characteristics of extra electrons introduced by donor-like oxygen vacancies, which include the formation of polarons. Our results provide insight into the fundamental properties of oxygen vacancies in Ta<sub>2</sub>O<sub>5</sub>, which is essential to controlling the properties of films and optimize the performance of devices.

<sup>1</sup>This research was supported by the AFOSR through MURI grant FA9550-12-1-0038 and the National Science Foundation CAREER award through Grant No. DMR-1254314. Computational resources were provided by the DOE NERSC facility.

**4:42PM P7.00010 Charge storage in oxygen deficient phases of TiO<sub>2</sub>: defect Physics without defects<sup>1</sup>**, A. C. M. PADILHA, Univ. Federal do ABC, Santo Andre, SP, Brazil, H. RAEBIGER, Yokohama Natl Univ., Yokohama, Japan, A. R. ROCHA, Univ. Est. Paulista, S SP, Brazil, G. M. DALPIAN, Univ. Federal do ABC, Santo Andre, Brazil — Defects in semiconductors can exhibit multiple charge states, which can be used for charge storage applications. Here we consider such charge storage in a series of oxygen deficient phases of TiO<sub>2</sub>, known as Magnli phases. These Ti<sub>n</sub>O<sub>2n-1</sub> Magnli phases present well-defined crystalline structures, i. e., their deviation from stoichiometry is accommodated by changes in space group as opposed to point defects. We show that these phases exhibit intermediate bands with the same electronic transitions akin to interstitial Ti defect levels in TiO<sub>2</sub>-rutile. Thus, the Magnli phases behave as if they contained a very large pseudo-defect density:  $\frac{1}{2}$  per formula unit Ti<sub>n</sub>O<sub>2n-1</sub>. Depending on the Fermi Energy the whole material will become charged. These crystals are natural charge storage materials with a storage capacity that rivals the best known supercapacitors.

<sup>1</sup>We thank financial support from FAPESP and CNPq.

**4:54PM P7.00011 Influence of the “second gap” on the optical absorption of transparent conducting oxides**, VIET-ANH HA, DAVID WAROQUIERS, GIAN-MARCO RIGNANESE, GEOFFROY HAUTIER, Institut de la matière condensée et des nanosciences (IMCN), Université catholique de Louvain, Louvain-la-Neuve 1348, Belgium — Transparent conducting oxides (TCOs) are critical to many technologies (e.g., thin-film solar cells, flat-panel displays or organic light-emitting diodes). TCOs are heavily doped (*n* or *p*-type) oxides that satisfy many design criteria such as high transparency to visible light (i.e., a band gap  $> 3$  eV), high concentration and mobility of carriers (leading to high conductivity), ... In such (highly doped) systems, optical transitions from the conduction band minimum to higher energy bands in *n*-type or from lower energy bands to the valence band maximum in *p*-type are possible and can degrade transparency. In fact, it has been claimed that a high energy ( $> 3$  eV) for any of these transitions made possible by doping, commonly referred as a high “second gap”, is a necessary design criterion for high performance TCOs. Here, we study the influence of this second gap on the transparency of doped TCOs by using *ab initio* calculations within the random phase approximation (RPA) for several well-known *p*-type and *n*-type TCOs. Our work highlights how the second gap affects the transparency of doped TCOs, shining light on more accurate design criteria for high performance TCOs.

**5:06PM P7.00012 Small polarons and point defects in  $\text{LaFeO}_3$** , ZHEN ZHU, HARTWIN PEELAERS, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The proton-conductive perovskite-type  $\text{LaFeO}_3$  is a promising negative-electrode material for Ni/metal-hydride (Ni-MH) batteries. It has a discharge capacity up to  $530 \text{ mAhg}^{-1}$  at 333 K, which is significantly higher than commercialized  $\text{AB}_5$ -type alloys. To elucidate the underlying mechanism of this performance, we have investigated the structural and electronic properties of bulk  $\text{LaFeO}_3$ , as well as the effect of point defects, using hybrid density functional methods.  $\text{LaFeO}_3$  is antiferromagnetic in the ground state with a band gap of 3.54 eV. Small hole and electron polarons can form through self- or point-defect-assisted trapping. We find that La vacancies and Sr substitutional on La sites are shallow acceptors with the induced holes trapped as small polarons, while O and Fe vacancies are deep defect centers. Hydrogen interstitials behave like shallow donors, with the donor electrons localized on nearby iron sites as electron polarons. With a large trapping energy, these polarons can act as electron or hole traps and affect the electrical performance of  $\text{LaFeO}_3$  as the negative electrode for Ni-MH batteries. We acknowledge DOE for financial support.

**5:18PM P7.00013 Time-resolved photoluminescence of  $\text{SiO}_x$  encapsulated  $\text{Si}^1$** , SEREF KALEM, Tubitak-Bilgem, AMAL HANNAS, TOMAS STERMAN, VILLY SUNDSTRM, Lund Laser Center, University of Lund, Sweden — Silicon and its oxide  $\text{SiO}_x$  offer a number of exciting electrical and optical properties originating from defects and size reduction enabling engineering new electronic devices including resistive switching memories. Here we present the results of photoluminescence dynamics relevant to defects and quantum confinement effects. Time-resolved luminescence at room temperature exhibits an ultrafast decay component of less than 10 ps at around 480 nm and a slower component of around 60 ps as measured by streak camera. Red shift at the initial stages of the blue luminescence decay confirms the presence of a charge transfer to long lived states. Time-correlated single photon counting measurements revealed a life-time of about 5 ns for these states. The same quantum structures emit in near infrared close to optical communication wavelengths. Nature of the emission is described and modeling is provided for the luminescence dynamics. The electrical characteristics of metal-oxide-semiconductor devices were correlated with the optical and vibrational measurement results in order to have better insight into the switching mechanisms in such resistive devices as possible next generation RAM memory elements.

## Wednesday, March 16, 2016 2:30PM - 5:30PM – Session P8 DCMP DMP: Superconductivity: Proximity Effects and SN Junctions I 304 -

**2:30PM P8.00001 Anisotropic Suppression of Superconductivity on  $\text{Pb(111)}/\text{Mn}_5\text{Ge}_3/\text{Ge(111)}$** , HOWON KIM, Institute for Solid State Physics, The Univ. of Tokyo, YUKI NAGAI, CCSE, Japan Atomic Energy Agency, TAKEO KATO, YUKIO HASEGAWA, Institute for Solid State Physics, The Univ. of Tokyo — When a superconductor comes in a good contact to non-superconducting materials, the superconducting pair correlation and its breaking penetrate each other from the interface. In particular, superconductor/ferromagnet(S/F) interface has been of great interests because of emergence of exotic superconducting (inverse) proximity effect on both sides. In spite of extensive efforts for the S/F interfaces, the experimental approach was limited because of difficulties in fabricating the high quality interface and probing it in the nanometer scales. Here, we studied superconductivity of  $\text{Pb(111)}$  layers which are formed on the ferromagnetic  $\text{Mn}_5\text{Ge}_3$  island structures grown on a  $\text{Ge(111)}$  substrate at  $T \sim 0.5 \text{ K}$ . From our spatially-resolved local tunneling spectra over the top surface of  $\text{Pb(111)}$  on the ferromagnetic islands, we found that the superconducting property above the magnetic island was strongly suppressed and that the suppression was laterally spread from the strongly suppressed area in an anisotropic manner. By considering the scattering and propagating behaviors of the broken cooper pairs at the fermi surface of  $\text{Pb(111)}$ , we calculate the local density of states at the top of the  $\text{Pb(111)}$  layer above the  $\text{Mn}_5\text{Ge}_3$  island, and found that the anisotropic suppression of superconductivity mainly due to the anisotropic shape of the fermi surface of Pb. Possible origins of anisotropic suppression of superconductivity will be discussed.

**2:42PM P8.00002 Spin-triplet superconducting proximity effect in  $\text{SrRuO}_3/\text{Sr}_2\text{RuO}_4$  hybrids**, MUHAMMAD SHAHBAZ ANWAR, Kyoto University, SEUNGRAN LEE, Seoul National University, R ISHIGURO, Tokyo University of Science, Y SUGIMOTO, Kyoto University, Y TANO, Tokyo University of Science, S. J. KANG, Y.J. SHIN, Seoul National University, SHINGO YONEZAWA, Kyoto University, H TAKAYANAGI, Tokyo University of Science, TAE WON NOH, Seoul National University, YOSHITERU MAENO, Kyoto University, YOSHITERU MAENO TEAM, TAE WON NOH TEAM, TAKAYANAGI COLLABORATION — Spin-triplet superconducting correlations can be induced into a ferromagnet (FM) out of a spin-singlet superconductor (SSC) via magnetic inhomogeneity at the SSC/FM interface. In this case, however, the proximity effect is not readily controllable because spins are quenched. In contrast, superconducting spintronics can be realized by using spin-triplet superconductors (TSCs) and FM hybrids. Theoretically, it has been predicted that spin-triplet proximity effect can be controlled by the relative orientations between the magnetization in the FM and the Cooper pair spin in TSC. We fabricate  $\text{Au(600-nm)}/\text{SrRuO}_3(15\text{-nm})/\text{Sr}_2\text{RuO}_4$  junctions by growing epitaxial  $\text{SrRuO}_3$  FM thin films on  $\text{Sr}_2\text{RuO}_4$  TSC single crystals. Differential conductance vs voltage shows the conductance enhancements with superconducting transitions at three different characteristic voltages. These three features can naturally be interpreted as originating from the SC gaps in bulk  $\text{Sr}_2\text{RuO}_4$  as well as at two distinct interfaces ( $\text{Au}/\text{SrRuO}_3$  and  $\text{SrRuO}_3/\text{Sr}_2\text{RuO}_4$ ). The effect of applied magnetic field reveals that the proximity effect is robust against the loss of magnetic inhomogeneity.

**2:54PM P8.00003 Waiting times of entangled electrons in normal-superconducting junctions**, DENIS CHEVALLIER, Univ of Basel, MATHIAS ALBERT, Univ of Nice Sophia-Antipolis, INLN, PIERRE DEVILLARD, Centre de Physique Thorique, Marseille — We consider a normal-superconducting junction in order to investigate the effect of new physical ingredients on waiting times. First, we study the interplay between Andreev and specular scattering at the interface on the distribution of waiting times of electrons or holes separately. In that case the distribution is not altered dramatically compared to the case of a single quantum channel with a quantum point contact since the interface acts as an Andreev mirror for holes. We then consider a fully entangled state originating from splitting of Cooper pairs at the interface and demonstrate a significant enhancement of the probability to detect two consecutive electrons in a short time interval. Finally, we discuss the electronic waiting time distribution in the more realistic situation of partial entanglement.

**3:06PM P8.00004 Measurements of the superconducting proximity effect in  $\text{Pd}/\text{Al}$  NS bilayers at GHz frequencies.**, ANI NERSISYAN, RICCARDO MANENTI, MICHAEL PETERER, EINAR MAGNUSSON, GIOVANNA TANCREDI, ANDREW PATTERSON, PETER LEEK, University of Oxford, Oxford, UK — The superconducting proximity effect, well known since the 1960s, describes superconductivity in the case of a superconductor contacted to a normal metal, and is typically studied experimentally using transport techniques such as tunneling spectroscopy [1-4]. Here we will present studies of the superconducting proximity effect in thin film palladium/aluminum NS bilayers using microwave frequency lumped element LC resonators. Measurements of the resonance frequency and quality factor as a function of temperature and film thickness reveal properties of the NS bilayers such as the critical temperature and penetration depth. Our results should be useful for understanding losses in superconducting quantum circuits that incorporate thin normal layers, and, in the particular case of Pd, should aid in design of hybrid superconducting quantum devices incorporating carbon nanotubes with high contact transparency [5]. **3:18PM P8.00005 Electrostatic effects in semiconductor-superconductor heterostructures.** , PIYAPONG SITTHISON, TUDOR STANESCU, West Virginia University — We study the effects of an interface-induced bias on the charge distribution, proximity-induced superconducting gap, and spin-orbit coupling strength in semiconductor-superconductor hybrid structures. The effective bias potential is generated by the work function difference across the interface. We show that the size of the induced superconducting gap (relative to the bulk gap) depends on the geometry of the structure and, in addition, is controlled by two effective parameters: the work function difference and the effective semiconductor-superconductor coupling. The interface-induced bias also breaks inversion symmetry, which leads to a nonzero value of the Rashba spin orbit coupling. We systematically study the dependence of the induced gap and Rashba coupling strength on the geometry of the structure (e.g., the diameter of the wire) and the relevant effective parameters (i.e. work function difference and semiconductor-superconductor coupling strength).

**3:30PM P8.00006 Differential Conductance in Semiconductor-Superconductor Hybrid Structures** , JOHN STENGER, TUDOR STANESCU, West Virginia University — We construct a theory for calculating the differential conductance in semiconductor-superconductor hybrid structures that accounts for both the current carried by quasiparticles in the bulk superconductor and the contributions due to proximity effects induced in the semiconductor. Starting with a Blonder-Tinkham-Klapwijk (BTK) type approach, we show that the superconductor degrees of freedom can be conveniently integrated out and replaced by an interface 'Green function' determined by the properties of the superconductor and the original outgoing-wave boundary conditions corresponding to quasiparticle propagation. We find that the features present in the differential conductance are associated with both semiconductor and bulk superconductor spectral features, with a relative strength that depends on the parameters of the structure. We systematically investigate the dependence of the differential conductance on the parameters of the system, including coupling strength, semiconductor band occupancy, and barrier transparency, and correlate our findings with recent experimental measurements on proximity-coupled semiconductor wires.

**3:42PM P8.00007 Super-Hard induced gap in InSb nanowires** , JUN CHEN, PENG YU, Univ of Pittsburgh, MORA HOCEVAR, CEA, Grenoble, France, SBASTIEN PLISSARD, DIANA CAR, ERIK BAKKERS, Eindhoven University of Technology, the Netherlands, SERGEY FROLOV, Univ of Pittsburgh — In recent years, Majorana bound states were observed experimentally in InSb nanowire-superconductor hybrid devices, which manifested themselves as a zero-bias conductance peak (ZBP). However, there was still significant conductance inside the superconducting gap, which would smear sub-gap features. Moreover, fermionic states inside the gap would also break topological protection. Therefore, a hard gap is required in search of more deterministic signatures of Majorana bound states, and building up Majorana qubits. We report the observation of a hard induced gap in an InSb Josephson junction with an optimized superconducting contact recipe. The gap is resolved in magnetic field up to 2 Tesla, and demonstrates a peculiar kinked field dependence. In addition, we observed rich sub-gap features: Andreev levels appeared close to pinch off regime, while multiple Andreev reflection appeared in open regime.

**3:54PM P8.00008 Proximity semiconducting nanowire junctions from Josephson to quantum dot regimes** , KAVEH GHARAVI, GREGORY HOLLOWAY, JONATHAN BAUGH, Institute for Quantum Computing, University of Waterloo — Experimental low-temperature transport results are presented on proximity-effect Josephson junctions made from low bandgap III-V semiconductor nanowires contacted with Nb. Two regimes are explored in terms of the Nb/nanowire interface transparency  $t$ . (i) High  $t$  allows a supercurrent to flow across the junction with magnitude  $I_c$ , which can be modulated using the voltage  $V_g$  on a global back gate or a local gate. Relatively high values are obtained for the figure-of-merit parameter  $I_c R_N / (e\Delta) \sim 0.5$ , and  $t \sim 0.75$ , where  $R_N$  is the normal state resistance and  $\Delta$  the superconducting gap of the Nb leads. With the application of an axial magnetic field,  $I_c$  decays but exhibits oscillations before being fully suppressed. The period and amplitude of the oscillations depend on  $V_g$ . Possible explanations for this behaviour are presented, including Josephson interference of the orbital subbands in the nanowire. (ii) Lower transparency correlates with a spontaneous quantum dot (QD) formed in the nanowire channel. Pairs of Andreev Bound States (ABS) appear at energies  $|E| < \Delta$ , with one pair unexpectedly pinned at  $E = 0$  for a wide range of  $V_g$ . A description of the QD-ABS system beyond the Anderson model is presented to explain the latter results.

**4:06PM P8.00009 Metal organic chemical vapor deposition of core-shell InAs-Al nanowires for proximity-induced superconductivity**<sup>1</sup> , T. R. HARTKE, J. STEHLIK, J. R. PETTA, Department of Physics, Princeton University — The zero-bias conductance peaks observed in proximitized InSb nanowires have been interpreted as evidence of Majorana fermions.<sup>2</sup> However, these observations are complicated by the presence of a non-zero conductance throughout the gap, which has been termed a “soft-gap.” The characteristics of the gap can be improved by using MBE to epitaxially grow a superconducting aluminum shell around an InAs core.<sup>3</sup> Here we use metal organic chemical vapor deposition (MOCVD) to grow high quality InAs nanowires on predefined Au catalyst sites. An aluminum shell is deposited immediately after the InAs growth is terminated. The resulting core-shell nanowires are structurally and electrically characterized.

**4:18PM P8.00010 Superconducting gap closing and Zero-bias peak in InSb nanowire** , PENG YU, JUN CHEN, Department of Physics and Astronomy, University of Pittsburgh, MORA HOCEVAR, CEA, Grenoble, France, SBASTIEN PLISSARD, DIANA CAR, ERIK BAKKERS, Eindhoven University of Technology, The Netherlands, SERGEY FROLOV, Department of Physics and Astronomy, University of Pittsburgh — In a 1D superconductor-nanowire-normal contact system, Majorana bound states are expected to appear after topological phase transition. Although there are many experiments reported possible zero-bias conductance peak from Majorana bound states, mapping out of the topological phase diagram is still missing. In our InSb nanowire hybrid devices, we observed possible superconducting gap closing and re-opening with magnetic field. These gap closings appear near conductance resonances which show some feature of 1D subband edges. Interestingly, zero-bias conductance peak appears inside the split regime of crossings at finite magnetic field. The magnetic field onset of the zero-bias peak can be tuned by gates underneath the superconductor, which may result from the changing of chemical potential.

**4:30PM P8.00011 Symmetry breaking in SNS junctions: edge transport and field asymmetries**<sup>1</sup> , HENRI SUOMINEN, FABRIZIO NICHELE, MORTEN KJAERGAARD, ASBJORN RASMUSSEN, JEROEN DANON, KARSTEN FLENSBERG, Center for Quantum Devices & Station Q Copenhagen, LEONID LEVITOV, Department of Physics, Massachusetts Institute of Technology, JAVAD SHABANI, Physics Department, City College of New York, CHRIS PALMSTROM, California NanoSystems Institute, University of California Santa Barbara, CHARLES MARCUS, Center for Quantum Devices & Station Q Copenhagen — We study magnetic diffraction patterns in a tunable superconductor-semiconductor-superconductor junction. By utilizing epitaxial growth of aluminum on InAs/InGaAs we obtain transparent junctions which display a conventional Fraunhofer pattern of the critical current as a function of applied perpendicular magnetic field,  $B_{\perp}$ . By studying the angular dependence of the critical current with applied magnetic fields in the plane of the junction we find a striking anisotropy. We attribute this effect to dephasing of Andreev states in the bulk of the junction, leading to SQUID like behavior when the magnetic field is applied parallel to current flow. Furthermore, in the presence of both in-plane and perpendicular fields, asymmetries in  $\pm B_{\perp}$  are observed. We suggest possible origins and discuss the role of spin-orbit and Zeeman physics together with a background disorder potential breaking spatial symmetries of the junction.

**4:42PM P8.00012 Proximity induced Shiba states in an organic radical molecular junction<sup>1</sup>**, JOSHUA ISLAND, ROCCO GAUDENZI, ENRIQUE BURZURI, HERRE VAN DER ZANT, Delft Univ of Tech — Superconductors containing magnetic impurities lead to interesting phenomena derived from the interaction between Cooper pairing and Kondo screening. Here, we present measurements on proximity induced superconducting break-junctions hosting a magnetic impurity in the form of a neutral and stable, all organic radical molecule. Transport measurements reveal sub-gap excitations which are characteristic of a spin-induced, Yu-Shiba-Rusinov (Shiba) bound state due to the interaction of the radical's unpaired spin with a strongly coupled, proximity-induced superconductor. We show that by applying an external magnetic field to suppress the proximity induced superconductivity, a zero bias peak emerges signaling Kondo screening of the radical's unpaired spin coupled to normal leads. Our results show that Shiba states are a robust feature of the interaction between a magnetic impurity and a proximity induced superconducting junction.

**4:54PM P8.00013 Observation of conductance doubling in an Andreev quantum point contact<sup>1</sup>**, M KJAERGAARD, F NICHELE, H SUOMINEN, Center for Quantum Devices & Station Q Copenhagen, M NOWAK, M WIMMER, A AKHMEROV, Kavli Institute for Nanoscience, TU Delft, J FOLK, Department of Physics and Astronomy, University of British Columbia, K FLENSBERG, Center for Quantum Devices & Station Q Copenhagen, J SHABANI, Physics Department, City College of New York, C PALMSTROM, California NanoSystems Institute, University of California Santa Barbara, C MARCUS, Center for Quantum Devices & Station Q Copenhagen — One route to study the non-Abelian nature of excitations in topological superconductors is to realise gateable two dimensional (2D) semiconducting systems, with spin-orbit coupling in proximity to an s-wave superconductor. Previous work on coupling 2D electron gases (2DEG) with superconductors has been hindered by a non-ideal interface and unstable gateability. We report measurements on a gateable 2DEG coupled to superconductors through a pristine interface, and use aluminum grown in situ epitaxially on an InGaAs/InAs electron gas. We demonstrate quantization in units of  $4e^2/h$  in a quantum point contact (QPC) in such hybrid systems. Operating the QPC as a tunnel probe, we observe a hard superconducting gap, overcoming the soft-gap problem in 2D superconductor/semiconductor systems. Our work paves way for a new and highly scalable system in which to pursue topological quantum information processing.

**5:06PM P8.00014 Origin of Mesoscopic Superconductivity at Cd<sub>3</sub>As<sub>2</sub> Point-Contacts**, LEENA AGGARWAL, ABHISHEK GOURAV SINHA, Indian Institute of Science Education and Research, Mohali (Punjab) India, GOHIL S. THAKUR, Indian Institute of Technology, New Delhi, India, ZEBA HAQUE, Indian Institute of Technology, New Delhi, ASHOK K. GANGULI, Indian Institute of Technology, New Delhi, Institute of Nano Science & Technology, Mohali, (Punjab) India, GOUTAM SHEET, Indian Institute of Science Education and Research, Mohali (Punjab) India — I will present our point-contact spectroscopy results on the nature and origin of superconductivity that is observed at the mesoscopic interfaces between the conventional metals and the 3-D Dirac semimetal Cd<sub>3</sub>As<sub>2</sub>. From our experiments with metallic tips of varying mechanical properties we show that the local superconducting phase does not emerge due to pressure. We show that quantum fluctuations may play a significant role in the emergence of such novel superconducting phase.

**5:18PM P8.00015 Two-dimensional epitaxial superconductor-semiconductor heterostructures: A platform for topological superconducting networks**, J. SHABANI, Physics Department, CCNY, M. KJAERGAARD, H. J. SUOMINEN, F. NICHELE, Center for Quantum Devices, Copenhagen, Y. KIM, UCSB, K. PAKROUSKI, Theoretical Physics, ETH Zurich, S. KRAEMER, UCSB, T. STANKEVIC, P. KROGSTROP, R. FEIDENHANS, Center for Quantum Devices, Copenhagen, R. M. LUTCHYN, C. NAYAK, Microsoft Research, Station Q, M. TROYER, Theoretical Physics, ETH Zurich, C. M. MARCUS, Center for Quantum Devices, Copenhagen, C. J. PALMSTROM, UCSB — Theory suggests that the interface between a one-dimensional semiconductor (Sm) with strong spin-orbit coupling and a superconductor (S) hosts Majorana modes with nontrivial topological properties. A key challenge in fabrication of such hybrid devices is forming highly transparent contacts between Sm and S. Recently, it has been shown that a near perfect interface and a highly transparent contact can be achieved using epitaxial growth of aluminum on InAs nanowires [1, 2]. In this work, we present the first two-dimensional epitaxial superconductor-semiconductor material system that can serve as a platform for topological superconductivity, and the search for quasiparticles such as Majorana zero modes that are predicted to obey non-abelian statistics. We show that our material system, Al-InAs, satisfies all the requirements necessary to reach into the topological superconducting regime by individual characterization of the semiconductor two dimensional electron system, superconductivity of Al and performance of S-Sm-S junctions [3].

## Wednesday, March 16, 2016 2:30PM - 5:30PM – Session P9 DCMP FIAP: Superlattices and Terahertz 305 -

**2:30PM P9.00001 Broadband Midwave Infrared InAs/GaSb Superlattice Light-Emitting Diodes**, RUSSELL RICKER, SYDNEY PROVENCE, University of Iowa, DENNIS NORTON, None, JOHN PRINEAS, THOMAS BOGGESE, University of Iowa — Broadband (3.0  $\mu\text{m}$  to 5.0  $\mu\text{m}$ ) emission is reported from InAs/GaSb superlattice light-emitting diodes grown via molecular beam epitaxy. Stacked active regions, each with a different emission wavelength, were connected with tunnel junctions, resulting in multiple emission wavelengths in a monolithic structure. Eight active regions provided eight overlapping emission spectra, simulating a broadband spectrum. Chips with mesas of sizes ranging from 24  $\mu\text{m}$   $\times$  24  $\mu\text{m}$  to 400  $\mu\text{m}$   $\times$  400  $\mu\text{m}$  were fabricated and wire bonded to a leadless chip carrier (LCC). The LCC was mounted in a liquid nitrogen cryostat. At low input currents, distinct peaks were observed at 3.3  $\mu\text{m}$ , 3.6  $\mu\text{m}$ , 3.9  $\mu\text{m}$ , 4.2  $\mu\text{m}$ , 4.5  $\mu\text{m}$ , 4.9  $\mu\text{m}$ , and 5.3  $\mu\text{m}$ . At high input currents a continuous spectrum was observed with a peak near 3.8  $\mu\text{m}$  and with a full-width at half-maximum of 1.42  $\mu\text{m}$ . In quasi-continuous operation at 77 K, radiances exceeding 0.35 W/cm<sup>2</sup>-sr in a Lambertian profile were achieved. Current dependent electroluminescent spectra measured at liquid nitrogen temperatures demonstrate the blending of the various colors from each stage into one smooth spectrum at high currents.

**2:42PM P9.00002 Long Minority Carrier Lifetimes in InAs/InAsSb Type-II Superlattices<sup>1</sup>**, YIGIT AYTAC, University of Iowa, BENJAMIN OLSON, JIM K KIM, ERIC A SHANER, SAMUEL HAWKINS, JOHN KLEM, Sandia National Laboratories, MICHAEL FLATT, THOMAS F BOGGESE, University of Iowa, UNIVERSITY OF IOWA COLLABORATION, SANDIA NATIONAL LABORATORIES COLLABORATION — Three unintentionally doped MWIR InAs/InAsSb type-II superlattices (T2SLs) were designed and grown to have 15 % Sb content in their alloy layers. The individual layer thicknesses of InAs and InAsSb are systematically altered in configurations of 174/218, 87/109, and 65/82 (Å/Å) while the total absorber thickness is nominally 4  $\mu\text{m}$  and the bandgap is approximately 5.2  $\mu\text{m}$  for all the samples. A time- and temperature- dependent differential-transmission technique was used to evaluate the carrier lifetime of each of the samples. Significantly long minority carrier (MC) lifetimes of ~14  $\mu\text{s}$  and ~19  $\mu\text{s}$  were obtained for the sample with 174 Å /218 Å InAs/InAsSb layer ratio at the temperatures of 77 K and 125 K, respectively. The defect energy levels of the InAs/InAsSb T2SLs reported here are determined to be ~300 25 meV relative to InAs valance band edge strained to GaSb. Additionally, the electron dominated Auger coefficients, C<sub>n</sub>, are obtained from the excess carrier density and temperature dependent recombination rate data. These coefficients are found to increase with decreasing individual layer thickness values from 3.4 to 29.9  $\times 10^{-27}$  cm<sup>6</sup>/s at 77 K.

<sup>1</sup>Administration under Contract No. DE-AC04-94AL85000. This research was funded by the U.S. Government.

**2:54PM P9.00003 Towards the design of high performance IR photonics: Optical analysis of textured gallium antimonide surfaces**, ELLA WASSWEILER, JOHN PRINEAS, FATIMA TOOR, University of Iowa — Gallium antimonide (GaSb) is used for fabrication of various optoelectronics devices, such as laser diodes, light emitting diodes, and photodetectors for the mid-infrared (MIR) wavelengths of  $3\text{ }\mu\text{m}$  to  $30\text{ }\mu\text{m}$ . Light extraction or collection efficiency of GaSb-based MIR devices can be significantly enhanced by surface texturing due to the density graded effect. However to the best of our knowledge no systematic study exists that analyzes the etch chemistries, surface textures and resultant reflectivity of GaSb surfaces. In this work we present the characterization of GaSb textures and how they correlate to reflectivity in the visible and MIR wavelengths. A parametric sweep of etch chemistries involving hydrofluoric acid (HF), hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), and citric acid ( $\text{C}_4\text{H}_6\text{O}_6$ ) provide a variety of surface textures that correspond to low reflectivity in different wavelength regimes. The size of the surface features causes scattering in wavelengths of the same magnitude and as a result lower the reflectivity. In addition an analytical equation derived from our experimental data is presented that correlates reflectivity measurements to etch depth and wavelength, which can be used to design high performance IR photonic devices.

**3:06PM P9.00004 Bias activated dielectric response of excitons and excitonic Mott transition in quantum confined lasers structures.**, KANIKA BANSAL, AMIT BHUNIA, SHOUVIK DATTA, Department of Physics, IISER, Pune 411008, Maharashtra, India, MARZOOK S ALSHAMMARI, National Center of Nanotechnology, KACST, Riyadh 11442, Saudi Arabia, MOHAMED HENINI, School of Physics and Astronomy, University of Nottingham, Nottingham NG7 2RD, UK — In contrast to the widely reported optical techniques, there are hardly any investigations on corresponding electrical signatures of condensed matter physics of excitonic phenomena. We studied small signal steady state capacitance response in III-V materials based multi quantum well (AlGaInP) and MBE grown quantum dot (InGaAs) laser diodes to identify signatures of excitonic presence. Conductance activation by forward bias was probed using frequency dependent differential capacitance response ( $\text{d}C/\text{d}f$ ), which changes characteristically with the onset of light emission indicating the occurrence of negative activation energy. Our analysis shows that it is connected with a steady state population of exciton like bound states. Calculated average energy of this bound state matches well with the binding energy of weakly confined excitons in this type of structures. Further increase in charge injection decreases the differential capacitive response in AlGaInP based diodes, indicating a gradual Mott transition of excitonic states into electron hole plasma. This electrical description of excitonic Mott transition is fully supplemented by standard optical spectroscopic signatures of band gap renormalization and phase space filling effects.

**3:18PM P9.00005 Effective chiral description of an exciton-polariton superfluid in one and two dimensions**, MANAS KULKARNI, GERMAN KOLMAKOV, Department of Physics, New York City College of Technology, City University of New York — There has been remarkable experiments recently on capturing hydrodynamic features of exciton-polariton condensates in optical microcavities which have potential implications for quantum and optical computing and information technologies. We present an effective chiral description for such one and two dimensional systems. This description captures the fingerprints of hydrodynamics, namely, nonlinearity, dispersion and dissipation. The resulting chiral equation for the condensate perturbation wave dynamics is found to be of the generalized-KdV-type. We describe the phenomenon of polariton shock waves, solitons and defects in such systems. Our mapping is expected to have broad implications for other systems and can further help one in engineering a delicate balance between the pump and damping to produce stable optical signals propagating in polariton circuits.

**3:30PM P9.00006 Optical bandgap determination of ultrathin amorphous films and superlattices**, STYLIANOS SIONTAS, PEI LIU, Brown University, PAOLO LONGO, Gatan Inc., ALEXANDER ZASLAVSKY, DOMENICO PACIFICI, Brown University — Quantum size confinement effects determine the optical bandgap of ultrathin  $<5\text{ nm}$  amorphous films and superlattices. Although widely used, the standard experimental approach of combining normal-incidence reflectance and transmittance measurements with a single-pass absorption model may not always provide reliable results. By using ultra-thin amorphous germanium (a-Ge) layers down to  $d = 2\text{ nm}$  thickness as an experimental platform, we show that a multiple-reflection interference model is necessary to provide a more accurate extraction of the absorption coefficient. We also compare the two most frequently-used analytical models (Tauc and Cody) used to extract the optical bandgap from the measured absorption coefficient and clearly demonstrate that the Cody model provides a more reliable bandgap dependence on  $d$ . Finally, we apply our proposed method to experimentally determine the optical bandgap of a-Ge/SiO<sub>2</sub> superlattices with alternating layers of a Ge and SiO<sub>2</sub> ranging from 2 to 30 nm. Such superlattice structures enable additional control over the optical bandgap that may prove useful for the fabrication of high-efficiency photodetectors and solar cells in the optical and near-infrared spectral ranges.

**3:42PM P9.00007 Imaging the Electronic States of a Two-Dimensional Assembled Quasicrystal**, LAURA C. COLLINS, THOMAS G. WITTE, University of Notre Dame, ROCHELLE SILVERMAN, Virginia Tech, DAVID B. GREEN, KENJIRO K. GOMES, University of Notre Dame — The behavior of electrons in a periodic lattice is well understood, but how do electrons move in quasicrystals, which are ordered but aperiodic? We used scanning tunneling microscopy and atomic manipulation to assemble a quasicrystal based on the Penrose tiling and we carried out scanning tunneling spectroscopy to study its electronic properties. Carbon monoxide molecules were arranged on Cu(111) to form a potential landscape. This constrained the electrons in the two-dimensional surface states to move along the edges of a Penrose tiling. We measured the differential conductance maps to visualize the electronic density of states of the assembled quasicrystal. The statistical analysis of these maps has been used to characterize the localization of the electronic states.

**3:54PM P9.00008 Conductivity Dynamics of the Metal-to-Insulator Transition in Nickelate Superlattices.**, VERNER THORSMOLLE, JINGDI ZHANG, University of California San Diego, SRIMANTA MIDDEY, University of Arkansas, ELSA ABREU, Swiss Federal Institute of Technology Zurich, GUFENG ZHANG, University of California San Diego, JAK CHAKHALIAN, University of Arkansas, RICHARD AVERITT, University of California San Diego — Complexity in transition metal oxides can be understood as a delicate balance between competing interactions, which give rise to an energy landscape whose details are not easily discerned. An increasingly successful approach to tackle this problem is that of time resolved experiments, where the fundamental timescales of the system properties can be investigated through their response to appropriately chosen femtosecond photoexcitation. Ultrafast optical studies of the insulator-metal transition (IMT) in transition metal oxides are of particular interest in terms of dynamics and control. The perovskite nickelates (RE)NiO<sub>3</sub> have emerged as an important class of IMT materials, exhibiting rich phenomena across the rare earth (RE) series that includes La, Pr, Nd, Sm, Eu, Y, and Lu. Quite recently, the growth of nickelate superlattices (SL) has been achieved, offering a route to control the IMT. Here, we will present the results of optical-pump THz-probe investigations of the IMT dynamics in these novel heterostructures.

**4:06PM P9.00009 First-principles Study of Atomic Rearrangement in GeTe-Sb<sub>2</sub>Te<sub>3</sub> Superlattice**, YOUNG-SUN SONG, SEUNG-HOON JHI, Pohang Univ of Sci & Tech, CNPL TEAM — GeTe-Sb<sub>2</sub>Te<sub>3</sub> chalcogenide superlattices, known as interfacial phase change memories (iPCMs), have been claimed to outperform Ge-Sb-Te-based phase-change materials. Despite its great potential as next-generation non-volatile memory devices, we still lack clear knowledge of the phase change mechanism. According to a recent work, the phase change processes in iPCMs involve two-step atomic rearrangements of Ge-Te layers, but the detailed interatomic features still remain unresolved. In this work, we studied the nature of atomic layer rearrangements in iPCMs using first-principles calculations and the interatomic potential model. We used the climbing image nudged elastic band (CI-NEB) method to obtain the intermediate structures and energies during the rearrangement processes. Applying a simple interatomic potential model to in-between steps, we investigated the interatomic motion during the phase change process. We found that a few selected atomic pairs determine most the energy barrier and also the response to external pressures.

**4:18PM P9.00010 Experimental demonstration of Luneburg waveguides**, CHRISTOPHER JENSEN, WILLIAM ZIMMERMAN, DAVID LAHNEMAN, TODD ADAMS, THOMAS GRESOCK, KATHRYN ZANDER, VERA SMOLYANINOVA, Towson University, IGOR SMOLYANINOV, University of Maryland — Transformation optics (TO) gives rise to numerous unusual optical devices, such as novel metamaterial lenses and invisibility cloaks. However, it is very difficult to create metamaterials with low-loss broadband performance, especially in the visible frequency range. In our TO devices we use metal/dielectric waveguides to emulate metamaterial properties [1]. Here we report the first experimental realization of TO Luneburg waveguides [2]. The individual Luneburg lenses in the fabricated design are based on lithographically defined metal/dielectric waveguides. We have studied wavelength and polarization dependent performance of the waveguides. Adiabatic variations of the waveguide shape enable control of the effective refractive index experienced by the TM light propagating inside the waveguide. Our experimental designs appear to be broadband, which has been verified in the 480-633 nm range. These novel optical devices considerably extend our ability to control light on sub-micrometer scales. [1]. V.N. Smolyaninova, et al., Phys. Rev. B 87, 075406 (2013); [2]. V.N. Smolyaninova, et al., Photonics 2, 440 (2015). This research was supported by the NSF grant DMR-1104676.

**4:30PM P9.00011 Terahertz radiation-induced sub-cycle field electron emission across a split-gap dipole antenna**<sup>1</sup>, JINGDI ZHANG, Department of Physics, University of California, San Diego, XIAO GUANG ZHAO, KEBIN FAN, XIAONING WANG, Department of Mechanical Engineering, Boston University, GU-FENG ZHANG, Department of Physics, University of California, San Diego, KUN GENG, Department of Physics, Boston University, XIN ZHANG, Department of Mechanical Engineering, Boston University, RICHARD D. AVERITT, Department of Physics, University of California, San Diego — We use intense terahertz pulses to excite the resonant mode (0.6THz) of a micro-fabricated dipole antenna with a vacuum gap. The dipole antenna structure enhances the peak amplitude of the in-gap THz electric field by a factor of ~170. Above an in-gap E-field threshold amplitude of ~10 MVcm<sup>-1</sup>, THz-induced field electron emission is observed (TIFEE) as indicated by the field-induced electric current across the dipole antenna gap. Field emission occurs within a fraction of the driving THz period. Our analysis of the current (I) and incident electric field (E) is in agreement with a Millikan-Lauritsen analysis where log (I) exhibits a linear dependence on 1/E. Numerical estimates indicate that the electrons are accelerated to a value of approximately one tenth of the speed of light. (arXiv: 1508.04737)

**4:42PM P9.00012 Fabrication of THz Sensor with Metamaterial Absorber**<sup>1</sup>, HUGO GONZALEZ, Naval Postgraduate School, FABIO ALVES, Alion Science and Technology, GAMANI KARUNASIRI, Naval Postgraduate School — The terahertz (THz) portion of the electromagnetic spectrum (0.1-10 THz) has not been fully utilized due to the lack of sensitive detectors. Real-time imaging in this spectral range has been demonstrated using uncooled infrared microbolometer cameras and external illumination provided by quantum cascade laser (QCL) based THz sources. However, the microbolometer pixels in the cameras have not been optimized to achieve high sensitivity in THz frequencies. Recently, we have developed a highly sensitive micromechanical THz sensor employing bi-material effect with an integrated metamaterial absorber tuned to the THz frequency of interest. The use of bi-material structures causes deflection on the sensor to as the absorbed THz radiation increases its temperature, which can be monitored optically by reflecting a light beam. This approach eliminates the integration of readout electronics needed in microbolometers. The absorption of THz by metamaterial can be tailored by controlling geometrical parameters. The sensors can be fabricated using conventional microelectronic materials and incorporated into pixels to form focal plane arrays (FPAs). In this presentation, characterization and readout of a THz sensor with integrated metamaterial structure will be described.

**4:54PM P9.00013 Nonperiodic metallic gratings transparent for broadband terahertz waves**, REN-HAO FAN, XIAO-PING REN, RU-WEN PENG, Nanjing University, XIAN-RONG HUANG, Argonne National Laboratory, MU WANG, Nanjing University — Recently, we demonstrate both theoretically and experimentally that nonperiodic metallic gratings can become transparent for broadband terahertz waves. Quasiperiodic and disordered metallic gratings effectively weaken and even eliminate Wood's anomalies, which are the diffraction-related characters of periodic gratings. Consequently, both the transparency bandwidth and transmission efficiency are significantly increased due to the structural aperiodicity. Furthermore, we show that for a specific light source, for example, a line source, a corresponding nonperiodic transparent grating can be also designed. We expect that our findings can be applied for transparent conducting panels, perfect white-beam polarizers, antireflective conducting solar cells, and beyond. References: X. P. Ren, R. H. Fan, R. W. Peng, X. R. Huang, D. H. Xu, Y. Zhou, and Mu Wang, Physical Review B, 91, 045111 (2015); R. H. Fan, R. W. Peng, X. R. Huang, J. Li, Y. Liu, Q. Hu, Mu. Wang, and X. **5:06PM P9.00014 Tuning the Polarization State of Light over a Broad Frequency Range with Metasurfaces**, MU WANG, SHANG-CHI JIANG, ZHENG-HAN WANG, XIANG XIONG, RU-WEN PENG, Nanjing University, NANJING UNIVERSITY TEAM — Controlling the polarization state, the transmission direction and the phase of light within a confined space is an important issue in optics. By integrating metallic metastructure and dielectric interlayer, it is possible to realize the dispersion-free broadband device on sub-wavelength scale, where the strong response of the metallic structures helps to decrease the device size while the dielectric interlayer helps to eliminate the dispersion simultaneously in both the amplitude and the phase difference of the reflected/transmitted light. As an examples to apply this concept, a broadband quarter-wave plate and a half-wave plate are experimentally demonstrated. By carefully selecting the structural parameters, the polarization state of light can be freely tuned across a broad frequency range, and all of the polarization states on the Poincaré sphere can be realized dispersion free. Some contents of this talk can be found in the following references: [1] S.-C. Jiang, et al., *High-efficiency generation of circularly polarized light via symmetry-induced anomalous reflection*, **Physical Review B** 91, 125421 (2015), [2] S.-C. **5:18PM P9.00015 Freely-tunable broadband polarization rotator for terahertz waves**<sup>1</sup>, RU-WEN PENG, REN-HAO FAN, YU ZHOU, SHANG-CHI JIANG, XIANG XIONG, Nanjing University, XIAN-RONG HUANG, Argonne National Laboratory, MU WANG, Nanjing University — It is known that commercially-available terahertz (THz) emitters usually generate linearly polarized waves only along certain directions, but in practice, a polarization rotator that is capable of rotating the polarization of THz waves to any direction is particularly desirable and it will have various important applications. In this work, we demonstrate a freely tunable polarization rotator for broadband THz waves using a three-rotating-layer metallic grating structure, which can conveniently rotate the polarization of a linearly polarized THz wave to any desired direction with nearly perfect conversion efficiency. The device performance has been experimentally demonstrated by both THz transmission spectra and direct imaging. The polarization rotation originates from multi wave interference in the three-layer grating structure based on the scattering-matrix analysis. We can expect that this active broadband polarization rotator has wide applications in analytical chemistry, biology, communication technology, imaging, etc.. Reference: R. H. Fan, Y. Zhou, X. P. Session P11 DMP: Correlations and Superconductivity in Fe chalcogenides II 307 - Makariy Tanatar, Ames Laboratory

**2:30PM P11.00001 BCS-BEC crossover physics in FeSe bulk superconductor<sup>1</sup>**, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo — The physics of the crossover between weak-coupling Bardeen-Cooper-Schrieffer (BCS) and strong-coupling Bose-Einstein-condensate (BEC) limits gives a unified framework of quantum bound (superfluid) states of interacting fermions. This crossover has been studied in the ultracold atomic systems, but is extremely difficult to be realized for electrons in solids. Through the superfluid response, transport, thermoelectric response [1], and quantum oscillations [2], we demonstrate that the Fermi energy of the bulk superconductor FeSe is extremely small, with the ratio of the gap to Fermi energy is of the order of unity, which qualifies FeSe to be deep inside the BCS-BEC crossover regime. Thus FeSe appears to be a key material to solve the longstanding issue in the crossover physics; the presence of preformed Cooper pairs giving rise to a pseudogap above the superconducting transition temperature  $T_c$ . We report experimental signatures of preformed Cooper pairing well above  $T_c = 8.5$  K in clean single crystals of FeSe. Our torque magnetometry reveals distinct diamagnetic signal below  $T^* \sim 20$  K indicating that the superconducting fluctuations above the transition temperature are strongly enhanced from the standard Gaussian theory. The transport and thermoelectric coefficients also exhibit distinct anomalies at  $\sim T^*$ , signaling a possible pseudogap formation. The multiband nature with the electron-hole compensation in FeSe may highlight a fundamentally new aspect of the BCS-BEC crossover physics. [1] S. Kasahara *et al.*, PNAS 111, 16309 (2014). [2] T. Terashima *et al.*, Phys. Rev. B 90, 144517 (2014); M. D. Watson *et al.*, Phys. Rev. Lett. 115, 027006 (2015).

**3:06PM P11.00002 Enhanced superconductivity in heavily electron doped surface layer of FeSe bulk crystal**, J.J. SEO, B.Y. KIM, Physics department, Yonsei University, B.S. KIM, Department of Physics and Astronomy, Seoul National University, J.K. JEONG, Physics department, Yonsei University, J.M. OK, J.S. KIM, Department of Physics, Pohang University of Science and Technology, J.D. DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, C. KIM, Department of Physics and Astronomy, Seoul National University, Y.K. KIM, Advanced Light Source, Lawrence Berkeley National Laboratory — The recording setting superconducting transition temperature of as high as 100 K discovered in 1 monolayer FeSe grown on SrTiO<sub>3</sub> immediately brought attention to the mechanism for the dramatically enhanced  $T_c$  from its original value of 7 K. At present, the two most popular views for the enhanced  $T_c$  are interfacial effect and excess electron with enhanced correlation strength. The issue is controversial and there are evidences supporting each view. Here, we report the observation of 20 K superconductivity in the electron doped surface layer mimics all the key spectroscopic aspects of the electronic structure of 1ML FeSe on STO but with a smaller superconducting gap opening of 4 meV. Our results clearly show that excess electron doping with enhanced correlation strength alone cannot induce the maximum  $T_c$ , which strongly suggests a need for additional interfacial effect.

**3:18PM P11.00003 Low temperature scanning tunneling microscopy and spectroscopy investigation of FeSe<sub>1- $\delta$</sub>  and FeSe<sub>1-x</sub>S<sub>x</sub> single crystals<sup>1</sup>**, S. A. MOORE, Department of Physics, Temple University, Philadelphia, PA 19122, J. CURTIS, Department of Physics, Temple University, Philadelphia, PA 19122 ; Department of Physics, Drexel University, Philadelphia, PA 19104, M. ABDEL-HAFIEZ, Center for High Pressure Science and Technology Advanced Research, Shanghai, 201203, China, O. S. VOLKOVA, A. N. VASILIEV, Low Temperature Physics and Superconductivity Department, Physics Faculty, M.V. Lomonosov Moscow State University, Moscow 119991, Russia, D. A. CHAREEV, Institute of Experimental Mineralogy, Russian Academy of Sciences, 142432 Chernogolovka, Moscow District, Russia, G. KARAPETROV, Department of Physics, Drexel University, Philadelphia, PA 19104, M. IAVARONE, Department of Physics, Temple University, Philadelphia, PA 19122 — Due to its relatively simple crystallographic structure, investigations into FeSe<sub>1- $\delta$</sub>  have held the promise to provide an avenue towards a better understanding of the mechanism of superconductivity in the iron-pnictides/chalcogenides and the relationship between nematicity and superconducting state. Here, we present low-temperature scanning tunneling microscopy and spectroscopy investigations of high purity FeSe<sub>1- $\delta$</sub>  and sulfur substituted FeSe<sub>1-x</sub>S<sub>x</sub> single crystals. Vortex core anisotropy and vortex matter in these systems will be discussed.

**3:30PM P11.00004 Thermal conductivity of the iron-based superconductor FeSe : Nodeless gap with strong two-band character**, PATRICK BOURGEOIS-HOPE, SVEN BADOUX, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, University of Sherbrooke, Sherbrooke, Canada, SHUN CHI, RUIXING LIANG, WALTER HARDY, DOUG BONN, University of British Columbia, Vancouver, Canada — The thermal conductivity  $\kappa$  of the iron-based superconductor FeSe was measured at temperatures down to 50 mK in magnetic fields up to 17 T. In zero magnetic field, the residual linear term in the  $T = 0$  limit,  $\kappa_0/T$ , is vanishingly small. Application of a magnetic field  $H$  causes no increase in  $\kappa_0/T$  initially. Those two facts show that there are no zero-energy quasiparticles that carry heat and therefore no nodes in the superconducting gap of FeSe. The full field dependence of  $\kappa_0/T$  has the classic shape of a two-band superconductor, such as MgB<sub>2</sub>. It rises initially with a characteristic field  $H^* \simeq H_{c2}/25$ , and then more slowly up to  $H_{c2} = 14$  T. We interpret this in terms of a small gap  $\Delta_A \simeq \Delta_0/5$  on some part of the Fermi surface, with a large gap  $\Delta_B = \Delta_0$  in the region that controls  $H_{c2}$ .

**3:42PM P11.00005 Pressure-dependent upper critical field of FeSe superconductor<sup>1</sup>**, UDHARA KALUARACHCHI, Iowa State University/ Ames LabLaboratory, VALENTIN TAUFOR, Iowa State University/ Ames Laboratory, ANNA BÖHMER, Ames Laboratory, MAKARIY TANATAR, SERGEY BUD'KO, Iowa State University/ Ames Laboratory, VLADIMIR KOGAN, Ames Laboratory, RUSLAN PROZOROV, PAUL CANFIELD, Iowa State University/ Ames Laboratory — In FeSe, the superconducting transition temperature  $T_c$  ( $\approx 9$  K at ambient pressure) has a complicated pressure dependence with a local maximum near  $p_1 \approx 0.8$  GPa and a local minimum at  $p_2 \approx 1.2$  GPa. In this work, we study the upper critical field,  $H_{c2,c}(T)$ , of FeSe using c-axis resistivity measurements under hydrostatic pressure up to 1.56 GPa with the magnetic field  $H \parallel c$ . Application of both current and magnetic field along the same axis reduces the flux flow motion and give sharper transition in applied fields. We observe a non-monotonic evolution of the slope of  $H_{c2,c}(T)|_{T_c}$  with pressure, with changes around  $p_1$  and  $p_2$ . We employ two-band orbital  $H_{c2,c}$  calculation to show that the data can be explained using the Fermi velocities extracted from the recent quantum oscillations study [1] over the whole pressure range. **3:54PM P11.00006 Microwave Conductivity Spectroscopy for Fe(Se,Te) Thin Films<sup>1</sup>**, FUYUKI NABESHIMA, KOSUKE NAGASAWA, DAISUKE ASAMI, YUICHI SAWADA, YOSHINORI IMAI, ATSUTAKA MAEDA, University of Tokyo — Iron chalcogenide superconductors Fe(Se,Te) have very small  $\epsilon_F$  and are considered to be in the BCS-BEC crossover regime[1]. Since Ginzburg number,  $G_i = (k_B T_c / \epsilon_F)^4$ , which is the relative temperature width of the superconducting fluctuation region, is large for materials in the BCS-BEC crossover regime, large superconducting fluctuations are expected in Fe(Se,Te). In order to investigate superconducting fluctuations in these materials we have performed microwave conductivity spectroscopy on Fe(Se,Te) thin films. Superfluid density of an Fe(Se,Te) film with  $T_c^{zero}=17$  K[2] took finite values above 25 K. This temperature is much higher than  $T_c$  estimated by the dc measurement, suggesting strong superconducting fluctuations in Fe(Se,Te). A dynamic scaling analysis of complex fluctuation conductivity revealed that the superconducting fluctuations of Fe(Se,Te) exhibit a 2-dimensional behavior, while BKT transition was not observed. We will also report on the thickness dependence and the Te content dependence of the superconducting fluctuation. [1] Y. Lubashevsky *et al.*, Nat. Phys. **8** (2012) 309. [2] Y. Imai *et al.*, PNAS **112** (2015) 1937.

**4:06PM P11.00007 Superconductivity and spin excitations in orbitally ordered FeSe<sup>1</sup>**, ANDREAS KREISEL, Niels Bohr Institute, Denmark, SHANTANU MUKHERJEE, Niels Bohr Institute, Denmark; State University of New York at Binghamton, USA, P. J. HIRSCHFELD, University of Florida, USA, B.M. ANDERSEN, Niels Bohr Institute, Denmark — We provide a band-structure with low-energy properties consistent with recent photoemission and quantum oscillations measurements on the Fe-based superconductor FeSe[1], including a mean-field like orbital ordering in the  $d_{xz}/d_{yz}$  channel, and show that this model also accounts for the temperature dependence of the measured Knight shift and the spin-relaxation rate[2]. An RPA calculation of the dynamical spin susceptibility yields spin excitations which are peaked at wave vector  $(\pi, 0)$  in the 1-Fe Brillouin zone, with a broad maximum at energies of order a few meV. Furthermore, the superconducting gap structure obtained from spin fluctuation theory exhibits nodes on the electron pockets, consistent with the 'V'-shaped density of states measured by tunneling spectroscopy on this material. The redistribution of spectral weight in the superconducting state creates a  $(\pi, 0)$  "neutron resonance" as seen in recent experiments[3]. Comparing to various experimental results, we give predictions for further studies. [1] S. Mukherjee, *et al.*, PRL **115**, 026402 (2015); A. Kresse, *et al.*, arXiv:1506.03593 [2] S.-H. **4:18PM P11.00008 Intercallation of  $\text{Li}_{1-x}\text{Fe}_x\text{O}_2$  in the superconducting FeSe**, DESPINA LOUCA, JUNJIE YANG, University of Virginia — The intercalation of  $\text{LiFeO}_2$  in the tetragonal lattice of the 8 K superconductor  $\text{Fe}_{1-y}\text{Se}$  leads to a great enhancement of the superconducting transition temperature,  $T_C \sim 43$  K, and to an antiferromagnetic transition at 8.5 K. While the  $\text{LiFeO}_2$  layer acts as a charge reservoir, its  $\text{Fe}^{3+}$  ion ( $3d^5$ ) is magnetic creating a magnetic buffer layer. Most recently, we developed a new synthesis method to control the Fe concentration in the intercalating layer as well as the filling ratio of the  $\text{Li}_{1-x}\text{Fe}_x\text{O}_2 : \text{FeSe}$  layers. Neutron scattering measurements were carried out on powder samples of  $(\text{Li}_{1-x}\text{Fe}_x\text{O}_2)_y\text{FeSe}$ . With the intercalation, no crystal structural transition from the  $P4/nmm$  symmetry occurs but the  $c$ -axis lattice constant expands substantially, evidence of the intercalation. At the same time, the tetrahedral FeSe layers remain intact with no compression or expansion and free of vacancies. Moreover, the intercalation along the  $c$ -axis although not uniform leads to a reduction in  $T_C$  when the ratio of  $\text{Li}_{1-x}\text{Fe}_x\text{O}_2 : \text{FeSe}$  layers is about 1 to 3. Our results also indicate that the amount of Fe in the  $\text{Li}_{1-x}\text{Fe}_x\text{O}_2$  layer has a direct correlation to the transition temperature as well.

**4:30PM P11.00009 The Dual Role of Fe Dopants in Enhancing Stability and Charge Transfer in  $(\text{Li}_{0.8}\text{Fe}_{0.2})\text{OHFeSe}$  Superconductors**, WEI CHEN, Harvard University; University of Science and Technology of China, CHANGGAN ZENG, University of Science and Technology of China, EFTHIMIOS KAXIRAS, Harvard University, ZHENYU ZHANG, University of Science and Technology of China — The recently discovered  $(\text{Li}_{0.8}\text{Fe}_{0.2})\text{OHFeSe}$  superconductor provides a new platform for exploiting the microscopic mechanisms of high- $T_C$  superconductivity in FeSe-derived systems. Using density functional theory calculations, we first show that substitution of Li by Fe not only significantly strengthens the attraction between the  $(\text{Li}_{0.8}\text{Fe}_{0.2})\text{OH}$  spacing layers and the FeSe superconducting layers along the  $c$  axis, but also minimizes the lattice mismatch between the two in the  $ab$  plane, both favorable for stabilizing the overall structure. Next we explore the electron injection into FeSe from the spacing layers, and unambiguously identify the  $\text{Fe}_{0.2}$  components to be the origin of the dramatically enhanced interlayer charge transfer. We further reveal that the system strongly favors collinear antiferromagnetic ordering in the FeSe layers, but the spacing layers can be either antiferromagnetic or ferromagnetic depending on the  $\text{Fe}_{0.2}$  spatial distribution. Based on these insights, we predict  $(\text{Li}_{0.8}\text{Co}_{0.2})\text{OHFeSe}$  to be structurally stable with even larger electron injection and potentially higher  $T_C$ .

**4:42PM P11.00010 Superconductivity in binary FeS single crystals**, DANIEL CAMPBELL, CHRIS ECKBERG, SHANTA SAHA, CHRIS BORG, XIUQUAN ZHOU, EFRAIN RODRIGUEZ, JOHNPierre PAGLIONE, Univ of Maryland-College Park — FeS is the third recently discovered member of the superconducting binary iron-chalcogenide series that includes the well-known FeSe and  $\text{FeSe}_{1-x}\text{Te}_x$  members. Grown via hydrothermal techniques, single crystals of FeS have been characterized using transport, thermodynamic and magnetic techniques. We will review experimental results and compare with the unconventional superconducting properties of the selenide and telluride counterparts.

**4:54PM P11.00011 High-pressure NMR Study of Magnetism and Superconductivity on FeSe Single Crystals**, WEIQIANG YU, PENGSHUAI WANG, WENHUA SONG, SHANSHAN SUN, YI CUI, TIANRUN LI, PING ZHOU, HECHANG LEI, Department of Physics, Renmin University of China, Beijing 100872, China — Bulk FeSe has a structure transition at  $T \sim 91$  K and a superconducting transition at  $T \sim 9.3$  K, but no magnetic ordering at the ambient pressure. With increasing pressure, the structure transition is suppressed, whereas a magnetic ordering emerges. This is in contrast to most iron arsenides, where the structure transition is usually accompanied by a stripe magnetic ordering. Here we report our high-pressure NMR study on high-quality FeSe single crystals. The spin fluctuations and the magnetic ordering observed by our measurements give fresh information for understanding the interplay among the structure transition, the superconductivity and the magnetism in bulk FeSe materials.

**5:06PM P11.00012 Cs vacancy ordering and properties of phase separated  $\text{Cs}_x\text{Fe}_{2-y}\text{Se}_2$ <sup>1</sup>**, OMAR CHMAISSEM, K.M. TADDEI, Physics - Northern Illinois University and Materials Science Division - Argonne National Lab, IL, S. ROSENKRANZ, R. OSBORN, H. CLAUS, M. STURZA, D.Y. CHUNG, Materials Science Division - ANL, M.G. KANATZIDIS, Chemistry, Northwestern University, IL, H.B. CAO, Quantum Condensed Matter Division, ORNL, TN — Iron-based selenides are among the most complex and least understood superconductors. At high temperature, a '122'-type structure with random iron vacancies undergoes a complex iron vacancy ordering scheme below  $\sim 500\text{K}$  causing the material to phase separate into  $\text{A}_2\text{Fe}_4\text{Se}_5$ , known as the 245 phase, and a minority A-site deficient and fully iron stoichiometric  $\text{A}_x\text{Fe}_2\text{Se}_2$  phase (122). At slightly lower temperatures, the material undergoes another transition with the Fe spins of the main '245' phase ordering into an exotic checkerboard-type magnetic structure with a large magnetic moment. The minority 122 phase is reported to either remain nonmagnetic or to become magnetic below  $\sim 200\text{K}$ . At temperatures below  $\sim 30\text{K}$ , the magnetic material becomes superconducting and the two states appear to coexist. I will present and discuss our recent synthesis and characterization of high quality  $\text{Cs}_x\text{Fe}_{2-y}\text{Se}_2$  single crystals and bulk samples with various Tc's that form a relatively large superconducting dome. I will discuss our findings of a previously unseen three dimensional cesium vacancy ordering in the low temperature 122 phase in addition to hosting superconductivity.

**5:18PM P11.00013 Effects of inversion symmetry breaking in monolayer FeSe**, JOSEPH O'HALLORAN, MINGXING CHEN, DANIEL AGTERBERG, MICHAEL WEINERT, Univ of Wisconsin, Milwaukee — In this talk, we will discuss the role of broken inversion symmetry due to a substrate on the electronic and magnetic correlated states of monolayer iron selenide (FeSe). We use the group theoretic method of invariants with first principles density functional theory (DFT) calculations to investigate differences between bulk and single layer superconducting and magnetic orders. We show that a spin vortex crystal phase is stabilized, and that two-gap superconductivity is stabilized (though the gaps may be of similar magnitude).

Session P12 DPOLY DCOMP FIAP: Bridging Time and Length Scales in Polymers and Soft Materials: Computational Pathways to Accelerate the Lab to Fab Transition - Industry Day 308 - Mark Stevens, Sandia National Laboratories

**2:30PM P12.00001 Spanning From Atoms to Micrometers in Simulations of Contact, Adhesion and Friction<sup>1</sup>**, MARK ROBBINS, Johns Hopkins University — Improved understanding of the forces between realistic solid surfaces is needed to optimize adhesion and friction. Modeling these forces is challenging because they arise from interactions between atoms separated by less than a nanometer, but the number and spatial distribution of these contacting atoms depends on surface roughness and deformation on micrometer and larger scales. There are also strong scale effects in the role of elastic deformations along the surface. The talk will first describe a seamless Greens function (GF) method that allows a full treatment of elastic deformations and atomic contact for micrometer scale surfaces and multibody potentials. Next applications of the method to calculations of the contact area, contact stiffness, adhesion and friction for a range of geometries and interactions will be described. The results can be captured with simple analytic expressions and explain why most contacting surfaces do not adhere. Theoretical and experimental studies of single nanometer-scale asperities show that the frictional shear stress depends strongly on whether surfaces are commensurate. A large constant stress is obtained for identical, aligned crystalline surfaces, but the stress averages to zero in the more common case of incommensurate surfaces. The resulting ultralow friction is called superlubricity and is found in experiments and simulations of small contacts. Our simulations reveal dramatic changes in this behavior because different parts of the surface are able to advance independently as the contact radius increases towards micrometer scales. The friction between identical surfaces drops with increasing radius and then saturates at a low value. The force between incommensurate surfaces saturates at a similar value that can be related to the Peierls stress for dislocation motion at the interface. Studies of multiasperity contacts also show that incoherent motion along the interface can lead to pronounced changes in the macroscopic friction.

**3:06PM P12.00002 Accelerating materials discovery through the development of polymer databases**, DEBRA AUDUS, Materials Science and Engineering Division, National Institute of Standards and Technology — Efficient materials discovery can be greatly aided by access to databases that tabulate material property measurements and that allow for the exploration of material-property relationships. Such databases are less prevalent for polymers than other materials such as metals, in part due to the variety of structures associated with a single polymer identifier. For example, polyethylene could be branched or linear; it could also have a narrow or broad molecular weight distribution. I will discuss initial efforts towards generating a polymer property database in collaboration with Prof. Juan de Pablo and colleagues at the University of Chicago. Specifically, we focused on tabulating the Flory-Huggins chi parameter, describing the miscibility of polymer blends, using a course-based approach coupled with specialty software. In the context of a class setting, the undergraduate students learned about the field of polymer physics and used the software to identify chi parameters and related quantities, such as the method of measurement, from previously identified articles from literature. Both successes and challenges of this approach are measured through metrics of the resulting database and feedback from the students.

**3:42PM P12.00003 Complex Suspension Rheology Using High Performance Computing**, DAVID HEINE, Corning, Incorporated — In processing advanced ceramic materials, the properties of the final product depend on the process conditions and the interactions between the materials at the scale of the individual particles. Along with general bulk properties, more subtle properties including particle orientation, segregation, and pore structure must be established during processing to achieve the desired functionality. Accomplishing this requires a thorough understanding of the mesoscale interactions and how they influence the macroscale behavior. We conduct a series of large scale simulations of highly filled polymer-nanoparticle composites as analogs of ceramic pastes and reveal how the ceramic particle and binder properties determine the structure and rheology of the bulk material. As with real ceramic pastes, particle shape and size distribution along with composition determine the shear modulus, extent of segregation, and degree of particle alignment. These factors are influenced by the binder through the rheology of the binder phase and the interaction between binder and particles. This talk presents the results of this study of polymer-nanoparticle composites along with a brief overview of research and development at Corning showing the similarities and differences between research in industry and academia.

#### **4:18PM P12.00004 Conduction and Narrow Escape in Dense, Disordered, Particulate-based Heterogeneous Materials**

JEREMY LECHMAN, Sandia National Laboratories — For optimal and reliable performance, many technological devices rely on complex, disordered heterogeneous or composite materials and their associated manufacturing processes. Examples include many powder and particulate-based materials found in phytotechnic devices for car airbags, electrodes in energy storage devices, and various advanced composite materials. Due to their technological importance and complex structure, these materials have been the subject of much research in a number of fields. Moreover, the advent of new manufacturing techniques based on powder bed and particulate process routes, the potential of functional nano-structured materials, and the additional recognition of persistent shortcomings in predicting reliable performance of high consequence applications; leading to ballooning costs of fielding and maintaining advanced technologies, should motivate renewed efforts in understanding, predicting and controlling these materials' fabrication and behavior. Our particular effort seeks to understand the link between the top-down control presented in specific non-equilibrium processes routes (i.e., manufacturing processes) and the variability and uncertainty of the end product performance. Our ultimate aim is to quantify the variability inherent in these constrained dynamical or random processes and to use it to optimize and predict resulting material properties/performance and to inform component design with precise margins. In fact, this raises a set of deep and broad-ranging issues that have been recognized and as touching the core of a major research challenge at Sandia National Laboratories. In this talk, we will give an overview of recent efforts to address aspects of this vision. In particular the case of conductive properties of packed particulate materials will be highlighted. Combining a number of existing approaches we will discuss new insights and potential directions for further development toward the stated goal. Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

#### **4:54PM P12.00005 Coarse-graining to the meso and continuum scales with molecular-dynamics-like models**

STEVE PLIMPTON, Sandia National Laboratories — Many engineering-scale problems that industry or the national labs try to address with particle-based simulations occur at length and time scales well beyond the most optimistic hopes of traditional coarse-graining methods for molecular dynamics (MD), which typically start at the atomic scale and build upward. However classical MD can be viewed as an engine for simulating particles at literally any length or time scale, depending on the models used for individual particles and their interactions. To illustrate I'll highlight several coarse-grained (CG) materials models, some of which are likely familiar to molecular-scale modelers, but others probably not. These include models for water droplet freezing on surfaces, dissipative particle dynamics (DPD) models of explosives where particles have internal state, CG models of nano or colloidal particles in solution, models for aspherical particles, Peridynamics models for fracture, and models of granular materials at the scale of industrial processing. All of these can be implemented as MD-style models for either soft or hard materials; in fact they are all part of our LAMMPS MD package, added either by our group or contributed by collaborators. Unlike most all-atom MD simulations, CG simulations at these scales often involve highly non-uniform particle densities. So I'll also discuss a load-balancing method we've implemented for these kinds of models, which can improve parallel efficiencies. From the physics point-of-view, these models may be viewed as non-traditional or ad hoc. But because they are MD-style simulations, there's an opportunity for physicists to add statistical mechanics rigor to individual models. Or, in keeping with a theme of this session, to devise methods that more accurately bridge models from one scale to the next.

#### **2:30PM P13.00001 IUPAP Award: Ion transport in 2D materials**

WENZHONG BAO, Fudan University — Intercalation in 2D materials drastically influences both physical and chemical properties, which leads to a new degree of freedom for fundamental studies and expands the potential applications of 2D materials. In this talk, I will discuss our work in the past two years related to ion intercalation of 2D materials, including insertion of Li and Na ions in graphene and MoS<sub>2</sub>. We focused on both fundamental mechanism and potential application, e.g. we measured in-situ optical transmittance spectra and electrical transport properties of few-layer graphene (FLG) nanostructures upon electrochemical lithiation/delithiation. By observing a simultaneous increase of both optical transmittance and DC conductivity, strikingly different from other materials, we proposed its application as a next generation transparent electrode.

#### **3:06PM P13.00002 Tuning frictions between graphene layers via Li ion intercalation<sup>1</sup>**

AIJIANG LU, Donghua University, JIAYU WAN, TENG LI, LIANGBING HU, Univ of Maryland-College Park, UNIVERSITY OF MARYLAND, COLLEGE PARK TEAM — Graphite intercalated with Li ions are widely studied and applied in Li ion batteries. It was revealed in experiments that, the Li ion intercalation leads to a phase transition of the graphite with about 10% volume expansion. The increased interlayer distance should contribute to decrease the frictions between the graphene layers, but the Li ion intercalation would take an opposite effect. In order to show the total effect of the Li ion intercalation, we studied the frictions between graphene layers with and without lithiation, based on density functional theory (DFT). In a sandwich-like model, slipping of the middle sheet of the graphene was simulated. Displacements between layers were fixed and the other parts were relaxed, thus the energies were recorded to estimate the energy barriers accordingly. We found that the frictions between the graphene layers with the Li ion intercalation are higher than those without intercalation. The energy barrier appears correlated with the concentration of the intercalated ions. As the atomic ratio between lithium and carbon increases from 0 (no intercalation) to 1:6, the energy barriers increase from 0.01 eV/atom to 0.05 eV/atom or so. Such an interesting result indicates that, just via ion intercalation, we can effectively tune the friction between graphene layers.

<sup>1</sup>Tuning frictions between graphene layers via Li ion intercalation

#### **3:18PM P13.00003 Lithium Intercalation of Single-Layer Graphene / Boron Nitride Heterostructures**

SHU YANG FRANK ZHAO, Harvard University, GISELLE A. ELBAZ, Columbia University, CYNDIA YU, D. KWABENA BEDIAKO, Harvard University, YINSHENG GUO, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, LOUIS BRUS, XAVIER ROY, Columbia University, PHILIP KIM, Harvard University — Graphene intercalate compounds form a new generation of graphene derivative systems where novel physical phenomena such as superconductivity and magnetism may emerge. Experimental realization of intercalated few-layer graphenes have been limited by harsh intercalation processes, often incompatible with mesoscopic device fabrication techniques. Using electrochemical methods, we demonstrate lithium intercalation of single and few-layer graphene encapsulated in hexagonal boron nitride (BN), where the BN simultaneously serves as a scaffold for the lithium atoms as well as protects the graphene from parasitic chemical reactions in the electrolyte. In addition, we developed techniques to monitor intercalation electronically. By performing in-situ Raman spectroscopy, we confirmed that the intercalated single layer graphene/BN heterostructure reached a Fermi energy in excess of 1.16eV, and corresponding Hall measurements showed a density in excess of  $7 \times 10^{13} \text{cm}^{-2}$ .

#### **3:30PM P13.00004 Slipping and friction at the interface between two-dimensional materials**

VIJAYASHREE PARSII SREENIVAS, RYAN NICHOLL, Vanderbilt University, KIRILL BOLOTIN, Vanderbilt University, Freie Universitt — Friction at the macroscopic scale is primarily due to the surface roughness while at the atomic scale it is governed by commensurability and environmental conditions. Here, we investigate slipping and friction at the interface between two dissimilar two-dimensional materials, such as graphene and monolayer molybdenum disulfide. Such a system provides a powerful platform to study frictional forces at the atomic scale as chemical nature of the interface and commensurability between the layers can be varied with ease. To carry out such a study, a monolayer of e.g. graphene is exfoliated onto a flexible substrate material – polypropylene – and clamped down by evaporating titanium to avoid slippage. A monolayer of e.g. MoS<sub>2</sub> is then transferred on top of graphene and the entire stack is strained using a four point bending apparatus. By measuring strain vs. bending via Raman spectroscopy, we detect slippage at graphene/MoS<sub>2</sub> interface and characterize frictional forces as a function of interface parameters.

### 3:42PM P13.00005 ABSTRACT WITHDRAWN —

**3:54PM P13.00006 Bilayer Graphene Electromechanical Systems**, ALEXANDRE CHAMPAGNE, Concordia University and Universit de Sherbrooke, MATTHEW STORMS, SERAP YIGEN, Concordia University, BERTRAND REULET, Universit de Sherbrooke — Bilayer graphene is an outstanding electromechanical system, and its electronic and mechanical properties, as well as their coupling, are widely tunable. To the best of our knowledge, simultaneous charge transport and mechanical spectroscopy (via RF mixing) has not been realized in bilayer graphene. We present data showing clear electromechanical resonances in three suspended bilayer devices whose length range from 1 to 2 microns. We first describe the low-temperature current annealing of the devices which is crucial to achieve the transconductance,  $I - V_G$ , necessary to implement a RF mixing detection method. We describe our RF mixing circuit and data. We measure clear mechanical resonances ranging in frequency from 50 to 140 MHz. We show that we can smoothly tune the resonance frequencies of our bilayer resonators with mechanical strain applied via a backgate voltage. We measure quality factors up to 4000. We briefly discuss the effects of the RF driving power on the dispersion of the mechanical resonance. We aim to use these high quality mechanical resonance as a mechanical sensor of the bilayer quantum Hall phase transitions. We show initial data of a bilayer mechanical resonance as a function of magnetic field and quantum Hall phase transitions.

**4:06PM P13.00007 Electro-vibronic Coupling Effects on "Intrinsic Friction" in Transition Metal Dichalcogenides<sup>1</sup>**, ANTONIO CAMMARATA, Czech Technical University in Prague, TOMAS POLCAR, Czech Technical University in Prague and University of Southampton — One of the main difficulties in understanding and predicting frictional response is the intrinsic complexity of highly non-equilibrium processes in any tribological contact, which include breaking and formation of multiple interatomic bonds between surfaces in relative motion. To understand the physical nature of the microscopic mechanism of friction and design new tribologic materials, we conducted a systematic quantum mechanic investigation at the atomic scale on prototypical Van der Waals MX<sub>2</sub> (M=Mo, W; X=S, Se, Te) Transition Metal Dichalcogenides under variable load. We combined the structural and dynamic information from group theoretical analysis and phonon band structure calculations with the characterisation of the electronic features using non-standard methods like orbital polarization and the recently formulated bond covalency and cophonicity analyses. We formulated guidelines on how to engineer macroscopic friction at nanoscale, and finally applied them to design a new Ti-doped MoS<sub>2</sub> phase. The formulated protocol can be promptly used for the design of new materials with diverse applications beyond tribology.

**4:18PM P13.00008 The positive piezoconductive effect in graphene**, KANG XU, Nanjing University, KE WANG, University of Science and Technology of China, WEI ZHAO, ERFU LIU, Nanjing University, WENZHONG BAO, MICHAEL S. FUHRER, University of Maryland, YAFEI REN, ZHENHUA QIAO, University of Science and Technology of China, BAIGENG WANG, DINGYU XING, FENG MIAO, Nanjing University — As the thinnest conductive and elastic material, graphene is expected to play a crucial role in post-Moore era. Besides applications on electronic devices, graphene has shown great potential for nano-electromechanical systems. While interlayer interactions play a key role in modifying the electronic structures of layered materials, no attention has been given to their impact on electromechanical properties. Here we report the positive piezoconductive effect observed in suspended bi- and multi-layer graphene. The effect is highly layer number dependent and shows the most pronounced response for tri-layer graphene. The effect, and its dependence on the layer number, can be understood as resulting from the strain-induced competition between interlayer coupling and intralayer transport, as confirmed by the numerical calculations based on the non-equilibrium Green's function method. Our results enrich the understanding of graphene and point to layer number as a powerful tool for tuning the electromechanical properties of graphene for future applications.

### 4:30PM P13.00009 ABSTRACT WITHDRAWN —

**4:42PM P13.00010 Mechanical Properties and Failure Mechanisms in Polycrystalline Graphene**, JOSEPH GONZALEZ, University of South Florida, ROMAIN PERRIOT, Los Alamos National Laboratory, IVAN OLEYNIK, University of South Florida — Large-scale growth of graphene using chemical vapor deposition produces polycrystalline material containing grain boundaries. Recent experiments demonstrate that polycrystalline graphene is nearly as strong as pristine. In this work, the mechanical properties of bi-crystal and polycrystalline graphene samples are investigated by simulating nano-indentation of a circular membrane using classical molecular dynamics and a novel Screened Environment Dependent Reactive Bond Order (SED-REBO) potential. The failure mechanisms and crack propagation in graphene samples containing grain boundaries are also discussed.

**4:54PM P13.00011 Highly Stretchable MoS<sub>2</sub> and Phosphorene Kirigami**, DAVID CAMPBELL, PAUL HANAKATA, HAROLD PARK, Boston University — Several recent works have shown how nanomesh and kirigami patterning can be used to increase the ductility of monolayer graphene and thin film electrodes, suggesting that this approach should be useful for other 2D materials. We have studied the effects of kirigami patterning on the mechanical properties of MoS<sub>2</sub> and phosphorene "monolayers," using classical molecular dynamics simulations. We have explored several different kirigami structures, focusing on two simple non-dimensional parameters found to be relevant in our previous study of graphene [1]. These parameters are related to the density of cuts and to the ratio of the overlapping cut length to the nanoribbon length. We found that these membranes, despite not having the single atomic layer planar structure of graphene, show a significantly enhanced ductility that can be understood in terms of the two geometric parameters. For instance, fracture strains of MoS<sub>2</sub> kirigami can be enhanced by a factor of six relative to pristine MoS<sub>2</sub> nanoribbons. Our findings suggest that the kirigami cuts are the key to changing the morphology of 2D membranes to allow out of plane deflection and to prevent early failure. [1] Zenan Qi, David K. Campbell, and Harold S. Park, Phys. Rev. B 90, 245437 (2014).

**5:06PM P13.00012 Modulated Nanoindentation (MoNI) – a novel characterization tool of two-dimensional materials and nanotubes<sup>1</sup>**, YANG GAO, CUNY Advanced Science Research Center, SUENNE KIM, Hanyang University, SI ZHOU, Georgia Institute of Technology, HSIANG-CHIH CHIU, National Taiwan Normal University, DANIEL NELIAS, Universit de Lyon, CNRS, INSA-Lyon, LaMCoS, CLAIRE BERGER, Institut Nel, Universit Grenoble Alpes-CNRS, WALT DE HEER, Georgia Institute of Technology, LAURA POLLONI, ROMAN SORDAN, L-NESS, Politecnico di Milano, CHRISTIAN KLINKE, University of Hamburg, ANGELO BONGIORNO, College of Staten Island, CUNY, ELISA RIEDO, CUNY Advanced Science Research Center — We report on a novel Atomic Force Microscopy (AFM) based technique with sub-angstrom vertical resolution – Modulated Nanoindentation (MoNI). MoNI has been applied to measure the radial elasticity of multi-walled nanotubes. Recently the interlayer coupling of two-dimensional materials (such as graphene and MoS<sub>2</sub>) characterized by strong in-plane bonds and weak interlayer interactions has been studied by MoNI combined with semi-analytical methods (SAM) and DFT calculations. The out-of-plane stiffness of varied 2D materials and its dependence on number of layers and intercalated water has been investigated in different environmental conditions. This non-destructive technique provides a new path to study the interlayer elastic coupling and the Van der Waals forces in few-layer-thick 2D materials, offering the possibility to understand how interlayer coupling is related to the electronic, phononic, and thermal properties of 2D materials.

**5:18PM P13.00013 Coherent Generation of Photo-Thermo-Acoustic Wave from Graphene Sheets<sup>1</sup>**, YICHAO TIAN, Institute of Physics, CAS, HE TIAN, Tsinghua University, YANLING WU, LEILEI ZHU, Institute of Physics, CAS, LUQI TAO, Tsinghua University, WEI ZHANG, Institute of Physics, CAS, YI SHU, DAN XIE, YI YANG, Tsinghua University, ZHIYI WEI, XINGHUA LU, Institute of Physics, CAS, TIAN-LING REN, Tsinghua University, CHIH-KANG SHIH, Department of Physics, Texas University at Austin, JIMIN ZHAO, Institute of Physics, CAS — Many remarkable properties of graphene are derived from its large energy window for Dirac-like electronic states and have been explored for applications in electronics and photonics. In addition, strong electron-phonon interaction in graphene has led to efficient photo-thermo energy conversions, which has been harnessed for energy applications. By combining the wavelength independent absorption property and the efficient photo-thermo energy conversion, here we report a new type of applications in sound wave generation underlined by a photo-thermo-acoustic energy conversion mechanism. Most significantly, by utilizing ultrafast optical pulses, we demonstrate the ability to control the phase of sound waves generated by the photo-thermal-acoustic process. Our finding paves the way for new types of applications for graphene, such as remote non-contact speakers, optical-switching acoustic devices, etc.

**2:30PM P14.00001 The European Theoretical Spectroscopy Facility: an illustration for the power of collective research**, LUCIA REINING, CNRS-Ecole Polytechnique — As researchers and citizens, we should contribute to facing the grand challenges of our epoch. It is important to work on problems such as climate change or limited resources. However, maybe the biggest challenge is to find ways to unite our forces and develop models of collaborative problem solving. This is mandatory to deal with complex problems, and it can boost efficiency in any case. Code development is just one example where a constructive and well-organized collaboration can take us much further than individual attempts. On the background of this general idea, we will analyze the impact of the European Theoretical Spectroscopy Facility (ETSF, [www.etsf.eu](http://www.etsf.eu)) on the day-to-day research of its members, on the theoretical and computational tools that are produced, and on a wider field of theoretical or experimental research. We will see that much can be learnt from this attempt to consider ideas in competition, with people in collaboration.

**3:06PM P14.00002 The ABINIT software project**, GIAN-MARCO RIGNANESE, Univ Catholique de Louvain — The ABINIT software project aims at providing the total energy, charge density and electronic structure of systems made of electrons and nuclei (molecules and periodic solids) thanks to a first-principle approach. The ground state properties are calculated in the framework of the Density-Functional Theory (DFT). The excited states properties are computed within the Many-Body Perturbation Theory (MBPT). Finally, the response properties are obtained from Density-Functional Perturbation Theory (DFPT). The ABINIT software project was started in 1997 as an open software project, without a definite goal, developed using several software engineering techniques to allow international collaboration of many different groups. The first publicly available version of ABINIT was released in December 2000 under the GNU GPL. The software has already been described in various articles [1-4]. The last stable version of the package (7.10.4) has now a 70 MBytes size, consisting in nearly 1400 files written in F90 (830000 lines) and including documentation, tutorials and more than one thousand tests. The code is developed by an always opened community (around fifty people) and it is used by more than a thousand individuals worldwide.

**4:18PM P14.00004 The CECAM Electronic Structure Library: community-driven development of software libraries for electronic structure simulations**, MICAEL OLIVEIRA, Universite de Liege — The CECAM Electronic Structure Library (ESL) is a community-driven effort to segregate shared pieces of software as libraries that could be contributed and used by the community. Besides allowing to share the burden of developing and maintaining complex pieces of software, these can also become a target for re-coding by software engineers as hardware evolves, ensuring that electronic structure codes remain at the forefront of HPC trends. In a series of workshops hosted at the CECAM HQ in Lausanne, the tools and infrastructure for the project were prepared, and the first contributions were included and made available online (<http://esl.cecam.org>). In this talk I will present the different aspects and aims of the ESL and how these can be useful for the electronic structure community.

**4:54PM P14.00005 The Yambo code: a comprehensive tool to perform ab-initio simulations of equilibrium and out-of-equilibrium properties<sup>1</sup>**, ANDREA MARINI, Istituto di Struttura della Materia of the National Research Council — Density functional theory and many-body perturbation theory methods (such as GW and Bethe-Salpeter equation) are standard approaches to the equilibrium ground and excited state properties of condensed matter systems, surfaces, molecules and other several kind of materials. At the same time ultra-fast optical spectroscopy is becoming a widely used and powerful tool for the observation of the out-of-equilibrium dynamical processes. In this case the theoretical tools (such as the Baym-Kadanoff equation) are well known but, only recently, have been merged with the ab-Initio approach. And, for this reason, highly parallel and efficient codes are lacking. Nevertheless, the combination of these two areas of research represents, for the ab-initio community, a challenging perspective as it requires the development of advanced theoretical, methodological and numerical tools. Yambo is a popular community software implementing the above methods using plane-waves and pseudo-potentials. Yambo is available to the community as open-source software, and oriented to high-performance computing. The Yambo project aims at making the simulation of these equilibrium and out-of-equilibrium complex processes available to a wide community of users. Indeed the code is used, in practice, in many countries and well beyond the European borders. Yambo is a member of the suite of codes of the MAX European Center of Excellence (Materials design at the exascale). It is also used by the user facilities of the European Spectroscopy Facility and of the NFFA European Center (nanoscience foundries & fine analysis). In this talk I will discuss some recent numerical and methodological developments that have been implemented in Yambo towards to exploitation of next generation HPC supercomputers. In particular, I will present the hybrid MPI+OpenMP parallelization and the specific case of the response function calculation. I will also discuss the future plans of the Yambo project and its potential use as tool for science dissemination, also in third world countries.

**2:30PM P15.00001 Electronic Transport Properties of New 2-D Materials GeH and NaSn<sub>2</sub>As<sub>2</sub><sup>1</sup>**, BIN HE, Department of Mechanical Engineering, the Ohio State University, Columbus, Ohio USA 43210, NICHOLAS CULTRARA, MAXX ARGUILLA, JOSHUA GOLDBERGER, Department of Chemistry and Biochemistry, the Ohio State University, Columbus, OH 43210, JOSEPH HEREMANS, Department of Mechanical Engineering, the Ohio State University, Columbus, Ohio USA 43210 — 2-D materials potentially have superior thermoelectric properties compared to traditional 3-D materials due to their layered structure. Here we present electrical and thermoelectric transport properties of 2 types of 2-D materials, GeH and NaSn<sub>2</sub>As<sub>2</sub>. GeH is a graphane analog which is prepared using chemical exfoliation of CaGe<sub>2</sub> crystals. Intrinsic GeH is proven to be a highly resistive material at room temperature. Resistance and Seebeck coefficient of Ga doped GeH are measured in a cryostat with a gating voltage varying from -100V to 100V. NaSn<sub>2</sub>As<sub>2</sub> is another 2-D system, with Na atom embedded between nearly-2D Sn-As layers. Unlike GeH, NaSn<sub>2</sub>As<sub>2</sub> is a metal based of Hall measurements, with p-type behavior, and with van der Pauw resistances on the order of 5mΩ/square. Thermoelectric transport properties of NaSn<sub>2</sub>As<sub>2</sub> will be reported.

**2:42PM P15.00002 Microwave Assisted 2D Materials Exfoliation**, YANBIN WANG, Univ of Maryland — Two-dimensional materials have emerged as extremely important materials with applications ranging from energy and environmental science to electronics and biology. Here we report our discovery of a universal, ultrafast, green, solvo-thermal technology for producing excellent-quality, few-layered nanosheets in liquid phase from well-known 2D materials such as such hexagonal boron nitride (h-BN), graphite, and MoS<sub>2</sub>. We start by mixing the uniform bulk-layered material with a common organic solvent that matches its surface energy to reduce the van der Waals attractive interactions between the layers; next, the solutions are heated in a commercial microwave oven to overcome the energy barrier between bulk and few-layers states. We discovered the minutes-long rapid exfoliation process is highly temperature dependent, which requires precise thermal management to obtain high-quality inks. We hypothesize a possible mechanism of this proposed solvo-thermal process; our theory confirms the basis of this novel technique for exfoliation of high-quality, layered 2D materials by using an as yet unknown role of the solvent.

**2:54PM P15.00003 A *first principles* investigation of point defects in monolayer, few-layer, and bulk WS<sub>2</sub><sup>1</sup>**, WUN-FAN LI, CHANGMING FANG, MARJOLEIN DIJKSTRA, MARIJN A. VAN HUIS, Soft Condensed Matter, Debye Institute for Nanomaterials Science, Utrecht University, SOFT CONDENSED MATTER TEAM — We present the results of a systematic study of physics of point defects in 2D WS<sub>2</sub> materials conducted by means of density functional theory. First, we investigate the physics of point defects in monolayer (ML) WS<sub>2</sub>. Second, we examine the impact of point defects on the physical properties of multi-layer defective WS<sub>2</sub> as a function of slab thickness. The studied point defects are: monovacancies, interstitials and anti-sites, and the considered physical properties include local geometry, defect formation energy, electronic structure and magnetism. Van der Waals interaction, spin-polarization and spin-orbit coupling effects are also incorporated in the calculations to ensure accurate results. In a ML WS<sub>2</sub>, we predict that I<sub>S</sub> is the most favorable defect inside WS<sub>2</sub> having a low formation energy of 1.21 eV. W<sub>S</sub> and WS<sub>2</sub> anti-sites result in a total magnetic moment of 2 μ<sub>B</sub>. By studying ML, few-layer (up to 4 layers), and bulk WS<sub>2</sub> slabs we find that, all point defects cause only localized perturbation, thus have little influence on the thickness-dependent evolution of the physical properties. The depth-dependence of the defect formation energy is also found: V<sub>S</sub> prefers to stay on the surface, while V<sub>W</sub> prefers the slab center.

**3:06PM P15.00004 Towards the Intrinsic Limit in As-Exfoliated MoS<sub>2</sub>**, ERIN SUTTON, EDWARD GEORGE, EMILY WHAPHAM, KENNETH BURCH, Boston College, BURCH GROUP TEAM — In recent years, two-dimensional transition metal dichalcogenide (TMDC) semiconductors have been intensively studied as exciting non-zero band gap analogs to graphene. For example, molybdenum disulfide (MoS<sub>2</sub>), a TMDC, is a van der Waals material which can be thinned down to single atomic layers less than a nanometer thick via micro-mechanical cleavage. In this regime, quantum confinement effects give rise to properties not seen in the bulk crystal. The attractive properties of ultrathin MoS<sub>2</sub> have inspired myriad applications, including spin- and valley-tronics, and LED and photo-detecting devices. As the performance of these devices is optimized, a method of modulating these properties is strongly desired. Through exfoliating MoS<sub>2</sub> on various substrates in an inert glovebox environment, we have produced as-exfoliated MoS<sub>2</sub> doped at the intrinsic level. We study the changes in the MoS<sub>2</sub> via Raman and photoluminescence spectra and see shifts in excitonic behavior. The ability to create intrinsic MoS<sub>2</sub> without the need for chemical doping or gating has exciting implications for optical studies of the material in addition to device applications such as photovoltaic, photocatalytic, and LED devices.

**3:18PM P15.00005 ABSTRACT WITHDRAWN –**

**3:30PM P15.00006 Preparation and Electronic Characterization of Substrate-Scale MoS<sub>2</sub> Single-Layer Films**, JOSEPH MARTINEZ, MICHAEL GOMEZ, MIKE VALENTIN, EDWIN PRECIADO, VELVETH KLEE, ARIANA NGUYEN, ADAM BERGES, DANIEL LU, MIGUEL ISARRARAZ, LUDWIG BARTELS, University of California Riverside — Using a novel high vacuum chemical vapor deposition process we synthesize substrate scale (2x2 cm) homogeneous monolayer MoS<sub>2</sub> films. Our process involves exposure of a hot Mo filament to organic chalcogen precursors that volatilize MoS<sub>x</sub> species which then precipitate on a thermally-controlled substrate. The resultant films are photoluminescent at 1.87 eV as expected for monolayer material; their Raman modes are indistinguishable from exfoliated material. Metal contact formation to these films was investigated under UHV conditions utilizing X-Ray Photoelectron Spectroscopy. These measurements permit us to follow the formation of a Schottky Barrier with increasing metal film thickness on the Angstrom scale. We utilize core level spectroscopy to indicate the evolution of the MoS<sub>2</sub> valence band under metal deposition. Our measurements provide direct indication on the charge transfer direction at metal contacts and the ensuing band-bending in two-terminal devices.

**3:42PM P15.00007 Synthesis and electronic structure of single-layer TaS<sub>2</sub>**, CHARLOTTE SANDERS, ARLETTE SOHANFO NGANKEU, MACIEJ DENDZIK, MARCO BIANCHI, PHILIP HOFMANN, Aarhus University — Bulk TaS<sub>2</sub> is an intriguing material that exhibits charge density wave phases, Mott physics, and superconductivity; however, little work has been done on single-layer (SL) TaS<sub>2</sub>. Progress in this area demands a method for controllably fabricating high-quality, uniform samples with low defect densities. We have succeeded in epitaxially growing SL TaS<sub>2</sub>, using the Au(111) substrate. The monolayer exhibits a well-defined orientation with respect to the substrate, a strong preference toward forming triangular islands, and a moire superstructure. Furthermore, long deposition times lead to smooth layer-by-layer growth of TaS<sub>2</sub>. In this talk, I will present band structure measurements acquired by angle-resolved photoemission spectroscopy (ARPES) on TaS<sub>2</sub>/Au samples fabricated in situ at the SGM3 end station of the ASTRID2 synchrotron facility in Denmark. Scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED) elucidate the material's structural properties and interaction with the substrate.

**3:54PM P15.00008 Observation of Interlayer Phonons in Transition Metal Dichalcogenide Heterostructures**, RUI HE, ZHIPENG YE, CHAO JI, CASIE MEANS-SHIVELY, HEIDI ANDERSON, TIM KIDD, University of Northern Iowa, KUANG-CHANG CHIU, CHENG-TSE CHOU, JENN-MING WU, YI-HSIEN LEE, National Tsing Hua Univ, Taiwan, TROND ANDERSEN, MIT, CHUN HUNG LUI, UC Riverside — Interlayer phonon modes in transition metal dichalcogenide (TMD) heterostructures are observed for the first time. We measured the low-frequency Raman response of MoS<sub>2</sub>/WSe<sub>2</sub> and MoSe<sub>2</sub>/MoS<sub>2</sub> heterobilayers. We discovered a distinct Raman mode (30 - 35 cm<sup>-1</sup>) that cannot be found in any individual monolayers. By comparing with Raman spectra of Bernal bilayer (2L) MoS<sub>2</sub>, 2L MoSe<sub>2</sub> and 2L WSe<sub>2</sub>, we identified the new Raman mode as the layer breathing vibration arising from the vertical displacement of the two TMD layers. The layer breathing mode (LBM) only emerges in bilayer regions with atomically close layer-layer proximity and clean interface. In addition, the LBM frequency exhibits noticeable dependence on the rotational angle between the two TMD layers, which implies a change of interlayer separation and interlayer coupling strength with the layer stacking.

**4:06PM P15.00009 Distinct Reconstruction Patterns and Spin-Resolved Electronic States along the Zigzag Edges of Transition Metal Dichalcogenides<sup>1</sup>**, PING CUI, JIN-HO CHOI, WEI CHEN, JIANG ZENG, University of Science and Technology of China, CHENDONG ZHANG, CHIH-KANG SHIH, University of Texas at Austin, ZHENYU LI, ZHENYU ZHANG, University of Science and Technology of China — Two-dimensional transition metal dichalcogenides are a new class of materials exhibiting various intriguing physical, chemical, and mechanical properties. Integration of such materials for potential device applications will necessarily encounter creation of different boundaries. Using first-principles approaches, here we investigate the structural, electronic, and magnetic properties along two inequivalent M- or X-terminated zigzag edges of MX<sub>2</sub> (M=Mo, W; X=S, Se). Along the M-terminated edges, we discover a previously unrecognized but energetically strongly preferred (2x1) reconstruction pattern, which is universal for all the MX<sub>2</sub>, characterized by place exchanges of the outmost X and M edge atoms. In contrast, the X-terminated edges undergo a more moderate (2x1) or (3x1) reconstruction for MoX<sub>2</sub> or WX<sub>2</sub>, respectively. We further use the prototypical examples of zigzag MoX<sub>2</sub> nanoribbons to demonstrate that the M- and X-terminated edges possess distinctly different electronic and magnetic properties, which can be exploited for a broad range of spintronic and catalytic applications

**4:18PM P15.00010 Low-frequency Raman modes as fingerprints of layer stacking configurations of transition metal dichalcogenides<sup>1</sup>**, LIANGBO LIANG, ALEXANDER PURETZKY, BOBBY SUMPTER, Oak Ridge National Lab, VINCENT MEUNIER, Rensselaer Polytechnic Institute, DAVID GEOHEGAN, Oak Ridge National Lab, DAVID B. GEOHEGAN TEAM, VINCENT MEUNIER TEAM — The tunable optoelectronic properties of stacked two-dimensional (2D) crystal monolayers are determined by their stacking orientation, order, and atomic registry. Atomic-resolution Z-contrast scanning transmission electron microscopy (AR-Z-STEM) can be used to determine the exact atomic registration between different layers in few-layer 2D stacks; however, fast and relatively inexpensive optical characterization techniques are essential for rapid development of the field. Using two- and three-layer MoSe<sub>2</sub> and WSe<sub>2</sub> crystals synthesized by chemical vapor deposition, we show that the generally unexplored low-frequency (LF) Raman modes (~50 cm<sup>-1</sup>) that originate from interlayer vibrations can serve as fingerprints to characterize not only the number of layers, but also their stacking configurations [Puretzky and Liang et al, ACS Nano 2015, 9, 6333]. First-principles Raman calculations and group theory analysis corroborate the experimental assignments determined by AR-Z-STEM and show that the calculated LF mode fingerprints are related to the 2D crystal symmetries. Our combined experimental/theoretical work demonstrates the LF Raman modes potentially more effective than HF Raman modes to probe the layer stacking and interlayer interaction for 2D materials.

**4:30PM P15.00011 Excitons and exciton-phonon interactions in 2D MoS<sub>2</sub>, WS<sub>2</sub> and WSe<sub>2</sub> studied by resonance Raman spectroscopy**, MARCOS PIMENTA, ELENA DEL CORRO, BRUNO CARVALHO, LEANDRO MALARD, JULIANA ALVES, CRISTIANO FANTINI, Departamento de Física, Universidade Federal de Minas Gerais, HUMBERTO TERRONES, Rensselaer Polytechnic Institute, Department of Physics, ANA LAURA ELIAS, MAURICIO TERRONES, Department of Physics and Materials Science and Engineering, Penn-State University — The 2D materials exhibit a very strong exciton binding energy, and the exciton-phonon coupling plays an important role in their optical properties. Resonance Raman spectroscopy (RRS) is a very useful tool to provide information about excitons and their couplings with phonons. We will present in this work a RRS study of different samples of 2D transition metal dichalcogenides (MoS<sub>2</sub>, WS<sub>2</sub> and WSe<sub>2</sub>) with one, two and three layers (1L, 2L, 3L) and bulk samples, using more than 30 different laser excitation lines covering the visible range. We have observed that all Raman features are enhanced by resonances with excitonic transitions. From the laser energy dependence of the Raman excitation profile (REP) we obtained the energies of the excitonic states and their dependence with the number of atomic layers. In the case of MoS<sub>2</sub>, we observed that the electron-phonon coupling is symmetry dependent, and our results provide experimental evidence of the C exciton recently predicted theoretically. The RRS results WSe<sub>2</sub> show that the Raman modes are enhanced by the excited excitonic states and we will present the dependence of the excited states energies on the number of layers.

**4:42PM P15.00012 Giant blue shifted photoluminescence peak from the edges of CVD grown monolayer MoS<sub>2</sub>**, ALEXANDER YORE, WENDY CRUMRINE, San Francisco State Univ, KIRBY SMITHE, ERIC POP, Stanford University, BIN WANG, University of Oklahoma, AKM NEWAZ, San Francisco State Univ — To probe the electronic and optical properties of direct band-gap monolayer transition metal dichalcogenides, such as band structure and excitons, micro-photoluminescence spectroscopy has become an attractive and standard tool. Here, we present our experimental work on spatial scanning of photoluminescence of monolayer MoS<sub>2</sub> grown by chemical vapor deposition (CVD) using an ultrasmall blue laser (wavelength 405 nm) beam spot with beam diameter as small as  $\sim 200$  nm. We have observed a giant blue shift, as large as  $\sim 40$  nm or  $\sim 100$  meV, of the A-excitonic peak in the photoluminescence spectra from the edges when compared to luminescence from the inside. This giant blue shift may result from the following: (i) compressive strain at the edges; (ii) the enhanced dielectric screening caused by the increased electron density at the metallic Mo-edges; and (iii) chemical impurities.

**4:54PM P15.00013 High Resolution X-ray investigation of few-layer Molybdenum Disulfide (MoS<sub>2</sub>) Based Heterostructures**, HASSANA SAMASSEKOU, RICHARD PETERSON, SAIKAT TALAPATRA, DIPANJAN MAZUMDAR, Southern Illinois University-Carbondale — Due to its favorable band gap, few-layer MoS<sub>2</sub> can play an important role in optoelectronics and magneto-optics applications. Device applications necessitate a heterostructure combination of MoS<sub>2</sub> with other compatible materials. Here we report the growth and characterization of structural properties of few-layer MoS<sub>2</sub> based prototypes on Si substrates deposited by means of magnetron sputtering. A number of heterostructure combinations such as MoS<sub>2</sub>/BN, MoS<sub>2</sub>/SiO<sub>2</sub> shall be analyzed using high resolution X-ray reflectivity, scattering and diffraction methods. Our preliminary work already indicates that MoS<sub>2</sub> deposited on BN is quite favorable for optoelectronic applications [1]. But substantial work remains in order to obtain abrupt interfaces and atomic-level control. High resolution X-ray analysis can provide the essential understanding into the various structural aspects (crystal structure, interface roughness, density thickness) which could be valuable for developing a diversity of optoelectronic applications using MoS<sub>2</sub> or other *transition metal dichalcogenides*. Ref 1: Wasala, Samassekou, et al. (under review).

**5:06PM P15.00014 Anisotropic Dielectric Breakdown of Hexagonal Boron Nitride Film<sup>1</sup>**, YOSHI-AKI HATTORI, The University of Tokyo, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, KOSUKE NAGASHIO, The University of Tokyo and PRESTO-JST — Hexagonal boron nitride (h-BN) is considered as ideal substrate for 2D material devices. However, the reliability of insulating properties of h-BN itself has not been clarified yet. In this study, the anisotropic dielectric breakdown of h-BN is studied. We have found that the dielectric breakdown in *c* axis direction using a conductive atomic force microscope proceeded in the layer-by-layer manner. The obtained dielectric field strength was  $\sim 12$  MV/cm, which is comparable to the conventional SiO<sub>2</sub>. On the other hand, to estimate the dielectric field strength in a direction perpendicular to *c* axis, voltage is applied to a relatively thick h-BN (10-60 nm) through Cr/Au electrodes fabricated on the h-BN. We realized that the absorbed water on h-BN significantly affect the *IV* characters and the breakdown voltage. After the adsorbed water was removed by the heating in vacuum, the dielectric field strength was determined to be  $\sim 3$  MV/cm, which is the same order as that in *c* axis direction. This value could be increased when we consider the effect of electric field concentration around the metal electrode. Although the large difference in dielectric field strength for two directions was initially expected due to the highly-anisotropic layered structure with the van der Waals bonding, it was not the case because the sp<sup>2</sup> bonding should be broken for dielectric breakdown regardless of its direction.

**5:18PM P15.00015 The effective bending rigidity of a fluctuating ribbon<sup>1</sup>**, DUANDUAN WAN, MARK BOWICK, Department of Physics, Syracuse University — We study the vibration of a two-dimensional ribbon using molecular dynamics. We find the effective bending rigidity tends to a constant which can be orders of magnitude larger than the bare bending rigidity in the limit that the bare bending rigidity goes to zero, consistent with theoretical expectations. Experimental realizations include graphene, molybdenum disulfide and some doped membranes.

Session P16 DMP: 2D Devices: Black Phosphorous, III-IV, and IV-VI Materials 315 - Jewook Park, ORNL

**2:30PM P16.00001 Twisted Phosphorene Nanoribbons**, WOOSUN JANG, KISUNG KANG, ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University — Many different forms of structural deformations have been employed to alter the electronic structure of various two-dimensional (2D) nanomaterials in various optoelectronic devices [1]. Given the recent interest in the new class of 2D nanomaterials – phosphorene, it is important to understand how the anisotropic strain-dependent electronic properties of low-dimensional phosphorene may be exploited for technological gain. Here, using first-principles density-functional theory, we investigate the mechanical stability of twisted one-dimensional phosphorene nanoribbons (PNR) by measuring its critical twist angle ( $\theta_c$ ) and shear modulus as a function of the applied mechanical torque [2-4]. We find a strong anisotropic behaviour in PNRs with different edge terminations and directions, and report the direct consequence of this applied mechanical stress on its corresponding electronic (and optical) properties. Zhang, *Nanotechnology*, **26**, 235707 (2015)

**2:42PM P16.00002 Ground state degeneracy, energy barriers, and molecular dynamics evidence for two-dimensional disorder in black phosphorus and monochalcogenide monolayers at finite temperature**, MEHRSHAD MEHBOUDI, SALVADOR BARRAZA-LOPEZ, ALEX M. DORIO, University of Arkansas, WENJUAN ZHU, AREND VAN DER ZANDE, University of Illinois, HUGH O. H. CHURCHILL, University of Arkansas, ALEJANDRO A. PACHECO-SANJUAN, Universidad del Norte, EDMUND O. HARRISS, PRADEEP KUMAR, University of Arkansas — Mono-layers of black phosphorus and other two dimensional materials such as mono-layers of SiSe, GeS, GeSe, GeTe, SnS, SnSe, and SnTe with a similar crystalline structure have a four-fold degenerate ground state that leads to two-dimensional disorder at finite temperature. Disorder happens when neighboring atoms gently re-accommodate bonds beyond a critical temperature. In this talk, the effect of atomic numbers on the transition temperature will be discussed. In addition Car-Parinello molecular dynamics calculations at temperatures 30, 300 and 1000 K were performed on supercells containing more than five hundred atoms and the results from these calculations confirm the transition onto a two-dimensional disordered structure past the critical temperature, which is close to room temperature for many of these compounds. References: M. Mehboudi, A.M. Dorio, W. Zhu, A. van der Zande, H.O.H. Churchill, A.A. Pacheco Sanjuan, E.O.H. Harris, P. Kumar, and S. Barraza-Lopez. arXiv:1510.09153.

**2:54PM P16.00003 Remarkably low-energy one-dimensional fault line defects in single-layered phosphorene**, ALOYSIUS SOON, WOOSUN JANG, KISUNG KANG, Department of Materials Science and Engineering, Yonsei University — Systematic engineering of atomic-scale low-dimensional defects in two-dimensional nanomaterials is a promising way to modulate the electronic properties of these nanomaterials. Defects at interfaces such as grain boundaries and line defects can often be detrimental to technologically important nanodevice operations and thus a fundamental understanding of how such one-dimensional defects may have an influence on its physio-chemical properties is pivotal to optimizing their device performance. In this study [1], using density-functional theory, we investigate the temperature-dependent energetics and electronic structure of a single-layered phosphorene with various fault line defects. We have generated different line defect models based on a fault method, rather than the conventional rotation method. This has allowed us to study and identify new low-energy line defects, and we show how these low-energy line defects could well modulate the electronic band gap energies of single-layered two-dimensional phosphorene – offering a range of metallic to semiconducting properties in these newly proposed low-energy line defects in phosphorene. **3:06PM P16.00004 Black phosphorus edges: a polarized Raman study<sup>1</sup>**, H RIBEIRO, Mackgraphe-Mackenzie University, C VILLEGAS, IFT-UNESP, D BAHAMON, Mackgraphe-Mackenzie University, A CASTRO NETO, CA2DM and GRC, National University of Singapore, E DE SOUZA, Mackgraphe-Mackenzie University, A ROCHA, IFT-UNESP, M PIMENTA, Departamento de Física, UFMG, C DE MATOS, Mackgraphe-Mackenzie University — Black phosphorus (BP) has been recently exfoliated down to few-layer thicknesses revealing numerous interesting features such as a tunable direct bandgap. Ever since, demonstrations of BP electronic devices have bloomed, as well as studies of the electric, optical, mechanical and thermal properties of its bulk and few-layer forms. However, the edges of BP crystals have, so far, been poorly characterized, even though the terminations of layered crystals are known to possess a range of interesting properties. In this work, the edges of exfoliated BP flakes are characterized by polarized confocal Raman spectroscopy. We will present experimental Raman spectra at zigzag and armchair edges, as well as density functional theory calculations that explain the peculiarities of the experimental data.

**3:18PM P16.00005 Tight-binding model study of topological properties in few-layer black phosphorus<sup>1</sup>**, HYEONJIN DOH, HYOUNG JOON CHOI, Yonsei Univ — We study the simplest tight-binding model describing the band structures of mono- and bilayer phosphorus. The band structures are analyzed for various tight-binding parameters, and the gap-closing conditions are found where the system turns into a Dirac semi-metal. We show the tight-binding model Hamiltonian can be reduced to Dirac Hamiltonian and investigate its topological properties. The doping, electric field and pressure effects on topological properties of black phosphorus are discussed and these analyses suggest directions the the control of the energy gap in these system.

**3:30PM P16.00006 N-type doping of black phosphorus by using benzyl viologen.**, DEWU YUE, DAEYEONG LEE, JUNGJIN RYU, MIN SUP CHOI, HYE JIN NAM, DUK-YOUNG JUNG, WON JONG YOO, Sungkyunkwan Univ, NDPL COLLABORATION — Black phosphorus (BP) meets several critical material requirements for the development of future nanoelectronic applications, but the realization of n-type semiconductor behavior form it has remained elusive. Here, we report the ambipolar characteristics of few-layer BP, induced using an novel technique: chemical doping with benzyl viologen (BV), which serves as a surface charge transfer donor for BP flakes. The n-doped BP devices exhibit excellent electron mobility up to  $\sim 83 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$  from 2-terminal measurement at 300K, thereby demonstrating n-type behavior. On the basis of ambipolar BP devices, we also comprehensively analyzes temperature and BP thickness dependence of ambipolar devices, in which we found the degenerate doping limit below around 150K and highest electron transport performance in  $\sim 10 \text{ nm}$  BP flakes at 300K. As a proof of concept, ultrafast BP photodetectors were fabricated with a very high photoresponsivity of  $\sim 10^4 \text{ mA/W}$  over the UV, visible, and IR spectral ranges. Furthermore, we fabricated a homogeneous BP based inverter through BV doping and h-BN capping that offers a feasible approach to fabricating a key building block of future 2D logic semiconductors.

**3:42PM P16.00007 Oxidation of black phosphorus from the side**, MARIO BORUNDA, Oklahoma State University, SALVADOR BARRAZA, University of Arkansas — Two-dimensional black phosphorus, a recently discovered two-dimensional semiconductor material, has promising properties of interest in physics and materials science. We have performed density functional theory calculations at the early stages of the oxidation process from its side, and contrasted these results with oxidation processes happening at the top exposed surface.

**3:54PM P16.00008 Intrinsic Defects, Fluctuations of the Local Shape, and the Photo-Oxidation of Black Phosphorus**, KAINEN UTT, SALVADOR BARRAZA-LOPEZ, Univ of Arkansas-Fayetteville, ALEJANDRO PACHECO SANJUAN, Universidad del Norte, PABLO RIVERO, MERSHAD MEHBOUDI, EDMUND HARRISS, Univ of Arkansas-Fayetteville, MARIO BORUNDA, Oklahoma State University — The rapid degradation of black phosphorus (BP) under ambient condition is a well-known, but poorly understood phenomenon that represents a significant challenge to the feasibility of BP-based devices. Nearly 60 years after its discovery, BP has experienced a resurgence in popularity among the condensed matter community due to its recently demonstrated promise as a tunable two-dimensional semi-conductor. Despite this resurgence in popularity, the oxidation pathways have yet to be explored in great detail. A full characterization of the material's shape and of its electronic properties at the early stages of the oxidation process is presented and provides fundamental insights into the degradation dynamics of this novel layered material. Reference: K. L. Utt, P. Rivero, M. Mehboudi, E. O. Harriss, M. F. Borunda, A. A. Pacheco SanJuan, and S. Barraza-Lopez, *ACS Cent. Sci.* 1, 320 (2015)

**4:06PM P16.00009 Humidity Effects and Anisotropic Etching During Exfoliated Black Phosphorus Degradation**, ALEXANDRE FAVRON, PATRICIA MORAILLE, ETIENNE GAUFRES, TYCHO ROORDA, PIERRE L. LEVESQUE, RICHARD LEONELLI, RICHARD MARTEL, Universite de Montreal — Black phosphorus, a lamellar structure similar to graphene, is a high mobility semiconductor having a tunable optical band gap from 0.3 eV up to  $\sim 2 \text{ eV}$  with decreasing layer thickness. Our previous study has highlighted a fast photo-oxidation in ambient conditions when black phosphorus is exfoliated as thin layers. The kinetics of this degradation is also enhanced by quantum confinement effects and faster for the thinnest layers, which represents an important hurdle to prepare few layers. Here we further investigate the role of water in the process by following the reaction kinetics in different humidity using fast AFM imaging. We report on important changes of wettability of thin layers at room temperature depending on the degradation stages and layer thickness. For a given level of humidity at equilibrium, we observe the formation of water droplets. Those droplets form preferentially on defects sites and cracks and then grow on the thicker parts of the flake to finally accumulate on to the thinnest regions. This sequence of water droplet growth faster from thick to thin layers is interpreted as being due to a lowering of surface tension with decreasing layer thickness. In a second study, the oxidation kinetics of layers completely immersed in water reveal an anisotropic oxidation process with preferential etching in specific orientations of the crystal. This study will be discussed in the context of a reactivity of black phosphorus that appears both anisotropic and thickness-dependent.

**4:18PM P16.00010 First-principle study of the energy barrier and diffusivity of a Li atom on phosphorene**, CONGYAN ZHANG, MING YU, Univ of Louisville — The energy landscape of a Li atom adsorbed on the phosphorene was studied using the first principle method. Four types of preferential adsorption positions were found: three of them are located along the zigzag direction with the adsorption energy of -2.0~-1.9 eV/atom, forming potential valleys along zigzag direction. The other type is located on the top of the puckered bridge with the adsorption energy of -1.4 eV/atom, forming small isolated shallow basins between the potential valleys. Based on this energy landscape, we calculated energy barriers along various diffusion paths. The lowest energy barrier is along the zigzag direction in the valley (0.09 eV). The highest energy barrier is along the armchair direction through the top of P atoms (1.01 eV). While the energy barrier on the top of the bridge along the zigzag direction and along the armchair direction through the P-P bonds are 0.20 eV and 0.79 eV, respectively. Estimated diffusivity along the zigzag direction in the valley is almost  $10^{16}$  fast than that along the armchair direction through the top of P atoms, indicating the anisotropic diffusion.

**4:30PM P16.00011 Large Ultraviolet Photoresponsivity of Few-layer Black Phosphorus<sup>1</sup>**, JING WU, GAVIN KOK WAI KOON, DU XIANG, ANTONIO H. CASTRO NETO, BARBAROS OZYILMAZ, Natl Univ of Singapore, CENTRE OF ADVANCED 2D MATERIALS TEAM — Black phosphorus has recently gained much attention in the scientific community. Black phosphorus can be seen as a crystal generated by periodic repetition of tetraphosphorus ( $P_4$ ) molecules. It is known that tetraphosphorus  $P_4$  can be transformed temporarily to diphosphorus  $P_2$  upon ultraviolet (UV) irradiation. Thus, it is expected that the  $P_4$  structured black phosphorus also has strong interaction with light especially in the UV range. Here we report on the optoelectronic characteristics of few-layer black phosphorus field effect transistors (FETs) ranging from the UV to the near infrared (NIR). We demonstrate that black phosphorus is an excellent ultraviolet (UV) photodetector with a specific detectivity  $\sim 3 \times 10^{13}$  Jones. We report also an exceptional photo responsivity of  $10^7$  times higher than previously reported values for black phosphorus visible light photodetectors. We attribute such a colossal UV photo responsivity to the resonant-interband transition between two specially nested valence and conduction bands. These nested bands provide an unusually high density of states for high-efficient UV absorption due to their singularity nature.

<sup>1</sup>Large Ultraviolet Photoresponsivity of Few-layer Black Phosphorus

**4:42PM P16.00012 Few-layer III-VI and IV-VI 2D semiconductor transistors**, SUKRIT SUCHARITAKUL, Case Western Reserve University, MEI LIU, Shandong Normal University, RAJESH KUMAR, RAMAN SANKAR, FANG C. CHOU, YIT-TSONG CHEN, National Taiwan University, XUAN GAO, Case Western Reserve University — Since the discovery of atomically thin graphene, a large variety of exfoliable 2D materials have been thoroughly explored for their exotic transport behavior and promises in technological breakthroughs. While most attention on 2D materials beyond graphene is focused on transition metal-dichalcogenides, relatively less attention is paid to layered III-VI and IV-VI semiconductors such as InSe, SnSe etc which bear stronger potential as 2D materials with high electron mobility or thermoelectric figure of merit. We will discuss our recent work on few-layer InSe 2D field effect transistors which exhibit carrier mobility approaching  $1000 \text{ cm}^2/\text{Vs}$  and ON-OFF ratio exceeding  $10^7$  at room temperature. In addition, the fabrication and device performance of transistors made of mechanically exfoliated multilayer IV-VI semiconductor SnSe and  $\text{SnSe}_2$  will be discussed. **References** [1] Sucharitakul. S. *et al. Nano Lett.* **15**, 3815–3819 (2015).

**4:54PM P16.00013 Puckering Inversion in Monolayer Group IV Monochalcogenides SnS and GeSe Through Strain Engineering**, PAUL HANAKATA, Boston University, ALEXANDRA CARVALHO, National University of Singapore, DAVID CAMPBELL, HAROLD PARK, Boston University — We use first principles calculations to study the electronic and mechanical properties of the monolayer group IV monochalcogenides SnS and GeSe under uniaxial stress in the armchair or zigzag direction. We find that monolayer SnS and GeSe can sustain tensile stresses up to 3.5 GPa and 7 GPa, respectively. Applying uniaxial stress in the zigzag direction results in a structural phase transition to a rocksalt-like structure for both GeSe and SnS and followed by an inversion in the puckering structure. This puckering inversion results in a change of the band structure, in particular the valley configuration. Our findings show the potential applications of SnS and GeSe monolayer for phase-change memory and valley-based electronic devices.

**5:06PM P16.00014 ABSTRACT WITHDRAWN —**

**5:18PM P16.00015 Field Effect Transistors Using Atomically Thin Layers of Copper Indium Selenide ( $\text{CuInSe}$ )<sup>1</sup>**, PRASANNA PATIL, SUJOY GHOSH, MILINDA WASALA, Southern Illinois University Carbondale, SIDONG LEI, ROBERT VAJTAI, PULICKEL AJAYAN, Rice University, SAIKAT TALAPATRA, Southern Illinois University Carbondale — We will report fabrication of field-effect transistors (FETs) using few-layers of Copper Indium Selenide ( $\text{CuInSe}$ ) flakes exfoliated from crystals grown using chemical vapor transport technique. Our transport measurements indicate n-type FET with electron mobility  $\approx 3 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  at room temperature when Silicon dioxide ( $\text{SiO}_2$ ) is used as a back gate. Mobility can be further increased significantly when ionic liquid 1-Butyl-3-methylimidazolium hexafluorophosphate ( $\text{BMIM-PF}_6$ ) is used as top gate. Similarly subthreshold swing can be further improved from 103 V/dec to 0.55 V/dec by using ionic liquid as a top gate. We also found ON/OFF ratio of  $\approx 10^2$  for both top and back gate. Comparison between ionic liquid top gate and  $\text{SiO}_2$  back gate will be presented and discussed.

**2:30PM P17.00001 Towards Lego Snapping; Integration of Carbon Nanotubes and Few-Layer Graphene**, MOHSEN NASSERI, MATHIAS BOLAND, M. JAVAD FARROKHI, DOUGLAS STRACHAN, University of Kentucky — Integration of semiconducting, conducting, and insulating nanomaterials into precisely aligned complicated systems is one of the main challenges to the ultimate size scaling of electronic devices, which is a key goal in nanoscience and nanotechnology. This integration could be made more effective through controlled alignment of the crystallographic lattices of the nanoscale components. Of the vast number of materials of atomically-thin materials, two of the  $sp^2$  bonded carbon structures, graphene and carbon nanotubes, are ideal candidates for this type of application since they are built from the same backbone carbon lattice. Here we report carbon nanotube and graphene hybrid nanostructures fabricated through their catalytic synthesis and etching. The growth formations we have investigated through various high-resolution microscopy techniques provide evidence of lego-snapped interfaces between nanotubes and graphene into device-relevant orientations. We will finish with a discussion of the various size and energy regimes relevant to these lego-snapped interfaces and their implications on developing these integrated formations.

**2:42PM P17.00002 Two-dimensional square structures of CuO and Cu<sub>2</sub>O monolayer.**<sup>1</sup>, YUYANG ZHANG, Vanderbilt Univ; Oak Ridge National Lab, KUIBO YIN, YILONG ZHOU, LITAO SUN, Southeast University, MATTHEW F. CHISHOLM, Oak Ridge National Lab, SOKRATES T. PANTELIDES, Vanderbilt Univ; Oak Ridge National Lab, WU ZHOU, Oak Ridge National Lab — Among 2D crystals, monolayer (ML) oxides are interesting because of the coupling of quantum confinement to other degrees of freedom that are present in bulk materials. However, as most oxides are not layered structures, fabrication of 2D oxides has been limited. Current studies focus on either two-to-three atomic layers thick materials, such as the exfoliated perovskites, or supported films that are bonded to the substrate. Unsupported single-atom-thick oxides have not been reported. Here we report the fabrication of single-atom-thick copper oxide ML. Quantum mechanical calculations indicate that free-standing copper oxide MLs are stable wide-bandgap semiconductors with a variable chemical stoichiometry ranging from CuO to Cu<sub>2</sub>O at similar lattice constants. The stoichiometry variation changes the bandgap from indirect for CuO ML to direct for Cu<sub>2</sub>O ML, suggesting that the electronic and optical properties of ML copper oxides can be tuned by the oxygen content.

**2:54PM P17.00003 Oxidation-derived two-dimensional MoO<sub>3</sub>/MoS<sub>2</sub> heterostructures**, TAEG YEOUNG KO, Department of Chemistry, Kyung Hee University, AREUM JEONG, Department of Applied Chemistry, Kyung Hee University, SUNMIN RYU<sup>1</sup>, Department of Chemistry, Division of Advanced Materials Science, Pohang University of Science and Technology — In order to explore the efficient formation of MoO<sub>3</sub>/MoS<sub>2</sub> heterostructures, we systematically investigated the course of surface oxidation of mechanically exfoliated single and few-layer MoS<sub>2</sub> induced by oxygen plasma treatment using photoluminescence (PL) and Raman spectroscopy, atomic force microscopy (AFM) and X-ray photoelectron spectroscopy (XPS). Raman and PL spectra served as sensitive indicators for defects generated by the plasma oxidation, showing Raman peak broadening and drastically reduced intensities for both Raman peaks and PL bands. XPS detected Mo<sup>6+</sup> as the major Mo species in the oxidized samples, confirming the conversion of MoS<sub>2</sub> into amorphous MoO<sub>3</sub>. The AFM studies also revealed that the thickness of MoS<sub>2</sub> layers more than doubles when oxidized and that the vertical reaction from the top dominates with a negligible contribution from the lateral attack when combined with the Raman measurements. Our results show that the oxygen plasma treatment can be successfully used in generating atomically thin MoO<sub>3</sub> or two-dimensional MoO<sub>3</sub>/MoS<sub>2</sub> heterostructures that may be useful for future electronic and optoelectronic application.

**3:06PM P17.00004 Microscopic theory of two-dimensional spatially-indirect-exciton condensates and exciton-polariton condensates**<sup>1</sup>, FEI XUE, FENG CHENG WU, ALLAN MACDONALD, Univ of Texas, Austin — BEC of excitons and polaritons have drawn attention in recent years because of the demonstration of their ability to host macroscopic quantum phenomena and because of their promise for applications. We study the case of a system containing two TMD monolayers that are separated and surrounded by h-BN. Under appropriate conditions this system is expected to support a spatially indirect thermal equilibrium exciton condensate. We combine a microscopic mean-field calculation and a weakly interacting boson model to explore the bilayer exciton condensates phase diagram. By varying the layer separation and exciton density, we find a phase transition occurs between states containing one and two condensate flavors. We also use a microscopic time-dependent mean-field theory to address condensate collective mode spectra and quantum fluctuations. Next we study the case of exciton-polariton formed by strong coupling between quantum well excitons and confined photon modes when the system is placed in a vertical microcavity. We build a microscopic mean-field theory starting from electrons and holes, and account for their coupling to coherent light field. We compare our model with the normal weakly interacting boson model that starts from weakly interacting excitons that are coupled to photons.

**3:18PM P17.00005 Preparation and Characterization of Large Area Monolayer Films of Pt Nanoparticles**<sup>1</sup>, BRIAN KELLY, Department of Physics and Astronomy, University of Delaware, RONALD CICHOCKI, JIE REN, Department of Chemistry and Biochemistry, University of Delaware, ROBERT SCHMIDT, Department of Physics and Astronomy, University of Delaware, KLAUS THEOPOLD, Department of Chemistry and Biochemistry, University of Delaware, KARL UNRUH, Department of Physics and Astronomy, University of Delaware — Highly uniform monolayer thick coatings of Pt nanoparticles with areas as large as 20 cm<sup>2</sup> have been prepared by first self-assembling the desired Pt film at the interface between two immiscible liquids and then transferring the film to a glass substrate. The controlled addition of ethyl alcohol to a phase separated mixture of an aqueous colloidal solution of Pt nanoparticles and hexane allowed both monolayer and multilayer films to be prepared. Optical microscopy and UV-vis spectrophotometry measurements have been used to verify the large scale uniformity of the coatings while transmission electron and atomic force microscopy measurements confirmed that single and multilayer films can be prepared.

**3:30PM P17.00006 The 2D Selfassembly of Benzimidazole and its Co-crystallization.**, PAULO COSTA, JACOB TEETER, DONNA KUNKEL, ALEXANDER SINITSKII, AXEL ENDERS, University of Nebraska-Lincoln — Benzimidazoles (BI) are organic molecules that form ferroelectric crystals. Key to their ferroelectric behavior are the switchable N···HN type bonds and how they couple to the electron system of the molecules. We attempted to crystallize BI on various metal surfaces and studied them using STM. We observed that on Au and Ag, BI joins into zipper chains characteristic of its bulk structure that can pack into a continuous 2D layer. Because the dipole of BI lies in the direction of its switchable hydrogen bond, these zippers should in principle have reversible polarizations that point along the direction they run. BI's crystallization is reminiscent to how croconic acid (CA) crystallizes in 2D using O···HO bonding, suggesting that these molecules may be able to co-crystallize through OH···N bonds. This would present the opportunity to modify BI's properties, such as the energy needed to switch a hydrogen from a donor to acceptor site. When co-deposited, CA and BI successfully combine into a co-crystal formed by building blocks consisting of 2 CA and 2 BI molecules. These findings demonstrate the usefulness of using STM as a preliminary check to verify if two molecules are compatible with each other without having to attempt crystallization with multiple solvents and mixing methods.

**3:42PM P17.00007 Correlating Structural and Electronic Degrees of Freedom in 2D Transition Metal Dichalcogenides**, I-CHENG TUNG, Z. ZHANG, Advanced Photon Source, Argonne National Laboratory, K. L. SEYLER, A. M. JONES, Department of Physics, University of Washington, G. CLARK, Department of Materials Science and Engineering, University of Washington, D. XIAO, Department of Physics, Carnegie Mellon University, N. LAANAIT, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, X. XU, Department of Physics, University of Washington, H. WEN, Advanced Photon Source, Argonne National Laboratory — We have conducted a microscopic study of the interplay between structural and electronic degrees of freedom in two-dimensional (2D) transition metal dichalcogenide (TMD) monolayers, multilayers and heterostructures. Using the recently developed full field x-ray reflection interface microscopy with the photoluminescence microscopic probe capability at the Advanced Photon Source, we demonstrated the x-ray reflection imaging of a monolayer 2D material for the first time. The structural variation across an exfoliated WSe<sub>2</sub> monolayer is quantified by interlayer spacing relative to the crystal substrate and the smoothness of the layer. This structural information is correlated with the electronic properties of TMDs characterized by the *in-situ* photoluminescence measurements. This work is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-SC0012509. The use of Advanced Photon Source is supported by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-06CH11357.

**3:54PM P17.00008 Symmetry protected topological phases in a multi-band 2D electron gas.** , PETR STEPANOV, YAFIS BARLAS, CHUN NING LAU, Univ of California - Riverside, DMITRY SMIRNOV, National High Magnetic Field Lab, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science — Recently the observation of symmetry protected topological phases was reported in monolayer and bilayer graphenes in the  $\nu = 0$  quantum Hall state. Ground state in a multi-band Dirac systems such as ABA-trilayer graphene shows more complex phases than their mono- and bilayer counterparts. Tight-binding Hamiltonian in the absence of out-of-plane displacement field along with the mirror symmetry about the middle layer leads to a presence of non-interacting two bands. Relative shift of bands in the Landau Level energy spectrum map exhibits the existence of conductive counterpropagating phases with values  $\sigma_{xx} = 2\alpha e^2/h$  where  $\alpha$  is the spin-degeneracy. In addition, out-of-plane displacement field plays a crucial role in mixing those bands leading to broken symmetries and polarizing charge carriers in only bottom or top layer. We will present our most recent studies on quantum Hall phase diagram of  $\nu = 0$  in ABA-trilayers.

**4:06PM P17.00009 Thermoelectronic emission from monolayer graphene with temperature dependent work functions** , DILIP DE<sup>1</sup>, OLUKUNLE OLAWOLE, Covenant University — For the first time we have derived an equation for the temperature (T) dependent work function (W(T)) that will be important for modeling thermoelectronic current density (J) and energy distribution of emitted electrons specially, from nano-materials. The equation containing terms up to fifth power of T gives a modified Richardson-Dushman (MRDE) equation that fits excellently well the experimental data of J vs T for suspended graphene. It provides a unique technique for accurate determination of  $W_0$ , Fermi energy,  $E_{F0}$  at 0 K and surface density of charge carriers,  $n_s$  of graphene. The corresponding values obtained for suspended graphene are:  $W_0 = 4.42 + 0.01$  eV,  $E_{F0} = 0.166 + 0.002$  eV;  $n_s = 2.34 \times 10^{12} \text{ cm}^{-2}$ . The model gives -ve thermal expansion coefficient of graphene ( $-8 \times 10^{-6} \text{ /K}$ ) which has been experimentally confirmed. The equations are expected to hold for carbon nanotubes.

<sup>1</sup>Please send us acceptance notice early so that we can apply for sponsorship from our University in time.

**4:18PM P17.00010 Effect of dopant distribution on thermal conductivity of  $C_{(1-x)}N_x$**  , YANG ZHOU, Fudan Univ — The thermal conductivities of nanoscale nitrogen doped graphene ( $C_{(1-x)}N_x$ ) with various nitrogen ratio and distribution is studied by performing nonequilibrium molecular dynamics. The thermal conductivity of randomly doped  $C_{(1-x)}N_x$  is found much smaller than that of the regular alloy when the dopant ratios are the same. Meanwhile, thermal conductivity of random alloys is dopant ratio sensitive while that of regular alloy is not. Interestingly, localization mode analysis indicates that the inequality of atoms under translation and inversion is responsible for the change of the thermal conductivity and a linear relationship between them is found. The results may provide a general guidance for phonon manipulation and thermal engineering in alloys.

**4:30PM P17.00011 Doping and Thermal Conductivity Studies of  $CrSiTe_3$**  , AMANDA HAGLUND, Dept. of Materials Science and Engineering, Univ of Tennessee, JIAQIANG YAN, Univ of Tennessee; Oak Ridge National Laboratory, VEERLE KEPPENS, Dept. of Materials Science and Engineering, Univ of Tennessee, DAVID MANDRUS, Univ of Tennessee; Oak Ridge National Laboratory —  $CrSiTe_3$  is a layered material with a 2-dimensional crystal structure, and has recently become of more interest due to the possibility of using its ferromagnetic and semiconducting properties for spintronics applications. To further investigate the properties of  $CrSiTe_3$ , we doped it with various transition elements on the Cr site in an attempt to tune and control the magnetism, as well as study changes in the thermal conductivity. We synthesized pure  $CrSiTe_3$  and doped samples through flux growth, producing plate-like bulk crystals. Crystal quality was checked by x-ray diffraction and energy dispersive spectroscopy, and then thermal conductivity and magnetization measurements were obtained on the doped materials to compare variations from the pristine  $CrSiTe_3$ .

**4:42PM P17.00012 Electronic and Mechanical Properties of Graphene-Germanium Interfaces Grown by Chemical Vapor Deposition** , BRIAN KIRALY, Northwestern University , ROBERT JACOBBERGER, University of Wisconsin-Madison, ANDREW MANNIX, GAVIN CAMPBELL, MICHAEL BEDZYK, Northwestern University, MICHAEL ARNOLD, University of Wisconsin-Madison, MARK HERSAM, Northwestern University, NATHAN GUISSINGER, Argonne National Laboratory — Epitaxial graphene grown directly on semiconducting Ge wafers holds potential for fundamental science and electronics applications. However, since the initial demonstration, little work has been done on the structural and electronic properties of this system. To gain insight into the interface between graphene and Ge, we performed ultra-high vacuum scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) along with Raman and X-ray photoelectron spectroscopy experiments to probe the atomic structure and chemistry at the interface. STS confirms stronger interfacial interaction on Ge(110), consistent with models of epitaxial growth. Raman spectroscopy shows that strain is highly prevalent after growth. Furthermore, the native strain modifies the atomic structure of the Germanium, inducing new and metastable Ge surface reconstructions following annealing. These reconstructions, in turn, modify both the electronic and mechanical properties of the graphene. Finally, graphene/Ge(001) represents the extremely strained case. Here graphene forces restructuring of the Ge surface into [107] facets. From this work, we see that the interaction between graphene and Ge is both dependent on the substrate crystallographic orientation and tunable.

**4:54PM P17.00013 Optical activity and circular dichroism of plasmonic nanorod assemblies<sup>1</sup>** , LAROUSSE KHOSRAVI KHORASHAD, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, USA, NA LIU, Max Planck Institute for Intelligent Systems, Heisenbergstrasse 3, D-70569 Stuttgart, Germany, ALEXANDER O. GOVOROV, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701, USA — Plasmonic circular dichroism (CD) has offered an efficient spectroscopy method for the electronic, chemical, and structural properties of different types of light active molecules in the subwavelength regime. Among the different chiral geometries of metal nanoparticles utilized by the plasmonic CD spectroscopy, gold nanorods (AuNRs) have shown strong CD signals in the visible frequency range. In this work, we theoretically study the CD signals of AuNR arrangements in order to mimic structures and chemical bonds of chiral biomolecules. In particular, our twisted three-AuNR geometries resemble a molecular structure of tartaric acid. This molecule played an important role in the discovery of chemical chirality. In our study, we show that the strength of CD signals changes dramatically by tuning the interparticle distances and angles. Since the CD signals are typically weak, we develop reliable computational approaches to calculate the plasmonic CD. Manipulating interparticle distances, size, and molecular bond angles result in full control over peak positions, handedness, and positive and negative bands which are observed in the CD spectra.

<sup>1</sup>This work has been supported under the grant from Volkswagen Foundation. We also acknowledge the financial support of Condensed Matter and Surface Science program of Ohio University.

**5:06PM P17.00014 Strong superchiral field in hot spots and its interaction with chiral molecules.<sup>1</sup>** , YINENG LIU, Xiamen University — We have found that strong superchiral fields created by surface plasmon resonance exist in hot spots of nonchiral plasmonic structure, which showed a chiral density greater than that of circularly polarized light by hundreds of times. We have demonstrated a direct correlation between the chirality of the local field and the circular dichroism (CD) response at the plasmon resonance bands induced by chiral molecules in the hot spots. Our results reveal that the wavelength-dependent superchiral fields in the hot spots can play a crucial role in the determination of the plasmonic CD effect. This finding is in contrast to the currently accepted physical model in which the electromagnetic field intensity in hot spots is a key factor to determine the peak intensity of the plasmonic CD spectrum. Some related experimental phenomena have been explained by using our theoretical analysis.

Session P18 GMAG DMP FIAP: Spin-Dynamics in Patterned Films and Devices 317 - Volker Sluka, New York University

**2:30PM P18.00001 Electrically driven magnetization dynamics in yttrium iron garnet<sup>1</sup>**, MATTHIAS BENJAMIN JUNGFLAISCH<sup>2</sup>, Argonne National Laboratory — Creation and manipulation of magnetization states by spin-orbital torques are important for novel spintronics applications. Magnetic insulators were mostly ignored for this particular purpose, despite their low Gilbert damping, which makes them outstanding materials for magnonic applications and investigation of nonlinear spin-wave phenomena. Here, we demonstrate the propagation of spin-wave modes in micro-structured yttrium iron garnet ( $\text{Y}_3\text{Fe}_5\text{O}_{12}$ , YIG) stripes. Spin waves propagating along the long side of the stripe are detected by means of spatially-resolved Brillouin light scattering (BLS) microscopy. The propagation distance of spin waves is determined in the linear regime, where an exponential decay of 10  $\mu\text{m}$  is observed<sup>3</sup>. We also explored the possibility of driving magnetization dynamics with spin Hall effects (SHE) in bilayers of YIG/Pt microstructures. For this purpose we adopted a spin-transfer torque ferromagnetic resonance (ST-FMR) approach. Here a *rf* charge current is passed through the Pt layer, which generates a spin-transfer torque at the interface from an oscillating spin current via the SHE. This gives rise to a resonant excitation of the magnetization dynamics. In all metallic systems the magnetization dynamics is detected via the homodyne anisotropic magnetoresistance of the ferromagnetic layer. However, since there is no charge flowing through ferromagnetic insulators there is no anisotropic magnetoresistance. Instead, we show that for the case of YIG/Pt the spin Hall magnetoresistance can be used. Our measured voltage spectra can be well fitted to an analytical model evidencing that the ST-FMR concept can be extended to insulating systems<sup>4</sup>. Furthermore, we employ spatially-resolved BLS spectroscopy to map the ST-FMR driven spin dynamics. We observe the formation of a strong, self-localized spin-wave intensity in the center of the sample<sup>5</sup>. This spin-wave 'bullet' is created due to nonlinear cross coupling of eigenmodes existing in the magnetic system, which is confirmed by micromagnetic simulations.

**3:06PM P18.00002 Spin Hall Control of Magnetization in a Perpendicularly-Magnetized Magnetic Insulator**, CHI-FENG PAI, ANDY QUINDEAU, ASTERA TANG, MEHMET ONBASLI, MAXWELL MANN, LUCAS CARETTA, CAROLINE ROSS, GEOFFREY BEACH, Massachusetts Institute of Technology — Spin Hall effect (SHE)-induced spin-orbit torque (SOT) has been shown to be an efficient mechanism to control the magnetization in magnetic heterostructures. Although numerous works have demonstrated the efficacy of SOT in manipulating the magnetization of ferromagnetic metals (FM), SOT-controlled switching of ferromagnetic insulators (FMI) has not yet been observed. In this work we show that spin Hall currents in Pt and Ta can generate SOTs strong enough to control the magnetization direction in an adjacent thulium iron garnet FMI film with perpendicular magnetic anisotropy. We find that dc current in the heavy metal (HM) generates an out-of-plane effective field in the FMI consistent with an antidamping torque whose magnitude is comparable to that observed in all-metallic systems. Spin Hall magnetoresistance (SMR) measurements reveal a large spin-mixing conductance, which implies considerable spin transparency at the metal/insulator interface and explains the observed strong current-induced torque. Our results show that charge currents flowing in a HM can be used to both control and detect the magnetization direction in a FMI electrically.

**3:18PM P18.00003 Spin transfer torque switching in MTJ arrays with nanoengineered uniaxial anisotropy<sup>1</sup>**, ILYAS A. H. FARHAT, Khalifa University, AMS Dept. and KSRC, Abu Dhabi, UAE, E. GALE, University of Bath, UK, M. ABI JAOUDE, A. F. ISAKOVIC, Khalifa University, AMS Dept. and KSRC, Abu Dhabi, UAE — Enhancing Magnetic Tunnel Junction (MTJ) energy efficiency is the key to embed it in low power applications. We report a detailed study on the behavior of the analytical expression of switching current density as a function of geometrical and magnetic parameters, for both I-MTJs and P-MTJs. Our study shows that the current model requires some modifications to improve the match between the model and the experiment. We also show under which criteria a scaled-down of MTJ devices can help in reduction of current density. We then used the device model of MTJ to study the power performance of MTJ device, proposing a roadmap to lower switching power of the device. Comparisons between ours and data for similar devices in literature, combined with the above analysis, suggests the need for qualitatively different model, and for this purpose, we explored the variations of the effective energy density model [1], which may explain the device behavior better. **3:30PM P18.00004 Vortex Gyrotropic Motion in patterned Ferromagnetic Dots<sup>1</sup>**, JUNJIA DING, PAVEL LAPA, TRUPTI CHAIR, CHRYSIAN POSADA, AXEL HOFFMANN, VALENTINE NOVOSAD, Argonne Natl Lab — A vortex state consists of a large region of in-plane curling magnetization and a small core region with out-of-plane magnetization. The gyrotropic oscillation frequency of the vortex core is known to be weakly dependent to the core position (which is adjustable by changing the applied field) and can only be efficiently tuned by changing the dimension of the dots. Here, we demonstrated that the vortex gyrotropic frequency can be stepwise tuned by introducing a vortex barrier to a regular ferromagnetic dot. Systematical investigations of the dynamic response of the engineered dots have been performed as a function of the outer dot diameter, barrier diameter and the barrier profile using both microwave absorption spectroscopy and micromagnetic simulation. We found that the vortex frequency is mostly dependent on the outer diameter of the dot when the core is outside the barrier, while it is more rely on the dimension of the barrier when the core is inside the barrier. This approach certainly gives several additional freedoms to adjust the vortex gyrotropic frequency and opens extra perspectives for spintronic applications.

**3:42PM P18.00005 Dynamics of spin valves investigated using Magneto-Optical Kerr Effect Spectroscopy<sup>1</sup>**, CHRISTOPHER STEVENS, JAGANNATH PAUL, PRASENJIT DEY, Univ of South Florida, CASEY MILLER, Rochester Institute of Technology, STEPHEN MCGILL, National High Magnetic Field Lab, FSU, DENIS KARAIKAJ, Univ of South Florida — Through an all-optical approach, we are investigating the spin dynamics in different spin torque based structures. Using pump-probe Time-Resolved Magneto-Optical Kerr Effect (TR-MOKE) spectroscopy, we are able to monitor the ultrafast magnon propagation on a sub-picosecond timescale as well as the longer lived oscillations and demagnetization. This represents a recent efforts to realize magnon induced spin torque using an all optical method.

<sup>1</sup>This research at USF is supported by the National Science Foundation, Division of Electrical, Communications and Cyber Systems under grant number: 1231929. The work was done in part at the NHMFL, Tallahassee, FSU under grants: DMR-1229217, DMR-1157490

**3:54PM P18.00006 The shot noise like feature of the magnetic 1/f noise in CoFeB/MgO/CoFeB magnetic tunnel junctions.** , LIANG LIU, JIASSEN NIU, HUIQIANG GUO, JIAN WEI, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China and Collaborative Innovation Center of Quantum, D. L. LI, J. F. FENG, X. F. HAN, Beijing National Laboratory of Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, X.-G. ZHANG, Center for Nanophase Materials Sciences, and Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6493, J. M. D. COEY, CRANN and School of Physics, Trinity College, Dublin 2, Ireland — The magnetic field dependent 1/f noise in magnetic multilayers and magnetic tunnel junctions (MTJs) is conventionally considered as resistance fluctuations ( $S_R$ ), for which an applied current ( $I$ ) is merely used to convert  $S_R$  to measurable voltage fluctuations ( $S_V = I^2 S_R$ ). From  $S_R$  and magnetoresistance, magnetization fluctuations can be inferred obeying the fluctuation-dissipation relation (FDR), thus comes the name magnetoresistive noise. However, we find that 1/f noise in CoFeB/MgO/CoFeB MTJs is better described by  $S_I/I$ , instead of  $S_V/I^2$ , particularly near the magnetic reversal fields of the reference layer and the free layer, the latter of which has not been previously investigated in detail. More surprisingly, the bias dependence resembles that of shot noise. These findings call for further investigation on FDR for magnetic noise in MTJs, especially in the far from equilibrium state with high bias and possible contribution from collective magnon excitations.

**4:06PM P18.00007 Coherent spin-transfer precession switching in orthogonal spin-torque devices** , COLM RYAN, GRAHAM ROWLANDS, BBN Technology - Massachusetts, DANIELE PINNA, LI YE, LAURA REHM, VOLKER SLUKA, ANDY KENT, Department of Physics, New York University, New York, NY 10003, USA, THOMAS OHKI, BBN Technology - Massachusetts — We present experimental results in concert with macrospin simulations of the switching characteristics of orthogonal spin-transfer devices incorporating an out-of-plane magnetized polarizing layer and an in-plane magnetized spin valve device at cryogenic temperatures. Switching at 3.4K between parallel and anti-parallel spin-valve states is investigated for current pulses with varying durations from 0.1 to 1.4ns to observe the averaged response of the time dependent dynamics of the spin-transfer induced precession of the magnetization. We demonstrate high speed switching at short pulse lengths, down to 100ps, and also observe ensemble decoherence effects with longer pulses. The results show that even at cryogenic temperatures finite temperature noise is still important in the dynamics of precessional switching.

**4:18PM P18.00008 Effects of spin relaxation on trap-assisted tunneling through ferromagnetic metal-oxide-semiconductor structures** , VIKTOR SVERDLOV, SIEGFRIED SELBERHERR, Institute for Microelectronics, TU Wien — A signal measured within a three-terminal setup at room temperature [1,2] is attributed to the spin injection from a ferromagnetic electrode into n-silicon; however, its amplitude is orders of magnitude larger than predicted by theory [3]. The reasons for this discrepancy are heavily debated [3-6], with trap-assisted resonant tunneling [4] and spin-dependent magnetoresistance gaining recognition. However, effects of spin relaxation important at room temperature were not considered in [4]. To elucidate the role of spin relaxation and coherence, corresponding Lindblad terms are added to the equation for the density matrix evolution of spin on a trap coupled to ferromagnetic contacts. Fast spin relaxation suppresses the magnetoresistance modulation. Interestingly, strong decoherence at fixed spin lifetime results in a more pronounced magnetoresistance modulation and in a narrower magnetoresistance linewidth as a function of the perpendicular magnetic field. 1.S.P.Dash *et al.*, Nature **462**,491 (2009). 2.C.Li *et al.*, Nature Commun.**2**, 245 (2011). 3.R.Jansen, Nature Mater.**11**, 400 (2012). 4.Y.Song and H.Dery, PRL **113**, 047205 (2014). 5.A.Spiesser *et al.*, PRB **90**, 205213 (2014). 6.K.-R.Jeon *et al.*, PRB **91**, 155305 (2015).

**4:30PM P18.00009 Thermally reliable clocked non-volatile spin wave logic device** , SOURAV DUTTA, Georgia Inst of Tech, DMITRI NIKONOV, SASIKANTH MANIPATRUNI, IAN YOUNG, Components Research, Intel Corporation, Hillsboro, AZAD NAEEMI, Georgia Inst of Tech — The possibility of utilizing spin waves for information transmission and computation has been an area of active research due to the unique ability to manipulate the amplitude and phase of the spin waves for building complex logic circuits. Here, we present a comprehensive scheme for building a thermally reliable clocked non-volatile spin wave logic device [1,2] (SWLD) by introducing a charge-to-spin converter that translates information from electrical domain to spin domain, exploiting the magneto-electric effect for spin wave transmission, detection and non-volatile memory, utilizing the phase of the spin wave as information token, ensuring phase-dependent deterministic switching of the magnetoelectric spin wave detector in the presence of thermal noise via compensation of demagnetization and a novel clocking scheme that ensures sequential transmission of information in a cascaded SWLD and non-reciprocity. [1] S. Dutta *et al.*, Non-volatile clocked spin wave interconnect for beyond-cmos nanomagnet pipelines, Scientific Reports **5** (2015). [2] S. Dutta *et al.*, Phase-dependent deterministic switching of magnetoelectric spin wave detector in the presence of thermal noise via compensation of demagnetization , Applied Physics Letters (accepted 2015).

**4:42PM P18.00010 Magnetotransport properties of Co<sub>90</sub>Fe<sub>10</sub>/Cu/Ni<sub>80</sub>Fe<sub>20</sub> pseudo-spin-valve with out-of-plane tilted magnetic field** , LINQIANG LUO, NAM DAO, SALINPORN KITTIWATANAKUL, STUART WOLF, JIWEI LU, Univ of Virginia, UVA NANOSTAR TEAM — The giant magnetoresistance (GMR) effect of a pseudo spin valve made of Co<sub>90</sub>Fe<sub>10</sub>/Cu/Ni<sub>80</sub>Fe<sub>20</sub> has been investigated, with a magnetic field applied perpendicularly tilted to the sample plane. Without using a pinning layer, the magnetic separation of the free and fixed layers is uniquely achieved by utilizing perpendicular fields due to different anisotropy energies between Ni<sub>80</sub>Fe<sub>20</sub> and Co<sub>90</sub>Fe<sub>10</sub>. The magneto-transport measurements are carried out by Van der Pauw method in current-in-plane geometry at room temperature. By tilting the magnetic field at different angles from out-of-plane, the GMR plateau's width can be tuned. A plateau width of about 2000 Oe is observed at tilted angle 0.5°, which opens a significantly larger window for high-resistance states comparing with a plateau width of 10 Oe for in-plane fields. With the out-of-plane tilted fields, the orientation of the magnetic moments can be tuned continuously out of the sample plane, and the relative orientation between Ni<sub>80</sub>Fe<sub>20</sub> and Co<sub>90</sub>Fe<sub>10</sub> can also be tuned by the tilted angle, enabling us to precisely control the sample's states for current-induced spin dynamics study that is very difficult in the case of in-plane applied magnetic fields.

## 4:54PM P18.00011 Spin-torque ferromagnetic resonance in arbitrarily magnetized thin films ,

JOSEPH SKLENAR<sup>1</sup>, Physics and Astronomy, Northwestern University, Evanston, IL. Materials Science Division, Argonne National Laboratory, Argonne, IL. — The spin Hall effect (SHE) in non-magnetic metals can be used to generate spin-transfer-torque (STT), subsequently inducing ferromagnetic resonance (FMR) in magnetic thin films; this experimental method is termed spin-torque ferromagnetic resonance (ST-FMR). Most ST-FMR experiments that are reported have an applied magnetic field in the plane of the sample and the research focuses on material combinations that have large and efficient STT. The most common way ST-FMR signals are detected is through an anisotropic magnetoresistance (AMR) rectification process. In this work we will present ST-FMR results in thin films where the magnetization has both an in-plane and out-of-plane component. The arbitrary magnetization direction is achieved by tipping the applied magnetic field out of the sample plane. We find that when the material system is a permalloy/Pt bilayer, ST-FMR signals are not mirror-symmetric upon magnetic field reversal<sup>2</sup>. This is because the combination of both a STT from the bulk SHE and the Oersted field-like torque from the device do not drive the dynamics in the same manner when the field is reversed. We interpret our results in the Py/Pt experiment by extending an already established ST-FMR lineshape model to describe the general case of arbitrarily magnetized films. We compare and contrast our Py/Pt experiment with another system we measured, a Py/MoS<sub>2</sub> bilayer. For the Py/MoS<sub>2</sub> system, in-plane experiments suggest that a large STT is present and are comparable to what is observed for the more traditional Py/Pt system<sup>3</sup>. On the other hand, the out-of-plane experiment for the Py/MoS<sub>2</sub> system is qualitatively very different from Py/Pt. Our results suggest that ST-FMR experiments for arbitrarily magnetized magnetic films are useful in characterizing STT generated from interface rather than bulk effects. ### 2:30PM P19.00001 Observation of Temperature Chaos in Mesoscopic Spin Glasses<sup>1</sup> , SAMARESH

GUCHHAIT, Laboratory for Physical Sciences, College Park, MD 20740 and Department of Physics, University of Maryland, College Park, MD 20742 — Temperature Chaos (TC) results from a change in temperature for spin glasses (SG), polymers, and other glassy materials. When the temperature is changed, TC means that the new state has no memory of the preparation of the initial state. TC was predicted long ago [PRL 48, 767 (1982)]. However, “An experimental measurement of TC is still missing” [EPL 103, 67003 (2013)]. One reason for this is the question of length scale. In the thermodynamic limit, even an infinitesimal temperature change,  $\Delta T$ , will create a chaotic condition. However, by working at the mesoscale, one can establish a length scale sufficiently small to exhibit reversible behavior before crossing over to chaotic behavior as the temperature change increases. Observation of TC is possible because, on reasonable laboratory time scales, the SG correlation length can grow to the size of the thickness of the film,  $L$ . The lower critical dimension for a SG is  $\sim 2.5$ , so that the thin film SG crosses over to a glass temperature  $T_g = 0$ . However, there remains quasi-equilibrium SG states with length scales  $< L$ . After crossover, a small  $\Delta T$  will generate a TC coherence length which, if greater than  $L$ , will leave the system in a reversible state. However, when  $\Delta T$  is sufficiently large, such that the TC coherence length is less than  $L$ , and chaos will ensue. I will discuss our recent results of temperature cycling on 15.5 nm SG films of amorphous Ge:Mn. By use of end of aging and temperature cycling, both the reversible region and the chaotic region are observed. Remarkably, the transition from a reversible to chaotic behavior is abrupt, and not smooth as a function of  $\Delta T$ . This is in contrast to previous work using polycrystalline materials where the distribution of length scales smoothed out the transition to chaos. Using the calculated TC critical exponent, the range of  $\Delta T$  for reversible behavior is calculated and is in very good agreement with the measured range.

### 3:06PM P19.00002 An Investigation of the Spin Glass Properties of the Solid Solution

$\text{CuAl}_{2-2x}\text{Ga}_{2x}\text{O}_4$  , THOMAS BULLARD, UES Inc, JACILYNN BRANT, National Research Council/TheAir Force Research Laboratory, CHARLES EBBING, The University of Dayton Research Institute, NEIL DILLEY, J. HAMILTON, Quantum Design, TIMOTHY HAUGAN, The Air Force Research Laboratory — The complete anti-ferromagnetic oxide spinel solid solution between end members  $\text{CuAl}_2\text{O}_4$  and  $\text{CuGa}_2\text{O}_4$  has been synthesized. The crystallographic and magnetic properties are examined as Ga is replaced with iso-valent Al. Crystallographic results show the solid solution obeys Vegard's law, and the cation distribution among the tetrahedral and octahedral sites matches well with prior results. The evolution of the magnetic susceptibility is examined as a function of temperature and doping percentage. Evidence is presented that indicates that the majority of the solution displays paramagnetic behaviour at high temperatures and spin glass behaviour below 3K. Specifically, a freezing temperature in the AC susceptibility, irreversibility in the DC magnetization, and relaxation dynamics in the presence of a changing applied field are observed.

### 3:18PM P19.00003 Nonlinear scaling variable at the lower critical dimension: Scaling in the 2D random field Ising model<sup>1</sup> , LORIEN HAYDEN, JAMES SETHNA, Cornell Univ —

We systematically analyze the nonlinear invariant scaling variables at bifurcations in the renormalization-group flow, and apply our methods to the two-dimensional random-field Ising model (RFIM). At critical points, the universal scaling functions are usually written in terms of homogeneous invariant combinations of variables, like  $Lt^\nu$  in the finite-size scaling form for the magnetization  $M(T|L) \sim t^{-\beta} M(Lt^\nu)$ , where  $t \propto T_c - T$ . The renormalization-group flow for the RFIM has a pitchfork bifurcation in two dimensions, where the correlation length has been argued to diverge exponentially,  $\xi \propto \exp^{1/2At^2}$ , leading to the invariant scaling combination  $L/\xi \sim L/\exp^{1/2At^2}$ . Our analysis, inspired by normal-form theory, suggests that this exponential divergence can take a richer, more general scaling form at a generic pitchfork bifurcation. We explore possible consequences for simulations.

**3:30PM P19.00004 Response to a field of the  $D = 3$  Ising spin glass with Janus and JanusII dedicated computers<sup>1</sup>**, BEATRIZ SEOANE, LPT, Ecole Normale Supérieure, JANUS COLLABORATION COLLABORATION<sup>2</sup> — Using the Janus dedicated computer, and its new generation JanusII, we study the linear response to a field of the Edwards-Anderson model for times that cover twelve orders of magnitude. The fluctuation-dissipation relations are investigated for several values of  $t_w$ . We observe that the violations of the fluctuation-dissipation theorem can be directly related to the  $P(q)$  measured in equilibrium at finite sizes, although a simple statics-dynamics dictionary  $L \leftrightarrow \xi(t_w)$  is not enough to account for the behavior at large times. We show that the equivalence can be easily restored by taking into account the growth of  $\xi(t + t_w)$ . Interestingly, experimental measurements of the spin glass correlation length rely precisely on the response of a spin glass to a field, although a direct relation between the measured object and the real  $\xi$  has never been established. In this work, we mimic the experimental protocol with Janus data, which lets us relate the experimental  $\xi$  with the length extracted from the spatial correlation function. These results allow us for the first time to make a quantitative comparison between experiments and simulations, finding a surprising good agreement with measurements in superspin glasses.

**3:42PM P19.00005 Extremely large magnetoresistance and magnetic logic by coupling semiconductor nonlinear transport effect and anomalous Hall Effect.**, XIAOZHONG ZHANG, ZHAOCHU LUO, Tsinghua University — Size limitation of silicon FET hinders the further scaling down of silicon based CPU. To solve this problem, spin based magnetic logic devices were proposed but almost all of them could not be realized experimentally except for NOT logic operation. A magnetic field controlled reconfigurable semiconductor logic using InSb was reported. However, InSb is very expensive and not compatible with the silicon technology. Based on our Si based magnetoresistance (MR) device [1], we developed a Si based reconfigurable magnetic logic device [2], which could do all four Boolean logic operations including AND, OR, NOR and NAND. By coupling nonlinear transport effect of semiconductor and anomalous Hall effect of magnetic material, we propose a PMA material based MR device with a remarkable non local MR of >20000 % at ~1 mT. Based on this MR device, we further developed a PMA material based magnetic logic device which could do all four Boolean logic operations. This makes it possible that magnetic material does both memory and logic. This may result in a memory-logic integrated system leading to a non von Neumann computer. [1] CH Wan, et al, Nature **477**, 304, (2011). [2] ZC Luo et al. Adv. Funct. Mater. **25**, 158, (2015).

**3:54PM P19.00006 Effects of transverse fields on spin-valve sensor magnetic field measurements**, ALEX JEFFERS, University of Maryland, ANTONIO OROZCO, Neocera, Beltsville, MD, ALFRED CAWTHORNE, Trevecca Nazarene University, Nashville, TN, CHRISTOPHER ROWLETT, STEVE GARRAHAN, Neocera, Beltsville, MD, FREDERICK WELLSTOOD, University of Maryland, College Park, MD — Spin-valve sensors have become a popular magnetic sensor, used in many applications such as magnetic imaging or hard drive heads. Spin-valves are designed to measure only one component of the magnetic field. This component is determined by the composition of the spin-valve layers, the manufacturing conditions, shape anisotropy, and other design decisions. We took magnetic images of L-shaped samples in order to determine if magnetic fields transverse to the direction of measurement affect spin-valve sensors. Specifically, we used a 2 m by 4 m Cu-Mn-Ir spin-valve sensor to take image of chips with “L-shaped” currents. We find that transverse fields can significantly affect the measurement direction of spin-valve sensors.

**4:06PM P19.00007 Effect of tantalum on magnetocrystalline anisotropy and tunneling magnetoresistance in MgO/CoFeB junction from ab-initio calculations**, ROMAN CHEPULSKYY, DMYTRO APALKOV, New Memory Technology, Samsung Semiconductor RD Center, Samsung Electronics — Using ab-initio calculations, we demonstrate that boron is energetically attracted toward interface between MgO and CoFeB in MgO/CoFeB junction. We show that both magnetocrystalline anisotropy (MCA) and tunneling magnetoresistance (TMR) decrease when boron is present at the interface. However, when tantalum is used as seeding or capping layer (Ta/CoFeB/MgO), the segregation profile of boron changes. Namely, the most energetically preferable position of boron is inside and near tantalum rather than at MgO/CoFeB interface. Such change of boron segregation profile results in boron diffusion from MgO/CoFeB interface toward tantalum at annealing. The diffusion of boron toward tantalum may explain the experimentally observed effect of tantalum on increase of both MCA and TMR in MgO/CoFeB junction

**4:18PM P19.00008 Growth and properties of High-quality metal/ yttrium iron garnet/metal sandwich structures<sup>1</sup>**, MOHAMMED ALDOSARY, JUNXUE LI, CHI TANG, YADONG XU, JING SHI, University of California — Sandwiched structures of magnetic insulators (e.g. yttrium iron garnet or YIG) between two normal metals are potentially useful for spintronics. In this work, we report our approach of growing a single crystalline YIG thin film on a Pt or Cu thin layer using the combination of sputtering and PLD. First, either 5 nm of Pt or Cu is deposited on (110)-oriented gadolinium gallium garnet (GGG) substrate using sputtering and then YIG is grown by PLD at intermediate temperatures followed by rapid thermal annealing at higher temperatures. Surprisingly, YIG films show a well-defined single-crystal reflection high energy electron diffraction (RHEED) pattern, despite that they are grown on polycrystalline Pt or Cu. TEM images show flat, clean and sharp interfaces between YIG/metals and metals/GGG. The magnetic properties show in-plane magnetic anisotropy. However, when thicker metallic layers (20 nm) or amorphous (metals/SiO<sub>2</sub>) substrate are used, only YIG polycrystalline phase is observed. We will show that by properly controlling the growth conditions the metal/YIG/ metal structures are not only of high structural quality, but also have desired properties for spin current transport.

**4:30PM P19.00009 Switching behavior of Nb/Exchange spring magnet/Nb Josephson Junctions fabricated by Nanosphere Lithography**, JIYEONG GU, GILBERT ARIAS, SAMUEL HEDGES, Dept. of Physics and Astronomy, California State University, Long Beach — Superconductor(S)/ferromagnet(F)/superconductor Josephson junction was fabricated by nanosphere lithography method. Samarium-Cobalt (SmCo)/Permalloy(Py) exchange spring magnet system was used to generate an inhomogeneous magnetic structure in Niobium(Nb)-based Josephson junctions. We introduced nanosphere lithography in our device fabrication in order to decrease the lateral size of junctions and improve the quality of our devices. A bigger size junctions (tens of microns) were fabricated by optical photolithography using a mask.\* Materials were deposited through DC magnetron sputtering. Base structure of devices was patterned through photolithography. Modulations of the critical current and IV-curve characteristics of the junction were used to search for direct evidence of the odd-triplet component. In addition, to investigate the switching behavior of S/F/S junction for memory application junction critical current was measured as a function of magnetic field and the angle between an easy axis of ferromagnetic layer and the external magnetic field by rotating the sample under magnetic field. Magnetic switching behavior of the ferromagnetic layers in our junction was also characterized based on this observation. \* Junction fabrication in this research by an optical photolithography using a mask was conducted at the Center for Nanophase Materials Sciences at Oak Ridge National Laboratory (CNMS User Project CNMS2014-257).

#### 4:42PM P19.00010 How to move domain walls in an antiferromagnet<sup>1</sup>, SE KWON KIM, Univ of California

- Los Angeles — Domain walls (DWs) in an easy-axis antiferromagnet can be driven by several stimuli: a charge current (in conducting antiferromagnets), a magnon current, and a temperature gradient. In this talk, we discuss the dynamics of a DW induced by two latter external perturbations, which are applicable in both metallic and insulating antiferromagnets. First of all, we study the Brownian dynamics of a DW subjected to a temperature gradient [1]. To this end, we derive the Langevin equation for the DW's center of mass with the aid of the fluctuation-dissipation theorem. A DW behaves as a classical massive particle immersed in a viscous medium. By considering a thermodynamic ensemble of DWs, we obtain the Fokker-Planck equation, from which we extract the average drift velocity of a DW. We briefly address other mechanisms of thermally driven DW motion. Secondly, we analyze the dynamics of a DW driven by circularly polarized magnons [2]. Magnons passing through a DW reverse their spin upon transmission, thereby transferring two quanta of angular momentum to the DW and causing it to precess. A precessing DW partially reflects magnons back to the source. The reflection of magnons creates a previously identified reactive force [3]. We point out a second mechanism of propulsion of the DW, which we term redshift: magnons passing through a precessing DW reduce their linear momentum and transfer the decrease to the DW. We solve the equations of motion for magnons in the background of a uniformly precessing DW with the aid of supersymmetric quantum mechanics and compute the net force and torque applied by magnons to the DW. The theory agrees well with micromagnetic simulations.

#### 5:18PM P19.00011 Spin correlations and spin-wave exci-

YASUFUMI ARAKI, Institute for Materials Research, Tohoku University; Frontier Research Institute for Material Science, Tohoku University; NOMURA, Institute for Materials Research, Tohoku University — We study correlations among spin correlations and spin-wave excitations in semimetals. Effective field theory for localized magnetic moments is derived by integrating out the spin correlation in the spatial direction parallel to local magnetization is more rigid than that in the nature of the Dirac Hamiltonian. Such an anisotropy becomes stronger for Fermi level close to the Dirac point by spin-orbit coupling. One can expect topologically nontrivial spin textures under this anisotropy, such as around an axis, as well as a uniform ferromagnetic order. We further investigate the characteristics of spin-wave dispersion also shows a spatial anisotropy, which is less dispersed in the direction transverse to the magnetization. The dispersion anisotropy can be traced back to the rigidity and flexibility of spin correlations discussed

ence and Technology (MEXT), Japan.

Session P20 DCOMP: Quantum Many-Body Systems and Methods III 319 - Herbert Fotso

#### 2:30PM P20.00001 QMC calculations of the dynamical local field factor of the 2D electron gas

, NATALIA MATVEEVA, MARKUS HOLZMANN, LPMCM, UMR 5493 of CNRS, Universite Grenoble Alpes, F-38100 Grenoble, France, DAVID CEPERLEY, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801, USA — We develop a new quantum Monte Carlo method to calculate imaginary time correlation functions for fermions in continuous space in order to access spectral functions. Linear response in imaginary time is obtained based on the variational expression of the thermal density matrix. The exact dynamics is recovered in the non-interacting limit. We apply our new method to the electron gas in two dimensions in the high and low density region and calculate the density fluctuations including many-body correlations in the density matrix. The dynamic structure factor can be accessed by analytic continuation. Our results provides accurate estimation of the dynamical local field factor which quantifies corrections to the RPA approximation.

#### 2:42PM P20.00002 Ab Initio Thermodynamic Results for the Degenerate Electron Gas at Finite Temperatures

, TIM SCHOOF, TOBIAS DORNHEIM, SIMON GROTH, Kiel University, JAN VORBERGER, Helmholtz-Zentrum Dresden-Rossendorf, MICHAEL BONITZ, Kiel University — Recent advances in warm dense matter physics, e.g. laser compressed matter, lead to an increasing interest in the description of correlated, degenerate electrons at finite temperatures. The uniform electron gas (UEG) is of key relevance for the understanding of such systems. Accurate thermodynamic data for the UEG are essential for the development of the finite-temperature density functional theory (FT-DFT). Based on first principles, the Configuration PIMC approach (CPIMC) allows for the exact computation of thermodynamic properties of strongly degenerate fermionic many-body systems in the highly degenerate regime [1]. We present CPIMC exchange-correlation energies for the UEG [2] and compare our results with previous restricted path integral Monte Carlo (RPIMC) [3] and recently published permutation-blocking PIMC (PB-PIMC) [4] data. We show that the complementary sign problem of the CPIMC and PB-PIMC methods allows for results with an unprecedented accuracy in a wide range of temperatures and densities.

#### 2:54PM P20.00003 Identification of polaronic defects in wide band gap semiconductors via diffusion Monte Carlo

, JAEHYUNG YU, ELIF ERTEKIN, Univ of Illinois - Urbana — Polaronic defects are important to understanding a wide variety of properties in semiconductors; for instance they are closely coupled to electron phonon interactions and can greatly affect carrier concentrations and mobilities. The formation of a polaronic defect in a semiconductor is an interesting phenomenon because it incorporates a trade off between electron localization and structural relaxation. Because of its small energy scale and the localized nature of polaronic defect levels, accurately describing polaronic defects in semiconductors requires high accuracy first principle calculation methods. We demonstrate the use of the fixed node diffusion Monte Carlo (DMC) method to the identification of polaronic nitrogen defects in the wide band gap semiconductor zinc oxide. Using DMC, we can demonstrate that nitrogen defects in ZnO are subject to a symmetry-breaking Jahn-Teller distortion, which deepens the defect level in the band gap. Our DMC results for defect transition levels and optical transitions are in good agreement with recent experiments. Our results demonstrates that highly accurate treatment of electron correlation can improve prediction of defect properties in challenging semiconductor materials.

**3:06PM P20.00004 Diffusion Monte Carlo study of the metal-insulator transition in stretched graphene<sup>1</sup>**, LI CHEN, LUCAS K. WAGNER, University of Illinois at Urbana Champaign — At low energies and equilibrium geometries, graphene is well-described by a single-band Hubbard model[1], with  $U/t$  1.4, which is well within the semimetal regime. One would expect that under tensile stress,  $U/t$  should increase and a transition from semimetal to Mott insulator should occur. However, the bonding  $\sigma$  electrons are also affected by the stretching and may affect the applicability of the single-band model. At the same time, the critical region near the metal-insulator transition is a highly multi-determinantal ground state which is a challenging case for fixed node diffusion Monte Carlo simulations. We address progress on both these points by assessing a number of wave functions for the critical region around the transition and assessing the validity of the single-band Hubbard model using the method of Ref 1. [1]. Changlani, Zheng, and Wagner, J. Chem. Phys. 143, 102814 (2015).

**3:18PM P20.00005 Time-dependent many-variable variational Monte Carlo method for nonequilibrium strongly correlated electron systems**, KOTA IDO, TAKAHIRO OHGOE, MASATOSHI IMADA, Univ. of Tokyo — Strongly correlated electron systems driven out of equilibrium have attracted much attention because of potential routes to realizing intriguing phenomena that are not attainable in the equilibrium. To treat such systems, we propose a time-dependent trial wave function with many variational parameters for the time-dependent variational Monte Carlo (t-VMC) method [1]. As the trial state, we adopt the generalized pair-product wave function with correlation factors and quantum-number projections. This trial wave function has been proven to accurately describe ground states of strongly correlated electron systems [2]. To show the accuracy and efficiency of our trial wave function in nonequilibrium states as well, we present our benchmarks for relaxation dynamics during and after interaction quench protocols of the Hubbard models both at and away from half-filling. We find that our trial wave function well reproduces the exact results for the time evolution of physical quantities such as momentum distribution and superconducting correlations. We discuss how the accuracy depends on the level of trial wave functions. [1] K. Ido, T. Ohgoe, and M. Imada, arXiv: 1507.00274. [2] D. Tahara and M. Imada, J. Phys. Soc. Jpn. 77,114701(2008).

**3:30PM P20.00006 ABSTRACT WITHDRAWN —**

**3:42PM P20.00007 Stochastic Approximation of Dynamical Exponent at Quantum Critical Point**, HIDEMARO SUWA, Department of Physics, The University of Tokyo, SHINYA YASUDA, Department of Applied Physics, The University of Tokyo, SYNGE TODO, Department of Physics, The University of Tokyo — We have developed a unified finite-size scaling method for quantum phase transitions that requires no prior knowledge of the dynamical exponent  $z$ . During a quantum Monte Carlo simulation, the temperature is automatically tuned by the Robbins-Monro stochastic approximation method, being proportional to the lowest gap of the finite-size system. The dynamical exponent is estimated in a straightforward way from the system-size dependence of the temperature. As a demonstration of our novel method, the two-dimensional  $S = 1/2$  quantum  $XY$  model, or equivalently the hard-core boson system, in uniform and staggered magnetic fields is investigated in the combination of the world-line quantum Monte Carlo worm algorithm. In the absence of a uniform magnetic field, we obtain the fully consistent result with the Lorentz invariance at the quantum critical point,  $z = 1$ . Under a finite uniform magnetic field, on the other hand, the dynamical exponent becomes two, and the mean-field universality with effective dimension  $(2+2)$  governs the quantum phase transition. We will discuss also the system with random magnetic fields, or the dirty boson system, bearing a non-trivial dynamical exponent.

**4:06PM P20.00009 Diffusion Quantum Monte Carlo predictions for bulk  $\text{MnNiO}_3$ <sup>1</sup>**, CHANDRIMA MITRA, JARON KROGEL, FERNANDO A. REBOREDO, Oak Ridge National Laboratory —  $\text{MnNiO}_3$  is a strongly correlated transition metal oxide that has recently been investigated theoretically for its potential application as an oxygen-evolution photo-catalyst. However, there is no experimental report on critical quantities like its band gap or its bulk modulus. Recent theoretical predictions with standard functionals, such as PBE+U and HSE show large discrepancies in the band-gaps (about 1.23 eV), depending on the nature of the functional used. Hence, there is clearly a need for an accurate quantitative prediction of the band-gap in order to decide its usefulness as a photo-catalyst. In this work, we present Diffusion Quantum Monte Carlo (DMC) study of the bulk properties of  $\text{MnNiO}_3$ . This includes the quasiparticle band gap for the two spin channels, the equilibrium lattice parameter and the bulk modulus. The DMC approach has already been shown to achieve excellent agreement with experimental results for other oxides such as  $\text{ZnO}$ ,  $\text{NiO}$  and  $\text{Fe}_2\text{O}_3$ . To our knowledge,  $\text{MnNiO}_3$  is the first case where this theory is applied before experiments are done.

**4:18PM P20.00010 Fragmented Molecular Orbital with Diffusion Monte Carlo for large molecular systems**, ANOUAR BENALI, SPENCER R. PRUITT, Argonne National Laboratory - USA, DMITRI G. FEDOROV, National Institute of Advanced Industrial Science and Technology (AIST) - Japan — Performing accurate quantum mechanics (QM) calculations on larger and larger systems, while maintaining a high level of accuracy is an ongoing effort in many ab initio fields. Many different attempts have been made to develop highly scalable and accurate methods. The fragment molecular orbital (FMO) method is an ab initio method capable of taking advantage of modern supercomputers, such as the Blue Gene Q system Mira at the Argonne National Laboratory Leadership Computing Facility (ALCF). FMO is based on dividing molecules into fragments and performing ab initio calculations on fragments, their dimers and, optionally, trimers. This decomposition makes it possible to perform QM calculations of real size biological molecules. In contrast to many other fragment-based methods, the effect of the environment is rigorously accounted for by computing the electrostatic potential (ESP) due to remaining fragments that are not explicitly included in a given monomer, dimer, or trimer calculation. The use of highly accurate levels of theory, such as Diffusion Monte Carlo (DMC-QMC), in conjunction with FMO allows for the goal of highly scalable and accurate all electron calculations demonstrated in this study, on a variety of relevant systems ( $\text{H}_2\text{O}$ )[3-6] and protein using GAMESS and QMCPACK.

**4:30PM P20.00011 Improved measurement scheme of the self energy in the worm-sampled hybridization-expansion quantum Monte Carlo**, MANCHEON HAN, CHOONG-KI LEE, HYOUNG JOON CHOI, Department of Physics, IPAP, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University — Hybridization-expansion continuous-time quantum Monte Carlo (CT-HYB) is a popular approach in real material researches because it allows to deal with non-density-density-type interaction. In the conventional CT-HYB, we measure Green's function and find the self energy from the Dyson equation. Because one needs to compute the inverse of the statistical data in this approach, obtained self energy is very sensitive to statistical noise. For that reason, the measurement is not reliable except for low frequencies. Such an error can be suppressed by measuring a special type of higher-order correlation function and is implemented for density-density-type interaction [1]. With the help of the recently reported worm-sampling measurement [2], we developed an improved self energy measurement scheme which can be applied to any type of interactions. As an illustration, we calculated the self energy for the 3-orbital Hubbard-Kanamori-type Hamiltonian with our newly developed method. This work was supported by NRF of Korea (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2015-C3-039). [1] H. Hafermann et al., Phys. Rev. B, 85, 205106 (2012) [2] P. Gunacker et al., Phys. Rev. B, 92, 155102 (2015)

**4:42PM P20.00012 Reducing memory demands of splined orbitals in diffusion Monte Carlo calculations**<sup>1</sup>, JARON KROGEL, FERNANDO REBORDO, Oak Ridge National Lab — Quantum Monte Carlo calculations of defect properties of transition metal oxides have become feasible in recent years due to increases in computing power. As the system size has grown, availability of on-node memory has become a limiting factor. The main growth in memory demand stems from the B-spline representation of the single particle orbitals, especially for heavier elements such as transition metals where semi-core states are present. Despite the associated memory costs, splines are computationally efficient. In this work, we explore alternatives to reduce the memory usage of splined orbitals without significantly affecting numerical fidelity or computational efficiency. For the example case of bulk MnO we have currently achieved a memory savings of 50% while only increasing the overall computational cost of the simulation by 15%.

**4:54PM P20.00013 Quantum Monte Carlo Computations of the (Mg<sub>1-x</sub>Fe<sub>x</sub>)SiO<sub>3</sub> Perovskite to Post-perovskite Phase Boundary**<sup>1</sup>, YANGZHENG LIN, Extreme Materials Initiative, Geophysical Lab, Carnegie Institution, R.E. COHEN, EMI, Geophysical Lab, Carnegie Inst; Dept. für Geo- und Umweltwissenschaften, Ludwig-Maximilians-Universität, ANDREA FLORIS, Dept Physics, King's College, LUKE SHULENBURGER, Sandia National Labs, KEVIN P. DRIVER, Dept Earth & Planet Sci, Univ of California, Berkeley — We have computed total energies of FeSiO<sub>3</sub> and MgSiO<sub>3</sub><sup>[1]</sup> perovskite and post-perovskite using diffusion Monte Carlo with the qmcpack GPU code. In conjunction with DFT+U computations for intermediate compositions (Mg<sub>1-x</sub>Fe<sub>x</sub>)SiO<sub>3</sub> and phonons computed using density functional perturbation theory (DFPT) with the pwscf code, we have derived the chemical potentials of perovskite (Pv) and post-perovskite (PPv) (Mg<sub>1-x</sub>Fe<sub>x</sub>)SiO<sub>3</sub> and computed the binary phase diagram versus P, T, and X using a non-ideal solid solution model. The finite temperature effects were considered within quasi-harmonic approximation (QHA). Our results show that ferrous iron stabilizes PPv and lowers the Pv-PPv transition pressure, which is consistent with previous theoretical and some experimental studies. We will discuss the correlation between the Earth's D layer and the Pv to PPv phase boundary. Computations were performed on XSEDE machines, and on the Oak Ridge Leadership Computing Facility (OLCF) machine Titan under project CPH103geo of INCITE program. [1] Lin et al., Phys. Rev. B 90(18), 184103 (2014)

**5:06PM P20.00014 Fixed-phase vs fixed-node quantum Monte Carlo with local and nonlocal interactions**, LUBOS MITAS, CODY MELTON, North Carolina State Univ — We study several systems that can be formulated in the fixed-phase and/or fixed-node framework in quantum Monte Carlo calculations. In particular, we try to understand the differences between the biases caused by these approximations that result from using complex vs real trial wave functions. One system is a model that enables us to construct systematically the same type of nodal errors in both real and complex formalism. The errors are comparably similar whenever trial functions are correspondingly accurate. Another aspect of the fixed-phase vs fixed-node approximations is studied for systems with nonlocal operators such as with pseudopotentials and/or spin-orbit effects. We specify how to obtain variational formulation for complex wave functions and nonlocal operators in a manner analogous to the fixed-node calculations with T-moves algorithm. In particular, we show that the fixed-phase/fixed-node is the primary condition for proving that the upper bound property holds.

**2:30PM P21.00001 Moving beyond feasibility in ultrafast shock chemistry experiments**<sup>1</sup>, MICHAEL ARMSTRONG, JAMES LEWICKI, JONATHAN CROWHURST, JOSEPH ZAUG, HARRY RADOUSKY, ELISSAIOS STAVROU, APRIL SAWVEL, Lawrence Livermore National Laboratory — Although ultrafast hydrodynamic methods to investigate the chemistry of shocked materials on ps to ns time scales are generally mature, questions about the interpretation of such experiments remain. Most ultrafast experiments employ shock etalon methods whose interpretation depends on assumptions about the index of refraction of the shocked state. Further, although signatures for chemistry in longer time scale time-of-flight (ToF) experiments are well understood, ultrafast chemistry experiments have not typically employed ToF methods. The use of ToF methods in ultrafast experiments would enable a more straightforward connection to longer time scale data, and would generally provide more information than shock etalon methods. Finally, ultrafast experiments have not been performed over time scales greater than a few hundred of picoseconds, significantly limiting the scope of experiments to observe shocked chemistry under typical conditions at larger length scales. Here we address all of these issues by presenting data from shocked polymers obtained using both ToF and shock etalon methods, using a 1 ns pump and observation window. We compare the results of these two methods to reconcile data from these different methods and strengthen the interpretation of both types of experiment.

**2:42PM P21.00002 High-temperature thermal degradation of polyethylene from reactive molecular dynamics**, J. MATTHEW D. LANE, NATHAN W. MOORE, Sandia Natl Labs — Thermal degradation of polyethylene is studied under extremely high-rate temperature ramp rates from  $10^{14}$  to  $10^{10}$  K/s in isochoric, condensed phases. The molecular evolution and macroscopic state variables are extracted as a function of density from reactive molecular dynamics simulations using the ReaxFF potential. These results are used to parameterize a kinetic rate model for the dissociation and coalescence of hydrocarbons as a function of temperature, temperature ramp rate, and density. The results are contrasted to first-order random-scission macrokinetic models often assumed for pyrolysis of linear polyethylene under ambient conditions. Sandia National Laboratories is a multi program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Administration under contract DE-AC04- 94AL85000.

**2:54PM P21.00003 Using Force-Matched Potentials To Improve the Accuracy of Density Functional Tight Binding for Reactive Conditions**, NIR GOLDMAN, Lawrence Livermore National Laboratory — In this work, we show that force matching can be used to determine accurate density functional tight binding (DFTB) models for reactive materials under extreme conditions. Determination of chemical reactivity in high-pressure experiments is an unsolved problem that can span timescales orders of magnitude longer than what can be achieved with standard quantum simulation approaches, such as Kohn-Sham Density Functional Theory. DFTB holds promise as a semi-empirical quantum simulation method that yields a high degree of computational efficiency while potentially retaining the accuracy of these higher order methods. Here, we show that force matching can be used to determine accurate repulsive energies for DFTB for chemical reactivity in condensed phases. Our new models yield improved predictions for physical properties of molten liquid carbon, as well as small molecule production in phenolic polymer combustion. Our approach is general and can be implemented as a way to extend quantum simulations to several orders of magnitude longer timescales than previously possible, allowing for direct comparison with experiments.

**3:06PM P21.00004 High-Velocity Collisions of Nanoparticles**, DONALD JOHNSON, WILLIAM MATTSON, Army Research Laboratory — Nanoparticles (NPs) are interesting materials with exciting applications due to their large surface-to-volume ratio and functionalizable surfaces. The large surface area and potentially high surface tension might result in unique materials behavior when subject to shock loading. Using density functional theory, we have simulated high-velocity NP collisions producing high-pressure, high-temperature, and extreme shock conditions. NPs composed of diamond-C, cubic-BN, and diamond-Si were considered with particle sizes up to 3.5 nm diameter. Some simulations involved NPs that were destabilized by incorporating internal strain. Normal, spherical NPs were carved out of bulk crystals and structurally optimized while the NPs with internal strain were constructed as a dense core (compressive strain) encompassed by a thin shell (tensile strain). Both on-axis and off-axis collisions were simulated at various speeds. Collision dynamics, shock propagation, and fragmentation will be presented and analyzed. The effect of material properties, internal strain, and collision velocity on the final temperature of the fragments will be discussed.

**3:18PM P21.00005 Non-equilibrium Reaction Kinetics in Molecular Solids**, MITCHELL WOOD, ALEJANDRO STRACHAN, Materials Engineering, Purdue University — We explore the possibility of non-statistical chemical reactions in condense-phase energetic materials via reactive molecular dynamics (MD) simulations. We characterize the response of three unique high energy density molecular crystals to different types of insults: electric fields of various frequencies ( $100\text{-}4000\text{cm}^{-1}$ ) and strengths and direct heating at various rates. We find that non-equilibrium states can be created for short timescales when energy input targets specific vibrations through the electric fields, and that equilibration eventually occurs even while the insults remain present. Interestingly, for strong fields these relaxation timescales are comparable to those of the initial chemical decomposition of the molecules. Details of how this vibrational energy localization affects the preferred uni- or multi-molecular reactions are discussed. These results provide insight into non-equilibrium or coherent initiation of chemistry in the condensed phase that would of interest in fields ranging from catalysis to explosives.

**3:30PM P21.00006 Detonation Propagation in Slabs and Axisymmetric Rate Sticks<sup>1</sup>**, CHRISTOPHER ROMICK, None, TARIQ ASLAM, Los Alamos National Laboratory — Insensitive high explosives (IHE) have many benefits; however, these IHEs exhibit longer reaction zones than more conventional high explosives (HE). This makes IHEs less ideal explosives and more susceptible to edge effects as well as other performance degradation issues. Thus, there is a resulting reduction in the detonation speed within the explosive. Many HE computational models, e. g. WSD, SURF, CREST, have shock-dependent reaction rates. This dependency places a high value on having an accurate shock speed. In the common practice of shock-capturing, there is ambiguity in the shock-state due to smoothing of the shock-front. Moreover, obtaining an accurate shock speed with shock-capturing becomes prohibitively computationally expensive in multiple dimensions. The use of shock-fitting removes the ambiguity of the shock-state as it is one of the boundaries. As such, the required resolution for a given error in the detonation speed is less than with shock-capturing. This allows for further insight into performance degradation. A two-dimensional shock-fitting scheme has been developed for unconfined slabs and rate sticks of HE. The HE modeling is accomplished by Euler equations utilizing several models with single-step irreversible kinetics in slab and rate stick geometries.

<sup>1</sup>Department of Energy - LANL

**3:42PM P21.00007 Laser-shocked energetic materials with metal additives: evaluation of detonation performance**, JENNIFER GOTTFRIED, ERIC BUKOWSKI, US Army Rsch Lab - Aberdeen — A focused, nanosecond-pulsed laser with sufficient energy to exceed the breakdown threshold of a material generates a laser-induced plasma with high peak temperatures, pressures, and shock velocities. Depending on the laser parameters and material properties, nanograms to micrograms of material is ablated, atomized, ionized and excited in the laser-induced plasma. The subsequent shock wave expansion into the air above the sample has been monitored using high-speed schlieren imaging in a recently developed technique, laser-induced air shock from energetic materials (LASEM) [1]. The estimated detonation velocities using LASEM agree well with published experimental values. A comparison of the measured shock velocities for various energetic materials including RDX, DNTF, and LLM-172 doped with Al or B to the detonation velocities predicted by CHEETAH for inert or active metal participation demonstrates that LASEM has potential for predicting the early time participation of metal additives in detonation events. The LASEM results show that reducing the amount of hydrogen present in B formulations increases the resulting detonation velocities. [1] J.L. Gottfried, Propellants Explos. Pyrotech. 40, 674 (2015).

**3:54PM P21.00008 The Equation of State of PBX 9502**, TARIQ ASLAM, Los Alamos Natl Lab — Reactive flow modeling of high explosives (HEs) requires accurate equation of states (EOS) for both the HE's reactants and products. The Wescott-Stewart-Davis "wide-ranging EOS" model will be examined. A procedure for calibrating both the reactants and products for this EOS will be presented. Several thermodynamic pathways will be explored for the plastic bonded HE PBX 9502. These include: isothermal compression, isentropic compression, single and multiple shock compression, isobaric thermal expansion, adiabatic expansion of the products and the overdriven detonation state. Data from several different experimental techniques are employed to constrain model parameters. Validation tests of the model EOS will also be presented.

**4:06PM P21.00009 Measuring HOMO/LUMO gap of explosive film at air interface using ESFG: model for explosive at void surface**, DARCIE FARROW, IAN KOHL, SEAN KEARNEY, STEPHEN RUPPER, LAURA MARTIN, KATHY ALAM, ROBERT KNEPPER, JEFFERY KAY, Sandia Natl Labs — Vibrational broadband sum frequency generation has enabled measurements of heat transfer/disorder under shock compression on monolayer length scales (Carter, JPCA, 2008). At Sandia, we are extending this approach to examine shock-induced changes in the electronic structure of secondary explosives at surfaces using electronic sum frequency generation (ESFG)(Yamaguchi, JCP, 2008). Theoretical studies suggest explosives at voids and grain boundaries may have different reactivity than bulk material based on shifts in the bandgap at defects (Kuklja, Appl. Phys. A 2003). We seek to measure these electronic shifts for the first time using a thin film explosive samples as a model for the void surface. We will report electronic sum frequency data from vapour deposited thin film explosive compared to UV/Vis data of the bulk film at ambient pressures and discuss application of ESFG technique to samples under shock compression.

**4:18PM P21.00010 Shock wave propagation in semi-crystalline polyethylene: An atomic-scale investigation**, ROBERT M. ELDER, U.S. Army Research Laboratory, THOMAS C. O'CONNOR, Johns Hopkins University, Physics and Astronomy, IN-CHUL YEH, TANYA L. CHANTAWANSRI, TIMOTHY W. SIRK, U.S. Army Research Laboratory, MARK O. ROBBINS, Johns Hopkins University, Physics and Astronomy, JAN W. ANDZELM, U.S. Army Research Laboratory — Highly oriented polyethylene (PE) fibers are used in protection applications, therefore elucidation of their response under high strain-rate impact events is vital. Although PE fibers can have high crystallinity (>95%), they also contain defects such as amorphous domains. Using molecular dynamics simulations, we investigate shock propagation through crystalline, amorphous, and semi-crystalline PE. We generate compressive shock waves of varying strength, quantify their dynamics, and characterize their effect on material properties at the atomic scale. In the semi-crystalline PE model, the differing density and molecular order of amorphous PE and crystalline PE result in differing shock impedances, which causes reflection and refraction of shock waves at interfaces between the phases. We quantify the properties (e.g. pressure, velocity) of the reflected and refracted waves, which differ from those of the incident wave, and compare with results from impedance matching. We also examine the reflection, absorption, and transmission of energy at the crystalline-amorphous interface. Depending on shock strength, amorphous defects can dissipate shock energy, which attenuates the shock and leads to effects such as localized heating.

**4:30PM P21.00011 Hierarchical Multiscale Framework for Materials Modeling: Advances in Scale-Bridging Applied to a Taylor Anvil Impact Test of RDX**, BRIAN BARNES, KENNETH LEITER, RICHARD BECKER, JAROSLAW KNAP, JOHN BRENNAN, US Army Research Laboratory — As part of a multiscale modeling effort, we present progress on a challenge in continuum-scale modeling: the direct incorporation of complex molecular-level processes in the constitutive evaluation. In this initial phase of the research we use a concurrent scale-bridging approach, with a hierarchical multiscale framework running in parallel to couple a particle-based model (the "lower scale") computing the equation of state (EOS) to the constitutive response in a finite-element multi-physics simulation (the "upper scale"). The lower scale simulations of 1,3,5-trinitroperhydro-1,3,5-triazine (RDX) use a force-matched coarse-grain model and dissipative particle dynamics methods, and the upper scale simulation is of a Taylor anvil impact experiment. Results emphasize use of adaptive sampling (via dynamic kriging) that accelerates time to solution, and its comparison to fully "on the fly" runs. Work towards inclusion of a fully reactive EOS is also discussed.

**4:42PM P21.00012 Instantaneous Point Explosion in Incompressible Fluid-like Media**, MICHAEL GRINFELD, STEVEN SEGLETES, The US Army Research Laboratory — The problem of point explosion is one of the most famous and extensively developed in in the sense of corresponding physics, mechanics, and applied mathematics. There are many reasons for that based on its practical importance and theoretical beauty. We refer interested readers to the publications of Sedov, Taylor, Landau and Lifshitz, and Lavrent'ev and Shabat. In the paper, we discuss this classical program from the standpoint of terminal ballistics and present our novel results relating to the special situation when the media can be treated as an "effective" incompressible liquid. Sedov, L.I., Similarity and Dimensional Methods in Mechanics, CRC Press, 1993. Taylor, J., Explosion. II. The Atomic Explosion of 1945. Proc. Roy. Soc. London, A201, 1065, 1950, p. 175. Landau, L.D. and Lifshitz, E.M., Fluid Mechanics, Pergamon Press, 1959. Zeldovich Ya. B. and Raizer, Yu.P., Physics of Shock Waves and High-Temperature Hydrodynamic Phenomena, Dover, New York, 2002. Lavrent'ev, M.A. and Shabat, B.V., Hydrodynamic Phenomena and Their Mathematical Models. Hauka, 1973 (in Russian).

**4:54PM P21.00013 Impacts on Dissipative Sonic Vacuum<sup>1</sup>**, YICHAO XU, VITALI NESTERENKO, Univ of California - San Diego — We investigate the propagating compression bell shape stress waves generated by the strikers with different masses impacting the sonic vacuum — the discrete dissipative strongly nonlinear metamaterial with zero long wave sound speed. The metamaterial is composed of alternating steel disks and Nitrile O-rings. Being a solid material, it has exceptionally low speed of the investigated stress waves in the range of 50 – 74 m/s, which is a few times smaller than the speed of sound or shock waves in air generated by blast. The shape of propagating stress waves was dramatically changed by the viscous dissipation. It prevented the incoming pulses from splitting into trains of solitary waves, a phenomenon characteristic of the non-dissipative strongly nonlinear discrete systems when the striker mass is larger than the cell mass. Both high-speed camera images and numerical simulations demonstrate the unusual rattling behavior of the top disk between the striker and the rest of the system. The linear momentum and energy from the striker were completely transferred to the metamaterial. This strongly nonlinear dissipative metamaterial can be designed for the optimal attenuation of dynamic loads generated by impact or contact explosion.

**5:06PM P21.00014 High-Pressure High-Temperature Phase Diagram of the Organic Crystal Paracetamol<sup>1</sup>**, SPENCER SMITH, JEFFREY MONTGOMERY, YOGESH VOHRA, Univ of Alabama - Birmingham — High-pressure high-temperature (HPHT) Raman spectroscopy studies have been performed on the organic crystal paracetamol in a diamond anvil cell utilizing boron-doped diamond as heating anvil. The HPHT data obtained from boron-doped diamond heater is cross-checked with data obtained using a standard block heater diamond anvil cell. Isobaric measurements were conducted at pressures up to 8.5 GPa and temperature up to 520 K in a number of different experiments. Solid state phase transitions from monoclinic Form I → orthorhombic Form II were observed at various pressures and temperatures as well as transitions from Form II → unknown Form IV. The melting temperature for paracetamol was observed to increase with increasing pressures to 8.5 GPa. Our previous angle dispersive x-ray diffraction studies at the Advanced Photon Source has confirmed the existence of two unknown crystal structures Form IV and Form V of paracetamol at high pressure and ambient temperature. The phase transformation from Form II to Form IV occurs at ~8.5 GPa and from Form IV to Form V occurs at ~11 GPa at ambient temperature. Our new data is combined with the previous ambient temperature high-pressure Raman and X-ray diffraction data to create the first HPHT phase diagram of paracetamol.

**5:18PM P21.00015 Modeling the mechanical behavior of ceramic and heterophase structures manufactured using selective laser sintering and spark plasma sintering**, VLADIMIR A. SKRIPNYAK, EVGENIYA G. SKRIPNYAK, VLADIMIR V. SKRIPNYAK, IRINA K. VAGANOVA, National Research Tomsk State University — A model for predicting mechanical properties of ultra-high temperature ceramics and composites manufactured by selective laser sintering (SLS) and spark plasma sintering (SPS) under shock loading is presented. The model takes into account the porous structure, the specific volume and average sizes of phases, and the temperature of sintering. Residual stresses in ceramic composites reinforced with particles of refractory borides, carbides and nitrides after SLS or SPS were calculated. It is shown that the spall strength of diboride-zirconium matrix composites can be increased by the decreasing of porosity and the introduction of inclusions of specially selected refractory strengthening phases.

**2:30PM P22.00001 First Principles Computation of G-Factors in Bi and Bi<sub>2</sub>Se<sub>3</sub>**, ZHIDA SONG, SIMIN NIE, XI DI, ZHONG FANG, Chinese Academy of Sci (CAS), T03 TEAM — In this talk, we propose a first principles computation method for g-factor tensor, which not only gives comparable results with experiments but also establishes a clear physical picture of Zeeman effect in materials. In our method, the Hilbert space of the electronic states is treated as a direct product of "inner" space and "orbital" space, which are spanned by Bloch wave-functions and envelope functions respectively. Correspondingly, vector-potential is divided into a periodic part acting only in inner space and a non-periodic part acting only in orbital space. With the above framework we define the g-factors as coupling coefficients between inner space and magnetic field. By the method we developed, we have further computed the g-factors of bismuth and Bi<sub>2</sub>Se<sub>3</sub> and get satisfactory results, which are in good agreement with the experimental data.

**2:42PM P22.00002 Adaptively truncated Hilbert spaces for Hamiltonian-based impurity solvers<sup>1</sup>**, ARA GO, ANDREW MILLIS, Columbia Univ — We investigate truncations of the exponentially large Hilbert space in the exact diagonalization (ED) as an impurity solver for the dynamical mean-field theory (DMFT). A key issue is to maintain the high degree of numerical accuracy required in the construction of Greens functions. We test various truncation schemes with similar number of Slater determinants in both Hilbert spaces for the ground state and a particle- or a hole-excited state, and show that the excited states play an important role in accurate computation as well as the ground state. Appropriate truncation for both spaces enables us to compute the accurate self-energy of the impurity Hamiltonian with up to eight correlated orbitals hybridized with a sufficient number of bath orbitals to obtain converged solutions of the self-consistent equation in the DMFT, which is not solvable by the original ED. Application to spin-orbit coupled multi-orbital models and the one-dimensional Hubbard model and comparison to results from exact diagonalization and the configuration interaction based impurity solvers demonstrate the power of the method.

**2:54PM P22.00003 Equilibration properties of a disordered interacting open quantum system**, EVERT VAN NIEUWENBURG, SEBASTIAN HUBER, ETH - Hoenggerberg — The central question in the field of many body localization is if a closed interacting quantum system effectively thermalizes in the presence of disorder. However, any experimental test necessarily involves the opening of the ideally closed quantum system. Both from a fundamental point of view as well as for concrete experimental investigations of many body localization phenomena, a solid understanding of the effect of an attached bath is of significant importance. We study the equilibration properties of disordered interacting open quantum systems. On the one hand we consider the equilibration of such a many body localized system by coupling baths to the ends of a 1D spin chain. We find non-monotonous behaviour of the slowest relaxation time towards equilibrium. On the other hand, we take the bath itself to be a disordered interacting open quantum system and investigate the dephasing of a single qubit coupled to it. The model for the bath has a many body localization transition, affecting the dephasing of the single qubit.

**3:06PM P22.00004 ABSTRACT WITHDRAWN –**

**3:18PM P22.00005 Accurate, efficient, and scalable parallel simulation of mesoscale electrostatic/magnetostatic problems accelerated by a fast multipole method.<sup>1</sup>**, XIKAI JIANG, Argonne National Laboratory, DMITRY KARPEEV, JIYUAN LI, JUAN DE PABLO, University of Chicago, JUAN HERNANDEZ-ORTIZ, National University of Colombia, OLLE HEINONEN, Argonne National Laboratory — Boundary integrals arise in many electrostatic and magnetostatic problems. In computational modeling of these problems, although the integral is performed only on the boundary of a domain, its direct evaluation needs  $O(N^2)$  operations, where  $N$  is number of unknowns on the boundary. The  $O(N^2)$  scaling impedes a wider usage of the boundary integral method in scientific and engineering communities. We have developed a parallel computational approach that utilize the Fast Multipole Method to evaluate the boundary integral in  $O(N)$  operations. To demonstrate the accuracy, efficiency, and scalability of our approach, we consider two test cases. In the first case, we solve a boundary value problem for a ferroelectric/ferromagnetic volume in free space using a hybrid finite element-boundary integral method. In the second case, we solve an electrostatic problem involving the polarization of dielectric objects in free space using the boundary element method. The results from test cases show that our parallel approach can enable highly efficient and accurate simulations of mesoscale electrostatic/magnetostatic problems.

**3:30PM P22.00006 Computational algorithms dealing with the classical and statistical mechanics of celestial scale polymers in space elevator technology**, STEVEN KNUDSEN, LEONARDO GOLUBOVIC, West Virginia University — Prospects to build Space Elevator (SE) systems have become realistic with ultra-strong materials such as carbon nano-tubes and diamond nano-threads. At cosmic length-scales, space elevators can be modeled as polymer like floppy strings of tethered mass beads. A new venue in SE science has emerged with the introduction of the Rotating Space Elevator (RSE) concept [1,2] supported by novel algorithms discussed in this presentation. An RSE is a loopy string reaching into outer space. Unlike the classical geostationary SE concepts of Tsiolkovsky, Artsutanov, and Pearson, our RSE exhibits an internal rotation. Thanks to this, objects sliding along the RSE loop spontaneously oscillate between two turning points, one of which is close to the Earth whereas the other one is in outer space. The RSE concept thus solves a major problem in SE technology which is how to supply energy to the climbers moving along space elevator strings. The investigation of the classical and statistical mechanics of a floppy string interacting with objects sliding along it required development of subtle computational algorithms described in this presentation. [1] L. Golubovic and S. Knudsen, Europhys. Lett. 86, 34001 (2009); [2] S. Knudsen and L. Golubovic, Eur. Phys. J. Plus 129, 242 (2014).

**3:42PM P22.00007 Convex Lower Bounds for Free Energy Minimization** , JONATHAN MOUSSA, Sandia National Laboratories — We construct lower bounds on free energy with convex relaxations from the nonlinear minimization over probabilities to linear programs over expectation values. Finite-temperature expectation values are further resolved into distributions over energy. A superset of valid expectation values is delineated by an incomplete set of linear constraints. Free energy bounds can be improved systematically by adding constraints, which also increases their computational cost. We compute several free energy bounds of increasing accuracy for the triangular-lattice Ising model to assess the utility of this method. This work was supported by the Laboratory Directed Research and Development program at Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**3:54PM P22.00008 Stabilized quasi-Newton optimization of noisy potential energy surfaces** , BASTIAN SCHAEFER, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland, S. ALIREZA GHASEMI, Institute for Advanced Studies in Basic Sciences, P.O. Box 45195-1159, IR-Zanjan, Iran, SHANTANU ROY, STEFAN GOEDECKER, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland, GOEDECKER GROUP TEAM — Optimizations of atomic positions belong to the most frequently performed tasks in electronic structure calculations. Many simulations like global minimum searches or the identification of chemical reaction pathways can require the computation of hundreds or thousands of minimizations or saddle points. To automatize these tasks, optimization algorithms must not only be efficient but also very reliable. Unfortunately, computational noise in forces and energies is inherent to electronic structure codes. This computational noise poses a severe problem to the stability of efficient optimization methods like the limited-memory BroydenFletcherGoldfarbShanno algorithm. In this talk a recently published technique that allows to obtain significant curvature information of noisy potential energy surfaces is presented. This technique was used to construct both, a stabilized quasi-Newton minimization method and a stabilized quasi-Newton saddle finding approach. With the help of benchmarks both the minimizer and the saddle finding approach were demonstrated to be superior to comparable existing methods.

**4:06PM P22.00009 Phonon softening and mechanical failure of graphene under tensile strain** , JEONGWOON HWANG, JISOON IHM, Seoul Natl Univ, KYUNG-SUK KIM, MOON-HYUN CHA, Brown Univ — Phonon softening of graphene under tensile strain is investigated based on ab initio density functional theory calculations. From calculated phonon band structures, we show that the Kohn anomaly point shifts from a high symmetry  $K$  point to a lower symmetry one as a consequence of the Dirac point shift in the electronic band structure. We demonstrate that, over a wide range of tensile strain directions, the strain-induced enhancement of phonon softening can give rise to phonon instabilities resulting in a mechanical failure of graphene at lower strains. It is shown that there are two types of instabilities associated with phonons near  $K$  and  $\Gamma$  points, respectively, which induce symmetry-breaking structural distortions, and both of them lead to mechanical failure prior to the elastic failure commonly expected when the structural symmetry is retained.

**4:18PM P22.00010 Adjoint based data assimilation for phase field model using second order information of a posterior distribution** , SHIN-ICHI ITO, HIROMICHI NAGAO, The University of Tokyo, AKINORI YAMANAKA, Tokyo University of Agriculture and Technology, YUHKI TSUKADA, TOSHIYUKI KOYAMA, Nagoya University, JUNYA INOUE, The University of Tokyo — Phase field (PF) method, which phenomenologically describes dynamics of microstructure evolutions during solidification and phase transformation, has progressed in the fields of hydromechanics and materials engineering. How to determine, based on observation data, an initial state and model parameters involved in a PF model is one of important issues since previous estimation methods require too much computational cost. We propose data assimilation (DA), which enables us to estimate the parameters and states by integrating the PF model and observation data on the basis of the Bayesian statistics. The adjoint method implemented on DA not only finds an optimum solution by maximizing a posterior distribution but also evaluates the uncertainty in the estimations by utilizing the second order information of the posterior distribution. We carried out an estimation test using synthetic data generated by the two-dimensional Kobayashi's PF model. The proposed method is confirmed to reproduce the true initial state and model parameters we assume in advance, and simultaneously estimate their uncertainties due to quality and quantity of the data. This result indicates that the proposed method is capable of suggesting the experimental design to achieve the required accuracy.

**4:30PM P22.00011 Quantum Monte Carlo study of 4d vs 5d atomic and molecular systems.** , MICHAEL BENNETT, North Carolina State University, ADEM KULAHLIOGLU, Melikshah University, CODY MELTON, LUBOS MITAS, North Carolina State University — We investigate the electronic properties of Mo and W atomic and molecular systems by quantum Monte Carlo (QMC) methods. One area of interest in these systems are the systematic changes in the fixed-node errors from 4d to 5d elements and corresponding changes in the correlation effects. We find that similarly to first and second-row systems the fixed-node biases grow with increasing degree of charge localization for similarly complex wave functions and bonding patterns. The second area of interest is the impact of relativistic effects on the electronic structure, in particular, to which extent they affect the bonding properties. We use scalar-relativistic energy-consistent pseudopotentials with averaged spin-orbit effects and we contrast these calculations with the explicit inclusion of the spin-orbit in the two-component framework.

**4:42PM P22.00012 Information geometry with correlated data: Bayesian explorations of cosmological predictions for the microwave background radiation<sup>1</sup>** , KATHERINE QUINN, FRANCESCO DE BERNARDIS, MICHAEL NIEMACK, JAMES SETHNA, Cornell Univ — We developed a new, generalized fitting algorithm for multiparameter models which incorporates varying and correlated errors. This was combined with geometrical methods of sampling to explore model prediction space, notably to plot geodesics and determine the size and edges of the model manifold. We illustrate this using the microwave background spectra for all possible universes, as described by the standard  $\Lambda$ -cold dark matter ( $\Lambda$ -CDM) cosmological model. In this case, the predicted data are fluctuations and highly correlated with varying errors, resulting in a manifold with a varying metric (as the natural metric to use is given by the Fisher information matrix). Furthermore, the model manifold shares the hyperribbon structure seen in other models, with the edges forming a strongly distorted image of a hypercube. Practical applications of such an analysis include optimizing experimental instrumentation designed to test more detailed cosmological theories.

**4:54PM P22.00013 Recasting the 3D Wigner-Liouville equation with spectral components of the force** , MAARTEN VAN DE PUT, BART SORE, WIM MAGNUS, Univ of Antwerp, imec — The phasespace approach to many-body quantum mechanics, by means of the Wigner-function is interesting through its connection to classical mechanics. Time-evolution of any statistical distribution of states under influence of a (time-dependent) Hamiltonian is obtained through use of the Wigner-Liouville equation. The standard form of this equation contains two 3D integrals, over the entire phase space. As a result, this form emphasizes the non-locality of the interaction of the potential, but lacks simplicity and ease of understanding. Furthermore, the integrals make numerical solution of the Wigner-Liouville equation challenging. We present an alternative form to the Wigner-Liouville equation based on the force rather than the potential, in alignment with the classical Boltzmann equation. Decomposition of the force in its spectral components yields a simpler form of the Wigner-Liouville equation. This new form has only one 3D integral over the spectral force components, and is local in position, simplifying both interpretation and numerical implementation. Because of its use of the force, it straightforwardly reduces to the Boltzmann equation under classical conditions.

**5:06PM P22.00014 Exciton condensation in one dimension<sup>1</sup>** , DAVID ABERGEL, ADRIAN KANTIAN, NORDITA — We show the existence of a stable bilayer exciton condensate in one dimension, which demonstrates both true long-range order and non-negligible pairing amplitude. The condensate is stabilized by a finite inter-wire tunneling between two parallel quasi-1D wires, which we propose as the system in which to realize the condensate. Combining numerical DMRG, mean-field approaches, and bosonization to go beyond perturbation theory, we analyze experiments which will demonstrate the off-diagonal long-range order and verify the associated non-negligible pairing amplitude of the exciton condensate.

**5:18PM P22.00015 Rotationally invariant ensembles of integrable matrices<sup>1</sup>** , JASEN SCARAMAZZA, EMIL YUZHASHYAN, Department of Physics and Astronomy, Rutgers University, SRIRAM SHASTRY, Physics Department, University of California, Santa Cruz — We construct ensembles of *random integrable matrices* with any prescribed number of nontrivial integrals and formulate *integrable matrix theory* (IMT) – a counterpart of random matrix theory (RMT) for quantum integrable models. A type- $M$  family of integrable matrices consists of exactly  $N - M$  independent commuting  $N \times N$  matrices linear in a real parameter. We first develop a rotationally invariant parameterization of such matrices, previously only constructed in a preferred basis. For example, an arbitrary choice of a vector and two commuting Hermitian matrices defines a type-1 family and vice-versa. Higher types similarly involve a random vector and two matrices. The basis-independent formulation allows us to derive the joint probability density for integrable matrices, in a manner similar to the construction of Gaussian ensembles in the RMT.

**5:30PM P22.00016 Matrix Elements for Hylleraas CI** , FRANK E. HARRIS, University of Florida — The limitation to at most a single interelectron distance in individual configurations of a Hylleraas-type multiconfiguration wave function restricts significantly the types of integrals occurring in matrix elements for energy calculations, but even then if the formulation is not handled efficiently the angular parts of these integrals escalate to create expressions of great complexity. This presentation reviews ways in which the angular-momentum calculus can be employed to systematize and simplify the matrix element formulas, particularly those for the kinetic-energy matrix elements.

**2:30PM P23.00001 Computational design of inorganic-organic hybrid materials energy storage and conversion** , ALEXIE KOLPAK, Massachusetts Inst of Tech-MIT — Hybrid inorganic-organic materials are of interest for the design of new functional materials that combine the advantages of both organic and inorganic components to optimize properties and/or obtain new physical phenomena. In this talk, I will discuss our recent work using first-principles density functional theory to design nanostructured hybrid materials for energy storage and conversion applications. In particular, I will discuss the electronic, optical, thermal, and mechanical properties of a class of nanostructured hybrid materials based on layered transition metal phosphates, showing that these materials offer a highly tunable platform for the design of efficient, flexible photovoltaics and thermoelectrics. In addition to optimizing individual properties, I will also discuss exciting possibilities for using this platform for the design of materials with strong coupling between functionalities.

**3:06PM P23.00002 Theoretical and Experimental Studies of Designed Molecular Interfaces for Improved Thermal Conductivity<sup>1</sup>** , ALEX KERR, KIERAN MULLEN, Homer L. Dodge Dept. of Physics and Astronomy, DANIEL GLATZHOFFER, MATTHEW HOUCK, Department of Chemistry and Biochemistry, University of Oklahoma, PAUL HUANG, School of Chemical, Biological & Materials Engineering, University of Oklahoma — Certain molecular structures such as carbon nanotubes (CNTs) can potentially improve the thermal conductivity of composite materials. However, their thermal boundary resistance is an obstacle to their effective implementation as a medium for heat flow. We are concerned with overcoming this Kapitza resistance with the aid of chemical functional groups. These functional groups will, in principal, eliminate phonon mismatch between our structures and their matrix. The result will maximize the transmission of thermal vibrations to and from their surrounding medium. We develop a method to predict the thermal properties of our functionalized materials through the calculation of vibrational normal modes and Green's functions. We show how the configuration of attached functional groups affect the samples' thermal conductivity ( $\kappa$ ) and attempt to find the arrangement in which  $\kappa$  is maximized. We will make explicit comparisons with thermal conductivity experiments done on nanocomposites of functionalized and pristine CNTs. We will discuss how the bonds connecting the functional groups to the CNT affects  $\kappa$ . We compare these results to measurements on our particular synthesized materials and discuss how to better optimize their design.

**3:18PM P23.00003 Modifying the Optoelectronic Properties of Rubrene by Strain<sup>1</sup>** , SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University, ASHWIN RAMASUBRAMANIAM, Department of Mechanical & Industrial Engineering, University of Massachusetts Amherst — Rubrene crystals are promising organic electronic and optoelectronic materials due to their high charge carrier mobility. Recent studies have shown that the electronic properties of rubrene films can be tuned by substrate-induced strain, suggesting a new route towards the design of more efficient devices. Here, we present a first-principles density functional theory and many-body perturbation theory analysis of strain-induced changes to the mechanical, electronic, and optical properties of rubrene crystals. With an applied strain that is consistent with experiment, we predict changes of hole mobilities in excellent agreement with electrical conductivity measurements. Furthermore, we predict that the optical absorption and nature of low-energy excitons within the crystal can be tuned by an applied strain as low as 1%.

**3:30PM P23.00004 First-principles studies of the electric-field effect on the band structure of trilayer graphenes<sup>1</sup>**, YUN-PENG WANG, XIANG-GUO LI, HAI-PING CHENG, University of Florida — Electric-field effects on the electronic structure of trilayer graphene are investigated using the density functional theory in the generalized gradient approximation. Two different stacking orders, namely Bernal and rhombohedral, of trilayer graphene are considered. Our calculations reproduce the experimentally data on band gap opening in Bernal stacking and band overlap in rhombohedral trilayer graphene. In addition, we studied effects of charge doping using dual gate configurations. The size of band gap opening in Bernal trilayer graphene can be tuned by charge doping, and charge doping also causes an electron-hole asymmetry in the density of states. Furthermore, hole-doping can reopen a band gap in the band overlapping region of rhombohedral trilayer graphene induced by electric fields, which contributes to an extra peak in the optical conductivity spectra.

**3:42PM P23.00005 Design of transparent conductors and periodic two-dimensional electron gases without doping**, XIUWEN ZHANG, LIJUN ZHANG, ALEX ZUNGER, Renewable and Sustainable Energy Institute, University of Colorado, Boulder, Colorado, JOHN PERKINS, National Renewable Energy Laboratory, Golden, Colorado, MATERIALS BY DESIGN TEAM, JOHN D. PERKINS COLLABORATION — The functionality of transparency plus conductivity plays an important role in renewable energy and information technologies, including applications such as solar cells, touch-screen sensors, and flat panel display. However, materials with such seemingly contraindicated properties are difficult to come by. The traditional strategy for designing bulk transparent conductors (TCs) starts from a wide-gap insulator and finds ways to make it conductive by extensive doping. We propose a different strategy [1] for TC design—starting with a metallic conductor and designing transparency by control of intrinsic interband transitions and intraband plasmonic frequency. We identified specific design principles for prototypical intrinsic TC classes and searched computationally for materials that satisfy them. The electron gases in the 3D intrinsic TCs demonstrate intriguing properties, such as periodic 2D electron gas regions with very high carrier density. We will discuss a more extended search of these functionalities, in parallel with stability and growability calculations. [1] X. Zhang, L. Zhang, J. D. Perkins, and A. Zunger, Phys. Rev. Lett. 115, 176602 (2015). Supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Grant No. DEFG02-13ER46959.

**3:54PM P23.00006 Role of  $sp^3$  Defect in Ordered Nanoporous Carbon**, ENSHI XU, ANGELA LUEKING, VINCENT CRESPI, PAUL LAMMERT, Pennsylvania State Univ, KATHLEEN MALESKI, Washington College — Schwarzite is considered an ideal model for nanoporous carbon and is energetically more stable than fullerene. However, carbon don't form well-ordered Schwarzite-type nanoporous material possibly due to kinetic arrests under pyrolytic conditions. We computationally discovered a new thermodynamically stable local defect in carbon  $sp^2$  networks: an  $sp^3$  carbon defect, which inspires new solutions to the problem. The defect is most stable in nanoporous carbon (i.e., networks with negative curvatures, known as Schwarzites) and its topological merit, carrying negative curvature, results in the design of new model structures of nanoporous materials (periodic, negatively-curved networks), and provides a handle of the negative curvature carrier in nanoporous carbon, and we propose a kinetics-dominated synthetic route to novel nanoporous carbon with long range order by controlling the  $sp^3$  defect through  $sp^3$  carbon atom injection or Si atom substitution, with the aid of first principle molecular dynamics simulation. Calculations also suggest the defect can be observed by Raman.

**4:06PM P23.00007 Computational Discovery of a Novel Semiconductor: A Vacancy-Ordered  $Fe_{1.5}TiSb$  Heusler Phase**, VINAY ISHWAR HEGDE, Northwestern University, NARIMAN NAGHIBOLASHRAFI, SAHAR KESHAVARZ, KAMARAM MUNIRA, WILLIAM BUTLER, PATRICK LECLAIR, The University of Alabama, CHRIS WOLVERTON, Northwestern University — Many full- and half-Heusler phase compounds are half-metallic ferromagnets, and are attractive for spintronic applications due to their relatively high Curie temperatures. However, while it is known that defects such as vacancies (on the X site of an  $X_2YZ$  Heusler phase) can lead to a loss of half-metallic character, their effect on the stability and order of these compounds has not been adequately explored. To address this shortcoming, we perform a binary cluster expansion (CE) of Fe and vacancies on the Fe sublattice of the  $Fe_xVac_{2-x}TiSb$  Heusler compound. From our CE, we computationally predict the stability of a novel semiconductor phase with an interesting new structure type:  $R\bar{3}m$  spacegroup with composition  $Fe_{1.5}TiSb$ , i.e., between the full- and half-Heusler compositions. By comparing the electronic structure of all the competing structures at  $x = 1.5$ , we find that the gap opened in the minority-spin channel due to vacancies strongly correlates with the stability of the structure. We study the effect of vacancies on the structural order in  $Fe_{1.5}TiSb$  by generating special quasi-random structures (SQSs) as approximations to the true disordered state, and find that the material undergoes an order-disorder transition at elevated temperatures of  $\sim 1450$  K.

**4:18PM P23.00008 Doping and defects by design:  $Ga_2O_3$ <sup>1</sup>**, STEPHAN LANY, NREL — Density functional supercell calculations are widely employed to describe the defect physics in semiconductors and insulators. Due to a variety of challenges such as finite size effects for charged defects and the band gap error of DFT, results were often controversial in the past. With developments over the past decade, defect theory should hopefully be truly predictive, and be able to guide experimental efforts. The present work on n-type doping in  $Ga_2O_3$  compares different potential doping routes via anion-site doping with F, and cation site doping with group IV elements (C, Si, Ge, Sn). The study addresses dopant solubility, electrical activity, and compensation by native defects, including non-equilibrium effects due to supersaturated dopant concentrations and the mechanism of dopant-defect pair formation.

**4:30PM P23.00009 Understanding the Impact of Point Defects on the Optoelectronic Properties of Gallium Nitride from First-Principles<sup>1</sup>**, KIRK LEWIS, MASAHICO MATSUBARA, ENRICO BELLOTTI, SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — Gallium nitride (GaN) and related alloys form a class of wide bandgap semiconductors that have broad applications as components in optoelectronic devices; in particular, power electronics and blue and ultraviolet optical devices. Nitride films grow with high defect densities, and understanding the relationship between structural defects and optoelectronic function will be central to the design of new high-performance materials. Here, we take a first-principles density functional theory (DFT) and many-body perturbation theory (MBPT) approach to quantify the influence of defects on the electronic and optical properties of GaN. We predict, as expected, that introduction of a N or Ga vacancy results in several energetically favorable charged states within bulk GaN; these energetically favorable defects result in a significant modification of the quasiparticle and excitonic properties of GaN. We will discuss the implications of defect-induced-states for the electron transport and absorption properties of GaN.

**4:42PM P23.00010 Prediction of direct band gap silicon superlattices with dipole-allowed optical transition<sup>1</sup>**, SUNGHYUN KIM, Department of physics, KAIST, Daejeon, Republic of Korea, YOUNG JUN OH, Department of Materials Science and Engineering, University of Texas at Dallas, Richardson, TX 75080, USA, IN-HO LEE, Korea Research Institute of Standards and Science, Daejeon, Korea, JOOYOUNG LEE, Center for In Silico Protein Science, School of Computational Science, Korea Institute for Advanced Study, Seoul, Korea, K. J. CHANG, Department of physics, KAIST, Daejeon, Republic of Korea — While cubic diamond silicon (c-Si) is an important element in electronic devices, it has poor optical properties owing to its indirect gap nature, thereby limiting its applications to optoelectronic devices. Here, we report Si superlattice structures which are computationally designed to possess direct band gaps and excellent optical properties. The computational approach adopts density functional calculations and conformational space annealing for global optimization. The Si superlattices, which consist of alternating stacks of Si(111) layers and a defective layer with Seiwatz chains, have either direct or quasi-direct band gaps depending on the details of attacking layers. The photovoltaic efficiencies are calculated by solving Bethe-Salpeter equation together with quasiparticle G0W0 calculations. The strong direct optical transition is attributed to the overlap of the valence and conduction band edge states in the interface region. Our Si superlattices exhibit high thermal stability, with the energies lower by an order of magnitude than those of the previously reported Si allotropes. We discuss a possible route to the synthesis of the superlattices through wafer bonding.

**4:54PM P23.00011 From facets to facets: how does work function vary over a gold nanocluster?**, LINGYUAN GAO, JAIME SOUTO, JAMES CHELIKOWSKY, ALEX DEMKOV, Univ of Texas, Austin — Owing to their potential applications in catalysis, gold nanoclusters are a focus of intense research. The work function  $\Phi$ , which can be measured using photoemission spectroscopy is a key parameter used to characterize the catalytic performance of the cluster.  $\Phi$  is determined by the difference between the electrostatic potential just outside the metal surface and the Fermi energy of the cluster. We use a relativistic version of the real space first-principles code PARSEC to compute the work function of gold nanoclusters with dimensions on the order of a nanometer, which is similar in size to those used in experiment. We illustrate how the work function depends on the surface orientation of the nanocluster facets and compare our results with available experimental data. We acknowledge supports from SciDAC program, Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences grant DE-SC0008877 for work on algorithms. Two of us (JRC and JS-C) acknowledge support for the work on nanostructures from grant from the U.S. Department of Energy: DE-FG02-06ER46286.

**5:06PM P23.00012 Gap engineering using Hellmann-Feynmann forces: method and applications<sup>1</sup>**, KIRAN PRASAI, Ohio University, PARTHAPRATIM BIAWAS, The University of Southern Mississippi, D. A. DRABOLD, Ohio University — Materials with optimized band gap are needed in many specialized applications. In this talk, we demonstrate that Hellmann-Feynman forces associated with the gap states can be used to find atomic coordinates that yield desired electronic density of states. Using tight-binding models, we show that this approach may be used to arrive at electronically designed models of amorphous silicon and carbon. We provide a simple recipe to include *a priori* electronic information in the formation of computer models of materials, and prove that this information may have profound structural consequences. We'll briefly discuss implementation of the method in *ab-initio* molecular dynamics simulations and highlight the latest feats of the method ranging from modeling amorphous semi-conducting materials to understanding the structure and properties of memory materials.

**5:18PM P23.00013 Bayesian cluster expansion with lattice parameter dependence for studying surface alloys**, LE NIU, TIM MUELLER, Johns Hopkins University, Department of Materials Science & Engineering — The Bayesian cluster expansion approach has proven to be an efficient method for predicting the structure and properties of materials with substitutional disorder. It is particularly effective for low-symmetry systems such as nanoparticles and surfaces. However for surfaces of solid solutions, the lattice parameter of the surface, and hence the interactions among near-surface atoms, varies with the composition of the underlying bulk material. We demonstrate that surfaces under a variety of strains can be used to train a single cluster expansion that predicts properties as a function of atomic order and surface strain. We have applied this method to study Ni-Pt alloys with up to a monolayer of adsorbed oxygen, an important class of catalysts for the oxygen reduction reaction. Through Monte Carlo simulations, we are able to determine how the structure and properties of these surfaces vary as a function of temperature, composition, chemical potential, and surface strain, enabling both the identification of thermodynamically stable surface structures and the rational design of Pt-Ni surfaces with high catalytic activity.

Session P24 DMP: Many-Body Perturbation Theory for Electronic Excitations: Electronic Structure 323 - Noa Marom, Tulane University

**2:30PM P24.00001 Electronic structure from relativistic quasiparticle self-consistent GW calculations<sup>1</sup>**, STEFAN BLÜGEL, Peter Grünberg Institut and Institut for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — Most theoretical studies of topological insulators (TIs) are based on tight-binding descriptions and density functional theory (DFT). But recently, many-body calculations within the GW approximation attract much attention in the study of these materials. We present an implementation of the quasiparticle self-consistent (QS) GW method where the spin-orbit coupling (SOC) is fully taken into account in each iteration rather than added a posteriori. Within the all-electron FLAPW formalism, we show DFT, one-shot GW, and QSGW calculations for several, well-known TIs. We present a comparison of the calculations to photoemission spectroscopy and show that the GW corrected bands agree much better with experiment. For example, we show that Bi<sub>2</sub>Se<sub>3</sub> [1,2] is a direct gap semiconductor, in contrast to what was believed for many years by interpreting experimental results on the basis of DFT and that small strains in Bi can lead to a semimetal-to-semiconductor or trivial-to-topological transitions [3]. Quasiparticle calculations for low-dimensional systems are still very demanding. In order to study the topological surface states with an approach based on GW, we use Wannier functions to construct a Hamiltonian that reproduces the many-body band structure of the bulk, and that is used to construct a slab Hamiltonian. With this approach, we discuss the effect of quasiparticle corrections on the surface states of TIs and on the interaction between bulk and surface states. [1] I. Aguilera *et al.*, PRB **88**, 045206 (2013), *ibid.*, PRB **88**, 165136 (2013). [2] M. Michiardi *et al.*, PRB **90**, 075105 (2014). [3] I. Aguilera *et al.*, PRB **91**, 125129 (2015).

**3:06PM P24.00002 Quasiparticle electronic structure of  $\text{Bi}_2\text{Se}_3$  via the sc-COHSEX+GW approach<sup>1</sup>**, BRADFORD A. BARKER, University of California-Berkeley and Lawrence Berkeley National Laboratory, JACK DESLIPPE, Lawrence Berkeley National Laboratory, OLEG YAZYEV, University of California-Berkeley and Ecole Polytechnique Federale de Lausanne (EPFL), STEVEN G. LOUIE, University of California-Berkeley and Lawrence Berkeley National Laboratory — We present ab initio calculations of the quasiparticle electronic band structure of three-dimensional topological insulator material  $\text{Bi}_2\text{Se}_3$  using the full spinor GW approach. The mean-field is initially computed at the DFT level in the local density approximation (LDA) using fully-relativistic pseudopotentials. We then improve the mean-field electronic structure by solving Dyson's equation in the static COHSEX approximation, self-consistently updating the eigenvalues, eigenvectors, and dielectric screening. After a few iterations, we then perform a GW calculation to determine the quasiparticle energies. We compare our calculated results to experimental values of the band gaps and effective masses.

<sup>1</sup>This work was supported by NSF grant No. DMR15-1508412 and U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been provided by DOE at LBNLs NERSC facility and the NSF through XSEDE resources at NICS.

**3:18PM P24.00003 Ubiquitous electron-plasmon coupling in doped semiconductors**, FABIO CARUSO, FELICIANO GIUSTINO, Department of Materials, University of Oxford — The interplay between electrons and bosonic excitations [as, e.g., phonons, collective charge-density fluctuations (plasmons), and magnons] is pervasive in matter and underlies an extremely broad spectrum of physical phenomena, as, for instance, current dissipation, superconductivity, hot-carrier thermalisation, and band structure replicas [1]. At variance with phonons, however, questions pertaining the strength of electron-plasmon coupling in solids are still awaiting further investigations. We developed and implemented a first-principles theory of electron-plasmon coupling based on many-body perturbation theory. Our first-principles calculations reveal that electron-plasmon coupling alters ubiquitously the dynamical and optical properties of semiconductors at high doping concentrations. This behaviour stems from the emergence of low-energy extrinsic plasmons which may couple electronic states in the vicinity of the Fermi energy. [1] F. Caruso, H. Lambert, and F. Giustino, *Phys. Rev. Lett.* **114**, 146404 (2015).

**3:30PM P24.00004 Quasiparticle excitations of adsorbates on doped graphene**, JOHANNES LISCHNER, Imperial College London, SEBASTIAN WICKENBURG, DILLON WONG, CHRISTOPH KARRASCH, YANG WANG, JIONG LU, ARASH A. OMRANI, VICTOR BRAR, HSIN-ZON TSAI, QIONG WU, UC Berkeley, FABIANO CORSETTI, ARASH MOSTOFI, Imperial College London, ROLAND K. KAWAKAMI, UC Riverside, Ohio State University, JOEL MOORE, ALEX ZETTL, STEVEN G. LOUIE, MIKE CROMMIE, UC Berkeley — Adsorbed atoms and molecules can modify the electronic structure of graphene, but in turn it is also possible to control the properties of adsorbates via the graphene substrate. In my talk, I will discuss the electronic structure of F4-TCNQ molecules on doped graphene and present a first-principles based theory of quasiparticle excitations that captures the interplay of doping-dependent image charge interactions between substrate and adsorbate and electron-electron interaction effects on the molecule. The resulting doping-dependent quasiparticle energies will be compared to experimental scanning tunnelling spectra. Finally, I will also discuss the effects of charged adsorbates on the electronic structure of doped graphene.

**3:42PM P24.00005 First Principles Charge Transfer Excitations in Curved Aromatic Materials**, LAURA ZOPPI, University of Zurich, LAYLA MARTIN SAMOS, University of Nova Gorica, KIM K. BALDRIDGE, University of Zurich — Understanding excitation properties and charge transport phenomena of curved  $\pi$ -conjugated materials is critical for a rational utilization of buckybowls as electrically active materials in solid-state devices. In this respect, the class of materials based on the smallest bowl-shaped fullerene fragment, corannulene,  $\text{C}_{20}\text{H}_{10}$ , offers a unique possibility for building up scaffolds with a tunable spectrum of structural and electronic properties.[1] Here, GW-BSE based approaches are applied to investigation and prediction of charge transfer excitations of  $\text{C}_{20}\text{H}_{10}$  materials systems at functional interfaces, [1-3] with a special emphasis on design aspects of materials relevant in the experimental domain. Theoretical predictions together with experimental findings illustrate the possibility of integrating corannulene electronic functions in molecular devices. [1] L. Zoppi, L. Martin-Samos, K. K. Baldrige, *Acc. Chem. Res.*, **47**, 3310–3320 (2014) [2] L. Zoppi, L. Martin-Samos, K. K. Baldrige, *J. Am. Chem. Soc.* **133**, 14002-14009 (2011) [3] L. Zoppi, L. Martin Samos, K. K. Baldrige, *Phys. Chem. Chem. Phys.* **17**, 6114-6121 (2015)

**3:54PM P24.00006 Electronic and optical excitations in building blocks of the metal organic framework MOF-5<sup>1</sup>**, BIN SHI, University of Illinois at Chicago, LINDA HUNG, TANER YILDIRIM, National Institute of Standards and Technology, SERDAR OGUT, University of Illinois at Chicago — Metal organic frameworks (MOFs) are a relatively new class of materials which are made of metal-oxide clusters linked by organic bridging ligands. In recent years, MOFs have received considerable attention due to their widely tunable structural, chemical and physical properties. We investigate one of the well characterized MOFs, MOF-5, whose framework consists of tetrahedral  $[\text{Zn}_4\text{O}]^{6+}$  units linked by rigid arylcarboxylate ligands. We use many-body perturbation (GW+BSE) and time-dependent DFT methods in real space to examine the electronic and optical excitations in the building blocks of MOF-5, such as  $\text{Zn}_4\text{O}(\text{COOH})_6$ , basic zinc acetate  $[\text{Zn}_4\text{O}(\text{CH}_3\text{COO})_6]$ , and tetranuclear zinc benzoate  $[\text{Zn}_4\text{O}(\text{C}_6\text{H}_5\text{COO})_6]$ . The calculated spectra are compared with available experimental measurements and existing calculations to shed light on the controversy regarding the nature (metal-ligand versus ligand-ligand) of low-energy electronic and optical excitations in MOF-5.

**4:06PM P24.00007 Energy level alignment at hybridized organic-metal interfaces from a GW projection approach<sup>1</sup>**, YIFENG CHEN, Department of Physics and Centre for Advanced 2D Materials, National University of Singapore, ISAAC TAMBLYN, Department of Physics, University of Ontario Institute of Technology, Canada, SU YING QUEK, Department of Physics and Centre for Advanced 2D Materials, National University of Singapore — Energy level alignments at organic-metal interfaces are of profound importance in numerous (opto)electronic applications. Standard density functional theory (DFT) calculations generally give incorrect energy level alignments and missing long-range polarization effects. Previous efforts to address this problem using the many-electron GW method have focused on physisorbed systems where hybridization effects are insignificant. Here, we use state-of-the-art GW methods to predict the level alignment at the amine-Au interface, where molecular levels do hybridize with metallic states. This non-trivial hybridization implies that DFT result is a poor approximation to the quasiparticle states. However, we find that the self-energy operator is approximately diagonal in the molecular basis, allowing us to use a projection approach to predict the level alignments. Our results indicate that the metallic substrate reduces the HOMO-LUMO gap by 3.5–4.0 eV, depending on the molecular coverage/presence of Au adatoms. Our GW results are further compared with those of a simple image charge model that describes the level alignment in physisorbed systems.

**4:18PM P24.00008 Nonequilibrium transport in the Anderson-Holstein model with interfacial screening<sup>1</sup>**, ENRICO PERFETTO, GIANLUCA STEFANUCCI, University of Rome Tor Vergata — Image charge effects in nanoscale junctions with strong electron-phonon coupling open the way to unexplored physical scenarios. Here we present a comprehensive study of the transport properties of the Anderson-Holstein model in the presence of dot-lead repulsion. We propose an accurate many-body approach to deal with the simultaneous occurrence of the Franck-Condon blockade and the screening-induced enhancement of the polaron mobility. Remarkably, we find that a novel mechanism of negative differential conductance originates from the competition between the charge blocking due to the electron-phonon interaction and the charge deblocking due to the image charges. An experimental setup to observe this phenomenon is discussed. References [1] E. Perfetto, G. Stefanucci and M. Cini, Phys. Rev. B 85, 165437 (2012). [2] E. Perfetto and G. Stefanucci, Phys. Rev. **4:30PM P24.00009 Many-body effects and ultraviolet renormalization in three-dimensional Dirac materials<sup>1</sup>**, ROBERT THROCKMORTON, University of Maryland, JOHANNES HOFMANN, University of Cambridge, EDWIN BARNES, Virginia Tech — We develop a theory for electron-electron interaction-induced many-body effects in three dimensional (3D) Weyl or Dirac semimetals, including interaction corrections to the polarizability, electron self-energy, and vertex function, up to second order in the effective fine structure constant of the Dirac material. These results are used to derive the higher-order ultraviolet renormalization of the Fermi velocity, effective coupling, and quasiparticle residue, revealing that the corrections to the renormalization group (RG) flows of both the velocity and coupling counteract the leading-order tendencies of velocity enhancement and coupling suppression at low energies. This in turn leads to the emergence of a critical coupling above which the interaction strength grows with decreasing energy scale. In addition, we identify a range of coupling strengths below the critical point in which the Fermi velocity varies non-monotonically as the low-energy, non-interacting fixed point is approached. Furthermore, we find that while the higher-order correction to the flow of the coupling is generally small compared to the leading order, the corresponding correction to the velocity flow carries an additional factor of the Dirac cone flavor number relative to the leading-order result.

**4:42PM P24.00010 Electron-electron interactions in Dirac and Weyl semimetals: collective modes and stability of the ground state<sup>1</sup>**, JOHN TOLSMA, ALLAN MACDONALD, Department of Physics, University of Texas at Austin — Three-dimensional Dirac and Weyl semimetals host linearly dispersive low-energy electronic bands in the bulk, and exotic Fermi-Arc states at the surface. Following theoretical proposals of candidate material classes [1,2], experimental observation of anomalous transport [3] and Fermi-Arc surface states [4] have recently been reported. Using time-dependent Hartree-Fock and renormalization group methods, we study collective mode dispersion and the influence of electron-electron interactions on the stability of the ground state. This work was supported by the DOE Division of Materials Sciences and Engineering under grant DE-FG02-ER45118. [1] Z. Wang et al., Phys. Rev. B. 88, 125427 (2013) [2] S.-M. Huang et al., Nat. **4:54PM P24.00011 First-principles DFT+GW study of oxygen doped CdTe<sup>1</sup>**, WALTER ORELLANA, Departamento de Ciencias Físicas, Universidad Andres Bello, MAURICIO A. FLORES, Departamento de Física and Departamento de Matemáticas, Facultad de Ciencias, Universidad de Chile, EDUARDO MENÉNDEZ-PROUPIN, Departamento de Física, Facultad de Ciencias, Universidad de Chile — The role of oxygen doping in CdTe is addressed by first-principles calculations. Formation energies, charge transition levels and quasiparticle defect states are calculated within the DFT+GW formalism. The formation of a new defect is identified, the  $(O_{Te} - Te_{Cd})$  complex. This complex is energetically favored over both isovalent  $(O_{Te})$  and interstitial oxygen  $(O_i)$ . We find that incorporation of oxygen passivates the harmful deep energy levels derived from Te antisites, suggesting an improvement in the efficiency of CdTe based solar cells. Our calculations indicate that both  $(O_{Te})$  and  $(O_i)$  have low formation energies. Moreover,  $(O_{Cd})$  is only stable in the neutral charge state and undergoes a Jahn-Teller distortion. The  $(V_{Cd} - O_{Te})$  complex is found to be a shallow acceptor with a high formation energy. We also report an oxygen-related interstitial defect, which plays a key role in the diffusion mechanism of oxygen in CdTe.

**5:06PM P24.00012 Quasi-particle band structure of potassium-doped few-layer black phosphorus with GW approximation**, HAN-GYU KIM, SEUNG SU BAIK, HYOUNG JOON CHOI, Department of Physics, IPAP, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University, Seoul, Korea — We calculate the quasi-particle band structure of pristine and potassium-doped black phosphorus (BP) by using the GW approximation. We obtain band gaps of pristine bulk and few-layer BP and compare them with the result of the density functional calculations and experimental measurements. For potassium-doped cases, we calculate the electronic band structure of potassium-doped few-layer BPs with various doping densities. We obtain the critical doping density for the band-gap closing, and the energy-band dispersions when the band gap is inverted. We discuss Dirac semimetal properties of doped few-layer BPs obtained by the GW approximation. This work was supported by NRF of Korea (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2015-C3-039).

**5:18PM P24.00013 Quasiparticle and optical band gaps of  $Sr_{n+1}Ti_nO_{3n+1}$  from *ab-initio* many-body perturbation theory**, SEBASTIAN E REYES-LILLO, TONATIUH RANGEL, Molecular Foundry, LBNL; Dept. of Physics, UC Berkeley, FABIEN BRUNEVAL, Molecular Foundry, LBNL; Dept. of Physics, UC Berkeley; CEA, DEN, SRMP, JEFFREY B NEATON, Molecular Foundry, LBNL; Dept. of Physics, UC Berkeley; Kavli ENSI — The Ruddlesden Popper homologous series  $Sr_{n+1}Ti_nO_{3n+1}$  provides a unique opportunity to study the effect of dimensionality and confinement on the band gap and absorption spectrum of the complex oxide  $SrTiO_3$ . In this work, we use many-body perturbation theory within the GW approximation and the Bethe-Salpeter equation (BSE) approach to study the electronic and optical properties of  $Sr_{n+1}Ti_nO_{3n+1}$ . We find that our GW/BSE direct and indirect band gaps are in excellent agreement with measured direct and indirect optical gaps. We discuss technical aspects of the calculations such as convergence and starting-point dependence, and compare to higher levels of theory. In addition, we find a relatively large exciton binding energy of 500 meV for  $Sr_2TiO_4$  ( $n = 1$ ). We explore the role of structural distortions and epitaxial strain in the properties of the localized exciton. Our work suggests that layered structures can provide a viable route for the design of complex oxide materials with desirable optoelectronic properties. This work is supported by DOE.

Richard Klemm, University of Central Florida

**2:30PM P25.00001 Effect of impurities on the Josephson current through helical metals: Exploiting a neutrino paradigm**, POUYAN GHAEMI, V. PARAMESWARAN NAIR, City College of City University of New York — In this talk we present our results on the effect of time-reversal symmetric impurities on the Josephson supercurrent through two dimensional helical metals such as on topological insulator surface state. We show that contrary to the usual superconducting-normal metal-superconducting junctions, the suppression of supercurrent in superconducting-helical metal-superconducting junction is mainly due to fluctuations of impurities in the junctions. Our results, which is a condensed matter realization of a part of the MSW effect for neutrinos, shows that the relationship between normal state conductance and critical current of Josephson junctions is significantly modified for Josephson junctions on the surface of topological insulators. We also study the temperature-dependence of supercurrent and present a two fluid model which can explain some of recent experimental results in Josephson junctions on the edge of topological insulators.

**2:42PM P25.00002 "Hybrid" multi-gap/single-gap Josephson junctions: Evidence of macroscopic quantum tunneling in superconducting-to-normal switching experiments on  $\text{MgB}_2/\text{I}/\text{Pb}$  and  $\text{MgB}_2/\text{I}/\text{Sn}$  junctions**, STEVE CARABELLO, JOSEPH LAMBERT, Drexel University, WENQING DAI, QI LI, Penn State University, KE CHEN, DANIEL CUNNANE, X. X. XI, Temple University, ROBERTO RAMOS, University of the Sciences — We report results of superconducting-to-normal switching experiments on  $\text{MgB}_2/\text{I}/\text{Pb}$  and  $\text{MgB}_2/\text{I}/\text{Sn}$  junctions, with and without microwaves. These results suggest that the switching behavior is dominated by quantum tunneling through the washboard potential barrier, rather than thermal excitations or electronic noise. Evidence includes a leveling in the standard deviation of the switching current distribution below a crossover temperature, a Lorentzian shape of the escape rate enhancement peak upon excitation by microwaves, and a narrowing in the histogram of escape counts in the presence of resonant microwave excitation relative to that in the absence of microwaves. These are the first such results reported in "hybrid" Josephson tunnel junctions, consisting of multi-gap and single-gap superconducting electrodes.

**2:54PM P25.00003  $\text{YBa}_2\text{Cu}_3\text{O}_7$  Nanowire Josephson Junctions Directly Written with a Focused Helium Ion Beam<sup>1</sup>**, SHANE A. CYBART, ETHAN Y. CHO, YUCHAO W. ZHOU, ROBERT C. DYNES, University of California - San Diego — We will present electrical transport measurements for superconducting nanowire Josephson junctions with widths ranging from 500 to 25 nm. The junctions were fabricated by using a 500-pm diameter helium ion beam to pattern superconducting nanowires, into 25-nm thick  $\text{YBa}_2\text{Cu}_3\text{O}_7$  (YBCO) thin films. The key to this direct-write method is that irradiated regions of the YBCO turn insulating for moderate ion doses which allows for very fine features to be defined ( $\sim 2$  nm). Nanowire junctions were fabricated with the length of the nanowire oriented along different crystallographic directions in the  $a-b$  plane. They exhibit a large increase in the anisotropy of the Josephson critical current and voltage state conductance as the nanowire width is decreased. In the narrowest of wires, the conductance changes by an order of magnitude. We interpret these observations to be due to the Josephson junctions being smaller than the granularity of the films. Measuring these single grains reveals characteristics of the  $a-b$  plane  $d$ -wave symmetry of superconductivity in YBCO.

<sup>1</sup>This work is funded by AFOSR.

**3:06PM P25.00004 Superconducting quantum interference devices made with normal metal and insulator barrier Josephson junctions in Y-Ba-Cu-O directly written with a focused helium beam**, ETHAN CHO, MENG MA, Univ of California - San Diego, CHUONG HUYNH, Carl Zeiss Microscopy LLC, KEVIN PRATT, DOUG PAULSON, Tristan Technologies Inc., VICTOR GLYANTSEV, Superconductor Technologies Inc., ROBERT DYNES, SHANE CYBART, Univ of California - San Diego — We will present electrical transport data for Y-Ba-Cu-O superconducting quantum interference devices (SQUIDS) with focused helium ion damage Josephson junctions. The junctions were directly written with a 30 keV focused helium ion beam, which locally creates disorder in Y-Ba-Cu-O that induces a superconducting-insulator transition. SQUIDS with Josephson junctions written with a dose of  $4 \times 10^{16} \text{ He}^+/\text{cm}^2$  have metallic barriers and show a current-voltage characteristic (I-V) well-described by the resistively shunted junction model. The spectral density of the flux noise is  $10 \mu\Phi_0/\sqrt{\text{Hz}}$  at 10 Hz and the white noise at higher frequencies is  $2 \mu\Phi_0/\sqrt{\text{Hz}}$ . SQUIDS with junctions written with higher ion doses ( $\sim 9 \times 10^{16} \text{ He}^+/\text{cm}^2$ ) have insulating Josephson barriers with a critical current of  $22 \mu\text{A}$  and a resistance of  $12 \Omega$  at 4 K. The I-V for all of these devices is not hysteretic due to the small capacitance and the resistance. At higher voltage the junction I-V curve shows tunnel-junction behavior and a superconducting energy gap edge at 20 mV. We will discuss how these results are a promising step forward for sensitive magnetic sensors made from high temperature superconductors at various temperatures.

**3:18PM P25.00005 Engineering the parity lifetime of  $\text{NbTiN}$  Cooper-pair transistors**, ATTILA GERESDI, DAVID VAN WOERKOM, TAMAS KRIVACHY, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands, SEBASTIAN RUBBERT, ANTON R. AKHMEROV, Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands, LEO P. KOUWENHOVEN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands — Controlling the quasiparticle occupation of a superconducting island is of fundamental importance for superconducting circuits as single electron tunneling results in decoherence. Thus far, engineering superconducting tunnel junctions for quantum bits was done exclusively based on aluminum, which limits integration with systems requiring finite magnetic field, such as topological superconductors based on spin-orbit coupled nanowires or spin ensembles. Here we present parity modulation of the switching current of a niobium titanium nitride ( $\text{NbTiN}$ ) Cooper-pair transistor coupled to aluminum (Al) leads for the first time. Owing to the gap profile  $\Delta_{\text{island}} \gg \Delta_{\text{leads}}$ , we observe a parity lifetime exceeding 1 minute in combination with a Josephson energy of  $50 \mu\text{eV}$ . We link this value to the finite subgap density of states of  $\text{NbTiN}$ , which is consistent with the subgap conductance measured by DC transport. We discuss our design of quasiparticle trapping and radiation shielding techniques, which resulted in a non-saturated parity lifetime down to a fridge temperature of 12 mK. Finally, we show that this circuit is compatible with magnetic fields in the range of 100 mT.

**3:30PM P25.00006 The cavity resonance mode of  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$  mesa terahertz sources as probed by scanning laser thermal microscopy<sup>1</sup>**, TIMOTHY BENSEMAN, Queens College CUNY, ALEXEI KOSHELEV, VITALII VLASKO-VLASOV, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory, YANG HAO, University of Illinois at Chicago, BORIS GROSS, MATTHIAS LANGE, DIETER KOELLE, REINHOLD KLEINER, University of Tuebingen, KAZUO KADOWAKI, University of Tsukuba — Stacked Intrinsic Josephson Junctions (IJJs) in the extremely anisotropic high- $T_c$  superconductor  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$  are a promising solid-state source of coherent terahertz radiation in the so-called "THz gap" range. In these devices, a geometric resonant mode of a stack of IJJs of typical dimensions  $300 \times 60 \times 1$  microns<sup>3</sup> acts to synchronize the individual junctions, resulting in coherent far-field THz emission. This resonance can be probed by scanning laser thermal microscopy, in which a modulated optical laser beam is rastered across the top surface of a stack. The resulting thermal perturbation to the stack's cavity mode can thus be mapped via the resulting xy-dependent modulation of the stack's electrical resistance. Here we discuss the experimentally measured scanning laser pattern of such a THz cavity mode, and the implications of its symmetry for the mechanism of IJJ synchronization in these devices.

<sup>1</sup>This research was supported by the Department of Energy, Office of Basic Energy Sciences, under Contract No. De-AC02-06CH11357.

**3:42PM P25.00007 Artificially induced hotspots in  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$  mesa terahertz sources<sup>1</sup>**, YANG HAO, University of Illinois at Chicago, ULRICH WELP, ALEXEI KOSHELEV, VITALII VLASKO-VLASOV, WAI-KWONG KWOK, Argonne National Laboratory, KAZUO KADOWAKI, University of Tsukuba, TIMOTHY BENSEMAN, Queens College CUNY — Mesa-shaped devices comprising stacked Intrinsic Josephson Junctions (IJJs) in the high-temperature superconductor  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$  can be used as compact sources of coherent terahertz radiation. Achieving high emission levels of THz emission power from these devices depends on efficient synchronization of the approximately 600 IJJs in the stack. Theoretical simulations of stacked IJJs, as well as some empirical results, suggest that thermal inhomogeneity of the stack may enhance THz emission power. There are a number of possible mechanisms by which this might occur, including a hotspot acting as a local resistive shunt for the IJJs (thus altering the spread of bias voltages in the stack and the junction damping dynamics) or by local self-heating reducing the phase-stiffness of the superconducting condensate in critical locations. Here we report results of artificially inducing local heating in these devices with thin film micro-heaters patterned on their surfaces, in order to determine which mechanism(s) could be responsible for self-heating-induced THz emission enhancement.

<sup>1</sup>Sample patterning was performed at the Center for Nanoscale Materials, an Office of Science user facility, supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

**3:54PM P25.00008 Scattering to different vortex polarity in coupled long Josephson junctions**, WALTRAUT WUSTMANN, KEVIN D. OSBORN, Laboratory for Physical Sciences, College Park, MD — We theoretically study the motion of flux vortices (fluxons) in structures made from discrete long Josephson junctions (DLJJs) which may have applications in the fields of reversible and low-power computing. We investigate the scattering of fluxons at specially designed interfaces where multiple DLJJs meet. Once fluxons approach the interface, flux oscillations at the interface can be temporarily excited before the fluxons continue along to another DLJJ. Under some conditions the fluxons will change their polarity (to antifluxons) and in other cases the fluxon continues without a change in polarity. We explain the dynamics through the resonant interaction of the soliton with bound states at the interface. We also study a controlled polarity gate, where the polarity of the target fluxon depends on a control fluxon which enters and exits the interface through separate DLJJs.

**4:06PM P25.00009 Instability of Driven Josephson Vortices in Long Underdamped Junctions<sup>1</sup>**, AHMAD SHEIKHZADA, ALEX GUREVICH, Department of Physics and Center for Accelerator Science, Old Dominion University — We show that a Josephson vortex driven by a dc current can become unstable due to strong Cherenkov radiation resulting from intrinsic nonlocal electrodynamics of long underdamped Josephson junctions. This instability is not captured by the conventional sine-Gordon equation but is described by a more general integro-differential equation for the phase difference,  $\theta(x, t)$ . Our numerical simulations of this nonlinear dynamic equation for different junction geometries have shown that, as the vortex reaches a critical velocity, it triggers a cascade of expanding vortex-antivortex pairs. As a result, vortices and antivortices become spatially separated and accumulate continuously on the opposite sides of expanding dissipative domain. This effect is most pronounced in thin film edge Josephson junctions at low temperatures where a single vortex can switch the whole junction into a resistive state at currents well below the Josephson critical current. Our results suggest that a rapidly moving Josephson vortex can destroy the superconducting long-range order in a way that is similar to the crack propagation in solids.

<sup>1</sup>This work was supported by DOE under grant No. DE-SC0010081.

**4:18PM P25.00010 Terahertz emission from a stack of intrinsic Josephson junctions in  $\text{Bi}_2\text{Sr}_2\text{Ca}_2\text{Cu}_3\text{O}_{10+\delta}$** , MANABU TSUJIMOTO, University of Tsukuba, ITSUHIRO KAKEYA, Kyoto University, SHINTARO ADACHI, TAKAO WATANABE, Hirosaki University, TAKANARI KASHIWAGI, HIDETOSHI MINAMI, KAZUO KADOWAKI, University of Tsukuba — Terahertz radiation in the 0.3–10 THz frequency range is a technologically attractive form of electromagnetic radiation, because it has applications in numerous fields. Terahertz generation from stacks of intrinsic Josephson junctions fabricated from  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$  (Bi-2212) has become a major focus of both experimental and theoretical research [U. Welp *et al.*, Nat. Photonics **7**, 702 (2013)]. Here, we observe continuous terahertz emission from a stack of intrinsic Josephson junctions made of  $\text{Bi}_2\text{Sr}_2\text{Ca}_2\text{Cu}_3\text{O}_{10+\delta}$  (Bi-2223). We investigate how triple  $\text{CuO}_2$  planes affect the c-axis current-voltage and emission characteristics. The terahertz emission spectra are measured by Fourier-transform infrared spectroscopy.

**4:30PM P25.00011 Josephson radiation from InSb-nanowire junction<sup>1</sup>**, DAVID VAN WOERKOM, ALEXANDER PROUTSKI, TAMAS KRIVACHY, DANIEL BOUMAN, RUBEN VAN GULIK, ONDER GUL, MAJA CASSIDY, Delft Univ. of Tech., The Netherlands, DIANA CAR, ERIK BAKKERS, Eindhoven Univ. of Tech., The Netherlands, LEO KOUWENHOVEN, ATTILA GERESDI, Delft Univ. of Tech., The Netherlands — Semiconducting nanowire Josephson junctions has recently gained interest as building blocks for Majorana circuits and gate-tuneable superconducting qubits. Here we investigate the rich physics of the Andreev bound state spectrum of InSb nanowire junctions utilizing the AC Josephson relation  $2eV_{\text{bias}} = \hbar f$ . We designed and characterized an on-chip microwave circuit coupling the nanowire junction to an  $\text{Al}/\text{AlO}_x/\text{Al}$  tunnel junction. The DC response of the tunnel junction is affected by photon-assisted quasiparticle current, which gives us the possibility to measure the radiation spectrum of the nanowire junction up to several tens of GHz in frequency. Our circuit design allows for voltage or phase biasing of the Josephson junction enabling direct mapping of Andreev bound states. We discuss our fabrication methods and choice of materials to achieve radiation detection up to a magnetic field of few hundred milliTesla, compatible with Majorana states in spin-orbit coupled nanowires.

**4:42PM P25.00012 Interaction between fractional Josephson vortices in multi-gap superconductor tunnel junctions**, JU H. KIM, Department of Physics, University of Houston-Clear Lake — In a long Josephson junction (LJJ) with two-band superconductors, fractionalization of Josephson vortices (fluxons) can occur in the broken time reversal symmetry state when spatial phase textures (i-solitons) are excited. Excitation of i-solitons in each superconductor layer of the junction, arising due to the presence of two condensates and the interband Josephson effect, leads to spatial variation of the critical current density between the superconductor layers. Similar to the situation in a  $Y\text{Ba}_2\text{Cu}_3\text{O}_{7-x}$  superconductor film grain boundary [1], this spatial dependence of the critical current density can self-generate magnetic flux in the insulator layer, resulting in fractional fluxons with large and small fraction of flux quantum. Similar to fluxons in one-band superconductor LJJ, these fractional fluxons are found to interact with each other. The interaction between large and small fractional fluxons determines the size of a fluxon which includes two (one large and one small) fractional fluxons. We discuss the nature of interaction between fractional fluxons and suggest that i-soliton excitations in multi-gap superconductor LJJ may be probed by using magnetic flux measurements.

**4:54PM P25.00013 The emission mechanism of THz electromagnetic waves from Bi2212 mesa device**, CHI HARU WATANABE, HIDETOSHI MINAMI, TAKEO KITAMURA, TAKANARI KASHIWAGI, University of Tsukuba, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — From the detailed study of the severe temperature inhomogeneity of the Bi2212 IJJ mesa structure often forming "hot-spot" at relatively higher bias current region, while the electromagnetic waves are emitted, multi terminal potential measurement of the mesa device has revealed that the equipotential part of the mesa can only give universal ac-Josephson relationship between the potential difference and the frequency measured by the FT-IR spectrometer, and it is violated as the potential is measured in the region where the hot-spot is formed. This means that the deviation of the emission frequency from the ac-Josephson effect comes from a gradient of the electrical potential distribution. This strongly suggests that the electromagnetic waves at THz frequency may be generated in the superconducting part of the mesa, where the static electric potential is uniform, satisfying the ac-Josephson relation universally no matter how much temperature gradient is.

**5:06PM P25.00014 Tunable plasma edge in Josephson junction loaded wire array metamaterial<sup>1</sup>**, MELISSA TREPANIER, DAIMENG ZHANG, University of Maryland, College Park, V. P. KOSHELETS, IREE, STEVEN ANLAGE, University of Maryland, College Park — It is desirable to have a tunable negative permittivity medium that operates in the microwave domain. The effective plasma frequency of a JJ-loaded wire array can be tuned as a function of dc current and temperature in the low current limit. To demonstrate this effect we observe a change in transmission through a single layer of 8 superconducting Nb wires that spans a rectangular waveguide. A simple model that treats the wires as an artificial dielectric with a tunable effective permittivity shows good agreement with measured results for tuning of the plasma edge. In addition we have observed interesting behavior at higher current and rf input power. The dynamics are very rich, highly hysteretic, and nonlinear.

**5:18PM P25.00015 A high  $T_c$  superconducting terahertz emitter operated from 0.5 to 2.4 THz**,<sup>1</sup> T. KASHIWAGI, K. SAKAMOTO, H. KUBO, Y. SHIBANO, T. ENOMOTO, T. KITAMURA, K. ASANUMA, T. YASUI, C. WATANABE, K. NAKADE, Y. SAIWAI, T. KATSURAGAWA, T. TANAKA, T. YUASA, Univ. of Tsukuba, M. TSUJIMOTO, Kyoto Univ., R. YOSHIKAWA, Univ. of Tsukuba, T. YAMAMOTO, Ulm Univ., H. MINAMI, Univ. of Tsukuba, R.A. KLEMM, Univ. of Central Florida, K. KADOWAKI, Univ. of Tsukuba — According to our previous studies, the efficiency of the THz radiation from a high  $T_c$  superconducting emitter can be improved greatly when the stand-alone mesa structure of Bi2212 single crystal is used for the emitter<sup>1)</sup>. The principal reason for that lies in the heat removal from the mesa. Recently, we developed a new device structure with high heat exhaust from the stand-alone mesa structures and studied the radiation characteristics from the different shape of mesa structures. The results obtained from a cylindrical stand alone mesa show very wide the radiation frequencies ranging from 0.5 to 2.4 THz. Strong emission power peaks were observed at about 1.0 THz and 1.6 THz<sup>2)</sup>. 1) T. Kitamura *et al.*, Appl. Phys. Lett. **105**, 202603 (2014) 2) T. Kashiwagi *et al.*, Appl. Phys. Lett. **107**, 082601 (2015)

**2:30PM P26.00001 Relative stability of ferroelectric and antiferroelectric states in  $(\text{Na}_{0.5}\text{Bi}_{0.5})\text{TiO}_3$ -based solid solutions**, V. SOBOLEV, South Dakota School of Mines & Technology, Rapid City, SD 57701, USA, V. M. ISHCHUK, L. G. GUSAKOVA, N. G. KISEL, D. V. KUZENKO, N. A. SPIRIDONOV, Science & Technology Center ReactivElectron of the National Academy of Sciences of Ukraine, 83049 Donetsk, Ukraine — Influence of the B-site ion substitutions on the of relative stability of the antiferroelectric and ferroelectric phases in  $[(\text{Na}_{0.5}\text{Bi}_{0.5})_{0.80}\text{B}_{0.20}](\text{Ti}_{1-x}\text{B}_x)\text{O}_3$  (NBT-BT) solid solutions has been investigated. Zirconium and tin ions along with  $(\text{In}_{0.5}\text{Nb}_{0.5})$ ,  $(\text{Fe}_{0.5}\text{Nb}_{0.5})$ , and  $(\text{Al}_{0.5}\text{V}_{0.5})$  ion complexes have been used for substitutions. It is found that an increase of content of the substituting ion results in a near linear variation in the size of the crystal lattice unit cell. The relative stability of the antiferroelectric and ferroelectric phases changes according to the variation of the tolerance factor of solid solution which in turn varies with the change of solid solution composition cause by substitutions. Obtained results demonstrate a predominant influence of the size of substituting ions on the relative stability of the antiferroelectric and ferroelectric states in  $(\text{Na}_{0.5}\text{Bi}_{0.5})\text{TiO}_3$ -based solid solutions. Our results open a new option for raising the temperature of the ferroelectric to antiferroelectric phase transition NBT-BT compounds.

**2:42PM P26.00002 Visible light absorption in La, Cr co-doped  $\text{SrTiO}_3$  and  $\text{BaTiO}_3$  for ferroelectric photovoltaics**, RYAN COMES, MARTIN MCBRIARTY, PHUONG-VU ONG, Pacific Northwest National Lab, STEVE HEALD, Argonne National Lab, GERARD CARROLL, DANIEL GAMELIN, University of Washington, KEREN FREEDY, University of Virginia, SERGEY SMOLIN, JASON BAXTER, Drexel University, TIFFANY KASPAR, MARK BOWDEN, PETER SUSHKO, SCOTT CHAMBERS, Pacific Northwest National Lab — Ferroelectric materials offer intriguing possibilities as photovoltaic materials, as their built-in electric field is ideal for separation of optically-excited electron-hole pairs without the need for a p-n junction. However, the majority of ferroelectrics suffer from a wide optical band gap outside the visible range. By co-doping La and Cr into epitaxial  $\text{SrTiO}_3$  and  $\text{BaTiO}_3$  (SLTCO/BLTCO) thin films, we show that absorption in the visible light regime can be achieved with a band gap of ~2.3 eV while preserving ideal stoichiometry. Through x-ray photoelectron spectroscopy, spectroscopic ellipsometry, photoconductivity and ultrafast pump-probe transient reflectance measurements, we show that visible light excitation of Cr 3d valence electrons into the Ti 3d conduction band produces optical carriers. Using piezoresponse force microscopy and polarized x-ray absorption fine structure measurements, we measure the ferroelectric polarization of the doped BLTCO films. These results are compared to density functional theory models to understand the optical and structural properties of the materials.

## 2:54PM P26.00003 ABSTRACT WITHDRAWN —

**3:06PM P26.00004 Strain effect on the visible emission in ferroelectric nanotubes: template and wall-thickness effect**, YUNSANG LEE, Soongsil University, SANGDON BU, JINKYU HAN, Chonbuk National University — We investigated the strain effect on temperature-dependent photoluminescence property in the clamped (with template) and free-standing (without template)  $\text{PbTiO}_3$  (PTO) nanotubes. The wall-thickness of nanotubes was varied from 25 to 80 nm with the outer diameter fixed to 420 nm. While all nanotubes show sizable green/yellow emission, the temperature dependent shift of the emission energy is significantly suppressed in the clamped PTO nanotubes, which is attributed to the lattice strain driven by the template clamping. This clamping effect is more significant for thinner nanotubes. Even in the free-standing PTO nanotubes the temperature-dependence of emission is affected by the wall-thickness. The similar behavior is identified in the  $\text{Pb}(\text{Zr,Ti})\text{O}_3$  nanotubes. Our finding is the clear manifestation of the template and geometrical shape effect on the optical property of the nanotubes.

**3:18PM P26.00005 Negative Refractive Index Materials for Optical Range of Spectrum**, VLADIMIR SOBOLEV, South Dakota School of Mines and Technology, Rapid City, SD 57701, VALERII ISHCHUK, Science & Technology Center Reaktivelektron, of the National Academy of Sciences of Ukraine, Donesk, Ukraine — A new method of manufacturing of negative refractive index media is presented. It is demonstrated that one can use of the controlled decomposition of solid solutions of oxides with perovskite crystal structure in the state of coexisting domains of the antiferroelectric and ferroelectric phases for manufacturing of such materials. The lead zirconate titanate based solid solutions are considered as an example of substances suitable for creation of such materials. Manufactured composites constitute a dielectric antiferroelectric matrix with a structure of conducting interphase boundaries separating domains of the ferroelectric and antiferroelectric phases. The electric conductivity of the interphase boundaries occurs as a result of the local decomposition of the solid solutions in the vicinity of these boundaries. The decomposition process and consequently the conductivity of the interphase boundaries can be controlled by means of external influences.

**3:30PM P26.00006 Incommensurate lattice modulations in Potassium Vanadate<sup>1</sup>**, BRYAN CHAKOUMAKOS, ARNAB BANERJEE, LUMSDEN MARK, HUIBO CAO, Quantum Condensed Matter Div., Oak Ridge National Laboratory, Oak Ridge, TN - 37830, JONG-WOO KIM, Advanced Photon Source, Argonne National Laboratory, Lemont, IL - 60439, CHRISTINA HOFFMAN, XIAOPING WANG, Chem. & Mat. Sci. Div., Oak Ridge Nat. Lab. Oak Ridge, TN - 37830 — Potassium Vanadate ( $K_2V_3O_8$ ) is an  $S = 2D$  square lattice antiferromagnet that shows spin reorientation indicating a strong coupling between the magnetism and its dielectric properties with a promise of rich physics that promises multiferroicity. These tangible physical properties are strongly tied through a spin-lattice coupling to the underlying lattice and superlattice behavior. It has a superlattice (SL) onset below  $T_c = 115$  K with an approximate  $[3 \times 3 \times 2]$  modulation. Here we present our recent experiments at TOPAZ beamline at SNS which for the first time proves conclusively that the lattice modulations are incommensurate, with an in-plane  $Q$  of 0.315. We will also show our attempts to refine the data using JANA which requires a redefinition of the lattice, as well as the temperature and  $Q$  dependence of the superlattice modulation measured using neutrons at HFIR and synchrotron x-rays at APS. Our results are not only relevant for the ongoing search of multifunctional behavior in  $K_2V_3O_8$  but also generally for the superlattice modulations observed in a large family of fersenoites.

**3:42PM P26.00007 Properties of Transition Metal Doped Alumina<sup>1</sup>**, ERIK NYKWEST, Univ of Connecticut - Storrs, KRISTA LIMMER, RAY BRENNAN, VICTORIA BLAIR, Army Research Lab, RAMPI RAMPRASAD, Univ of Connecticut - Storrs — Crystallographic texture can have profound effects on the properties of a material. One method of texturing is through the application of an external magnetic field during processing. While this method works with highly magnetic systems, doping is required to couple non-magnetic systems with the external field. Experiments have shown that low concentrations of rare earth (RE) dopants in alumina powders have enabled this kind of texturing. The magnetic properties of RE elements are directly related to their  $f$  orbital, which can have as many as 7 unpaired electrons. Since  $d$ -block elements can have as many as 5 unpaired electrons the effects of substitutional doping of 3d transition metals (TM) for Al in alpha (stable) and theta (metastable) alumina on the local structure and magnetic properties, in addition to the energetic cost, have been calculated by performing first-principles calculations based on density functional theory. This study has led to the development of general guidelines for the magnetic moment distribution at and around the dopant atom, and the dependence of this distribution on the dopant atom type and its coordination environment. It is anticipated that these findings can aid in the selection of suitable dopants help to guide parallel experimental efforts.

<sup>1</sup>This project was supported in part by an internship at the Army Research Laboratory, administered by the Oak Ridge Institute for Science and Education, along with a grant of computer time from the DoD High Performance Computing Modernization Program.

**3:54PM P26.00008 Incursion of water and Cu ions into porous low dielectric constant (LKD) thin films and interconnects resulting in damage, time dependent dielectric breakdown (TDDB) and decreased lifetime and reliability.**, ROBERT LAIBOWITZ, ARCHANA RAJA, Columbia University, THOMAS SHAW, ERIC LINIGER, STEPHAN COHEN, IBM Research Division, COLUMBIA UNIVERSITY COLLABORATION, IBM RESEARCH DIVISION COLLABORATION — Porous dielectrics, their interfaces and related processing details provide many opportunities for water and Cu incursion. The Cu typically starts as part of the electrode and needs a liner to keep it away from the dielectric. As scaling continues thinner liners and imperfections in the liner layer can expose the Cu to the LKD. This will lead to TDDB with greatly reduced lifetimes. Water exposure can come from processing or through defects in the passivation layer. Most studies of these breakdown effects have been accomplished using accelerated DC measurements in which the sample is destroyed. Dielectric relaxation provides a new set of measurements at low fields, low temperatures and reusable samples. In this way we have observed the presence of both physisorbed and chemisorbed water, determined their activation energy of motion and removal of the water by various annealing protocols. Initial measurements of Cu incursion have also been made. Preliminary measurement of samples containing Cu and water and processing damage show reduced reliability. We also have begun studies to determine the minimum liner thickness. .

**4:06PM P26.00009 Strong Red Luminescent Twin ZnO Nanorods for Nano-thermometry and Phonon Tunnel Device Application**, AVANENDRA SINGH, KARTIK SENAPATI, NISER, KARUNAKAR NANDA, IISC, BISWARUP SATPATI, SINP, PRATAP SAHOO, NISER — Two segments of horizontally grown crystalline ZnO nanorods (NRs) connected with an amorphous layer have been successfully synthesized using aqueous growth technique. The amorphous layer between the crystalline ZnO sections is tunable with growth parameters and confirmed by transmission electron microscopy. The confocal photoluminescence (PL) imaging and spectroscopy of twin ZnO NRs at different temperature shows stable and intense red emission with comparably weak UV emission. Red emission from the twin NRs are the consequence of surface defect and structural imperfections of lattice disorder. The disappearance of asymmetry in UV emission after 293K indicates the weak exciton-phonon coupling at higher temperature while the coupling is stronger at lower temperatures. An indirect analysis from phonon bands of PL shows that the amorphous layer acts as a phonon barrier beyond certain thickness. Such crystalline-amorphous-crystalline architecture may be suitable for fundamental studies of the phonon tunneling in nanostructure. We also show that the individual NRs can be used for sensing and mapping of temperature in a wide range of 80-373 K with an accuracy of 0.1K with good sensitivity. These NRs may have suitable application for non-contact nano-thermometry.

**4:18PM P26.00010 Analysis of metastable ultrasmall titanium oxide clusters using a hybrid global search algorithm and first-principles approach<sup>1</sup>**, ERIC INCLAN, Georgia Institute of Technology, Atlanta, GA 30332, JACK LASSESTER, Middle Tennessee State University, Murfreesboro, TN 37130, DAVID GEOHEGAN, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Research in  $TiO_2$  materials is highly relevant to energy and device applications, however, precise control of their morphologies and characterization are still a grand challenge in the field. We developed and applied a hybrid optimization algorithm to explore configuration spaces of energetically metastable  $TiO_2$ . Our approach was to minimize the total energy of  $TiO_2$  clusters in order to identify the energy landscape of plausible  $(TiO_2)_n$  ( $n = 1-100$ ). The hybrid algorithm retained good agreement with a regression on structures published in literature up to  $n = 25$ . Using first-principles density functional theory, we analyze basic properties of the hybrid-algorithm generated  $TiO_2$  nanoparticles. Our results show the expected convergence to bulk material characteristics as the cluster size increases in that the band gap varies with respect to the size of the nanocluster. The nanoclusters trended toward compact, low surface area structures that share characteristics of the bulk, namely octahedral microstructures as the nanoclusters increased in size. Our study helps in better identifying and characterizing experimentally observed structures.

**4:30PM P26.00011 Low energy THz excitations in distorted perovskites under strong magnetic fields and low temperature.** , N. E. MASSA, LANAIS EFO-CEQUINOR, UNLP, La Plata, Argentina, K. HOLLDAK, HZB-BESSY II, Berlin, Germany , V. TA PHUOC, R. SOPRACASE, GREMAN, Tours, France, L. DEL CAMPO, D. DE SOUSA MENESES, P. ECHEGUT, CNRS-CEMHTI, Orlans, France, J.A. ALONSO, ICMN-CSIC, Madrid, Spain — We report on the magnetic field evolution of distinctive absorption bands in several zero field cooled polycrystalline  $\text{RMO}_3$  ( $\text{R} = \text{Pr, Nd, Sm, Er, Tm, Lu}$ ;  $\text{M} = \text{Cr, Mn, Fe, Ni}$ ) at low temperatures. Measurements below  $120 \text{ cm}^{-1}$  were done in an 11 T magnet combined with a Bruker IFS125-HR interferometer at the THz beamline of the BESSY II storage ring. At the reordering spin temperature, the spectra of  $\text{ErCrO}_3$  show an Er-Kramers doublet at  $\sim 55 \text{ cm}^{-1}$  following a second order continuous reorientation. It suggests strong anisotropic  $\text{Er}^{3+}$ - $\text{Cr}^{3+}$  magnetic exchange interactions. The band strength of its triplet excited states decreases upon increasing the magnetic field. Non-Kramers Pr in  $\text{PrCrO}_3$  implies a magnetic field induced quasi-doublet system. Spin wave modes AF and F are also tentatively assigned. In  $\text{ErFeO}_3$ , the spin reordering of the canted transition metal, and the  $\text{Er}^{3+}$  exchange, is monitored emerging above 80 K. Temperature dependent multiplet transitions centered at  $50 \text{ cm}^{-1}$  and  $110 \text{ cm}^{-1}$  appear as asymmetric field dependent broad lines. The absence of activity at  $\sim 4 \text{ K}$  in  $\text{SmCrO}_3$ , shared by  $\text{SmMO}_3$  ( $\text{M} = \text{Fe, Ni}$ ), is consequence of near Cr-canted-Rare-Earth-opposite moment compensation juxtaposed to random micrograin orientation. We will also comment on observed only in  $\text{ErNiO}_3$  field dependent Er transitions and band profiles.

Session P27 DCMP: VO<sub>2</sub>: Experiment and Theory 326 - Mengkun Liu, State University of New York, Stonybrook

**2:30PM P27.00001 Ultrafast Pump-Probe Studies of the Light-Induced MIT and Recovery of Niobium Dioxide Thin Films** , MELISSA BEEBE, College of William & Mary, J. MICHAEL KLOPF, Helmholtz-Zentrum Dresden-Rossendorf, SALINPORN KITTIWATANAKUL, JIWEI LU, STUART A. WOLF, University of Virginia, R. ALEJANDRA LUKASZEW, College of William & Mary — Niobium dioxide ( $\text{NbO}_2$ ) is a highly correlated binary oxide that, like vanadium dioxide ( $\text{VO}_2$ ), exhibits a first-order insulator-to-metal transition (IMT) at a material-dependent critical temperature, accompanied by a structural transformation from monoclinic to rutile. The nature of the IMT in  $\text{VO}_2$  has been discussed at length, while fewer studies have been carried out on  $\text{NbO}_2$ . Previous studies show that the IMT can also be optically induced in  $\text{VO}_2$  on a sub-picosecond timescale; here, we present the first ultrafast pump-probe studies showing this optically-induced transition in  $\text{NbO}_2$  thin films and compare these results to similar ones carried out on  $\text{VO}_2$  thin films.

**2:42PM P27.00002 OPTICAL SPECTROSCOPY OF THE  $M_2$  AND T PHASES OF VANADIUM DIOXIDE** , T.J. HUFFMAN, M.M. QAZILBASH, C. HENDRIKS, E.J. WALTER, H. KRAKAUER, College of William and Mary, JOONSEOK YOON, HONGLYOUL JU, Yonsei University, R. SMITH, G.L. CARR, Brookhaven National Laboratory — The salient feature of the familiar structural transition that accompanies the metal-insulator transition in bulk  $\text{VO}_2$  is a pairing of all of the vanadium ions in the  $M_1$  insulating phase. This pairing has long been thought critical to the emergence of insulating behavior. However, there exist two less familiar insulating states,  $M_2$  and T. These phases notably exhibit distinctly different V-V pairing. In the  $M_2$  phase, only half of the vanadium ions exhibit pairing while the other half carry local spin 1/2 magnetic moments and are equally spaced in quasi-one dimensional chains. The T phase has two types of inequivalent vanadium chains, each consisting of V-V pairs but with different spacing between V ions in the pairs. The  $M_1$  phase has been studied extensively with optical spectroscopy. By studying the two less familiar insulating phases,  $M_2$  and T, one can investigate how changes in V-V pairing affect the properties of the  $\text{VO}_2$  insulating state. We performed infrared and optical spectroscopy on the  $M_2$  and T phases in the same sample. Despite a clear change in the lattice structure, the inter-band transitions are insensitive to changes in the V-V pairing. This result conclusively establishes that intra-atomic Coulomb repulsion between electrons provides the dominant contribution to the energy gap in all insulating phases of  $\text{VO}_2$ . Our work highlights the necessity of considering the  $M_2$  and T phases of  $\text{VO}_2$  in future experimental and theoretical research.

**2:54PM P27.00003 Photoinduced phase transitions in narrow-gap Mott insulators: the case of  $\text{VO}_2$** <sup>1</sup> , ZHUORAN HE, ANDREW MILLIS, Columbia University — The nonequilibrium dynamics of strongly correlated electrons in photoexcited  $\text{VO}_2$  is studied using the quantum Boltzmann equation and nonequilibrium Hartree-Fock methods applied to a band structure given by extended density functional theory (DFT+ $U$ + $V$ ) and realistic dynamical interactions. The initial equilibration of electrons occurs in hundreds of femtoseconds. For physically reasonable parameters, our Hartree-Fock calculation sustains a new metastable  $M_1$  metal phase that is qualitatively consistent with the recent experiment of Morrison et al [1]. The long-term stability of the  $M_1$  metal phase will also be considered. [1] V. R. Morrison, R. P. Chatelain, K. L. Tiwari, A. Hendaoui, A. Bruhács, M. Chaker, and B. J. Siwick, Science 346, 445 (2014).

**3:06PM P27.00004 Random Field Driven Spatial Complexity at the Mott Transition in  $\text{VO}_2$**  , ERICA CARLSON, SHUO LIU, BENJAMIN PHILLABAUM, Purdue University, West Lafayette, IN, USA, KARIN DAHMEN, University of Illinois at Urbana-Champaign, Urbana, IL, USA, NARSIMHAMURTHY VIDHYADHIRAJA, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, INDIA , MUMTAZ QAZILBASH, College of William and Mary, Williamsburg, VA, USA , DIMITRI BASOV, University of California San Diego, La Jolla, CA, USA — We report the first application of critical cluster techniques to the Mott metal-insulator transition in vanadium dioxide. We show that the geometric properties of the metallic and insulating puddles observed by scanning near-field infrared microscopy are consistent with the system passing near criticality of the random field Ising model as temperature is varied. The resulting large barriers to equilibrium may be the source of the unusually robust hysteresis phenomena associated with the metal-insulator transition in this system.

**3:18PM P27.00005 Field-Effect Modulation of Ambipolar Doping and Domain Wall Band Alignment in P-type Vanadium Dioxide Nanowires** , YASEN HOU, XINGYUE PENG, YIMING YANG, DONG YU, Univ of California - Davis — The sub-picosecond metal-insulator phase transition in vanadium dioxide ( $\text{VO}_2$ ) has attracted extensive attention with potential applications in ultrafast Mott transistors. However, the development of  $\text{VO}_2$ -based transistors lags behind, owing to the lack of an efficient and hysteresis-free electrostatic doping control. Here we report the first synthesis of p-type single crystalline  $\text{VO}_2$  nanowires via catalyst-free chemical vapor deposition. The p-type doping was unambiguously confirmed by both solid and electrochemical gating methods, and further evidenced by the scanning photocurrent microscopic measurements. Interestingly, we observed that the photocurrent spot polarity at the metal-insulator domain walls was reversibly switched by electrochemical gating, which indicates a band bending flipping. Furthermore, we eliminated the common hysteresis in gate sweep and greatly shortened the transistor response time via a hybrid gating method, which combines the merits of liquid ionic and solid gating. The capability of efficient field effect modulation of ambipolar conduction and band alignment offers new opportunities on understanding the phase transition mechanism and enables novel electronic applications based on  $\text{VO}_2$ .

**3:30PM P27.00006 Electric Field-induced Resistance Switching in VO<sub>2</sub> Channels using Hybrid Gate Dielectric of High-*k* Ta<sub>2</sub>O<sub>5</sub>/Organic material Parylene-C.** , TINGTING WEI, TERUO KANKI, Institute of Scientific and Industrial Research, Osaka University, KOHEI FUJIWARA, Institute for Materials Research, Tohoku University, MASASHI CHIKANARI, HIDEKAZU TANAKA, Institute of Scientific and Industrial Research, Osaka University — Electrostatic approach utilizing field-effect transistor (FET) with correlated electron materials provides an avenue to realize the novel devices (Mott-transistor) and to clarify condensed matter physics. In this study, we have prepared Mott-transistors using vanadium dioxide (VO<sub>2</sub>) channels and employed hybrid gate dielectric consisted of high-*k* material Ta<sub>2</sub>O<sub>5</sub> and organic polymer parylene-C to trigger carrier transport modulation in VO<sub>2</sub>. Obvious resistance modulations were observed in insulating regime through time-dependent resistance measurement at varied square-shaped gate bias ( $V_G$ ). Contrasting to the hysteretic response in electric double layer transistor (EDLT), an abrupt resistance switching in less than of 2-second-interval enables us to attribute such immediate modulation to pure electrostatic effect. Moreover, the maximum of resistance change was identified to appear around phase transition temperature ( $T_{MI}$ ), which confirmed the disordered heterogeneous regime at  $T_{MI}$ . Taking advantage of systematic modulation using VO<sub>2</sub>-based devices, we demonstrated the pronounced shifts of  $T_{MI}$  by gate bias. Another fascinating behavior on asymmetric drop in  $T_{MI}$  by hole-electron carrier doping was observed.

**3:42PM P27.00007 Resistance modulation in VO<sub>2</sub> nanowires induced by an electric field *via* air-gap gates** , TERUO KANKI, MASASHI CHIKANARI, TINGTING WEI, HIDEKAZU TANAKA, Osaka University, THE INSTITUTE OF SCIENTIFIC AND INDUSTRIAL RESEARCH TEAM — Vanadium dioxide (VO<sub>2</sub>) shows huge resistance change with metal-insulator transition (MIT) at around room temperature. Controlling of the MIT by applying an electric field is a topical ongoing research toward the realization of Mott transistor. In this study, we have successfully switched channel resistance of VO<sub>2</sub> nano-wire channels by a pure electrostatic field effect using a side-gate-type field-effect transistor (SG-FET) *via* air gap and found that single crystalline VO<sub>2</sub> nanowires and the channels with narrower width enhance transport modulation rate. The rate of change in resistance ( $(R_0-R)/R$ , where  $R_0$  and  $R$  is the resistance of VO<sub>2</sub> channel with off state and on state gate voltage ( $V_G$ ), respectively) was 0.42 % at  $V_G = 30$  V in in-plane poly-crystalline VO<sub>2</sub> channels on Al<sub>2</sub>O<sub>3</sub>(0001) substrates, while the rate in single crystalline channels on TiO<sub>2</sub> (001) substrates was 3.84 %, which was 9 times higher than that using the poly-crystalline channels. With reducing wire width from 3000 nm to 400 nm of VO<sub>2</sub> on TiO<sub>2</sub> (001) substrate, furthermore, resistance modulation ratio enhanced from 0.67 % to 3.84 %. This change can not be explained by a simple free-electron model. In this presentation, we will compare the electronic properties between in-plane polycrystalline VO<sub>2</sub> on Al<sub>2</sub>O<sub>3</sub> (0001) and single crystalline VO<sub>2</sub> on TiO<sub>2</sub> (001) substrates, and show experimental data in detail..

**3:54PM P27.00008 Resistance noise spectroscopy across the thermally and electrically driven metal-insulator transitions in VO<sub>2</sub> nanobeams<sup>1</sup>** , ALI ALSAQQA, COLIN KILCOYNE, SUJAY SINGH, State Univ of NY - Buffalo, GREGORY HORROCKS, PETER MARLEY, SARBAJIT BANERJEE, Texas AM University, College Station, G. SAMBANDAMURTHY, State Univ of NY - Buffalo — Vanadium dioxide (VO<sub>2</sub>) is a strongly correlated material that exhibits a sharp thermally driven metal-insulator transition at  $T_c \sim 340$  K. The transition can also be triggered by a DC voltage in the insulating phase with a threshold ( $V_{th}$ ) behavior. The mechanisms behind these transitions are hotly discussed and resistance noise spectroscopy is a suitable tool to delineate different transport mechanisms in correlated systems. We present results from a systematic study of the low frequency ( $1 \text{ mHz} < f < 10 \text{ Hz}$ ) noise behavior in VO<sub>2</sub> nanobeams across the thermally and electrically driven transitions. In the thermal transition, the power spectral density (PSD) of the resistance noise is unchanged as we approach  $T_c$  from 300 K and an abrupt drop in the magnitude is seen above  $T_c$  and it remains unchanged till 400 K. However, the noise behavior in the electrically driven case is distinctly different: as the voltage is ramped from zero, the PSD gradually increases by an order of magnitude before reaching  $V_{th}$  and an abrupt increase is seen at  $V_{th}$ . The noise magnitude decreases above  $V_{th}$ , approaching the  $V = 0$  value. The individual roles of percolation, Joule heating and signatures of correlated behavior will be discussed.

**4:06PM P27.00009 Strain-dependent ultrafast dynamics of insulator-to-metal phase transition in VO<sub>2</sub><sup>1</sup>** , SERGIY LYSENKO, ARMANDO RUA, JOSE FIGUEROA, FELIX FERNANDEZ, Department of Physics, University of Puerto Rico, Mayaguez, Puerto Rico 00681, USA — Much attention has been devoted recently to visualize and understand the strain effects in phase transition dynamics of vanadium oxide materials. In this study, using femtosecond angle-resolved light scattering technique we show strong influence of internal misfit strain in epitaxial VO<sub>2</sub>(M1) films on insulator-to-metal phase transition within less than 1 ps. Anisotropic strain in twinned domains and in domains of different size results mostly in antiphase oscillatory dynamics of coherent phonons. Depending on domain pattern and type of the substrate, this dynamics was found to be dependent on azimuthal angle and/or on spatial frequency of surface roughness. The origin of observed photoinduced antiphase oscillations is associated with compressive and tensile strain in VO<sub>2</sub> domains which alters the initial phase of the oscillations. In contrast to pure VO<sub>2</sub>(M1), the Cr-doped VO<sub>2</sub>(M2) shows strong phonon scattering signatures with noticeable random component in the phase of coherent phonons.

**4:18PM P27.00010 Straining to observe the M2 phase in epitaxial VO<sub>2</sub> films<sup>1</sup>** , NICHOLAS QUACK-ENBUSH, MATTHEW WAHILA, LOUIS PIPER, Dept. of Physics, Binghamton University, HANJONG PAIK, MEGAN HOLTZ, XIN HUANG, JOEL BROCK, DAVID MULLER, DARRELL SCHLOM, Dept. of Materials Science and Engineering, Cornell University, JOSEPH WOICK, Materials Science and Engineering Laboratory, National Institute of Standards and Technology, DARIO ARENA, Dept. of Physics, University of South Florida — It has been more than a decade since it was shown that the transition temperature  $T_{MIT}$  of VO<sub>2</sub> in epitaxial thin films can be tuned by compressive and tensile strain along the rutile c-axis. Since this discovery, uniaxial strain studies of VO<sub>2</sub> nanobeams have demonstrated that compressive strain indeed lowers  $T_{MIT}$ , thus stabilizing the metallic rutile phase. However, even minor tensile strain induces an intermediate insulating monoclinic M2 phase. Whether this phase can be stabilized in thin films remains contentious owing to the constraints of sample and/or interface quality. Here, we present hard x-ray photoelectron spectroscopy and temperature-dependent soft x-ray absorption spectroscopy of high quality ultrathin epitaxial VO<sub>2</sub> films on TiO<sub>2</sub> (001) and (100) substrates. The VO<sub>2</sub>/TiO<sub>2</sub>(001) are absent of intermediate phases and maintain a MIT similar to unstrained VO<sub>2</sub>, while the VO<sub>2</sub>/TiO<sub>2</sub>(100) films display a stable M2 phase between the M1 and rutile endpoint phases. We discuss our findings in terms of differences between uniaxial and biaxial strain.

<sup>1</sup>This research is supported by the National Science Foundation under DMR-1409912

**4:30PM P27.00011 Metallic bubbles nucleation and growth in VO<sub>2</sub> nanofilms: insights from TDDFT+DMFT<sup>1</sup>**, VOLODYMYR TURKOWSKI, Dep. of Physics, Univ. of Central Florida, Orlando, FL 32816, JOSE MARIO GALICIA-HERNANDEZ, Inst. of Physics, Univ. of Puebla, Puebla 72550, Mexico and Univ. of Central Florida, Orlando, FL 32816, GREGORIO HERNANDEZ-COCOLETZI, Inst. of Physics, Univ. of Puebla, Puebla 72550, Mexico, TALAT S. RAHMAN, Dep. of Physics, Univ. of Central Florida, Orlando, FL 32816 — We apply a time-dependent density-functional theory + dynamical mean-field theory (TDDFT+DMFT) approach to model the response of insulating nanofilms of VO<sub>2</sub> to perturbations by ultrafast laser pulses. We focus on the spatially-resolved metallization of the systems, and especially on the process of nucleation and time-dependence of the size of the "surface" and "bulk" metallic domains (bubbles) as a function of film width. In particular, we find that the initial universal (parameter-independent) growth of the domains (radius  $R \sim t^{1/2}$ ), changes by the bubbles shrinking ( $R \sim t^{-a}$ ,  $a \sim 1$ ) as a result of Coulomb scattering effects, and eventually by post-femto-second phonon-involved relaxation of the systems to the equilibrium accompanied by infrared photoemission. The time-dependent conductivity obtained from the above results is in a good agreement with available experimental data.[1,2] [1] D.J. Hilton et al., PRL 99, 226401 (2007); [2] T.L. Cocker et al., PRB 85, 155120 (2012).

**4:42PM P27.00012 Observation of impact ionization in vanadium dioxide<sup>1</sup>**, JOSHUA HOLLEMAN, Florida State University/NHMFL, MICHAEL BISHOP, National High Magnetic Field Laboratory, CARLOS GARCIA, CHRISTIANNE BEEKMAN, Florida State University/NHMFL, SHINBUHM LEE, HO NYUNG LEE, Oak Ridge National Laboratory, EFSTRATIOS MANOUSAKIS, Florida State University/NHMFL, STEPHEN MCGILL, National High Magnetic Field Laboratory — Pump-probe optical spectroscopy was used to investigate the possibility of charge carrier multiplication by impact ionization in a 100 nm film of VO<sub>2</sub> in the M<sub>1</sub> insulating phase. The film was excited by pump pulses with energies above and below twice the band gap energy and observed with two different probe wavelengths. The transient reflectivities of the film were then compared. We observed an enhancement of the reflectivity for the higher energy pump pulses near zero delay compared to the reflectivity for the lower energy pump pulses for both probe wavelengths. Additionally, we identified and described multiple timescales within the charge dynamics. This experiment demonstrated that impact ionization acts as a carrier multiplication process in this prototypical strongly-correlated system.

**4:54PM P27.00013 Visualization of local phase transition behaviors in ultrathin VO<sub>2</sub>/TiO<sub>2</sub> thin films**, AHRUM SOHN, Ewha womans university, TEROU KANKI, HIDEKAZU TANAKA, Osaka university, DONG-WOOK KIM, Ewha womans university — VO<sub>2</sub> undergoes the first order phase transition and two electronic phases can coexist near the critical temperature. We investigated evolution of the surface work function maps of epitaxial VO<sub>2</sub>/TiO<sub>2</sub> thin films (thickness: 15, 30, and 45 nm) using Kelvin probe force microscopy (KPFM) measurements in the temperature range of 285-330 K. Fully strained thin films were almost free of grain boundaries and thicker films had dislocations caused by strain relaxation. The sample's work function decreases, while spanning the metal-insulator transition (MIT). The work function maps clearly revealed coexistence of the two distinct phase domains. The surface area fraction of the insulating phase near the dislocations was higher than that in other regions. Thicker films have complicated domain patterns; hence, the three-dimensional percolation model properly described the MIT behaviors. In contrast, the two-dimensional percolation model well explained the transition behaviors of uniformly strained thinner films.

**5:06PM P27.00014 A Microscopic Model for the Strongly Coupled Electron-Ion System in VO<sub>2</sub><sup>1</sup>**, TIMOTHY LOVERN, SANJOY SARKER, Department of Physics and Astronomy, University of Alabama — The metal-insulator transition (MIT) in vanadium dioxide (VO<sub>2</sub>) near 340 K is accompanied by a structural transition, suggesting strong coupling between electronic and lattice degrees of freedom [1]. To help elucidate this relationship, we construct and analyze a microscopic model in which electrons, described by a tight-binding Hamiltonian, are dynamically coupled to Ising-like ionic degrees of freedom. A mean-field decoupling leads to an interacting two-component (pseudo) spin-1 Ising model describing the ions. An analysis of the minimal ionic model reproduces the observed M1 and M2 dimerized phases and rutile metal phase, occurring in the observed order with increasing temperature. All three transitions are first order, as observed. We further find that both dimerization and correlations play crucial roles in describing the insulating M1 phase. We discuss why dynamical coupling of electrons and ions is key to obtain a full understanding of the phenomenology of VO<sub>2</sub>, particularly in the context of the phase coexistence [2] observed near the MIT.

**5:18PM P27.00015 Controlling Oxygen Vacancy Creation In Ionic Liquid Gated Vanadate Nanostructures**, COLIN KILCOYNE, SUJAY SINGH, State Univ of NY - Buffalo, GREGORY HORROCKS, PETER MARLEY, SARBAJIT BANERJEE, Texas AM University, College Station, G. SAMBANDAMURTHY, State Univ of NY - Buffalo — Vanadium dioxide (VO<sub>2</sub>) is a correlated material with a transition from a monoclinic insulator to a rutile metal at  $\sim 340$  K. Through ionic liquid gating, oxygen vacancies can be electrochemically induced in VO<sub>2</sub> and it is found that the vacancies formation is greatly facilitated in the rutile phase, leading to the suppression of the metal-insulator transition. The reversibility, the rate and kinetics of the electrochemical reaction can be readily controlled with the gate voltage sweeps suggesting a potential defect engineering route to tune the electrical and structural properties of VO<sub>2</sub>. Vanadium pentoxide (V<sub>2</sub>O<sub>5</sub>) is a related system with diverse structural and electronic phases that can be obtained by intercalation of various cations. The electrochemical role of ionic liquid gating in creating new phases and modulating conductance in exfoliated thin flakes of V<sub>2</sub>O<sub>5</sub> will also be presented. This work is supported by NSF DMR 0847324.

**Session P28 DMP: Advances in Topological Materials I** 327 - Anton Burkov, University of Waterloo

### **2:30PM P28.00001 Quantum Transport of Spin-helical Dirac Fermion Topological Surface States in Topological Insulators**

**YONG P. CHEN**, Purdue University — Three-dimensional (3D) topological insulators (TI) are a novel class of electronic materials with topologically-nontrivial band structure such that the bulk is gapped and insulating yet the surface has topologically protected gapless conducting states. Such topological surface states (TSS) give helically spin polarized Dirac fermions, and offer a promising platform to realize various other novel physics such as topological magnetoelectric effects and Majorana fermions. However, it is often challenging to unambiguously access and study the transport properties of TSS in many practical TI materials due to non-negligible bulk conducting states. I will discuss our recent experiments on high-quality intrinsic TIs with insulating bulk and surface-dominated conduction that allow us to reveal a number of characteristic transport properties of spin-helical Dirac fermion topological surface states. We have observed, for example, a thickness-independent and surface-dominated conductance (even at room temperature) in exfoliated TI thin films [1] and well-developed half-integer Dirac fermion quantum Hall effect (QHE) arising from TSS (observed up to 40K) [1]; fully-tunable two-species Dirac fermion QHE and other intriguing states in dual gated devices where both top and bottom surfaces can be independently controlled [2]; current-induced helical spin-polarization detected by spin sensitive transport measurements using magnetic electrodes [3]; and in TI nanoribbons, Shubnikov-de Haas (SdH) oscillations showing gate-tunable Berry phase and ultra-relativistic Dirac mass [4]; and a half-integer Aharonov-Bohm effect (ABE) unique to the circumferentially quantized spin helical Dirac fermion surface state modes (sub-bands), with a gate-tunable conductance oscillation and alternation between the half-integer ABE and regular ABE periodic in fermi momentum [5]. Such TIs and related devices may enable promising future applications in spintronics, thermoelectrics and various topological quantum devices. References: [1] Y. ### **3:06PM P28.00002 Large linear magnetoresistance and high carrier mobility in a new Dirac semimetal candidate**

**JOHNPIERRE PAGLIONE**, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, **KEFENG WANG**, Center for Nanophysics and Advanced Materials Department of Physics, University of Maryland, **DAVID GRAF**, National High Magnetic Field Laboratory, Florida State University, **LIMIN WANG**, Center for Nanophysics and Advanced Materials Department of Physics, University of Maryland, **F. BOSCHINI**, **A. DAMASCELLI**, Department of Physics & Astronomy, University of British Columbia — We report experimental results on a new potential Dirac semimetal, the skutterudite material RhSb<sub>3</sub>. Together with a very large magnetoresistance and carrier mobility, the linear dispersion of the electronic band structure suggests properties similar to other recently reported Dirac and Weyl semimetals that deserve further investigation. Together with angle-resolved photoemission data, we present high field transport and quantum oscillations measurements that point to very large Fermi velocity and aspects of Berry's curvature that warrant further investigation.

### **3:18PM P28.00003 Temperature-Induced Lifshitz Transition in WTe<sub>2</sub>**

**NA HYUN JO**, **YUN WU**, Ames Laboratory/ISU, **MASAYUKI OCHI**, **RIKEN**, **LUNAN HUANG**, **DAIXIANG MOU**, **SERGEY L. BUD'KO**, **P.C. CANFIELD**, Ames Laboratory/ISU, **NANDINI TRIVEDI**, Ohio State University, **RYOTARO ARITA**, **RIKEN/Tohoku University**, **ADAM KAMINSKI**, Ames Laboratory/ISU — We use thermoelectric power (TEP), temperature- and field-dependent resistivity, and ultrahigh resolution, tunable, vacuum ultraviolet laser-based, angle-resolved photoemission spectroscopy (ARPES) measurements to study the electronic properties of WTe<sub>2</sub>, a compound that manifests exceptionally large, temperature-dependent magnetoresistance. The Fermi surface consists of two pairs of electron and two pairs of hole pockets along the  $X-\Gamma-X$  direction. We find a rare example of a temperature-induced Lifshitz transition at  $T \approx 160$  K. Temperature dependent TEP shows a change of slope at  $T \approx 175$  K and Kohler's rule was breakdown in the 70-140 K range. ARPES temperature scans confirm that the hole pockets completely disappear around 160 K. Our electronic structure calculations show a clear and substantial shift of the chemical potential  $\mu(T)$  due to the semimetal nature of this material driven by modest changes in temperature. [PRL 115, 166602 (2015)]

### **3:30PM P28.00004 High-field magnetoconductivity of topological semimetals**

**HAI-ZHOU LU**, South University of Science and Technology of China, **SONG-BO ZHANG**, **SHUN-QING SHEN**, The University of Hong Kong — The chiral anomaly has been widely believed to give a positive magnetoconductivity or negative magnetoresistivity in strong and parallel fields in topological semimetals. However, several recent experiments on both Weyl and Dirac topological semimetals show a negative magnetoconductivity in high fields. Here, we study the magnetoconductivity of Weyl and Dirac semimetals in a strong magnetic field applied along the direction that connects the Weyl nodes, we find that the conductivity along the field direction is not only determined by the Landau degeneracy, but also depends on the Fermi velocity and scattering potentials. We identify several scenarios in which the high-field magnetoconductivity is negative. It shows that the high-field positive magnetoconductivity may not be a compelling signature of the chiral anomaly. The quantum linear magnetoresistance will also be discussed.

### **3:42PM P28.00005 Orbital and anisotropy effects on the itinerant exchange interaction in 3D Dirac semimetals**

**SERGIO ULLOA**, Ohio University, **DIEGO MASTROGIUSEPPE**, Instituto de Fisica Rosario, **NANCY SANDLER**, Ohio University — Dirac semimetals are new materials that can be considered analogues of graphene in three dimensions. Their band structure exhibits robust Dirac points that are protected by crystalline symmetry, and strong spin-orbit interaction. These unusual properties suggest that magnetic impurities may reveal exotic behavior with potential technological importance. In metallic hosts, magnetic impurities interact through the electron gas via the Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction that depends strongly on the band structure of the material. We report on the RKKY interaction in 3D Dirac semimetals, such as Na<sub>3</sub>Bi and Cd<sub>3</sub>As<sub>2</sub> [1, 2]. We discuss asymptotic expressions for the interaction corresponding to settings with magnetic impurities at different distances and relative angle with respect to high symmetry directions on the lattice. We show that the Fermi velocity anisotropy produces a strong renormalization of the magnitude of the interaction, and a correction to the frequency of oscillation in real space. Hybridization of the impurities to different conduction electron orbitals results in interesting anisotropic interactions which can generate spiral spin structures in doped samples. [1] Z. Liu et al., Science 343, 864 (2014); [2] Z. Liu et al., Nat. Mater. 13, 677 (2014)

### **3:54PM P28.00006 Study of angle dependent magnetoresistance in half-Heusler YPtBi**

**HYUNSOO KIM**, **KEFENG WANG**, **HALYNA HODOVANETS**, **JOHNPIERRE PAGLIONE**, Univ of Maryland-College Park — Semimetallic half-Heusler compounds (RTBi, R = rare earth, T = Pd, Pt) have been attracting much attention because multiple theoretical calculations predicted the topologically non-trivial band structure. However, the detail band structure near the  $\Gamma$  point depends on the specific calculation methods, and also the band structure inferred from experimental results show discrepancy from the theoretical one. Particularly in RPtBi (R=Y, Lu, Dy, Gd), the surface metallic states, which is absent in most of the theoretical results, were evident by recent ARPES measurements, but there has not been any detailed study on the metallic surface states. Moreover, the observation of topological nodal superconductivity in YPtBi makes the knowledge of Fermiology crucial to understand the pairing mechanism in the half-Heusler superconductors. Here, we present experimental results on angular dependence of magnetoresistance at various temperatures in single crystals of YPtBi. Based on observation of the angular dependence of Shubnikov-de Haas quantum oscillations, we discuss possible topologies of the bulk as well as the surface Fermi surfaces.

**4:06PM P28.00007 Large transverse current in topological Dirac semimetal Cd<sub>3</sub>As<sub>2</sub>**, WEI-LI LEE, SHIH-TING GUO, R. SANKAR, YUNG-YU CHIEN, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, TAY-RONG CHANG, HORNG-TAY JENG, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, GUANG-YU GUO, Department of Physics, National Taiwan University, Taipei 10617, Taiwan, F. C. CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan — Cadmium arsenide (Cd<sub>3</sub>As<sub>2</sub>) is known for its inverted band structure and ultra-high electron mobility. It has been theoretically predicted and also confirmed by ARPES experiments to exhibit a 3D Dirac semimetal phase containing degenerate Weyl nodes. From magneto-transport measurements in high quality single crystals of Cd<sub>3</sub>As<sub>2</sub>, a small effective mass  $m^* \approx 0.05 m_e$  is determined from the Shubnikov-de Haas (SdH) oscillations. In certain field orientations, we find a splitting of the SdH oscillation frequency in the FFT spectrum suggesting a possible lifting of the double degeneracy in accord with the helical spin texture at outer and inner Fermi surfaces with opposite chirality predicted by our *ab initio* calculations. Strikingly, a large antisymmetric magnetoresistance with respect to the applied magnetic fields is uncovered over a wide temperature range in needle crystal of Cd<sub>3</sub>As<sub>2</sub> with its long axis along [112] crystal direction. It reveals a significant contribution of intrinsic anomalous velocity term in the transport equation intimately related to the unique 3D Rashba-like spin splitted bands in defected Cd<sub>3</sub>As<sub>2</sub>.

**4:18PM P28.00008 Magnetic Torque Anomaly in the Quantum Limit of Weyl and Dirac Semimetals**, NITYAN L. NAIR, PHILIP J.W. MOLL, ANDREW C. POTTER, Univ of California - Berkeley, BRAD RAMSHAW, KIMBERLY MODIC, National High Magnetic Field Laboratory, Los Alamos, SCOTT RIGGS, BIN ZENG, National High Magnetic Field Laboratory, Tallahassee, NIRMAL GHIMIRE, ERIC BAUER, Los Alamos National Laboratory, ROBERT KEALHOFFER, ZHENGLU LI, STEVEN LOUIE, Univ of California - Berkeley, FILIP RONNING, Los Alamos National Laboratory, JAMES G. ANALYTIS, Univ of California - Berkeley — Three dimensional Dirac and Weyl semimetals, characterized by bulk quasiparticles that behave as massless, linearly dispersing Dirac or Weyl fermions, have excited physicists with their unique topological properties and potential for applications. The experimental signatures of Weyl or Dirac fermions, however, are often subtle and indirect, especially in systems where they coexist with trivial electrons. Here, we report a novel method by which these topological systems can be unambiguously experimentally identified. Magnetic torque measurements were performed on the Weyl semimetal NbAs in high magnetic field, showing a large anomaly upon entering the quantum limit. The torque exhibits a striking sign reversal, corresponding to a change in the magnetic anisotropy that is a direct result of the topological properties of the charge carriers. This result can be generalized to other Dirac and Weyl semimetal systems and establishes quantum limit torque measurements as a simple and direct experimental method of distinguishing topologically non-trivial Weyl and Dirac systems from trivial semiconductors.

**4:30PM P28.00009 Large magnetoresistance and electronic anisotropy in NbAs<sub>2</sub>**<sup>1</sup>, BING SHEN, SHAN JIANG, NI NI, UCLA — Recently, extremely large magnetoresistance (XMR) was discovered in semimetal such as WTe<sub>2</sub> LaSb and so on, triggering extensive research on these materials and the origin of XMR. In this talk, we will report the transport properties of non-magnetic layered pnictide material NbAs<sub>2</sub>. Large transverse magnetoresistance is observed. At 10 K, the magnetoresistance is around 13000 % in the field of 9 T and shows no saturation behavior. The temperature dependent resistivity at various fields exhibits metal-to-semiconductor transition behavior around 100 K, which is coincident with the sudden increase of the Hall signal in the same temperature region. The angle dependent magnetoresistance at various temperatures follows the 3D scaling behavior with the mass anisotropy around 1.3-1.4, indicative of its 3D electron structure. Quantum oscillation data reveal the existence of at least three Fermi pockets in this material.

<sup>1</sup>Work at UCLA was supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences (BES) under Award Number DE-SC0011978.

**4:42PM P28.00010 Magnetic torque study of Weyl semimetal compounds TaP and NbP up to 45 Tesla**, GANG LI, TOMOYA ASABA, COLIN TINSMAN, FAN YU, BENJAMIN LAWSON, University of Michigan, YULIN CHEN, University of Oxford, LU LI, University of Michigan — Weyl semimetal is a recently proposed new state in condensed matter physics, in which the bulk bands could have three dimensional linear dispersion but the degeneracy at the cross point is lifted into a pair of Weyl points with opposite chirality. Among the predicted candidates, Tantalum monophosphide (TaP) and Niobium monophosphide (NbP) have the simplest composition and do not require extrinsic tuning. Photoemission data is accumulating and the unique Fermi-arc surface state is observed. Magnetotransport experiments has shown highly anisotropic magnetoresistance and quantum oscillations has been observed. Because both linear dispersive bands and conventional bands exist in these materials, a detailed study of the electronic structure of the bulk is highly desirable. We use torque magnetometry to study quantum oscillations of TaP and NbP down to 300 mK, and up to 45 Tesla, with focus on the angular dependence of oscillation frequencies. Our comparison shows clear difference in geometry of different bulk bands in these materials. Besides, a discussion will be made on high field torque data since 45 Tesla is high enough to push several of the bands into quantum limit.

**4:54PM P28.00011  $\pi$  Berry phase and Zeeman splitting of Weyl semimetal TaP**<sup>1</sup>, JIN HU, JINYU LIU, Tulane University, DAVID GRAF, National High Magnetic Field Laboratory, SEYED RADMANESH, DANIEL ADAMS, University of New Orleans, ALYSSA CHUANG, YU WANG, Tulane University, IRINEL CHIORESCU, Florida State University, JIANG WEI, Tulane University, LEONARD SPINU, University of New Orleans, ZHIQIANG MAO, Tulane University — The recent breakthrough in the discovery of Weyl fermions in mononitride semimetals provides opportunities to explore the exotic properties of relativistic fermions in condensed matter. The chiral anomaly-induced negative magnetoresistance and  $\pi$  Berry phase are two fundamental transport properties associated with the topological characteristics of Weyl semimetals. Since mononitride semimetals are multiple-band systems, resolving clear  $\pi$  Berry phase for each Fermi pocket remains a challenge. We report the determination of Berry phases of multiple Fermi pockets of Weyl semimetal TaP through high field quantum transport measurements. We show our TaP single crystal has the signatures of a Weyl state, including light effective quasiparticle masses, ultrahigh carrier mobility, as well as negative longitudinal magnetoresistance. Furthermore, we have generalized the Lifshitz-Kosevich (LK) formula for multiple-band Shubnikov-de Haas (SdH) oscillations and extracted the Berry phases of  $\pi$  for multiple Fermi pockets in TaP through the direct fits of the modified LK formula to the SdH oscillations. In high fields, we also probed signatures of Zeeman splitting, from which the Landé  $g$ -factor is extracted.

<sup>1</sup>Supported by the DOE (DE-SC0012432) and the NSF (EPS- 1003897)

**5:06PM P28.00012 Quantum Oscillations from generic surface Fermi arcs in Weyl semi-metals**, YI ZHANG, DANIEL BULMASH, PAVAN HOSUR, Stanford University, ANDREW POTTER, ASHVIN VISHWANATH, University of California, Berkeley — We re-examine the semiclassical derivation of quantum oscillations, and emphasize the correct definition of the chemical potential from the energy-time quantization perspective. In particular, for a Weyl semi-metal with surface Fermi arcs, the most natural energy reference point does not necessarily coincide with the energy of the bulk Weyl nodes. This results in several important amendments to previous conclusions for generic Weyl semi-metals. We also propose a simple lattice realization of Weyl semi-metals following the layered prescription and verify our theoretical conclusions with exact numerical studies.

**5:18PM P28.00013 Thermo-electric transports in double-Weyl semimetals**, QI CHEN, GREGORY A. FIETE, The University of Texas at Austin — Topological Weyl semimetals with linearly dispersing nodal points have received a surge of interest due to their experimental realization in real materials. Another nontrivial type of band crossing whose dispersion is not simply linear is the double Weyl point, around which the spectrum disperses linearly along one momentum direction but quadratically along the two remaining directions. In this work, we apply the semi-classical Boltzmann transport theory to study the thermo-electric conductivity of a double-Weyl fermion model. We find that the transport quantities exhibit an interesting dependence on the chemical potential and spatial anisotropic model parameters, differing from a simple quadratically or linearly dispersing electron gas. By applying a static magnetic field, we find that the double-Weyl point is only stable for a magnetic field along the linearly dispersing direction. The longitudinal and transverse electrical and thermal magneto-conductivity show a similar dependence on the in-plane cyclotron frequency to the linearly dispersing Weyl nodes. In the extreme quantum limit of chemical potential being much smaller than the cyclotron energy, we find that the lowest Landau levels are both chiral and doubly degenerate. The chiral anomaly contribution to the longitudinal magneto-conductivity is double that of a linearly dispersing Weyl node.

## Wednesday, March 16, 2016 2:30PM - 5:30PM –

Session P29 DCMP: Optical Spectroscopy on 3D Topological Insulators 328 - Dennis Drew, University of Maryland

**2:30PM P29.00001 Infrared studies of topological insulator systems**, KIRK POST, BRIAN CHAPLER, ALEX SCHAFGANS, Univ of California - San Diego, MENGKUN LIU, SUNY - Stonybrook, JIH-SHENG WU, Univ of California - San Diego, ANTHONY RICHARDELLA, JOON SUE LEE, Pennsylvania State University, ANJAN REIJNDERS, University of Toronto, YUN SANG LEE, Soongsil University, LIANG HE, XUFENG KOU, Univ of California - Los Angeles, MARIO NOVAK, ALEXEY TASKIN, KOUJI SEGAWA, Osaka University, MICHAEL GOLDFLAM, H. THEODORE STINSON, Univ of California - San Diego, XIAO LIANG QI, Stanford University, KENNETH BURCH, Boston College, KANG WANG, Univ of California - Los Angeles, MICHAEL FOGLER, Univ of California - San Diego, NITIN SAMARTH, Pennsylvania State University, YOICHI ANDO, Osaka University, DIMITRI BASOV, Univ of California - San Diego — The theoretical prediction, and subsequent experimental realization, of topological insulator (TI) systems, has vaulted this new class of materials to the vanguard of condensed matter physics. Since their discovery, we have carried out a number of infrared studies on various TI systems, including  $\text{Bi}_2\text{Se}_3$ ,  $\text{Bi}_{1-x}\text{Sb}_x$ , and  $\text{Bi}_{2-x}\text{Sb}_x\text{Te}_{3-y}\text{Se}_y$  crystals as well as  $\text{Bi}_2\text{Se}_3$  and  $(\text{Bi,Sb})_2\text{Te}_3$  thin films. A key element of these works is the revelation that the infrared response of  $\text{Bi}_{1-x}\text{Sb}_x$  crystals and  $(\text{Bi,Sb})_2\text{Te}_3$  thin films possess a significant, or even dominant, component from the topologically protected surface states. I will review these works and discuss future prospects of measuring the surface state response through optical spectroscopy techniques

**2:42PM P29.00002 Cyclotron resonance and Faraday rotation in topological insulator  $(\text{Bi,Sb})_2\text{Te}_3$** , YINMING SHAO, KIRK POST, JIH-SHENG WU, Univ of California - San Diego, ANTHONY RICHARDELLA, JOON SUE LEE, The Pennsylvania State University, MICHAEL FOGLER, Univ of California - San Diego, NITIN SAMARTH, The Pennsylvania State University, DIMITRI BASOV, Univ of California - San Diego — Using magneto-optical spectroscopy, we have explored the complex electronic structure of  $(\text{Bi,Sb})_2\text{Te}_3$  (BST) film. From the magneto-optical transmission spectra, we extracted the cyclotron resonance (CR) energy, and subsequently measured the broadband Faraday rotation spectra (FR). From these complementary FR-CR datasets, we were able to identify the conducting channels associated with the topological surface states of the film at the interface with the substrate and with the amorphous capping layer on top of the film. According to the FR data the two surfaces are dominated by carriers of opposite sign, in accord with earlier transport measurements. These results elucidate the origin of the zero-field optical response, observed previously, and give direct evidence of significant SS contribution using a bulk sensitive probe.

**2:54PM P29.00003 Terahertz Faraday Rotation in the Quantum Anomalous Hall System V-doped  $(\text{Bi,Sb})_2\text{Te}_3$** , OZGE OZEL, Massachusetts Inst of Tech-MIT, ALEX FRENZEL, UCSD, CUI-ZU CHANG, DANIEL PILON, JAGADEESH MOODERA, NUH GEDIK, Massachusetts Inst of Tech-MIT, GEDIK GROUP TEAM, MOODERA GROUP COLLABORATION — Time-reversal symmetry breaking in a topological insulator (TI) can be achieved by introducing ferromagnetism, which opens up a gap in the Dirac surface states. When the chemical potential is tuned to lie within the surface gap, the quantum anomalous Hall state emerges, which can be regarded as the quantum Hall state at zero external magnetic field. Recently, this state has been observed by static transport measurements in thin films of magnetically doped TIs. Time-domain terahertz spectroscopy has been demonstrated to be an effective probe of surface states and Hall effects in topological materials. Here, we use polarization modulation terahertz spectroscopy to study the intrinsic properties of massive Dirac electrons in V-doped  $(\text{Bi,Sb})_2\text{Te}_3$  via Faraday rotation measurements.

**3:06PM P29.00004 Quantized Faraday rotation of surface states in 3D topological insulator thin films**, LIANG WU, Department of Physics and Astronomy, The Johns Hopkins University, MARYAM SALEHI, Department of Materials Science and Engineering, Rutgers, The State University of New Jersey, NIKESH KOIRALA, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers, The State University of New Jersey, N. PETER ARMITAGE, Department of Physics and Astronomy, The Johns Hopkins University, JOHNS HOPKINS UNIVERSITY TEAM, RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY TEAM — Axion electrodynamics of topological surface states have been predicted a while ago, but the experimental observation has not been realized yet. One of the consequences of axion electrodynamics is a topological magneto-electric effect. In my talk, I will talk about utilizing a charge-transfer-doping method to lower the chemical point near the Dirac point in thin films of the topological insulator  $\text{Bi}_2\text{Se}_3$ . Using time-domain THz spectroscopy, we observed a crossover from semi-classical cyclotron resonances from topological surface states in the low field regime to a quantum regime at higher fields. A quantized Faraday rotation in the units of the fine structure constant was observed at high fields, which may provide the evidence for the topological magneto-electric effect.

**3:18PM P29.00005 Nonlinear optical properties of bismuth selenide**, DEREK BAS, SERCAN BABAKIRAY, TUDOR STANESCU, DAVID LEDERMAN, ALAN BRISTOW, West Virginia University — Bismuth selenide ( $\text{Bi}_2\text{Se}_3$ ) is a topological insulator with many interesting photonic properties. Much research has been done involving various types of photocurrents in an attempt to highlight the differences between the bulk electronic states and massless conducting surface states. Here,  $\text{Bi}_2\text{Se}_3$  films varying in thickness from 6 to 40 quintuple layers have been produced via molecular beam epitaxy as a means to vary the relative contributions of bulk and surface. On these samples, optical measurements were performed at around 1.6 eV, which is enough energy to stimulate transitions from the Fermi level to a region near the second Dirac cone. Z-scan was used to measure saturable absorption, time-resolved two-color pump-probe was used to measure two-photon absorption, and a Fourier transform infrared spectrometer was used to measure linear absorption. Results were examined and analyzed with respect to thickness. Thickness-dependent band structures were produced using a tight-binding model and used to compare with experimental results.

**3:30PM P29.00006 Fano  $q$  reversal in topological insulator  $\text{Bi}_2\text{Se}_3$** , S.V. DORDEVIC, G.M. FOSTER, M.S. WOLF, The University of Akron, N. STOJILOVIC, University of Wisconsin Oshkosh, H. LEI, C. PETROVIC, Brookhaven National Lab, Z. CHEN, Z.Q. LI, National High Magnetic Field Lab, L.C. TUNG, University of North Dakota — We studied magneto-optical response of a canonical topological insulator  $\text{Bi}_2\text{Se}_3$  with the goal of addressing a controversial issue of electron-phonon coupling. Magnetic-field induced modifications of reflectance are very pronounced in the infrared part of the spectrum, indicating strong electron-phonon coupling. This coupling causes an asymmetric line-shape of the  $60\text{ cm}^{-1}$  phonon mode, and is analyzed within the Fano formalism. The analysis reveals that the Fano asymmetry parameter ( $q$ ) changes sign when the cyclotron resonance is degenerate with the phonon mode. To the best of our knowledge this is the first example of magnetic field driven  $q$ -reversal.

### 3:42PM P29.00007 Evolving optical second-harmonic anisotropy at the cleaved $\text{Bi}_2\text{Se}_3$ surface.<sup>1</sup>

, YONG AN, AVERY GREEN, ALAIN DIEBOLD, SUNY Polytechnic Institute — Bismuth selenide ( $\text{Bi}_2\text{Se}_3$ ) is a centrosymmetric topological insulator with conducting surface states. The surface states have been studied by various electrical and optical techniques in air, but ambience effects and surface aging have not been adequately addressed. Optical second-harmonic generation (SHG) is a suitable probe for the  $\text{Bi}_2\text{Se}_3$  surface because SHG arises from symmetry breaking at the surface and thus should detect surface states preferentially over bulk states. However, a strong time dependence of SHG is often observed, hampering the detection and investigation of the surface states. Here we find a new phenomenon in which the major and minor intensity lobes of a measured rotational-anisotropy SHG pattern from a cleaved  $\text{Bi}_2\text{Se}_3$  (111) surface can significantly change with time and eventually switch their amplitudes. This switching provides a means for tracking the progress of surface oxidation inside a quintuple layer of  $\text{Bi}_2\text{Se}_3$ . We also perform pump-probe SHG experiments, comparatively on freshly cleaved and oxidized  $\text{Bi}_2\text{Se}_3$  surfaces, to study charge dynamics at the oxide/ $\text{Bi}_2\text{Se}_3$  interface and to detect spin polarization of photoexcited surface states in the  $\text{Bi}_2\text{Se}_3$  topological insulator.

### 3:54PM P29.00008 Tight-binding theory of NMR shifts in topological insulators<sup>1</sup>, ION GARATE,

SAMUEL BOUTIN, Université de Sherbrooke, JORGE RAMIREZ RUIZ, Universidad Autónoma de México — To date, most experiments in topological insulators have focused on probing the surface states of these materials and suppressing the often inevitable contribution from bulk states. However, the latter are of interest on their own and contain useful information that can be extracted with a local probe like nuclear magnetic resonance (NMR). Recently,  $^{77}\text{Se}$  NMR experiments on  $\text{Bi}_2\text{Se}_3$  single crystals have reported unusual field-independent linewidths and short spin-echo decays [1]. It is likely that an unexpectedly strong indirect internuclear coupling, characteristic of some inverted band structures, is the cause of these peculiar results. Motivated by this hypothesis, we report on a microscopic theory of NMR shifts and linewidths in  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$ . Our theory provides quantitative estimates for the Knight shift, the orbital shift, the Ruderman-Kittel-Kasuya-Yoshida coupling and the Bloembergen-Rowland coupling. We will compare our findings with the available experimental data. [1] N. Georgieva, D. Rybicki, R. Guhne, G. Williams, S. Chong, I. Garate and J. Haase, arXiv:1511.01727 (2015)

### 4:06PM P29.00009 Gate Tunable Infrared Optical Response of $(\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3$ Topological

Insulators, WILLIAM WHITNEY, VICTOR BRAR, California Institute of Technology, YUNBO OU, Institute of Physics, Chinese Academy of Sciences, KE HE, QI-KUN XUE, Tsinghua University, HARRY ATWATER, California Institute of Technology — The electronic properties of topological insulators – narrow band-gap semiconductors that exhibit insulating bulk and semimetallic Dirac surface states – have been the subject of intense study over the past several years. The optical and optoelectronic behavior of these materials, however, remain widely uncharacterized. It has previously been shown that electrostatic gating can be used to tune the Fermi level in the Dirac semimetal graphene, modifying interband transitions and free carrier absorption. We report here experiments that demonstrate electronic control of the optical properties of 5-20 nm thick  $(\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3$  films grown by Van der Waals epitaxy and transferred to silicon dioxide on silicon via an epitaxial lift off process. We find that infrared transmission and reflection from 3 to 10 microns are consistent with modulation of free-carrier absorption and bulk interband transitions in  $(\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3$ . We discuss transport results as well as the contributions that bulk and topological surface electronic transitions make to the optical response of these materials.

### 4:18PM P29.00010 Optical Second Harmonic Generation Study of Topological Insulator

$\text{Bi}_{2-x}\text{Sb}_x\text{Se}_3$ <sup>1</sup>, JISUN KIM, ZHENYU ZHANG, MATTHEW T. CURTIS, LOUIS H. HABER, RONGYING JIN, Louisiana State University — Second-order nonlinear optical spectroscopy such as second harmonic generation (SHG) is well-established and versatile technique for surface and interface studies. We apply this technique to study the surface symmetry of topological insulator  $\text{Bi}_{2-x}\text{Sb}_x\text{Se}_3$  in reflection geometry under four possible polarization configurations. By measuring the azimuthal angular dependence of SHG from the (111) surface of  $\text{Bi}_{2-x}\text{Sb}_x\text{Se}_3$  single crystals, we identify responses from both in-plane Se-Se bonds and out-of-plane Se-Bi/Sb bonds. This provides us information about the doping effect on the surface crystalline structure, which is critical for understanding the surface properties. The transition from topological to trivial insulator upon Sb doping will be discussed based on SHG data. Future work using sum frequency generation on these crystals will be considered as well.

### 4:30PM P29.00011 Current induced Optical Activity in Topological Insulator $\text{Bi}_2\text{Te}_2\text{Se}_1$ ,

NIRAJAN MANDAL<sup>1</sup>, IREK MITKOWSKI, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907, MIKHAIL GLAZOV, Ioffe Institute, Polytechnicheskaya 26, 194021 St. Petersburg, Russia, YONG CHEN<sup>2</sup>, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907 — Current induced polarization rotation of light (provided by a laser with wavelength=635nm) was studied from topological insulator (TI),  $\text{Bi}_2\text{Te}_2\text{Se}_1$ , grown by Bridgman method. The magnitude of the observed response increases linearly with the applied current and reverses sign upon reversing the current direction. Possible origins of the rotation can include the linear electro-optic Pockels effect (linear birefringence) and spin-Kerr effect due to the current induced spin polarization (e.g. resulting from the spin momentum locking of the surface states) at the sample surface. At room temperature, the rotation was measured as a function of the angle of incidence and laser polarization. Dependence of the rotation angle on the polarization of light (S or P) was used to isolate contributions from these two effects. The contribution from the electro optic effect was found to dominate over that from the current-induced spin- Kerr effect.

### 4:42PM P29.00012 STM studies of topological phase transition in $(\text{Bi},\text{In})_2\text{Se}_3$ <sup>1</sup>, WENHAN ZHANG,

XUEYUN WANG, SANG-WOOK CHEONG, WEIDA WU, Rutgers Univ, WEIDA WU TEAM, SANG-WOOK CHEONG COLLABORATION — Topological insulators (TI) are a class of materials with insulating bulk and metallic surface state, which is the result of band inversion induced by strong spin-orbit coupling (SOC). The transition from topological phase to non-topological phase is of great significance. In theory, topological phase transition is realized by tuning SOC strength. It is characterized by the process of gap closing and reopening. Experimentally it was observed in two systems:  $\text{TlBi}(\text{S}_{1-x}\text{Se}_x)_2$  and  $(\text{Bi}_{1-x}\text{In}_x)_2\text{Se}_3$  where the transition is realized by varying isovalent elements doping concentration. However, none of the previous studies addressed the impact of disorder, which is inevitable in doped systems. Here, we present a systematic scanning tunneling microscopy/spectroscopy study on  $(\text{Bi}_{1-x}\text{In}_x)_2\text{Se}_3$  single crystals with different In concentrations across the transition. Our results reveal an electronic inhomogeneity due to the random distribution of In defects which locally suppress the topological surface states. Our study provides a new angle of understanding the topological transition in the presence of strong disorders.

**4:54PM P29.00013 First-Principle Calculations and Raman Studies of Surface Phonons in the Topological Insulators  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$ .** , IBRAHIM BOULARES, GUANGSHA SHI, CTIRAD UHER, EMMANOUIL KIOUPAKIS, ROBERTO MERLIN, U. Michigan, PETR LOSTAK, U. Pardubice - Czech Republic — Raman [1-2], helium scattering [3] and photoemission experiments [4] on the topological insulators  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$  show features in the range  $\sim 50$ -150  $\text{cm}^{-1}$ , which have been assigned to Raman-forbidden, infrared modes due to symmetry breaking at the surface [1-2] or surface phonons [3,4], which couple to the topologically protected electronic states [4]. We present first-principle LDA calculations and temperature-dependent Raman studies showing strong evidence of the existence of surface phonons in both  $\text{Bi}_2\text{Se}_3$  and  $\text{Bi}_2\text{Te}_3$ . The calculations reveal that these modes are quite insensitive to spin-orbit coupling, an indication that their occurrence is unrelated to the topological properties of these materials. [1] K. M. F. Shahil et al., Appl. Phys. Lett. 96, 153103 (2010). [2] V. Gnezdilov et al., Phys. Rev. B 84, 195118 (2011). [3] X. Zhu et al., Phys. Rev. Lett. 107, 186102 (2011). [4] J. A. Sobota et al., Phys. Rev. Lett. 113, (2014).

**5:06PM P29.00014 Optical helicity control of surface current in  $\text{SmB}_6$** <sup>1</sup>, SANJAY ADHIKARI, West Virginia University, YANJUN MA, CHANG-BEOM EOM, University of Wisconsin-Madison, CHENG CEN, West Virginia University —  $\text{SmB}_6$  is a promising candidate for topological Kondo insulator. One hallmark signature of topological states is the helical Dirac dispersion with perfect momentum-spin lockage. Here, we report current injection in  $\text{SmB}_6$  thin film with circularly polarized light at oblique incidence. A polarization-independent photovoltage was also detected. Both signals exhibited strong temperature dependences. While the polarization-independent photovoltage is likely due to thermoelectric effects, the circular photogalvanic effect (CPGE) has two possible origins: topological surface states or regular surface states with strong Rashba type spin-orbit coupling. The drastically different penetration depths of topological and regular surface states in  $\text{SmB}_6$  provide an opportunity to distinguish them by investigating films with different thicknesses. The strong correlation observed between the film thickness and CPGE photovoltage strongly supports the topological origin of the surface states. This research enhances our knowledge in controlling the spin and orbital degrees of freedom at  $\text{SmB}_6$  surface, and can also lead to exciting spintronic applications using optical tools.

**5:18PM P29.00015 Photoinduced Anomalous Hall Effects in Weyl Semimetals**, CHING-KIT CHAN, PATRICK A. LEE, Massachusetts Institute of Technology, KENNETH S. BURCH, Boston College, JUNG HOON HAN, Sungkyunkwan University, YING RAN, Boston College — We examine theoretically the interplay between chiral photons and chiral electrons in Weyl semimetals. Owing to its monopole nature, a three-dimensional Weyl node is topologically-robust against a circularly polarized light. A driven Weyl system exhibits node shifts in the momentum space, in sharp contrast to the gap opening in a driven two-dimensional Dirac system. We show that the node shift leads to a change of the Chern vector which gives arise to a net photoinduced anomalous Hall conductivity, in the plane perpendicular to the light propagation. We shall describe the basic idea behind this generic photoinduced Hall effect, illustrate it with a concrete microscope model, and estimate its feasibility based on current optical experimental techniques.

**2:30PM P30.00001 Oxygenation Dependence of the Resistance Upturn in  $\text{LaAlO}_3/\text{SrTiO}_3$  Heterostructures**<sup>1</sup>, H. ZHANG, University of Toronto, K. A. MAJLAN, J. H. NGAI, University of Texas at Arlington, C. MCMAHON, D. G. HAWTHORN, University of Waterloo, J. Y. T. WEI, University of Toronto & Canadian Institute for Advanced Research — Among the phenomena exhibited by  $\text{LaAlO}_3/\text{SrTiO}_3$  (LAO/STO) heterostructures, the appearance of a low-temperature resistance upturn has attracted much recent debate [1-4]. This phenomenon has been observed to co-occur with both nonlinear Hall effect and anisotropic magnetoresistance, and attributed to either Kondo effect, multiband conduction, or localization. It is primarily seen in samples grown by pulsed laser deposition, and is sensitive to film thickness, growth condition and electrostatic gating, all of which could affect the oxygen content. In this work, we study the effect of post-growth oxygenation on the resistance upturn in samples grown by molecular beam epitaxy, and how the Hall conductance and magnetoresistance are related to the occurrence of the upturn. X-ray photoelectron spectroscopy is used to monitor the valence states of Ti ions, in an effort to correlate them with the conduction and magnetic properties. Our results are analyzed in terms of oxygen vacancies in the presence of polar charge transfer, and the effect of these vacancies on the resistance upturn in LAO/STO heterostructures. [1] S. Das et al., PRB 90 (2014). [2] V. K. Guduru et al., PRB 88 (2013). [3] Z. Huang et al., PRB 88 (2013). [4] C. Bell et al., APL 94 (2009).

**2:42PM P30.00002 Controlling Kondo Scattering at the Conducting Oxide Interfaces via Lattice Mismatch and Growth Oxygen Pressure**, KUN HAN, Physics department & NUSNNI-NanoCore, NUS, Singapore, SHENGWEI ZHENG, ZHEN HUANG, CHANGJIAN LI, NUSNNI-NanoCore, NUS, Singapore, WENXIONG ZHOU, NUSNNI-NanoCore, NUS, Singapore, T VENKATESAN, NUSNNI-NanoCore, NUS, Singapore, ARIANDO ARIANDO, Physics department NUSNNI-NanoCore, NUS, Singapore, ARIANDO TEAM — The interface magnetism, such as Kondo effect and ferromagnetism at the conducting interfaces between nonmagnetic oxides, has attracted great attention in recent years. In this report, we show that the interfacial Kondo scattering is enhanced by large lattice mismatch and high growth oxygen pressure. For the (001)  $\text{LaAlO}_3/\text{SrTiO}_3$  interface with 3.0% lattice mismatch, the sheet resistance upturn appears around 40 K when the growth oxygen pressure  $P_{\text{O}_2}$  is beyond 1 mTorr. By contrast, for the (001)  $(\text{La}_{0.3}\text{Sr}_{0.7})(\text{Al}_{0.65}\text{Ta}_{0.35})\text{O}_3/\text{SrTiO}_3$  interface with 1.0% lattice mismatch, no resistance upturn is observed until  $P_{\text{O}_2}$  is increased to 100 mTorr. Moreover, the magnetoresistance data confirm the resistance upturn is caused by Kondo scattering. We propose that the interface disorders, which can be induced by a large lattice mismatch and high  $P_{\text{O}_2}$ , are important for forming localized  $\text{Ti}^{3+}$  ions. These  $\text{Ti}^{3+}$  ions can be spin-polarized and scatter electrons that are confined near the interface by high  $P_{\text{O}_2}$ . This explains why the stronger magnetic interaction is observed at the  $\text{SrTiO}_3$ -based interfaces with the higher  $P_{\text{O}_2}$  and larger lattice mismatch, paving the way for manipulating the interface magnetism at the functional oxide interface.

**2:54PM P30.00003 Metal-insulator transition at lanthanum aluminate-strontium titanate interface induced by oxygen plasma treatment.**, WEITAO DAI, CHENG CEN, West Virginia Univ — The formation of two-dimensional electron gas (2DEG) at lanthanum aluminate (LAO)-strontium titanate (STO) interface, as well as the 2DEG's unique characters in metal-insulator transition, have evoked widespread interest. Highly insulating interfaces are obtained for the structures with LAO thickness below 3 unit cell (uc) and abrupt transition from an insulating to conducting interface was observed for samples with thicker LAO layers. For 3uc LAO/STO samples, reversible nanoscale control of the metal-insulator transition was implemented by a conductive AFM writing. Our research furtherly discovered a very stable metal-insulator transition can be achieved by oxygen plasma (OP) treatment for samples with thicker LAO layers. AFM imaging and XPS measurement demonstrated the low energy OP treatment altered only the surface bonds, which confirmed the importance of surface properties in the heterostructures. Then microscale Hall bars were patterned at the interface and imaged by electrostatic force microscope. Their transport and magnetic properties were measured. This research will promote deeper understanding about the interfacial metal-insulator transition mechanism and open new device opportunities. This work is supported by the Department of Energy Grant No. DE-SC-0010399 and National Science Foundation Grant No. NSF-1454950.

### 3:06PM P30.00004 On the Growth of Complex Oxides by Molecular Beam Epitaxy , DILLON FONG,

Argonne Natl Lab — Functional materials based on complex oxides in thin film form offer new and exciting strategies for meeting many of our outstanding energy challenges through systematic control of layer sequencing, strain, etc. However, the synthesis of such oxide films can be a major challenge even when utilizing reactive molecular-beam epitaxy (MBE), a powerful deposition technique that allows the construction of materials atomic plane by atomic plane. To understand the fundamental physics of oxide growth by reactive MBE, we present *in situ* surface x-ray diffraction results on the growth of SrTiO<sub>3</sub> and SrO-SrTiO<sub>3</sub> thin films on (001)-oriented SrTiO<sub>3</sub> substrates. For homoepitaxy, we compare sequential deposition (alternating Sr and Ti monolayer doses) with that of co-deposition of Sr and Ti, both in a background of oxygen pressure, and observe drastically different growth pathways due to the presence of a TiO<sub>2</sub> double layer. For heteroepitaxial growth of Ruddlesden-Popper SrO-SrTiO<sub>3</sub> films, we find that layers rearrange dynamically, resulting in layer sequences distinct from the shutter sequence. In general, the starting surface structure and composition, in combination with local thermodynamic considerations, strongly influence our ability to atomically construct new complex oxides.

### 3:42PM P30.00005 Self-regulating MBE growth of stoichiometric BaSnO<sub>3</sub> films *via* reactive radical mechanism<sup>1</sup> , ABHINAV PRAKASH, JOHN DEWEY, HWANHUI YUN, JONG SEOK JEONG, K. ANDRE MKHOYAN, BHARAT JALAN,

Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — Growth of thin films comprising of element with low oxidation potential such as Sn often requires reactive oxidants such as ozone or high-pressure oxygen plasma. By utilizing the chemistry of highly reactive radical of Sn, we will present on the growth of phase-pure, epitaxial BaSnO<sub>3</sub> films using a hybrid molecular beam epitaxy (MBE) approach with scalable growth rates. The notable finding was that Sn radicals are very reactive to yield phase-pure BaSnO<sub>3</sub> films even in molecular oxygen [1]. In this approach, we use hexamethylditin (HMDT) as a tin source, a solid effusion cell for Ba and either molecular oxygen or an rf oxygen plasma source. Phase-pure BaSnO<sub>3</sub> films were grown at 900 °C, and oxygen pressure of 5x10<sup>-6</sup> Torr as a function Sn:Ba ratio. *In-situ* time-dependent RHEED intensity oscillations were observed establishing a layer-by-layer growth mode and a critical thickness of ≈1 nm for strain relaxation [1]. Rutherford backscattering spectrometry and lattice constant determined using high-resolution X-ray diffraction was used to optimize cation stoichiometry. “MBE growth window” was identified where films show bulk-like lattice parameter (4.116 Å) over a wide-range of cation flux ratios. A correlation between RHEED patterns, stoichiometry, and surface morphology was established. [1] A. Prakash *et al.*, J. Vac. Sci. & Technol. A **33**, 060608 (2015).

<sup>1</sup>This work is supported primarily by NSF (DMR-1410888)

### 3:54PM P30.00006 Single phase growth of materials with high polar mismatch at the interface<sup>1</sup> , MOHAMMAD SAGHAYEZHIAN, ZHEN WANG, HANGWEN GUO, GAOMIN WANG, LINA CHEN, WARD PLUMMER, JIANDI ZHANG, Louisiana State Univ - Baton Rouge, LA, 70803 — Growing thin films on polar surfaces has always been a challenge. An even greater challenge though, has been growing thin films on polar surfaces with polar mismatch at the interface. The divergence of surface free energy inhibits appearance of a sharp interface in these materials. Here for the first time, we report successful growth of LaNiO<sub>3</sub> on SrTiO<sub>3</sub> in (111) direction with correct phase. We show that by controlling the substrate's electronic and stoichiometric properties along with careful tune of thermodynamic parameters during the growth, it is possible to grow a single phase thin film of LaNiO<sub>3</sub>. Using RHEED, LEED, STM and TEM, we show that the interface is sharp and there is no structural discontinuity, and the surface of the film preserves its symmetry during the growth. In addition, angle-resolved core-level photoelectron spectroscopy confirms the single phase growth.

<sup>1</sup>Supported by U.S. DOE under Grant No. DOE DE-SC0002136

### 4:06PM P30.00007 Surface structural reconstruction of SrVO<sub>3</sub> thin films on SrTiO<sub>3</sub> (001)<sup>1</sup> , GAOMIN WANG, MOHAMMAD SAGHAYEZHIAN, LINA CHEN, HANGWEN GUO, JIANDI ZHANG, Louisiana State University — Paramagnetic metallic oxide SrVO<sub>3</sub> (SVO) is an itinerant system known to undergo thickness-induced metal-insulator-transition (MIT) in ultrathin film form, which makes it a prototype system for the study of the mechanism behind metal-insulator-transition like structure distortion, electron correlations and disorder-induced localization. We have grown SrVO<sub>3</sub> thin film with atomically flat surface through the layer-by-layer deposition by laser Molecular Beam Epitaxy (laser-MBE) on SrTiO<sub>3</sub> (001) surface. Low Energy Electron Diffraction (LEED) measurements reveal that there is a ( $\sqrt{2}\times\sqrt{2}$ ) R45 surface reconstruction independent of film thickness. By using LEED-I(V) structure refinement, we determine the surface structure. In combination with X-ray Photoelectron Spectroscopy (XPS) and Scanning Tunneling Microscopy (STM), we discuss the implication on the MIT in ultrathin films below 2-3 unit cell thickness.

### 4:18PM P30.00008 Van der Waals Epitaxy of Functional Oxide Heterostructures , YING-HAO CHU,

National Chiao Tung University — In the diligent pursuit of low-power consumption, multifunctional, and environmentally friendly electronics, more sophisticated requirements on functional materials are on demand. Recently, the discovery of 2D layered materials has created a revolution to this field. Pioneered by graphene, these new 2D materials exhibit abundant unusual physical phenomena that is undiscovered in bulk forms. These materials are characterized with their layer form and almost pure 2D electronic behavior. The confinement of charge and heat transport at such ultrathin planes offers possibilities to overcome the bottleneck of present device development in thickness limitation, and thus push the technologies into next generation. Van der Waals epitaxy, an epitaxial growth method to combine 2D and 3D materials, is one of current reliable manufacturing processes to fabricate 2D materials by growing these 2D materials epitaxially on 3D materials. Then, transferring the 2D materials to the substrates for practical applications. In the mean time, van der Waals epitaxy has also been used to create free-standing 3D materials by growing 3D materials on 2D materials and then removing them from 2D materials since the interfacial bonding between 2D and 3D materials should be weak van der Waals bonds. In this study, we intend to take the same concept, but to integrate a family of functional materials in order to open new avenue to flexible electronics. Due to the interplay of lattice, charge, orbital, and spin degrees of freedom, correlated electrons in oxides generate a rich spectrum of competing phases and physical properties. Recently, lots of studies have suggested that oxide heterostructures provide a powerful route to create and manipulate the degrees of freedom and offer new possibilities for next generation devices, thus create a new playground for researchers to investigate novel physics and the emergence of fascinating states of condensed matter. In this talk, we use a 2D layered material as the substrate. And we take several oxides as examples to demonstrate a pathway to integrate 3D functional oxides on 2D layered materials.

### 4:54PM P30.00009 Atomic-level sculpting in STEM for studies of thickness dependent structural behavior in oxide thin films , ALBINA BORISEVICH, QIAN HE, STEPHEN JESSE, Oak Ridge National Lab, ANDREW AKBASHEV, JONATHAN SPANIER, Drexel University, MIGUEL FUENTES-CABRERA, BOBBY SUMPTER, Oak Ridge National Lab — Oxide thin films offer a rich playground for fundamental physics and possible applications due to a wide variety of electronic and magnetic properties and control of chemistry and strain conditions during growth. Scanning Transmission Electron Microscopy (STEM) studies of thin films often demonstrate that film structure is highly dependent on thickness; changes in overall symmetry at a two-atomic-layer scale have been reported. At the same time it was recently shown that crystalline oxide nanostructures can be grown locally during a STEM experiment from amorphous precursors. This method can be used for producing crystalline structures as small as 1-2 nm and the process can be observed *in situ* with atomic resolution. Here we utilize the sculpting approach to study size effects in ultrathin films of oxides as they are being grown inside a microscope. Transitions such as emergence of tilted structure, misfit defects and rotational domains can now be pinpointed with single atomic layer precision. Atomistic molecular dynamics simulations are used to establish theoretical underpinnings of the beam-induced growth mechanism. This work is funded by DMSE of the DOE BES (QH, AB), and by CNMS, which is funded at ORNL by SUFD of the DOE BES.

**5:06PM P30.00010 Electrical properties of solid-solution  $\text{SrZr}_x\text{Ti}_{1-x}\text{O}_3$  grown epitaxially on Ge by molecular beam epitaxy**, REZA MOGHADAM, KAMYAR AHMADI, University of Texas at Arlington, Z.-Y. XIAO, XIA HONG, University of NebraskaLincoln, JOSEPH NGAI, University of Texas at Arlington — The epitaxial growth of crystalline oxides on semiconductors enables new functionalities to be introduced to semiconductor devices. In particular, dielectric and ferroelectric oxides grown epitaxially on semiconductors provide a pathway to realize ultra-low power logic and memory devices. Here we present electrical characterization of solid-solution  $\text{SrZr}_x\text{Ti}_{1-x}\text{O}_3$  grown epitaxially on Ge through oxide molecular beam epitaxy.  $\text{SrZr}_x\text{Ti}_{1-x}\text{O}_3$  is of particular interest since the band offset with respect to the semiconductor can be tuned through Zr content  $x$ . We will present current-voltage, capacitance-voltage and piezoforce microscopy characterization of  $\text{SrZr}_x\text{Ti}_{1-x}\text{O}_3$ -Ge heterojunctions. In particular, we will discuss how the electrical characteristics of  $\text{SrZr}_x\text{Ti}_{1-x}\text{O}_3$ -Ge heterojunctions evolve with respect to composition, annealing and film thickness.

**5:18PM P30.00011 First principles study of Al/ $\text{SrTiO}_3$  interface formation**, ALI HAMZE, AGHAM POSADAS, KRISTY KORMONDY, ALEXANDER DEMKOV, Univ of Texas, Austin — Two-dimensional electron gases (2DEGs) at the interfaces of oxides have been the subject of much interest in recent years due to their relatively high carrier mobilities and potential for use in all-oxide devices. In particular, the  $\gamma\text{-Al}_2\text{O}_3$  ( $\gamma$ -alumina)- $\text{SrTiO}_3$  (STO) system has been the focus of much research. It exhibits a 2DEG at the interface with a carrier mobility ranging from  $10^3$ - $10^5$   $\text{cm}^2 \text{V}^{-1} \text{s}^{-1}$ , depending on the thickness of the STO and how the  $\gamma$ -alumina film was grown. It is believed that Al atoms steal oxygen from the STO substrate at growth temperature and thus create a conductive channel in STO near the interface. We investigate the initial studies of the interface formation using density functional theory. The results of first principles calculations are compared with those of x-ray photoemission spectroscopy (XPS) performed in situ on thin Al films deposited on STO by molecular beam epitaxy. Analysis of the Al 2p XPS spectrum shows one layer of aluminum is fully oxidized during growth at 400C and 4 layers of aluminum are fully oxidized during growth at 600C. Furthermore, the Ti 2p XPS spectrum shows the titanium atoms are reduced, which is consistent with the presence of oxygen vacancies in STO.

**Session P31 DCP: Water at Interfaces: From Spectroscopy Techniques to Computer Simulations** 331 - Songi Han

**2:30PM P31.00001 Water at surfaces with tunable surface chemistries and the chiral imprint of water around DNA.**<sup>1</sup>, POUL PETERSEN, Cornell University — Aqueous interfaces are ubiquitous in atmospheric chemistry and biological systems but are notoriously hard to probe experimentally. Surface-specific vibrational spectroscopy offers an avenue to directly probe the vibrational modes of the water OH stretching band but this method is challenging to implement to buried surfaces. Here we present results from sum-frequency generation (SFG) spectroscopy probing the buried interface between a functionalized surface and aqueous solutions. Studying such buried surfaces offers the advantage of being able to systematically tune the surface chemistry using self-assembled monolayers, i.e. the hydrophobic and hydrophilic character, and examine the effect on the interfacial water. In addition to water at these controlled surfaces, we have initiated studying water at biological surfaces. This includes the solvation structure around DNA. X-ray experiments at cryogenic temperatures have found crystallographic water in the minor groove of DNA giving rise to the notion of a spine of hydration surrounding DNA. Such structured water should exhibit a chiral structure adapted from DNA. We investigate if such a chiral water structure exist around DNA at room temperature using chiral SFG.

**3:06PM P31.00002 Molecular Views of Water at the Water/Air and Water/Lipid Interface**, MISCHA BONN, Max Planck Inst — At the surface of water, the water hydrogen-bonded network is interrupted, conferring properties on interfacial water different from bulk water. We elucidate, using a combined experimental and computational molecular dynamics approach, how the water hydrogen bond network is terminated at a phospholipid interface, and how this is different from conventional surfactant interface [1]. Moreover, for the water/air interface, we show that the evaporation of water – i.e. the release of individual water molecules from the bulk into the gas phase – is not a purely stochastic event. Rather, the evaporation follows one specific pathway, involving a delicately timed, concerted motion of several water molecules to 'launch' a single molecule from the surface [2]. [1] Lipid Carbonyl Groups Terminate the Hydrogen-Bond Network of Membrane-Bound Water, T. Ohto, E.H.G. Backus, C. Hsieh, M. Sulpizi, M. Bonn, Y. Nagata, J. Phys. Chem. Lett. J. Phys. Chem. Lett. 6, 4499–4503 (2015). [2] Molecular Mechanism of Water Evaporation, Nagata, Y.; Usui, K.; Bonn, M., Phys. Rev. Lett. 2015, in print.

**3:42PM P31.00003 Correlation between Pyroelectricity and Alignment of Interfacial Water**, DAVID EHRE, ELENA MEIRZADEH, ALIK BELITZKY, ERAN MISHUK, MEIR LAHAV, IGOR LUBOMIRSKY, Weizmann Institute of Science — In this work we investigate the connection between arrangement of water and pyroelectricity. Before the current work, pyroelectricity was attributed only to polar materials. Nevertheless, nonpolar Amino acid crystals and Yttrium doped Barium Zirconate ceramics exhibit pyroelectricity. Experimental results with MD simulation suggest that the source of pyroelectricity is polar arrangement of water molecules at the crystal surface, which leads to the formation of a deformed polar layer in the crystal. This makes the surface pyroelectricity an important surface characterization tool. Another phenomenon suggests that the converse effect to surface pyroelectricity is also exists i.e. alignment of water by pyroelectricity. We demonstrated that polar crystals in general and specifically positive pyroelectric charge can catalyze the freezing of supercooled water (SCW). Our studies show that pyroelectric effect increases the freezing point of SCW by 2 to 8 degrees. The fact that the freezing point is correlated to the amount of the surface charge together with the relative low electric field, implying that the surface charge aligns the interfacial water molecules or stabilizes sub-critical ice nuclei.

**3:54PM P31.00004 High-resolution imaging and spectroscopy of interfacial water at single bond limit**, YING JIANG, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, P. R. China — Hydrogen bond is one of the most important weak interactions in nature and plays an essential role in a broad spectrum of physics, chemistry, biology, energy and material sciences. The conventional methods for studying hydrogen-bonding interaction are all based on spectroscopic or diffraction techniques. However, those techniques have poor spatial resolution and only measure the average properties of many hydrogen bonds, which are susceptible to the structural inhomogeneity and local environments, especially when interfacial systems are concerned. The spatial variation and inter-bond coupling of the hydrogen bonds leads to significant spectral broadening, which prohibits the accurate understanding of the experimental data. In this talk, I will present our recent progress on the development of new-generation scanning probe microscopy/spectroscopy (SPM/S) with unprecedentedly high sensitivity and resolution [1,2], for addressing weak inter- and intra-molecular interactions, such as hydrogen bonds and van der Waals force. Based on a qPlus sensor, we have succeeded to push the real-space study of a prototypical hydrogen-bonded system, i.e. water, down to single bond limit. Combined with state-of-the-arts quantum simulations, we have discovered exotic nuclear quantum effects (NQE) in interfacial water and revealed the quantum nature of the hydrogen bond from a completely new perspective [3]. [1] J. Guo et al., Nature Materials 13, 184 (2014). [2] J. Chen et al., Nature Communications 5, 4056 (2014). [3] X. Meng et al., Nature Physics 11, 235 (2015).

**4:30PM P31.00005 Water at lipid and surfactant interfaces—structure, dynamics, and spectroscopy**, JAMES SKINNER, University of Wisconsin — I will consider water confined by reverse micelles, multi-bilayers, and gyroid phases of a number of lipids and surfactants. Theoretical and simulation results will be compared with several non-linear IR experiments, including 2DIR and pump-probe anisotropy. In addition, I will discuss water near lipid and surfactant monolayers, especially making the connection with SFG and 2DSFG experiments.

**5:06PM P31.00006 Orientational dynamics of water at an extended hydrophobic interface<sup>1</sup>**, FLORIAN FIGGE, SHUNHAO XIAO, JOHN A. MCGUIRE, Department of Physics and Astronomy, Michigan State University, GUILLAUME STIRNEMANN, Institut de Biologie Physico-Chimique, Univ. Paris Diderot, DAMIEN LAAGE, Département de Chimie, École Normale Supérieure — Aqueous interfaces are central to many physical processes, but the dynamics of interfacial water molecules have been little studied. We have measured the orientational dynamics of water at its interface with a self-assembled monolayer of octadecylsilane on fused silica. A surface-sensitive sum-frequency probe generated by mixing a visible and a vibrationally resonant infrared (IR) pulse is used to monitor the dangling (non-hydrogen-bonded) OH stretch vibration after excitation with a resonant IR pump pulse. By measuring pure and isotopically diluted water with orthogonal pump polarizations, we find that relaxation of the dangling OH stretch excitation is dominated by the out-of-plane jump from a dangling to a hydrogen-bonded configuration and the subsequent redistribution of energy from the surface hydrogen-bonded OH stretch excitation. The out-of-plane jump time is 1.5(1)ps, 30% slower than that reported for the air-water interface and twice as short as the jump time between hydrogen bonded configurations in the bulk. Molecular dynamics simulations indicate that the slower dynamics at the hydrophobic interface compared to the water-air interface are due to the hydrogen bonds at the hydrophobic interface being stronger than those at the water-air interface.

**5:18PM P31.00007 Water Adsorption on the LaMnO<sub>3</sub> Surface**, CHRIS BILLMAN, Physics Department and Quantum Theory Project, University of Florida, YAN WANG, Materials Science and Engineering, Massachusetts Institute of Technology, HAI-PING CHENG, Dept. of Physics and Quantum Theory Project, University of Florida — Studying the adsorption of water on the metallic LaMnO<sub>3</sub> surface can provide insight into this complicated surface-adsorbate interaction. Using density functional theory, we investigated the adsorption of a water monomer, dimer, trimer and a monolayer on the surface. The electronic structure of ground state configurations is explored using analysis of density of states, charge density, and crystal orbital overlap populations. We found that the interaction between the surface and water molecules is stronger than hydrogen bonding between molecules, which facilitates wetting of the surface. Adsorbed water molecules form very strong hydrogen bonds, with substantially shifted OH stretch modes. For the monolayer of adsorbed water, a hint of a bilayer is observed with a height separation of only 0.2 Å. However, simulated scanning tunneling microscopy (STM) images and vibrational spectra suggest a significant difference between the two layers due to intermolecular bonding and interaction with the substrate.

## Wednesday, March 16, 2016 2:30PM - 5:30PM —

Session P32 DMP GERA FIAP: Quantum Thermoelectric Systems 332 - Jeff Urban, Molecular Foundry, UC Berkeley

**2:30PM P32.00001 Evolutionary structure search of efficient thermoelectric compounds**, MARIBEL NÚÑEZ VALDEZ, Moscow Institute of Physics and Technology, ARTEM OGANOV, Skolkovo Inst Sci and Tech; Moscow Inst of Phys and Tech; SUNY Stony Brook, Dept Geosci Ctr Mat Design; SUNY Stony Brook, Inst Adv Computat — Thermoelectric materials, which are used to harvest waste heat to generate power, are taking an important role for energy solutions. However, it is of fundamental significance the optimization of a variety of conflicting properties in order to obtain a high efficiency thermoelectric device to be cost-effective for applications. This efficiency or figure of merit ( $ZT$ ), which depends on the Seebeck coefficient, electrical resistivity and heat conductivity, is restricted by currently available materials and fabricating technologies. Therefore, the main objective of our study is the identification of thermodynamically stable compounds and their crystal structures with high  $ZT$  given just a set of elements by using an evolutionary algorithm in which the figure of merit is a degree of freedom to be optimized. We test the performance of our methods within the system Bi<sub>2</sub>Te<sub>3</sub>-Sb<sub>2</sub>Te<sub>3</sub>. These compounds are well known for their large  $ZT$ 's and their use in technological applications. Our results indicate a high feasibility for the employment of our evolutionary algorithm search using a wide variety of elements for optimizing and designing new thermoelectric materials.

**2:42PM P32.00002 High-throughput screening for thermoelectric sulphides by using crystal structure features as descriptors<sup>1</sup>**, RUIZHI ZHANG, BAOLI DU, KAN CHEN, MIKE REECE, Queen Mary University of London, MATERIALS RESEARCH INSTITUTE TEAM — With the increasing computational power and reliable databases, high-throughput screening is playing a more and more important role in the search of new thermoelectric materials. Rather than the well established density functional theory (DFT) calculation based methods, we propose an alternative approach to screen for new TE materials: using crystal structural features as descriptors. We show that a non-distorted transition metal sulphide polyhedral network can be a good descriptor for high power factor according to crystal field theory. By using Cu/S containing compounds as an example, 1600+ Cu/S containing entries in the Inorganic Crystal Structure Database (ICSD) were screened, and of those 84 phases are identified as promising thermoelectric materials. The screening results are validated by both electronic structure calculations and experimental results from the literature. We also fabricated some new compounds to test our screening results. Another advantage of using crystal structure features as descriptors is that we can easily establish structural relationships between the identified phases. Based on this, two material design approaches are discussed: 1) High-pressure synthesis of metastable phase; 2) In-situ 2-phase composites with coherent interface.

**2:54PM P32.00003 Thermal Conductivities in Solids from First Principles: Accurate Computations and Rapid Estimates**, CHRISTIAN CARBOGNO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — In spite of significant research efforts, a first-principles determination of the thermal conductivity  $\kappa$  at high temperatures has remained elusive. Boltzmann transport techniques that account for anharmonicity perturbatively become inaccurate under such conditions. *Ab initio* molecular dynamics (MD) techniques using the *Green-Kubo* (GK) formalism capture the full anharmonicity, but can become prohibitively costly to converge in time and size. We developed a formalism that accelerates such GK simulations by several orders of magnitude and that thus enables its application within the limited time and length scales accessible in *ab initio* MD. For this purpose, we determine the *effective* harmonic potential occurring during the MD, the associated temperature-dependent phonon properties and lifetimes. Interpolation in reciprocal and frequency space then allows to extrapolate to the macroscopic scale. For both force-field and *ab initio* MD, we validate this approach by computing  $\kappa$  for Si and ZrO<sub>2</sub>, two materials known for their particularly harmonic and anharmonic character. Eventually, we demonstrate how these techniques facilitate reasonable estimates of  $\kappa$  from existing MD calculations at virtually no additional computational cost.

**3:06PM P32.00004 Local thermoelectric probes of nonequilibrium quantum systems<sup>1</sup>**, CHARLES STAFFORD, University of Arizona — A theory of local temperature and voltage measurement in an interacting quantum system far from equilibrium is developed. We prove that a steady-state measurement by a floating thermoelectric probe is unique if it exists. Furthermore, we show that a solution exists provided there is no net local population inversion. In the case of population inversion, the system may be assigned a (unique) negative temperature. An expression for the local entropy of a nonequilibrium quantum system is introduced that, together with the local temperature and voltage, allows for a complete analysis of the local thermodynamics of the thermoelectric processes in the system. The Clausius form of the second law and the third law are shown to hold exactly locally, while the zeroth and first laws are shown to be valid to leading order in the Sommerfeld expansion. The local quantum thermodynamics underlying the enhancement of thermoelectricity by quantum interference is discussed.

**3:42PM P32.00005 Nanoelectronic primary thermometry below 4 millikelvin**, MATTHEW SARSBY, RICHARD HALEY, DAVID IAN BRADLEY, RICHARD GEORGE, YURI PASHKIN, JONATHAN PRANCE, University of Lancaster, UK, DAVID GUNNARSSON, HANNELE HEIKKINEN, MIKA PRUNNILA, VTT Technical Research Centre of Finland, PENTTIL JARI, LEIF ROSCHIER, Aivon Oy, Finland. — We present measurements of nanoelectronic Coulomb Blockade Thermometers that are optimised for operation below 10 mK. Their design incorporates on-chip electronic filters and cooling fins with a high electron-phonon coupling. By immersing the devices in the 3He/4He mixture of a dilution refrigerator, and by minimising electrical noise in the measurement circuit, the on-chip electron temperature reaches a value of 3.7 mK, the lowest yet measured in any nanoelectronic device. Above 7 mK the devices are in good thermal contact with their environment and are not susceptible to self-heating. Below 7 mK the device continues to provide accurate thermometry of the on-chip electron temperature, which is seen to diverge from the ambient temperature. In this regime the device provides valuable information about noise and heat-leaks from the environment, which points the way towards cooling nanoelectronic structures to lower temperatures.

**3:54PM P32.00006 Thermoelectric Corrections to Quantum Measurement**, JUSTIN BERGFELD, Department of Physics, Department of Chemistry, Illinois State University, MARK RATNER, Department of Chemistry, Northwestern University, CHARLES STAFFORD, Department of Physics, University of Arizona, MASSIMILIANO DI VENTRA, Department of Physics, University of California — The voltage and temperature measured by a floating probe of a nonequilibrium quantum system is shown to exhibit nontrivial thermoelectric corrections at finite temperature. Using a realistic model of a scanning thermal microscope to calculate the voltage and temperature distributions, we predict quantum temperature variations along graphene nanoribbons subject to a thermal bias which are not simply related to the local density of states. Experimentally, the wavelength of the oscillations can be tuned over several orders of magnitude by gating/doping, bringing quantum temperature oscillations within reach of the spatial resolution of existing measurement techniques. We also find that the Peltier cooling/heating which causes the temperature oscillations can lead to significant errors in voltage measurements for a wide range of system.

**4:06PM P32.00007 Deciphering the Landauer-Büttiker Transmission Function from Single Molecule Break Junction Experiments**, MATTHEW REUTER, Department of Applied Mathematics and Statistics and Institute for Advanced Computational Science, Stony Brook University, STEPHEN TSCHUDI, Stony Brook University — When investigating the electrical response properties of molecules, experiments often measure conductance whereas computation predicts transmission probabilities. Although the Landauer-Büttiker theory relates the two in the limit of coherent scattering through the molecule, a direct comparison between experiment and computation can still be difficult. Experimental data (specifically that from break junctions) is statistical and computational results are deterministic. Many studies compare the most probable experimental conductance with computation, but such an analysis discards almost all of the experimental statistics. In this work we develop tools to decipher the Landauer-Büttiker transmission function directly from experimental statistics and then apply them to enable a fairer comparison between experimental and computational results.

**4:18PM P32.00008 A simple Quantum heat engine operating between two negative temperatures<sup>1</sup>**, TOLASA A DIMA, PhD Student, MULUGETA BEKELE, Associate Professor of Physics — We study a heat engine that operates between two reservoirs at negative temperatures. A system of spin-half particles, in the thermodynamic limit, subject to a time dependent external magnetic field, is used as a working substance because of its capability to demonstrate negative absolute temperature. We explored the finite-time quantities: period, power and efficiency. The engine is explored in its maximum power and optimum mode of operation from which its figure of merit is defined as the product of scaled power and scaled efficiency. We found that power-wise the engine provides better performance under its maximum power mode of operation than the optimized mode; however, efficiency-wise, the optimized mode of operation is better than its maximum mode operation.

<sup>1</sup>We thank the International Science programme, IPS, Uppsala, Sweden for the support to this research?

**4:30PM P32.00009 Thermal Memristive Devices**, LUKE SHAPIRO, KAMIL WALCZAK, Pace University — We examine heat transfer via Coulomb Blockaded quantum systems connected to two heat reservoirs (thermal baths). Specifically, we propose simple models for negative differential thermal conductance and pinched hysteretic loops in the heat fluxes as functions of temperature. Our computational method is based on the theory of propagators, where additional mechanisms of shifting and blocking specific energy levels is incorporated. Those devices may play a major role in the future thermal management.

**4:42PM P32.00010 Density of States for Warped or non-Warped Energy Bands<sup>1</sup>**, NICHOLAS MECHOLSKY, LORENZO RESCA, IAN PEGG, Catholic Univ of America, MARCO FORNARI, Central Michigan University — The goal of this talk is to investigate when band warping affects density-of-states effective mass. Further, band "corrugation," a form of band warping referring to energy dispersions that deviate "more severely" from being twice-differentiable at isolated critical points, may also correlate in different ways with density-of-states effective masses and other band warping parameters. In this talk, an angular effective mass formalism is developed and used to study the electronic density of states of warped and non-warped energy bands towards an application in thermoelectric transport design. We demonstrate effects of band warping and prove the superiority of the angular effective mass treatment for valence energy bands in cubic materials. We explore examples that can also be critical to precisely distinguish the contributions due to band warping and to band non-parabolicity in non-degenerate bands of thermoelectric materials that have a consequent practical interest.

<sup>1</sup>The presenter wished to thank the Vitreous State Laboratory

**4:54PM P32.00011 A generalized Sommerfeld expansion for thermopower calculation**, JIE GU, XIAO GUANG ZHANG, HAI-PING CHENG, Univ of Florida - Gainesville — Kelvin formula relates the thermopower to the temperature derivative of the chemical potential. The latter can be evaluated using the Sommerfeld expansion as a standard approximation at low temperatures. We present a generalized expansion with improved accuracy at intermediate and high temperatures. We apply the formula to sodium cobaltate  $\text{Na}_x\text{CoO}_2$  and other thermoelectric materials to verify its validity over a wide temperature range.

**5:06PM P32.00012 Temperature Dependent Structure of Thermoelectric  $\text{Ca}_3\text{Co}_4\text{O}_9$** , TAO WU, TREVOR TYSON, HAN ZHANG, NJIT, MILINDA ABEYKOON, Photon Sciences, BNL — Structural studies of thermoelectric “ $\text{Ca}_3\text{Co}_4\text{O}_9$ ” have been conducted for a broad range of temperatures using probes covering multiple length scales. Details on the structure and its connection to the electron transport and thermal properties will be discussed. This work is supported by DOE Grant DE-FG02-07ER46402.

**5:18PM P32.00013 DYNAMICAL CORRECTION OF THERMOELECTRIC COEFFICIENTS FOR STRONGLY INTERACTING ELECTRONS IN THE COULOMB BLOCKADE REGIME**, KAIKE YANG, Universidad del Pais Vasco, San Sebastian, Spain — FOR MOLECULES WEAKLY COUPLED TO LEADS THE EXACT ZERO-BIAS KOHN-SHAM CONDUCTANCE CAN BE ORDERS OF MAGNITUDE LARGER THAN THE TRUE CONDUCTANCE DUE TO THE LACK OF DYNAMICAL EXCHANGE-CORRELATION (XC) EFFECTS. RECENTLY, IT HAS BEEN SHOWN [1] HOW THESE DYNAMICAL XC CORRECTIONS CAN BE CALCULATED USING ONLY QUANTITIES OBTAINED FROM STATIC DENSITY FUNCTIONAL THEORY. HERE, WE INVESTIGATE THE THERMOELECTRIC TRANSPORT AND DERIVE THE XC CORRECTION TO THE SEEBECK COEFFICIENT. WE FIND THAT THE DYNAMICAL CORRECTION TO THE SEEBECK COEFFICIENT IS DETERMINANT IN EVALUATING THE THERMOPOWER: THE ABSOLUTE VALUE OF THE DYNAMICAL CORRECTION FOR THE SEEBECK COEFFICIENT IS, FOR CERTAIN VALUES OF GATE VOLTAGE, MUCH LARGER THAN THAT OF THE KOHN-SHAM TERM. FINALLY, WE COMPARE OUR DENSITY FUNCTIONAL CALCULATIONS TO THE RATE EQUATION [2] AND THE EXPERIMENTAL RESULTS [3]. [1] S. KURTH, ET AL., PRL, 030601 (2013). [2] C. W. J. BEENAKKER, ET AL., PRB, 9667 (1992). [3] J. P. SMALL, ET AL., PRL, 256801 (2003).
